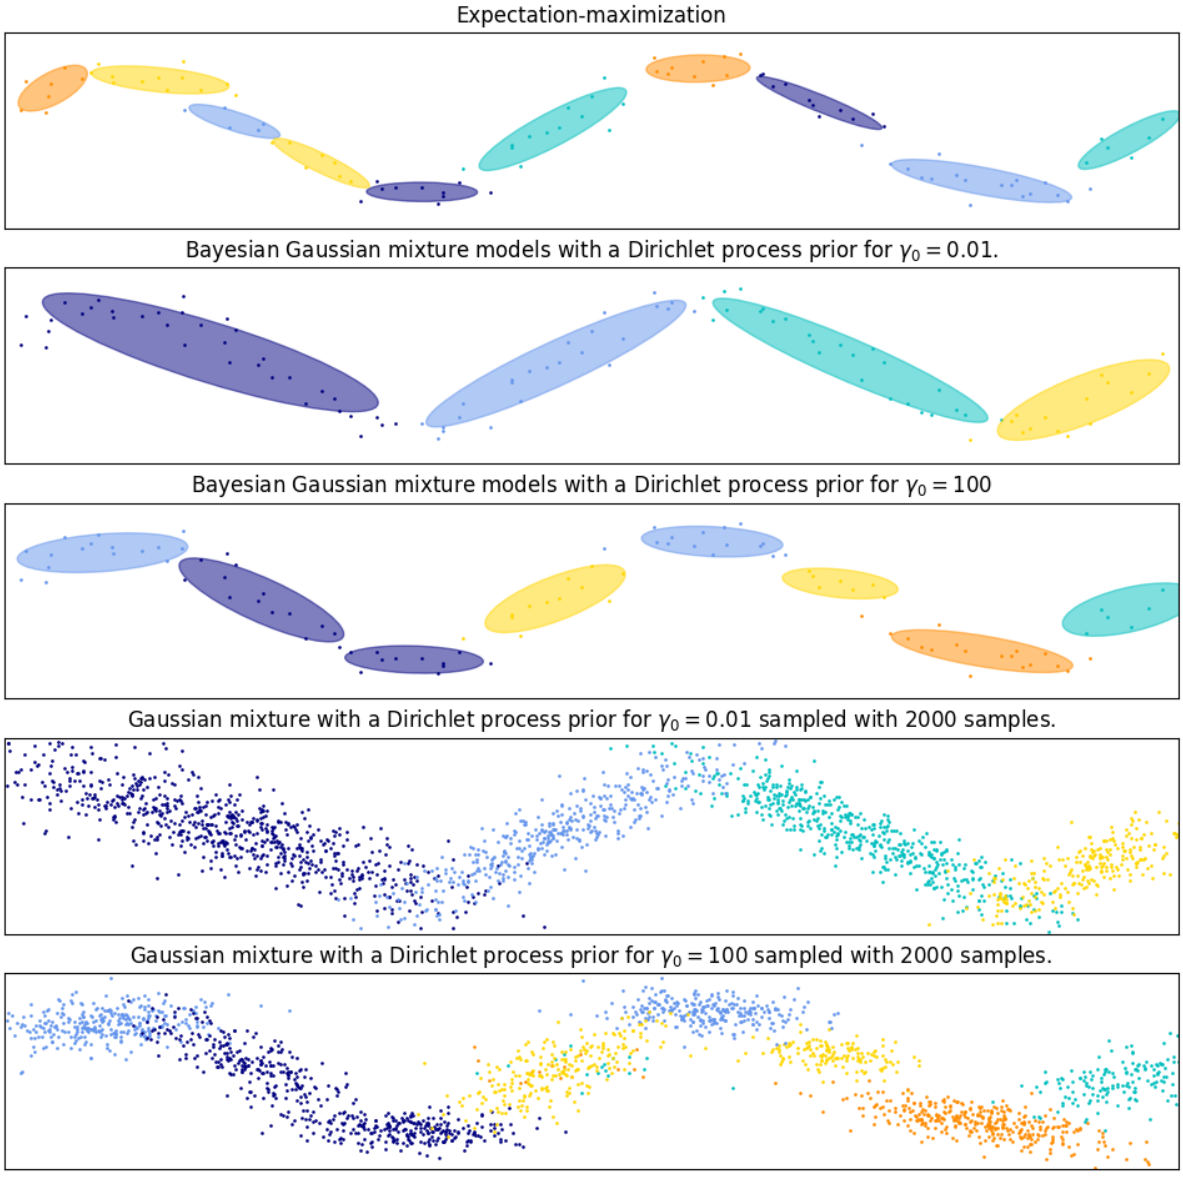
The first model is a classical Gaussian Mixture Model with 10 components fit with the Expectation-Maximization algorithm.



The second model is a Bayesian Gaussian Mixture Model with a Dirichlet process prior fit with variational inference. The low value of the concentration prior makes the model favor a lower number of active components. This models "decides" to focus its modeling power on the big picture of the structure of the dataset: groups of points with alternating directions modeled by non-diagonal covariance matrices. Those alternating directions roughly capture the alternating nature of the original sine signal.

The third model is also a Bayesian Gaussian mixture model with a Dirichlet process prior but this time the value of the concentration prior is higher giving the model more liberty to model the fine-grained structure of the data. The result

is a mixture with a larger number of active components that is similar to the first model where we arbitrarily decided to fix the number of components to 10.

Which model is the best is a matter of subjective judgement: do we want to favor models that only capture the big picture to summarize and explain most of the structure of the data while ignoring the details or do we prefer models that closely follow the high density regions of the signal?

The last two panels show how we can sample from the last two models. The resulting samples distributions do not look exactly like the original data distribution. The difference primarily stems from the approximation error we made by using a model that assumes that the data was generated by a finite number of Gaussian components instead of a continuous noisy sine curve.

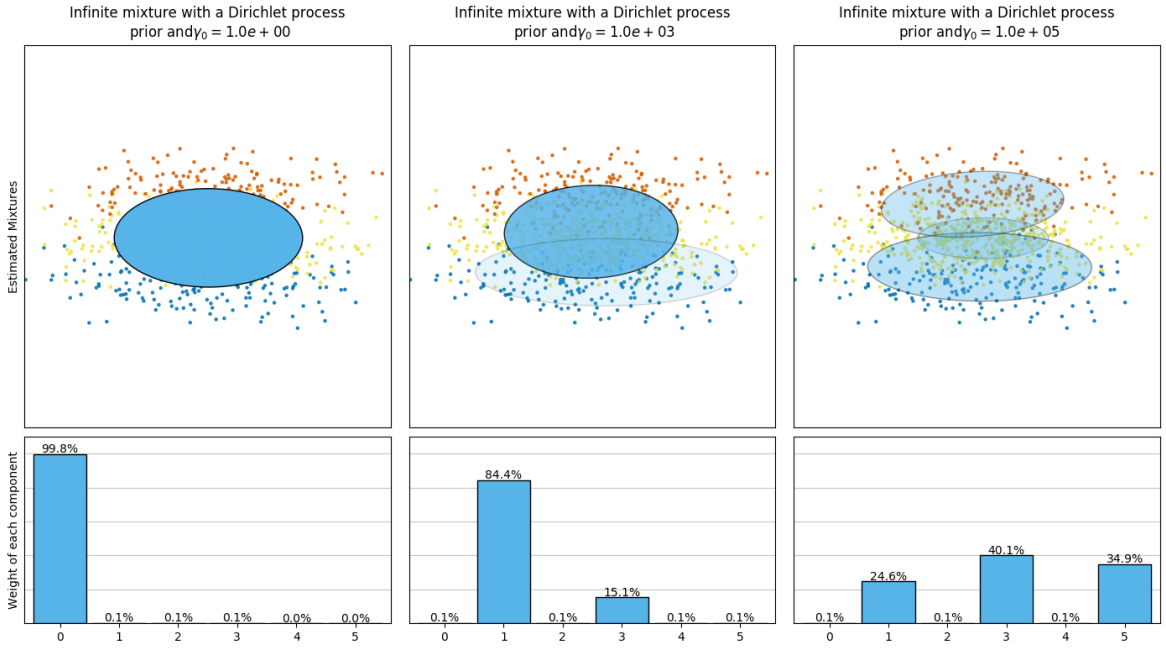
20.6 Concentration Prior Type Analysis of Variation Bayesian Gaussian Mixture



This example plots the ellipsoids obtained from a toy dataset (mixture of three Gaussians) fitted by the `BayesianGaussianMixture` class models with a Dirichlet distribution prior (`weight_concentration_prior_type='dirichlet_distribution'`) and a Dirichlet process prior (`weight_concentration_prior_type='dirichlet_process'`). On each figure, we plot the results for three different values of the weight concentration prior.

The `BayesianGaussianMixture` class can adapt its number of mixture componentsautomatically. The parameter `weight_concentration_prior` has a direct link with the resulting number of components with non-zero weights. Specifying a low value for the concentration prior will make the model put most of the weight on few components set the remaining components weights very close to zero. High values of the concentration prior will allow a larger number of components to be active in the mixture.

The Dirichlet process prior allows to define an infinite number of components and automatically selects the correct number of components: it activates a component only if it is necessary.

On the contrary the classical finite mixture model with a Dirichlet distribution prior will favor more uniformly weighted components and therefore tends to divide natural clusters into unnecessary sub-components.

MODEL SELECTION

Examples related to the *sklearn.model_selection* module.

21.1 Plotting Validation Curves

In this plot you can see the training scores and validation scores of an SVM for different values of the kernel parameter gamma. For very low values of gamma, you can see that both the training score and the validation score are low. This is called underfitting. Medium values of gamma will result in high values for both scores, i.e. the classifier is performing fairly well. If gamma is too high, the classifier will overfit, which means that the training score is good but the validation score is poor.

```
print(__doc__)

21.2 Underfitting vs. Overfitting

This example demonstrates the problems of underfitting and overfitting and how we can use linear regression with polynomial features to approximate nonlinear functions. The plot shows the function that we want to approximate, which is a part of the cosine function. In addition, the samples from the real function and the approximations of different models are displayed. The models have polynomial features of different degrees. We can see that a linear function (polynomial with degree 1) is not sufficient to fit the training samples. This is called **underfitting**. A polynomial of degree 4 approximates the true function almost perfectly. However, for higher degrees the model will **overfit** the training data, i.e. it learns the noise of the training data. We evaluate quantitatively **overfitting /**

underfitting by using cross-validation. We calculate the mean squared error (MSE) on the validation set, the higher, the less likely the model generalizes correctly from the training data.

```
print(__doc__)

import numpy as np

21.3 Parameter estimation using grid search with cross-validation

This examples shows how a classifier is optimized by cross-validation, which is done using the *sklearn.model_selection.GridSearchCV* object on a development set that comprises only half of the available labeled data.

The performance of the selected hyper-parameters and trained model is then measured on a dedicated evaluation set that was not used during the model selection step.

More details on tools available for model selection can be found in the sections on *Cross-validation: evaluating estimator performance* and *Tuning the hyper-parameters of an estimator*.

21.4 Train error vs Test error

Illustration of how the performance of an estimator on unseen data (test data) is not the same as the performance on training data. As the regularization increases the performance on train decreases while the performance on test is optimal within a range of values of the regularization parameter. The example with an Elastic-Net regression model and the performance is measured using the explained variance a.k.a. R^2.

Out:

```
Optimal regularization parameter : 0.000335292414925
```

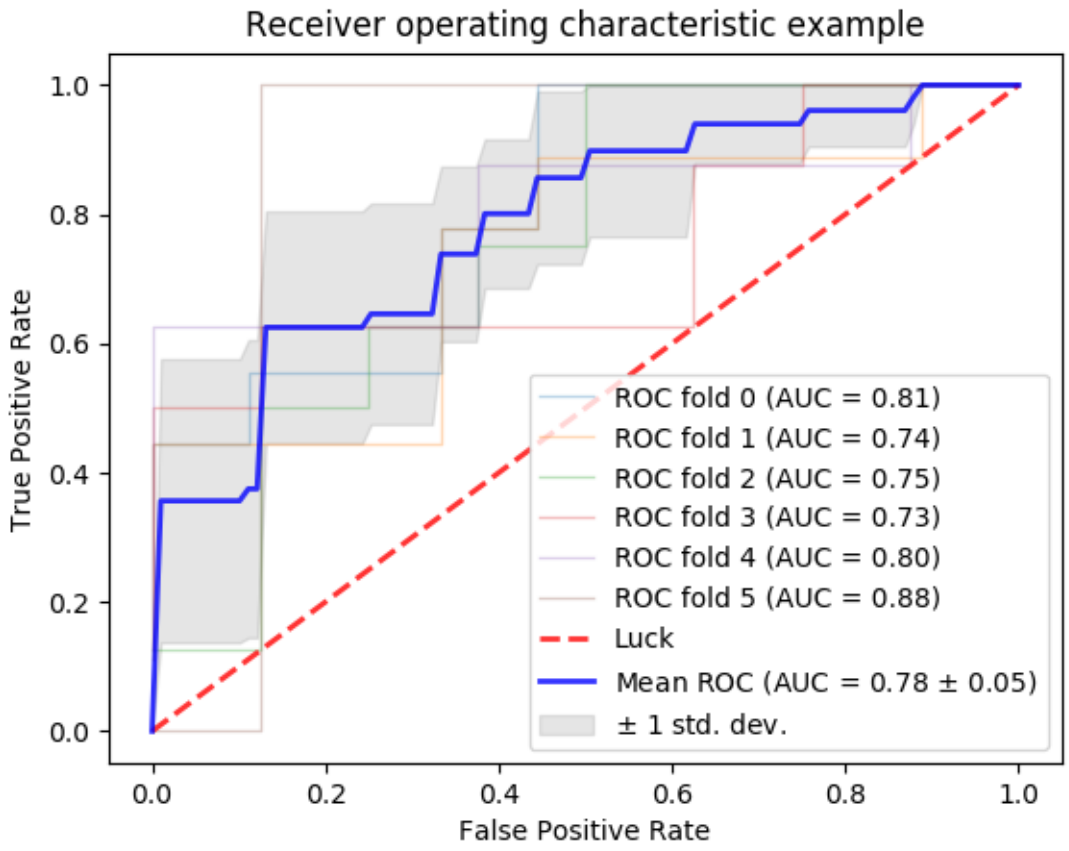
21.5 Receiver Operating Characteristic (ROC) with cross validation

Example of Receiver Operating Characteristic (ROC) metric to evaluate classifier output quality using cross-validation.

ROC curves typically feature true positive rate on the Y axis, and false positive rate on the X axis. This means that the top left corner of the plot is the "ideal" point - a false positive rate of zero, and a true positive rate of one. This is not very realistic, but it does mean that a larger area under the curve (AUC) is usually better.



The "steepness" of ROC curves is also important, since it is ideal to maximize the true positive rate while minimizing the false positive rate.

This example shows the ROC response of different datasets, created from K-fold cross-validation. Taking all of these curves, it is possible to calculate the mean area under curve, and see the variance of the curve when the training set is split into different subsets. This roughly shows how the classifier output is affected by changes in the training data, and how different the splits generated by K-fold cross-validation are from one another.

Note:

See also `sklearn.metrics.auc_score`, *`sklearn.model_selection.cross_val_score`*, *Receiver Operating Characteristic (ROC)*,

21.6 Confusion matrix

Example of confusion matrix usage to evaluate the quality of the output of a classifier on the iris data set. The diagonal elements represent the number of points for which the predicted label is equal to the true label, while off-diagonal elements are those that are mislabeled by the classifier. The higher the diagonal values of the confusion matrix the better, indicating many correct predictions.

The figures show the confusion matrix with and without normalization by class support size (number of elements in each class). This kind of normalization can be interesting in case of class imbalance to have a more visual interpretation of which class is being misclassified.

Here the results are not as good as they could be as our choice for the regularization parameter C was not the best. In real life applications this parameter is usually chosen using *Tuning the hyper-parameters of an estimator*.

21.7 Comparing randomized search and grid search for hyperparameter estimation

Compare randomized search and grid search for optimizing hyperparameters of a random forest. All parameters that influence the learning are searched simultaneously (except for the number of estimators, which poses a time / quality tradeoff).

The randomized search and the grid search explore exactly the same space of parameters. The result in parameter settings is quite similar, while the run time for randomized search is drastically lower.

The performance is slightly worse for the randomized search, though this is most likely a noise effect and would not carry over to a held-out test set.

Note that in practice, one would not search over this many different parameters simultaneously using grid search, but pick only the ones deemed most important.

Out:

```
RandomizedSearchCV took 4.97 seconds for 20 candidates parameter settings.

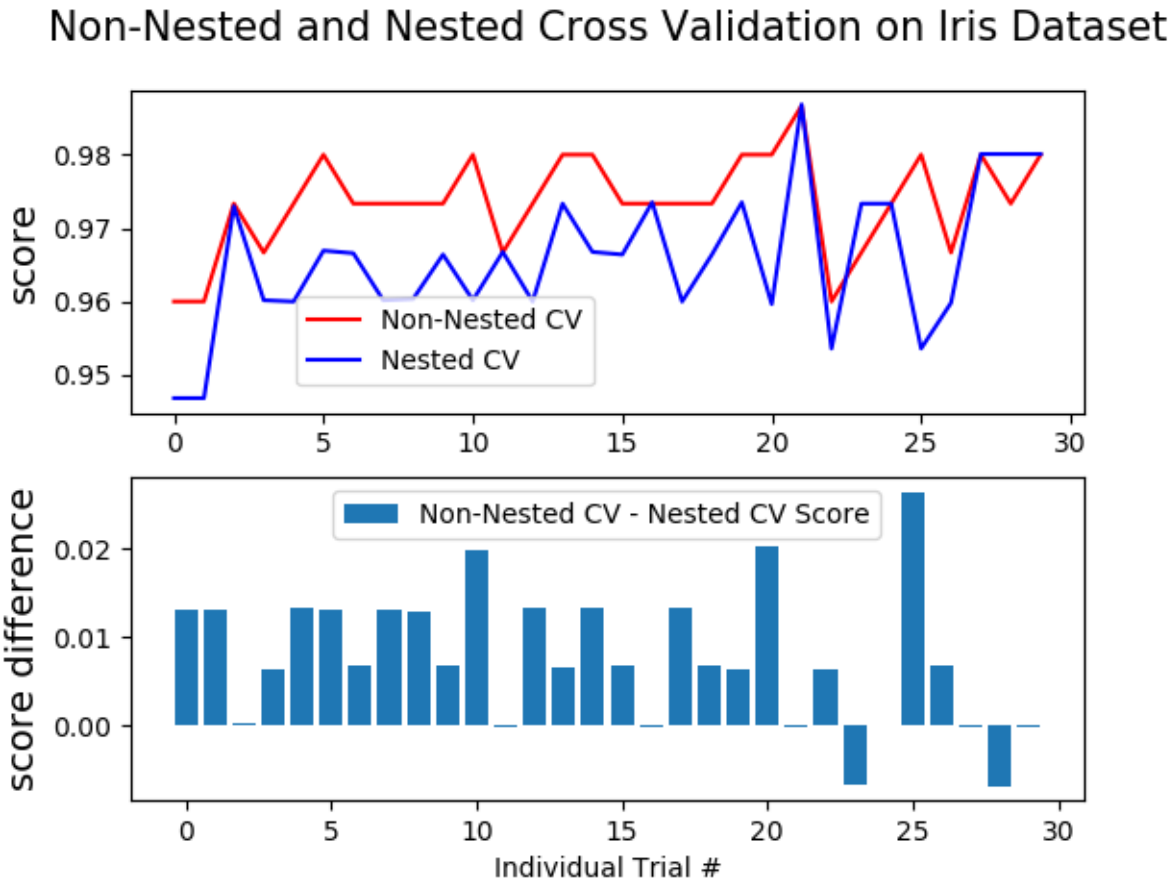
21.8 Nested versus non-nested cross-validation

This example compares non-nested and nested cross-validation strategies on a classifier of the iris data set. Nested cross-validation (CV) is often used to train a model in which hyperparameters also need to be optimized. Nested CV estimates the generalization error of the underlying model and its (hyper)parameter search. Choosing the parameters that maximize non-nested CV biases the model to the dataset, yielding an overly-optimistic score.

Model selection without nested CV uses the same data to tune model parameters and evaluate model performance. Information may thus "leak" into the model and overfit the data. The magnitude of this effect is primarily dependent on the size of the dataset and the stability of the model. See Cawley and Talbot[1] for an analysis of these issues.

To avoid this problem, nested CV effectively uses a series of train/validation/test set splits. In the inner loop (here executed by *GridSearchCV*), the score is approximately maximized by fitting a model to each training

[1] Cawley, G.C.; Talbot, N.L.C. On over-fitting in model selection and subsequent selection bias in performance evaluation. J. Mach. Learn. Res 2010,11, 2079-2107.



set, and then directly maximized in selecting (hyper)parameters over the validation set. In the outer loop (here in `cross_val_score`), generalization error is estimated by averaging test set scores over several dataset splits.

The example below uses a support vector classifier with a non-linear kernel to build a model with optimized hyperparameters by grid search. We compare the performance of non-nested and nested CV strategies by taking the difference between their scores.

21.9 Sample pipeline for text feature extraction and evaluation

The dataset used in this example is the 20 newsgroups dataset which will be automatically downloaded and then cached and reused for the document classification example.

You can adjust the number of categories by giving their names to the dataset loader or setting them to None to get the 20 of them.

Here is a sample output of a run on a quad-core machine:

```
Loading 20 newsgroups dataset for categories:
['alt.atheism', 'talk.religion.misc']
1427 documents
2 categories

Performing grid search...
pipeline: ['vect', 'tfidf', 'clf']
parameters:
{'clf__alpha': (1.0000000000000001e-05, 9.9999999999999995e-07),
 'clf__n_iter': (10, 50, 80),
 'clf__penalty': ('l2', 'elasticnet'),
 'tfidf__use_idf': (True, False),
 'vect__max_n': (1, 2),
 'vect__max_df': (0.5, 0.75, 1.0),
 'vect__max_features': (None, 5000, 10000, 50000)}
done in 1737.030s

Best score: 0.940
Best parameters set:
    clf__alpha: 9.9999999999999995e-07
    clf__n_iter: 50
    clf__penalty: 'elasticnet'
    tfidf__use_idf: True
    vect__max_n: 2
```

```
    vect__max_df: 0.75
    vect__max_features: 50000
```

```

21.10 Receiver Operating Characteristic (ROC)

Example of Receiver Operating Characteristic (ROC) metric to evaluate classifier output quality.

ROC curves typically feature true positive rate on the Y axis, and false positive rate on the X axis. This means that the top left corner of the plot is the "ideal" point - a false positive rate of zero, and a true positive rate of one. This is not very realistic, but it does mean that a larger area under the curve (AUC) is usually better.

The "steepness" of ROC curves is also important, since it is ideal to maximize the true positive rate while minimizing the false positive rate.

21.10.1 Multiclass settings

ROC curves are typically used in binary classification to study the output of a classifier. In order to extend ROC curve and ROC area to multi-class or multi-label classification, it is necessary to binarize the output. One ROC curve can

be drawn per label, but one can also draw a ROC curve by considering each element of the label indicator matrix as a binary prediction (micro-averaging).

Another evaluation measure for multi-class classification is macro-averaging, which gives equal weight to the classification of each label.

Note:

See also ***sklearn.metrics.roc_auc_score***, *Receiver Operating Characteristic (ROC) with cross validation*.

```

21.11 Plotting Learning Curves

On the left side the learning curve of a naive Bayes classifier is shown for the digits dataset. Note that the training score and the cross-validation score are both not very good at the end. However, the shape of the curve can be found in more complex datasets very often: the training score is very high at the beginning and decreases and the cross-validation score is very low at the beginning and increases. On the right side we see the learning curve of an SVM with RBF kernel. We can see clearly that the training score is still around the maximum and the validation score could be increased with more training samples.

- 

- 

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn.naive_bayes import GaussianNB
from sklearn.svm import SVC
from sklearn.datasets import load_digits
from sklearn.model_selection import learning_curve
from sklearn.model_selection import ShuffleSplit

def plot_learning_curve(estimator, title, X, y, ylim=None, cv=None,
                        n_jobs=1, train_sizes=np.linspace(.1, 1.0, 5)):
    """
    Generate a simple plot of the test and training learning curve.

    Parameters
    ----------
    estimator : object type that implements the "fit" and "predict" methods
        An object of that type which is cloned for each validation.

    title : string
        Title for the chart.

    X : array-like, shape (n_samples, n_features)
        Training vector, where n_samples is the number of samples and
        n_features is the number of features.
```

```
    y : array-like, shape (n_samples) or (n_samples, n_features), optional
        Target relative to X for classification or regression;
        None for unsupervised learning.

    ylim : tuple, shape (ymin, ymax), optional
        Defines minimum and maximum yvalues plotted.

    cv : int, cross-validation generator or an iterable, optional
        Determines the cross-validation splitting strategy.
        Possible inputs for cv are:
          - None, to use the default 3-fold cross-validation,
          - integer, to specify the number of folds.
          - An object to be used as a cross-validation generator.
          - An iterable yielding train/test splits.

        For integer/None inputs, if ``y`` is binary or multiclass,
        :class:`StratifiedKFold` used. If the estimator is not a classifier
        or if ``y`` is neither binary nor multiclass, :class:`KFold` is used.

        Refer :ref:`User Guide <cross_validation>` for the various
        cross-validators that can be used here.

    n_jobs : integer, optional
        Number of jobs to run in parallel (default 1).
    """

21.12 Precision-Recall

Example of Precision-Recall metric to evaluate classifier output quality.

Precision-Recall is a useful measure of success of prediction when the classes are very imbalanced. In information retrieval, precision is a measure of result relevancy, while recall is a measure of how many truly relevant results are returned.

The precision-recall curve shows the tradeoff between precision and recall for different threshold. A high area under the curve represents both high recall and high precision, where high precision relates to a low false positive rate, and high recall relates to a low false negative rate. High scores for both show that the classifier is returning accurate results (high precision), as well as returning a majority of all positive results (high recall).

A system with high recall but low precision returns many results, but most of its predicted labels are incorrect when compared to the training labels. A system with high precision but low recall is just the opposite, returning very few results, but most of its predicted labels are correct when compared to the training labels. An ideal system with high precision and high recall will return many results, with all results labeled correctly.

Precision (P) is defined as the number of true positives (T_p) over the number of true positives plus the number of false positives (F_p).

$P = \frac{T_p}{T_p+F_p}$

Recall (R) is defined as the number of true positives (T_p) over the number of true positives plus the number of false negatives (F_n).

$R = \frac{T_p}{T_p+F_n}$

These quantities are also related to the (F_1) score, which is defined as the harmonic mean of precision and recall.

$F1 = 2\frac{P \times R}{P+R}$

Note that the precision may not decrease with recall. The definition of precision ($\frac{T_p}{T_p+F_p}$) shows that lowering the threshold of a classifier may increase the denominator, by increasing the number of results returned. If the threshold

was previously set too high, the new results may all be true positives, which will increase precision. If the previous threshold was about right or too low, further lowering the threshold will introduce false positives, decreasing precision.

Recall is defined as $\frac{T_p}{T_p+F_n}$, where $T_p + F_n$ does not depend on the classifier threshold. This means that lowering the classifier threshold may increase recall, by increasing the number of true positive results. It is also possible that lowering the threshold may leave recall unchanged, while the precision fluctuates.

The relationship between recall and precision can be observed in the stairstep area of the plot - at the edges of these steps a small change in the threshold considerably reduces precision, with only a minor gain in recall.

Average precision summarizes such a plot as the weighted mean of precisions achieved at each threshold, with the increase in recall from the previous threshold used as the weight:

$\text{AP} = \sum_n (R_n - R_{n-1}) P_n$

where P_n and R_n are the precision and recall at the nth threshold. A pair (R_k, P_k) is referred to as an *operating point*.

Precision-recall curves are typically used in binary classification to study the output of a classifier. In order to extend the precision-recall curve and average precision to multi-class or multi-label classification, it is necessary to binarize the output. One curve can be drawn per label, but one can also draw a precision-recall curve by considering each element of the label indicator matrix as a binary prediction (micro-averaging).

Note:

See also ***sklearn.metrics.average_precision_score***, *sklearn.metrics.recall_score*, *sklearn.metrics.precision_score*, *sklearn.metrics.f1_score*

21.12.1 In binary classification settings

Create simple data

Try to differentiate the two first classes of the iris data

```
from sklearn import svm, datasets
from sklearn.model_selection import train_test_split
import numpy as np

iris = datasets.load_iris()
X = iris.data
y = iris.target

# Add noisy features
random_state = np.random.RandomState(0)
n_samples, n_features = X.shape
X = np.c_[X, random_state.randn(n_samples, 200 * n_features)]

# Limit to the two first classes, and split into training and test
X_train, X_test, y_train, y_test = train_test_split(X[y < 2], y[y < 2],
                                                    test_size=.5,
                                                    random_state=random_state)

# Create a simple classifier
classifier = svm.LinearSVC(random_state=random_state)
```

```
classifier.fit(X_train, y_train)
y_score = classifier.decision_function(X_test)
```

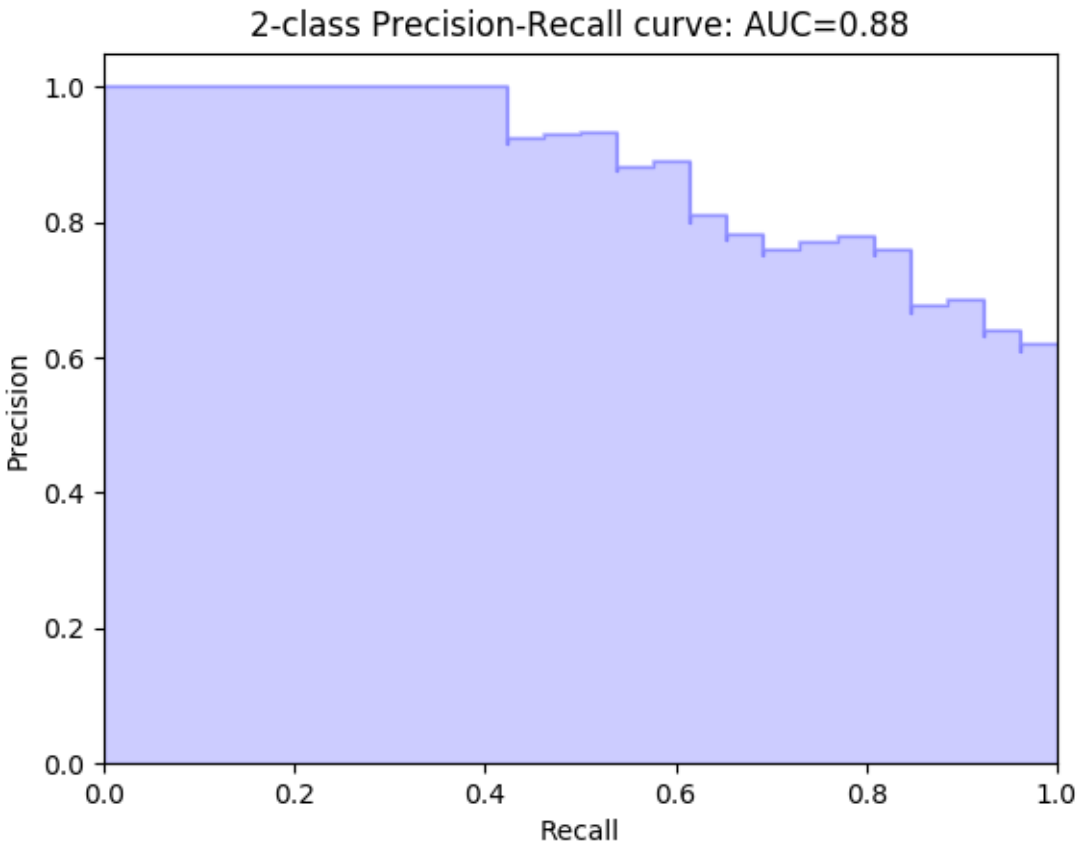
Compute the average precision score

```
from sklearn.metrics import average_precision_score
average_precision = average_precision_score(y_test, y_score)

print('Average precision-recall score: {0:0.2f}'.format(
      average_precision))
```

Out:

```
Average precision-recall score: 0.88
```



Plot the Precision-Recall curve

```
from sklearn.metrics import precision_recall_curve
import matplotlib.pyplot as plt

precision, recall, _ = precision_recall_curve(y_test, y_score)

plt.step(recall, precision, color='b', alpha=0.2,
         where='post')
plt.fill_between(recall, precision, step='post', alpha=0.2,
                 color='b')

plt.xlabel('Recall')
plt.ylabel('Precision')
plt.ylim([0.0, 1.05])
plt.xlim([0.0, 1.0])
plt.title('2-class Precision-Recall curve: AUC={0:0.2f}'.format(
          average_precision))
```

21.12.2 In multi-label settings

Create multi-label data, fit, and predict

We create a multi-label dataset, to illustrate the precision-recall in multi-label settings

```
from sklearn.preprocessing import label_binarize

# Use label_binarize to be multi-label like settings
Y = label_binarize(y, classes=[0, 1, 2])
n_classes = Y.shape[1]

# Split into training and test
X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size=.5,
                                                    random_state=random_state)

# We use OneVsRestClassifier for multi-label prediction
from sklearn.multiclass import OneVsRestClassifier

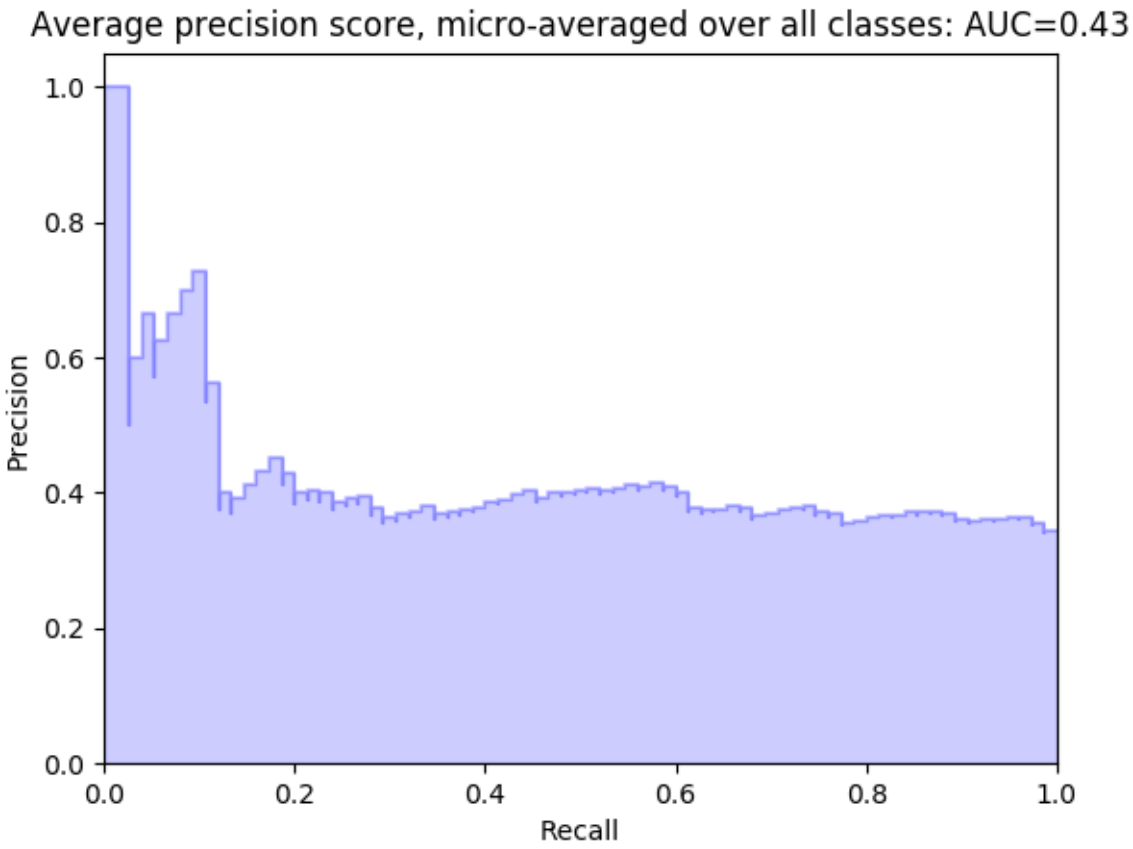
# Run classifier
classifier = OneVsRestClassifier(svm.LinearSVC(random_state=random_state))
classifier.fit(X_train, Y_train)
y_score = classifier.decision_function(X_test)
```

The average precision score in multi-label settings

```
from sklearn.metrics import precision_recall_curve
from sklearn.metrics import average_precision_score

# For each class
precision = dict()
recall = dict()
average_precision = dict()
for i in range(n_classes):
    precision[i], recall[i], _ = precision_recall_curve(Y_test[:, i],
                                                        y_score[:, i])
    average_precision[i] = average_precision_score(Y_test[:, i], y_score[:, i])

# A "micro-average": quantifying score on all classes jointly
precision["micro"], recall["micro"], _ = precision_recall_curve(Y_test.ravel(),
    y_score.ravel())
average_precision["micro"] = average_precision_score(Y_test, y_score,
                                                     average="micro")
print('Average precision score, micro-averaged over all classes: {0:0.2f}'
      .format(average_precision["micro"]))
```



Out:

```
Average precision score, micro-averaged over all classes: 0.43
```

Plot the micro-averaged Precision-Recall curve

```
plt.figure()
plt.step(recall['micro'], precision['micro'], color='b', alpha=0.2,
         where='post')
plt.fill_between(recall["micro"], precision["micro"], step='post', alpha=0.2,
                 color='b')

plt.xlabel('Recall')
plt.ylabel('Precision')
plt.ylim([0.0, 1.05])
plt.xlim([0.0, 1.0])
plt.title(
    'Average precision score, micro-averaged over all classes: AUC={0:0.2f}'

NEAREST NEIGHBORS

Examples concerning the *sklearn.neighbors* module.

22.1 Anomaly detection with Local Outlier Factor (LOF)

This example presents the Local Outlier Factor (LOF) estimator. The LOF algorithm is an unsupervised outlier detection method which computes the local density deviation of a given data point with respect to its neighbors. It considers as outlier samples that have a substantially lower density than their neighbors.

The number of neighbors considered, (parameter n_neighbors) is typically chosen 1) greater than the minimum number of objects a cluster has to contain, so that other objects can be local outliers relative to this cluster, and 2) smaller than the maximum number of close by objects that can potentially be local outliers. In practice, such informations are generally not available, and taking n_neighbors=20 appears to work well in general.

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn.neighbors import LocalOutlierFactor

np.random.seed(42)

# Generate train data
X = 0.3 * np.random.randn(100, 2)
# Generate some abnormal novel observations
X_outliers = np.random.uniform(low=-4, high=4, size=(20, 2))
X = np.r_[X + 2, X - 2, X_outliers]

# fit the model
clf = LocalOutlierFactor(n_neighbors=20)
y_pred = clf.fit_predict(X)
y_pred_outliers = y_pred[200:]

# plot the level sets of the decision function
xx, yy = np.meshgrid(np.linspace(-5, 5, 50), np.linspace(-5, 5, 50))
Z = clf._decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)

plt.title("Local Outlier Factor (LOF)")
plt.contourf(xx, yy, Z, cmap=plt.cm.Blues_r)
```

```
a = plt.scatter(X[:200, 0], X[:200, 1], c='white',
                edgecolor='k', s=20)
b = plt.scatter(X[200:, 0], X[200:, 1], c='red',
                edgecolor='k', s=20)
plt.axis('tight')
plt.xlim((-5, 5))
plt.ylim((-5, 5))
plt.legend([a, b],
           ["normal observations",
            "abnormal observations"],
           loc="upper left")
plt.show()

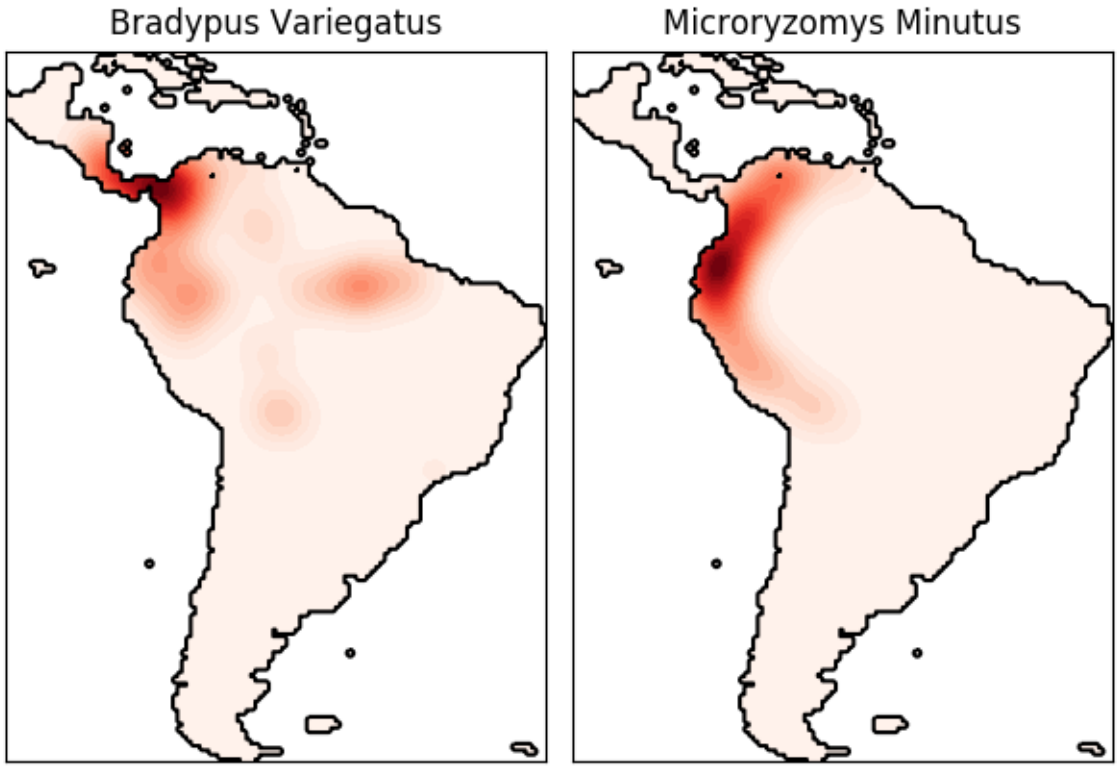
22.6 Kernel Density Estimate of Species Distributions

This shows an example of a neighbors-based query (in particular a kernel density estimate) on geospatial data, using a Ball Tree built upon the Haversine distance metric – i.e. distances over points in latitude/longitude. The dataset is provided by Phillips et. al. (2006). If available, the example uses basemap to plot the coast lines and national boundaries of South America.

This example does not perform any learning over the data (see *Species distribution modeling* for an example of classification based on the attributes in this dataset). It simply shows the kernel density estimate of observed data points in geospatial coordinates.



The two species are:

- "Bradypus variegatus" , the Brown-throated Sloth.

- "Microryzomys minutus" , also known as the Forest Small Rice Rat, a rodent that lives in Peru, Colombia, Ecuador, Peru, and Venezuela.

22.6.1 References

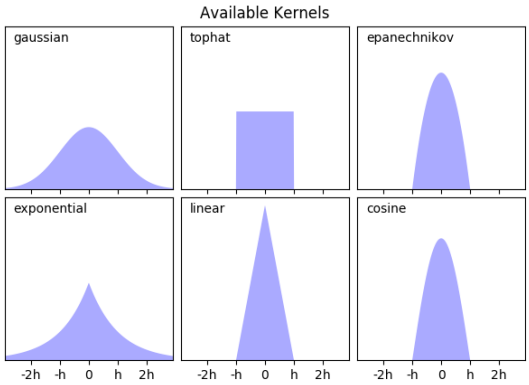
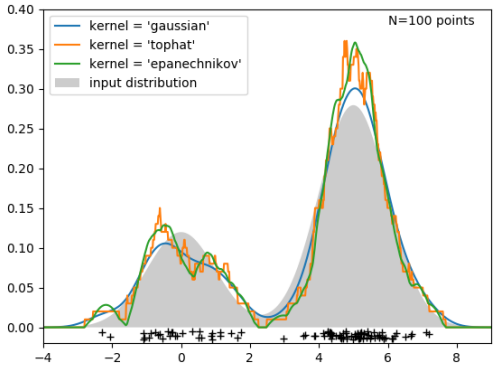
22.7 Simple 1D Kernel Density Estimation



This example uses the *sklearn.neighbors.KernelDensity* class to demonstrate the principles of Kernel Density Estimation in one dimension.



The first plot shows one of the problems with using histograms to visualize the density of points in 1D. Intuitively, a histogram can be thought of as a scheme in which a unit "block" is stacked above each point on a regular grid. As the top two panels show, however, the choice of gridding for these blocks can lead to wildly divergent ideas about the underlying shape of the density distribution. If we instead center each block on the point it represents, we get the estimate shown in the bottom left panel. This is a kernel density estimation with a "top hat" kernel. This idea can be generalized to other kernel shapes: the bottom-right panel of the first figure shows a Gaussian kernel density estimate over the same distribution.

Scikit-learn implements efficient kernel density estimation using either a Ball Tree or KD Tree structure, through the *sklearn.neighbors.KernelDensity* estimator. The available kernels are shown in the second figure of this example.

The third figure compares kernel density estimates for a distribution of 100 samples in 1 dimension. Though this example uses 1D distributions, kernel density estimation is easily and efficiently extensible to higher dimensions as well.

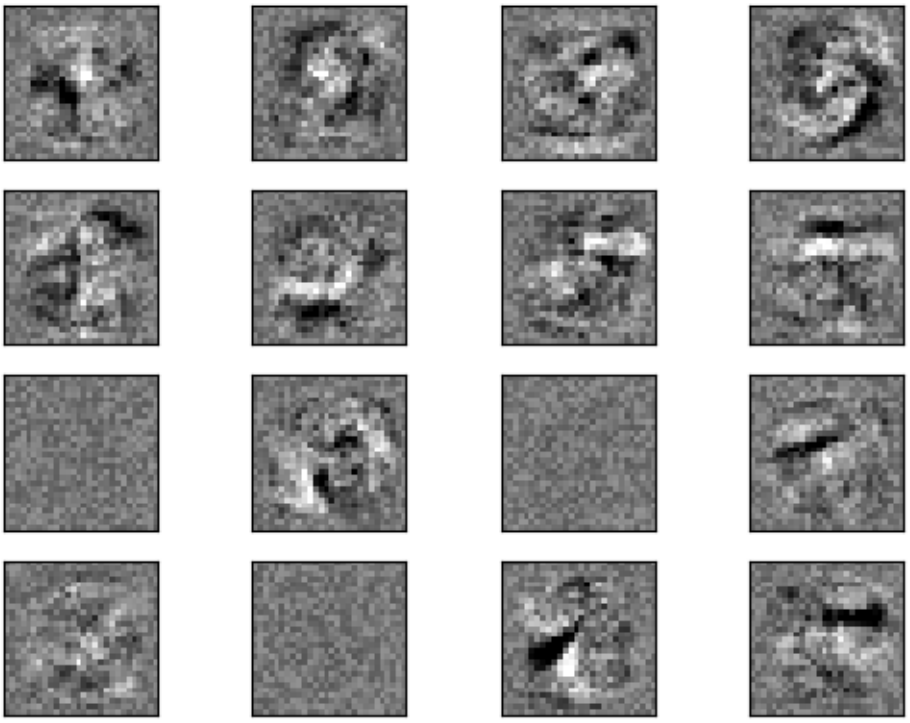
CHAPTER

TWENTYTHREE

NEURAL NETWORKS

Examples concerning the *sklearn.neural_network* module.



23.1 Visualization of MLP weights on MNIST

Sometimes looking at the learned coefficients of a neural network can provide insight into the learning behavior. For example if weights look unstructured, maybe some were not used at all, or if very large coefficients exist, maybe regularization was too low or the learning rate too high.

This example shows how to plot some of the first layer weights in a MLPClassifier trained on the MNIST dataset.

The input data consists of 28x28 pixel handwritten digits, leading to 784 features in the dataset. Therefore the first layer weight matrix have the shape (784, hidden_layer_sizes[0]). We can therefore visualize a single column of the weight matrix as a 28x28 pixel image.

To make the example run faster, we use very few hidden units, and train only for a very short time. Training longer would result in weights with a much smoother spatial appearance.

23.2 Compare Stochastic learning strategies for MLPClassifier

This example visualizes some training loss curves for different stochastic learning strategies, including SGD and Adam. Because of time-constraints, we use several small datasets, for which L-BFGS might be more suitable. The general trend shown in these examples seems to carry over to larger datasets, however.

Note that those results can be highly dependent on the value of `learning_rate_init`.

23.3 Restricted Boltzmann Machine features for digit classification

For greyscale image data where pixel values can be interpreted as degrees of blackness on a white background, like handwritten digit recognition, the Bernoulli Restricted Boltzmann machine model (*BernoulliRBM*) can perform effective non-linear feature extraction.

In order to learn good latent representations from a small dataset, we artificially generate more labeled data by perturbing the training data with linear shifts of 1 pixel in each direction.

This example shows how to build a classification pipeline with a BernoulliRBM feature extractor and a *LogisticRegression* classifier. The hyperparameters of the entire model (learning rate, hidden layer size, regularization) were optimized by grid search, but the search is not reproduced here because of runtime constraints.

Logistic regression on raw pixel values is presented for comparison. The example shows that the features extracted by the BernoulliRBM help improve the classification accuracy.

Out:

```

23.4 Varying regularization in Multi-layer Perceptron

A comparison of different values for regularization parameter 'alpha' on synthetic datasets. The plot shows that different alphas yield different decision functions.

Alpha is a parameter for regularization term, aka penalty term, that combats overfitting by constraining the size of the weights. Increasing alpha may fix high variance (a sign of overfitting) by encouraging smaller weights, resulting in a decision boundary plot that appears with lesser curvatures. Similarly, decreasing alpha may fix high bias (a sign of underfitting) by encouraging larger weights, potentially resulting in a more complicated decision boundary.

PREPROCESSING

Examples concerning the *sklearn.preprocessing* module.

24.1 Using FunctionTransformer to select columns

Shows how to use a function transformer in a pipeline. If you know your dataset's first principle component is irrelevant for a classification task, you can use the FunctionTransformer to select all but the first column of the PCA transformed data.

- 

```
import matplotlib.pyplot as plt
import numpy as np
```

```
from sklearn.model_selection import train_test_split
from sklearn.decomposition import PCA
from sklearn.pipeline import make_pipeline
from sklearn.preprocessing import FunctionTransformer

def _generate_vector(shift=0.5, noise=15):
    return np.arange(1000) + (np.random.rand(1000) - shift) * noise

def generate_dataset():
    """
    This dataset is two lines with a slope ~ 1, where one has
    a y offset of ~100
    """
    return np.vstack((
        np.vstack((
            _generate_vector(),
            _generate_vector() + 100,
        )).T,
        np.vstack((
            _generate_vector(),
            _generate_vector(),
        )).T,
    )), np.hstack((np.zeros(1000), np.ones(1000)))

def all_but_first_column(X):
    return X[:, 1:]

def drop_first_component(X, y):
    """
    Create a pipeline with PCA and the column selector and use it to
    transform the dataset.
    """
    pipeline = make_pipeline(
        PCA(), FunctionTransformer(all_but_first_column),
    )
    X_train, X_test, y_train, y_test = train_test_split(X, y)
    pipeline.fit(X_train, y_train)
    return pipeline.transform(X_test), y_test

if __name__ == '__main__':
    X, y = generate_dataset()
    lw = 0
    plt.figure()
    plt.scatter(X[:, 0], X[:, 1], c=y, lw=lw)
    plt.figure()
    X_transformed, y_transformed = drop_first_component(*generate_dataset())
    plt.scatter(
        X_transformed[:, 0],
        np.zeros(len(X_transformed)),
        c=y_transformed,
        lw=lw,
        s=60
    )
```

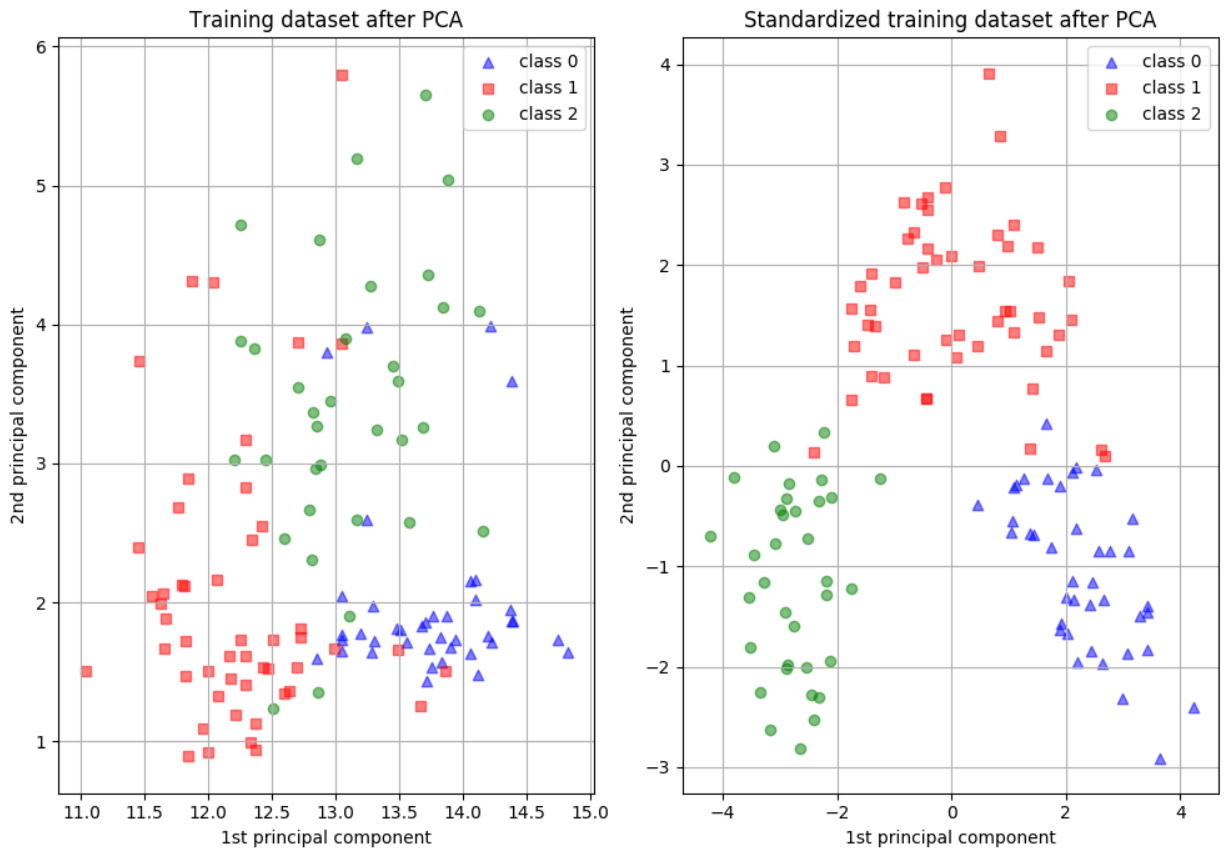
24.2 Importance of Feature Scaling



Feature scaling though standardization (or Z-score normalization) can be an important preprocessing step for many machine learning algorithms. Standardization involves rescaling the features such that they have the properties of a standard normal distribution with a mean of zero and a standard deviation of one.

While many algorithms (such as SVM, K-nearest neighbors, and logistic regression) require features to be normalized, intuitively we can think of Principle Component Analysis (PCA) as being a prime example of when normalization is important. In PCA we are interested in the components that maximize the variance. If one component (e.g. human height) varies less than another (e.g. weight) because of their respective scales (meters vs. kilos), PCA might determine that the direction of maximal variance more closely corresponds with the 'weight' axis, if those features are not scaled. As a change in height of one meter can be considered much more important than the change in weight of one kilogram, this is clearly incorrect.

To illustrate this, PCA is performed comparing the use of data with `StandardScaler` applied, to unscaled data. The results are visualized and a clear difference noted. The 1st principal component in the unscaled set can be seen. It can be seen that feature #13 dominates the direction, being a whole two orders of magnitude above the other features. This is contrasted when observing the principal component for the scaled version of the data. In the scaled version, the orders of magnitude are roughly the same across all the features.

The dataset used is the Wine Dataset available at UCI. This dataset has continuous features that are heterogeneous in scale due to differing properties that they measure (i.e alcohol content, and malic acid).

The transformed data is then used to train a naive Bayes classifier, and a clear difference in prediction accuracies is observed wherein the dataset which is scaled before PCA vastly outperforms the unscaled version.

Out:

```
Prediction accuracy for the normal test dataset with PCA
81.48%

Prediction accuracy for the standardized test dataset with PCA
98.15%

PC 1 without scaling:
 [  1.76e-03  -8.36e-04   1.55e-04  -5.31e-03   2.02e-02   1.02e-03
   1.53e-03  -1.12e-04   6.31e-04   2.33e-03   1.54e-04   7.43e-04
   1.00e+00]

PC 1 with scaling:
 [ 0.13 -0.26 -0.01 -0.23  0.16  0.39  0.42 -0.28  0.33 -0.11  0.3   0.38
  0.28]

24.3 Compare the effect of different scalers on data with outliers

Feature 0 (median income in a block) and feature 5 (number of households) of the California housing dataset have very different scales and contain some very large outliers. These two characteristics lead to difficulties to visualize the data and, more importantly, they can degrade the predictive performance of many machine learning algorithms. Unscaled data can also slow down or even prevent the convergence of many gradient-based estimators.

Indeed many estimators are designed with the assumption that each feature takes values close to zero or more importantly that all features vary on comparable scales. In particular, metric-based and gradient-based estimators often assume approximately standardized data (centered features with unit variances). A notable exception are decision tree-based estimators that are robust to arbitrary scaling of the data.

This example uses different scalers, transformers, and normalizers to bring the data within a pre-defined range.

Scalers are linear (or more precisely affine) transformers and differ from each other in the way to estimate the parameters used to shift and scale each feature.

`QuantileTransformer` provides a non-linear transformation in which distances between marginal outliers and inliers are shrunk.

Unlike the previous transformations, normalization refers to a per sample transformation instead of a per feature transformation.

The following code is a bit verbose, feel free to jump directly to the analysis of the *results*.

```

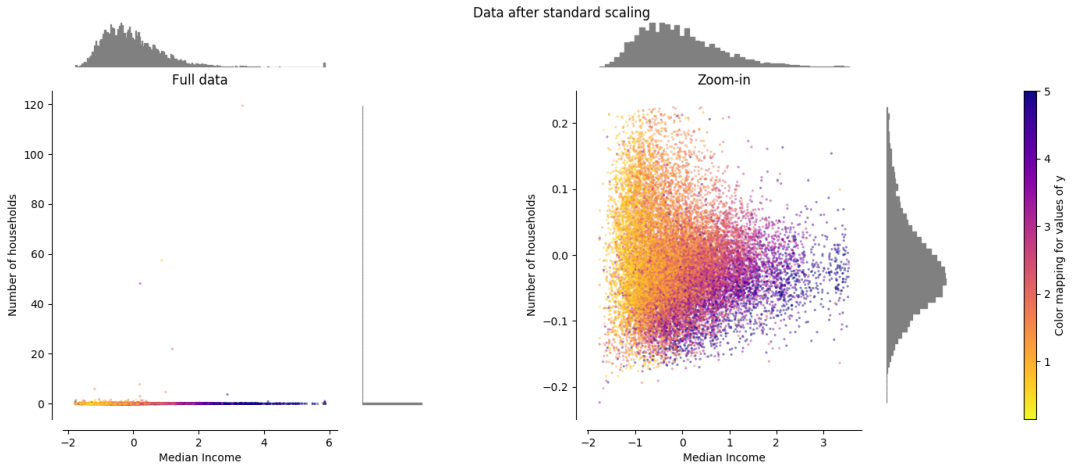
24.3.1 Original data

Each transformation is plotted showing two transformed features, with the left plot showing the entire dataset, and the right zoomed-in to show the dataset without the marginal outliers. A large majority of the samples are compacted to a specific range, [0, 10] for the median income and [0, 6] for the number of households. Note that there are some marginal outliers (some blocks have more than 1200 households). Therefore, a specific pre-processing can be very beneficial depending of the application. In the following, we present some insights and behaviors of those

pre-processing methods in the presence of marginal outliers.

```
make_plot(0)
```

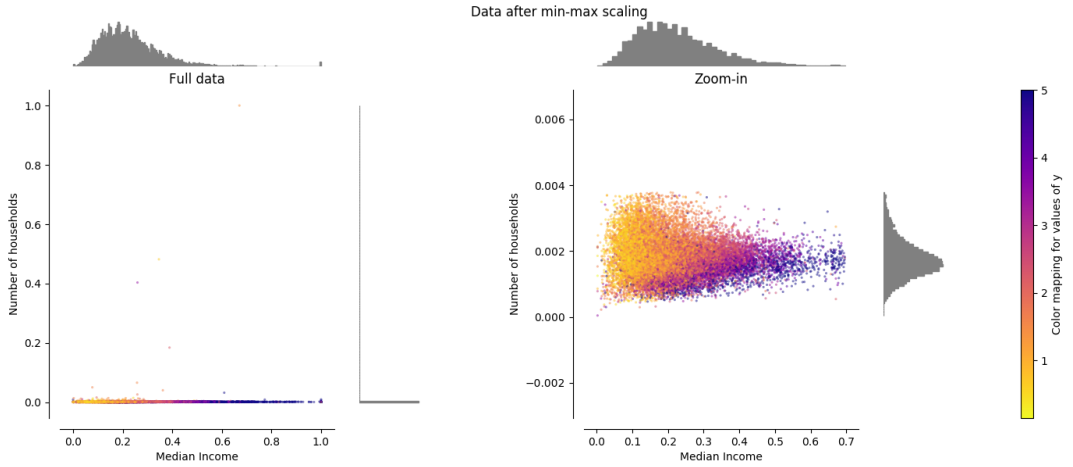


24.3.2 StandardScaler

`StandardScaler` removes the mean and scales the data to unit variance. However, the outliers have an influence when computing the empirical mean and standard deviation which shrink the range of the feature values as shown in the left figure below. Note in particular that because the outliers on each feature have different magnitudes, the spread of the transformed data on each feature is very different: most of the data lie in the [-2, 4] range for the transformed median income feature while the same data is squeezed in the smaller [-0.2, 0.2] range for the transformed number of households.

`StandardScaler` therefore cannot guarantee balanced feature scales in the presence of outliers.

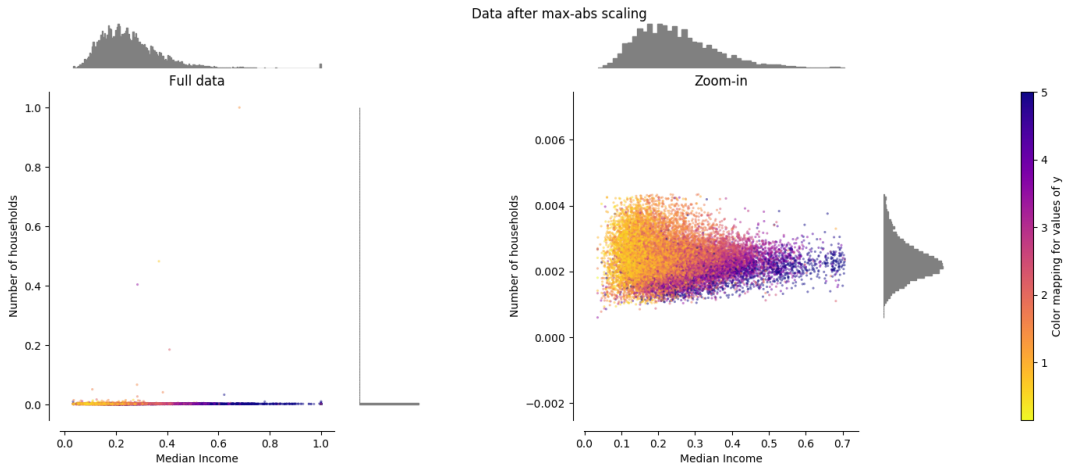
```
make_plot(1)
```



24.3.3 MinMaxScaler

`MinMaxScaler` rescales the data set such that all feature values are in the range [0, 1] as shown in the right panel below. However, this scaling compress all inliers in the narrow range [0, 0.005] for the transformed number of households.

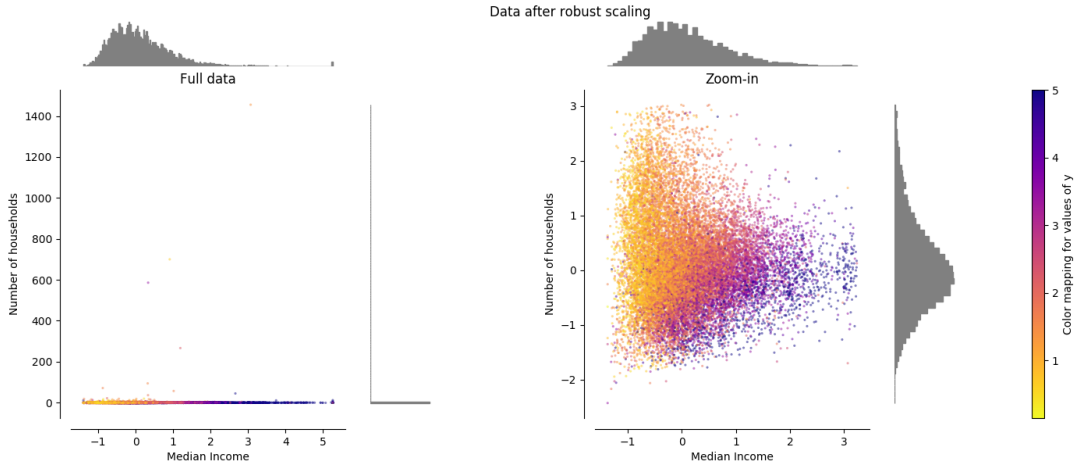
As `StandardScaler`, `MinMaxScaler` is very sensitive to the presence of outliers.



```
make_plot(2)
```

24.3.4 MaxAbsScaler

`MaxAbsScaler` differs from the previous scaler such that the absolute values are mapped in the range [0, 1]. On positive only data, this scaler behaves similarly to `MinMaxScaler` and therefore also suffers from the presence of large outliers.

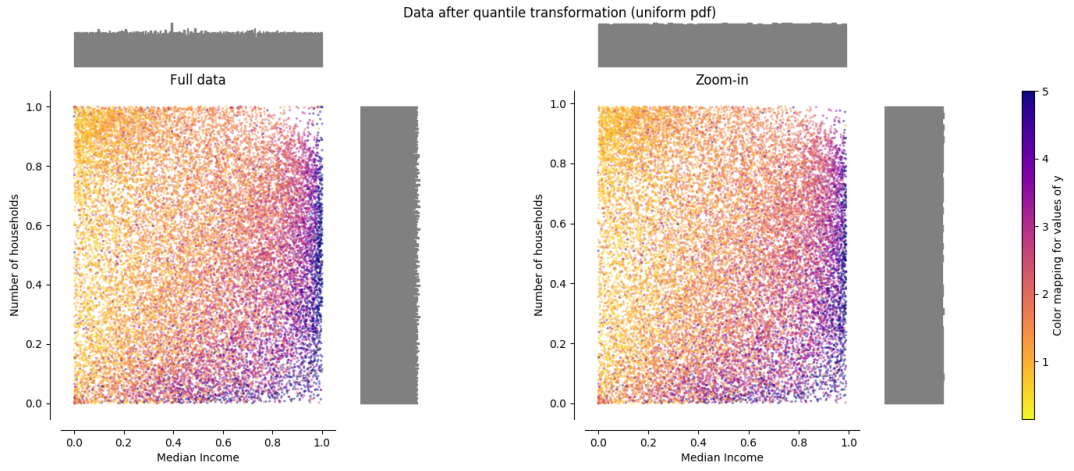


```
make_plot(3)
```

24.3.5 RobustScaler

Unlike the previous scalers, the centering and scaling statistics of this scaler are based on percentiles and are therefore not influenced by a few number of very large marginal outliers. Consequently, the resulting range of the transformed feature values is larger than for the previous scalers and, more importantly, are approximately similar: for both features most of the transformed values lie in a [-2, 3] range as seen in the zoomed-in figure. Note that the outliers themselves are still present in the transformed data. If a separate outlier clipping is desirable, a non-linear transformation is required (see below).

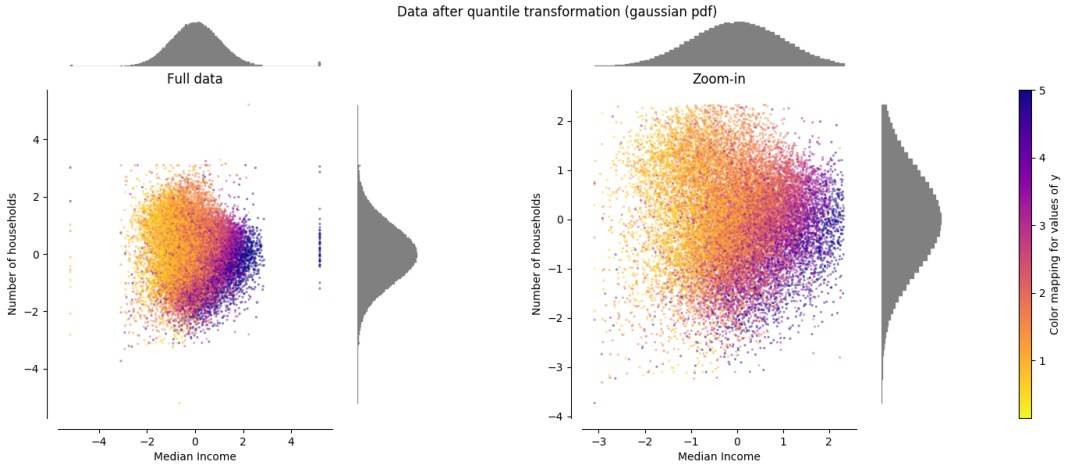
```
make_plot(4)
```



24.3.6 QuantileTransformer (uniform output)

`QuantileTransformer` applies a non-linear transformation such that the probability density function of each feature will be mapped to a uniform distribution. In this case, all the data will be mapped in the range [0, 1], even the outliers which cannot be distinguished anymore from the inliers.

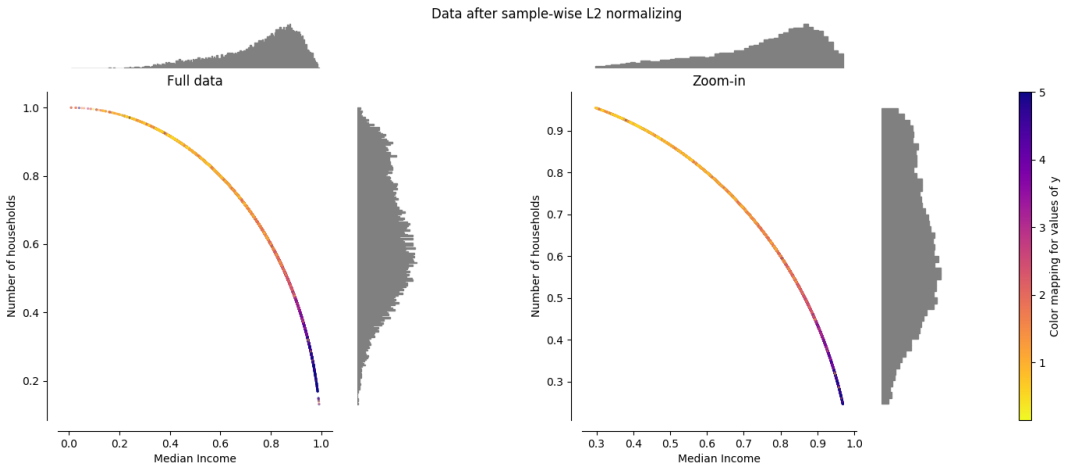
As `RobustScaler`, `QuantileTransformer` is robust to outliers in the sense that adding or removing outliers in the training set will yield approximately the same transformation on held out data. But contrary to `RobustScaler`, `QuantileTransformer` will also automatically collapse any outlier by setting them to the a priori defined range boundaries (0 and 1).



```
make_plot(5)
```

24.3.7 QuantileTransformer (Gaussian output)

`QuantileTransformer` has an additional `output_distribution` parameter allowing to match a Gaussian distribution instead of a uniform distribution. Note that this non-parametetric transformer introduces saturation artifacts for extreme values.



```
make_plot(6)
```

24.3.8 Normalizer

The `Normalizer` rescales the vector for each sample to have unit norm, independently of the distribution of the samples. It can be seen on both figures below where all samples are mapped onto the unit circle. In our example the two selected features have only positive values; therefore the transformed data only lie in the positive quadrant. This would not be the case if some original features had a mix of positive and negative values.

```
make_plot(7)
plt.show()
```

25.2 Label Propagation learning a complex structure

Example of LabelPropagation learning a complex internal structure to demonstrate "manifold learning". The outer circle should be labeled "red" and the inner circle "blue". Because both label groups lie inside their own distinct shape, we can see that the labels propagate correctly around the circle.

```

25.3 Label Propagation digits: Demonstrating performance

This example demonstrates the power of semisupervised learning by training a Label Spreading model to classify handwritten digits with sets of very few labels.

The handwritten digit dataset has 1797 total points. The model will be trained using all points, but only 30 will be labeled. Results in the form of a confusion matrix and a series of metrics over each class will be very good.

At the end, the top 10 most uncertain predictions will be shown.

Out:

```
Label Spreading model: 30 labeled & 300 unlabeled points (330 total)
              precision    recall  f1-score   support

           0       1.00      1.00      1.00        23
           1       0.58      0.54      0.56        28
           2       0.96      0.93      0.95        29
           3       0.00      0.00      0.00        28
           4       0.91      0.80      0.85        25

25.4 Label Propagation digits active learning

Demonstrates an active learning technique to learn handwritten digits using label propagation.

We start by training a label propagation model with only 10 labeled points, then we select the top five most uncertain points to label. Next, we train with 15 labeled points (original 10 + 5 new ones). We repeat this process four times to have a model trained with 30 labeled examples. Note you can increase this to label more than 30 by changing *max_iterations*. Labeling more than 30 can be useful to get a sense for the speed of convergence of this active learning technique.

A plot will appear showing the top 5 most uncertain digits for each iteration of training. These may or may not contain mistakes, but we will train the next model with their true labels.

Out:

```
Iteration 0 ______________________________________________________________________
Label Spreading model: 10 labeled & 320 unlabeled (330 total)

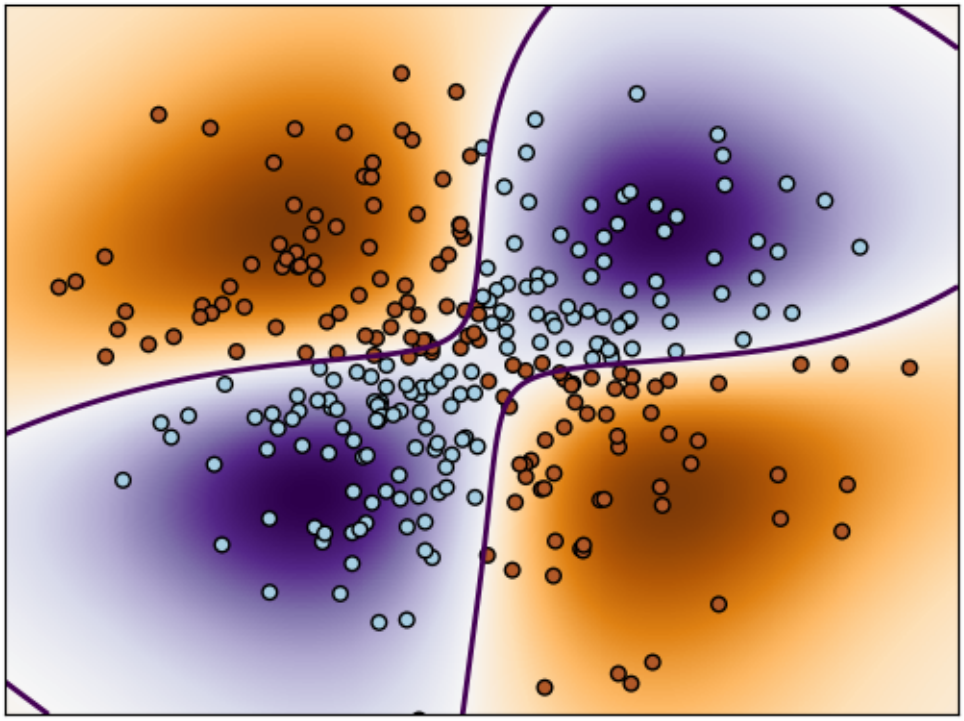
CHAPTER

TWENTYSIX



SUPPORT VECTOR MACHINES

Examples concerning the *sklearn.svm* module.

26.1 Non-linear SVM

Perform binary classification using non-linear SVC with RBF kernel. The target to predict is a XOR of the inputs.

The color map illustrates the decision function learned by the SVC.

```
print(__doc__)
```

```
import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm

xx, yy = np.meshgrid(np.linspace(-3, 3, 500),
                     np.linspace(-3, 3, 500))
np.random.seed(0)
X = np.random.randn(300, 2)
Y = np.logical_xor(X[:, 0] > 0, X[:, 1] > 0)

# fit the model
clf = svm.NuSVC()
clf.fit(X, Y)

# plot the decision function for each datapoint on the grid
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)

plt.imshow(Z, interpolation='nearest',
           extent=(xx.min(), xx.max(), yy.min(), yy.max()), aspect='auto',
           origin='lower', cmap=plt.cm.PuOr_r)
contours = plt.contour(xx, yy, Z, levels=[0], linewidths=2,
                       linetypes='--')
plt.scatter(X[:, 0], X[:, 1], s=30, c=Y, cmap=plt.cm.Paired,
            edgecolors='k')
plt.xticks(())
plt.yticks(())
plt.axis([-3, 3, -3, 3])
plt.show()
```

26.2 SVM: Maximum margin separating hyperplane

Plot the maximum margin separating hyperplane within a two-class separable dataset using a Support Vector Machine classifier with linear kernel.

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm

# we create 40 separable points
np.random.seed(0)
X = np.r_[np.random.randn(20, 2) - [2, 2], np.random.randn(20, 2) + [2, 2]]
Y = [0] * 20 + [1] * 20

# fit the model
clf = svm.SVC(kernel='linear')
clf.fit(X, Y)

# get the separating hyperplane
w = clf.coef_[0]
a = -w[0] / w[1]
xx = np.linspace(-5, 5)
yy = a * xx - (clf.intercept_[0]) / w[1]

# plot the parallels to the separating hyperplane that pass through the
# support vectors
b = clf.support_vectors_[0]
yy_down = a * xx + (b[1] - a * b[0])
b = clf.support_vectors_[-1]
```

```
yy_up = a * xx + (b[1] - a * b[0])

# plot the line, the points, and the nearest vectors to the plane
plt.plot(xx, yy, 'k-')
plt.plot(xx, yy_down, 'k--')
plt.plot(xx, yy_up, 'k--')

plt.scatter(clf.support_vectors_[:, 0], clf.support_vectors_[:, 1],
            s=80, facecolors='none')
plt.scatter(X[:, 0], X[:, 1], c=Y, cmap=plt.cm.Paired)

plt.axis('tight')
plt.show()
```

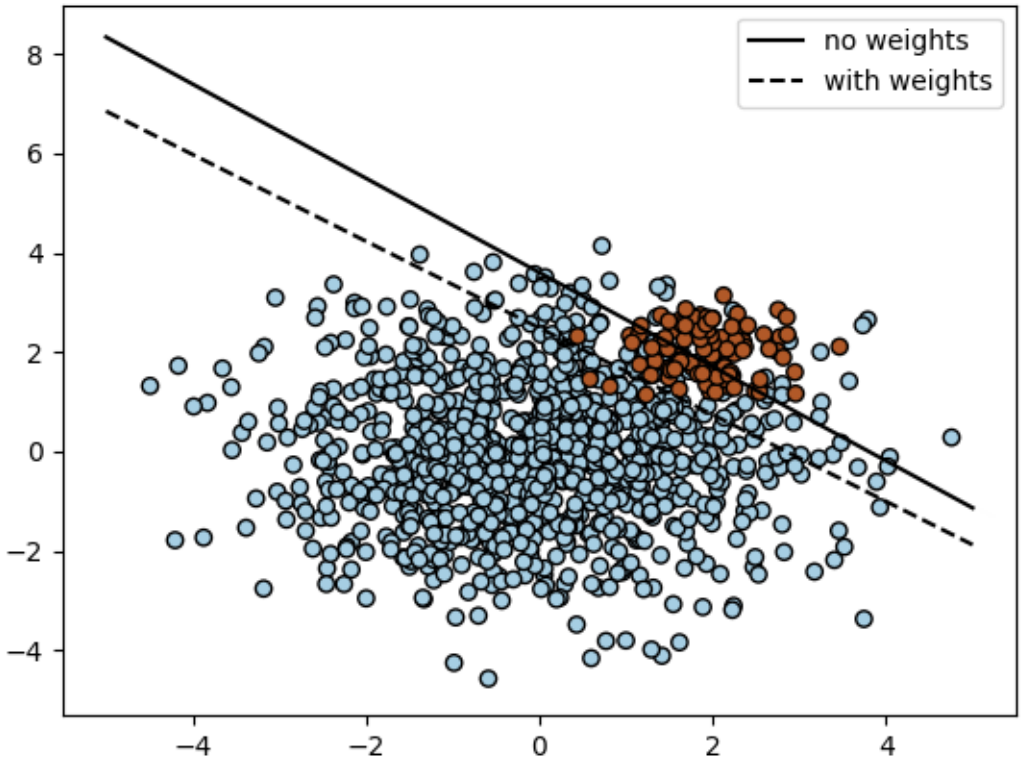
26.3 SVM: Separating hyperplane for unbalanced classes



Find the optimal separating hyperplane using an SVC for classes that are unbalanced.

We first find the separating plane with a plain SVC and then plot (dashed) the separating hyperplane with automatically correction for unbalanced classes.

Note: This example will also work by replacing `SVC(kernel="linear")` with `SGDClassifier(loss="hinge")`. Setting the `loss` parameter of the *`SGDClassifier`* equal to `hinge` will yield behaviour such as that of a SVC with a linear kernel.

For example try instead of the `SVC`:

```
clf = SGDClassifier(n_iter=100, alpha=0.01)
```

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm
#from sklearn.linear_model import SGDClassifier

# we create 40 separable points
rng = np.random.RandomState(0)
n_samples_1 = 1000
n_samples_2 = 100
X = np.r_[1.5 * rng.randn(n_samples_1, 2),
          0.5 * rng.randn(n_samples_2, 2) + [2, 2]]
y = [0] * (n_samples_1) + [1] * (n_samples_2)

# fit the model and get the separating hyperplane
clf = svm.SVC(kernel='linear', C=1.0)
clf.fit(X, y)

w = clf.coef_[0]
a = -w[0] / w[1]
xx = np.linspace(-5, 5)
yy = a * xx - clf.intercept_[0] / w[1]

# get the separating hyperplane using weighted classes
```

```
wclf = svm.SVC(kernel='linear', class_weight={1: 10})
wclf.fit(X, y)

ww = wclf.coef_[0]
wa = -ww[0] / ww[1]
wyy = wa * xx - wclf.intercept_[0] / ww[1]

# plot separating hyperplanes and samples
h0 = plt.plot(xx, yy, 'k-', label='no weights')
h1 = plt.plot(xx, wyy, 'k--', label='with weights')
plt.scatter(X[:, 0], X[:, 1], c=y, cmap=plt.cm.Paired, edgecolors='k')
plt.legend()

plt.axis('tight')
plt.show()
```

26.6 SVM: Weighted samples

Plot decision function of a weighted dataset, where the size of points is proportional to its weight.

The sample weighting rescales the C parameter, which means that the classifier puts more emphasis on getting these points right. The effect might often be subtle. To emphasize the effect here, we particularly weight outliers, making the deformation of the decision boundary very visible.

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm

def plot_decision_function(classifier, sample_weight, axis, title):
    # plot the decision function
    xx, yy = np.meshgrid(np.linspace(-4, 5, 500), np.linspace(-4, 5, 500))

    Z = classifier.decision_function(np.c_[xx.ravel(), yy.ravel()])
    Z = Z.reshape(xx.shape)

    # plot the line, the points, and the nearest vectors to the plane
    axis.contourf(xx, yy, Z, alpha=0.75, cmap=plt.cm.bone)
    axis.scatter(X[:, 0], X[:, 1], c=y, s=100 * sample_weight, alpha=0.9,
                 cmap=plt.cm.bone, edgecolors='black')

    axis.axis('off')
    axis.set_title(title)

# we create 20 points
np.random.seed(0)
X = np.r_[np.random.randn(10, 2) + [1, 1], np.random.randn(10, 2)]

26.9 SVM Margins Example

The plots below illustrate the effect the parameter *C* has on the separation line. A large value of *C* basically tells our model that we do not have that much faith in our data's distribution, and will only consider points close to line of separation.

A small value of *C* includes more/all the observations, allowing the margins to be calculated using all the data in the area.

```
print(__doc__)

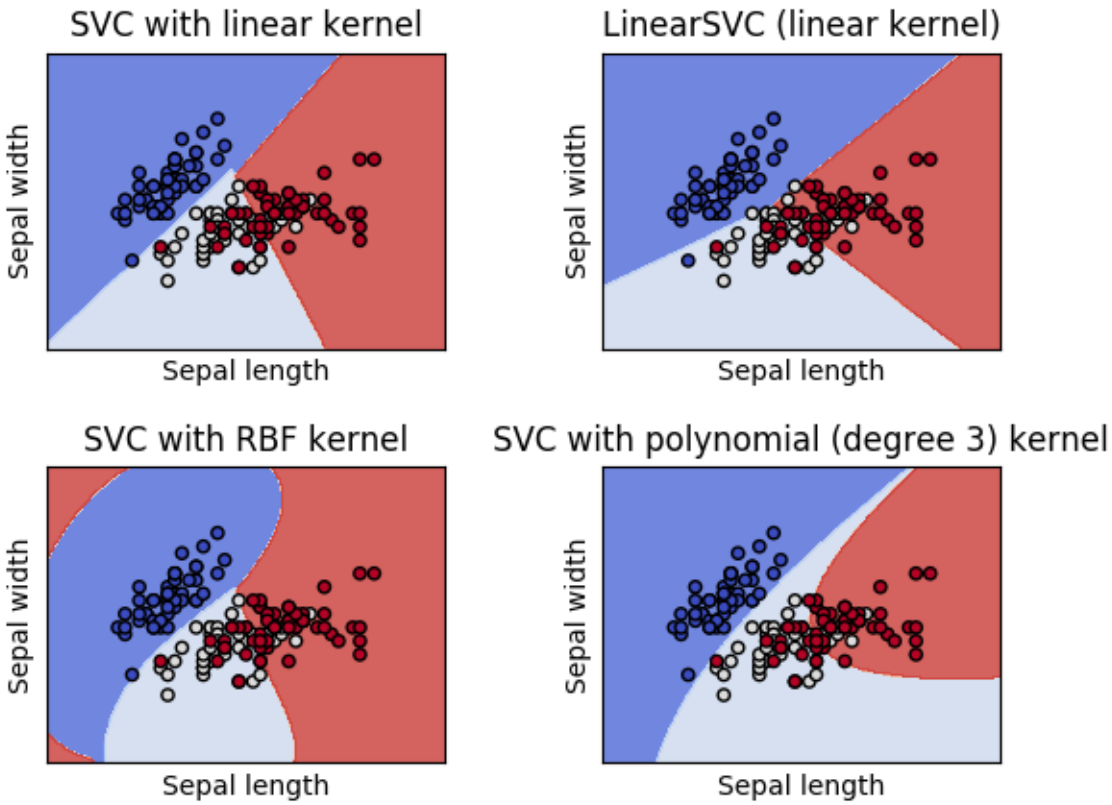
26.11 Plot different SVM classifiers in the iris dataset

Comparison of different linear SVM classifiers on a 2D projection of the iris dataset. We only consider the first 2 features of this dataset:

- Sepal length
- Sepal width



This example shows how to plot the decision surface for four SVM classifiers with different kernels.

The linear models `LinearSVC()` and `SVC(kernel='linear')` yield slightly different decision boundaries. This can be a consequence of the following differences:

- `LinearSVC` minimizes the squared hinge loss while `SVC` minimizes the regular hinge loss.
- `LinearSVC` uses the One-vs-All (also known as One-vs-Rest) multiclass reduction while `SVC` uses the One-vs-One multiclass reduction.

Both linear models have linear decision boundaries (intersecting hyperplanes) while the non-linear kernel models (polynomial or Gaussian RBF) have more flexible non-linear decision boundaries with shapes that depend on the kind of kernel and its parameters.

Note: while plotting the decision function of classifiers for toy 2D datasets can help get an intuitive understanding of their respective expressive power, be aware that those intuitions don't always generalize to more realistic high-dimensional problems.

```

26.12 Scaling the regularization parameter for SVCs

The following example illustrates the effect of scaling the regularization parameter when using *Support Vector Machines* for *classification*. For SVC classification, we are interested in a risk minimization for the equation:

$$C \sum_{i=1,n} \mathcal{L}(f(x_i), y_i) + \Omega(w)$$

where

- C is used to set the amount of regularization
- $\mathcal{L}$ is a *loss* function of our samples and our model parameters.
- Ω is a *penalty* function of our model parameters

If we consider the loss function to be the individual error per sample, then the data-fit term, or the sum of the error for each sample, will increase as we add more samples. The penalization term, however, will not increase.

When using, for example, *cross validation*, to set the amount of regularization with *C*, there will be a different amount of samples between the main problem and the smaller problems within the folds of the cross validation.

Since our loss function is dependent on the amount of samples, the latter will influence the selected value of *C*. The question that arises is *How do we optimally adjust C to account for the different amount of training samples?*

The figures below are used to illustrate the effect of scaling our *C* to compensate for the change in the number of samples, in the case of using an *l1* penalty, as well as the *l2* penalty.

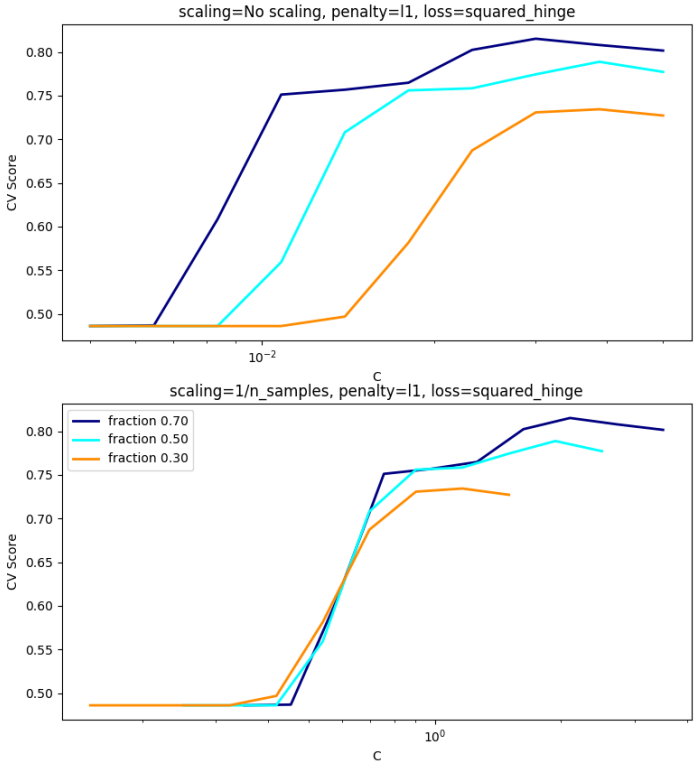
26.12.1 l1-penalty case

In the *l1* case, theory says that prediction consistency (i.e. that under given hypothesis, the estimator learned predicts as well as a model knowing the true distribution) is not possible because of the bias of the *l1*. It does say, however, that model consistency, in terms of finding the right set of non-zero parameters as well as their signs, can be achieved by scaling *C1*.

26.12.2 l2-penalty case

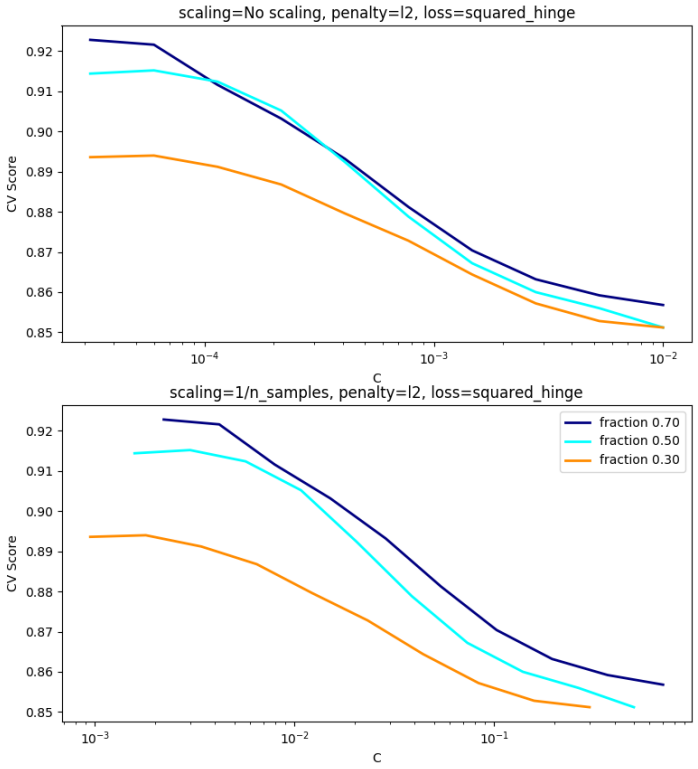
The theory says that in order to achieve prediction consistency, the penalty parameter should be kept constant as the number of samples grow.

26.12.3 Simulations



The two figures below plot the values of *C* on the *x-axis* and the corresponding cross-validation scores on the *y-axis*, for several different fractions of a generated data-set.

In the *l1* penalty case, the cross-validation-error correlates best with the test-error, when scaling our *C* with the number of samples, *n*, which can be seen in the first figure.



For the *l2* penalty case, the best result comes from the case where *C* is not scaled.

Note:

Two separate datasets are used for the two different plots. The reason behind this is the *l1* case works better on sparse data, while *l2* is better suited to the non-sparse case.

26.13 RBF SVM parameters

This example illustrates the effect of the parameters `gamma` and `C` of the Radial Basis Function (RBF) kernel SVM.

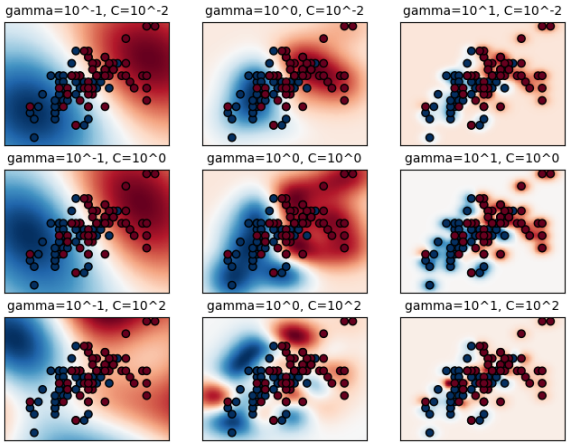
Intuitively, the `gamma` parameter defines how far the influence of a single training example reaches, with low values meaning 'far' and high values meaning 'close'. The `gamma` parameters can be seen as the inverse of the radius of influence of samples selected by the model as support vectors.

The `C` parameter trades off misclassification of training examples against simplicity of the decision surface. A low `C` makes the decision surface smooth, while a high `C` aims at classifying all training examples correctly by giving the model freedom to select more samples as support vectors.

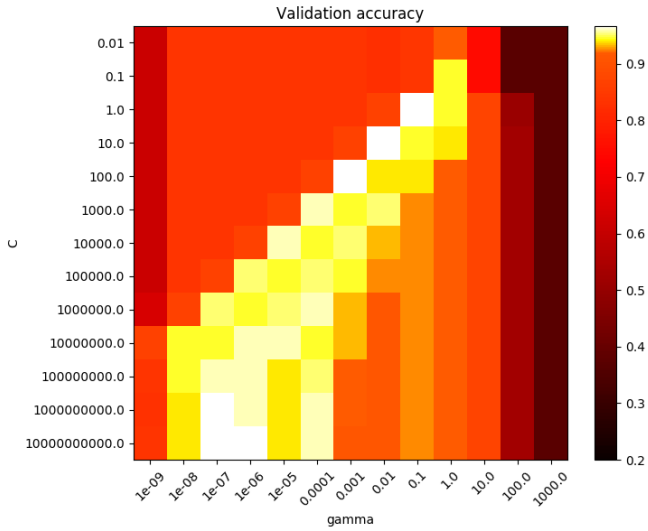
The first plot is a visualization of the decision function for a variety of parameter values on a simplified classification problem involving only 2 input features and 2 possible target classes (binary classification). Note that this kind of plot is not possible to do for problems with more features or target classes.

The second plot is a heatmap of the classifier's cross-validation accuracy as a function of `C` and `gamma`. For this example we explore a relatively large grid for illustration purposes. In practice, a logarithmic grid from 10^{-3} to 10^{3} is usually sufficient. If the best parameters lie on the boundaries of the grid, it can be extended in that direction in a subsequent search.

Note that the heat map plot has a special colorbar with a midpoint value close to the score values of the best performing models so as to make it easy to tell them appart in the blink of an eye.



The behavior of the model is very sensitive to the `gamma` parameter. If `gamma` is too large, the radius of the area of influence of the support vectors only includes the support vector itself and no amount of regularization with `C` will be able to prevent overfitting.



When `gamma` is very small, the model is too constrained and cannot capture the complexity or "shape" of the data. The region of influence of any selected support vector would include the whole training set. The resulting model will behave similarly to a linear model with a set of hyperplanes that separate the centers of high density of any pair of two classes.

For intermediate values, we can see on the second plot that good models can be found on a diagonal of `C` and `gamma`. Smooth models (lower `gamma` values) can be made more complex by selecting a larger number of support vectors (larger `C` values) hence the diagonal of good performing models.

Finally one can also observe that for some intermediate values of `gamma` we get equally performing models when `C` becomes very large: it is not necessary to regularize by limiting the number of support vectors. The radius of the RBF kernel alone acts as a good structural regularizer. In practice though it might still be interesting to limit the number of support vectors with a lower value of `C` so as to favor models that use less memory and that are faster to predict.

We should also note that small differences in scores results from the random splits of the cross-validation procedure. Those spurious variations can be smoothed out by increasing the number of CV iterations `n_splits` at the expense of compute time. Increasing the value number of `C_range` and `gamma_range` steps will increase the resolution of the hyper-parameter heat map.

-

CHAPTER

TWENTYSEVEN

WORKING WITH TEXT DOCUMENTS

Examples concerning the *sklearn.feature_extraction.text* module.

27.1 FeatureHasher and DictVectorizer Comparison

Compares FeatureHasher and DictVectorizer by using both to vectorize text documents.

The example demonstrates syntax and speed only; it doesn't actually do anything useful with the extracted vectors. See the example scripts {document_classification_20newsgroups,clustering}.py for actual learning on text documents.

A discrepancy between the number of terms reported for DictVectorizer and for FeatureHasher is to be expected due to hash collisions.

27.2 Clustering text documents using k-means

This is an example showing how the scikit-learn can be used to cluster documents by topics using a bag-of-words approach. This example uses a scipy.sparse matrix to store the features instead of standard numpy arrays.

Two feature extraction methods can be used in this example:

- TfidfVectorizer uses a in-memory vocabulary (a python dict) to map the most frequent words to features indices and hence compute a word occurrence frequency (sparse) matrix. The word frequencies are then reweighted using the Inverse Document Frequency (IDF) vector collected feature-wise over the corpus.
- HashingVectorizer hashes word occurrences to a fixed dimensional space, possibly with collisions. The word count vectors are then normalized to each have l2-norm equal to one (projected to the euclidean unit-ball) which seems to be important for k-means to work in high dimensional space.

  HashingVectorizer does not provide IDF weighting as this is a stateless model (the fit method does nothing). When IDF weighting is needed it can be added by pipelining its output to a TfidfTransformer instance.

Two algorithms are demoed: ordinary k-means and its more scalable cousin minibatch k-means.

Additionally, latent semantic analysis can also be used to reduce dimensionality and discover latent patterns in the data.

It can be noted that k-means (and minibatch k-means) are very sensitive to feature scaling and that in this case the IDF weighting helps improve the quality of the clustering by quite a lot as measured against the "ground truth" provided by the class label assignments of the 20 newsgroups dataset.

This improvement is not visible in the Silhouette Coefficient which is small for both as this measure seem to suffer from the phenomenon called "Concentration of Measure" or "Curse of Dimensionality" for high dimensional datasets such as text data. Other measures such as V-measure and Adjusted Rand Index are information theoretic based evaluation scores: as they are only based on cluster assignments rather than distances, hence not affected by the curse of dimensionality.

Note: as k-means is optimizing a non-convex objective function, it will likely end up in a local optimum. Several runs with independent random init might be necessary to get a good convergence.

27.3 Classification of text documents using sparse features

This is an example showing how scikit-learn can be used to classify documents by topics using a bag-of-words approach. This example uses a scipy.sparse matrix to store the features and demonstrates various classifiers that can efficiently handle sparse matrices.

The dataset used in this example is the 20 newsgroups dataset. It will be automatically downloaded, then cached.

The bar plot indicates the accuracy, training time (normalized) and test time (normalized) of each classifier.

DECISION TREES

Examples concerning the `sklearn.tree` module.

28.1 Decision Tree Regression

A 1D regression with decision tree.

The *decision trees* is used to fit a sine curve with addition noisy observation. As a result, it learns local linear regressions approximating the sine curve.

We can see that if the maximum depth of the tree (controlled by the *max_depth* parameter) is set too high, the decision trees learn too fine details of the training data and learn from the noise, i.e. they overfit.

```
print(__doc__)

# Import the necessary modules and libraries
import numpy as np
from sklearn.tree import DecisionTreeRegressor
import matplotlib.pyplot as plt

# Create a random dataset
rng = np.random.RandomState(1)
X = np.sort(5 * rng.rand(80, 1), axis=0)
y = np.sin(X).ravel()
y[::5] += 3 * (0.5 - rng.rand(16))

# Fit regression model
regr_1 = DecisionTreeRegressor(max_depth=2)
regr_2 = DecisionTreeRegressor(max_depth=5)
regr_1.fit(X, y)
regr_2.fit(X, y)

# Predict
X_test = np.arange(0.0, 5.0, 0.01)[:, np.newaxis]
y_1 = regr_1.predict(X_test)
y_2 = regr_2.predict(X_test)

# Plot the results
plt.figure()
plt.scatter(X, y, s=20, edgecolor="black",
            c="darkorange", label="data")
plt.plot(X_test, y_1, color="cornflowerblue",
         label="max_depth=2", linewidth=2)
plt.plot(X_test, y_2, color="yellowgreen", label="max_depth=5", linewidth=2)
plt.xlabel("data")
plt.ylabel("target")
plt.title("Decision Tree Regression")
plt.legend()
plt.show()
```

28.2 Multi-output Decision Tree Regression

An example to illustrate multi-output regression with decision tree.

The *decision trees* is used to predict simultaneously the noisy x and y observations of a circle given a single underlying feature. As a result, it learns local linear regressions approximating the circle.

We can see that if the maximum depth of the tree (controlled by the *max_depth* parameter) is set too high, the decision trees learn too fine details of the training data and learn from the noise, i.e. they overfit.

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn.tree import DecisionTreeRegressor

# Create a random dataset
rng = np.random.RandomState(1)
X = np.sort(200 * rng.rand(100, 1) - 100, axis=0)
y = np.array([np.pi * np.sin(X).ravel(), np.pi * np.cos(X).ravel()]).T
y[::5, :] += (0.5 - rng.rand(20, 2))

# Fit regression model
regr_1 = DecisionTreeRegressor(max_depth=2)

28.3 Plot the decision surface of a decision tree on the iris dataset

Plot the decision surface of a decision tree trained on pairs of features of the iris dataset.

See *decision tree* for more information on the estimator.

For each pair of iris features, the decision tree learns decision boundaries made of combinations of simple thresholding rules inferred from the training samples.

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt

from sklearn.datasets import load_iris
from sklearn.tree import DecisionTreeClassifier

# Parameters
n_classes = 3
plot_colors = "bry"
plot_step = 0.02

# Load data
iris = load_iris()

for pairidx, pair in enumerate([[0, 1], [0, 2], [0, 3],
                                [1, 2], [1, 3], [2, 3]]):
    # We only take the two corresponding features
    X = iris.data[:, pair]
    y = iris.target

    # Train
    clf = DecisionTreeClassifier().fit(X, y)

    # Plot the decision boundary
```

```
    plt.subplot(2, 3, pairidx + 1)

    x_min, x_max = X[:, 0].min() - 1, X[:, 0].max() + 1
    y_min, y_max = X[:, 1].min() - 1, X[:, 1].max() + 1
    xx, yy = np.meshgrid(np.arange(x_min, x_max, plot_step),
                         np.arange(y_min, y_max, plot_step))

    Z = clf.predict(np.c_[xx.ravel(), yy.ravel()])
    Z = Z.reshape(xx.shape)
    cs = plt.contourf(xx, yy, Z, cmap=plt.cm.Paired)

    plt.xlabel(iris.feature_names[pair[0]])
    plt.ylabel(iris.feature_names[pair[1]])
    plt.axis("tight")

    # Plot the training points
    for i, color in zip(range(n_classes), plot_colors):
        idx = np.where(y == i)
        plt.scatter(X[idx, 0], X[idx, 1], c=color, label=iris.target_names[i],
                    cmap=plt.cm.Paired)

    plt.axis("tight")

plt.suptitle("Decision surface of a decision tree using paired features")
plt.legend()
plt.show()
```

28.4 Understanding the decision tree structure

The decision tree structure can be analysed to gain further insight on the relation between the features and the target to predict. In this example, we show how to retrieve:

- the binary tree structure;
- the depth of each node and whether or not it's a leaf;
- the nodes that were reached by a sample using the `decision_path` method;
- the leaf that was reached by a sample using the apply method;
- the rules that were used to predict a sample;
- the decision path shared by a group of samples.

Out:

```
The binary tree structure has 5 nodes and has the following tree structure:
node=0 test node: go to node 1 if X[:, 3] <= 0.800000011921 else to node 2.
        node=1 leaf node.
        node=2 test node: go to node 3 if X[:, 2] <= 4.94999980927 else to node 4.
                node=3 leaf node.
```

```
                node=4 leaf node.

Rules used to predict sample 0:
decision id node 4 : (X_test[0, -2] (= 5.1) > -2.0)

The following samples [0, 1] share the node [0 2] in the tree
It is 40.0 % of all nodes.
```

```
import numpy as np

from sklearn.model_selection import train_test_split
from sklearn.datasets import load_iris
from sklearn.tree import DecisionTreeClassifier

iris = load_iris()
X = iris.data
y = iris.target
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=0)

estimator = DecisionTreeClassifier(max_leaf_nodes=3, random_state=0)
estimator.fit(X_train, y_train)

# The decision estimator has an attribute called tree_  which stores the entire
# tree structure and allows access to low level attributes. The binary tree
# tree_ is represented as a number of parallel arrays. The i-th element of each
# array holds information about the node `i`. Node 0 is the tree's root. NOTE:
# Some of the arrays only apply to either leaves or split nodes, resp. In this
# case the values of nodes of the other type are arbitrary!
#
# Among those arrays, we have:
#   - left_child, id of the left child of the node
#   - right_child, id of the right child of the node
#   - feature, feature used for splitting the node
#   - threshold, threshold value at the node
#

# Using those arrays, we can parse the tree structure:

n_nodes = estimator.tree_.node_count
children_left = estimator.tree_.children_left
children_right = estimator.tree_.children_right
feature = estimator.tree_.feature
threshold = estimator.tree_.threshold

# The tree structure can be traversed to compute various properties such
# as the depth of each node and whether or not it is a leaf.
node_depth = np.zeros(shape=n_nodes, dtype=np.int64)
is_leaves = np.zeros(shape=n_nodes, dtype=bool)
stack = [(0, -1)]  # seed is the root node id and its parent depth
while len(stack) > 0:
    node_id, parent_depth = stack.pop()
    node_depth[node_id] = parent_depth + 1
```

```
    # If we have a test node
    if (children_left[node_id] != children_right[node_id]):
        stack.append((children_left[node_id], parent_depth + 1))
        stack.append((children_right[node_id], parent_depth + 1))
    else:
        is_leaves[node_id] = True

print("The binary tree structure has %s nodes and has "
      "the following tree structure:"
      % n_nodes)
for i in range(n_nodes):
    if is_leaves[i]:
        print("%snode=%s leaf node." % (node_depth[i] * "\t", i))
    else:
        print("%snode=%s test node: go to node %s if X[:, %s] <= %s else to "
              "node %s."
              % (node_depth[i] * "\t",
                 i,
                 children_left[i],
                 feature[i],
                 threshold[i],
                 children_right[i],
                 ))
print()

# First let's retrieve the decision path of each sample. The decision_path
# method allows to retrieve the node indicator functions. A non zero element of
# indicator matrix at the position (i, j) indicates that the sample i goes
# through the node j.

node_indicator = estimator.decision_path(X_test)

# Similarly, we can also have the leaves ids reached by each sample.

leave_id = estimator.apply(X_test)

# Now, it's possible to get the tests that were used to predict a sample or
# a group of samples. First, let's make it for the sample.

sample_id = 0
node_index = node_indicator.indices[node_indicator.indptr[sample_id]:
                                    node_indicator.indptr[sample_id + 1]]

print('Rules used to predict sample %s: ' % sample_id)
for node_id in node_index:
    if leave_id[sample_id] != node_id:
        continue

    if (X_test[sample_id, feature[node_id]] <= threshold[node_id]):
        threshold_sign = "<="
    else:
        threshold_sign = ">"

    print("decision id node %s : (X_test[%s, %s] (= %s) %s %s)"
          % (node_id,
             sample_id,
             feature[node_id],
```

```
            X_test[sample_id, feature[node_id]],
            threshold_sign,
            threshold[node_id]))

# For a group of samples, we have the following common node.
sample_ids = [0, 1]
common_nodes = (node_indicator.toarray()[sample_ids].sum(axis=0) ==
                len(sample_ids))

common_node_id = np.arange(n_nodes)[common_nodes]

print("\nThe following samples %s share the node %s in the tree"
      % (sample_ids, common_node_id))
print("It is %s %% of all nodes." % (100 * len(common_node_id) / n_nodes,))
```

CHAPTER

TWENTYNINE

API REFERENCE

This is the class and function reference of scikit-learn. Please refer to the *full user guide* for further details, as the class and function raw specifications may not be enough to give full guidelines on their uses.

29.1 `sklearn.base`: Base classes and utility functions

Base classes for all estimators.

29.1.1 Base classes

base.BaseEstimator	Base class for all estimators in scikit-learn
base.ClassifierMixin	Mixin class for all classifiers in scikit-learn.
base.ClusterMixin	Mixin class for all cluster estimators in scikit-learn.
base.RegressorMixin	Mixin class for all regression estimators in scikit-learn.
base.TransformerMixin	Mixin class for all transformers in scikit-learn.

sklearn.base.BaseEstimator

class sklearn.base.**BaseEstimator**
Base class for all estimators in scikit-learn

Notes

All estimators should specify all the parameters that can be set at the class level in their `__init__` as explicit keyword arguments (no `*args` or `**kwargs`).

Methods

get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.

__init__()
Initialize self. See help(type(self)) for accurate signature.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.base.BaseEstimator`

- *Feature Union with Heterogeneous Data Sources*

sklearn.base.ClassifierMixin

class sklearn.base.**ClassifierMixin**
Mixin class for all classifiers in scikit-learn.

Methods

score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.

__init__ ()
Initialize self. See help(type(self)) for accurate signature.

score (*X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

sklearn.base.ClusterMixin

class sklearn.base.**ClusterMixin**
Mixin class for all cluster estimators in scikit-learn.

Methods

fit_predict(X[, y])	Performs clustering on X and returns cluster labels.

__init__()
Initialize self. See help(type(self)) for accurate signature.

fit_predict(*X*, *y=None*)
Performs clustering on X and returns cluster labels.

Parameters **X** : ndarray, shape (n_samples, n_features)

Input data.

Returns **y** : ndarray, shape (n_samples,)

cluster labels

sklearn.base.RegressorMixin

class sklearn.base.**RegressorMixin**
Mixin class for all regression estimators in scikit-learn.

Methods

score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.

__init__()
Initialize self. See help(type(self)) for accurate signature.

score(*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

sklearn.base.TransformerMixin

class sklearn.base.**TransformerMixin**

Mixin class for all transformers in scikit-learn.

Methods

fit_transform(X[, y])	Fit to data, then transform it.

__init__()

Initialize self. See help(type(self)) for accurate signature.

fit_transform(*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

Examples using sklearn.base.TransformerMixin

- *Feature Union with Heterogeneous Data Sources*

29.1.2 Functions

base.clone(estimator[, safe])	Constructs a new estimator with the same parameters.
config_context(**new_config)	Context manager for global scikit-learn configuration
set_config([assume_finite])	Set global scikit-learn configuration
get_config()	Retrieve current values for configuration set by *set_config*

sklearn.base.clone

sklearn.base.**clone**(*estimator*, *safe=True*)

Constructs a new estimator with the same parameters.

Clone does a deep copy of the model in an estimator without actually copying attached data. It yields a new estimator with the same parameters that has not been fit on any data.

Parameters **estimator** : estimator object, or list, tuple or set of objects

The estimator or group of estimators to be cloned

safe : boolean, optional

If safe is false, clone will fall back to a deep copy on objects that are not estimators.

sklearn.config_context

sklearn.**config_context**(***new_config*)

Context manager for global scikit-learn configuration

Parameters **assume_finite** : bool, optional

If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error.

Notes

All settings, not just those presently modified, will be returned to their previous values when the context manager is exited. This is not thread-safe.

Examples

```
>>> import sklearn
>>> from sklearn.utils.validation import assert_all_finite
>>> with sklearn.config_context(assume_finite=True):
...     assert_all_finite([float('nan')])
>>> with sklearn.config_context(assume_finite=True):
...     with sklearn.config_context(assume_finite=False):
...         assert_all_finite([float('nan')])
...
Traceback (most recent call last):
...
ValueError: Input contains NaN, ...
```

sklearn.set_config

sklearn.**set_config**(*assume_finite=None*)

Set global scikit-learn configuration

Parameters **assume_finite** : bool, optional

If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error.

sklearn.get_config

sklearn.**get_config**()

Retrieve current values for configuration set by *set_config*

Returns **config** : dict

Keys are parameter names that can be passed to *set_config*.

29.2 sklearn.cluster: Clustering

The *sklearn.cluster* module gathers popular unsupervised clustering algorithms.

User guide: See the *Clustering* section for further details.

29.2.1 Classes

cluster.AffinityPropagation([damping, ...])	Perform Affinity Propagation Clustering of data.
cluster.AgglomerativeClustering([...])	Agglomerative Clustering
cluster.Birch([threshold, branching_factor, ...])	Implements the Birch clustering algorithm.
cluster.DBSCAN([eps, min_samples, metric, ...])	Perform DBSCAN clustering from vector array or distance matrix.
cluster.FeatureAgglomeration([n_clusters, ...])	Agglomerate features.
cluster.KMeans([n_clusters, init, n_init, ...])	K-Means clustering
cluster.MiniBatchKMeans([n_clusters, init, ...])	Mini-Batch K-Means clustering
cluster.MeanShift([bandwidth, seeds, ...])	Mean shift clustering using a flat kernel.
cluster.SpectralClustering([n_clusters, ...])	Apply clustering to a projection to the normalized laplacian.

sklearn.cluster.AffinityPropagation

class sklearn.cluster.**AffinityPropagation**(*damping=0.5*, *max_iter=200*, *convergence_iter=15*, *copy=True*, *preference=None*, *affinity='euclidean'*, *verbose=False*)

Perform Affinity Propagation Clustering of data.

Read more in the *User Guide*.

Parameters **damping** : float, optional, default: 0.5

Damping factor between 0.5 and 1.

convergence_iter : int, optional, default: 15

Number of iterations with no change in the number of estimated clusters that stops the convergence.

max_iter : int, optional, default: 200

Maximum number of iterations.

copy : boolean, optional, default: True

Make a copy of input data.

preference : array-like, shape (n_samples,) or float, optional

Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The number of exemplars, ie of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities.

affinity : string, optional, default=‘‘euclidean‘‘

Which affinity to use. At the moment `precomputed` and `euclidean` are supported. `euclidean` uses the negative squared euclidean distance between points.

verbose : boolean, optional, default: False

Whether to be verbose.

Attributes **cluster_centers_indices_** : array, shape (n_clusters,)

Indices of cluster centers

cluster_centers_ : array, shape (n_clusters, n_features)

Cluster centers (if affinity != `precomputed`).

labels_ : array, shape (n_samples,)

Labels of each point

affinity_matrix_ : array, shape (n_samples, n_samples)

Stores the affinity matrix used in `fit`.

n_iter_ : int

Number of iterations taken to converge.

Notes

For an example, see *examples/cluster/plot_affinity_propagation.py*.

The algorithmic complexity of affinity propagation is quadratic in the number of points.

References

Brendan J. Frey and Delbert Dueck, "Clustering by Passing Messages Between Data Points", Science Feb. 2007

Methods

fit(X[, y])	Create affinity matrix from negative euclidean distances, then apply affinity propagation clustering.
fit_predict(X[, y])	Performs clustering on X and returns cluster labels.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict the closest cluster each sample in X belongs to.
set_params(**params)	Set the parameters of this estimator.

__init__(*damping=0.5*, *max_iter=200*, *convergence_iter=15*, *copy=True*, *preference=None*, *affinity='euclidean'*, *verbose=False*)

fit(*X*, *y=None*)

Create affinity matrix from negative euclidean distances, then apply affinity propagation clustering.

Parameters **X** : array-like, shape (n_samples, n_features) or (n_samples, n_samples)

Data matrix or, if affinity is `precomputed`, matrix of similarities / affinities.

fit_predict(*X*, *y=None*)

Performs clustering on X and returns cluster labels.

Parameters **X** : ndarray, shape (n_samples, n_features)

Input data.

Returns **y** : ndarray, shape (n_samples,)

cluster labels

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)
Predict the closest cluster each sample in X belongs to.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

New data to predict.

Returns **labels** : array, shape (n_samples,)

Index of the cluster each sample belongs to.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.cluster.AffinityPropagation`

- *Demo of affinity propagation clustering algorithm*
- *Comparing different clustering algorithms on toy datasets*

`sklearn.cluster`.AgglomerativeClustering

class `sklearn.cluster.`**AgglomerativeClustering**(*n_clusters=2*, *affinity='euclidean'*, *memory=None*, *connectivity=None*, *compute_full_tree='auto'*, *linkage='ward'*, *pooling_func=<function mean>*)

Agglomerative Clustering

Recursively merges the pair of clusters that minimally increases a given linkage distance.

Read more in the *User Guide*.

Parameters **n_clusters** : int, default=2

The number of clusters to find.

connectivity : array-like or callable, optional

Connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from kneighbors_graph. Default is None, i.e, the hierarchical clustering algorithm is unstructured.

affinity : string or callable, default: "euclidean"

Metric used to compute the linkage. Can be "euclidean", "l1", "l2", "manhattan", "cosine", or 'precomputed'. If linkage is "ward", only "euclidean" is accepted.

memory : Instance of sklearn.externals.joblib.Memory or string, optional (default=None)

Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.

compute_full_tree : bool or 'auto' (optional)

Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree.

linkage : {"ward", "complete", "average"}, optional, default: "ward"

Which linkage criterion to use. The linkage criterion determines which distance to use between sets of observation. The algorithm will merge the pairs of cluster that minimize this criterion.

- ward minimizes the variance of the clusters being merged.
- average uses the average of the distances of each observation of the two sets.
- complete or maximum linkage uses the maximum distances between all observations of the two sets.

pooling_func : callable, default=np.mean

This combines the values of agglomerated features into a single value, and should accept an array of shape [M, N] and the keyword argument `axis=1`, and reduce it to an array of size [M].

Attributes **labels_** : array [n_samples]

cluster labels for each point

n_leaves_ : int

Number of leaves in the hierarchical tree.

n_components_ : int

The estimated number of connected components in the graph.

children_ : array-like, shape (n_nodes-1, 2)

The children of each non-leaf node. Values less than *n_samples* correspond to leaves of the tree which are the original samples. A node *i* greater than or equal to *n_samples* is a non-leaf node and has children *children_[i - n_samples]*. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node *n_samples + i*

Methods

fit(X[, y])	Fit the hierarchical clustering on the data
fit_predict(X[, y])	Performs clustering on X and returns cluster labels.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_clusters=2*, *affinity='euclidean'*, *memory=None*, *connectivity=None*, *compute_full_tree='auto'*, *linkage='ward'*, *pooling_func=<function mean>*)

fit (*X*, *y=None*)
Fit the hierarchical clustering on the data

Parameters **X** : array-like, shape = [n_samples, n_features]

The samples a.k.a. observations.

Returns **self** :

fit_predict (*X*, *y=None*)
Performs clustering on X and returns cluster labels.

Parameters **X** : ndarray, shape (n_samples, n_features)

Input data.

Returns **y** : ndarray, shape (n_samples,)

cluster labels

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.cluster.AgglomerativeClustering`

- *Agglomerative clustering with and without structure*
- *Agglomerative clustering with different metrics*
- *Comparing different clustering algorithms on toy datasets*
- *Various Agglomerative Clustering on a 2D embedding of digits*

sklearn.cluster.Birch

class sklearn.cluster.**Birch**(*threshold=0.5*, *branching_factor=50*, *n_clusters=3*, *compute_labels=True*, *copy=True*)

Implements the Birch clustering algorithm.

It is a memory-efficient, online-learning algorithm provided as an alternative to `MiniBatchKMeans`. It constructs a tree data structure with the cluster centroids being read off the leaf. These can be either the final cluster centroids or can be provided as input to another clustering algorithm such as `AgglomerativeClustering`.

Read more in the *User Guide*.

Parameters **threshold** : float, default 0.5

The radius of the subcluster obtained by merging a new sample and the closest subcluster should be lesser than the threshold. Otherwise a new subcluster is started. Setting this value to be very low promotes splitting and vice-versa.

branching_factor : int, default 50

Maximum number of CF subclusters in each node. If a new samples enters such that the number of subclusters exceed the branching_factor then that node is split into two nodes with the subclusters redistributed in each. The parent subcluster of that node is removed and two new subclusters are added as parents of the 2 split nodes.

n_clusters : int, instance of sklearn.cluster model, default 3

Number of clusters after the final clustering step, which treats the subclusters from the leaves as new samples.

- *None* : the final clustering step is not performed and the subclusters are returned as they are.
- *sklearn.cluster* Estimator : If a model is provided, the model is fit treating the subclusters as new samples and the initial data is mapped to the label of the closest subcluster.
- *int* : the model fit is `AgglomerativeClustering` with *n_clusters* set to be equal to the int.

compute_labels : bool, default True

Whether or not to compute labels for each fit.

copy : bool, default True

Whether or not to make a copy of the given data. If set to False, the initial data will be overwritten.

Attributes **root_** : _CFNode

Root of the CFTree.

dummy_leaf_ : _CFNode

Start pointer to all the leaves.

subcluster_centers_ : ndarray,

Centroids of all subclusters read directly from the leaves.

subcluster_labels_ : ndarray,

Labels assigned to the centroids of the subclusters after they are clustered globally.

labels_ : ndarray, shape (n_samples,)

Array of labels assigned to the input data. if partial_fit is used instead of fit, they are assigned to the last batch of data.

Notes

The tree data structure consists of nodes with each node consisting of a number of subclusters. The maximum number of subclusters in a node is determined by the branching factor. Each subcluster maintains a linear sum, squared sum and the number of samples in that subcluster. In addition, each subcluster can also have a node as its child, if the subcluster is not a member of a leaf node.

For a new point entering the root, it is merged with the subcluster closest to it and the linear sum, squared sum and the number of samples of that subcluster are updated. This is done recursively till the properties of the leaf node are updated.

Examples

```
>>> from sklearn.cluster import Birch
>>> X = [[0, 1], [0.3, 1], [-0.3, 1], [0, -1], [0.3, -1], [-0.3, -1]]
>>> brc = Birch(branching_factor=50, n_clusters=None, threshold=0.5,
... compute_labels=True)
>>> brc.fit(X)
Birch(branching_factor=50, compute_labels=True, copy=True, n_clusters=None,
   threshold=0.5)
>>> brc.predict(X)
array([0, 0, 0, 1, 1, 1])
```

Methods

fit(X[, y])	Build a CF Tree for the input data.
fit_predict(X[, y])	Performs clustering on X and returns cluster labels.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
partial_fit([X, y])	Online learning.
predict(X)	Predict data using the `centroids_` of subclusters.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Transform X into subcluster centroids dimension.

__init__ (*threshold=0.5*, *branching_factor=50*, *n_clusters=3*, *compute_labels=True*, *copy=True*)

fit (*X*, *y=None*)
Build a CF Tree for the input data.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Input data.

fit_predict(*X*, *y=None*)
Performs clustering on X and returns cluster labels.

Parameters **X** : ndarray, shape (n_samples, n_features)

Input data.

Returns **y** : ndarray, shape (n_samples,)

cluster labels

fit_transform(*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

partial_fit(*X=None*, *y=None*)
Online learning. Prevents rebuilding of CFTree from scratch.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features), None

Input data. If X is not provided, only the global clustering step is done.

predict(*X*)
Predict data using the `centroids_` of subclusters.

Avoid computation of the row norms of X.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Input data.

Returns **labels** : ndarray, shape(n_samples)

Labelled data.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)

Transform X into subcluster centroids dimension.

Each dimension represents the distance from the sample point to each cluster centroid.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Input data.

Returns **X_trans** : {array-like, sparse matrix}, shape (n_samples, n_clusters)

Transformed data.

Examples using sklearn.cluster.Birch

- *Compare BIRCH and MiniBatchKMeans*
- *Comparing different clustering algorithms on toy datasets*

sklearn.cluster.DBSCAN

class sklearn.cluster.**DBSCAN**(*eps=0.5*, *min_samples=5*, *metric='euclidean'*, *metric_params=None*, *algorithm='auto'*, *leaf_size=30*, *p=None*, *n_jobs=1*)

Perform DBSCAN clustering from vector array or distance matrix.

DBSCAN - Density-Based Spatial Clustering of Applications with Noise. Finds core samples of high density and expands clusters from them. Good for data which contains clusters of similar density.

Read more in the *User Guide*.

Parameters **eps** : float, optional

The maximum distance between two samples for them to be considered as in the same neighborhood.

min_samples : int, optional

The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.

metric : string, or callable

The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by metrics.pairwise.calculate_distance for its metric parameter. If metric is "precomputed", X is assumed to be a distance matrix and must be square. X may be a sparse matrix, in which case only "nonzero" elements may be considered neighbors for DBSCAN.

New in version 0.17: metric *precomputed* to accept precomputed sparse matrix.

metric_params : dict, optional

Additional keyword arguments for the metric function.

New in version 0.19.

algorithm : {'auto', 'ball_tree', 'kd_tree', 'brute'}, optional

The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.

leaf_size : int, optional (default = 30)

Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p : float, optional

The power of the Minkowski metric to be used to calculate distance between points.

n_jobs : int, optional (default = 1)

The number of parallel jobs to run. If `-1`, then the number of jobs is set to the number of CPU cores.

Attributes **core_sample_indices_** : array, shape = [n_core_samples]

Indices of core samples.

components_ : array, shape = [n_core_samples, n_features]

Copy of each core sample found by training.

labels_ : array, shape = [n_samples]

Cluster labels for each point in the dataset given to fit(). Noisy samples are given the label -1.

Notes

For an example, see *examples/cluster/plot_dbscan.py*.

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to O(n.d) where d is the average number of neighbors, while original DBSCAN had memory complexity O(n).

Sparse neighborhoods can be precomputed using *NearestNeighbors.radius_neighbors_graph* with `mode='distance'`.

Ester, M., H. P. Kriegel, J. Sander, and X. Xu, "A Density-Based Algorithm for Discovering Clusters in Large Spatial Databases with Noise". In: Proceedings of the 2nd International Conference on Knowledge Discovery and Data Mining, Portland, OR, AAAI Press, pp. 226-231. 1996

Methods

fit(X[, y, sample_weight])	Perform DBSCAN clustering from features or distance matrix.
fit_predict(X[, y, sample_weight])	Performs clustering on X and returns cluster labels.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.

__init__(*eps=0.5*, *min_samples=5*, *metric='euclidean'*, *metric_params=None*, *algorithm='auto'*, *leaf_size=30*, *p=None*, *n_jobs=1*)

fit(*X*, *y=None*, *sample_weight=None*)
Perform DBSCAN clustering from features or distance matrix.

Parameters **X** : array or sparse (CSR) matrix of shape (n_samples, n_features), or array of shape (n_samples, n_samples)

A feature array, or array of distances between samples if `metric='precomputed'`.

sample_weight : array, shape (n_samples,), optional

Weight of each sample, such that a sample with a weight of at least `min_samples` is by itself a core sample; a sample with negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.

fit_predict(*X*, *y=None*, *sample_weight=None*)
Performs clustering on X and returns cluster labels.

Parameters **X** : array or sparse (CSR) matrix of shape (n_samples, n_features), or array of shape (n_samples, n_samples)

A feature array, or array of distances between samples if `metric='precomputed'`.

sample_weight : array, shape (n_samples,), optional

Weight of each sample, such that a sample with a weight of at least `min_samples` is by itself a core sample; a sample with negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.

Returns **y** : ndarray, shape (n_samples,)

cluster labels

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.cluster.DBSCAN`

- *Comparing different clustering algorithms on toy datasets*
- *Demo of DBSCAN clustering algorithm*

sklearn.cluster.FeatureAgglomeration

class sklearn.cluster.**FeatureAgglomeration**(*n_clusters=2*, *affinity='euclidean'*, *memory=None*, *connectivity=None*, *compute_full_tree='auto'*, *linkage='ward'*, *pooling_func=<function mean>*)

Agglomerate features.

Similar to AgglomerativeClustering, but recursively merges features instead of samples.

Read more in the *User Guide*.

Parameters **n_clusters** : int, default 2

The number of clusters to find.

connectivity : array-like or callable, optional

Connectivity matrix. Defines for each feature the neighboring features following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from kneighbors_graph. Default is None, i.e, the hierarchical clustering algorithm is unstructured.

affinity : string or callable, default "euclidean"

Metric used to compute the linkage. Can be "euclidean", "l1", "l2", "manhattan", "cosine", or 'precomputed'. If linkage is "ward", only "euclidean" is accepted.

memory : Instance of sklearn.externals.joblib.Memory or string, optional (default=None)

Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.

compute_full_tree : bool or 'auto', optional, default "auto"

Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of features. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree.

linkage : {"ward", "complete", "average"}, optional, default "ward"

Which linkage criterion to use. The linkage criterion determines which distance to use between sets of features. The algorithm will merge the pairs of cluster that minimize this criterion.

- ward minimizes the variance of the clusters being merged.
- average uses the average of the distances of each feature of the two sets.
- complete or maximum linkage uses the maximum distances between all features of the two sets.

pooling_func : callable, default np.mean

This combines the values of agglomerated features into a single value, and should accept an array of shape [M, N] and the keyword argument *axis=1*, and reduce it to an array of size [M].

Attributes **labels_** : array-like, (n_features,)

cluster labels for each feature.

n_leaves_ : int

Number of leaves in the hierarchical tree.

n_components_ : int

The estimated number of connected components in the graph.

children_ : array-like, shape (n_nodes-1, 2)

The children of each non-leaf node. Values less than *n_features* correspond to leaves of the tree which are the original samples. A node *i* greater than or equal to *n_features* is a non-leaf node and has children *children_[i - n_features]*. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node *n_features + i*

Methods

fit(X[, y])	Fit the hierarchical clustering on the data
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
inverse_transform(Xred)	Inverse the transformation.
pooling_func(a[, axis, dtype, out, keepdims])	Compute the arithmetic mean along the specified axis.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Transform a new matrix using the built clustering

__init__(*n_clusters=2*, *affinity='euclidean'*, *memory=None*, *connectivity=None*, *compute_full_tree='auto'*, *linkage='ward'*, *pooling_func=<function mean>*)

fit(*X*, *y=None*, ***params*)

Fit the hierarchical clustering on the data

Parameters **X** : array-like, shape = [n_samples, n_features]

The data

Returns **self** :

fit_transform(*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform(*Xred*)

Inverse the transformation. Return a vector of size nb_features with the values of Xred assigned to each group of features

Parameters **Xred** : array-like, shape=[n_samples, n_clusters] or [n_clusters,]

The values to be assigned to each cluster of samples

Returns **X** : array, shape=[n_samples, n_features] or [n_features]

A vector of size n_samples with the values of Xred assigned to each of the cluster of samples.

pooling_func(*a*, *axis=None*, *dtype=None*, *out=None*, *keepdims=<class 'numpy._globals._NoValue'>*)

Compute the arithmetic mean along the specified axis.

Returns the average of the array elements. The average is taken over the flattened array by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

Parameters **a** : array_like

Array containing numbers whose mean is desired. If *a* is not an array, a conversion is attempted.

axis : None or int or tuple of ints, optional

Axis or axes along which the means are computed. The default is to compute the mean of the flattened array.

New in version 1.7.0.

If this is a tuple of ints, a mean is performed over multiple axes, instead of a single axis or all the axes as before.

dtype : data-type, optional

Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.

out : ndarray, optional

Alternate output array in which to place the result. The default is `None`; if provided, it must have the same shape as the expected output, but the type will be cast if necessary. See *doc.ufuncs* for details.

keepdims : bool, optional

If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array.

If the default value is passed, then *keepdims* will not be passed through to the *mean* method of sub-classes of *ndarray*, however any non-default value will be. If the sub-classes *sum* method does not implement *keepdims* any exceptions will be raised.

Returns **m** : ndarray, see dtype parameter above

If *out=None*, returns a new array containing the mean values, otherwise a reference to the output array is returned.

See also:

average Weighted average

`std`, `var`, `nanmean`, `nanstd`, `nanvar`

Notes

The arithmetic mean is the sum of the elements along the axis divided by the number of elements.

Note that for floating-point input, the mean is computed using the same precision the input has. Depending on the input data, this can cause the results to be inaccurate, especially for *float32* (see example below). Specifying a higher-precision accumulator using the *dtype* keyword can alleviate this issue.

By default, *float16* results are computed using *float32* intermediates for extra precision.

Examples

```
>>> a = np.array([[1, 2], [3, 4]])
>>> np.mean(a)
2.5
>>> np.mean(a, axis=0)
array([ 2.,  3.])
>>> np.mean(a, axis=1)
array([ 1.5,  3.5])
```

In single precision, *mean* can be inaccurate:

```
>>> a = np.zeros((2, 512*512), dtype=np.float32)
>>> a[0, :] = 1.0
>>> a[1, :] = 0.1
>>> np.mean(a)
0.54999924
```

Computing the mean in float64 is more accurate:

```
>>> np.mean(a, dtype=np.float64)
0.55000000074505806
```

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Transform a new matrix using the built clustering

Parameters **X** : array-like, shape = [n_samples, n_features] or [n_features]

A M by N array of M observations in N dimensions or a length M array of M one-dimensional observations.

Returns **Y** : array, shape = [n_samples, n_clusters] or [n_clusters]

The pooled values for each feature cluster.

Examples using `sklearn.cluster.FeatureAgglomeration`

- *Feature agglomeration*
- *Feature agglomeration vs. univariate selection*

`sklearn.cluster.KMeans`

class `sklearn.cluster.KMeans`(*n_clusters=8*, *init='k-means++'*, *n_init=10*, *max_iter=300*, *tol=0.0001*, *precompute_distances='auto'*, *verbose=0*, *random_state=None*, *copy_x=True*, *n_jobs=1*, *algorithm='auto'*)

K-Means clustering

Read more in the *User Guide*.

Parameters **n_clusters** : int, optional, default: 8

The number of clusters to form as well as the number of centroids to generate.

max_iter : int, default: 300

Maximum number of iterations of the k-means algorithm for a single run.

n_init : int, default: 10

Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

init : {'k-means++', 'random' or an ndarray}

Method for initialization, defaults to 'k-means++':

'k-means++' : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.

'random': choose k observations (rows) at random from data for the initial centroids.

If an ndarray is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.

algorithm : "auto", "full" or "elkan", default="auto"

K-means algorithm to use. The classical EM-style algorithm is "full". The "elkan" variation is more efficient by using the triangle inequality, but currently doesn't support sparse data. "auto" chooses "elkan" for dense data and "full" for sparse data.

precompute_distances : {'auto', True, False}

Precompute distances (faster but takes more memory).

'auto' : do not precompute distances if n_samples * n_clusters > 12 million. This corresponds to about 100MB overhead per job using double precision.

True : always precompute distances

False : never precompute distances

tol : float, default: 1e-4

Relative tolerance with regards to inertia to declare convergence

n_jobs : int

The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

random_state : int, RandomState instance or None, optional, default: None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

verbose : int, default 0

Verbosity mode.

copy_x : boolean, default True

When pre-computing distances it is more numerically accurate to center the data first. If copy_x is True, then the original data is not modified. If False, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean.

Attributes **cluster_centers_** : array, [n_clusters, n_features]

Coordinates of cluster centers

labels_ : :

Labels of each point

inertia_ : float

Sum of distances of samples to their closest cluster center.

See also:

MiniBatchKMeans Alternative online implementation that does incremental updates of the centers positions using mini-batches. For large scale learning (say n_samples > 10k) MiniBatchKMeans is probably much faster than the default batch implementation.

Notes

The k-means problem is solved using Lloyd's algorithm.

The average complexity is given by O(k n T), were n is the number of samples and T is the number of iteration.

The worst case complexity is given by O(n^(k+2/p)) with n = n_samples, p = n_features. (D. Arthur and S. Vassilvitskii, 'How slow is the k-means method?' SoCG2006)

In practice, the k-means algorithm is very fast (one of the fastest clustering algorithms available), but it falls in local minima. That's why it can be useful to restart it several times.

Examples

```
>>> from sklearn.cluster import KMeans
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0],
...               [4, 2], [4, 4], [4, 0]])
```

```
>>> kmeans = KMeans(n_clusters=2, random_state=0).fit(X)
>>> kmeans.labels_
array([0, 0, 0, 1, 1, 1], dtype=int32)
>>> kmeans.predict([[0, 0], [4, 4]])
array([0, 1], dtype=int32)
>>> kmeans.cluster_centers_
array([[ 1.,  2.],
       [ 4.,  2.]])
```

Methods

fit(X[, y])	Compute k-means clustering.
fit_predict(X[, y])	Compute cluster centers and predict cluster index for each sample.
fit_transform(X[, y])	Compute clustering and transform X to cluster-distance space.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict the closest cluster each sample in X belongs to.
score(X[, y])	Opposite of the value of X on the K-means objective.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Transform X to a cluster-distance space.

__init__(*n_clusters=8*, *init='k-means++'*, *n_init=10*, *max_iter=300*, *tol=0.0001*, *precompute_distances='auto'*, *verbose=0*, *random_state=None*, *copy_x=True*, *n_jobs=1*, *algorithm='auto'*)

fit(*X*, *y=None*)

Compute k-means clustering.

Parameters **X** : array-like or sparse matrix, shape=(n_samples, n_features)

Training instances to cluster.

fit_predict(*X*, *y=None*)

Compute cluster centers and predict cluster index for each sample.

Convenience method; equivalent to calling fit(X) followed by predict(X).

fit_transform(*X*, *y=None*)

Compute clustering and transform X to cluster-distance space.

Equivalent to fit(X).transform(X), but more efficiently implemented.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Predict the closest cluster each sample in X belongs to.

In the vector quantization literature, *cluster_centers_* is called the code book and each value returned by *predict* is the index of the closest code in the code book.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

New data to predict.

Returns **labels** : array, shape [n_samples,]

Index of the cluster each sample belongs to.

score(*X*, *y=None*)

Opposite of the value of X on the K-means objective.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

New data.

Returns **score** : float

Opposite of the value of X on the K-means objective.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)

Transform X to a cluster-distance space.

In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by *transform* will typically be dense.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

New data to transform.

Returns **X_new** : array, shape [n_samples, k]

X transformed in the new space.

class sklearn.cluster.**MiniBatchKMeans**(*n_clusters=8*, *init='k-means++'*, *max_iter=100*, *batch_size=100*, *verbose=0*, *compute_labels=True*, *random_state=None*, *tol=0.0*, *max_no_improvement=10*, *init_size=None*, *n_init=3*, *reassignment_ratio=0.01*)

Mini-Batch K-Means clustering

Read more in the *User Guide*.

Parameters **n_clusters** : int, optional, default: 8

The number of clusters to form as well as the number of centroids to generate.

max_iter : int, optional

Maximum number of iterations over the complete dataset before stopping independently of any early stopping criterion heuristics.

max_no_improvement : int, default: 10

Control early stopping based on the consecutive number of mini batches that does not yield an improvement on the smoothed inertia.

To disable convergence detection based on inertia, set max_no_improvement to None.

tol : float, default: 0.0

Control early stopping based on the relative center changes as measured by a smoothed, variance-normalized of the mean center squared position changes. This early stopping heuristics is closer to the one used for the batch variant of the algorithms but induces a slight computational and memory overhead over the inertia heuristic.

To disable convergence detection based on normalized center change, set tol to 0.0 (default).

batch_size : int, optional, default: 100

Size of the mini batches.

init_size : int, optional, default: 3 * batch_size

Number of samples to randomly sample for speeding up the initialization (sometimes at the expense of accuracy): the only algorithm is initialized by running a batch KMeans on a random subset of the data. This needs to be larger than n_clusters.

init : {'k-means++', 'random' or an ndarray}, default: 'k-means++'

Method for initialization, defaults to 'k-means++':

'k-means++' : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.

'random': choose k observations (rows) at random from data for the initial centroids.

If an ndarray is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.

n_init : int, default=3

Number of random initializations that are tried. In contrast to KMeans, the algorithm is only run once, using the best of the `n_init` initializations as measured by inertia.

compute_labels : boolean, default=True

Compute label assignment and inertia for the complete dataset once the minibatch optimization has converged in fit.

random_state : int, RandomState instance or None, optional, default: None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

reassignment_ratio : float, default: 0.01

Control the fraction of the maximum number of counts for a center to be reassigned. A higher value means that low count centers are more easily reassigned, which means that the model will take longer to converge, but should converge in a better clustering.

verbose : boolean, optional

Verbosity mode.

Attributes **cluster_centers_** : array, [n_clusters, n_features]

Coordinates of cluster centers

labels_ : :

Labels of each point (if compute_labels is set to True).

inertia_ : float

The value of the inertia criterion associated with the chosen partition (if compute_labels is set to True). The inertia is defined as the sum of square distances of samples to their nearest neighbor.

See also:

KMeans The classic implementation of the clustering method based on the Lloyd's algorithm. It consumes the whole set of input data at each iteration.

Notes

See http://www.eecs.tufts.edu/~dsculley/papers/fastkmeans.pdf

Methods

fit(X[, y])	Compute the centroids on X by chunking it into mini-batches.
fit_predict(X[, y])	Compute cluster centers and predict cluster index for each sample.
fit_transform(X[, y])	Compute clustering and transform X to cluster-distance space.
get_params([deep])	Get parameters for this estimator.
partial_fit(X[, y])	Update k means estimate on a single mini-batch X.
predict(X)	Predict the closest cluster each sample in X belongs to.
score(X[, y])	Opposite of the value of X on the K-means objective.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Transform X to a cluster-distance space.

__init__(*n_clusters=8*, *init='k-means++'*, *max_iter=100*, *batch_size=100*, *verbose=0*, *compute_labels=True*, *random_state=None*, *tol=0.0*, *max_no_improvement=10*, *init_size=None*, *n_init=3*, *reassignment_ratio=0.01*)

fit(*X*, *y=None*)
Compute the centroids on X by chunking it into mini-batches.

Parameters **X** : array-like or sparse matrix, shape=(n_samples, n_features)

Training instances to cluster.

fit_predict(*X*, *y=None*)
Compute cluster centers and predict cluster index for each sample.

Convenience method; equivalent to calling fit(X) followed by predict(X).

fit_transform(*X*, *y=None*)
Compute clustering and transform X to cluster-distance space.

Equivalent to fit(X).transform(X), but more efficiently implemented.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

partial_fit(*X*, *y=None*)
Update k means estimate on a single mini-batch X.

Parameters **X** : array-like, shape = [n_samples, n_features]

Coordinates of the data points to cluster.

predict(*X*)
Predict the closest cluster each sample in X belongs to.

In the vector quantization literature, *cluster_centers_* is called the code book and each value returned by *predict* is the index of the closest code in the code book.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

New data to predict.

Returns **labels** : array, shape [n_samples,]

Index of the cluster each sample belongs to.

score(*X*, *y=None*)
Opposite of the value of X on the K-means objective.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

New data.

Returns **score** : float

Opposite of the value of X on the K-means objective.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Transform X to a cluster-distance space.

In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by *transform* will typically be dense.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

New data to transform.

Returns **X_new** : array, shape [n_samples, k]

X transformed in the new space.

Examples using `sklearn.cluster.MiniBatchKMeans`

- *Biclustering documents with the Spectral Co-clustering algorithm*
- *Compare BIRCH and MiniBatchKMeans*
- *Comparing different clustering algorithms on toy datasets*
- *Online learning of a dictionary of parts of faces*
- *Empirical evaluation of the impact of k-means initialization*
- *Comparison of the K-Means and MiniBatchKMeans clustering algorithms*
- *Faces dataset decompositions*
- *Clustering text documents using k-means*

sklearn.cluster.MeanShift

class sklearn.cluster.**MeanShift**(*bandwidth=None*, *seeds=None*, *bin_seeding=False*, *min_bin_freq=1*, *cluster_all=True*, *n_jobs=1*)
Mean shift clustering using a flat kernel.

Mean shift clustering aims to discover "blobs" in a smooth density of samples. It is a centroid-based algorithm, which works by updating candidates for centroids to be the mean of the points within a given region. These candidates are then filtered in a post-processing stage to eliminate near-duplicates to form the final set of centroids.

Seeding is performed using a binning technique for scalability.

Read more in the *User Guide*.

Parameters **bandwidth** : float, optional

Bandwidth used in the RBF kernel.

If not given, the bandwidth is estimated using sklearn.cluster.estimate_bandwidth; see the documentation for that function for hints on scalability (see also the Notes, below).

seeds : array, shape=[n_samples, n_features], optional

Seeds used to initialize kernels. If not set, the seeds are calculated by clustering.get_bin_seeds with bandwidth as the grid size and default values for other parameters.

bin_seeding : boolean, optional

If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. default value: False Ignored if seeds argument is not None.

min_bin_freq : int, optional

To speed up the algorithm, accept only those bins with at least min_bin_freq points as seeds. If not defined, set to 1.

cluster_all : boolean, default True

If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.

n_jobs : int

The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

Attributes **cluster_centers_** : array, [n_clusters, n_features]

Coordinates of cluster centers.

labels_ : :

Labels of each point.

Notes

Scalability:

Because this implementation uses a flat kernel and a Ball Tree to look up members of each kernel, the complexity will tend towards O(T*n*log(n)) in lower dimensions, with n the number of samples and T the number of points. In higher dimensions the complexity will tend towards O(T*n^2).

Scalability can be boosted by using fewer seeds, for example by using a higher value of min_bin_freq in the get_bin_seeds function.

Note that the estimate_bandwidth function is much less scalable than the mean shift algorithm and will be the bottleneck if it is used.

Methods

fit(X[, y])	Perform clustering.
fit_predict(X[, y])	Performs clustering on X and returns cluster labels.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict the closest cluster each sample in X belongs to.
set_params(**params)	Set the parameters of this estimator.

__init__(*bandwidth=None*, *seeds=None*, *bin_seeding=False*, *min_bin_freq=1*, *cluster_all=True*, *n_jobs=1*)

fit(*X*, *y=None*)
Perform clustering.

Parameters **X** : array-like, shape=[n_samples, n_features]

Samples to cluster.

fit_predict(*X*, *y=None*)
Performs clustering on X and returns cluster labels.

Parameters **X** : ndarray, shape (n_samples, n_features)

Input data.

Returns **y** : ndarray, shape (n_samples,)

cluster labels

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)
Predict the closest cluster each sample in X belongs to.

Parameters **X** : {array-like, sparse matrix}, shape=[n_samples, n_features]

New data to predict.

Returns **labels** : array, shape [n_samples,]

Index of the cluster each sample belongs to.

set_params(**params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.cluster.MeanShift`

- *Comparing different clustering algorithms on toy datasets*
- *A demo of the mean-shift clustering algorithm*

`sklearn.cluster`.SpectralClustering

class `sklearn.cluster.`**`SpectralClustering`**(*n_clusters=8*, *eigen_solver=None*, *random_state=None*, *n_init=10*, *gamma=1.0*, *affinity='rbf'*, *n_neighbors=10*, *eigen_tol=0.0*, *assign_labels='kmeans'*, *degree=3*, *coef0=1*, *kernel_params=None*, *n_jobs=1*)

Apply clustering to a projection to the normalized laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance when clusters are nested circles on the 2D plan.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

When calling `fit`, an affinity matrix is constructed using either kernel function such the Gaussian (aka RBF) kernel of the euclidean distanced `d(X, X)`:

```
np.exp(-gamma * d(X,X) ** 2)
```

or a k-nearest neighbors connectivity matrix.

Alternatively, using `precomputed`, a user-provided affinity matrix can be used.

Read more in the *User Guide*.

Parameters **n_clusters** : integer, optional

The dimension of the projection subspace.

affinity : string, array-like or callable, default 'rbf'

If a string, this may be one of 'nearest_neighbors', 'precomputed', 'rbf' or one of the kernels supported by *sklearn.metrics.pairwise_kernels*.

Only kernels that produce similarity scores (non-negative values that increase with similarity) should be used. This property is not checked by the clustering algorithm.

gamma : float, default=1.0

Kernel coefficient for rbf, poly, sigmoid, laplacian and chi2 kernels. Ignored for `affinity='nearest_neighbors'`.

degree : float, default=3

Degree of the polynomial kernel. Ignored by other kernels.

coef0 : float, default=1

Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

n_neighbors : integer

Number of neighbors to use when constructing the affinity matrix using the nearest neighbors method. Ignored for `affinity='rbf'`.

eigen_solver : {None, 'arpack', 'lobpcg', or 'amg'}

The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities

random_state : int, RandomState instance or None, optional, default: None

A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when eigen_solver == 'amg' and by the K-Means initialization. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

n_init : int, optional, default: 10

Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

eigen_tol : float, optional, default: 0.0

Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen_solver.

assign_labels : {'kmeans', 'discretize'}, default: 'kmeans'

The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding. k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization.

kernel_params : dictionary of string to any, optional

Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.

n_jobs : int, optional (default = 1)

The number of parallel jobs to run. If `-1`, then the number of jobs is set to the number of CPU cores.

Attributes **affinity_matrix_** : array-like, shape (n_samples, n_samples)

Affinity matrix used for clustering. Available only if after calling `fit`.

labels_ : :

Labels of each point

Notes

If you have an affinity matrix, such as a distance matrix, for which 0 means identical elements, and high values means very dissimilar elements, it can be transformed in a similarity matrix that is well suited for the algorithm by applying the Gaussian (RBF, heat) kernel:

```
np.exp(- dist_matrix ** 2 / (2. * delta ** 2))
```

Where `delta` is a free parameter representing the width of the Gaussian kernel.

Another alternative is to take a symmetric version of the k nearest neighbors connectivity matrix of the points.

If the pyamg package is installed, it is used: this greatly speeds up computation.

Methods

fit(X[, y])	Creates an affinity matrix for X using the selected affinity, then applies spectral clustering to this affinity matrix.
fit_predict(X[, y])	Performs clustering on X and returns cluster labels.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_clusters=8*, *eigen_solver=None*, *random_state=None*, *n_init=10*, *gamma=1.0*, *affinity='rbf'*, *n_neighbors=10*, *eigen_tol=0.0*, *assign_labels='kmeans'*, *degree=3*, *coef0=1*, *kernel_params=None*, *n_jobs=1*)

fit (*X*, *y=None*)
Creates an affinity matrix for X using the selected affinity, then applies spectral clustering to this affinity matrix.

Parameters **X** : array-like or sparse matrix, shape (n_samples, n_features)

OR, if affinity==‘precomputed‘, a precomputed affinity matrix of shape (n_samples, n_samples)

fit_predict (*X*, *y=None*)
Performs clustering on X and returns cluster labels.

Parameters **X** : ndarray, shape (n_samples, n_features)

Input data.

Returns **y** : ndarray, shape (n_samples,)

cluster labels

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.cluster.SpectralClustering`

- *Comparing different clustering algorithms on toy datasets*

29.2.2 Functions

cluster.estimate_bandwidth(X[, quantile, ...])	Estimate the bandwidth to use with the mean-shift algorithm.
cluster.k_means(X, n_clusters[, init, ...])	K-means clustering algorithm.
cluster.ward_tree(X[, connectivity, ...])	Ward clustering based on a Feature matrix.
cluster.affinity_propagation(S[, ...])	Perform Affinity Propagation Clustering of data
cluster.dbscan(X[, eps, min_samples, ...])	Perform DBSCAN clustering from vector array or distance matrix.
cluster.mean_shift(X[, bandwidth, seeds, ...])	Perform mean shift clustering of data using a flat kernel.
cluster.spectral_clustering(affinity[, ...])	Apply clustering to a projection to the normalized laplacian.

`sklearn.cluster.estimate_bandwidth`

sklearn.cluster.**estimate_bandwidth**(*X*, *quantile=0.3*, *n_samples=None*, *random_state=0*, *n_jobs=1*)

Estimate the bandwidth to use with the mean-shift algorithm.

That this function takes time at least quadratic in n_samples. For large datasets, it's wise to set that parameter to a small value.

Parameters **X** : array-like, shape=[n_samples, n_features]

Input points.

quantile : float, default 0.3

should be between [0, 1] 0.5 means that the median of all pairwise distances is used.

n_samples : int, optional

The number of samples to use. If not given, all samples are used.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

n_jobs : int, optional (default = 1)

The number of parallel jobs to run for neighbors search. If `-1`, then the number of jobs is set to the number of CPU cores.

Returns **bandwidth** : float

The bandwidth parameter.

Examples using `sklearn.cluster.estimate_bandwidth`

- *Comparing different clustering algorithms on toy datasets*
- *A demo of the mean-shift clustering algorithm*

`sklearn.cluster.k_means`

`sklearn.cluster.k_means(X, n_clusters, init='k-means++', precompute_distances='auto', n_init=10, max_iter=300, verbose=False, tol=0.0001, random_state=None, copy_x=True, n_jobs=1, algorithm='auto', return_n_iter=False)`

K-means clustering algorithm.

Read more in the *User Guide*.

Parameters **X** : array-like or sparse matrix, shape (n_samples, n_features)

The observations to cluster.

n_clusters : int

The number of clusters to form as well as the number of centroids to generate.

max_iter : int, optional, default 300

Maximum number of iterations of the k-means algorithm to run.

n_init : int, optional, default: 10

Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

init : {'k-means++', 'random', or ndarray, or a callable}, optional

Method for initialization, default to 'k-means++':

'k-means++' : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.

'random': generate k centroids from a Gaussian with mean and variance estimated from the data.

If an ndarray is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.

If a callable is passed, it should take arguments X, k and and a random state and return an initialization.

algorithm : "auto", "full" or "elkan", default="auto"

K-means algorithm to use. The classical EM-style algorithm is "full". The "elkan" variation is more efficient by using the triangle inequality, but currently doesn't support sparse data. "auto" chooses "elkan" for dense data and "full" for sparse data.

precompute_distances : {'auto', True, False}

Precompute distances (faster but takes more memory).

'auto' : do not precompute distances if n_samples * n_clusters > 12 million. This corresponds to about 100MB overhead per job using double precision.

True : always precompute distances

False : never precompute distances

tol : float, optional

The relative increment in the results before declaring convergence.

verbose : boolean, optional

Verbosity mode.

random_state : int, RandomState instance or None, optional, default: None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

copy_x : boolean, optional

When pre-computing distances it is more numerically accurate to center the data first. If copy_x is True, then the original data is not modified. If False, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean.

n_jobs : int

The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

return_n_iter : bool, optional

Whether or not to return the number of iterations.

Returns **centroid** : float ndarray with shape (k, n_features)

Centroids found at the last iteration of k-means.

label : integer ndarray with shape (n_samples,)

label[i] is the code or index of the centroid the i'th observation is closest to.

inertia : float

The final value of the inertia criterion (sum of squared distances to the closest centroid for all observations in the training set).

best_n_iter : int

Number of iterations corresponding to the best results. Returned only if *return_n_iter* is set to True.

sklearn.cluster.ward_tree

sklearn.cluster.**ward_tree**(*X*, *connectivity=None*, *n_clusters=None*, *return_distance=False*)

Ward clustering based on a Feature matrix.

Recursively merges the pair of clusters that minimally increases within-cluster variance.

The inertia matrix uses a Heapq-based representation.

This is the structured version, that takes into account some topological structure between samples.

Read more in the *User Guide*.

Parameters **X** : array, shape (n_samples, n_features)

feature matrix representing n_samples samples to be clustered

connectivity : sparse matrix (optional).

connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. The matrix is assumed to be symmetric and only the upper triangular half is used. Default is None, i.e, the Ward algorithm is unstructured.

n_clusters : int (optional)

Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. In this case, the complete tree is not computed, thus the 'children' output is of limited use, and the 'parents' output should rather be used. This option is valid only when specifying a connectivity matrix.

return_distance : bool (optional)

If True, return the distance between the clusters.

Returns **children** : 2D array, shape (n_nodes-1, 2)

The children of each non-leaf node. Values less than *n_samples* correspond to leaves of the tree which are the original samples. A node *i* greater than or equal to *n_samples* is a non-leaf node and has children *children_[i - n_samples]*. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node *n_samples + i*

n_components : int

The number of connected components in the graph.

n_leaves : int

The number of leaves in the tree

parents : 1D array, shape (n_nodes,) or None

The parent of each node. Only returned when a connectivity matrix is specified, elsewhere 'None' is returned.

distances : 1D array, shape (n_nodes-1,)

Only returned if return_distance is set to True (for compatibility). The distances between the centers of the nodes. *distances[i]* corresponds to a weighted euclidean distance between the nodes *children[i, 1]* and *children[i, 2]*. If the nodes refer to leaves of the tree, then *distances[i]* is their unweighted euclidean distance. Distances are updated in the following way (from scipy.hierarchy.linkage):

The new entry $d(u, v)$ is computed as follows,

$$d(u,v) = \sqrt{\frac{|v|+|s|}{T}d(v,s)^2 + \frac{|v|+|t|}{T}d(v,t)^2 - \frac{|v|}{T}d(s,t)^2}$$

where u is the newly joined cluster consisting of clusters s and t, v is an unused cluster in the forest, $T = |v| + |s| + |t|$, and $|*|$ is the cardinality of its argument. This is also known as the incremental algorithm.

sklearn.cluster.affinity_propagation

sklearn.cluster.**affinity_propagation**(*S*, *preference=None*, *convergence_iter=15*, *max_iter=200*, *damping=0.5*, *copy=True*, *verbose=False*, *return_n_iter=False*)

Perform Affinity Propagation Clustering of data

Read more in the *User Guide*.

Parameters **S** : array-like, shape (n_samples, n_samples)

Matrix of similarities between points

preference : array-like, shape (n_samples,) or float, optional

Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The number of exemplars, i.e. of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities (resulting in a moderate number of clusters). For a smaller amount of clusters, this can be set to the minimum value of the similarities.

convergence_iter : int, optional, default: 15

Number of iterations with no change in the number of estimated clusters that stops the convergence.

max_iter : int, optional, default: 200

Maximum number of iterations

damping : float, optional, default: 0.5

Damping factor between 0.5 and 1.

copy : boolean, optional, default: True

If copy is False, the affinity matrix is modified inplace by the algorithm, for memory efficiency

verbose : boolean, optional, default: False

The verbosity level

return_n_iter : bool, default False

Whether or not to return the number of iterations.

Returns **cluster_centers_indices** : array, shape (n_clusters,)

index of clusters centers

labels : array, shape (n_samples,)

cluster labels for each point

n_iter : int

number of iterations run. Returned only if *return_n_iter* is set to True.

Notes

For an example, see *examples/cluster/plot_affinity_propagation.py*.

Read more in the *User Guide*.

Parameters **X** : array or sparse (CSR) matrix of shape (n_samples, n_features), or array of shape (n_samples, n_samples)

A feature array, or array of distances between samples if `metric='precomputed'`.

eps : float, optional

The maximum distance between two samples for them to be considered as in the same neighborhood.

min_samples : int, optional

The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.

metric : string, or callable

The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by metrics.pairwise.pairwise_distances for its metric parameter. If metric is "precomputed", X is assumed to be a distance matrix and must be square. X may be a sparse matrix, in which case only "nonzero" elements may be considered neighbors for DBSCAN.

metric_params : dict, optional

Additional keyword arguments for the metric function.

New in version 0.19.

algorithm : {'auto', 'ball_tree', 'kd_tree', 'brute'}, optional

The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.

leaf_size : int, optional (default = 30)

Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p : float, optional

The power of the Minkowski metric to be used to calculate distance between points.

sample_weight : array, shape (n_samples,), optional

Weight of each sample, such that a sample with a weight of at least `min_samples` is by itself a core sample; a sample with negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.

n_jobs : int, optional (default = 1)

The number of parallel jobs to run for neighbors search. If `-1`, then the number of jobs is set to the number of CPU cores.

Returns **core_samples** : array [n_core_samples]

Indices of core samples.

labels : array [n_samples]

Cluster labels for each point. Noisy samples are given the label -1.

Notes

For an example, see *examples/cluster/plot_dbscan.py*.

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to O(n.d) where d is the average number of neighbors, while original DBSCAN had memory complexity O(n).

Sparse neighborhoods can be precomputed using *NearestNeighbors.radius_neighbors_graph* with `mode='distance'`.

References

Ester, M., H. P. Kriegel, J. Sander, and X. Xu, "A Density-Based Algorithm for Discovering Clusters in Large Spatial Databases with Noise". In: Proceedings of the 2nd International Conference on Knowledge Discovery and Data Mining, Portland, OR, AAAI Press, pp. 226-231. 1996

sklearn.cluster.mean_shift

sklearn.cluster.**mean_shift**(*X*, *bandwidth=None*, *seeds=None*, *bin_seeding=False*, *min_bin_freq=1*, *cluster_all=True*, *max_iter=300*, *n_jobs=1*)

Perform mean shift clustering of data using a flat kernel.

Read more in the *User Guide*.

Parameters **X** : array-like, shape=[n_samples, n_features]

Input data.

bandwidth : float, optional

Kernel bandwidth.

If bandwidth is not given, it is determined using a heuristic based on the median of all pairwise distances. This will take quadratic time in the number of samples. The sklearn.cluster.estimate_bandwidth function can be used to do this more efficiently.

seeds : array-like, shape=[n_seeds, n_features] or None

Point used as initial kernel locations. If None and bin_seeding=False, each data point is used as a seed. If None and bin_seeding=True, see bin_seeding.

bin_seeding : boolean, default=False

If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. Ignored if seeds argument is not None.

min_bin_freq : int, default=1

To speed up the algorithm, accept only those bins with at least min_bin_freq points as seeds.

cluster_all : boolean, default True

If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.

max_iter : int, default 300

Maximum number of iterations, per seed point before the clustering operation terminates (for that seed point), if has not converged yet.

n_jobs : int

The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

New in version 0.17: Parallel Execution using *n_jobs*.

Returns **cluster_centers** : array, shape=[n_clusters, n_features]

Coordinates of cluster centers.

labels : array, shape=[n_samples]

Cluster labels for each point.

Notes

For an example, see *examples/cluster/plot_mean_shift.py*.

sklearn.cluster.spectral_clustering

sklearn.cluster.**spectral_clustering**(*affinity*, *n_clusters=8*, *n_components=None*, *eigen_solver=None*, *random_state=None*, *n_init=10*, *eigen_tol=0.0*, *assign_labels='kmeans'*)

Apply clustering to a projection to the normalized laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance when clusters are nested circles on the 2D plan.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

Read more in the *User Guide*.

Parameters **affinity** : array-like or sparse matrix, shape: (n_samples, n_samples)

The affinity matrix describing the relationship of the samples to embed. **Must be symmetric**.

Possible examples:

- adjacency matrix of a graph,
- heat kernel of the pairwise distance matrix of the samples,

- symmetric k-nearest neighbours connectivity matrix of the samples.

n_clusters : integer, optional

Number of clusters to extract.

n_components : integer, optional, default is n_clusters

Number of eigen vectors to use for the spectral embedding

eigen_solver : {None, 'arpack', 'lobpcg', or 'amg'}

The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities

random_state : int, RandomState instance or None, optional, default: None

A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when eigen_solver == 'amg' and by the K-Means initialization. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

n_init : int, optional, default: 10

Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

eigen_tol : float, optional, default: 0.0

Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen_solver.

assign_labels : {'kmeans', 'discretize'}, default: 'kmeans'

The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding. k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization. See the 'Multiclass spectral clustering' paper referenced below for more details on the discretization approach.

Returns **labels** : array of integers, shape: n_samples

The labels of the clusters.

Notes

The graph should contain only one connect component, elsewhere the results make little sense.

This algorithm solves the normalized cut for k=2: it is a normalized spectral clustering.

29.3 `sklearn.cluster.bicluster`: Biclustering

Spectral biclustering algorithms.

Authors : Kemal Eren License: BSD 3 clause

User guide: See the *Biclustering* section for further details.

29.3.1 Classes

SpectralBiclustering([n_clusters, method, ...])	Spectral biclustering (Kluger, 2003).
SpectralCoclustering([n_clusters, ...])	Spectral Co-Clustering algorithm (Dhillon, 2001).

`sklearn.cluster.bicluster.SpectralBiclustering`

class sklearn.cluster.bicluster.**SpectralBiclustering**(*n_clusters=3*, *method='bistochastic'*, *n_components=6*, *n_best=3*, *svd_method='randomized'*, *n_svd_vecs=None*, *mini_batch=False*, *init='k-means++'*, *n_init=10*, *n_jobs=1*, *random_state=None*)

Spectral biclustering (Kluger, 2003).

Partitions rows and columns under the assumption that the data has an underlying checkerboard structure. For instance, if there are two row partitions and three column partitions, each row will belong to three biclusters, and each column will belong to two biclusters. The outer product of the corresponding row and column label vectors gives this checkerboard structure.

Read more in the *User Guide*.

Parameters **n_clusters** : integer or tuple (n_row_clusters, n_column_clusters)

The number of row and column clusters in the checkerboard structure.

method : string, optional, default: 'bistochastic'

Method of normalizing and converting singular vectors into biclusters. May be one of 'scale', 'bistochastic', or 'log'. The authors recommend using 'log'. If the data is sparse, however, log normalization will not work, which is why the default is 'bistochastic'. CAUTION: if *method='log'*, the data must not be sparse.

n_components : integer, optional, default: 6

Number of singular vectors to check.

n_best : integer, optional, default: 3

Number of best singular vectors to which to project the data for clustering.

svd_method : string, optional, default: 'randomized'

Selects the algorithm for finding singular vectors. May be 'randomized' or 'arpack'. If 'randomized', uses *sklearn.utils.extmath.randomized_svd*, which may be faster for large matrices. If 'arpack', uses *scipy.sparse.linalg.svds*, which is more accurate, but possibly slower in some cases.

n_svd_vecs : int, optional, default: None

Number of vectors to use in calculating the SVD. Corresponds to *ncv* when *svd_method=arpack* and *n_oversamples* when *svd_method* is 'randomized'.

mini_batch : bool, optional, default: False

Whether to use mini-batch k-means, which is faster but may get different results.

init : {'k-means++', 'random' or an ndarray}

Method for initialization of k-means algorithm; defaults to 'k-means++'.

n_init : int, optional, default: 10

Number of random initializations that are tried with the k-means algorithm.

If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.

n_jobs : int, optional, default: 1

The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

random_state : int, RandomState instance or None, optional, default: None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **rows_** : array-like, shape (n_row_clusters, n_rows)

Results of the clustering. *rows[i, r]* is True if cluster *i* contains row *r*. Available only after calling `fit`.

columns_ : array-like, shape (n_column_clusters, n_columns)

Results of the clustering, like *rows*.

row_labels_ : array-like, shape (n_rows,)

Row partition labels.

column_labels_ : array-like, shape (n_cols,)

Column partition labels.

References

- Kluger, Yuval, et. al., 2003. Spectral biclustering of microarray data: coclustering genes and conditions.

Methods

fit(X[, y])	Creates a biclustering for X.
get_indices(i)	Row and column indices of the i'th bicluster.
get_params([deep])	Get parameters for this estimator.
get_shape(i)	Shape of the i'th bicluster.
get_submatrix(i, data)	Returns the submatrix corresponding to bicluster *i*.
set_params(**params)	Set the parameters of this estimator.

__init__(*n_clusters=3*, *method='bistochastic'*, *n_components=6*, *n_best=3*, *svd_method='randomized'*, *n_svd_vecs=None*, *mini_batch=False*, *init='k-means++'*, *n_init=10*, *n_jobs=1*, *random_state=None*)

biclusters_

Convenient way to get row and column indicators together.

Returns the `rows_` and `columns_` members.

fit(*X*, *y=None*)

Creates a biclustering for X.

Parameters **X** : array-like, shape (n_samples, n_features)

get_indices(*i*)

Row and column indices of the i'th bicluster.

Only works if `rows_` and `columns_` attributes exist.

Returns **row_ind** : np.array, dtype=np.intp

Indices of rows in the dataset that belong to the bicluster.

col_ind : np.array, dtype=np.intp

Indices of columns in the dataset that belong to the bicluster.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_shape(*i*)

Shape of the i'th bicluster.

Returns **shape** : (int, int)

Number of rows and columns (resp.) in the bicluster.

get_submatrix(*i*, *data*)

Returns the submatrix corresponding to bicluster *i*.

Works with sparse matrices. Only works if `rows_` and `columns_` attributes exist.

set_params(**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

sklearn.cluster.bicluster.SpectralCoclustering

class sklearn.cluster.bicluster.**SpectralCoclustering**(*n_clusters=3*, *svd_method='randomized'*, *n_svd_vecs=None*, *mini_batch=False*, *init='k-means++'*, *n_init=10*, *n_jobs=1*, *random_state=None*)

Spectral Co-Clustering algorithm (Dhillon, 2001).

Clusters rows and columns of an array *X* to solve the relaxed normalized cut of the bipartite graph created from *X* as follows: the edge between row vertex *i* and column vertex *j* has weight *X[i, j]*.

The resulting bicluster structure is block-diagonal, since each row and each column belongs to exactly one bicluster.

Supports sparse matrices, as long as they are nonnegative.

Read more in the *User Guide*.

Parameters **n_clusters** : integer, optional, default: 3

The number of biclusters to find.

svd_method : string, optional, default: 'randomized'

Selects the algorithm for finding singular vectors. May be 'randomized' or 'arpack'. If 'randomized', use `sklearn.utils.extmath.randomized_svd`, which may be faster for large matrices. If 'arpack', use `scipy.sparse.linalg.svds`, which is more accurate, but possibly slower in some cases.

n_svd_vecs : int, optional, default: None

Number of vectors to use in calculating the SVD. Corresponds to *ncv* when *svd_method=arpack* and *n_oversamples* when *svd_method* is 'randomized'.

mini_batch : bool, optional, default: False

Whether to use mini-batch k-means, which is faster but may get different results.

init : {'k-means++', 'random' or an ndarray}

Method for initialization of k-means algorithm; defaults to 'k-means++'.

n_init : int, optional, default: 10

Number of random initializations that are tried with the k-means algorithm.

If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.

n_jobs : int, optional, default: 1

The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

random_state : int, RandomState instance or None, optional, default: None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **rows_** : array-like, shape (n_row_clusters, n_rows)

Results of the clustering. *rows[i, r]* is True if cluster *i* contains row *r*. Available only after calling `fit`.

columns_ : array-like, shape (n_column_clusters, n_columns)

Results of the clustering, like *rows*.

row_labels_ : array-like, shape (n_rows,)

The bicluster label of each row.

column_labels_ : array-like, shape (n_cols,)

The bicluster label of each column.

Methods

fit(X[, y])	Creates a biclustering for X.
get_indices(i)	Row and column indices of the i'th bicluster.
get_params([deep])	Get parameters for this estimator.
get_shape(i)	Shape of the i'th bicluster.
get_submatrix(i, data)	Returns the submatrix corresponding to bicluster *i*.
set_params(**params)	Set the parameters of this estimator.

__init__(*n_clusters=3*, *svd_method='randomized'*, *n_svd_vecs=None*, *mini_batch=False*, *init='k-means++'*, *n_init=10*, *n_jobs=1*, *random_state=None*)

biclusters_

Convenient way to get row and column indicators together.

Returns the `rows_` and `columns_` members.

fit(*X*, *y=None*)

Creates a biclustering for X.

Parameters **X** : array-like, shape (n_samples, n_features)

get_indices(*i*)

Row and column indices of the i'th bicluster.

Only works if `rows_` and `columns_` attributes exist.

Returns **row_ind** : np.array, dtype=np.intp

Indices of rows in the dataset that belong to the bicluster.

col_ind : np.array, dtype=np.intp

Indices of columns in the dataset that belong to the bicluster.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_shape(*i*)
Shape of the i'th bicluster.

Returns **shape** : (int, int)

Number of rows and columns (resp.) in the bicluster.

get_submatrix(*i*, *data*)
Returns the submatrix corresponding to bicluster *i*.

Works with sparse matrices. Only works if `rows_` and `columns_` attributes exist.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.4 `sklearn.covariance`: Covariance Estimators

The *`sklearn.covariance`* module includes methods and algorithms to robustly estimate the covariance of features given a set of points. The precision matrix defined as the inverse of the covariance is also estimated. Covariance estimation is closely related to the theory of Gaussian Graphical Models.

User guide: See the *Covariance estimation* section for further details.

`covariance.EmpiricalCovariance`([...])	Maximum likelihood covariance estimator
`covariance.EllipticEnvelope`([...])	An object for detecting outliers in a Gaussian distributed dataset.
`covariance.GraphLasso`([alpha, mode, tol, ...])	Sparse inverse covariance estimation with an l1-penalized estimator.
`covariance.GraphLassoCV`([alphas, ...])	Sparse inverse covariance w/ cross-validated choice of the l1 penalty
`covariance.LedoitWolf`([store_precision, ...])	LedoitWolf Estimator
`covariance.MinCovDet`([store_precision, ...])	Minimum Covariance Determinant (MCD): robust estimator of covariance.
`covariance.OAS`([store_precision, ...])	Oracle Approximating Shrinkage Estimator
`covariance.ShrunkCovariance`([...])	Covariance estimator with shrinkage

29.4.1 sklearn.covariance.EmpiricalCovariance

class sklearn.covariance.**EmpiricalCovariance**(*store_precision=True*, *assume_centered=False*)

Maximum likelihood covariance estimator

Read more in the *User Guide*.

Parameters **store_precision** : bool

Specifies if the estimated precision is stored.

assume_centered : bool

If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data are centered before computation.

Attributes **covariance_** : 2D ndarray, shape (n_features, n_features)

Estimated covariance matrix

precision_ : 2D ndarray, shape (n_features, n_features)

Estimated pseudo-inverse matrix. (stored only if store_precision is True)

Methods

error_norm(comp_cov[, norm, scaling, squared])	Computes the Mean Squared Error between two covariance estimators.
fit(X[, y])	Fits the Maximum Likelihood Estimator covariance model according to the given training data and parameters.
get_params([deep])	Get parameters for this estimator.
get_precision()	Getter for the precision matrix.
mahalanobis(observations)	Computes the squared Mahalanobis distances of given observations.
score(X_test[, y])	Computes the log-likelihood of a Gaussian data set with *self.covariance_* as an estimator of its covariance matrix.
set_params(**params)	Set the parameters of this estimator.

__init__(*store_precision=True*, *assume_centered=False*)

error_norm(*comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters **comp_cov** : array-like, shape = [n_features, n_features]

The covariance to compare with.

norm : str

The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling : bool

If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared : bool

Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns The Mean Squared Error (in the sense of the Frobenius norm) between :

'self' and 'comp_cov' covariance estimators. :

fit(*X*, *y=None*)

Fits the Maximum Likelihood Estimator covariance model according to the given training data and parameters.

Parameters X : array-like, shape = [n_samples, n_features]

Training data, where n_samples is the number of samples and n_features is the number of features.

y : not used, present for API consistence purpose.

Returns self : object

Returns self.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters deep : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns params : mapping of string to any

Parameter names mapped to their values.

get_precision()

Getter for the precision matrix.

Returns precision_ : array-like,

The precision matrix associated to the current covariance object.

mahalanobis(*observations*)

Computes the squared Mahalanobis distances of given observations.

Parameters observations : array-like, shape = [n_observations, n_features]

The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns mahalanobis_distance : array, shape = [n_observations,]

Squared Mahalanobis distances of the observations.

score(*X_test*, *y=None*)

Computes the log-likelihood of a Gaussian data set with *self.covariance_* as an estimator of its covariance matrix.

Parameters X_test : array-like, shape = [n_samples, n_features]

Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y : not used, present for API consistence purpose.

Returns **res** : float

The likelihood of the data set with *self.covariance_* as an estimator of its covariance matrix.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.covariance.EmpiricalCovariance`

- *Robust covariance estimation and Mahalanobis distances relevance*
- *Robust vs Empirical covariance estimate*

29.4.2 `sklearn.covariance.`EllipticEnvelope

class `sklearn.covariance.`**EllipticEnvelope**(*store_precision=True*, *assume_centered=False*, *support_fraction=None*, *contamination=0.1*, *random_state=None*)

An object for detecting outliers in a Gaussian distributed dataset.

Read more in the *User Guide*.

Parameters **store_precision** : boolean, optional (default=True)

Specify if the estimated precision is stored.

assume_centered : boolean, optional (default=False)

If True, the support of robust location and covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, the robust location and covariance are directly computed with the FastMCD algorithm without additional treatment.

support_fraction : float in (0., 1.), optional (default=None)

The proportion of points to be included in the support of the raw MCD estimate. If None, the minimum value of support_fraction will be used within the algorithm: *[n_sample + n_features + 1] / 2*.

contamination : float in (0., 0.5), optional (default=0.1)

The amount of contamination of the data set, i.e. the proportion of outliers in the data set.

Attributes **location_** : array-like, shape (n_features,)

Estimated robust location

covariance_ : array-like, shape (n_features, n_features)

Estimated robust covariance matrix

precision_ : array-like, shape (n_features, n_features)

Estimated pseudo inverse matrix. (stored only if store_precision is True)

support_ : array-like, shape (n_samples,)

A mask of the observations that have been used to compute the robust estimates of location and shape.

See also:

EmpiricalCovariance, *MinCovDet*

Notes

Outlier detection from covariance estimation may break or not perform well in high-dimensional settings. In particular, one will always take care to work with `n_samples > n_features ** 2`.

References

Methods

correct_covariance(data)	Apply a correction to raw Minimum Covariance Determinant estimates.
decision_function(X[, raw_values])	Compute the decision function of the given observations.
error_norm(comp_cov[, norm, scaling, squared])	Computes the Mean Squared Error between two covariance estimators.
`fit`(X[, y])	
get_params([deep])	Get parameters for this estimator.
get_precision()	Getter for the precision matrix.
mahalanobis(observations)	Computes the squared Mahalanobis distances of given observations.
predict(X)	Outlyingness of observations in X according to the fitted model.
reweight_covariance(data)	Re-weight raw Minimum Covariance Determinant estimates.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__(*store_precision=True*, *assume_centered=False*, *support_fraction=None*, *contamination=0.1*, *random_state=None*)

correct_covariance(*data*)

Apply a correction to raw Minimum Covariance Determinant estimates.

Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in *[Rouseeuw1984]*.

Parameters **data** : array-like, shape (n_samples, n_features)

The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

Returns **covariance_corrected** : array-like, shape (n_features, n_features)

Corrected robust covariance estimate.

decision_function(*X*, *raw_values=False*)
Compute the decision function of the given observations.

Parameters **X** : array-like, shape (n_samples, n_features)

raw_values : bool

Whether or not to consider raw Mahalanobis distances as the decision function. Must be False (default) for compatibility with the others outlier detection tools.

Returns **decision** : array-like, shape (n_samples,)

Decision function of the samples. It is equal to the Mahalanobis distances if *raw_values* is True. By default (`raw_values=False`), it is equal to the cubic root of the shifted Mahalanobis distances. In that case, the threshold for being an outlier is 0, which ensures a compatibility with other outlier detection tools such as the One-Class SVM.

error_norm(*comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters **comp_cov** : array-like, shape = [n_features, n_features]

The covariance to compare with.

norm : str

The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling : bool

If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared : bool

Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns **The Mean Squared Error (in the sense of the Frobenius norm) between** :

'self' and 'comp_cov' covariance estimators. :

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_precision()
Getter for the precision matrix.

Returns **precision_** : array-like,

The precision matrix associated to the current covariance object.

mahalanobis(*observations*)

Computes the squared Mahalanobis distances of given observations.

Parameters **observations** : array-like, shape = [n_observations, n_features]

The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns **mahalanobis_distance** : array, shape = [n_observations,]

Squared Mahalanobis distances of the observations.

predict(*X*)

Outlyingness of observations in X according to the fitted model.

Parameters **X** : array-like, shape = (n_samples, n_features)

Returns **is_outliers** : array, shape = (n_samples,), dtype = bool

For each observation, tells whether or not it should be considered as an outlier according to the fitted model.

threshold : float,

The values of the less outlying point's decision function.

reweight_covariance(*data*)

Re-weight raw Minimum Covariance Determinant estimates.

Re-weight observations using Rousseeuw's method (equivalent to deleting outlying observations from the data set before computing location and covariance estimates). *[Rouseeuw1984]*

Parameters **data** : array-like, shape (n_samples, n_features)

The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

Returns **location_reweighted** : array-like, shape (n_features,)

Re-weighted robust location estimate.

covariance_reweighted : array-like, shape (n_features, n_features)

Re-weighted robust covariance estimate.

support_reweighted : array-like, type boolean, shape (n_samples,)

A mask of the observations that have been used to compute the re-weighted robust location and covariance estimates.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples,) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = (n_samples,), optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.covariance.EllipticEnvelope`

- *Outlier detection on a real data set*
- *Outlier detection with several methods.*

29.4.3 `sklearn.covariance`.GraphLasso

class sklearn.covariance.**GraphLasso**(*alpha=0.01*, *mode='cd'*, *tol=0.0001*, *enet_tol=0.0001*, *max_iter=100*, *verbose=False*, *assume_centered=False*)
Sparse inverse covariance estimation with an l1-penalized estimator.

Read more in the *User Guide*.

Parameters **alpha** : positive float, default 0.01

The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance.

mode : {'cd', 'lars'}, default 'cd'

The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where p > n. Elsewhere prefer cd which is more numerically stable.

tol : positive float, default 1e-4

The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

enet_tol : positive float, optional

The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'.

max_iter : integer, default 100

The maximum number of iterations.

verbose : boolean, default False

If verbose is True, the objective function and dual gap are plotted at each iteration.

assume_centered : boolean, default False

If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

Attributes **covariance_** : array-like, shape (n_features, n_features)

Estimated covariance matrix

precision_ : array-like, shape (n_features, n_features)

Estimated pseudo inverse matrix.

n_iter_ : int

Number of iterations run.

graph_lasso, *GraphLassoCV*

Methods

error_norm(comp_cov[, norm, scaling, squared])	Computes the Mean Squared Error between two covariance estimators.
fit(X[, y])	
get_params([deep])	Get parameters for this estimator.
get_precision()	Getter for the precision matrix.
mahalanobis(observations)	Computes the squared Mahalanobis distances of given observations.
score(X_test[, y])	Computes the log-likelihood of a Gaussian data set with *self.covariance_* as an estimator of its covariance matrix.
set_params(**params)	Set the parameters of this estimator.

__init__(*alpha=0.01*, *mode='cd'*, *tol=0.0001*, *enet_tol=0.0001*, *max_iter=100*, *verbose=False*, *assume_centered=False*)

error_norm(*comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters **comp_cov** : array-like, shape = [n_features, n_features]

The covariance to compare with.

norm : str

The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling : bool

If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared : bool

Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns **The Mean Squared Error (in the sense of the Frobenius norm) between** :

'self' and 'comp_cov' covariance estimators. :

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_precision()
Getter for the precision matrix.

Returns **precision_** : array-like,

The precision matrix associated to the current covariance object.

mahalanobis(*observations*)
Computes the squared Mahalanobis distances of given observations.

Parameters **observations** : array-like, shape = [n_observations, n_features]

The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns **mahalanobis_distance** : array, shape = [n_observations,]

Squared Mahalanobis distances of the observations.

score(*X_test*, *y=None*)
Computes the log-likelihood of a Gaussian data set with *self.covariance_* as an estimator of its covariance matrix.

Parameters **X_test** : array-like, shape = [n_samples, n_features]

Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y : not used, present for API consistence purpose.

Returns **res** : float

The likelihood of the data set with *self.covariance_* as an estimator of its covariance matrix.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.4.4 sklearn.covariance.GraphLassoCV

class sklearn.covariance.**GraphLassoCV**(*alphas=4*, *n_refinements=4*, *cv=None*, *tol=0.0001*, *enet_tol=0.0001*, *max_iter=100*, *mode='cd'*, *n_jobs=1*, *verbose=False*, *assume_centered=False*)
Sparse inverse covariance w/ cross-validated choice of the l1 penalty

Read more in the *User Guide*.

Parameters **alphas** : integer, or list positive float, optional

If an integer is given, it fixes the number of points on the grids of alpha to be used. If a list is given, it gives the grid to be used. See the notes in the class docstring for more details.

n_refinements : strictly positive integer

The number of times the grid is refined. Not used if explicit values of alphas are passed.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

tol : positive float, optional

The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

enet_tol : positive float, optional

The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'.

max_iter : integer, optional

Maximum number of iterations.

mode : {'cd', 'lars'}

The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where number of features is greater than number of samples. Elsewhere prefer cd which is more numerically stable.

n_jobs : int, optional

number of jobs to run in parallel (default 1).

verbose : boolean, optional

If verbose is True, the objective function and duality gap are printed at each iteration.

assume_centered : Boolean

If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

Attributes **covariance_** : numpy.ndarray, shape (n_features, n_features)

Estimated covariance matrix.

precision_ : numpy.ndarray, shape (n_features, n_features)

Estimated precision matrix (inverse covariance).

alpha_ : float

Penalization parameter selected.

cv_alphas_ : list of float

All penalization parameters explored.

grid_scores_ : 2D numpy.ndarray (n_alphas, n_folds)

Log-likelihood score on left-out data across folds.

n_iter_ : int

Number of iterations run for the optimal alpha.

See also:

graph_lasso, *GraphLasso*

Notes

The search for the optimal penalization parameter (alpha) is done on an iteratively refined grid: first the cross-validated scores on a grid are computed, then a new refined grid is centered around the maximum, and so on.

One of the challenges which is faced here is that the solvers can fail to converge to a well-conditioned estimate. The corresponding values of alpha then come out as missing values, but the optimum may be close to these missing values.

Methods

error_norm(comp_cov[, norm, scaling, squared])	Computes the Mean Squared Error between two covariance estimators.
fit(X[, y])	Fits the GraphLasso covariance model to X.
get_params([deep])	Get parameters for this estimator.
get_precision()	Getter for the precision matrix.
mahalanobis(observations)	Computes the squared Mahalanobis distances of given observations.
score(X_test[, y])	Computes the log-likelihood of a Gaussian data set with *self.covariance_* as an estimator of its covariance matrix.
set_params(**params)	Set the parameters of this estimator.

__init__(*alphas=4*, *n_refinements=4*, *cv=None*, *tol=0.0001*, *enet_tol=0.0001*, *max_iter=100*, *mode='cd'*, *n_jobs=1*, *verbose=False*, *assume_centered=False*)

error_norm(*comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters **comp_cov** : array-like, shape = [n_features, n_features]

The covariance to compare with.

norm : str

The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling : bool

If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared : bool

Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns **The Mean Squared Error (in the sense of the Frobenius norm) between** :

'self' and 'comp_cov' covariance estimators. :

fit (*X*, *y=None*)
Fits the GraphLasso covariance model to X.

Parameters **X** : ndarray, shape (n_samples, n_features)

Data from which to compute the covariance estimate

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_precision ()
Getter for the precision matrix.

Returns **precision_** : array-like,

The precision matrix associated to the current covariance object.

grid_scores
DEPRECATED: Attribute grid_scores was deprecated in version 0.19 and will be removed in 0.21. Use '**grid_scores_**' instead

mahalanobis (*observations*)
Computes the squared Mahalanobis distances of given observations.

Parameters **observations** : array-like, shape = [n_observations, n_features]

The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns **mahalanobis_distance** : array, shape = [n_observations,]

Squared Mahalanobis distances of the observations.

score (*X_test*, *y=None*)
Computes the log-likelihood of a Gaussian data set with *self.covariance_* as an estimator of its covariance matrix.

Parameters **X_test** : array-like, shape = [n_samples, n_features]

Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y : not used, present for API consistence purpose.

Returns **res** : float

The likelihood of the data set with *self.covariance_* as an estimator of its covariance matrix.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.covariance.GraphLassoCV`

- *Visualizing the stock market structure*
- *Sparse inverse covariance estimation*

29.4.5 `sklearn.covariance`.LedoitWolf

class `sklearn.covariance.`**LedoitWolf** (*store_precision=True*, *assume_centered=False*, *block_size=1000*)
LedoitWolf Estimator

Ledoit-Wolf is a particular form of shrinkage, where the shrinkage coefficient is computed using O. Ledoit and M. Wolf's formula as described in "A Well-Conditioned Estimator for Large-Dimensional Covariance Matrices", Ledoit and Wolf, Journal of Multivariate Analysis, Volume 88, Issue 2, February 2004, pages 365-411.

Read more in the *User Guide*.

Parameters **store_precision** : bool, default=True

Specify if the estimated precision is stored.

assume_centered : bool, default=False

If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data are centered before computation.

block_size : int, default=1000

Size of the blocks into which the covariance matrix will be split during its Ledoit-Wolf estimation. This is purely a memory optimization and does not affect results.

Attributes **covariance_** : array-like, shape (n_features, n_features)

Estimated covariance matrix

precision_ : array-like, shape (n_features, n_features)

Estimated pseudo inverse matrix. (stored only if store_precision is True)

shrinkage_ : float, 0 <= shrinkage <= 1

Coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularised covariance is:

```
(1 - shrinkage)*cov
       + shrinkage*mu*np.identity(n_features)
```

where mu = trace(cov) / n_features and shrinkage is given by the Ledoit and Wolf formula (see References)

Methods

error_norm(comp_cov[, norm, scaling, squared])	Computes the Mean Squared Error between two covariance estimators.
fit(X[, y])	Fits the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.
get_params([deep])	Get parameters for this estimator.
get_precision()	Getter for the precision matrix.
mahalanobis(observations)	Computes the squared Mahalanobis distances of given observations.
score(X_test[, y])	Computes the log-likelihood of a Gaussian data set with *self.covariance_* as an estimator of its covariance matrix.
set_params(**params)	Set the parameters of this estimator.

__init__(*store_precision=True*, *assume_centered=False*, *block_size=1000*)

error_norm(*comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters **comp_cov** : array-like, shape = [n_features, n_features]

The covariance to compare with.

norm : str

The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling : bool

If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared : bool

Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns **The Mean Squared Error (in the sense of the Frobenius norm) between** :

'self' and 'comp_cov' covariance estimators. :

fit (*X*, *y=None*)

Fits the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.

Parameters **X** : array-like, shape = [n_samples, n_features]

Training data, where n_samples is the number of samples and n_features is the number of features.

y : not used, present for API consistence purpose.

Returns **self** : object

Returns self.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_precision ()

Getter for the precision matrix.

Returns **precision_** : array-like,

The precision matrix associated to the current covariance object.

mahalanobis (*observations*)

Computes the squared Mahalanobis distances of given observations.

Parameters **observations** : array-like, shape = [n_observations, n_features]

The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns **mahalanobis_distance** : array, shape = [n_observations,]

Squared Mahalanobis distances of the observations.

score (*X_test*, *y=None*)

Computes the log-likelihood of a Gaussian data set with *self.covariance_* as an estimator of its covariance matrix.

Parameters **X_test** : array-like, shape = [n_samples, n_features]

Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y : not used, present for API consistence purpose.

Returns **res** : float

The likelihood of the data set with *self.covariance_* as an estimator of its covariance matrix.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.covariance.LedoitWolf`

- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*
- *Ledoit-Wolf vs OAS estimation*
- *Model selection with Probabilistic PCA and Factor Analysis (FA)*

29.4.6 `sklearn.covariance`.MinCovDet

class `sklearn.covariance.`**MinCovDet**(*store_precision=True*, *assume_centered=False*, *support_fraction=None*, *random_state=None*)
Minimum Covariance Determinant (MCD): robust estimator of covariance.

The Minimum Covariance Determinant covariance estimator is to be applied on Gaussian-distributed data, but could still be relevant on data drawn from a unimodal, symmetric distribution. It is not meant to be used with multi-modal data (the algorithm used to fit a MinCovDet object is likely to fail in such a case). One should consider projection pursuit methods to deal with multi-modal datasets.

Read more in the *User Guide*.

Parameters **store_precision** : bool

Specify if the estimated precision is stored.

assume_centered : Boolean

If True, the support of the robust location and the covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, the robust location and covariance are directly computed with the FastMCD algorithm without additional treatment.

support_fraction : float, 0 < support_fraction < 1

The proportion of points to be included in the support of the raw MCD estimate. Default is None, which implies that the minimum value of support_fraction will be used within the algorithm: [n_sample + n_features + 1] / 2

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **raw_location_** : array-like, shape (n_features,)

The raw robust estimated location before correction and re-weighting.

raw_covariance_ : array-like, shape (n_features, n_features)

The raw robust estimated covariance before correction and re-weighting.

raw_support_ : array-like, shape (n_samples,)

A mask of the observations that have been used to compute the raw robust estimates of location and shape, before correction and re-weighting.

location_ : array-like, shape (n_features,)

Estimated robust location

covariance_ : array-like, shape (n_features, n_features)

Estimated robust covariance matrix

precision_ : array-like, shape (n_features, n_features)

Estimated pseudo inverse matrix. (stored only if store_precision is True)

support_ : array-like, shape (n_samples,)

A mask of the observations that have been used to compute the robust estimates of location and shape.

dist_ : array-like, shape (n_samples,)

Mahalanobis distances of the training set (on which *fit* is called) observations.

set_params(**params)	Set the parameters of this estimator.

__init__(*store_precision=True*, *assume_centered=False*, *support_fraction=None*, *random_state=None*)

correct_covariance(*data*)

Apply a correction to raw Minimum Covariance Determinant estimates.

Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in *[Rouseeuw1984]*.

Parameters **data** : array-like, shape (n_samples, n_features)

The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

Returns **covariance_corrected** : array-like, shape (n_features, n_features)

Corrected robust covariance estimate.

error_norm(*comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters **comp_cov** : array-like, shape = [n_features, n_features]

The covariance to compare with.

norm : str

The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling : bool

If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared : bool

Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns **The Mean Squared Error (in the sense of the Frobenius norm) between** :

'self' and 'comp_cov' covariance estimators. :

fit(*X*, *y=None*)

Fits a Minimum Covariance Determinant with the FastMCD algorithm.

Parameters **X** : array-like, shape = [n_samples, n_features]

Training data, where n_samples is the number of samples and n_features is the number of features.

y : not used, present for API consistence purpose.

Returns **self** : object

Returns self.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_precision()

Getter for the precision matrix.

Returns **precision_** : array-like,

The precision matrix associated to the current covariance object.

mahalanobis(*observations*)
Computes the squared Mahalanobis distances of given observations.

Parameters **observations** : array-like, shape = [n_observations, n_features]

The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns **mahalanobis_distance** : array, shape = [n_observations,]

Squared Mahalanobis distances of the observations.

reweight_covariance(*data*)
Re-weight raw Minimum Covariance Determinant estimates.

Re-weight observations using Rousseeuw's method (equivalent to deleting outlying observations from the data set before computing location and covariance estimates). *[Rouseeuw1984]*

Parameters **data** : array-like, shape (n_samples, n_features)

The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

Returns **location_reweighted** : array-like, shape (n_features,)

Re-weighted robust location estimate.

covariance_reweighted : array-like, shape (n_features, n_features)

Re-weighted robust covariance estimate.

support_reweighted : array-like, type boolean, shape (n_samples,)

A mask of the observations that have been used to compute the re-weighted robust location and covariance estimates.

score(*X_test*, *y=None*)
Computes the log-likelihood of a Gaussian data set with *self.covariance_* as an estimator of its covariance matrix.

Parameters **X_test** : array-like, shape = [n_samples, n_features]

Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y : not used, present for API consistence purpose.

Returns **res** : float

The likelihood of the data set with *self.covariance_* as an estimator of its covariance matrix.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.covariance.MinCovDet`

- *Robust covariance estimation and Mahalanobis distances relevance*
- *Robust vs Empirical covariance estimate*

29.4.7 `sklearn.covariance.OAS`

class `sklearn.covariance.OAS`(*store_precision=True*, *assume_centered=False*)

Oracle Approximating Shrinkage Estimator

Read more in the *User Guide*.

OAS is a particular form of shrinkage described in "Shrinkage Algorithms for MMSE Covariance Estimation" Chen et al., IEEE Trans. on Sign. Proc., Volume 58, Issue 10, October 2010.

The formula used here does not correspond to the one given in the article. It has been taken from the Matlab program available from the authors' webpage (http://tbayes.eecs.umich.edu/yilun/covestimation). In the original article, formula (23) states that 2/p is multiplied by Trace(cov*cov) in both the numerator and denominator, this operation is omitted in the author's MATLAB program because for a large p, the value of 2/p is so small that it doesn't affect the value of the estimator.

Parameters **store_precision** : bool, default=True

Specify if the estimated precision is stored.

assume_centered : bool, default=False

If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data are centered before computation.

Attributes **covariance_** : array-like, shape (n_features, n_features)

Estimated covariance matrix.

precision_ : array-like, shape (n_features, n_features)

Estimated pseudo inverse matrix. (stored only if store_precision is True)

shrinkage_ : float, 0 <= shrinkage <= 1

coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularised covariance is:

```
(1 - shrinkage)*cov
        + shrinkage*mu*np.identity(n_features)
```

where mu = trace(cov) / n_features and shrinkage is given by the OAS formula (see References)

References

"Shrinkage Algorithms for MMSE Covariance Estimation" Chen et al., IEEE Trans. on Sign. Proc., Volume 58, Issue 10, October 2010.

Methods

error_norm(comp_cov[, norm, scaling, squared])	Computes the Mean Squared Error between two covariance estimators.
fit(X[, y])	Fits the Oracle Approximating Shrinkage covariance model according to the given training data and parameters.
get_params([deep])	Get parameters for this estimator.
get_precision()	Getter for the precision matrix.
mahalanobis(observations)	Computes the squared Mahalanobis distances of given observations.
score(X_test[, y])	Computes the log-likelihood of a Gaussian data set with *self.covariance_* as an estimator of its covariance matrix.
set_params(**params)	Set the parameters of this estimator.

__init__(*store_precision=True*, *assume_centered=False*)

error_norm(*comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters **comp_cov** : array-like, shape = [n_features, n_features]

The covariance to compare with.

norm : str

The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling : bool

If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared : bool

Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns **The Mean Squared Error (in the sense of the Frobenius norm) between** :

'self' and 'comp_cov' covariance estimators. :

fit(*X*, *y=None*)

Fits the Oracle Approximating Shrinkage covariance model according to the given training data and parameters.

Parameters **X** : array-like, shape = [n_samples, n_features]

Training data, where n_samples is the number of samples and n_features is the number of features.

y : not used, present for API consistence purpose.

Returns **self** : object

Returns self.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_precision()
Getter for the precision matrix.

Returns **precision_** : array-like,

The precision matrix associated to the current covariance object.

mahalanobis(*observations*)
Computes the squared Mahalanobis distances of given observations.

Parameters **observations** : array-like, shape = [n_observations, n_features]

The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns **mahalanobis_distance** : array, shape = [n_observations,]

Squared Mahalanobis distances of the observations.

score(*X_test*, *y=None*)
Computes the log-likelihood of a Gaussian data set with *self.covariance_* as an estimator of its covariance matrix.

Parameters **X_test** : array-like, shape = [n_samples, n_features]

Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y : not used, present for API consistence purpose.

Returns **res** : float

The likelihood of the data set with *self.covariance_* as an estimator of its covariance matrix.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.covariance.OAS`

- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*
- *Ledoit-Wolf vs OAS estimation*

29.4.8 sklearn.covariance.ShrunkCovariance

class sklearn.covariance.**ShrunkCovariance**(*store_precision=True*, *assume_centered=False*, *shrinkage=0.1*)

Covariance estimator with shrinkage

Read more in the *User Guide*.

Parameters **store_precision** : boolean, default True

Specify if the estimated precision is stored

shrinkage : float, 0 <= shrinkage <= 1, default 0.1

Coefficient in the convex combination used for the computation of the shrunk estimate.

assume_centered : boolean, default False

If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

Attributes **covariance_** : array-like, shape (n_features, n_features)

Estimated covariance matrix

precision_ : array-like, shape (n_features, n_features)

Estimated pseudo inverse matrix. (stored only if store_precision is True)

shrinkage : float, 0 <= shrinkage <= 1

Coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularized covariance is given by

(1 - shrinkage)*cov

- shrinkage*mu*np.identity(n_features)

where mu = trace(cov) / n_features

Methods

error_norm(comp_cov[, norm, scaling, squared])	Computes the Mean Squared Error between two covariance estimators.
fit(X[, y])	Fits the shrunk covariance model according to the given training data and parameters.

set_params(**params)	Set the parameters of this estimator.

__init__(*store_precision=True*, *assume_centered=False*, *shrinkage=0.1*)

error_norm(*comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters **comp_cov** : array-like, shape = [n_features, n_features]

The covariance to compare with.

norm : str

The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling : bool

If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared : bool

Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns **The Mean Squared Error (in the sense of the Frobenius norm) between** :

'self' and 'comp_cov' covariance estimators. :

fit(*X*, *y=None*)
Fits the shrunk covariance model according to the given training data and parameters.

Parameters **X** : array-like, shape = [n_samples, n_features]

Training data, where n_samples is the number of samples and n_features is the number of features.

y : not used, present for API consistence purpose.

Returns **self** : object

Returns self.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_precision()
Getter for the precision matrix.

Returns **precision_** : array-like,

The precision matrix associated to the current covariance object.

mahalanobis(*observations*)
Computes the squared Mahalanobis distances of given observations.

Parameters **observations** : array-like, shape = [n_observations, n_features]

The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns **mahalanobis_distance** : array, shape = [n_observations,]

Squared Mahalanobis distances of the observations.

score (*X_test*, *y=None*)

Computes the log-likelihood of a Gaussian data set with *self.covariance_* as an estimator of its covariance matrix.

Parameters **X_test** : array-like, shape = [n_samples, n_features]

Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y : not used, present for API consistence purpose.

Returns **res** : float

The likelihood of the data set with *self.covariance_* as an estimator of its covariance matrix.

set_params (***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.covariance.ShrunkCovariance`

- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*
- *Model selection with Probabilistic PCA and Factor Analysis (FA)*

covariance.empirical_covariance(X[, ...])	Computes the Maximum likelihood covariance estimator
covariance.ledoit_wolf(X[, assume_centered, ...])	Estimates the shrunk Ledoit-Wolf covariance matrix.
covariance.shrunk_covariance(emp_cov[, ...])	Calculates a covariance matrix shrunk on the diagonal
covariance.oas(X[, assume_centered])	Estimate covariance with the Oracle Approximating Shrinkage algorithm.
covariance.graph_lasso(emp_cov, alpha[, ...])	l1-penalized covariance estimator

29.4.9 `sklearn.covariance`.empirical_covariance

sklearn.covariance.**empirical_covariance** (*X*, *assume_centered=False*)

Computes the Maximum likelihood covariance estimator

Parameters **X** : ndarray, shape (n_samples, n_features)

Data from which to compute the covariance estimate

assume_centered : Boolean

If True, data are not centered before computation. Useful when working with data

whose mean is almost, but not exactly zero. If False, data are centered before computation.

Returns **covariance** : 2D ndarray, shape (n_features, n_features)

Empirical covariance (Maximum Likelihood Estimator).

Examples using `sklearn.covariance.empirical_covariance`

- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*

29.4.10 `sklearn.covariance`.ledoit_wolf

`sklearn.covariance.`**`ledoit_wolf`**(*X*, *assume_centered=False*, *block_size=1000*)

Estimates the shrunk Ledoit-Wolf covariance matrix.

Read more in the *User Guide*.

Parameters **X** : array-like, shape (n_samples, n_features)

Data from which to compute the covariance estimate

assume_centered : boolean, default=False

If True, data are not centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data are centered before computation.

block_size : int, default=1000

Size of the blocks into which the covariance matrix will be split. This is purely a memory optimization and does not affect results.

Returns **shrunk_cov** : array-like, shape (n_features, n_features)

Shrunk covariance.

shrinkage : float

Coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularized (shrunk) covariance is:

(1 - shrinkage)*cov

- shrinkage * mu * np.identity(n_features)

where mu = trace(cov) / n_features

Examples using `sklearn.covariance.ledoit_wolf`

- *Sparse inverse covariance estimation*

29.4.11 sklearn.covariance.shrunk_covariance

sklearn.covariance.**shrunk_covariance**(*emp_cov*, *shrinkage=0.1*)

Calculates a covariance matrix shrunk on the diagonal

Read more in the *User Guide*.

Parameters **emp_cov** : array-like, shape (n_features, n_features)

Covariance matrix to be shrunk

shrinkage : float, 0 <= shrinkage <= 1

Coefficient in the convex combination used for the computation of the shrunk estimate.

Returns **shrunk_cov** : array-like

Shrunk covariance.

Notes

The regularized (shrunk) covariance is given by

(1 - shrinkage)*cov

- shrinkage*mu*np.identity(n_features)

where mu = trace(cov) / n_features

29.4.12 sklearn.covariance.oas

sklearn.covariance.**oas**(*X*, *assume_centered=False*)

Estimate covariance with the Oracle Approximating Shrinkage algorithm.

Parameters **X** : array-like, shape (n_samples, n_features)

Data from which to compute the covariance estimate.

assume_centered : boolean

If True, data are not centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data are centered before computation.

Returns **shrunk_cov** : array-like, shape (n_features, n_features)

Shrunk covariance.

shrinkage : float

Coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularised (shrunk) covariance is:

(1 - shrinkage)*cov

- shrinkage * mu * np.identity(n_features)

where mu = trace(cov) / n_features

The formula we used to implement the OAS does not correspond to the one given in the article. It has been taken from the MATLAB program available from the author's webpage (http://tbayes.eecs.umich.edu/yilun/covestimation).

29.4.13 sklearn.covariance.graph_lasso

sklearn.covariance.**graph_lasso**(*emp_cov*, *alpha*, *cov_init=None*, *mode='cd'*, *tol=0.0001*, *enet_tol=0.0001*, *max_iter=100*, *verbose=False*, *return_costs=False*, *eps=2.2204460492503131e-16*, *return_n_iter=False*)

l1-penalized covariance estimator

Read more in the *User Guide*.

Parameters **emp_cov** : 2D ndarray, shape (n_features, n_features)

Empirical covariance from which to compute the covariance estimate.

alpha : positive float

The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance.

cov_init : 2D array (n_features, n_features), optional

The initial guess for the covariance.

mode : {'cd', 'lars'}

The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where p > n. Elsewhere prefer cd which is more numerically stable.

tol : positive float, optional

The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

enet_tol : positive float, optional

The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'.

max_iter : integer, optional

The maximum number of iterations.

verbose : boolean, optional

If verbose is True, the objective function and dual gap are printed at each iteration.

return_costs : boolean, optional

If return_costs is True, the objective function and dual gap at each iteration are returned.

eps : float, optional

The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems.

return_n_iter : bool, optional

Whether or not to return the number of iterations.

Returns **covariance** : 2D ndarray, shape (n_features, n_features)

The estimated covariance matrix.

precision : 2D ndarray, shape (n_features, n_features)

The estimated (sparse) precision matrix.

costs : list of (objective, dual_gap) pairs

The list of values of the objective function and the dual gap at each iteration. Returned only if return_costs is True.

n_iter : int

Number of iterations. Returned only if *return_n_iter* is set to True.

See also:

GraphLasso, *GraphLassoCV*

Notes

The algorithm employed to solve this problem is the GLasso algorithm, from the Friedman 2008 Biostatistics paper. It is the same algorithm as in the R *glasso* package.

One possible difference with the *glasso* R package is that the diagonal coefficients are not penalized.

29.5 `sklearn.model_selection`: Model Selection

User guide: See the *Cross-validation: evaluating estimator performance*, *Tuning the hyper-parameters of an estimator* and *Learning curve* sections for further details.

29.5.1 Splitter Classes

model_selection.KFold([n_splits, shuffle, ...])	K-Folds cross-validator
model_selection.GroupKFold([n_splits])	K-fold iterator variant with non-overlapping groups.
model_selection.StratifiedKFold([n_splits, ...])	Stratified K-Folds cross-validator
model_selection.LeaveOneGroupOut()	Leave One Group Out cross-validator
model_selection.LeavePGroupsOut(n_groups)	Leave P Group(s) Out cross-validator
model_selection.LeaveOneOut()	Leave-One-Out cross-validator
model_selection.LeavePOut(p)	Leave-P-Out cross-validator
model_selection.RepeatedKFold([n_splits, ...])	Repeated K-Fold cross validator.
model_selection.RepeatedStratifiedKFold([...])	Repeated Stratified K-Fold cross validator.
model_selection.ShuffleSplit([n_splits, ...])	Random permutation cross-validator
model_selection.GroupShuffleSplit([...])	Shuffle-Group(s)-Out cross-validation iterator
model_selection.StratifiedShuffleSplit([...])	Stratified ShuffleSplit cross-validator
model_selection.PredefinedSplit(test_fold)	Predefined split cross-validator
model_selection.TimeSeriesSplit([n_splits, ...])	Time Series cross-validator

sklearn.model_selection.KFold

class sklearn.model_selection.**KFold**(*n_splits=3*, *shuffle=False*, *random_state=None*)

K-Folds cross-validator

Provides train/test indices to split data in train/test sets. Split dataset into k consecutive folds (without shuffling by default).

Each fold is then used once as a validation while the k - 1 remaining folds form the training set.

Read more in the *User Guide*.

Parameters **n_splits** : int, default=3

Number of folds. Must be at least 2.

shuffle : boolean, optional

Whether to shuffle the data before splitting into batches.

random_state : int, RandomState instance or None, optional, default=None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `shuffle` == True.

See also:

StratifiedKFold Takes group information into account to avoid building folds with imbalanced class distributions (for binary or multiclass classification tasks).

GroupKFold K-fold iterator variant with non-overlapping groups.

RepeatedKFold Repeats K-Fold n times.

Notes

The first `n_samples % n_splits` folds have size `n_samples // n_splits + 1`, other folds have size `n_samples // n_splits`, where `n_samples` is the number of samples.

Examples

```
>>> from sklearn.model_selection import KFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4])
>>> kf = KFold(n_splits=2)
>>> kf.get_n_splits(X)
2
>>> print(kf)
KFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in kf.split(X):
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [0 1] TEST: [2 3]
```

Methods

get_n_splits([X, y, groups])	Returns the number of splitting iterations in the cross-validator
split(X[, y, groups])	Generate indices to split data into training and test set.

__init__ (*n_splits=3*, *shuffle=False*, *random_state=None*)

get_n_splits (*X=None*, *y=None*, *groups=None*)
Returns the number of splitting iterations in the cross-validator

Parameters **X** : object

Always ignored, exists for compatibility.

y : object

Always ignored, exists for compatibility.

groups : object

Always ignored, exists for compatibility.

Returns **n_splits** : int

Returns the number of splitting iterations in the cross-validator.

split (*X*, *y=None*, *groups=None*)
Generate indices to split data into training and test set.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape (n_samples,)

The target variable for supervised learning problems.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

Examples using `sklearn.model_selection.KFold`

- *Feature agglomeration vs. univariate selection*
- *Gradient Boosting Out-of-Bag estimates*
- *Cross-validation on diabetes Dataset Exercise*
- *Nested versus non-nested cross-validation*

sklearn.model_selection.GroupKFold

class sklearn.model_selection.**GroupKFold**(*n_splits=3*)

K-fold iterator variant with non-overlapping groups.

The same group will not appear in two different folds (the number of distinct groups has to be at least equal to the number of folds).

The folds are approximately balanced in the sense that the number of distinct groups is approximately the same in each fold.

Parameters **n_splits** : int, default=3

Number of folds. Must be at least 2.

See also:

LeaveOneGroupOut For splitting the data according to explicit domain-specific stratification of the dataset.

Examples

```
>>> from sklearn.model_selection import GroupKFold
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> groups = np.array([0, 0, 2, 2])
>>> group_kfold = GroupKFold(n_splits=2)
>>> group_kfold.get_n_splits(X, y, groups)
2
>>> print(group_kfold)
GroupKFold(n_splits=2)
>>> for train_index, test_index in group_kfold.split(X, y, groups):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
...
TRAIN: [0 1] TEST: [2 3]
[[1 2]
 [3 4]] [[5 6]
 [7 8]] [1 2] [3 4]
TRAIN: [2 3] TEST: [0 1]
[[5 6]
 [7 8]] [[1 2]
 [3 4]] [3 4] [1 2]
```

Methods

get_n_splits([X, y, groups])	Returns the number of splitting iterations in the cross-validator
split(X[, y, groups])	Generate indices to split data into training and test set.

__init__(*n_splits=3*)

get_n_splits(*X=None*, *y=None*, *groups=None*)

Returns the number of splitting iterations in the cross-validator

Parameters **X** : object

Always ignored, exists for compatibility.

y : object

Always ignored, exists for compatibility.

groups : object

Always ignored, exists for compatibility.

Returns **n_splits** : int

Returns the number of splitting iterations in the cross-validator.

split(*X*, *y=None*, *groups=None*)

Generate indices to split data into training and test set.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape (n_samples,)

The target variable for supervised learning problems.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

sklearn.model_selection.StratifiedKFold

class sklearn.model_selection.**StratifiedKFold**(*n_splits=3*, *shuffle=False*, *random_state=None*)

Stratified K-Folds cross-validator

Provides train/test indices to split data in train/test sets.

This cross-validation object is a variation of KFold that returns stratified folds. The folds are made by preserving the percentage of samples for each class.

Read more in the *User Guide*.

Parameters **n_splits** : int, default=3

Number of folds. Must be at least 2.

shuffle : boolean, optional

Whether to shuffle each stratification of the data before splitting into batches.

random_state : int, RandomState instance or None, optional, default=None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `shuffle` == True.

See also:

RepeatedStratifiedKFold Repeats Stratified K-Fold n times.

Notes

All the folds have size `trunc(n_samples / n_splits)`, the last one has the complementary.

Examples

```
>>> from sklearn.model_selection import StratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> skf = StratifiedKFold(n_splits=2)
>>> skf.get_n_splits(X, y)
2
>>> print(skf)
StratifiedKFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in skf.split(X, y):
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [0 2] TEST: [1 3]
```

Methods

get_n_splits([X, y, groups])	Returns the number of splitting iterations in the cross-validator
split(X, y[, groups])	Generate indices to split data into training and test set.

__init__ (*n_splits=3*, *shuffle=False*, *random_state=None*)

get_n_splits (*X=None*, *y=None*, *groups=None*)
Returns the number of splitting iterations in the cross-validator

Parameters **X** : object

Always ignored, exists for compatibility.

y : object

Always ignored, exists for compatibility.

groups : object

Always ignored, exists for compatibility.

Returns **n_splits** : int

Returns the number of splitting iterations in the cross-validator.

split (*X*, *y*, *groups=None*)
Generate indices to split data into training and test set.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

Note that providing `y` is sufficient to generate the splits and hence `np.zeros(n_samples)` may be used as a placeholder for `X` instead of actual training data.

y : array-like, shape (n_samples,)

The target variable for supervised learning problems. Stratification is done based on the y labels.

groups : object

Always ignored, exists for compatibility.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

Examples using `sklearn.model_selection.StratifiedKFold`

- *Test with permutations the significance of a classification score*
- *Recursive feature elimination with cross-validation*
- *GMM covariances*
- *Receiver Operating Characteristic (ROC) with cross validation*

`sklearn.model_selection.LeaveOneGroupOut`

class `sklearn.model_selection.`**`LeaveOneGroupOut`**

Leave One Group Out cross-validator

Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

Read more in the *User Guide*.

Examples

```
>>> from sklearn.model_selection import LeaveOneGroupOut
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 1, 2])
>>> groups = np.array([1, 1, 2, 2])
>>> logo = LeaveOneGroupOut()
>>> logo.get_n_splits(X, y, groups)
2
>>> logo.get_n_splits(groups=groups) # 'groups' is always required
```

```
2
>>> print(logo)
LeaveOneGroupOut()
>>> for train_index, test_index in logo.split(X, y, groups):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
TRAIN: [2 3] TEST: [0 1]
[[5 6]
 [7 8]] [[1 2]
 [3 4]] [1 2] [1 2]
TRAIN: [0 1] TEST: [2 3]
[[1 2]
 [3 4]] [[5 6]
 [7 8]] [1 2] [1 2]
```

Methods

get_n_splits([X, y, groups])	Returns the number of splitting iterations in the cross-validator
split(X[, y, groups])	Generate indices to split data into training and test set.

__init__()

get_n_splits(*X=None*, *y=None*, *groups=None*)
Returns the number of splitting iterations in the cross-validator

Parameters **X** : object, optional

Always ignored, exists for compatibility.

y : object, optional

Always ignored, exists for compatibility.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set. This 'groups' parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.

Returns **n_splits** : int

Returns the number of splitting iterations in the cross-validator.

split(*X*, *y=None*, *groups=None*)
Generate indices to split data into training and test set.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, of length n_samples

The target variable for supervised learning problems.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

sklearn.model_selection.LeavePGroupsOut

class sklearn.model_selection.**LeavePGroupsOut**(*n_groups*)

Leave P Group(s) Out cross-validator

Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePGroupsOut and LeaveOneGroupOut is that the former builds the test sets with all the samples assigned to `p` different values of the groups while the latter uses samples all assigned the same groups.

Read more in the *User Guide*.

Parameters **n_groups** : int

Number of groups (`p`) to leave out in the test split.

See also:

GroupKFold K-fold iterator variant with non-overlapping groups.

Examples

```
>>> from sklearn.model_selection import LeavePGroupsOut
>>> X = np.array([[1, 2], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1])
>>> groups = np.array([1, 2, 3])
>>> lpgo = LeavePGroupsOut(n_groups=2)
>>> lpgo.get_n_splits(X, y, groups)
3
>>> lpgo.get_n_splits(groups=groups)  # 'groups' is always required
3
>>> print(lpgo)
LeavePGroupsOut(n_groups=2)
>>> for train_index, test_index in lpgo.split(X, y, groups):
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
...    print(X_train, X_test, y_train, y_test)
TRAIN: [2] TEST: [0 1]
[[5 6]] [[1 2]
 [3 4]] [1] [1 2]
TRAIN: [1] TEST: [0 2]
[[3 4]] [[1 2]
 [5 6]] [2] [1 1]
```

```
TRAIN: [0] TEST: [1 2]
[[1 2]] [[3 4]
 [5 6]] [1] [2 1]
```

Methods

get_n_splits([X, y, groups])	Returns the number of splitting iterations in the cross-validator
split(X[, y, groups])	Generate indices to split data into training and test set.

__init__ (*n_groups*)

get_n_splits (*X=None*, *y=None*, *groups=None*)
Returns the number of splitting iterations in the cross-validator

Parameters **X** : object, optional

Always ignored, exists for compatibility.

y : object, optional

Always ignored, exists for compatibility.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set. This 'groups' parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.

Returns **n_splits** : int

Returns the number of splitting iterations in the cross-validator.

split (*X*, *y=None*, *groups=None*)
Generate indices to split data into training and test set.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, of length n_samples

The target variable for supervised learning problems.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

sklearn.model_selection.LeaveOneOut

class sklearn.model_selection.**LeaveOneOut**

Leave-One-Out cross-validator

Provides train/test indices to split data in train/test sets. Each sample is used once as a test set (singleton) while the remaining samples form the training set.

Note: `LeaveOneOut()` is equivalent to `KFold(n_splits=n)` and `LeavePOut(p=1)` where `n` is the number of samples.

Due to the high number of test sets (which is the same as the number of samples) this cross-validation method can be very costly. For large datasets one should favor *KFold*, *ShuffleSplit* or *StratifiedKFold*.

Read more in the *User Guide*.

See also:

LeaveOneGroupOut For splitting the data according to explicit, domain-specific stratification of the dataset.

GroupKFold K-fold iterator variant with non-overlapping groups.

Examples

```
>>> from sklearn.model_selection import LeaveOneOut
>>> X = np.array([[1, 2], [3, 4]])
>>> y = np.array([1, 2])
>>> loo = LeaveOneOut()
>>> loo.get_n_splits(X)
2
>>> print(loo)
LeaveOneOut()
>>> for train_index, test_index in loo.split(X):
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
...    print(X_train, X_test, y_train, y_test)
TRAIN: [1] TEST: [0]
[[3 4]] [[1 2]] [2] [1]
TRAIN: [0] TEST: [1]
[[1 2]] [[3 4]] [1] [2]
```

Methods

get_n_splits(X[, y, groups])	Returns the number of splitting iterations in the cross-validator
split(X[, y, groups])	Generate indices to split data into training and test set.

__init__()

get_n_splits(*X*, *y=None*, *groups=None*)

Returns the number of splitting iterations in the cross-validator

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number

of features.

y : object

Always ignored, exists for compatibility.

groups : object

Always ignored, exists for compatibility.

Returns **n_splits** : int

Returns the number of splitting iterations in the cross-validator.

split(*X*, *y=None*, *groups=None*)

Generate indices to split data into training and test set.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, of length n_samples

The target variable for supervised learning problems.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

sklearn.model_selection.LeavePOut

class sklearn.model_selection.**LeavePOut**(*p*)

Leave-P-Out cross-validator

Provides train/test indices to split data in train/test sets. This results in testing on all distinct samples of size p, while the remaining n - p samples form the training set in each iteration.

Note: `LeavePOut(p)` is NOT equivalent to `KFold(n_splits=n_samples // p)` which creates non-overlapping test sets.

Due to the high number of iterations which grows combinatorically with the number of samples this cross-validation method can be very costly. For large datasets one should favor *KFold*, *StratifiedKFold* or *ShuffleSplit*.

Read more in the *User Guide*.

Parameters **p** : int

Size of the test sets.

Examples

```
>>> from sklearn.model_selection import LeavePOut
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> lpo = LeavePOut(2)
>>> lpo.get_n_splits(X)
6
>>> print(lpo)
LeavePOut(p=2)
>>> for train_index, test_index in lpo.split(X):
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
TRAIN: [0 2] TEST: [1 3]
TRAIN: [0 1] TEST: [2 3]
```

Methods

get_n_splits(X[, y, groups])	Returns the number of splitting iterations in the cross-validator
split(X[, y, groups])	Generate indices to split data into training and test set.

__init__ (*p*)

get_n_splits (*X*, *y=None*, *groups=None*)
Returns the number of splitting iterations in the cross-validator

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

y : object

Always ignored, exists for compatibility.

groups : object

Always ignored, exists for compatibility.

split (*X*, *y=None*, *groups=None*)
Generate indices to split data into training and test set.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, of length n_samples

The target variable for supervised learning problems.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

sklearn.model_selection.RepeatedKFold

class sklearn.model_selection.**RepeatedKFold**(*n_splits=5*, *n_repeats=10*, *random_state=None*)

Repeated K-Fold cross validator.

Repeats K-Fold n times with different randomization in each repetition.

Read more in the *User Guide*.

Parameters **n_splits** : int, default=5

Number of folds. Must be at least 2.

n_repeats : int, default=10

Number of times cross-validator needs to be repeated.

random_state : int, RandomState instance or None, optional, default=None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

See also:

RepeatedStratifiedKFold Repeates Stratified K-Fold n times.

Examples

```
>>> from sklearn.model_selection import RepeatedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rkf = RepeatedKFold(n_splits=2, n_repeats=2, random_state=2652124)
>>> for train_index, test_index in rkf.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...
TRAIN: [0 1] TEST: [2 3]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
```

Methods

get_n_splits([X, y, groups])	Returns the number of splitting iterations in the cross-validator

Continued on next page

Table 29.40 – continued from previous page

split(X[, y, groups])	Generates indices to split data into training and test set.

__init__ (*n_splits=5*, *n_repeats=10*, *random_state=None*)

get_n_splits (*X=None*, *y=None*, *groups=None*)

Returns the number of splitting iterations in the cross-validator

Parameters **X** : object

Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.

y : object

Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

Returns **n_splits** : int

Returns the number of splitting iterations in the cross-validator.

split (*X*, *y=None*, *groups=None*)

Generates indices to split data into training and test set.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, of length n_samples

The target variable for supervised learning problems.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

sklearn.model_selection.RepeatedStratifiedKFold

class sklearn.model_selection.**RepeatedStratifiedKFold**(*n_splits=5*, *n_repeats=10*, *random_state=None*)

Repeated Stratified K-Fold cross validator.

Repeats Stratified K-Fold n times with different randomization in each repetition.

Read more in the *User Guide*.

Parameters **n_splits** : int, default=5

Number of folds. Must be at least 2.

n_repeats : int, default=10

Number of times cross-validator needs to be repeated.

random_state : None, int or RandomState, default=None

Random state to be used to generate random state for each repetition.

See also:

RepeatedKFold Repeats K-Fold n times.

Examples

```
>>> from sklearn.model_selection import RepeatedStratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rskf = RepeatedStratifiedKFold(n_splits=2, n_repeats=2,
...     random_state=36851234)
>>> for train_index, test_index in rskf.split(X, y):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [0 2] TEST: [1 3]
```

Methods

get_n_splits([X, y, groups])	Returns the number of splitting iterations in the cross-validator
split(X[, y, groups])	Generates indices to split data into training and test set.

__init__ (*n_splits=5*, *n_repeats=10*, *random_state=None*)

get_n_splits (*X=None*, *y=None*, *groups=None*)

Returns the number of splitting iterations in the cross-validator

Parameters **X** : object

Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.

y : object

Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

Returns **n_splits** : int

Returns the number of splitting iterations in the cross-validator.

split(*X*, *y=None*, *groups=None*)

Generates indices to split data into training and test set.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, of length n_samples

The target variable for supervised learning problems.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

sklearn.model_selection.ShuffleSplit

class sklearn.model_selection.**ShuffleSplit**(*n_splits=10*, *test_size='default'*, *train_size=None*, *random_state=None*)

Random permutation cross-validator

Yields indices to split data into training and test sets.

Note: contrary to other cross-validation strategies, random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the *User Guide*.

Parameters **n_splits** : int, default 10

Number of re-shuffling & splitting iterations.

test_size : float, int, None, default=0.1

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. By default (the is parameter unspecified), the value is set to 0.1. The default will change in version 0.21. It will remain 0.1 only if `train_size` is unspecified, otherwise it will complement the specified `train_size`.

train_size : float, int, or None, default=None

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Examples

```
>>> from sklearn.model_selection import ShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 1, 2])
>>> rs = ShuffleSplit(n_splits=3, test_size=.25, random_state=0)
>>> rs.get_n_splits(X)
3
>>> print(rs)
ShuffleSplit(n_splits=3, random_state=0, test_size=0.25, train_size=None)
>>> for train_index, test_index in rs.split(X):
...    print("TRAIN:", train_index, "TEST:", test_index)
...
TRAIN: [3 1 0] TEST: [2]
TRAIN: [2 1 3] TEST: [0]
TRAIN: [0 2 1] TEST: [3]
>>> rs = ShuffleSplit(n_splits=3, train_size=0.5, test_size=.25,
...                   random_state=0)
>>> for train_index, test_index in rs.split(X):
...    print("TRAIN:", train_index, "TEST:", test_index)
...
TRAIN: [3 1] TEST: [2]
TRAIN: [2 1] TEST: [0]
TRAIN: [0 2] TEST: [3]
```

Methods

get_n_splits([X, y, groups])	Returns the number of splitting iterations in the cross-validator
split(X[, y, groups])	Generate indices to split data into training and test set.

__init__ (*n_splits=10*, *test_size='default'*, *train_size=None*, *random_state=None*)

get_n_splits (*X=None*, *y=None*, *groups=None*)

Returns the number of splitting iterations in the cross-validator

Parameters **X** : object

Always ignored, exists for compatibility.

y : object

Always ignored, exists for compatibility.

groups : object

Always ignored, exists for compatibility.

Returns **n_splits** : int

Returns the number of splitting iterations in the cross-validator.

split (*X*, *y=None*, *groups=None*)

Generate indices to split data into training and test set.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape (n_samples,)

The target variable for supervised learning problems.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

Examples using `sklearn.model_selection.ShuffleSplit`

- *Plotting Learning Curves*
- *Scaling the regularization parameter for SVCs*

`sklearn.model_selection.GroupShuffleSplit`

class `sklearn.model_selection.`**`GroupShuffleSplit`**(*n_splits=5*, *test_size='default'*, *train_size=None*, *random_state=None*)

Shuffle-Group(s)-Out cross-validation iterator

Provides randomized train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePGroupsOut and GroupShuffleSplit is that the former generates splits using all subsets of size `p` unique groups, whereas GroupShuffleSplit generates a user-determined number of random test splits, each with a user-determined fraction of unique groups.

For example, a less computationally intensive alternative to `LeavePGroupsOut(p=10)` would be `GroupShuffleSplit(test_size=10, n_splits=100)`.

Note: The parameters `test_size` and `train_size` refer to groups, and not to samples, as in ShuffleSplit.

Parameters **n_splits** : int (default 5)

Number of re-shuffling & splitting iterations.

test_size : float, int, None, optional

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. By default, the value is set to 0.2. The default will change in version 0.21. It will remain 0.2 only if `train_size` is unspecified, otherwise it will complement the specified `train_size`.

train_size : float, int, or None, default is None

If float, should be between 0.0 and 1.0 and represent the proportion of the groups to include in the train split. If int, represents the absolute number of train groups. If None, the value is automatically set to the complement of the test size.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Methods

get_n_splits([X, y, groups])	Returns the number of splitting iterations in the cross-validator
split(X[, y, groups])	Generate indices to split data into training and test set.

__init__ (*n_splits=5*, *test_size='default'*, *train_size=None*, *random_state=None*)

get_n_splits (*X=None*, *y=None*, *groups=None*)
Returns the number of splitting iterations in the cross-validator

Parameters **X** : object

Always ignored, exists for compatibility.

y : object

Always ignored, exists for compatibility.

groups : object

Always ignored, exists for compatibility.

Returns **n_splits** : int

Returns the number of splitting iterations in the cross-validator.

split (*X*, *y=None*, *groups=None*)
Generate indices to split data into training and test set.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape (n_samples,)

The target variable for supervised learning problems.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

sklearn.model_selection.StratifiedShuffleSplit

class sklearn.model_selection.**StratifiedShuffleSplit**(*n_splits=10*, *test_size='default'*, *train_size=None*, *random_state=None*)

Stratified ShuffleSplit cross-validator

Provides train/test indices to split data in train/test sets.

This cross-validation object is a merge of StratifiedKFold and ShuffleSplit, which returns stratified randomized folds. The folds are made by preserving the percentage of samples for each class.

Note: like the ShuffleSplit strategy, stratified random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the *User Guide*.

Parameters **n_splits** : int, default 10

Number of re-shuffling & splitting iterations.

test_size : float, int, None, optional

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. By default, the value is set to 0.1. The default will change in version 0.21. It will remain 0.1 only if `train_size` is unspecified, otherwise it will complement the specified `train_size`.

train_size : float, int, or None, default is None

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Examples

```
>>> from sklearn.model_selection import StratifiedShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> sss = StratifiedShuffleSplit(n_splits=3, test_size=0.5, random_state=0)
>>> sss.get_n_splits(X, y)
3
>>> print(sss)
StratifiedShuffleSplit(n_splits=3, random_state=0, ...)
>>> for train_index, test_index in sss.split(X, y):
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 2] TEST: [3 0]
TRAIN: [0 2] TEST: [1 3]
TRAIN: [0 2] TEST: [3 1]
```

Methods

get_n_splits([X, y, groups])	Returns the number of splitting iterations in the cross-validator
split(X, y[, groups])	Generate indices to split data into training and test set.

__init__ (*n_splits=10*, *test_size='default'*, *train_size=None*, *random_state=None*)

get_n_splits (*X=None*, *y=None*, *groups=None*)
Returns the number of splitting iterations in the cross-validator

Parameters **X** : object

Always ignored, exists for compatibility.

y : object

Always ignored, exists for compatibility.

groups : object

Always ignored, exists for compatibility.

Returns **n_splits** : int

Returns the number of splitting iterations in the cross-validator.

split (*X*, *y*, *groups=None*)
Generate indices to split data into training and test set.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

Note that providing `y` is sufficient to generate the splits and hence `np.zeros(n_samples)` may be used as a placeholder for `X` instead of actual training data.

y : array-like, shape (n_samples,)

The target variable for supervised learning problems. Stratification is done based on the y labels.

groups : object

Always ignored, exists for compatibility.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

Examples using `sklearn.model_selection.StratifiedShuffleSplit`

- *RBF SVM parameters*

sklearn.model_selection.PredefinedSplit

class sklearn.model_selection.**PredefinedSplit**(*test_fold*)

Predefined split cross-validator

Splits the data into training/test set folds according to a predefined scheme. Each sample can be assigned to at most one test set fold, as specified by the user through the `test_fold` parameter.

Read more in the *User Guide*.

Examples

```
>>> from sklearn.model_selection import PredefinedSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> test_fold = [0, 1, -1, 1]
>>> ps = PredefinedSplit(test_fold)
>>> ps.get_n_splits()
2
>>> print(ps)
PredefinedSplit(test_fold=array([ 0,  1, -1,  1]))
>>> for train_index, test_index in ps.split():
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 2 3] TEST: [0]
TRAIN: [0 2] TEST: [1 3]
```

Methods

get_n_splits([X, y, groups])	Returns the number of splitting iterations in the cross-validator
split([X, y, groups])	Generate indices to split data into training and test set.

__init__(*test_fold*)

get_n_splits(*X=None*, *y=None*, *groups=None*)

Returns the number of splitting iterations in the cross-validator

Parameters **X** : object

Always ignored, exists for compatibility.

y : object

Always ignored, exists for compatibility.

groups : object

Always ignored, exists for compatibility.

Returns **n_splits** : int

Returns the number of splitting iterations in the cross-validator.

split(*X=None*, *y=None*, *groups=None*)

Generate indices to split data into training and test set.

Parameters **X** : object

Always ignored, exists for compatibility.

y : object

Always ignored, exists for compatibility.

groups : object

Always ignored, exists for compatibility.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

sklearn.model_selection.TimeSeriesSplit

class sklearn.model_selection.**TimeSeriesSplit**(*n_splits=3*, *max_train_size=None*)

Time Series cross-validator

Provides train/test indices to split time series data samples that are observed at fixed time intervals, in train/test sets. In each split, test indices must be higher than before, and thus shuffling in cross validator is inappropriate.

This cross-validation object is a variation of *KFold*. In the kth split, it returns first k folds as train set and the (k+1)th fold as test set.

Note that unlike standard cross-validation methods, successive training sets are supersets of those that come before them.

Read more in the *User Guide*.

Parameters **n_splits** : int, default=3

Number of splits. Must be at least 1.

max_train_size : int, optional

Maximum size for a single training set.

Notes

The training set has size `i * n_samples // (n_splits + 1) + n_samples % (n_splits + 1)` in the `i``th split, with a test set of size ``n_samples//(n_splits + 1)`, where `n_samples` is the number of samples.

Examples

```
>>> from sklearn.model_selection import TimeSeriesSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4])
>>> tscv = TimeSeriesSplit(n_splits=3)
>>> print(tscv)
TimeSeriesSplit(max_train_size=None, n_splits=3)
>>> for train_index, test_index in tscv.split(X):
...    print("TRAIN:", train_index, "TEST:", test_index)
```

```
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [0] TEST: [1]
TRAIN: [0 1] TEST: [2]
TRAIN: [0 1 2] TEST: [3]
```

Methods

get_n_splits([X, y, groups])	Returns the number of splitting iterations in the cross-validator
split(X[, y, groups])	Generate indices to split data into training and test set.

__init__ (*n_splits=3*, *max_train_size=None*)

get_n_splits (*X=None*, *y=None*, *groups=None*)
Returns the number of splitting iterations in the cross-validator

Parameters **X** : object

Always ignored, exists for compatibility.

y : object

Always ignored, exists for compatibility.

groups : object

Always ignored, exists for compatibility.

Returns **n_splits** : int

Returns the number of splitting iterations in the cross-validator.

split (*X*, *y=None*, *groups=None*)
Generate indices to split data into training and test set.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape (n_samples,)

Always ignored, exists for compatibility.

groups : array-like, with shape (n_samples,), optional

Always ignored, exists for compatibility.

Returns **train** : ndarray

The training set indices for that split.

test : ndarray

The testing set indices for that split.

29.5.2 Splitter Functions

model_selection.train_test_split(*arrays, ...)	Split arrays or matrices into random train and test subsets
model_selection.check_cv([cv, y, classifier])	Input checker utility for building a cross-validator

sklearn.model_selection.train_test_split

sklearn.model_selection.**train_test_split**(**arrays*, ***options*)

Split arrays or matrices into random train and test subsets

Quick utility that wraps input validation and `next(ShuffleSplit().split(X, y))` and application to input data into a single call for splitting (and optionally subsampling) data in a oneliner.

Read more in the *User Guide*.

Parameters ***arrays** : sequence of indexables with same length / shape[0]

Allowed inputs are lists, numpy arrays, scipy-sparse matrices or pandas dataframes.

test_size : float, int, None, optional

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. By default, the value is set to 0.25. The default will change in version 0.21. It will remain 0.25 only if `train_size` is unspecified, otherwise it will complement the specified `train_size`.

train_size : float, int, or None, default None

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

shuffle : boolean, optional (default=True)

Whether or not to shuffle the data before splitting. If shuffle=False then stratify must be None.

stratify : array-like or None (default is None)

If not None, data is split in a stratified fashion, using this as the class labels.

Returns **splitting** : list, length=2 * len(arrays)

List containing train-test split of inputs.

New in version 0.16: If the input is sparse, the output will be a `scipy.sparse.csr_matrix`. Else, output type is the same as the input type.

Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import train_test_split
>>> X, y = np.arange(10).reshape((5, 2)), range(5)
>>> X
```

```
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7],
       [8, 9]])
>>> list(y)
[0, 1, 2, 3, 4]
```

```
>>> X_train, X_test, y_train, y_test = train_test_split(
...     X, y, test_size=0.33, random_state=42)
...
>>> X_train
array([[4, 5],
       [0, 1],
       [6, 7]])
>>> y_train
[2, 0, 3]
>>> X_test
array([[2, 3],
       [8, 9]])
>>> y_test
[1, 4]
```

```
>>> train_test_split(y, shuffle=False)
[[0, 1, 2], [3, 4]]
```

sklearn.model_selection.check_cv

sklearn.model_selection.**check_cv**(*cv=3*, *y=None*, *classifier=False*)

Input checker utility for building a cross-validator

Parameters **cv** : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if classifier is True and `y` is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

y : array-like, optional

The target variable for supervised learning problems.

classifier : boolean, optional, default False

Whether the task is a classification task, in which case stratified KFold will be used.

Returns **checked_cv** : a cross-validator instance.

The return value is a cross-validator which generates the train/test splits via the `split` method.

29.5.3 Hyper-parameter optimizers

model_selection.GridSearchCV(estimator, ...)	Exhaustive search over specified parameter values for an estimator.
model_selection.RandomizedSearchCV(...[, ...])	Randomized search on hyper parameters.
model_selection.ParameterGrid(param_grid)	Grid of parameters with a discrete number of values for each.
model_selection.ParameterSampler(...[, ...])	Generator on parameters sampled from given distributions.

sklearn.model_selection.GridSearchCV

class sklearn.model_selection.**GridSearchCV**(*estimator*, *param_grid*, *scoring=None*, *fit_params=None*, *n_jobs=1*, *iid=True*, *refit=True*, *cv=None*, *verbose=0*, *pre_dispatch='2*n_jobs'*, *error_score='raise'*, *return_train_score=True*)

Exhaustive search over specified parameter values for an estimator.

Important members are fit, predict.

GridSearchCV implements a "fit" and a "score" method. It also implements "predict", "predict_proba", "decision_function", "transform" and "inverse_transform" if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated grid-search over a parameter grid.

Read more in the *User Guide*.

Parameters **estimator** : estimator object.

This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

param_grid : dict or list of dictionaries

Dictionary with parameters names (string) as keys and lists of parameter settings to try as values, or a list of such dictionaries, in which case the grids spanned by each dictionary in the list are explored. This enables searching over any sequence of parameter settings.

scoring : string, callable or None, default=None

A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`. If `None`, the `score` method of the estimator is used.

fit_params : dict, optional

Parameters to pass to the fit method.

Deprecated since version 0.19: `fit_params` as a constructor argument was deprecated in version 0.19 and will be removed in version 0.21. Pass fit parameters to the `fit` method instead.

n_jobs : int, default=1

Number of jobs to run in parallel.

pre_dispatch : int, or string, optional

Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in '2*n_jobs'

iid : boolean, default=True

If True, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a *(Stratified)KFold*,
- An object to be used as a cross-validation generator.
- An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

refit : boolean, default=True

Refit the best estimator with the entire dataset. If "False", it is impossible to make predictions using this GridSearchCV instance after fitting.

verbose : integer

Controls the verbosity: the higher, the more messages.

error_score : 'raise' (default) or numeric

Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

return_train_score : boolean, default=True

If `'False'`, the `cv_results_` attribute will not include training scores.

Attributes **cv_results_** : dict of numpy (masked) ndarrays

A dict with keys as column headers and values as columns, that can be imported into a pandas `DataFrame`.

For instance the below given table

param_kernel	param_gamma	param_degree	split0_test_score	...	rank_...
'poly'	–	2	0.8	...	2
'poly'	–	3	0.7	...	4
'rbf'	0.1	–	0.8	...	3
'rbf'	0.2	–	0.9	...	1

will be represented by a `cv_results_` dict of:

```
{
'param_kernel': masked_array(data = ['poly', 'poly', 'rbf', 'rbf
↪'],
                             mask = [False False False False]...
↪)
'param_gamma': masked_array(data = [-- -- 0.1 0.2],
                            mask = [ True  True False False]...
↪),
'param_degree': masked_array(data = [2.0 3.0 -- --],
                             mask = [False False  True  True]...
↪),
```

```
'split0_test_score'  : [0.8, 0.7, 0.8, 0.9],
'split1_test_score'  : [0.82, 0.5, 0.7, 0.78],
'mean_test_score'    : [0.81, 0.60, 0.75, 0.82],
'std_test_score'     : [0.02, 0.01, 0.03, 0.03],
'rank_test_score'    : [2, 4, 3, 1],
'split0_train_score' : [0.8, 0.9, 0.7],
'split1_train_score' : [0.82, 0.5, 0.7],
'mean_train_score'   : [0.81, 0.7, 0.7],
'std_train_score'    : [0.03, 0.03, 0.04],
'mean_fit_time'      : [0.73, 0.63, 0.43, 0.49],
'std_fit_time'       : [0.01, 0.02, 0.01, 0.01],
'mean_score_time'    : [0.007, 0.06, 0.04, 0.04],
'std_score_time'     : [0.001, 0.002, 0.003, 0.005],
'params'             : [{'kernel': 'poly', 'degree': 2}, ...],
}
```

NOTE that the key `'params'` is used to store a list of parameter settings dict for all the parameter candidates.

The `mean_fit_time`, `std_fit_time`, `mean_score_time` and `std_score_time` are all in seconds.

best_estimator_ : estimator

Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

best_score_ : float

Score of best_estimator on the left out data.

best_params_ : dict

Parameter setting that gave the best results on the hold out data.

best_index_ : int

The index (of the `cv_results_` arrays) which corresponds to the best candidate parameter setting.

The dict at `search.cv_results_['params'][search.best_index_]` gives the parameter setting for the best model, that gives the highest mean score (`search.best_score_`).

scorer_ : function

Scorer function used on the held out data to choose the best parameters for the model.

n_splits_ : int

The number of cross-validation splits (folds/iterations).

See also:

ParameterGrid generates all the combinations of a hyperparameter grid.

sklearn.model_selection.train_test_split utility function to split the data into a development set usable for fitting a GridSearchCV instance and an evaluation set for its final evaluation.

sklearn.metrics.make_scorer Make a scorer from a performance metric or loss function.

Notes

The parameters selected are those that maximize the score of the left out data, unless an explicit score is passed in which case it is used instead.

If *n_jobs* was set to a value higher than one, the data is copied for each point in the grid (and not *n_jobs* times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set *pre_dispatch*. Then, the memory is copied only *pre_dispatch* many times. A reasonable value for *pre_dispatch* is *2 * n_jobs*.

Examples

```
>>> from sklearn import svm, datasets
>>> from sklearn.model_selection import GridSearchCV
>>> iris = datasets.load_iris()
>>> parameters = {'kernel':('linear', 'rbf'), 'C':[1, 10]}
>>> svc = svm.SVC()
>>> clf = GridSearchCV(svc, parameters)
>>> clf.fit(iris.data, iris.target)
...
GridSearchCV(cv=None, error_score=...,
       estimator=SVC(C=1.0, cache_size=..., class_weight=..., coef0=...,
                     decision_function_shape='ovr', degree=..., gamma=...,
                     kernel='rbf', max_iter=-1, probability=False,
                     random_state=None, shrinking=True, tol=...,
                     verbose=False),
       fit_params=None, iid=..., n_jobs=1,
       param_grid=..., pre_dispatch=..., refit=..., return_train_score=...,
       scoring=..., verbose=...)
>>> sorted(clf.cv_results_.keys())
...
['mean_fit_time', 'mean_score_time', 'mean_test_score',...
 'mean_train_score', 'param_C', 'param_kernel', 'params',...
 'rank_test_score', 'split0_test_score',...
 'split0_train_score', 'split1_test_score', 'split1_train_score',...
 'split2_test_score', 'split2_train_score',...
 'std_fit_time', 'std_score_time', 'std_test_score', 'std_train_score'...]
```

Methods

decision_function(X)	Call decision_function on the estimator with the best found parameters.
fit(X[, y, groups])	Run fit with all sets of parameters.
get_params([deep])	Get parameters for this estimator.
inverse_transform(Xt)	Call inverse_transform on the estimator with the best found params.
predict(X)	Call predict on the estimator with the best found parameters.
predict_log_proba(X)	Call predict_log_proba on the estimator with the best found parameters.
predict_proba(X)	Call predict_proba on the estimator with the best found parameters.

Continued on next page

Table 29.49 – continued from previous page

score(X[, y])	Returns the score on the given data, if the estimator has been refit.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Call transform on the estimator with the best found parameters.

__init__(*estimator*, *param_grid*, *scoring=None*, *fit_params=None*, *n_jobs=1*, *iid=True*, *refit=True*, *cv=None*, *verbose=0*, *pre_dispatch='2*n_jobs'*, *error_score='raise'*, *return_train_score=True*)

decision_function(*X*)

Call decision_function on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `decision_function`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

fit(*X*, *y=None*, *groups=None*, ***fit_params*)

Run fit with all sets of parameters.

Parameters **X** : array-like, shape = [n_samples, n_features]

Training vector, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples] or [n_samples, n_output], optional

Target relative to X for classification or regression; None for unsupervised learning.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

****fit_params** : dict of string -> object

Parameters passed to the `fit` method of the estimator

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform(*Xt*)

Call inverse_transform on the estimator with the best found params.

Only available if the underlying estimator implements `inverse_transform` and `refit=True`.

Parameters **Xt** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

predict(*X*)

Call predict on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

predict_log_proba(*X*)

Call predict_log_proba on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_log_proba`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

predict_proba(*X*)

Call predict_proba on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_proba`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

score(*X*, *y=None*)

Returns the score on the given data, if the estimator has been refit.

This uses the score defined by `scoring` where provided, and the `best_estimator_.score` method otherwise.

Parameters **X** : array-like, shape = [n_samples, n_features]

Input data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples] or [n_samples, n_output], optional

Target relative to X for classification or regression; None for unsupervised learning.

Returns **score** : float

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)

Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports `transform` and `refit=True`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

sklearn.model_selection.RandomizedSearchCV

class sklearn.model_selection.**RandomizedSearchCV**(*estimator*, *param_distributions*, *n_iter=10*, *scoring=None*, *fit_params=None*, *n_jobs=1*, *iid=True*, *refit=True*, *cv=None*, *verbose=0*, *pre_dispatch='2*n_jobs'*, *random_state=None*, *error_score='raise'*, *return_train_score=True*)

Randomized search on hyper parameters.

RandomizedSearchCV implements a "fit" and a "score" method. It also implements "predict", "predict_proba", "decision_function", "transform" and "inverse_transform" if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated search over parameter settings.

In contrast to GridSearchCV, not all parameter values are tried out, but rather a fixed number of parameter settings is sampled from the specified distributions. The number of parameter settings that are tried is given by n_iter.

If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Read more in the *User Guide*.

Parameters **estimator** : estimator object.

A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

param_distributions : dict

Dictionary with parameters names (string) as keys and distributions or lists of parameters to try. Distributions must provide a `rvs` method for sampling (such as those from scipy.stats.distributions). If a list is given, it is sampled uniformly.

n_iter : int, default=10

Number of parameter settings that are sampled. n_iter trades off runtime vs quality of the solution.

scoring : string, callable or None, default=None

A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`. If `None`, the `score` method of the estimator is used.

fit_params : dict, optional

Parameters to pass to the fit method.

Deprecated since version 0.19: `fit_params` as a constructor argument was deprecated in version 0.19 and will be removed in version 0.21. Pass fit parameters to the `fit` method instead.

n_jobs : int, default=1

Number of jobs to run in parallel.

pre_dispatch : int, or string, optional

Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in '2*n_jobs'

iid : boolean, default=True

If True, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a *(Stratified)KFold*,
- An object to be used as a cross-validation generator.
- An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *`StratifiedKFold`* is used. In all other cases, *`KFold`* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

refit : boolean, default=True

Refit the best estimator with the entire dataset. If "False", it is impossible to make predictions using this RandomizedSearchCV instance after fitting.

verbose : integer

Controls the verbosity: the higher, the more messages.

random_state : int, RandomState instance or None, optional, default=None

Pseudo random number generator state used for random uniform sampling from lists of possible values instead of scipy.stats distributions. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

error_score : 'raise' (default) or numeric

Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

return_train_score : boolean, default=True

If `'False'`, the `cv_results_` attribute will not include training scores.

Attributes **cv_results_** : dict of numpy (masked) ndarrays

A dict with keys as column headers and values as columns, that can be imported into a pandas `DataFrame`.

For instance the below given table

param_kernel	param_gamma	split0_test_score	...	rank_test_score
'rbf'	0.1	0.8	...	2
'rbf'	0.2	0.9	...	1
'rbf'	0.3	0.7	...	1

will be represented by a `cv_results_` dict of:

```
{
'param_kernel' : masked_array(data = ['rbf', 'rbf', 'rbf'],
                              mask = False),
'param_gamma'  : masked_array(data = [0.1 0.2 0.3], mask =␣
↪False),
'split0_test_score'  : [0.8, 0.9, 0.7],
'split1_test_score'  : [0.82, 0.5, 0.7],
'mean_test_score'    : [0.81, 0.7, 0.7],
'std_test_score'     : [0.02, 0.2, 0.],
'rank_test_score'    : [3, 1, 1],
'split0_train_score' : [0.8, 0.9, 0.7],
'split1_train_score' : [0.82, 0.5, 0.7],
'mean_train_score'   : [0.81, 0.7, 0.7],
'std_train_score'    : [0.03, 0.03, 0.04],
'mean_fit_time'      : [0.73, 0.63, 0.43, 0.49],
'std_fit_time'       : [0.01, 0.02, 0.01, 0.01],
'mean_score_time'    : [0.007, 0.06, 0.04, 0.04],
'std_score_time'     : [0.001, 0.002, 0.003, 0.005],
'params' : [{'kernel' : 'rbf', 'gamma' : 0.1}, ...],
}
```

NOTE that the key `'params'` is used to store a list of parameter settings dict for all the parameter candidates.

The `mean_fit_time`, `std_fit_time`, `mean_score_time` and `std_score_time` are all in seconds.

best_estimator_ : estimator

Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

best_score_ : float

Score of best_estimator on the left out data.

best_params_ : dict

Parameter setting that gave the best results on the hold out data.

best_index_ : int

The index (of the `cv_results_` arrays) which corresponds to the best candidate parameter setting.

The dict at `search.cv_results_['params'][search.best_index_]` gives the parameter setting for the best model, that gives the highest mean score (`search.best_score_`).

scorer_ : function

Scorer function used on the held out data to choose the best parameters for the model.

n_splits_ : int

The number of cross-validation splits (folds/iterations).

See also:

GridSearchCV Does exhaustive search over a grid of parameters.

ParameterSampler A generator over parameter settins, constructed from param_distributions.

Notes

The parameters selected are those that maximize the score of the held-out data, according to the scoring parameter.

If *n_jobs* was set to a value higher than one, the data is copied for each parameter setting(and not *n_jobs* times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set *pre_dispatch*. Then, the memory is copied only *pre_dispatch* many times. A reasonable value for *pre_dispatch* is *2 * n_jobs*.

Methods

decision_function(X)	Call decision_function on the estimator with the best found parameters.
fit(X[, y, groups])	Run fit with all sets of parameters.
get_params([deep])	Get parameters for this estimator.
inverse_transform(Xt)	Call inverse_transform on the estimator with the best found params.
predict(X)	Call predict on the estimator with the best found parameters.
predict_log_proba(X)	Call predict_log_proba on the estimator with the best found parameters.

Continued on next page

Table 29.50 – continued from previous page

predict_proba(X)	Call predict_proba on the estimator with the best found parameters.
score(X[, y])	Returns the score on the given data, if the estimator has been refit.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Call transform on the estimator with the best found parameters.

__init__ (*estimator*, *param_distributions*, *n_iter=10*, *scoring=None*, *fit_params=None*, *n_jobs=1*, *iid=True*, *refit=True*, *cv=None*, *verbose=0*, *pre_dispatch='2*n_jobs'*, *random_state=None*, *error_score='raise'*, *return_train_score=True*)

decision_function (*X*)

Call decision_function on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `decision_function`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

fit (*X*, *y=None*, *groups=None*, ***fit_params*)

Run fit with all sets of parameters.

Parameters **X** : array-like, shape = [n_samples, n_features]

Training vector, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples] or [n_samples, n_output], optional

Target relative to X for classification or regression; None for unsupervised learning.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

****fit_params** : dict of string -> object

Parameters passed to the `fit` method of the estimator

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform (*Xt*)

Call inverse_transform on the estimator with the best found params.

Only available if the underlying estimator implements `inverse_transform` and `refit=True`.

Parameters **Xt** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

predict(*X*)
Call predict on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

predict_log_proba(*X*)
Call predict_log_proba on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_log_proba`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

predict_proba(*X*)
Call predict_proba on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_proba`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

score(*X*, *y=None*)
Returns the score on the given data, if the estimator has been refit.

This uses the score defined by `scoring` where provided, and the `best_estimator_.score` method otherwise.

Parameters **X** : array-like, shape = [n_samples, n_features]

Input data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples] or [n_samples, n_output], optional

Target relative to X for classification or regression; None for unsupervised learning.

Returns **score** : float

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports `transform` and `refit=True`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

Examples using `sklearn.model_selection.RandomizedSearchCV`

- *Comparing randomized search and grid search for hyperparameter estimation*

sklearn.model_selection.ParameterGrid

class sklearn.model_selection.**ParameterGrid**(*param_grid*)

Grid of parameters with a discrete number of values for each.

Can be used to iterate over parameter value combinations with the Python built-in function iter.

Read more in the User Guide.

Parameters **param_grid** : dict of string to sequence, or sequence of such

The parameter grid to explore, as a dictionary mapping estimator parameters to sequences of allowed values.

An empty dict signifies default parameters.

A sequence of dicts signifies a sequence of grids to search, and is useful to avoid exploring parameter combinations that make no sense or have no effect. See the examples below.

See also:

GridSearchCV

Uses class:*ParameterGrid* to perform a full parallelized parameter search.

Examples

```
>>> from sklearn.model_selection import ParameterGrid
>>> param_grid = {'a': [1, 2], 'b': [True, False]}
>>> list(ParameterGrid(param_grid)) == (
...    [{'a': 1, 'b': True}, {'a': 1, 'b': False},
...     {'a': 2, 'b': True}, {'a': 2, 'b': False}])
True
```

```
>>> grid = [{'kernel': ['linear']}, {'kernel': ['rbf'], 'gamma': [1, 10]}]
>>> list(ParameterGrid(grid)) == [{'kernel': 'linear'},
...                               {'kernel': 'rbf', 'gamma': 1},
...                               {'kernel': 'rbf', 'gamma': 10}]
True
>>> ParameterGrid(grid)[1] == {'kernel': 'rbf', 'gamma': 1}
True
.. automethod:: __init__
```

sklearn.model_selection.ParameterSampler

class sklearn.model_selection.**ParameterSampler**(*param_distributions*, *n_iter*, *random_state=None*)

Generator on parameters sampled from given distributions.

Non-deterministic iterable over random candidate combinations for hyper- parameter search. If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Note that before SciPy 0.16, the `scipy.stats.distributions` do not accept a custom RNG instance and always use the singleton RNG from `numpy.random`. Hence setting `random_state` will not guarantee

a deterministic iteration whenever `scipy.stats` distributions are used to define the parameter search space. Deterministic behavior is however guaranteed from SciPy 0.16 onwards.

Read more in the User Guide.

Parameters **param_distributions** : dict

Dictionary where the keys are parameters and values are distributions from which a parameter is to be sampled. Distributions either have to provide a `rvs` function to sample from them, or can be given as a list of values, where a uniform distribution is assumed.

n_iter : integer

Number of parameter settings that are produced.

random_state : int, RandomState instance or None, optional (default=None)

Pseudo random number generator state used for random uniform sampling from lists of possible values instead of scipy.stats distributions. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **params** : dict of string to any

Yields dictionaries mapping each estimator parameter to as sampled value.

Examples

```
>>> from sklearn.model_selection import ParameterSampler
>>> from scipy.stats.distributions import expon
>>> import numpy as np
>>> np.random.seed(0)
>>> param_grid = {'a':[1, 2], 'b': expon()}
>>> param_list = list(ParameterSampler(param_grid, n_iter=4))
>>> rounded_list = [dict((k, round(v, 6)) for (k, v) in d.items())
...                 for d in param_list]
>>> rounded_list == [{'b': 0.89856, 'a': 1},
...                  {'b': 0.923223, 'a': 1},
...                  {'b': 1.878964, 'a': 2},
...                  {'b': 1.038159, 'a': 2}]
True
.. automethod:: __init__
```

model_selection.fit_grid_point(X, y, ...[, ...])	Run fit on one set of parameters.

sklearn.model_selection.fit_grid_point

sklearn.model_selection.**fit_grid_point**(*X*, *y*, *estimator*, *parameters*, *train*, *test*, *scorer*, *verbose*, *error_score='raise'*, ***fit_params*)

Run fit on one set of parameters.

Parameters **X** : array-like, sparse matrix or list

Input data.

y : array-like or None

Targets for input data.

estimator : estimator object

A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

parameters : dict

Parameters to be set on estimator for this grid point.

train : ndarray, dtype int or bool

Boolean mask or indices for training set.

test : ndarray, dtype int or bool

Boolean mask or indices for test set.

scorer : callable or None.

If provided must be a scorer callable object / function with signature `scorer(estimator, X, y)`.

verbose : int

Verbosity level.

****fit_params** : kwargs

Additional parameter passed to the fit function of the estimator.

error_score : 'raise' (default) or numeric

Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

Returns **score** : float

Score of this parameter setting on given training / test split.

parameters : dict

The parameters that have been evaluated.

n_samples_test : int

Number of test samples in this split.

29.5.4 Model validation

model_selection.cross_val_score(estimator, X)	Evaluate a score by cross-validation
model_selection.cross_val_predict(estimator, X)	Generate cross-validated estimates for each input data point
model_selection.permutation_test_score(...)	Evaluate the significance of a cross-validated score with permutations
model_selection.learning_curve(estimator, X, y)	Learning curve.

Continued on next page

Table 29.52 – continued from previous page

model_selection.validation_curve(estimator, ...)	Validation curve.

sklearn.model_selection.cross_val_score

sklearn.model_selection.**cross_val_score**(*estimator*, *X*, *y=None*, *groups=None*, *scoring=None*, *cv=None*, *n_jobs=1*, *verbose=0*, *fit_params=None*, *pre_dispatch='2*n_jobs'*)

Evaluate a score by cross-validation

Read more in the *User Guide*.

Parameters **estimator** : estimator object implementing 'fit'

The object to use to fit the data.

X : array-like

The data to fit. Can be, for example a list, or an array at least 2d.

y : array-like, optional, default: None

The target variable to try to predict in the case of supervised learning.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

scoring : string, callable or None, optional, default: None

A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a *(Stratified)KFold*,
- An object to be used as a cross-validation generator.
- An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

n_jobs : integer, optional

The number of CPUs to use to do the computation. -1 means 'all CPUs'.

verbose : integer, optional

The verbosity level.

fit_params : dict, optional

Parameters to pass to the fit method of the estimator.

pre_dispatch : int, or string, optional

Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in '2*n_jobs'

Returns **scores** : array of float, shape=(len(list(cv)),)

Array of scores of the estimator for each run of the cross validation.

See also:

sklearn.metrics.make_scorer Make a scorer from a performance metric or loss function.

Examples

```
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_score
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> print(cross_val_score(lasso, X, y))
[ 0.33150734  0.08022311  0.03531764]
```

- *Model selection with Probabilistic PCA and Factor Analysis (FA)*
- *Cross-validation on Digits Dataset Exercise*
- *Nested versus non-nested cross-validation*
- *Underfitting vs. Overfitting*
- *SVM-Anova: SVM with univariate feature selection*

`sklearn.model_selection.`cross_val_predict

`sklearn.model_selection.`**`cross_val_predict`**(*estimator*, *X*, *y=None*, *groups=None*, *cv=None*, *n_jobs=1*, *verbose=0*, *fit_params=None*, *pre_dispatch='2*n_jobs'*, *method='predict'*)

Generate cross-validated estimates for each input data point

Read more in the *User Guide*.

Parameters **estimator** : estimator object implementing 'fit' and 'predict'

The object to use to fit the data.

X : array-like

The data to fit. Can be, for example a list, or an array at least 2d.

y : array-like, optional, default: None

The target variable to try to predict in the case of supervised learning.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a *(Stratified)KFold*,
- An object to be used as a cross-validation generator.
- An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

n_jobs : integer, optional

The number of CPUs to use to do the computation. -1 means 'all CPUs'.

verbose : integer, optional

The verbosity level.

fit_params : dict, optional

Parameters to pass to the fit method of the estimator.

pre_dispatch : int, or string, optional

Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in '2*n_jobs'

method : string, optional, default: 'predict'

Invokes the passed method name of the passed estimator. For method='predict_proba', the columns correspond to the classes in sorted order.

Returns **predictions** : ndarray

This is the result of calling `method`

Examples

```
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_predict
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> y_pred = cross_val_predict(lasso, X, y)
```

Examples using `sklearn.model_selection.cross_val_predict`

- *Plotting Cross-Validated Predictions*

`sklearn.model_selection`.permutation_test_score

`sklearn.model_selection.`**`permutation_test_score`**(*estimator*, *X*, *y*, *groups=None*, *cv=None*, *n_permutations=100*, *n_jobs=1*, *random_state=0*, *verbose=0*, *scoring=None*)

Evaluate the significance of a cross-validated score with permutations

Read more in the *User Guide*.

Parameters **estimator** : estimator object implementing 'fit'

The object to use to fit the data.

X : array-like of shape at least 2D

The data to fit.

y : array-like

The target variable to try to predict in the case of supervised learning.

groups : array-like, with shape (n_samples,), optional

Labels to constrain permutation within groups, i.e. `y` values are permuted among samples with the same group identifier. When not specified, `y` values are permuted among all samples.

When a grouped cross-validator is used, the group labels are also passed on to the `split` method of the cross-validator. The cross-validator uses them for grouping the samples while splitting the dataset into train/test set.

scoring : string, callable or None, optional, default: None

A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a *(Stratified)KFold*,
- An object to be used as a cross-validation generator.
- An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

n_permutations : integer, optional

Number of times to permute `y`.

n_jobs : integer, optional

The number of CPUs to use to do the computation. -1 means 'all CPUs'.

random_state : int, RandomState instance or None, optional (default=0)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

verbose : integer, optional

The verbosity level.

Returns **score** : float

The true score without permuting targets.

permutation_scores : array, shape (n_permutations,)

The scores obtained for each permutations.

pvalue : float

The p-value, which approximates the probability that the score would be obtained by chance. This is calculated as:

(C + 1) / (n_permutations + 1)

Where C is the number of permutations whose score >= the true score.

The best possible p-value is 1/(n_permutations + 1), the worst is 1.0.

Notes

This function implements Test 1 in:

Ojala and Garriga. Permutation Tests for Studying Classifier Performance. The Journal of Machine Learning Research (2010) vol. 11

Examples using `sklearn.model_selection.permutation_test_score`

- *Test with permutations the significance of a classification score*

`sklearn.model_selection.learning_curve`

`sklearn.model_selection.`**`learning_curve`**(*estimator*, *X*, *y*, *groups=None*, *train_sizes=array([0.1, 0.33, 0.55, 0.78, 1.])*, *cv=None*, *scoring=None*, *exploit_incremental_learning=False*, *n_jobs=1*, *pre_dispatch='all'*, *verbose=0*, *shuffle=False*, *random_state=None*)

Learning curve.

Determines cross-validated training and test scores for different training set sizes.

A cross-validation generator splits the whole dataset k times in training and test data. Subsets of the training set with varying sizes will be used to train the estimator and a score for each training subset size and the test set will be computed. Afterwards, the scores will be averaged over all k runs for each training subset size.

Read more in the *User Guide*.

Parameters **estimator** : object type that implements the "fit" and "predict" methods

An object of that type which is cloned for each validation.

X : array-like, shape (n_samples, n_features)

Training vector, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape (n_samples) or (n_samples, n_features), optional

Target relative to X for classification or regression; None for unsupervised learning.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

train_sizes : array-like, shape (n_ticks,), dtype float or int

Relative or absolute numbers of training examples that will be used to generate the learning curve. If the dtype is float, it is regarded as a fraction of the maximum size of the training set (that is determined by the selected validation method), i.e. it has to be within (0, 1]. Otherwise it is interpreted as absolute sizes of the training sets. Note that for classification the number of samples usually have to be big enough to contain at least one sample from each class. (default: np.linspace(0.1, 1.0, 5))

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a *(Stratified)KFold*,
- An object to be used as a cross-validation generator.
- An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *`StratifiedKFold`* is used. In all other cases, *`KFold`* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

scoring : string, callable or None, optional, default: None

A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

exploit_incremental_learning : boolean, optional, default: False

If the estimator supports incremental learning, this will be used to speed up fitting for different training set sizes.

n_jobs : integer, optional

Number of jobs to run in parallel (default 1).

pre_dispatch : integer or string, optional

Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The string can be an expression like '2*n_jobs'.

verbose : integer, optional

Controls the verbosity: the higher, the more messages.

shuffle : boolean, optional

Whether to shuffle training data before taking prefixes of it based on''train_sizes''.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `shuffle` == 'True'.

———- :

train_sizes_abs : array, shape = (n_unique_ticks,), dtype int

Numbers of training examples that has been used to generate the learning curve. Note that the number of ticks might be less than n_ticks because duplicate entries will be removed.

train_scores : array, shape (n_ticks, n_cv_folds)

Scores on training sets.

test_scores : array, shape (n_ticks, n_cv_folds)

Scores on test set.

Notes

See *examples/model_selection/plot_learning_curve.py*

sklearn.model_selection.validation_curve

sklearn.model_selection.**validation_curve**(*estimator*, *X*, *y*, *param_name*, *param_range*, *groups=None*, *cv=None*, *scoring=None*, *n_jobs=1*, *pre_dispatch='all'*, *verbose=0*)

Validation curve.

Determine training and test scores for varying parameter values.

Compute scores for an estimator with different values of a specified parameter. This is similar to grid search with one parameter. However, this will also compute training scores and is merely a utility for plotting the results.

Read more in the *User Guide*.

Parameters **estimator** : object type that implements the "fit" and "predict" methods

An object of that type which is cloned for each validation.

X : array-like, shape (n_samples, n_features)

Training vector, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape (n_samples) or (n_samples, n_features), optional

Target relative to X for classification or regression; None for unsupervised learning.

param_name : string

Name of the parameter that will be varied.

param_range : array-like, shape (n_values,)

The values of the parameter that will be evaluated.

groups : array-like, with shape (n_samples,), optional

Group labels for the samples used while splitting the dataset into train/test set.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a *(Stratified)KFold*,
- An object to be used as a cross-validation generator.
- An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *`StratifiedKFold`* is used. In all other cases, *`KFold`* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

scoring : string, callable or None, optional, default: None

A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

n_jobs : integer, optional

Number of jobs to run in parallel (default 1).

pre_dispatch : integer or string, optional

Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The string can be an expression like '2*n_jobs'.

verbose : integer, optional

Controls the verbosity: the higher, the more messages.

Returns **train_scores** : array, shape (n_ticks, n_cv_folds)

Scores on training sets.

test_scores : array, shape (n_ticks, n_cv_folds)

Scores on test set.

Notes

See *Plotting Validation Curves*

Examples using `sklearn.model_selection.validation_curve`

- *Plotting Validation Curves*

29.6 sklearn.datasets: Datasets

The *sklearn.datasets* module includes utilities to load datasets, including methods to load and fetch popular reference datasets. It also features some artificial data generators.

User guide: See the *Dataset loading utilities* section for further details.

29.6.1 Loaders

datasets.clear_data_home([data_home])	Delete all the content of the data home cache.
datasets.get_data_home([data_home])	Return the path of the scikit-learn data dir.
datasets.fetch_20newsgroups([data_home, ...])	Load the filenames and data from the 20 newsgroups dataset.
datasets.fetch_20newsgroups_vectorized([...])	Load the 20 newsgroups dataset and transform it into tf-idf vectors.
datasets.load_boston([return_X_y])	Load and return the boston house-prices dataset (regression).
datasets.load_breast_cancer([return_X_y])	Load and return the breast cancer wisconsin dataset (classification).
datasets.load_diabetes([return_X_y])	Load and return the diabetes dataset (regression).
datasets.load_digits([n_class, return_X_y])	Load and return the digits dataset (classification).
datasets.load_files(container_path[, ...])	Load text files with categories as subfolder names.
datasets.load_iris([return_X_y])	Load and return the iris dataset (classification).
datasets.load_wine([return_X_y])	Load and return the wine dataset (classification).
datasets.fetch_lfw_pairs([subset, ...])	Loader for the Labeled Faces in the Wild (LFW) pairs dataset
datasets.fetch_lfw_people([data_home, ...])	Loader for the Labeled Faces in the Wild (LFW) people dataset
datasets.load_linnerud([return_X_y])	Load and return the linnerud dataset (multivariate regression).
datasets.mldata_filename(dataname)	Convert a raw name for a data set in a mldata.org filename.
datasets.fetch_mldata(dataname[, ...])	Fetch an mldata.org data set
datasets.fetch_olivetti_faces([data_home, ...])	Loader for the Olivetti faces data-set from AT&T.
datasets.fetch_california_housing([...])	Loader for the California housing dataset from StatLib.
datasets.fetch_covtype([data_home, ...])	Load the covertype dataset, downloading it if necessary.
datasets.fetch_kddcup99([subset, shuffle, ...])	Load and return the kddcup 99 dataset (classification).
datasets.fetch_rcv1([data_home, subset, ...])	Load the RCV1 multilabel dataset, downloading it if necessary.
datasets.load_mlcomp(*args, **kwargs)	DEPRECATED: since the http://mlcomp.org/ website will shut down in March 2017, the load_mlcomp function was deprecated in version 0.19 and will be removed in 0.21.
datasets.load_sample_image(image_name)	Load the numpy array of a single sample image
datasets.load_sample_images()	Load sample images for image manipulation.
datasets.fetch_species_distributions([...])	Loader for species distribution dataset from Phillips et.
datasets.load_svmlight_file(f[, n_features, ...])	Load datasets in the svmlight / libsvm format into sparse CSR matrix
datasets.load_svmlight_files(files[, ...])	Load dataset from multiple files in SVMlight format
datasets.dump_svmlight_file(X, y, f[, ...])	Dump the dataset in svmlight / libsvm file format.

sklearn.datasets.clear_data_home

sklearn.datasets.**clear_data_home**(*data_home=None*)
Delete all the content of the data home cache.

sklearn.datasets.get_data_home

sklearn.datasets.**get_data_home**(*data_home=None*)
Return the path of the scikit-learn data dir.

This folder is used by some large dataset loaders to avoid downloading the data several times.

By default the data dir is set to a folder named 'scikit_learn_data' in the user home folder.

Alternatively, it can be set by the 'SCIKIT_LEARN_DATA' environment variable or programmatically by giving an explicit folder path. The '~' symbol is expanded to the user home folder.

If the folder does not already exist, it is automatically created.

Examples using sklearn.datasets.get_data_home

- *Out-of-core classification of text documents*

sklearn.datasets.fetch_20newsgroups

sklearn.datasets.**fetch_20newsgroups**(*data_home=None*, *subset='train'*, *categories=None*, *shuffle=True*, *random_state=42*, *remove=()*, *download_if_missing=True*)
Load the filenames and data from the 20 newsgroups dataset.

Read more in the *User Guide*.

Parameters **subset** : 'train' or 'test', 'all', optional

Select the dataset to load: 'train' for the training set, 'test' for the test set, 'all' for both, with shuffled ordering.

data_home : optional, default: None

Specify a download and cache folder for the datasets. If None, all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

categories : None or collection of string or unicode

If None (default), load all the categories. If not None, list of category names to load (other categories ignored).

shuffle : bool, optional

Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.

random_state : numpy random number generator or seed integer

Used to shuffle the dataset.

download_if_missing : optional, True by default

If False, raise an IOError if the data is not locally available instead of trying to download the data from the source site.

remove : tuple

May contain any subset of ('headers', 'footers', 'quotes'). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.

'headers' removes newsgroup headers, 'footers' removes blocks at the ends of posts that look like signatures, and 'quotes' removes lines that appear to be quoting another post.

'headers' follows an exact standard; the other filters are not always correct.

Examples using `sklearn.datasets.fetch_20newsgroups`

- *Feature Union with Heterogeneous Data Sources*
- *Topic extraction with Non-negative Matrix Factorizationand Latent Dirichlet Allocation*
- *Biclustering documents with the Spectral Co-clustering algorithm*
- *Sample pipeline for text feature extraction and evaluation*
- *Classification of text documents using sparse features*
- *Clustering text documents using k-means*
- *FeatureHasher and DictVectorizer Comparison*

`sklearn.datasets`.fetch_20newsgroups_vectorized

`sklearn.datasets.`**`fetch_20newsgroups_vectorized`**(*subset='train'*, *remove=()*, *data_home=None*)

Load the 20 newsgroups dataset and transform it into tf-idf vectors.

This is a convenience function; the tf-idf transformation is done using the default settings for *sklearn.feature_extraction.text.Vectorizer*. For more advanced usage (stopword filtering, n-gram extraction, etc.), combine fetch_20newsgroups with a custom *Vectorizer* or *CountVectorizer*.

Read more in the *User Guide*.

Parameters **subset** : 'train' or 'test', 'all', optional

Select the dataset to load: 'train' for the training set, 'test' for the test set, 'all' for both, with shuffled ordering.

data_home : optional, default: None

Specify an download and cache folder for the datasets. If None, all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

remove : tuple

May contain any subset of ('headers', 'footers', 'quotes'). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.

'headers' removes newsgroup headers, 'footers' removes blocks at the ends of posts that look like signatures, and 'quotes' removes lines that appear to be quoting another post.

Returns **bunch** : Bunch object

bunch.data: sparse matrix, shape [n_samples, n_features] bunch.target: array, shape [n_samples] bunch.target_names: list, length [n_classes]

Examples using `sklearn.datasets.fetch_20newsgroups_vectorized`

- *The Johnson-Lindenstrauss bound for embedding with random projections*
- *Model Complexity Influence*
- *Multiclass sparse logisitic regression on newgroups20*

`sklearn.datasets.load_boston`

`sklearn.datasets.load_boston`(*return_X_y=False*)

Load and return the boston house-prices dataset (regression).

Samples total	506
Dimensionality	13
Features	real, positive
Targets	real 5. - 50.

Parameters **return_X_y** : boolean, default=False.

If True, returns `(data, target)` instead of a Bunch object. See below for more information about the *data* and *target* object.

New in version 0.18.

Returns **data** : Bunch

Dictionary-like object, the interesting attributes are: 'data', the data to learn, 'target', the regression targets, and 'DESCR', the full description of the dataset.

(data, target) : tuple if `return_X_y` is True

New in version 0.18.

Examples

```
>>> from sklearn.datasets import load_boston
>>> boston = load_boston()
>>> print(boston.data.shape)
(506, 13)
```

Examples using `sklearn.datasets.load_boston`

- *Plotting Cross-Validated Predictions*
- *Imputing missing values before building an estimator*
- *Model Complexity Influence*
- *Outlier detection on a real data set*
- *Gradient Boosting regression*
- *Feature selection using SelectFromModel and LassoCV*

sklearn.datasets.load_breast_cancer

sklearn.datasets.**load_breast_cancer**(*return_X_y=False*)

Load and return the breast cancer wisconsin dataset (classification).

The breast cancer dataset is a classic and very easy binary classification dataset.

Classes	2
Samples per class	212(M),357(B)
Samples total	569
Dimensionality	30
Features	real, positive

Parameters **return_X_y** : boolean, default=False

If True, returns `(data, target)` instead of a Bunch object. See below for more information about the *data* and *target* object.

New in version 0.18.

Returns **data** : Bunch

Dictionary-like object, the interesting attributes are: 'data', the data to learn, 'target', the classification labels, 'target_names', the meaning of the labels, 'feature_names', the meaning of the features, and 'DESCR', the full description of the dataset.

(data, target) : tuple if `return_X_y` is True

New in version 0.18.

The copy of UCI ML Breast Cancer Wisconsin (Diagnostic) dataset is :

downloaded from: :

https://goo.gl/U2Uwz2 :

Examples

Let's say you are interested in the samples 10, 50, and 85, and want to know their class name.

```
>>> from sklearn.datasets import load_breast_cancer
>>> data = load_breast_cancer()
>>> data.target[[10, 50, 85]]
array([0, 1, 0])
>>> list(data.target_names)
['malignant', 'benign']
```

sklearn.datasets.load_diabetes

sklearn.datasets.**load_diabetes**(*return_X_y=False*)

Load and return the diabetes dataset (regression).

Samples total	442
Dimensionality	10
Features	real, -.2 < x < .2
Targets	integer 25 - 346

Read more in the *User Guide*.

Parameters **return_X_y** : boolean, default=False.

If True, returns `(data, target)` instead of a Bunch object. See below for more information about the *data* and *target* object.

New in version 0.18.

Returns **data** : Bunch

Dictionary-like object, the interesting attributes are: 'data', the data to learn and 'target', the regression target for each sample.

(data, target) : tuple if `return_X_y` is True

New in version 0.18.

Examples using `sklearn.datasets.load_diabetes`

- *Cross-validation on diabetes Dataset Exercise*
- *Lasso and Elastic Net*
- *Lasso path using LARS*
- *Lasso model selection: Cross-Validation / AIC / BIC*
- *Linear Regression Example*
- *Sparsity Example: Fitting only features 1 and 2*

`sklearn.datasets`.load_digits

`sklearn.datasets.`**`load_digits`**(*n_class=10*, *return_X_y=False*)

Load and return the digits dataset (classification).

Each datapoint is a 8x8 image of a digit.

Classes	10
Samples per class	~180
Samples total	1797
Dimensionality	64
Features	integers 0-16

Read more in the *User Guide*.

Parameters **n_class** : integer, between 0 and 10, optional (default=10)

The number of classes to return.

return_X_y : boolean, default=False.

If True, returns `(data, target)` instead of a Bunch object. See below for more information about the *data* and *target* object.

New in version 0.18.

Returns **data** : Bunch

Dictionary-like object, the interesting attributes are: 'data', the data to learn, 'images', the images corresponding to each sample, 'target', the classification labels for each sample, 'target_names', the meaning of the labels, and 'DESCR', the full description of the dataset.

(data, target) : tuple if `return_X_y` is True

New in version 0.18.

This is a copy of the test set of the UCI ML hand-written digits datasets :

http://archive.ics.uci.edu/ml/datasets/Optical+Recognition+of+Handwritten+Digits :

Examples

To load the data and visualize the images:

```
>>> from sklearn.datasets import load_digits
>>> digits = load_digits()
>>> print(digits.data.shape)
(1797, 64)
>>> import matplotlib.pyplot as plt
>>> plt.gray()
>>> plt.matshow(digits.images[0])
>>> plt.show()
```

Examples using `sklearn.datasets.load_digits`

- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *Pipelining: chaining a PCA and a logistic regression*
- *The Johnson-Lindenstrauss bound for embedding with random projections*
- *Explicit feature map approximation for RBF kernels*
- *Recognizing hand-written digits*
- *Feature agglomeration*
- *Various Agglomerative Clustering on a 2D embedding of digits*
- *A demo of K-Means clustering on the handwritten digits data*
- *The Digit Dataset*
- *Cross-validation on Digits Dataset Exercise*
- *Digits Classification Exercise*
- *Recursive feature elimination*
- *L1 Penalty and Sparsity in Logistic Regression*
- *Comparing various online solvers*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*
- *Parameter estimation using grid search with cross-validation*
- *Plotting Learning Curves*
- *Comparing randomized search and grid search for hyperparameter estimation*
- *Plotting Validation Curves*
- *Kernel Density Estimation*
- *Compare Stochastic learning strategies for MLPClassifier*

- *Restricted Boltzmann Machine features for digit classification*
- *Label Propagation digits: Demonstrating performance*
- *Label Propagation digits active learning*
- *SVM-Anova: SVM with univariate feature selection*

sklearn.datasets.load_files

sklearn.datasets.**load_files**(*container_path*, *description=None*, *categories=None*, *load_content=True*, *shuffle=True*, *encoding=None*, *decode_error='strict'*, *random_state=0*)

Load text files with categories as subfolder names.

Individual samples are assumed to be files stored a two levels folder structure such as the following:

container_folder/

category_1_folder/ file_1.txt file_2.txt ... file_42.txt

category_2_folder/ file_43.txt file_44.txt ...

The folder names are used as supervised signal label names. The individual file names are not important.

This function does not try to extract features into a numpy array or scipy sparse matrix. In addition, if load_content is false it does not try to load the files in memory.

To use text files in a scikit-learn classification or clustering algorithm, you will need to use the *sklearn.feature_extraction.text* module to build a feature extraction transformer that suits your problem.

If you set load_content=True, you should also specify the encoding of the text using the 'encoding' parameter. For many modern text files, 'utf-8' will be the correct encoding. If you leave encoding equal to None, then the content will be made of bytes instead of Unicode, and you will not be able to use most functions in *sklearn.feature_extraction.text*.

Similar feature extractors should be built for other kind of unstructured data input such as images, audio, video, ...

Read more in the *User Guide*.

Parameters **container_path** : string or unicode

Path to the main folder holding one subfolder per category

description : string or unicode, optional (default=None)

A paragraph describing the characteristic of the dataset: its source, reference, etc.

categories : A collection of strings or None, optional (default=None)

If None (default), load all the categories. If not None, list of category names to load (other categories ignored).

load_content : boolean, optional (default=True)

Whether to load or not the content of the different files. If true a 'data' attribute containing the text information is present in the data structure returned. If not, a filenames attribute gives the path to the files.

encoding : string or None (default is None)

If None, do not try to decode the content of the files (e.g. for images or other non-text content). If not None, encoding to use to decode text files to Unicode if load_content is True.

decode_error : {'strict', 'ignore', 'replace'}, optional

Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given *encoding*. Passed as keyword argument 'errors' to bytes.decode.

shuffle : bool, optional (default=True)

Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.

random_state : int, RandomState instance or None, optional (default=0)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **data** : Bunch

Dictionary-like object, the interesting attributes are: either data, the raw text data to learn, or 'filenames', the files holding it, 'target', the classification labels (integer index), 'target_names', the meaning of the labels, and 'DESCR', the full description of the dataset.

sklearn.datasets.load_iris

sklearn.datasets.**load_iris**(*return_X_y=False*)

Load and return the iris dataset (classification).

The iris dataset is a classic and very easy multi-class classification dataset.

Classes	3
Samples per class	50
Samples total	150
Dimensionality	4
Features	real, positive

Read more in the *User Guide*.

Parameters **return_X_y** : boolean, default=False.

If True, returns `(data, target)` instead of a Bunch object. See below for more information about the *data* and *target* object.

New in version 0.18.

Returns **data** : Bunch

Dictionary-like object, the interesting attributes are: 'data', the data to learn, 'target', the classification labels, 'target_names', the meaning of the labels, 'feature_names', the meaning of the features, and 'DESCR', the full description of the dataset.

(data, target) : tuple if `return_X_y` is True

New in version 0.18.

Examples

Let's say you are interested in the samples 10, 25, and 50, and want to know their class name.

```
>>> from sklearn.datasets import load_iris
>>> data = load_iris()
>>> data.target[[10, 25, 50]]
array([0, 0, 1])
>>> list(data.target_names)
['setosa', 'versicolor', 'virginica']
```

Examples using `sklearn.datasets.load_iris`

- *Concatenating multiple feature extraction methods*
- *Plot classification probability*
- *K-means Clustering*
- *The Iris Dataset*
- *Incremental PCA*
- *PCA example with Iris Data-set*
- *Comparison of LDA and PCA 2D projection of Iris dataset*
- *Plot the decision surfaces of ensembles of trees on the iris dataset*
- *Plot the decision boundaries of a VotingClassifier*
- *SVM Exercise*
- *Univariate Feature Selection*
- *Test with permutations the significance of a classification score*
- *Gaussian process classification (GPC) on iris dataset*
- *Logistic Regression 3-class Classifier*
- *Path with L1- Logistic Regression*
- *Plot multi-class SGD on the iris dataset*
- *GMM covariances*
- *Confusion matrix*
- *Nested versus non-nested cross-validation*
- *Precision-Recall*
- *Receiver Operating Characteristic (ROC)*
- *Receiver Operating Characteristic (ROC) with cross validation*
- *Nearest Neighbors Classification*
- *Nearest Centroid Classification*
- *Compare Stochastic learning strategies for MLPClassifier*
- *Decision boundary of label propagation versus SVM on the Iris dataset*
- *SVM with custom kernel*
- *Plot different SVM classifiers in the iris dataset*
- *RBF SVM parameters*

- *Plot the decision surface of a decision tree on the iris dataset*
- *Understanding the decision tree structure*

sklearn.datasets.load_wine

sklearn.datasets.**load_wine**(*return_X_y=False*)

Load and return the wine dataset (classification).

New in version 0.18.

The wine dataset is a classic and very easy multi-class classification dataset.

Classes	3
Samples per class	[59,71,48]
Samples total	178
Dimensionality	13
Features	real, positive

Read more in the *User Guide*.

Parameters **return_X_y** : boolean, default=False.

If True, returns `(data, target)` instead of a Bunch object. See below for more information about the *data* and *target* object.

Returns **data** : Bunch

Dictionary-like object, the interesting attributes are: 'data', the data to learn, 'target', the classification labels, 'target_names', the meaning of the labels, 'feature_names', the meaning of the features, and 'DESCR', the full description of the dataset.

(data, target) : tuple if `return_X_y` is True

The copy of UCI ML Wine Data Set dataset is :

downloaded and modified to fit standard format from: :

https://archive.ics.uci.edu/ml/machine-learning-databases/wine/wine.data :

Examples

Let's say you are interested in the samples 10, 80, and 140, and want to know their class name.

```
>>> from sklearn.datasets import load_wine
>>> data = load_wine()
>>> data.target[[10, 80, 140]]
array([0, 1, 2])
>>> list(data.target_names)
['class_0', 'class_1', 'class_2']
```

Examples using sklearn.datasets.load_wine

- *Importance of Feature Scaling*

sklearn.datasets.fetch_lfw_pairs

sklearn.datasets.**fetch_lfw_pairs**(*subset='train'*, *data_home=None*, *funneled=True*, *resize=0.5*, *color=False*, *slice_=(slice(70, 195, None), slice(78, 172, None))*, *download_if_missing=True*)

Loader for the Labeled Faces in the Wild (LFW) pairs dataset

This dataset is a collection of JPEG pictures of famous people collected on the internet, all details are available on the official website:

http://vis-www.cs.umass.edu/lfw/

Each picture is centered on a single face. Each pixel of each channel (color in RGB) is encoded by a float in range 0.0 - 1.0.

The task is called Face Verification: given a pair of two pictures, a binary classifier must predict whether the two images are from the same person.

In the official README.txt this task is described as the "Restricted" task. As I am not sure as to implement the "Unrestricted" variant correctly, I left it as unsupported for now.

The original images are 250 x 250 pixels, but the default slice and resize arguments reduce them to 62 x 47.

Read more in the *User Guide*.

Parameters **subset** : optional, default: 'train'

Select the dataset to load: 'train' for the development training set, 'test' for the development test set, and '10_folds' for the official evaluation set that is meant to be used with a 10-folds cross validation.

data_home : optional, default: None

Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

funneled : boolean, optional, default: True

Download and use the funneled variant of the dataset.

resize : float, optional, default 0.5

Ratio used to resize the each face picture.

color : boolean, optional, default False

Keep the 3 RGB channels instead of averaging them to a single gray level channel. If color is True the shape of the data has one more dimension than the shape with color = False.

slice_ : optional

Provide a custom 2D slice (height, width) to extract the 'interesting' part of the jpeg files and avoid use statistical correlation from the background

download_if_missing : optional, True by default

If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

Returns **The data is returned as a Bunch object with the following attributes:** :

data : numpy array of shape (2200, 5828). Shape depends on `subset`.

Each row corresponds to 2 ravel'd face images of original size 62 x 47 pixels. Changing the `slice_`, `resize` or `subset` parameters will change the shape of the output.

pairs : numpy array of shape (2200, 2, 62, 47). Shape depends on `subset`.

Each row has 2 face images corresponding to same or different person from the dataset containing 5749 people. Changing the `slice_`, `resize` or `subset` parameters will change the shape of the output.

target : numpy array of shape (2200,). Shape depends on `subset`.

Labels associated to each pair of images. The two label values being different persons or the same person.

DESCR : string

Description of the Labeled Faces in the Wild (LFW) dataset.

sklearn.datasets.fetch_lfw_people

sklearn.datasets.**fetch_lfw_people**(*data_home=None*, *funneled=True*, *resize=0.5*, *min_faces_per_person=0*, *color=False*, *slice_=(slice(70, 195, None), slice(78, 172, None))*, *download_if_missing=True*)

Loader for the Labeled Faces in the Wild (LFW) people dataset

This dataset is a collection of JPEG pictures of famous people collected on the internet, all details are available on the official website:

http://vis-www.cs.umass.edu/lfw/

Each picture is centered on a single face. Each pixel of each channel (color in RGB) is encoded by a float in range 0.0 - 1.0.

The task is called Face Recognition (or Identification): given the picture of a face, find the name of the person given a training set (gallery).

The original images are 250 x 250 pixels, but the default slice and resize arguments reduce them to 62 x 47.

Parameters **data_home** : optional, default: None

Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

funneled : boolean, optional, default: True

Download and use the funneled variant of the dataset.

resize : float, optional, default 0.5

Ratio used to resize the each face picture.

min_faces_per_person : int, optional, default None

The extracted dataset will only retain pictures of people that have at least *min_faces_per_person* different pictures.

color : boolean, optional, default False

Keep the 3 RGB channels instead of averaging them to a single gray level channel. If color is True the shape of the data has one more dimension than the shape with color = False.

slice_ : optional

Provide a custom 2D slice (height, width) to extract the 'interesting' part of the jpeg files and avoid use statistical correlation from the background

download_if_missing : optional, True by default

If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

Returns **dataset** : dict-like object with the following attributes:

dataset.data : numpy array of shape (13233, 2914)

Each row corresponds to a ravelled face image of original size 62 x 47 pixels. Changing the `slice_` or resize parameters will change the shape of the output.

dataset.images : numpy array of shape (13233, 62, 47)

Each row is a face image corresponding to one of the 5749 people in the dataset. Changing the `slice_` or resize parameters will change the shape of the output.

dataset.target : numpy array of shape (13233,)

Labels associated to each face image. Those labels range from 0-5748 and correspond to the person IDs.

dataset.DESCR : string

Description of the Labeled Faces in the Wild (LFW) dataset.

Examples using `sklearn.datasets.fetch_lfw_people`

- *Faces recognition example using eigenfaces and SVMs*

`sklearn.datasets`.load_linnerud

`sklearn.datasets.`**`load_linnerud`**(*return_X_y=False*)

Load and return the linnerud dataset (multivariate regression).

Samples total	20
Dimensionality	3 (for both data and target)
Features	integer
Targets	integer

Parameters **return_X_y** : boolean, default=False.

If True, returns `(data, target)` instead of a Bunch object. See below for more information about the *data* and *target* object.

New in version 0.18.

Returns **data** : Bunch

Dictionary-like object, the interesting attributes are: 'data' and 'targets', the two multivariate datasets, with 'data' corresponding to the exercise and 'targets' corresponding to the physiological measurements, as well as 'feature_names' and 'target_names'.

(data, target) : tuple if `return_X_y` is True

New in version 0.18.

sklearn.datasets.mldata_filename

sklearn.datasets.**mldata_filename**(*dataname*)
Convert a raw name for a data set in a mldata.org filename.

sklearn.datasets.fetch_mldata

sklearn.datasets.**fetch_mldata**(*dataname*, *target_name='label'*, *data_name='data'*, *transpose_data=True*, *data_home=None*)
Fetch an mldata.org data set

If the file does not exist yet, it is downloaded from mldata.org .

mldata.org does not have an enforced convention for storing data or naming the columns in a data set. The default behavior of this function works well with the most common cases:

1. data values are stored in the column 'data', and target values in the column 'label'
2. alternatively, the first column stores target values, and the second data values
3. the data array is stored as *n_features x n_samples* , and thus needs to be transposed to match the *sklearn* standard

Keyword arguments allow to adapt these defaults to specific data sets (see parameters *target_name*, *data_name*, *transpose_data*, and the examples below).

mldata.org data sets may have multiple columns, which are stored in the Bunch object with their original name.

Parameters **dataname :** :

Name of the data set on mldata.org, e.g.: "leukemia", "Whistler Daily Snowfall", etc. The raw name is automatically converted to a mldata.org URL .

target_name : optional, default: 'label'

Name or index of the column containing the target values.

data_name : optional, default: 'data'

Name or index of the column containing the data.

transpose_data : optional, default: True

If True, transpose the downloaded data array.

data_home : optional, default: None

Specify another download and cache folder for the data sets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

Returns **data** : Bunch

Dictionary-like object, the interesting attributes are: 'data', the data to learn, 'target', the classification labels, 'DESCR', the full description of the dataset, and 'COL_NAMES', the original names of the dataset columns.

Examples

Load the 'iris' dataset from mldata.org:

```
>>> from sklearn.datasets.mldata import fetch_mldata
>>> import tempfile
>>> test_data_home = tempfile.mkdtemp()
```

```
>>> iris = fetch_mldata('iris', data_home=test_data_home)
>>> iris.target.shape
(150,)
>>> iris.data.shape
(150, 4)
```

Load the 'leukemia' dataset from mldata.org, which needs to be transposed to respects the scikit-learn axes convention:

```
>>> leuk = fetch_mldata('leukemia', transpose_data=True,
...                     data_home=test_data_home)
>>> leuk.data.shape
(72, 7129)
```

Load an alternative 'iris' dataset, which has different names for the columns:

```
>>> iris2 = fetch_mldata('datasets-UCI iris', target_name=1,
...                      data_name=0, data_home=test_data_home)
>>> iris3 = fetch_mldata('datasets-UCI iris',
...                      target_name='class', data_name='double0',
...                      data_home=test_data_home)
```

```
>>> import shutil
>>> shutil.rmtree(test_data_home)
```

Examples using `sklearn.datasets.fetch_mldata`

- *Gaussian process regression (GPR) on Mauna Loa CO2 data.*
- *MNIST classfification using multinomial logistic + L1*
- *Visualization of MLP weights on MNIST*

`sklearn.datasets`.fetch_olivetti_faces

sklearn.datasets.**fetch_olivetti_faces**(*data_home=None*, *shuffle=False*, *random_state=0*, *download_if_missing=True*)

Loader for the Olivetti faces data-set from AT&T.

Read more in the *User Guide*.

Parameters **data_home** : optional, default: None

Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

shuffle : boolean, optional

If True the order of the dataset is shuffled to avoid having images of the same person grouped.

download_if_missing : optional, True by default

If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

random_state : int, RandomState instance or None, optional (default=0)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **An object with the following attributes:** :

data : numpy array of shape (400, 4096)

Each row corresponds to a ravelled face image of original size 64 x 64 pixels.

images : numpy array of shape (400, 64, 64)

Each row is a face image corresponding to one of the 40 subjects of the dataset.

target : numpy array of shape (400,)

Labels associated to each face image. Those labels are ranging from 0-39 and correspond to the Subject IDs.

DESCR : string

Description of the modified Olivetti Faces Dataset.

Notes

This dataset consists of 10 pictures each of 40 individuals. The original database was available from (now defunct)

http://www.cl.cam.ac.uk/research/dtg/attarchive/facedatabase.html

The version retrieved here comes in MATLAB format from the personal web page of Sam Roweis:

http://www.cs.nyu.edu/~roweis/

Examples using `sklearn.datasets.fetch_olivetti_faces`

- *Face completion with a multi-output estimators*
- *Online learning of a dictionary of parts of faces*
- *Faces dataset decompositions*
- *Pixel importances with a parallel forest of trees*

`sklearn.datasets`.fetch_california_housing

`sklearn.datasets.`**`fetch_california_housing`**(*data_home=None*, *download_if_missing=True*)

Loader for the California housing dataset from StatLib.

Read more in the *User Guide*.

Parameters **data_home** : optional, default: None

Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

download_if_missing : optional, True by default

If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

Returns **dataset** : dict-like object with the following attributes:

dataset.data : ndarray, shape [20640, 8]

Each row corresponding to the 8 feature values in order.

dataset.target : numpy array of shape (20640,)

Each value corresponds to the average house value in units of 100,000.

dataset.feature_names : array of length 8

Array of ordered feature names used in the dataset.

dataset.DESCR : string

Description of the California housing dataset.

Notes

This dataset consists of 20,640 samples and 9 features.

Examples using `sklearn.datasets.fetch_california_housing`

- *Partial Dependence Plots*
- *Compare the effect of different scalers on data with outliers*

`sklearn.datasets`.fetch_covtype

`sklearn.datasets.`**`fetch_covtype`**(*data_home=None*, *download_if_missing=True*, *random_state=None*, *shuffle=False*)

Load the covertype dataset, downloading it if necessary.

Read more in the *User Guide*.

Parameters **data_home** : string, optional

Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

download_if_missing : boolean, default=True

If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

random_state : int, RandomState instance or None, optional (default=None)

Random state for shuffling the dataset. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

shuffle : bool, default=False

Whether to shuffle dataset.

Returns **dataset** : dict-like object with the following attributes:

dataset.data : numpy array of shape (581012, 54)

Each row corresponds to the 54 features in the dataset.

dataset.target : numpy array of shape (581012,)

Each value corresponds to one of the 7 forest covertypes with values ranging between 1 to 7.

dataset.DESCR : string

Description of the forest covertype dataset.

sklearn.datasets.fetch_kddcup99

sklearn.datasets.**fetch_kddcup99**(*subset=None*, *shuffle=False*, *random_state=None*, *percent10=True*, *download_if_missing=True*)

Load and return the kddcup 99 dataset (classification).

The KDD Cup '99 dataset was created by processing the tcpdump portions of the 1998 DARPA Intrusion Detection System (IDS) Evaluation dataset, created by MIT Lincoln Lab [1]. The artificial data was generated using a closed network and hand-injected attacks to produce a large number of different types of attack with normal activity in the background. As the initial goal was to produce a large training set for supervised learning algorithms, there is a large proportion (80.1%) of abnormal data which is unrealistic in real world, and inappropriate for unsupervised anomaly detection which aims at detecting 'abnormal' data, ie

1. qualitatively different from normal data.
2. in large minority among the observations.

We thus transform the KDD Data set into two different data sets: SA and SF.

- SA is obtained by simply selecting all the normal data, and a small proportion of abnormal data to gives an anomaly proportion of 1%.
- SF is obtained as in [2] by simply picking up the data whose attribute logged_in is positive, thus focusing on the intrusion attack, which gives a proportion of 0.3% of attack.
- http and smtp are two subsets of SF corresponding with third feature equal to 'http' (resp. to 'smtp')

General KDD structure :

Samples total	4898431
Dimensionality	41
Features	discrete (int) or continuous (float)
Targets	str, 'normal.' or name of the anomaly type

SA structure :

Samples total	976158
Dimensionality	41
Features	discrete (int) or continuous (float)
Targets	str, 'normal.' or name of the anomaly type

SF structure :

Samples total	699691
Dimensionality	4
Features	discrete (int) or continuous (float)
Targets	str, 'normal.' or name of the anomaly type

http structure :

Samples total	619052
Dimensionality	3
Features	discrete (int) or continuous (float)
Targets	str, 'normal.' or name of the anomaly type

smtp structure :

Samples total	95373
Dimensionality	3
Features	discrete (int) or continuous (float)
Targets	str, 'normal.' or name of the anomaly type

New in version 0.18.

Parameters **subset** : None, 'SA', 'SF', 'http', 'smtp'

To return the corresponding classical subsets of kddcup 99. If None, return the entire kddcup 99 dataset.

random_state : int, RandomState instance or None, optional (default=None)

Random state for shuffling the dataset. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

shuffle : bool, default=False

Whether to shuffle dataset.

percent10 : bool, default=True

Whether to load only 10 percent of the data.

download_if_missing : bool, default=True

If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

Returns **data** : Bunch

Dictionary-like object, the interesting attributes are: 'data', the data to learn and 'target', the regression target for each sample.

References

[R138], *[R139]*

sklearn.datasets.fetch_rcv1

sklearn.datasets.**fetch_rcv1**(*data_home=None*, *subset='all'*, *download_if_missing=True*, *random_state=None*, *shuffle=False*)

Load the RCV1 multilabel dataset, downloading it if necessary.

Version: RCV1-v2, vectors, full sets, topics multilabels.

Classes	103
Samples total	804414
Dimensionality	47236
Features	real, between 0 and 1

Read more in the *User Guide*.

New in version 0.17.

Parameters **data_home** : string, optional

Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

subset : string, 'train', 'test', or 'all', default='all'

Select the dataset to load: 'train' for the training set (23149 samples), 'test' for the test set (781265 samples), 'all' for both, with the training samples first if shuffle is False. This follows the official LYRL2004 chronological split.

download_if_missing : boolean, default=True

If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

random_state : int, RandomState instance or None, optional (default=None)

Random state for shuffling the dataset. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

shuffle : bool, default=False

Whether to shuffle dataset.

Returns **dataset** : dict-like object with the following attributes:

dataset.data : scipy csr array, dtype np.float64, shape (804414, 47236)

The array has 0.16% of non zero values.

dataset.target : scipy csr array, dtype np.uint8, shape (804414, 103)

Each sample has a value of 1 in its categories, and 0 in others. The array has 3.15% of non zero values.

dataset.sample_id : numpy array, dtype np.uint32, shape (804414,)

Identification number of each sample, as ordered in dataset.data.

dataset.target_names : numpy array, dtype object, length (103)

Names of each target (RCV1 topics), as ordered in dataset.target.

dataset.DESCR : string

Description of the RCV1 dataset.

References

Lewis, D. D., Yang, Y., Rose, T. G., & Li, F. (2004). RCV1: A new benchmark collection for text categorization research. The Journal of Machine Learning Research, 5, 361-397.

sklearn.datasets.load_mlcomp

sklearn.datasets.**load_mlcomp**(**args*, ***kwargs*)

DEPRECATED: since the http://mlcomp.org/ website will shut down in March 2017, the load_mlcomp function was deprecated in version 0.19 and will be removed in 0.21.

Load a datasets as downloaded from http://mlcomp.org

Parameters **name_or_id** : the integer id or the string name metadata of the MLComp

dataset to load

set_ : select the portion to load: 'train', 'test' or 'raw'

mlcomp_root [the filesystem path to the root folder where MLComp datasets] are stored, if mlcomp_root is None, the MLCOMP_DATASETS_HOME environment variable is looked up instead.

**kwargs : domain specific kwargs to be passed to the dataset loader.

Read more in the *User Guide*.

Returns **data** : Bunch

Dictionary-like object, the interesting attributes are: 'filenames', the files holding the raw to learn, 'target', the classification labels (integer index), 'target_names', the meaning of the labels, and 'DESCR', the full description of the dataset.

Note on the lookup process: depending on the type of name_or_id, will choose between integer id lookup or metadata name lookup by looking at the unzipped archives and metadata file.

TODO: implement zip dataset loading too

sklearn.datasets.load_sample_image

sklearn.datasets.**load_sample_image**(*image_name*)

Load the numpy array of a single sample image

Parameters **image_name** : {*china.jpg*, *flower.jpg*}

The name of the sample image loaded

Returns **img** : 3D array

The image as a numpy array: height x width x color

Examples

```
>>> from sklearn.datasets import load_sample_image
>>> china = load_sample_image('china.jpg')
>>> china.dtype
dtype('uint8')
>>> china.shape
(427, 640, 3)
>>> flower = load_sample_image('flower.jpg')
>>> flower.dtype
dtype('uint8')
>>> flower.shape
(427, 640, 3)
```

Examples using `sklearn.datasets.load_sample_image`

- *Color Quantization using K-Means*

`sklearn.datasets.load_sample_images`

`sklearn.datasets.load_sample_images()`
Load sample images for image manipulation. Loads both, `china` and `flower`.

Returns **data** : Bunch

Dictionary-like object with the following attributes : 'images', the two sample images, 'filenames', the file names for the images, and 'DESCR' the full description of the dataset.

Examples

To load the data and visualize the images:

```
>>> from sklearn.datasets import load_sample_images
>>> dataset = load_sample_images()
>>> len(dataset.images)
2
>>> first_img_data = dataset.images[0]
>>> first_img_data.shape
(427, 640, 3)
>>> first_img_data.dtype
dtype('uint8')
```

`sklearn.datasets.fetch_species_distributions`

`sklearn.datasets.fetch_species_distributions(data_home=None, download_if_missing=True)`
Loader for species distribution dataset from Phillips et. al. (2006)

Read more in the *User Guide*.

Parameters **data_home** : optional, default: None

Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

download_if_missing : optional, True by default

If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

Returns **The data is returned as a Bunch object with the following attributes:** :

coverages : array, shape = [14, 1592, 1212]

These represent the 14 features measured at each point of the map grid. The latitude/longitude values for the grid are discussed below. Missing data is represented by the value -9999.

train : record array, shape = (1623,)

The training points for the data. Each point has three fields:

- train['species'] is the species name
- train['dd long'] is the longitude, in degrees
- train['dd lat'] is the latitude, in degrees

test : record array, shape = (619,)

The test points for the data. Same format as the training data.

Nx, Ny : integers

The number of longitudes (x) and latitudes (y) in the grid

x_left_lower_corner, y_left_lower_corner : floats

The (x,y) position of the lower-left corner, in degrees

grid_size : float

The spacing between points of the grid, in degrees

Notes

- For an example of using this dataset with scikit-learn, see *examples/applications/plot_species_distribution_modeling.py*.

- *Kernel Density Estimate of Species Distributions*

`sklearn.datasets`.load_svmlight_file

`sklearn.datasets.`**`load_svmlight_file`**(*f*, *n_features=None*, *dtype=<class 'numpy.float64'>*, *multilabel=False*, *zero_based='auto'*, *query_id=False*, *offset=0*, *length=-1*)

Load datasets in the svmlight / libsvm format into sparse CSR matrix

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

This format is used as the default format for both svmlight and the libsvm command line programs.

Parsing a text based source can be expensive. When working on repeatedly on the same dataset, it is recommended to wrap this loader with joblib.Memory.cache to store a memmapped backup of the CSR results of the first call and benefit from the near instantaneous loading of memmapped structures for the subsequent calls.

In case the file contains a pairwise preference constraint (known as "qid" in the svmlight format) these are ignored unless the query_id parameter is set to True. These pairwise preference constraints can be used to

constraint the combination of samples when using pairwise loss functions (as is the case in some learning to rank problems) so that only pairs with the same query_id value are considered.

This implementation is written in Cython and is reasonably fast. However, a faster API-compatible loader is also available at:

https://github.com/mblondel/svmlight-loader

Parameters **f** : {str, file-like, int}

(Path to) a file to load. If a path ends in ".gz" or ".bz2", it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. A file-like or file descriptor will not be closed by this function. A file-like object must be opened in binary mode.

n_features : int or None

The number of features to use. If None, it will be inferred. This argument is useful to load several files that are subsets of a bigger sliced dataset: each subset might not have examples of every feature, hence the inferred shape might vary from one slice to another. n_features is only required if `offset` or `length` are passed a non-default value.

multilabel : boolean, optional, default False

Samples may have several labels each (see http://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

zero_based : boolean or "auto", optional, default "auto"

Whether column indices in f are zero-based (True) or one-based (False). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to "auto", a heuristic check is applied to determine this from the file contents. Both kinds of files occur "in the wild", but they are unfortunately not self-identifying. Using "auto" or True should always be safe when no `offset` or `length` is passed. If `offset` or `length` are passed, the "auto" mode falls back to `zero_based=True` to avoid having the heuristic check yield inconsistent results on different segments of the file.

query_id : boolean, default False

If True, will return the query_id array for each file.

dtype : numpy data type, default np.float64

Data type of dataset to be loaded. This will be the data type of the output numpy arrays `X` and `y`.

offset : integer, optional, default 0

Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

length : integer, optional, default -1

If strictly positive, stop reading any new line of data once the position in the file has reached the (offset + length) bytes threshold.

Returns **X** : scipy.sparse matrix of shape (n_samples, n_features)

y : ndarray of shape (n_samples,), or, in the multilabel a list of

tuples of length n_samples.

query_id : array of shape (n_samples,)

query_id for each sample. Only returned when query_id is set to True.

See also:

load_svmlight_files similar function for loading multiple files in this

format, enforcing

Examples

To use joblib.Memory to cache the svmlight file:

```
from sklearn.externals.joblib import Memory
from sklearn.datasets import load_svmlight_file
mem = Memory("./mycache")

@mem.cache
def get_data():
    data = load_svmlight_file("mysvmlightfile")
    return data[0], data[1]

X, y = get_data()
```

sklearn.datasets.load_svmlight_files

sklearn.datasets.**load_svmlight_files**(*files*, *n_features=None*, *dtype=<class 'numpy.float64'>*, *multilabel=False*, *zero_based='auto'*, *query_id=False*, *offset=0*, *length=-1*)

Load dataset from multiple files in SVMlight format

This function is equivalent to mapping load_svmlight_file over a list of files, except that the results are concatenated into a single, flat list and the samples vectors are constrained to all have the same number of features.

In case the file contains a pairwise preference constraint (known as "qid" in the svmlight format) these are ignored unless the query_id parameter is set to True. These pairwise preference constraints can be used to constraint the combination of samples when using pairwise loss functions (as is the case in some learning to rank problems) so that only pairs with the same query_id value are considered.

Parameters **files** : iterable over {str, file-like, int}

(Paths of) files to load. If a path ends in ".gz" or ".bz2", it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. File-likes and file descriptors will not be closed by this function. File-like objects must be opened in binary mode.

n_features : int or None

The number of features to use. If None, it will be inferred from the maximum column index occurring in any of the files.

This can be set to a higher value than the actual number of features in any of the input files, but setting it to a lower value will cause an exception to be raised.

multilabel : boolean, optional

Samples may have several labels each (see http://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

zero_based : boolean or "auto", optional

Whether column indices in f are zero-based (True) or one-based (False). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to "auto", a heuristic check is applied to determine this from the file contents. Both kinds of files occur "in the wild", but they are unfortunately not self-identifying. Using "auto" or True should always be safe when no offset or length is passed. If offset or length are passed, the "auto" mode falls back to zero_based=True to avoid having the heuristic check yield inconsistent results on different segments of the file.

query_id : boolean, defaults to False

If True, will return the query_id array for each file.

dtype : numpy data type, default np.float64

Data type of dataset to be loaded. This will be the data type of the output numpy arrays `X` and `y`.

offset : integer, optional, default 0

Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

length : integer, optional, default -1

If strictly positive, stop reading any new line of data once the position in the file has reached the (offset + length) bytes threshold.

Returns [X1, y1, ..., Xn, yn] :

where each (Xi, yi) pair is the result from load_svmlight_file(files[i]). :

If query_id is set to True, this will return instead [X1, y1, q1, :

..., Xn, yn, qn] where (Xi, yi, qi) is the result from :

load_svmlight_file(files[i]) :

See also:

load_svmlight_file

Notes

When fitting a model to a matrix X_train and evaluating it against a matrix X_test, it is essential that X_train and X_test have the same number of features (X_train.shape[1] == X_test.shape[1]). This may not be the case if you load the files individually with load_svmlight_file.

sklearn.datasets.dump_svmlight_file

sklearn.datasets.**dump_svmlight_file**(*X*, *y*, *f*, *zero_based=True*, *comment=None*, *query_id=None*, *multilabel=False*)

Dump the dataset in svmlight / libsvm file format.

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training vectors, where n_samples is the number of samples and n_features is the number of features.

y : {array-like, sparse matrix}, shape = [n_samples (, n_labels)]

Target values. Class labels must be an integer or float, or array-like objects of integer or float for multilabel classifications.

f : string or file-like in binary mode

If string, specifies the path that will contain the data. If file-like, data will be written to f. f should be opened in binary mode.

zero_based : boolean, optional

Whether column indices should be written zero-based (True) or one-based (False).

comment : string, optional

Comment to insert at the top of the file. This should be either a Unicode string, which will be encoded as UTF-8, or an ASCII byte string. If a comment is given, then it will be preceded by one that identifies the file as having been dumped by scikit-learn. Note that not all tools grok comments in SVMlight files.

query_id : array-like, shape = [n_samples]

Array containing pairwise preference constraints (qid in svmlight format).

multilabel : boolean, optional

Samples may have several labels each (see http://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

New in version 0.17: parameter *multilabel* to support multilabel datasets.

Examples using `sklearn.datasets.dump_svmlight_file`

- *Libsvm GUI*

29.6.2 Samples generator

`datasets.make_blobs`([n_samples, n_features, ...])	Generate isotropic Gaussian blobs for clustering.
`datasets.make_classification`([n_samples, ...])	Generate a random n-class classification problem.
`datasets.make_circles`([n_samples, shuffle, ...])	Make a large circle containing a smaller circle in 2d.
`datasets.make_friedman1`([n_samples, ...])	Generate the "Friedman #1" regression problem
`datasets.make_friedman2`([n_samples, noise, ...])	Generate the "Friedman #2" regression problem
`datasets.make_friedman3`([n_samples, noise, ...])	Generate the "Friedman #3" regression problem
`datasets.make_gaussian_quantiles`([mean, ...])	Generate isotropic Gaussian and label samples by quantile
`datasets.make_hastie_10_2`([n_samples, ...])	Generates data for binary classification used in Hastie et al.
`datasets.make_low_rank_matrix`([n_samples, ...])	Generate a mostly low rank matrix with bell-shaped singular values

Continued on next page

Table 29.54 – continued from previous page

datasets.make_moons([n_samples, shuffle, ...])	Make two interleaving half circles
datasets.make_multilabel_classification([...])	Generate a random multilabel classification problem.
datasets.make_regression([n_samples, ...])	Generate a random regression problem.
datasets.make_s_curve([n_samples, noise, ...])	Generate an S curve dataset.
datasets.make_sparse_coded_signal(n_samples, ...)	Generate a signal as a sparse combination of dictionary elements.
datasets.make_sparse_spd_matrix([dim, ...])	Generate a sparse symmetric definite positive matrix.
datasets.make_sparse_uncorrelated([...])	Generate a random regression problem with sparse uncorrelated design
datasets.make_spd_matrix(n_dim[, random_state])	Generate a random symmetric, positive-definite matrix.
datasets.make_swiss_roll([n_samples, noise, ...])	Generate a swiss roll dataset.
datasets.make_biclusters(shape, n_clusters)	Generate an array with constant block diagonal structure for biclustering.
datasets.make_checkerboard(shape, n_clusters)	Generate an array with block checkerboard structure for biclustering.

sklearn.datasets.make_blobs

sklearn.datasets.**make_blobs**(*n_samples=100*, *n_features=2*, *centers=3*, *cluster_std=1.0*, *center_box=(-10.0, 10.0)*, *shuffle=True*, *random_state=None*)

Generate isotropic Gaussian blobs for clustering.

Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=100)

The total number of points equally divided among clusters.

n_features : int, optional (default=2)

The number of features for each sample.

centers : int or array of shape [n_centers, n_features], optional

(default=3) The number of centers to generate, or the fixed center locations.

cluster_std : float or sequence of floats, optional (default=1.0)

The standard deviation of the clusters.

center_box : pair of floats (min, max), optional (default=(-10.0, 10.0))

The bounding box for each cluster center when centers are generated at random.

shuffle : boolean, optional (default=True)

Shuffle the samples.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_samples, n_features]

The generated samples.

y : array of shape [n_samples]

The integer labels for cluster membership of each sample.

`sklearn.datasets`.make_classification

`sklearn.datasets.`**`make_classification`**(*n_samples=100*, *n_features=20*, *n_informative=2*, *n_redundant=2*, *n_repeated=0*, *n_classes=2*, *n_clusters_per_class=2*, *weights=None*, *flip_y=0.01*, *class_sep=1.0*, *hypercube=True*, *shift=0.0*, *scale=1.0*, *shuffle=True*, *random_state=None*)

Generate a random n-class classification problem.

This initially creates clusters of points normally distributed (std=1) about vertices of a *2 * class_sep*-sided hypercube, and assigns an equal number of clusters to each class. It introduces interdependence between these features and adds various types of further noise to the data.

Prior to shuffling, *X* stacks a number of these primary "informative" features, "redundant" linear combinations of these, "repeated" duplicates of sampled features, and arbitrary noise for and remaining features.

Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=100)

The number of samples.

n_features : int, optional (default=20)

The total number of features. These comprise *n_informative* informative features, *n_redundant* redundant features, *n_repeated* duplicated features and *n_features-n_informative-n_redundant- n_repeated* useless features drawn at random.

n_informative : int, optional (default=2)

The number of informative features. Each class is composed of a number of gaussian clusters each located around the vertices of a hypercube in a subspace of dimension *n_informative*. For each cluster, informative features are drawn independently from N(0, 1) and then randomly linearly combined within each cluster in order to add covariance. The clusters are then placed on the vertices of the hypercube.

n_redundant : int, optional (default=2)

The number of redundant features. These features are generated as random linear combinations of the informative features.

n_repeated : int, optional (default=0)

The number of duplicated features, drawn randomly from the informative and the redundant features.

n_classes : int, optional (default=2)

The number of classes (or labels) of the classification problem.

n_clusters_per_class : int, optional (default=2)

The number of clusters per class.

weights : list of floats or None (default=None)

The proportions of samples assigned to each class. If None, then classes are balanced. Note that if *len(weights) == n_classes - 1*, then the last class weight is automatically inferred. More than *n_samples* samples may be returned if the sum of *weights* exceeds 1.

flip_y : float, optional (default=0.01)

The fraction of samples whose class are randomly exchanged.

class_sep : float, optional (default=1.0)

The factor multiplying the hypercube dimension.

hypercube : boolean, optional (default=True)

If True, the clusters are put on the vertices of a hypercube. If False, the clusters are put on the vertices of a random polytope.

shift : float, array of shape [n_features] or None, optional (default=0.0)

Shift features by the specified value. If None, then features are shifted by a random value drawn in [-class_sep, class_sep].

scale : float, array of shape [n_features] or None, optional (default=1.0)

Multiply features by the specified value. If None, then features are scaled by a random value drawn in [1, 100]. Note that scaling happens after shifting.

shuffle : boolean, optional (default=True)

Shuffle the samples and the features.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_samples, n_features]

The generated samples.

y : array of shape [n_samples]

The integer labels for class membership of each sample.

sklearn.datasets.make_circles

sklearn.datasets.**make_circles**(*n_samples=100*, *shuffle=True*, *noise=None*, *random_state=None*, *factor=0.8*)

Make a large circle containing a smaller circle in 2d.

A simple toy dataset to visualize clustering and classification algorithms.

Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=100)

The total number of points generated.

shuffle : bool, optional (default=True)

Whether to shuffle the samples.

noise : double or None (default=None)

Standard deviation of Gaussian noise added to the data.

factor : double < 1 (default=.8)

Scale factor between inner and outer circle.

Returns **X** : array of shape [n_samples, 2]

The generated samples.

y : array of shape [n_samples]

The integer labels (0 or 1) for class membership of each sample.

sklearn.datasets.make_friedman1

sklearn.datasets.**make_friedman1**(*n_samples=100*, *n_features=10*, *noise=0.0*, *random_state=None*)

Generate the "Friedman #1" regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs *X* are independent features uniformly distributed on the interval [0, 1]. The output *y* is created according to the formula:

```
y(X) = 10 * sin(pi * X[:, 0] * X[:, 1]) + 20 * (X[:, 2] - 0.5) ** 2 + 10 * X[:,␣
↪3] + 5 * X[:, 4] + noise * N(0, 1).
```

Out of the *n_features* features, only 5 are actually used to compute *y*. The remaining features are independent of *y*.

The number of features has to be >= 5.

Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=100)

The number of samples.

n_features : int, optional (default=10)

The number of features. Should be at least 5.

noise : float, optional (default=0.0)

The standard deviation of the gaussian noise applied to the output.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_samples, n_features]

The input samples.

y : array of shape [n_samples]

The output values.

References

[R143], *[R144]*

sklearn.datasets.make_friedman2

sklearn.datasets.**make_friedman2**(*n_samples=100*, *noise=0.0*, *random_state=None*)

Generate the "Friedman #2" regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs *X* are 4 independent features uniformly distributed on the intervals:

```
0 <= X[:, 0] <= 100,
40 * pi <= X[:, 1] <= 560 * pi,
0 <= X[:, 2] <= 1,
1 <= X[:, 3] <= 11.
```

The output *y* is created according to the formula:

```
y(X) = (X[:, 0] ** 2 + (X[:, 1] * X[:, 2]  - 1 / (X[:, 1] * X[:, 3])) ** 2) ** 0.
↪5 + noise * N(0, 1).
```

Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=100)

The number of samples.

noise : float, optional (default=0.0)

The standard deviation of the gaussian noise applied to the output.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_samples, 4]

The input samples.

y : array of shape [n_samples]

The output values.

References

[R145], *[R146]*

sklearn.datasets.make_friedman3

sklearn.datasets.**make_friedman3**(*n_samples=100*, *noise=0.0*, *random_state=None*)

Generate the "Friedman #3" regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs *X* are 4 independent features uniformly distributed on the intervals:

```
0 <= X[:, 0] <= 100,
40 * pi <= X[:, 1] <= 560 * pi,
0 <= X[:, 2] <= 1,
1 <= X[:, 3] <= 11.
```

The output *y* is created according to the formula:

```
y(X) = arctan((X[:, 1] * X[:, 2] - 1 / (X[:, 1] * X[:, 3])) / X[:, 0]) + noise *␣
↪N(0, 1).
```

Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=100)

The number of samples.

noise : float, optional (default=0.0)

The standard deviation of the gaussian noise applied to the output.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_samples, 4]

The input samples.

y : array of shape [n_samples]

The output values.

sklearn.datasets.make_gaussian_quantiles

sklearn.datasets.**make_gaussian_quantiles**(*mean=None*, *cov=1.0*, *n_samples=100*, *n_features=2*, *n_classes=3*, *shuffle=True*, *random_state=None*)

Generate isotropic Gaussian and label samples by quantile

This classification dataset is constructed by taking a multi-dimensional standard normal distribution and defining classes separated by nested concentric multi-dimensional spheres such that roughly equal numbers of samples are in each class (quantiles of the χ^2 distribution).

Read more in the *User Guide*.

Parameters **mean** : array of shape [n_features], optional (default=None)

The mean of the multi-dimensional normal distribution. If None then use the origin (0, 0, ...).

cov : float, optional (default=1.)

The covariance matrix will be this value times the unit matrix. This dataset only produces symmetric normal distributions.

n_samples : int, optional (default=100)

The total number of points equally divided among classes.

n_features : int, optional (default=2)

The number of features for each sample.

n_classes : int, optional (default=3)

The number of classes

shuffle : boolean, optional (default=True)

Shuffle the samples.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_samples, n_features]

The generated samples.

y : array of shape [n_samples]

The integer labels for quantile membership of each sample.

Notes

The dataset is from Zhu et al [1].

`sklearn.datasets`.make_hastie_10_2

`sklearn.datasets.`**`make_hastie_10_2`**(*n_samples=12000*, *random_state=None*)

Generates data for binary classification used in Hastie et al. 2009, Example 10.2.

The ten features are standard independent Gaussian and the target `y` is defined by:

```
y[i] = 1 if np.sum(X[i] ** 2) > 9.34 else -1
```

Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=12000)

The number of samples.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_samples, 10]

The input samples.

y : array of shape [n_samples]

The output values.

- *Discrete versus Real AdaBoost*
- *Gradient Boosting regularization*

sklearn.datasets.make_low_rank_matrix

sklearn.datasets.**make_low_rank_matrix**(*n_samples=100*, *n_features=100*, *effective_rank=10*, *tail_strength=0.5*, *random_state=None*)

Generate a mostly low rank matrix with bell-shaped singular values

Most of the variance can be explained by a bell-shaped curve of width effective_rank: the low rank part of the singular values profile is:

```
(1 - tail_strength) * exp(-1.0 * (i / effective_rank) ** 2)
```

The remaining singular values' tail is fat, decreasing as:

```
tail_strength * exp(-0.1 * i / effective_rank).
```

The low rank part of the profile can be considered the structured signal part of the data while the tail can be considered the noisy part of the data that cannot be summarized by a low number of linear components (singular vectors).

This kind of singular profiles is often seen in practice, for instance:

- gray level pictures of faces
- TF-IDF vectors of text documents crawled from the web

Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=100)

The number of samples.

n_features : int, optional (default=100)

The number of features.

effective_rank : int, optional (default=10)

The approximate number of singular vectors required to explain most of the data by linear combinations.

tail_strength : float between 0.0 and 1.0, optional (default=0.5)

The relative importance of the fat noisy tail of the singular values profile.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_samples, n_features]

The matrix.

sklearn.datasets.make_moons

sklearn.datasets.**make_moons**(*n_samples=100*, *shuffle=True*, *noise=None*, *random_state=None*)

Make two interleaving half circles

A simple toy dataset to visualize clustering and classification algorithms. Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=100)

The total number of points generated.

shuffle : bool, optional (default=True)

Whether to shuffle the samples.

noise : double or None (default=None)

Standard deviation of Gaussian noise added to the data.

Returns **X** : array of shape [n_samples, 2]

The generated samples.

y : array of shape [n_samples]

The integer labels (0 or 1) for class membership of each sample.

Examples using `sklearn.datasets.make_moons`

- *Classifier comparison*
- *Comparing different clustering algorithms on toy datasets*
- *Varying regularization in Multi-layer Perceptron*
- *Compare Stochastic learning strategies for MLPClassifier*

`sklearn.datasets`.make_multilabel_classification

`sklearn.datasets.`**`make_multilabel_classification`**(*n_samples=100*, *n_features=20*, *n_classes=5*, *n_labels=2*, *length=50*, *allow_unlabeled=True*, *sparse=False*, *return_indicator='dense'*, *return_distributions=False*, *random_state=None*)

Generate a random multilabel classification problem.

For each sample, the generative process is:

- pick the number of labels: n ~ Poisson(n_labels)
- n times, choose a class c: c ~ Multinomial(theta)
- pick the document length: k ~ Poisson(length)
- k times, choose a word: w ~ Multinomial(theta_c)

In the above process, rejection sampling is used to make sure that n is never zero or more than *n_classes*, and that the document length is never zero. Likewise, we reject classes which have already been chosen.

Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=100)

The number of samples.

n_features : int, optional (default=20)

The total number of features.

n_classes : int, optional (default=5)

The number of classes of the classification problem.

n_labels : int, optional (default=2)

The average number of labels per instance. More precisely, the number of labels per sample is drawn from a Poisson distribution with `n_labels` as its expected value, but samples are bounded (using rejection sampling) by `n_classes`, and must be nonzero if `allow_unlabeled` is False.

length : int, optional (default=50)

The sum of the features (number of words if documents) is drawn from a Poisson distribution with this expected value.

allow_unlabeled : bool, optional (default=True)

If `True`, some instances might not belong to any class.

sparse : bool, optional (default=False)

If `True`, return a sparse feature matrix

New in version 0.17: parameter to allow *sparse* output.

return_indicator : 'dense' (default) | 'sparse' | False

If `dense` return `Y` in the dense binary indicator format. If `'sparse'` return `Y` in the sparse binary indicator format. `False` returns a list of lists of labels.

return_distributions : bool, optional (default=False)

If `True`, return the prior class probability and conditional probabilities of features given classes, from which the data was drawn.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_samples, n_features]

The generated samples.

Y : array or sparse CSR matrix of shape [n_samples, n_classes]

The label sets.

p_c : array, shape [n_classes]

The probability of each class being drawn. Only returned if `return_distributions=True`.

p_w_c : array, shape [n_features, n_classes]

The probability of each feature being drawn given each class. Only returned if `return_distributions=True`.

Examples using `sklearn.datasets.make_multilabel_classification`

- *Multilabel classification*
- *Plot randomly generated multilabel dataset*

sklearn.datasets.make_regression

sklearn.datasets.**make_regression**(*n_samples=100*, *n_features=100*, *n_informative=10*, *n_targets=1*, *bias=0.0*, *effective_rank=None*, *tail_strength=0.5*, *noise=0.0*, *shuffle=True*, *coef=False*, *random_state=None*)

Generate a random regression problem.

The input set can either be well conditioned (by default) or have a low rank-fat tail singular profile. See *make_low_rank_matrix* for more details.

The output is generated by applying a (potentially biased) random linear regression model with *n_informative* nonzero regressors to the previously generated input and some gaussian centered noise with some adjustable scale.

Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=100)

The number of samples.

n_features : int, optional (default=100)

The number of features.

n_informative : int, optional (default=10)

The number of informative features, i.e., the number of features used to build the linear model used to generate the output.

n_targets : int, optional (default=1)

The number of regression targets, i.e., the dimension of the y output vector associated with a sample. By default, the output is a scalar.

bias : float, optional (default=0.0)

The bias term in the underlying linear model.

effective_rank : int or None, optional (default=None)

if not None: The approximate number of singular vectors required to explain most of the input data by linear combinations. Using this kind of singular spectrum in the input allows the generator to reproduce the correlations often observed in practice.

if None: The input set is well conditioned, centered and gaussian with unit variance.

tail_strength : float between 0.0 and 1.0, optional (default=0.5)

The relative importance of the fat noisy tail of the singular values profile if *effective_rank* is not None.

noise : float, optional (default=0.0)

The standard deviation of the gaussian noise applied to the output.

shuffle : boolean, optional (default=True)

Shuffle the samples and the features.

coef : boolean, optional (default=False)

If True, the coefficients of the underlying linear model are returned.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_samples, n_features]

The input samples.

y : array of shape [n_samples] or [n_samples, n_targets]

The output values.

coef : array of shape [n_features] or [n_features, n_targets], optional

The coefficient of the underlying linear model. It is returned only if coef is True.

Examples using `sklearn.datasets.make_regression`

- *Prediction Latency*
- *HuberRegressor vs Ridge on dataset with strong outliers*
- *Lasso on dense and sparse data*
- *Robust linear model estimation using RANSAC*
- *Plot Ridge coefficients as a function of the L2 regularization*

`sklearn.datasets.make_s_curve`

`sklearn.datasets.make_s_curve`(*n_samples=100*, *noise=0.0*, *random_state=None*)

Generate an S curve dataset.

Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=100)

The number of sample points on the S curve.

noise : float, optional (default=0.0)

The standard deviation of the gaussian noise.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_samples, 3]

The points.

t : array of shape [n_samples]

The univariate position of the sample according to the main dimension of the points in the manifold.

Examples using `sklearn.datasets.make_s_curve`

- *Comparison of Manifold Learning methods*

sklearn.datasets.make_sparse_coded_signal

sklearn.datasets.**make_sparse_coded_signal**(*n_samples*, *n_components*, *n_features*, *n_nonzero_coefs*, *random_state=None*)

Generate a signal as a sparse combination of dictionary elements.

Returns a matrix Y = DX, such as D is (n_features, n_components), X is (n_components, n_samples) and each column of X has exactly n_nonzero_coefs non-zero elements.

Read more in the *User Guide*.

Parameters **n_samples** : int

number of samples to generate

n_components : int,

number of components in the dictionary

n_features : int

number of features of the dataset to generate

n_nonzero_coefs : int

number of active (non-zero) coefficients in each sample

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **data** : array of shape [n_features, n_samples]

The encoded signal (Y).

dictionary : array of shape [n_features, n_components]

The dictionary with normalized components (D).

code : array of shape [n_components, n_samples]

The sparse code such that each column of this matrix has exactly n_nonzero_coefs non-zero items (X).

Examples using sklearn.datasets.make_sparse_coded_signal

- *Orthogonal Matching Pursuit*

sklearn.datasets.make_sparse_spd_matrix

sklearn.datasets.**make_sparse_spd_matrix**(*dim=1*, *alpha=0.95*, *norm_diag=False*, *smallest_coef=0.1*, *largest_coef=0.9*, *random_state=None*)

Generate a sparse symmetric definite positive matrix.

Read more in the *User Guide*.

Parameters **dim** : integer, optional (default=1)

The size of the random matrix to generate.

alpha : float between 0 and 1, optional (default=0.95)

The probability that a coefficient is zero (see notes). Larger values enforce more sparsity.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

largest_coef : float between 0 and 1, optional (default=0.9)

The value of the largest coefficient.

smallest_coef : float between 0 and 1, optional (default=0.1)

The value of the smallest coefficient.

norm_diag : boolean, optional (default=False)

Whether to normalize the output matrix to make the leading diagonal elements all 1

Returns **prec** : sparse matrix of shape (dim, dim)

The generated matrix.

See also:

make_spd_matrix

Notes

The sparsity is actually imposed on the cholesky factor of the matrix. Thus alpha does not translate directly into the filling fraction of the matrix itself.

Examples using `sklearn.datasets.make_sparse_spd_matrix`

- *Sparse inverse covariance estimation*

`sklearn.datasets`.make_sparse_uncorrelated

`sklearn.datasets.`**`make_sparse_uncorrelated`**(*n_samples=100*, *n_features=10*, *random_state=None*)

Generate a random regression problem with sparse uncorrelated design

This dataset is described in Celeux et al [1]. as:

```
X ~ N(0, 1)
y(X) = X[:, 0] + 2 * X[:, 1] - 2 * X[:, 2] - 1.5 * X[:, 3]
```

Only the first 4 features are informative. The remaining features are useless.

Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=100)

The number of samples.

n_features : int, optional (default=10)

The number of features.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_samples, n_features]

The input samples.

y : array of shape [n_samples]

The output values.

References

[R151]

sklearn.datasets.make_spd_matrix

sklearn.datasets.**make_spd_matrix**(*n_dim*, *random_state=None*)

Generate a random symmetric, positive-definite matrix.

Read more in the *User Guide*.

Parameters **n_dim** : int

The matrix dimension.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_dim, n_dim]

The random symmetric, positive-definite matrix.

See also:

make_sparse_spd_matrix

sklearn.datasets.make_swiss_roll

sklearn.datasets.**make_swiss_roll**(*n_samples=100*, *noise=0.0*, *random_state=None*)

Generate a swiss roll dataset.

Read more in the *User Guide*.

Parameters **n_samples** : int, optional (default=100)

The number of sample points on the S curve.

noise : float, optional (default=0.0)

The standard deviation of the gaussian noise.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape [n_samples, 3]

The points.

t : array of shape [n_samples]

The univariate position of the sample according to the main dimension of the points in the manifold.

Notes

The algorithm is from Marsland [1].

`sklearn.datasets.make_biclusters`

`sklearn.datasets.`**`make_biclusters`**(*shape*, *n_clusters*, *noise=0.0*, *minval=10*, *maxval=100*, *shuffle=True*, *random_state=None*)

Generate an array with constant block diagonal structure for biclustering.

Read more in the *User Guide*.

Parameters **shape** : iterable (n_rows, n_cols)

The shape of the result.

n_clusters : integer

The number of biclusters.

noise : float, optional (default=0.0)

The standard deviation of the gaussian noise.

minval : int, optional (default=10)

Minimum value of a bicluster.

maxval : int, optional (default=100)

Maximum value of a bicluster.

shuffle : boolean, optional (default=True)

Shuffle the samples.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape *shape*

The generated array.

rows : array of shape (n_clusters, X.shape[0],)

The indicators for cluster membership of each row.

cols : array of shape (n_clusters, X.shape[1],)

The indicators for cluster membership of each column.

`sklearn.datasets`.make_checkerboard

`sklearn.datasets.`**`make_checkerboard`**(*shape*, *n_clusters*, *noise=0.0*, *minval=10*, *maxval=100*, *shuffle=True*, *random_state=None*)

Generate an array with block checkerboard structure for biclustering.

Read more in the *User Guide*.

Parameters **shape** : iterable (n_rows, n_cols)

The shape of the result.

n_clusters : integer or iterable (n_row_clusters, n_column_clusters)

The number of row and column clusters.

noise : float, optional (default=0.0)

The standard deviation of the gaussian noise.

minval : int, optional (default=10)

Minimum value of a bicluster.

maxval : int, optional (default=100)

Maximum value of a bicluster.

shuffle : boolean, optional (default=True)

Shuffle the samples.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array of shape *shape*

The generated array.

rows : array of shape (n_clusters, X.shape[0],)

The indicators for cluster membership of each row.

cols : array of shape (n_clusters, X.shape[1],)

The indicators for cluster membership of each column.

29.7 `sklearn.decomposition`: Matrix Decomposition

The *sklearn.decomposition* module includes matrix decomposition algorithms, including among others PCA, NMF or ICA. Most of the algorithms of this module can be regarded as dimensionality reduction techniques.

User guide: See the *Decomposing signals in components (matrix factorization problems)* section for further details.

decomposition.PCA([n_components, copy, ...])	Principal component analysis (PCA)
decomposition.IncrementalPCA([n_components, ...])	Incremental principal components analysis (IPCA).
decomposition.KernelPCA([n_components, ...])	Kernel Principal component analysis (KPCA)
decomposition.FactorAnalysis([n_components, ...])	Factor Analysis (FA)
decomposition.FastICA([n_components, ...])	FastICA: a fast algorithm for Independent Component Analysis.
decomposition.TruncatedSVD([n_components, ...])	Dimensionality reduction using truncated SVD (aka LSA).
decomposition.NMF([n_components, init, ...])	Non-Negative Matrix Factorization (NMF)
decomposition.SparsePCA([n_components, ...])	Sparse Principal Components Analysis (SparsePCA)
decomposition.MiniBatchSparsePCA([...])	Mini-batch Sparse Principal Components Analysis
decomposition.SparseCoder(dictionary[, ...])	Sparse coding
decomposition.DictionaryLearning([...])	Dictionary learning
decomposition.MiniBatchDictionaryLearning([...])	Mini-batch dictionary learning
decomposition.LatentDirichletAllocation([...])	Latent Dirichlet Allocation with online variational Bayes algorithm

29.7.1 sklearn.decomposition.PCA

class sklearn.decomposition.**PCA**(*n_components=None*, *copy=True*, *whiten=False*, *svd_solver='auto'*, *tol=0.0*, *iterated_power='auto'*, *random_state=None*)

Principal component analysis (PCA)

Linear dimensionality reduction using Singular Value Decomposition of the data to project it to a lower dimensional space.

It uses the LAPACK implementation of the full SVD or a randomized truncated SVD by the method of Halko et al. 2009, depending on the shape of the input data and the number of components to extract.

It can also use the scipy.sparse.linalg ARPACK implementation of the truncated SVD.

Notice that this class does not support sparse input. See *TruncatedSVD* for an alternative with sparse data.

Read more in the *User Guide*.

Parameters **n_components** : int, float, None or string

Number of components to keep. if n_components is not set all components are kept:

```
n_components == min(n_samples, n_features)
```

if n_components == 'mle' and svd_solver == 'full', Minka's MLE is used to guess the dimension if `0 < n_components < 1` and svd_solver == 'full', select the number of components such that the amount of variance that needs to be explained is greater than the percentage specified by n_components n_components cannot be equal to n_features for svd_solver == 'arpack'.

copy : bool (default True)

If False, data passed to fit are overwritten and running fit(X).transform(X) will not yield the expected results, use fit_transform(X) instead.

whiten : bool, optional (default False)

When True (False by default) the *components_* vectors are multiplied by the square root of n_samples and then divided by the singular values to ensure uncorrelated outputs with unit component-wise variances.

Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometime improve the predictive accuracy of the downstream estimators by making their data respect some hard-wired assumptions.

svd_solver : string {'auto', 'full', 'arpack', 'randomized'}

auto : the solver is selected by a default policy based on *X.shape* and *n_components*: if the input data is larger than 500x500 and the number of components to extract is lower than 80% of the smallest dimension of the data, then the more efficient 'randomized' method is enabled. Otherwise the exact full SVD is computed and optionally truncated afterwards.

full : run exact full SVD calling the standard LAPACK solver via *scipy.linalg.svd* and select the components by postprocessing

arpack : run SVD truncated to n_components calling ARPACK solver via *scipy.sparse.linalg.svds*. It requires strictly 0 < n_components < X.shape[1]

randomized : run randomized SVD by the method of Halko et al.

New in version 0.18.0.

tol : float >= 0, optional (default .0)

Tolerance for singular values computed by svd_solver == 'arpack'.

New in version 0.18.0.

iterated_power : int >= 0, or 'auto', (default 'auto')

Number of iterations for the power method computed by svd_solver == 'randomized'.

New in version 0.18.0.

random_state : int, RandomState instance or None, optional (default None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `svd_solver` == 'arpack' or 'randomized'.

New in version 0.18.0.

Attributes **components_** : array, shape (n_components, n_features)

Principal axes in feature space, representing the directions of maximum variance in the data. The components are sorted by `explained_variance_`.

explained_variance_ : array, shape (n_components,)

The amount of variance explained by each of the selected components.

New in version 0.18.

explained_variance_ratio_ : array, shape (n_components,)

Percentage of variance explained by each of the selected components.

If `n_components` is not set then all components are stored and the sum of explained variances is equal to 1.0.

singular_values_ : array, shape (n_components,)

The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the `n_components` variables in the lower-dimensional space.

mean_ : array, shape (n_features,)

Per-feature empirical mean, estimated from the training set.

Equal to *X.mean(axis=1)*.

n_components_ : int

The estimated number of components. When n_components is set to 'mle' or a number between 0 and 1 (with svd_solver == 'full') this number is estimated from input data. Otherwise it equals the parameter n_components, or n_features if n_components is None.

noise_variance_ : float

The estimated noise covariance following the Probabilistic PCA model from Tipping and Bishop 1999. See "Pattern Recognition and Machine Learning" by C. Bishop, 12.2.1 p. 574 or http://www.miketipping.com/papers/met-mppca.pdf. It is required to computed the estimated data covariance and score samples.

KernelPCA, *SparsePCA*, *TruncatedSVD*, *IncrementalPCA*

References

For n_components == 'mle', this class uses the method of *Thomas P. Minka: Automatic Choice of Dimensionality for PCA. NIPS 2000: 598-604*

Implements the probabilistic PCA model from: M. Tipping and C. Bishop, Probabilistic Principal Component Analysis, Journal of the Royal Statistical Society, Series B, 61, Part 3, pp. 611-622 via the score and score_samples methods. See http://www.miketipping.com/papers/met-mppca.pdf

For svd_solver == 'arpack', refer to *scipy.sparse.linalg.svds*.

For svd_solver == 'randomized', see: *Finding structure with randomness: Stochastic algorithms for constructing approximate matrix decompositions Halko, et al., 2009 (arXiv:909) A randomized algorithm for the decomposition of matrices Per-Gunnar Martinsson, Vladimir Rokhlin and Mark Tygert*

Examples

```
>>> import numpy as np
>>> from sklearn.decomposition import PCA
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> pca = PCA(n_components=2)
>>> pca.fit(X)
PCA(copy=True, iterated_power='auto', n_components=2, random_state=None,
  svd_solver='auto', tol=0.0, whiten=False)
>>> print(pca.explained_variance_ratio_)
[ 0.99244...  0.00755...]
>>> print(pca.singular_values_)
[ 6.30061...  0.54980...]
```

```
>>> pca = PCA(n_components=2, svd_solver='full')
>>> pca.fit(X)
PCA(copy=True, iterated_power='auto', n_components=2, random_state=None,
  svd_solver='full', tol=0.0, whiten=False)
>>> print(pca.explained_variance_ratio_)
[ 0.99244...  0.00755...]
>>> print(pca.singular_values_)
[ 6.30061...  0.54980...]
```

```
>>> pca = PCA(n_components=1, svd_solver='arpack')
>>> pca.fit(X)
PCA(copy=True, iterated_power='auto', n_components=1, random_state=None,
  svd_solver='arpack', tol=0.0, whiten=False)
>>> print(pca.explained_variance_ratio_)
[ 0.99244...]
>>> print(pca.singular_values_)
[ 6.30061...]
```

Methods

fit(X[, y])	Fit the model with X.
fit_transform(X[, y])	Fit the model with X and apply the dimensionality reduction on X.
get_covariance()	Compute data covariance with the generative model.
get_params([deep])	Get parameters for this estimator.
get_precision()	Compute data precision matrix with the generative model.
inverse_transform(X[, y])	Transform data back to its original space.
score(X[, y])	Return the average log-likelihood of all samples.
score_samples(X)	Return the log-likelihood of each sample.
set_params(**params)	Set the parameters of this estimator.
transform(X[, y])	Apply dimensionality reduction to X.

__init__(*n_components=None*, *copy=True*, *whiten=False*, *svd_solver='auto'*, *tol=0.0*, *iterated_power='auto'*, *random_state=None*)

fit(*X*, *y=None*)
Fit the model with X.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples in the number of samples and n_features is the number of features.

Returns **self** : object

Returns the instance itself.

fit_transform(*X*, *y=None*)
Fit the model with X and apply the dimensionality reduction on X.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

Returns **X_new** : array-like, shape (n_samples, n_components)

get_covariance()
Compute data covariance with the generative model.

`cov = components_.T * S**2 * components_ + sigma2 * eye(n_features)`
where S**2 contains the explained variances, and sigma2 contains the noise variances.

Returns **cov** : array, shape=(n_features, n_features)

Estimated covariance of data.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_precision()
Compute data precision matrix with the generative model.

Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency.

Returns **precision** : array, shape=(n_features, n_features)

Estimated precision of data.

inverse_transform(*X*, *y=None*)
Transform data back to its original space.

In other words, return an input X_original whose transform would be X.

Parameters **X** : array-like, shape (n_samples, n_components)

New data, where n_samples is the number of samples and n_components is the number of components.

Returns **X_original array-like, shape (n_samples, n_features)** :

Notes

If whitening is enabled, inverse_transform will compute the exact inverse operation, which includes reversing whitening.

score(*X*, *y=None*)
Return the average log-likelihood of all samples.

See. "Pattern Recognition and Machine Learning" by C. Bishop, 12.2.1 p. 574 or http://www.miketipping.com/papers/met-mppca.pdf

Parameters **X** : array, shape(n_samples, n_features)

The data.

Returns **ll** : float

Average log-likelihood of the samples under the current model

score_samples(*X*)
Return the log-likelihood of each sample.

See. "Pattern Recognition and Machine Learning" by C. Bishop, 12.2.1 p. 574 or http://www.miketipping.com/papers/met-mppca.pdf

Parameters **X** : array, shape(n_samples, n_features)

The data.

Returns **ll** : array, shape (n_samples,)

Log-likelihood of each sample under the current model

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *y=None*)

Apply dimensionality reduction to X.

X is projected on the first principal components previously extracted from a training set.

Parameters **X** : array-like, shape (n_samples, n_features)

New data, where n_samples is the number of samples and n_features is the number of features.

Returns **X_new** : array-like, shape (n_samples, n_components)

Examples

```
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, copy=True, n_components=2, whiten=False)
>>> ipca.transform(X)
```

29.7.2 sklearn.decomposition.IncrementalPCA

class sklearn.decomposition.**IncrementalPCA**(*n_components=None*, *whiten=False*, *copy=True*, *batch_size=None*)

Incremental principal components analysis (IPCA).

Linear dimensionality reduction using Singular Value Decomposition of centered data, keeping only the most significant singular vectors to project the data to a lower dimensional space.

Depending on the size of the input data, this algorithm can be much more memory efficient than a PCA.

This algorithm has constant memory complexity, on the order of `batch_size`, enabling use of np.memmap files without loading the entire file into memory.

The computational overhead of each SVD is `O(batch_size * n_features ** 2)`, but only 2 * batch_size samples remain in memory at a time. There will be `n_samples / batch_size` SVD computations to get the principal components, versus 1 large SVD of complexity `O(n_samples * n_features ** 2)` for PCA.

Read more in the *User Guide*.

Parameters **n_components** : int or None, (default=None)

Number of components to keep. If `n_components `` is ``None`, then `n_components` is set to `min(n_samples, n_features)`.

batch_size : int or None, (default=None)

The number of samples to use for each batch. Only used when calling `fit`. If `batch_size` is `None`, then `batch_size` is inferred from the data and set to `5 * n_features`, to provide a balance between approximation accuracy and memory consumption.

copy : bool, (default=True)

If False, X will be overwritten. `copy=False` can be used to save memory but is unsafe for general use.

whiten : bool, optional

When True (False by default) the `components_` vectors are divided by `n_samples` times `components_` to ensure uncorrelated outputs with unit component-wise variances.

Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometimes improve the predictive accuracy of the downstream estimators by making data respect some hard-wired assumptions.

Attributes **components_** : array, shape (n_components, n_features)

Components with maximum variance.

explained_variance_ : array, shape (n_components,)

Variance explained by each of the selected components.

explained_variance_ratio_ : array, shape (n_components,)

Percentage of variance explained by each of the selected components. If all components are stored, the sum of explained variances is equal to 1.0.

singular_values_ : array, shape (n_components,)

The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the `n_components` variables in the lower-dimensional space.

mean_ : array, shape (n_features,)

Per-feature empirical mean, aggregate over calls to `partial_fit`.

var_ : array, shape (n_features,)

Per-feature empirical variance, aggregate over calls to `partial_fit`.

noise_variance_ : float

The estimated noise covariance following the Probabilistic PCA model from Tipping and Bishop 1999. See "Pattern Recognition and Machine Learning" by C. Bishop, 12.2.1 p. 574 or http://www.miketipping.com/papers/met-mppca.pdf.

n_components_ : int

The estimated number of components. Relevant when `n_components=None`.

n_samples_seen_ : int

The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across `partial_fit` calls.

PCA, *RandomizedPCA*, *KernelPCA*, *SparsePCA*, *TruncatedSVD*

Notes

Implements the incremental PCA model from: *D. Ross, J. Lim, R. Lin, M. Yang, Incremental Learning for Robust Visual Tracking, International Journal of Computer Vision, Volume 77, Issue 1-3, pp. 125-141, May 2008.* See http://www.cs.toronto.edu/~dross/ivt/RossLimLinYang_ijcv.pdf

This model is an extension of the Sequential Karhunen-Loeve Transform from: *A. Levy and M. Lindenbaum, Sequential Karhunen-Loeve Basis Extraction and its Application to Images, IEEE Transactions on Image Processing, Volume 9, Number 8, pp. 1371-1374, August 2000.* See http://www.cs.technion.ac.il/~mic/doc/skl-ip.pdf

We have specifically abstained from an optimization used by authors of both papers, a QR decomposition used in specific situations to reduce the algorithmic complexity of the SVD. The source for this technique is *Matrix Computations, Third Edition, G. Holub and C. Van Loan, Chapter 5, section 5.4.4, pp 252-253.*. This technique has been omitted because it is advantageous only when decomposing a matrix with `n_samples` (rows) >= 5/3 * `n_features` (columns), and hurts the readability of the implemented algorithm. This would be a good opportunity for future optimization, if it is deemed necessary.

Methods

fit(X[, y])	Fit the model with X, using minibatches of size batch_size.
fit_transform(X[, y])	Fit to data, then transform it.
get_covariance()	Compute data covariance with the generative model.
get_params([deep])	Get parameters for this estimator.
get_precision()	Compute data precision matrix with the generative model.
inverse_transform(X[, y])	Transform data back to its original space.
partial_fit(X[, y, check_input])	Incremental fit with X.
set_params(**params)	Set the parameters of this estimator.
transform(X[, y])	Apply dimensionality reduction to X.

__init__ (*n_components=None*, *whiten=False*, *copy=True*, *batch_size=None*)

fit (*X*, *y=None*)
Fit the model with X, using minibatches of size batch_size.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

y : Passthrough for `Pipeline` compatibility.

Returns **self** : object

Returns the instance itself.

fit_transform (*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_covariance ()
Compute data covariance with the generative model.

`cov = components_.T * S**2 * components_ + sigma2 * eye(n_features)`
where S**2 contains the explained variances, and sigma2 contains the noise variances.

Returns **cov** : array, shape=(n_features, n_features)

Estimated covariance of data.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_precision()
Compute data precision matrix with the generative model.

Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency.

Returns **precision** : array, shape=(n_features, n_features)

Estimated precision of data.

inverse_transform(*X*, *y=None*)
Transform data back to its original space.

In other words, return an input X_original whose transform would be X.

Parameters **X** : array-like, shape (n_samples, n_components)

New data, where n_samples is the number of samples and n_components is the number of components.

Returns **X_original array-like, shape (n_samples, n_features)** :

Notes

If whitening is enabled, inverse_transform will compute the exact inverse operation, which includes reversing whitening.

partial_fit(*X*, *y=None*, *check_input=True*)
Incremental fit with X. All of X is processed as a single batch.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

Returns **self** : object

Returns the instance itself.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *y=None*)
Apply dimensionality reduction to X.

X is projected on the first principal components previously extracted from a training set.

Parameters **X** : array-like, shape (n_samples, n_features)

New data, where n_samples is the number of samples and n_features is the number of features.

Returns **X_new** : array-like, shape (n_samples, n_components)

Examples

```
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, copy=True, n_components=2, whiten=False)
>>> ipca.transform(X)
```

Examples using `sklearn.decomposition.IncrementalPCA`

- *Incremental PCA*

29.7.3 `sklearn.decomposition.KernelPCA`

class `sklearn.decomposition.`**`KernelPCA`**(*n_components=None*, *kernel='linear'*, *gamma=None*, *degree=3*, *coef0=1*, *kernel_params=None*, *alpha=1.0*, *fit_inverse_transform=False*, *eigen_solver='auto'*, *tol=0*, *max_iter=None*, *remove_zero_eig=False*, *random_state=None*, *copy_X=True*, *n_jobs=1*)

Kernel Principal component analysis (KPCA)

Non-linear dimensionality reduction through the use of kernels (see *Pairwise metrics, Affinities and Kernels*).

Read more in the *User Guide*.

Parameters **n_components** : int, default=None

Number of components. If None, all non-zero components are kept.

kernel : "linear" | "poly" | "rbf" | "sigmoid" | "cosine" | "precomputed"

Kernel. Default="linear".

degree : int, default=3

Degree for poly kernels. Ignored by other kernels.

gamma : float, default=1/n_features

Kernel coefficient for rbf, poly and sigmoid kernels. Ignored by other kernels.

coef0 : float, default=1

Independent term in poly and sigmoid kernels. Ignored by other kernels.

kernel_params : mapping of string to any, default=None

Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.

alpha : int, default=1.0

Hyperparameter of the ridge regression that learns the inverse transform (when fit_inverse_transform=True).

fit_inverse_transform : bool, default=False

Learn the inverse transform for non-precomputed kernels. (i.e. learn to find the pre-image of a point)

eigen_solver : string ['auto'|'dense'|'arpack'], default='auto'

Select eigensolver to use. If n_components is much less than the number of training samples, arpack may be more efficient than the dense eigensolver.

tol : float, default=0

Convergence tolerance for arpack. If 0, optimal value will be chosen by arpack.

max_iter : int, default=None

Maximum number of iterations for arpack. If None, optimal value will be chosen by arpack.

remove_zero_eig : boolean, default=False

If True, then all components with zero eigenvalues are removed, so that the number of components in the output may be < n_components (and sometimes even zero due to numerical instability). When n_components is None, this parameter is ignored and components with zero eigenvalues are removed regardless.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `eigen_solver` == 'arpack'.

New in version 0.18.

n_jobs : int, default=1

The number of parallel jobs to run. If *-1*, then the number of jobs is set to the number of CPU cores.

New in version 0.18.

copy_X : boolean, default=True

If True, input X is copied and stored by the model in the *X_fit_* attribute. If no further changes will be done to X, setting *copy_X=False* saves memory by storing a reference.

New in version 0.18.

Attributes **lambdas_** : array, (n_components,)

Eigenvalues of the centered kernel matrix in decreasing order. If *n_components* and *remove_zero_eig* are not set, then all values are stored.

alphas_ : array, (n_samples, n_components)

Eigenvectors of the centered kernel matrix. If *n_components* and *remove_zero_eig* are not set, then all components are stored.

dual_coef_ : array, (n_samples, n_features)

Inverse transform matrix. Set if *fit_inverse_transform* is True.

X_transformed_fit_ : array, (n_samples, n_components)

Projection of the fitted data on the kernel principal components.

X_fit_ : (n_samples, n_features)

The data used to fit the model. If *copy_X=False*, then *X_fit_* is a reference. This attribute is used for the calls to transform.

Kernel PCA was introduced in: Bernhard Schoelkopf, Alexander J. Smola, and Klaus-Robert Mueller. 1999. Kernel principal component analysis. In Advances in kernel methods, MIT Press, Cambridge, MA, USA 327-352.

Methods

fit(X[, y])	Fit the model from data in X.
fit_transform(X[, y])	Fit the model from data in X and transform X.
get_params([deep])	Get parameters for this estimator.
inverse_transform(X)	Transform X back to original space.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Transform X.

__init__(*n_components=None*, *kernel='linear'*, *gamma=None*, *degree=3*, *coef0=1*, *kernel_params=None*, *alpha=1.0*, *fit_inverse_transform=False*, *eigen_solver='auto'*, *tol=0*, *max_iter=None*, *remove_zero_eig=False*, *random_state=None*, *copy_X=True*, *n_jobs=1*)

fit(*X*, *y=None*)
Fit the model from data in X.

Parameters **X** : array-like, shape (n_samples, n_features)

Training vector, where n_samples in the number of samples and n_features is the number of features.

Returns **self** : object

Returns the instance itself.

fit_transform(*X*, *y=None*, ***params*)
Fit the model from data in X and transform X.

Parameters **X** : array-like, shape (n_samples, n_features)

Training vector, where n_samples in the number of samples and n_features is the number of features.

Returns **X_new** : array-like, shape (n_samples, n_components)

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform(*X*)
Transform X back to original space.

Parameters **X** : array-like, shape (n_samples, n_components)

Returns **X_new** : array-like, shape (n_samples, n_features)

References

"Learning to Find Pre-Images", G BakIr et al, 2004.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Transform X.

Parameters **X** : array-like, shape (n_samples, n_features)

Returns **X_new** : array-like, shape (n_samples, n_components)

Examples using `sklearn.decomposition.KernelPCA`

- *Kernel PCA*

29.7.4 `sklearn.decomposition`.FactorAnalysis

class `sklearn.decomposition.`**FactorAnalysis**(*n_components=None*, *tol=0.01*, *copy=True*, *max_iter=1000*, *noise_variance_init=None*, *svd_method='randomized'*, *iterated_power=3*, *random_state=0*)
Factor Analysis (FA)

A simple linear generative model with Gaussian latent variables.

The observations are assumed to be caused by a linear transformation of lower dimensional latent factors and added Gaussian noise. Without loss of generality the factors are distributed according to a Gaussian with zero mean and unit covariance. The noise is also zero mean and has an arbitrary diagonal covariance matrix.

If we would restrict the model further, by assuming that the Gaussian noise is even isotropic (all diagonal entries are the same) we would obtain `PPCA`.

FactorAnalysis performs a maximum likelihood estimate of the so-called *loading* matrix, the transformation of the latent variables to the observed ones, using expectation-maximization (EM).

Read more in the *User Guide*.

Parameters **n_components** : int | None

Dimensionality of latent space, the number of components of `X` that are obtained after `transform`. If None, n_components is set to the number of features.

tol : float

Stopping tolerance for EM algorithm.

copy : bool

Whether to make a copy of X. If `False`, the input X gets overwritten during fitting.

max_iter : int

Maximum number of iterations.

noise_variance_init : None | array, shape=(n_features,)

The initial guess of the noise variance for each feature. If None, it defaults to np.ones(n_features)

svd_method : {'lapack', 'randomized'}

Which SVD method to use. If 'lapack' use standard SVD from scipy.linalg, if 'randomized' use fast `randomized_svd` function. Defaults to 'randomized'. For most applications 'randomized' will be sufficiently precise while providing significant speed gains. Accuracy can also be improved by setting higher values for *iterated_power*. If this is not sufficient, for maximum precision you should choose 'lapack'.

iterated_power : int, optional

Number of iterations for the power method. 3 by default. Only used if `svd_method` equals 'randomized'

random_state : int, RandomState instance or None, optional (default=0)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Only used when `svd_method` equals 'randomized'.

Attributes **components_** : array, [n_components, n_features]

Components with maximum variance.

loglike_ : list, [n_iterations]

The log likelihood at each iteration.

noise_variance_ : array, shape=(n_features,)

The estimated noise variance for each feature.

n_iter_ : int

Number of iterations run.

See also:

PCA Principal component analysis is also a latent linear variable model which however assumes equal noise variance for each feature. This extra assumption makes probabilistic PCA faster as it can be computed in closed form.

FastICA Independent component analysis, a latent variable model with non-Gaussian latent variables.

Methods

fit(X[, y])	Fit the FactorAnalysis model to X using EM
fit_transform(X[, y])	Fit to data, then transform it.
get_covariance()	Compute data covariance with the FactorAnalysis model.
get_params([deep])	Get parameters for this estimator.

Continued on next page

Table 29.59 – continued from previous page

get_precision()	Compute data precision matrix with the FactorAnalysis model.
score(X[, y])	Compute the average log-likelihood of the samples
score_samples(X)	Compute the log-likelihood of each sample
set_params(**params)	Set the parameters of this estimator.
transform(X)	Apply dimensionality reduction to X using the model.

__init__(*n_components=None*, *tol=0.01*, *copy=True*, *max_iter=1000*, *noise_variance_init=None*, *svd_method='randomized'*, *iterated_power=3*, *random_state=0*)

fit(*X*, *y=None*)

Fit the FactorAnalysis model to X using EM

Parameters **X** : array-like, shape (n_samples, n_features)

Training data.

Returns **self** :

fit_transform(*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_covariance()

Compute data covariance with the FactorAnalysis model.

```
cov = components_.T * components_ + diag(noise_variance)
```

Returns **cov** : array, shape (n_features, n_features)

Estimated covariance of data.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_precision()

Compute data precision matrix with the FactorAnalysis model.

Returns **precision** : array, shape (n_features, n_features)

Estimated precision of data.

score(*X*, *y=None*)
Compute the average log-likelihood of the samples

Parameters **X** : array, shape (n_samples, n_features)

The data

Returns **ll** : float

Average log-likelihood of the samples under the current model

score_samples(*X*)
Compute the log-likelihood of each sample

Parameters **X** : array, shape (n_samples, n_features)

The data

Returns **ll** : array, shape (n_samples,)

Log-likelihood of each sample under the current model

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Apply dimensionality reduction to X using the model.

Compute the expected mean of the latent variables. See Barber, 21.2.33 (or Bishop, 12.66).

Parameters **X** : array-like, shape (n_samples, n_features)

Training data.

Returns **X_new** : array-like, shape (n_samples, n_components)

The latent variables of X.

Examples using `sklearn.decomposition.FactorAnalysis`

- *Faces dataset decompositions*
- *Model selection with Probabilistic PCA and Factor Analysis (FA)*

29.7.5 `sklearn.decomposition`.FastICA

class `sklearn.decomposition.`**FastICA**(*n_components=None*, *algorithm='parallel'*, *whiten=True*, *fun='logcosh'*, *fun_args=None*, *max_iter=200*, *tol=0.0001*, *w_init=None*, *random_state=None*)
FastICA: a fast algorithm for Independent Component Analysis.

Read more in the *User Guide*.

Parameters **n_components** : int, optional

Number of components to use. If none is passed, all are used.

algorithm : {'parallel', 'deflation'}

Apply parallel or deflational algorithm for FastICA.

whiten : boolean, optional

If whiten is false, the data is already considered to be whitened, and no whitening is performed.

fun : string or function, optional. Default: 'logcosh'

The functional form of the G function used in the approximation to neg-entropy. Could be either 'logcosh', 'exp', or 'cube'. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. Example:

def my_g(x): return x ** 3, 3 * x ** 2

fun_args : dictionary, optional

Arguments to send to the functional form. If empty and if fun='logcosh', fun_args will take value {'alpha' : 1.0}.

max_iter : int, optional

Maximum number of iterations during fit.

tol : float, optional

Tolerance on update at each iteration.

w_init : None of an (n_components, n_components) ndarray

The mixing matrix to be used to initialize the algorithm.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **components_** : 2D array, shape (n_components, n_features)

The unmixing matrix.

mixing_ : array, shape (n_features, n_components)

The mixing matrix.

n_iter_ : int

If the algorithm is "deflation", n_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge.

Notes

Implementation based on *A. Hyvarinen and E. Oja, Independent Component Analysis: Algorithms and Applications, Neural Networks, 13(4-5), 2000, pp. 411-430*

Methods

fit(X[, y])	Fit the model to X.
fit_transform(X[, y])	Fit the model and recover the sources from X.

Continued on next page

Table 29.60 – continued from previous page

get_params([deep])	Get parameters for this estimator.
inverse_transform(X[, copy])	Transform the sources back to the mixed data (apply mixing matrix).
set_params(**params)	Set the parameters of this estimator.
transform(X[, y, copy])	Recover the sources from X (apply the unmixing matrix).

__init__ (*n_components=None*, *algorithm='parallel'*, *whiten=True*, *fun='logcosh'*, *fun_args=None*, *max_iter=200*, *tol=0.0001*, *w_init=None*, *random_state=None*)

fit (*X*, *y=None*)
Fit the model to X.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

Returns **self** :

fit_transform (*X*, *y=None*)
Fit the model and recover the sources from X.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples is the number of samples and n_features is the number of features.

Returns **X_new** : array-like, shape (n_samples, n_components)

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform (*X*, *copy=True*)
Transform the sources back to the mixed data (apply mixing matrix).

Parameters **X** : array-like, shape (n_samples, n_components)

Sources, where n_samples is the number of samples and n_components is the number of components.

copy : bool (optional)

If False, data passed to fit are overwritten. Defaults to True.

Returns **X_new** : array-like, shape (n_samples, n_features)

set_params (**params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *y=None*, *copy=True*)

Recover the sources from X (apply the unmixing matrix).

Parameters **X** : array-like, shape (n_samples, n_features)

Data to transform, where n_samples is the number of samples and n_features is the number of features.

copy : bool (optional)

If False, data passed to fit are overwritten. Defaults to True.

Returns **X_new** : array-like, shape (n_samples, n_components)

Examples using `sklearn.decomposition.FastICA`

- *Faces dataset decompositions*
- *Blind source separation using FastICA*
- *FastICA on 2D point clouds*

29.7.6 `sklearn.decomposition`.TruncatedSVD

class sklearn.decomposition.**TruncatedSVD**(*n_components=2*, *algorithm='randomized'*, *n_iter=5*, *random_state=None*, *tol=0.0*)

Dimensionality reduction using truncated SVD (aka LSA).

This transformer performs linear dimensionality reduction by means of truncated singular value decomposition (SVD). Contrary to PCA, this estimator does not center the data before computing the singular value decomposition. This means it can work with scipy.sparse matrices efficiently.

In particular, truncated SVD works on term count/tf-idf matrices as returned by the vectorizers in sklearn.feature_extraction.text. In that context, it is known as latent semantic analysis (LSA).

This estimator supports two algorithms: a fast randomized SVD solver, and a "naive" algorithm that uses ARPACK as an eigensolver on (X * X.T) or (X.T * X), whichever is more efficient.

Read more in the *User Guide*.

Parameters **n_components** : int, default = 2

Desired dimensionality of output data. Must be strictly less than the number of features. The default value is useful for visualisation. For LSA, a value of 100 is recommended.

algorithm : string, default = "randomized"

SVD solver to use. Either "arpack" for the ARPACK wrapper in SciPy (scipy.sparse.linalg.svds), or "randomized" for the randomized algorithm due to Halko (2009).

n_iter : int, optional (default 5)

Number of iterations for randomized SVD solver. Not used by ARPACK. The default is larger than the default in *randomized_svd* to handle sparse matrices that may have large slowly decaying spectrum.

random_state : int, RandomState instance or None, optional, default = None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

tol : float, optional

Tolerance for ARPACK. 0 means machine precision. Ignored by randomized SVD solver.

Attributes **components_** : array, shape (n_components, n_features)

explained_variance_ : array, shape (n_components,)

The variance of the training samples transformed by a projection to each component.

explained_variance_ratio_ : array, shape (n_components,)

Percentage of variance explained by each of the selected components.

singular_values_ : array, shape (n_components,)

The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the `n_components` variables in the lower-dimensional space.

See also:

PCA, *RandomizedPCA*

Notes

SVD suffers from a problem called "sign indeterminancy", which means the sign of the `components_` and the output from transform depend on the algorithm and random state. To work around this, fit instances of this class to data once, then keep the instance around to do transformations.

Examples

```
>>> from sklearn.decomposition import TruncatedSVD
>>> from sklearn.random_projection import sparse_random_matrix
>>> X = sparse_random_matrix(100, 100, density=0.01, random_state=42)
>>> svd = TruncatedSVD(n_components=5, n_iter=7, random_state=42)
>>> svd.fit(X)
TruncatedSVD(algorithm='randomized', n_components=5, n_iter=7,
        random_state=42, tol=0.0)
>>> print(svd.explained_variance_ratio_)
[ 0.0606... 0.0584... 0.0497... 0.0434... 0.0372...]
>>> print(svd.explained_variance_ratio_.sum())
0.249...
>>> print(svd.singular_values_)
[ 2.5841... 2.5245... 2.3201... 2.1753... 2.0443...]
```

Methods

fit(X[, y])	Fit LSI model on training data X.
fit_transform(X[, y])	Fit LSI model to X and perform dimensionality reduction on X.
get_params([deep])	Get parameters for this estimator.
inverse_transform(X)	Transform X back to its original space.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Perform dimensionality reduction on X.

__init__ (*n_components=2*, *algorithm='randomized'*, *n_iter=5*, *random_state=None*, *tol=0.0*)

fit (*X*, *y=None*)
Fit LSI model on training data X.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Training data.

Returns **self** : object

Returns the transformer object.

fit_transform (*X*, *y=None*)
Fit LSI model to X and perform dimensionality reduction on X.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Training data.

Returns **X_new** : array, shape (n_samples, n_components)

Reduced version of X. This will always be a dense array.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform (*X*)
Transform X back to its original space.

Returns an array X_original whose transform would be X.

Parameters **X** : array-like, shape (n_samples, n_components)

New data.

Returns **X_original** : array, shape (n_samples, n_features)

Note that this is always a dense array.

set_params (**params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)

Perform dimensionality reduction on X.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

New data.

Returns **X_new** : array, shape (n_samples, n_components)

Reduced version of X. This will always be a dense array.

Examples using sklearn.decomposition.TruncatedSVD

- *Feature Union with Heterogeneous Data Sources*
- *Hashing feature transformation using Totally Random Trees*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*
- *Clustering text documents using k-means*

29.7.7 sklearn.decomposition.NMF

class sklearn.decomposition.**NMF**(*n_components=None*, *init=None*, *solver='cd'*, *beta_loss='frobenius'*, *tol=0.0001*, *max_iter=200*, *random_state=None*, *alpha=0.0*, *l1_ratio=0.0*, *verbose=0*, *shuffle=False*)

Non-Negative Matrix Factorization (NMF)

Find two non-negative matrices (W, H) whose product approximates the non- negative matrix X. This factorization can be used for example for dimensionality reduction, source separation or topic extraction.

The objective function is:

```
0.5 * ||X - WH||_Fro^2
+ alpha * l1_ratio * ||vec(W)||_1
+ alpha * l1_ratio * ||vec(H)||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
+ 0.5 * alpha * (1 - l1_ratio) * ||H||_Fro^2
```

Where:

```
||A||_Fro^2 = \sum_{i,j} A_{ij}^2 (Frobenius norm)
||vec(A)||_1 = \sum_{i,j} abs(A_{ij}) (Elementwise L1 norm)
```

For multiplicative-update ('mu') solver, the Frobenius norm (0.5 * ||X - WH||_Fro^2) can be changed into another beta-divergence loss, by changing the beta_loss parameter.

The objective function is minimized with an alternating minimization of W and H.

Read more in the *User Guide*.

Parameters **n_components** : int or None

Number of components, if n_components is not set all features are kept.

init : ‘random’ | ‘nndsvd’ | ‘nndsvda’ | ‘nndsvdar’ | ‘custom’

Method used to initialize the procedure. Default: ‘nndsvd’ if n_components < n_features, otherwise random. Valid options:

- **‘random’: non-negative random matrices, scaled with:** sqrt(X.mean() / n_components)
- **‘nndsvd’: Nonnegative Double Singular Value Decomposition (NNDSVD)** initialization (better for sparseness)
- **‘nndsvda’: NNDSVD with zeros filled with the average of X** (better when sparsity is not desired)
- **‘nndsvdar’: NNDSVD with zeros filled with small random values** (generally faster, less accurate alternative to NNDSVDa for when sparsity is not desired)
- ‘custom’: use custom matrices W and H

solver : ‘cd’ | ‘mu’

Numerical solver to use: ‘cd’ is a Coordinate Descent solver. ‘mu’ is a Multiplicative Update solver.

New in version 0.17: Coordinate Descent solver.

New in version 0.19: Multiplicative Update solver.

beta_loss : float or string, default ‘frobenius’

String must be in {‘frobenius’, ‘kullback-leibler’, ‘itakura-saito’}. Beta divergence to be minimized, measuring the distance between X and the dot product WH. Note that values different from ‘frobenius’ (or 2) and ‘kullback-leibler’ (or 1) lead to significantly slower fits. Note that for beta_loss <= 0 (or ‘itakura-saito’), the input matrix X cannot contain zeros. Used only in ‘mu’ solver.

New in version 0.19.

tol : float, default: 1e-4

Tolerance of the stopping condition.

max_iter : integer, default: 200

Maximum number of iterations before timing out.

random_state : int, RandomState instance or None, optional, default: None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

alpha : double, default: 0.

Constant that multiplies the regularization terms. Set it to zero to have no regularization.

New in version 0.17: *alpha* used in the Coordinate Descent solver.

l1_ratio : double, default: 0.

The regularization mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an elementwise L2 penalty (aka Frobenius Norm). For l1_ratio = 1 it is an elementwise L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

New in version 0.17: Regularization parameter *l1_ratio* used in the Coordinate Descent solver.

shuffle : boolean, default: False

If true, randomize the order of coordinates in the CD solver.

New in version 0.17: *shuffle* parameter used in the Coordinate Descent solver.

Attributes components_ : array, [n_components, n_features]

Factorization matrix, sometimes called 'dictionary'.

reconstruction_err_ : number

Frobenius norm of the matrix difference, or beta-divergence, between the training data `X` and the reconstructed data `WH` from the fitted model.

n_iter_ : int

Actual number of iterations.

Examples

```
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [3, 1.2], [4, 1], [5, 0.8], [6, 1]])
>>> from sklearn.decomposition import NMF
>>> model = NMF(n_components=2, init='random', random_state=0)
>>> W = model.fit_transform(X)
>>> H = model.components_
```

Methods

fit(X[, y])	Learn a NMF model for the data X.
fit_transform(X[, y, W, H])	Learn a NMF model for the data X and returns the transformed data.
get_params([deep])	Get parameters for this estimator.
inverse_transform(W)	Transform data back to its original space.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Transform the data X according to the fitted NMF model

__init__ (*n_components=None*, *init=None*, *solver='cd'*, *beta_loss='frobenius'*, *tol=0.0001*, *max_iter=200*, *random_state=None*, *alpha=0.0*, *l1_ratio=0.0*, *verbose=0*, *shuffle=False*)

fit (*X*, *y=None*, ***params*)
Learn a NMF model for the data X.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Data matrix to be decomposed

Returns **self** :

fit_transform(*X*, *y=None*, *W=None*, *H=None*)
Learn a NMF model for the data X and returns the transformed data.

This is more efficient than calling fit followed by transform.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Data matrix to be decomposed

W : array-like, shape (n_samples, n_components)

If init='custom', it is used as initial guess for the solution.

H : array-like, shape (n_components, n_features)

If init='custom', it is used as initial guess for the solution.

Returns **W** : array, shape (n_samples, n_components)

Transformed data.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform(*W*)
Transform data back to its original space.

Parameters **W** : {array-like, sparse matrix}, shape (n_samples, n_components)

Transformed data matrix

Returns **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Data matrix of original shape

.. versionadded:: 0.18 :

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Transform the data X according to the fitted NMF model

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Data matrix to be transformed by the model

Returns **W** : array, shape (n_samples, n_components)

Transformed data

Examples using `sklearn.decomposition.NMF`

- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *Topic extraction with Non-negative Matrix Factorizationand Latent Dirichlet Allocation*
- *Faces dataset decompositions*

29.7.8 `sklearn.decomposition.SparsePCA`

class `sklearn.decomposition.`**`SparsePCA`**(*n_components=None*, *alpha=1*, *ridge_alpha=0.01*, *max_iter=1000*, *tol=1e-08*, *method='lars'*, *n_jobs=1*, *U_init=None*, *V_init=None*, *verbose=False*, *random_state=None*)

Sparse Principal Components Analysis (SparsePCA)

Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter alpha.

Read more in the *User Guide*.

Parameters **n_components** : int,

Number of sparse atoms to extract.

alpha : float,

Sparsity controlling parameter. Higher values lead to sparser components.

ridge_alpha : float,

Amount of ridge shrinkage to apply in order to improve conditioning when calling the transform method.

max_iter : int,

Maximum number of iterations to perform.

tol : float,

Tolerance for the stopping condition.

method : {'lars', 'cd'}

lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

n_jobs : int,

Number of parallel jobs to run.

U_init : array of shape (n_samples, n_components),

Initial values for the loadings for warm restart scenarios.

V_init : array of shape (n_components, n_features),

Initial values for the components for warm restart scenarios.

verbose : :

Degree of verbosity of the printed output.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **components_** : array, [n_components, n_features]

Sparse components extracted from the data.

error_ : array

Vector of errors at each iteration.

n_iter_ : int

Number of iterations run.

See also:

PCA, *MiniBatchSparsePCA*, *DictionaryLearning*

Methods

fit(X[, y])	Fit the model from data in X.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X[, ridge_alpha])	Least Squares projection of the data onto the sparse components.

__init__ (*n_components=None*, *alpha=1*, *ridge_alpha=0.01*, *max_iter=1000*, *tol=1e-08*, *method='lars'*, *n_jobs=1*, *U_init=None*, *V_init=None*, *verbose=False*, *random_state=None*)

fit (*X*, *y=None*)

Fit the model from data in X.

Parameters **X** : array-like, shape (n_samples, n_features)

Training vector, where n_samples in the number of samples and n_features is the number of features.

Returns **self** : object

Returns the instance itself.

fit_transform (*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *ridge_alpha='deprecated'*)
Least Squares projection of the data onto the sparse components.

To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the *ridge_alpha* parameter.

Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

Parameters **X** : array of shape (n_samples, n_features)

Test data to be transformed, must have the same number of features as the data used to train the model.

ridge_alpha: float, default: 0.01 :

Amount of ridge shrinkage to apply in order to improve conditioning.

Deprecated since version 0.19: This parameter will be removed in 0.21. Specify `ridge_alpha` in the `SparsePCA` constructor.

Returns **X_new array, shape (n_samples, n_components)** :

Transformed data.

29.7.9 sklearn.decomposition.MiniBatchSparsePCA

class sklearn.decomposition.**MiniBatchSparsePCA**(*n_components=None*, *alpha=1*, *ridge_alpha=0.01*, *n_iter=100*, *callback=None*, *batch_size=3*, *verbose=False*, *shuffle=True*, *n_jobs=1*, *method='lars'*, *random_state=None*)
Mini-batch Sparse Principal Components Analysis

Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter alpha.

Read more in the *User Guide*.

Parameters **n_components** : int,

number of sparse atoms to extract

alpha : int,

Sparsity controlling parameter. Higher values lead to sparser components.

ridge_alpha : float,

Amount of ridge shrinkage to apply in order to improve conditioning when calling the transform method.

n_iter : int,

number of iterations to perform for each mini batch

callback : callable,

callable that gets invoked every five iterations

batch_size : int,

the number of features to take in each mini batch

verbose : :

degree of output the procedure will print

shuffle : boolean,

whether to shuffle the data before splitting it in batches

n_jobs : int,

number of parallel jobs to run, or -1 to autodetect.

method : {'lars', 'cd'}

lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes components_ : array, [n_components, n_features]

Sparse components extracted from the data.

error_ : array

Vector of errors at each iteration.

n_iter_ : int

Number of iterations run.

get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X[, ridge_alpha])	Least Squares projection of the data onto the sparse components.

__init__ (*n_components=None*, *alpha=1*, *ridge_alpha=0.01*, *n_iter=100*, *callback=None*, *batch_size=3*, *verbose=False*, *shuffle=True*, *n_jobs=1*, *method='lars'*, *random_state=None*)

fit (*X*, *y=None*)

Fit the model from data in X.

Parameters **X** : array-like, shape (n_samples, n_features)

Training vector, where n_samples in the number of samples and n_features is the number of features.

Returns **self** : object

Returns the instance itself.

fit_transform (*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params (***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform (*X*, *ridge_alpha='deprecated'*)

Least Squares projection of the data onto the sparse components.

To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the *ridge_alpha* parameter.

Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

Parameters **X** : array of shape (n_samples, n_features)

Test data to be transformed, must have the same number of features as the data used to train the model.

ridge_alpha: float, default: 0.01 :

Amount of ridge shrinkage to apply in order to improve conditioning.

Deprecated since version 0.19: This parameter will be removed in 0.21. Specify `ridge_alpha` in the `SparsePCA` constructor.

Returns **X_new array, shape (n_samples, n_components)** :

Transformed data.

Examples using `sklearn.decomposition.MiniBatchSparsePCA`

- *Faces dataset decompositions*

29.7.10 `sklearn.decomposition.SparseCoder`

class `sklearn.decomposition.`**`SparseCoder`**(*dictionary*, *transform_algorithm='omp'*, *transform_n_nonzero_coefs=None*, *transform_alpha=None*, *split_sign=False*, *n_jobs=1*)

Sparse coding

Finds a sparse representation of data against a fixed, precomputed dictionary.

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array *code* such that:

```
X ~= code * dictionary
```

Read more in the *User Guide*.

Parameters **dictionary** : array, [n_components, n_features]

The dictionary atoms used for sparse coding. Lines are assumed to be normalized to unit norm.

transform_algorithm : {'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}

Algorithm used to transform the data: lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection `dictionary * X'`

transform_n_nonzero_coefs : int, `0.1 * n_features` by default

Number of nonzero coefficients to target in each column of the solution. This is only used by *algorithm='lars'* and *algorithm='omp'* and is overridden by *alpha* in the *omp* case.

transform_alpha : float, 1. by default

If *algorithm='lasso_lars'* or *algorithm='lasso_cd'*, *alpha* is the penalty applied to the L1 norm. If *algorithm='threshold'*, *alpha* is the absolute value of the threshold below which coefficients will be squashed to zero. If *algorithm='omp'*, *alpha* is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides *n_nonzero_coefs*.

split_sign : bool, False by default

Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

n_jobs : int,

number of parallel jobs to run

Attributes components_ : array, [n_components, n_features]

The unchanged dictionary atoms

See also:

DictionaryLearning, *MiniBatchDictionaryLearning*, *SparsePCA*, *MiniBatchSparsePCA*, *sparse_encode*

Methods

fit(X[, y])	Do nothing and return the estimator unchanged
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Encode the data as a sparse combination of the dictionary atoms.

__init__(*dictionary*, *transform_algorithm='omp'*, *transform_n_nonzero_coefs=None*, *transform_alpha=None*, *split_sign=False*, *n_jobs=1*)

fit(*X*, *y=None*)
Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

fit_transform(*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters X : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns X_new : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters deep : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter *transform_algorithm*.

Parameters **X** : array of shape (n_samples, n_features)

Test data to be transformed, must have the same number of features as the data used to train the model.

Returns **X_new** : array, shape (n_samples, n_components)

Transformed data

Examples using `sklearn.decomposition.SparseCoder`

- *Sparse coding with a precomputed dictionary*

29.7.11 `sklearn.decomposition`.DictionaryLearning

class `sklearn.decomposition.`**DictionaryLearning**(*n_components=None*, *alpha=1*, *max_iter=1000*, *tol=1e-08*, *fit_algorithm='lars'*, *transform_algorithm='omp'*, *transform_n_nonzero_coefs=None*, *transform_alpha=None*, *n_jobs=1*, *code_init=None*, *dict_init=None*, *verbose=False*, *split_sign=False*, *random_state=None*)

Dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

```
(U^*,V^*) = argmin 0.5 || Y - U V ||_2^2 + alpha * || U ||_1
            (U,V)
            with || V_k ||_2 = 1 for all  0 <= k < n_components
```

Read more in the *User Guide*.

Parameters **n_components** : int,

number of dictionary elements to extract

alpha : float,

sparsity controlling parameter

max_iter : int,

maximum number of iterations to perform

tol : float,

tolerance for numerical error

fit_algorithm : {'lars', 'cd'}

lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

New in version 0.17: *cd* coordinate descent method to improve speed.

transform_algorithm : {'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}

Algorithm used to transform the data lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection `dictionary * X'`

New in version 0.17: *lasso_cd* coordinate descent method to improve speed.

transform_n_nonzero_coefs : int, `0.1 * n_features` by default

Number of nonzero coefficients to target in each column of the solution. This is only used by *algorithm='lars'* and *algorithm='omp'* and is overridden by *alpha* in the *omp* case.

transform_alpha : float, 1. by default

If *algorithm='lasso_lars'* or *algorithm='lasso_cd'*, *alpha* is the penalty applied to the L1 norm. If *algorithm='threshold'*, *alpha* is the absolute value of the threshold below which coefficients will be squashed to zero. If *algorithm='omp'*, *alpha* is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides *n_nonzero_coefs*.

split_sign : bool, False by default

Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

n_jobs : int,

number of parallel jobs to run

code_init : array of shape (n_samples, n_components),

initial value for the code, for warm restart

dict_init : array of shape (n_components, n_features),

initial values for the dictionary, for warm restart

verbose : :

degree of verbosity of the printed output

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **components_** : array, [n_components, n_features]

dictionary atoms extracted from the data

error_ : array

vector of errors at each iteration

n_iter_ : int

Number of iterations run.

fit(*X*, *y=None*)

Fit the model from data in X.

Parameters **X** : array-like, shape (n_samples, n_features)

Training vector, where n_samples in the number of samples and n_features is the number of features.

Returns **self** : object

Returns the object itself

fit_transform(*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter *transform_algorithm*.

Parameters **X** : array of shape (n_samples, n_features)

Test data to be transformed, must have the same number of features as the data used to train the model.

Returns **X_new** : array, shape (n_samples, n_components)

Transformed data

29.7.12 sklearn.decomposition.MiniBatchDictionaryLearning

class sklearn.decomposition.**MiniBatchDictionaryLearning**(*n_components=None*, *alpha=1*, *n_iter=1000*, *fit_algorithm='lars'*, *n_jobs=1*, *batch_size=3*, *shuffle=True*, *dict_init=None*, *transform_algorithm='omp'*, *transform_n_nonzero_coefs=None*, *transform_alpha=None*, *verbose=False*, *split_sign=False*, *random_state=None*)

Mini-batch dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

```
(U^*,V^*) = argmin 0.5 || Y - U V ||_2^2 + alpha * || U ||_1
             (U,V)
             with || V_k ||_2 = 1 for all  0 <= k < n_components
```

Read more in the *User Guide*.

Parameters **n_components** : int,

number of dictionary elements to extract

alpha : float,

sparsity controlling parameter

n_iter : int,

total number of iterations to perform

fit_algorithm : {'lars', 'cd'}

lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

transform_algorithm : {'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}

Algorithm used to transform the data. lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary * X'

transform_n_nonzero_coefs : int, `0.1 * n_features` by default

Number of nonzero coefficients to target in each column of the solution. This is only used by *algorithm='lars'* and *algorithm='omp'* and is overridden by *alpha* in the *omp* case.

transform_alpha : float, 1. by default

If *algorithm='lasso_lars'* or *algorithm='lasso_cd'*, *alpha* is the penalty applied to the L1 norm. If *algorithm='threshold'*, *alpha* is the absolute value of the threshold below which coefficients will be squashed to zero. If *algorithm='omp'*, *alpha* is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides *n_nonzero_coefs*.

split_sign : bool, False by default

Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

n_jobs : int,

number of parallel jobs to run

dict_init : array of shape (n_components, n_features),

initial value of the dictionary for warm restart scenarios

verbose : :

degree of verbosity of the printed output

batch_size : int,

number of samples in each mini-batch

shuffle : bool,

whether to shuffle the samples before forming batches

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **components_** : array, [n_components, n_features]

components extracted from the data

inner_stats_ : tuple of (A, B) ndarrays

Internal sufficient statistics that are kept by the algorithm. Keeping them is useful in online settings, to avoid loosing the history of the evolution, but they shouldn't have any use for the end user. A (n_components, n_components) is the dictionary covariance matrix. B (n_features, n_components) is the data approximation matrix

n_iter_ : int

Number of iterations run.

Methods

fit(X[, y])	Fit the model from data in X.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
partial_fit(X[, y, iter_offset])	Updates the model using the data in X as a mini-batch.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Encode the data as a sparse combination of the dictionary atoms.

__init__ (*n_components=None*, *alpha=1*, *n_iter=1000*, *fit_algorithm='lars'*, *n_jobs=1*, *batch_size=3*, *shuffle=True*, *dict_init=None*, *transform_algorithm='omp'*, *transform_n_nonzero_coefs=None*, *transform_alpha=None*, *verbose=False*, *split_sign=False*, *random_state=None*)

fit (*X*, *y=None*)

Fit the model from data in X.

Parameters **X** : array-like, shape (n_samples, n_features)

Training vector, where n_samples in the number of samples and n_features is the num-

ber of features.

Returns **self** : object

Returns the instance itself.

fit_transform(*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

partial_fit(*X*, *y=None*, *iter_offset=None*)

Updates the model using the data in X as a mini-batch.

Parameters **X** : array-like, shape (n_samples, n_features)

Training vector, where n_samples in the number of samples and n_features is the number of features.

iter_offset : integer, optional

The number of iteration on data batches that has been performed before this call to partial_fit. This is optional: if no number is passed, the memory of the object is used.

Returns **self** : object

Returns the instance itself.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)

Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter *transform_algorithm*.

Parameters **X** : array of shape (n_samples, n_features)

Test data to be transformed, must have the same number of features as the data used to train the model.

Returns **X_new** : array, shape (n_samples, n_components)

Transformed data

Examples using `sklearn.decomposition.MiniBatchDictionaryLearning`

- *Faces dataset decompositions*
- *Image denoising using dictionary learning*

29.7.13 `sklearn.decomposition`.LatentDirichletAllocation

class `sklearn.decomposition.`**`LatentDirichletAllocation`**(*n_components=10*, *doc_topic_prior=None*, *topic_word_prior=None*, *learning_method=None*, *learning_decay=0.7*, *learning_offset=10.0*, *max_iter=10*, *batch_size=128*, *evaluate_every=-1*, *total_samples=1000000.0*, *perp_tol=0.1*, *mean_change_tol=0.001*, *max_doc_update_iter=100*, *n_jobs=1*, *verbose=0*, *random_state=None*, *n_topics=None*)

Latent Dirichlet Allocation with online variational Bayes algorithm

New in version 0.17.

Read more in the *User Guide*.

Parameters **n_components** : int, optional (default=10)

Number of topics.

doc_topic_prior : float, optional (default=None)

Prior of document topic distribution *theta*. If the value is None, defaults to *1 / n_components*. In the literature, this is called *alpha*.

topic_word_prior : float, optional (default=None)

Prior of topic word distribution *beta*. If the value is None, defaults to *1 / n_components*. In the literature, this is called *eta*.

learning_method : 'batch' | 'online', default='online'

Method used to update *_component*. Only used in *fit* method. In general, if the data size is large, the online update will be much faster than the batch update. The default learning method is going to be changed to 'batch' in the 0.20 release. Valid options:

```
'batch': Batch variational Bayes method. Use all training data␣
↪in
    each EM update.
```

```
    Old `components_` will be overwritten in each iteration.
'online': Online variational Bayes method. In each EM update,␣
↪use
    mini-batch of training data to update the ``components_``
    variable incrementally. The learning rate is controlled by␣
↪the
    ``learning_decay`` and the ``learning_offset`` parameters.
```

learning_decay : float, optional (default=0.7)

It is a parameter that control learning rate in the online learning method. The value should be set between (0.5, 1.0] to guarantee asymptotic convergence. When the value is 0.0 and batch_size is `n_samples`, the update method is same as batch learning. In the literature, this is called kappa.

learning_offset : float, optional (default=10.)

A (positive) parameter that downweights early iterations in online learning. It should be greater than 1.0. In the literature, this is called tau_0.

max_iter : integer, optional (default=10)

The maximum number of iterations.

total_samples : int, optional (default=1e6)

Total number of documents. Only used in the *partial_fit* method.

batch_size : int, optional (default=128)

Number of documents to use in each EM iteration. Only used in online learning.

evaluate_every : int optional (default=0)

How often to evaluate perplexity. Only used in *fit* method. set it to 0 or negative number to not evalute perplexity in training at all. Evaluating perplexity can help you check convergence in training process, but it will also increase total training time. Evaluating perplexity in every iteration might increase training time up to two-fold.

perp_tol : float, optional (default=1e-1)

Perplexity tolerance in batch learning. Only used when `evaluate_every` is greater than 0.

mean_change_tol : float, optional (default=1e-3)

Stopping tolerance for updating document topic distribution in E-step.

max_doc_update_iter : int (default=100)

Max number of iterations for updating document topic distribution in the E-step.

n_jobs : int, optional (default=1)

The number of jobs to use in the E-step. If -1, all CPUs are used. For `n_jobs` below -1, (n_cpus + 1 + n_jobs) are used.

verbose : int, optional (default=0)

Verbosity level.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

n_topics : int, optional (default=None)

This parameter has been renamed to n_components and will be removed in version 0.21. .. deprecated:: 0.19

Attributes **components_** : array, [n_components, n_features]

Variational parameters for topic word distribution. Since the complete conditional for topic word distribution is a Dirichlet, `components_[i, j]` can be viewed as pseudocount that represents the number of times word *j* was assigned to topic *i*. It can also be viewed as distribution over the words for each topic after normalization: `model.components_ / model.components_.sum(axis=1)[:, np.newaxis]`.

n_batch_iter_ : int

Number of iterations of the EM step.

n_iter_ : int

Number of passes over the dataset.

Methods

fit(X[, y])	Learn model for the data X with variational Bayes method.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
partial_fit(X[, y])	Online VB with Mini-Batch update.
perplexity(X[, doc_topic_distr, sub_sampling])	Calculate approximate perplexity for data X.
score(X[, y])	Calculate approximate log-likelihood as score.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Transform data X according to the fitted model.

__init__(*n_components=10*, *doc_topic_prior=None*, *topic_word_prior=None*, *learning_method=None*, *learning_decay=0.7*, *learning_offset=10.0*, *max_iter=10*, *batch_size=128*, *evaluate_every=-1*, *total_samples=1000000.0*, *perp_tol=0.1*, *mean_change_tol=0.001*, *max_doc_update_iter=100*, *n_jobs=1*, *verbose=0*, *random_state=None*, *n_topics=None*)

fit(*X*, *y=None*)

Learn model for the data X with variational Bayes method.

When *learning_method* is 'online', use mini-batch update. Otherwise, use batch update.

Parameters **X** : array-like or sparse matrix, shape=(n_samples, n_features)

Document word matrix.

Returns **self** :

fit_transform(*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

partial_fit(*X*, *y=None*)
Online VB with Mini-Batch update.

Parameters **X** : array-like or sparse matrix, shape=(n_samples, n_features)

Document word matrix.

Returns **self** :

perplexity(*X*, *doc_topic_distr='deprecated'*, *sub_sampling=False*)
Calculate approximate perplexity for data X.

Perplexity is defined as exp(-1. * log-likelihood per word)

Changed in version 0.19: *doc_topic_distr* argument has been deprecated and is ignored because user no longer has access to unnormalized distribution

Parameters **X** : array-like or sparse matrix, [n_samples, n_features]

Document word matrix.

doc_topic_distr : None or array, shape=(n_samples, n_components)

Document topic distribution. This argument is deprecated and is currently being ignored.

Deprecated since version 0.19.

Returns **score** : float

Perplexity score.

score(*X*, *y=None*)
Calculate approximate log-likelihood as score.

Parameters **X** : array-like or sparse matrix, shape=(n_samples, n_features)

Document word matrix.

Returns **score** : float

Use approximate bound as score.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Transform data X according to the fitted model.

Changed in version 0.18: *doc_topic_distr* is now normalized

Parameters **X** : array-like or sparse matrix, shape=(n_samples, n_features)

Document word matrix.

Returns **doc_topic_distr** : shape=(n_samples, n_components)

Document topic distribution for X.

Examples using `sklearn.decomposition.LatentDirichletAllocation`

- *Topic extraction with Non-negative Matrix Factorizationand Latent Dirichlet Allocation*

decomposition.fastica(X[, n_components, ...])	Perform Fast Independent Component Analysis.
decomposition.dict_learning(X, n_components, ...)	Solves a dictionary learning matrix factorization problem.
decomposition.dict_learning_online(X[, ...])	Solves a dictionary learning matrix factorization problem online.
decomposition.sparse_encode(X, dictionary[, ...])	Sparse coding

29.7.14 `sklearn.decomposition.fastica`

sklearn.decomposition.**fastica**(*X*, *n_components=None*, *algorithm='parallel'*, *whiten=True*, *fun='logcosh'*, *fun_args=None*, *max_iter=200*, *tol=0.0001*, *w_init=None*, *random_state=None*, *return_X_mean=False*, *compute_sources=True*, *return_n_iter=False*)
Perform Fast Independent Component Analysis.

Read more in the *User Guide*.

Parameters **X** : array-like, shape (n_samples, n_features)

Training vector, where n_samples is the number of samples and n_features is the number of features.

n_components : int, optional

Number of components to extract. If None no dimension reduction is performed.

algorithm : {'parallel', 'deflation'}, optional

Apply a parallel or deflational FASTICA algorithm.

whiten : boolean, optional

If True perform an initial whitening of the data. If False, the data is assumed to have already been preprocessed: it should be centered, normed and white. Otherwise you will get incorrect results. In this case the parameter n_components will be ignored.

fun : string or function, optional. Default: 'logcosh'

The functional form of the G function used in the approximation to neg-entropy. Could be either 'logcosh', 'exp', or 'cube'. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. Example:

def my_g(x): return x ** 3, 3 * x ** 2

fun_args : dictionary, optional

Arguments to send to the functional form. If empty or None and if fun='logcosh', fun_args will take value {'alpha' : 1.0}

max_iter : int, optional

Maximum number of iterations to perform.

tol : float, optional

A positive scalar giving the tolerance at which the un-mixing matrix is considered to have converged.

w_init : (n_components, n_components) array, optional

Initial un-mixing array of dimension (n.comp,n.comp). If None (default) then an array of normal r.v.'s is used.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

return_X_mean : bool, optional

If True, X_mean is returned too.

compute_sources : bool, optional

If False, sources are not computed, but only the rotation matrix. This can save memory when working with big data. Defaults to True.

return_n_iter : bool, optional

Whether or not to return the number of iterations.

Returns **K** : array, shape (n_components, n_features) | None.

If whiten is 'True', K is the pre-whitening matrix that projects data onto the first n_components principal components. If whiten is 'False', K is 'None'.

W : array, shape (n_components, n_components)

Estimated un-mixing matrix. The mixing matrix can be obtained by:

```
w = np.dot(W, K.T)
A = w.T * (w * w.T).I
```

S : array, shape (n_samples, n_components) | None

Estimated source matrix

X_mean : array, shape (n_features,)

The mean over features. Returned only if return_X_mean is True.

n_iter : int

If the algorithm is "deflation", n_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge. This is returned only when return_n_iter is set to *True*.

Notes

The data matrix X is considered to be a linear combination of non-Gaussian (independent) components i.e. X = AS where columns of S contain the independent components and A is a linear mixing matrix. In short ICA attempts to *un-mix' the data by estimating an un-mixing matrix W where ''S = W K X.'*

This implementation was originally made for data of shape [n_features, n_samples]. Now the input is transposed before the algorithm is applied. This makes it slightly faster for Fortran-ordered input.

Implemented using FastICA: *A. Hyvarinen and E. Oja, Independent Component Analysis: Algorithms and Applications, Neural Networks, 13(4-5), 2000, pp. 411-430*

29.7.15 sklearn.decomposition.dict_learning

sklearn.decomposition.**dict_learning**(*X*, *n_components*, *alpha*, *max_iter=100*, *tol=1e-08*, *method='lars'*, *n_jobs=1*, *dict_init=None*, *code_init=None*, *callback=None*, *verbose=False*, *random_state=None*, *return_n_iter=False*)

Solves a dictionary learning matrix factorization problem.

Finds the best dictionary and the corresponding sparse code for approximating the data matrix X by solving:

```
(U^*, V^*) = argmin 0.5 || X - U V ||_2^2 + alpha * || U ||_1
             (U,V)
            with || V_k ||_2 = 1 for all  0 <= k < n_components
```

where V is the dictionary and U is the sparse code.

Read more in the *User Guide*.

Parameters **X** : array of shape (n_samples, n_features)

Data matrix.

n_components : int,

Number of dictionary atoms to extract.

alpha : int,

Sparsity controlling parameter.

max_iter : int,

Maximum number of iterations to perform.

tol : float,

Tolerance for the stopping condition.

method : {'lars', 'cd'}

lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

n_jobs : int,

Number of parallel jobs to run, or -1 to autodetect.

dict_init : array of shape (n_components, n_features),

Initial value for the dictionary for warm restart scenarios.

code_init : array of shape (n_samples, n_components),

Initial value for the sparse code for warm restart scenarios.

callback : :

Callable that gets invoked every five iterations.

verbose : :

Degree of output the procedure will print.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

return_n_iter : bool

Whether or not to return the number of iterations.

Returns **code** : array of shape (n_samples, n_components)

The sparse code factor in the matrix factorization.

dictionary : array of shape (n_components, n_features),

The dictionary factor in the matrix factorization.

errors : array

Vector of errors at each iteration.

n_iter : int

Number of iterations run. Returned only if *return_n_iter* is set to True.

dict_learning_online, *DictionaryLearning*, *MiniBatchDictionaryLearning*, *SparsePCA*, *MiniBatchSparsePCA*

29.7.16 sklearn.decomposition.dict_learning_online

sklearn.decomposition.**dict_learning_online**(*X*, *n_components=2*, *alpha=1*, *n_iter=100*, *return_code=True*, *dict_init=None*, *callback=None*, *batch_size=3*, *verbose=False*, *shuffle=True*, *n_jobs=1*, *method='lars'*, *iter_offset=0*, *random_state=None*, *return_inner_stats=False*, *inner_stats=None*, *return_n_iter=False*)

Solves a dictionary learning matrix factorization problem online.

Finds the best dictionary and the corresponding sparse code for approximating the data matrix X by solving:

```
(U^*, V^*) = argmin 0.5 || X - U V ||_2^2 + alpha * || U ||_1
             (U,V)
             with || V_k ||_2 = 1 for all  0 <= k < n_components
```

where V is the dictionary and U is the sparse code. This is accomplished by repeatedly iterating over mini-batches by slicing the input data.

Read more in the *User Guide*.

Parameters **X** : array of shape (n_samples, n_features)

Data matrix.

n_components : int,

Number of dictionary atoms to extract.

alpha : float,

Sparsity controlling parameter.

n_iter : int,

Number of iterations to perform.

return_code : boolean,

Whether to also return the code U or just the dictionary V.

dict_init : array of shape (n_components, n_features),

Initial value for the dictionary for warm restart scenarios.

callback : :

Callable that gets invoked every five iterations.

batch_size : int,

The number of samples to take in each batch.

verbose : :

Degree of output the procedure will print.

shuffle : boolean,

Whether to shuffle the data before splitting it in batches.

n_jobs : int,

Number of parallel jobs to run, or -1 to autodetect.

method : {'lars', 'cd'}

lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

iter_offset : int, default 0

Number of previous iterations completed on the dictionary used for initialization.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

return_inner_stats : boolean, optional

Return the inner statistics A (dictionary covariance) and B (data approximation). Useful to restart the algorithm in an online setting. If return_inner_stats is True, return_code is ignored

inner_stats : tuple of (A, B) ndarrays

Inner sufficient statistics that are kept by the algorithm. Passing them at initialization is useful in online settings, to avoid loosing the history of the evolution. A (n_components, n_components) is the dictionary covariance matrix. B (n_features, n_components) is the data approximation matrix

return_n_iter : bool

Whether or not to return the number of iterations.

Returns **code** : array of shape (n_samples, n_components),

the sparse code (only returned if *return_code=True*)

dictionary : array of shape (n_components, n_features),

the solutions to the dictionary learning problem

n_iter : int

Number of iterations run. Returned only if *return_n_iter* is set to *True*.

See also:

dict_learning, *DictionaryLearning*, *MiniBatchDictionaryLearning*, *SparsePCA*, *MiniBatchSparsePCA*

29.7.17 sklearn.decomposition.sparse_encode

sklearn.decomposition.**sparse_encode**(*X*, *dictionary*, *gram=None*, *cov=None*, *algorithm='lasso_lars'*, *n_nonzero_coefs=None*, *alpha=None*, *copy_cov=True*, *init=None*, *max_iter=1000*, *n_jobs=1*, *check_input=True*, *verbose=0*)

Sparse coding

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array *code* such that:

```
X ~= code * dictionary
```

Read more in the *User Guide*.

Parameters **X** : array of shape (n_samples, n_features)

Data matrix

dictionary : array of shape (n_components, n_features)

The dictionary matrix against which to solve the sparse coding of the data. Some of the algorithms assume normalized rows for meaningful output.

gram : array, shape=(n_components, n_components)

Precomputed Gram matrix, dictionary * dictionary'

cov : array, shape=(n_components, n_samples)

Precomputed covariance, dictionary' * X

algorithm : {'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}

lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary * X'

n_nonzero_coefs : int, 0.1 * n_features by default

Number of nonzero coefficients to target in each column of the solution. This is only used by *algorithm='lars'* and *algorithm='omp'* and is overridden by *alpha* in the *omp* case.

alpha : float, 1. by default

If *algorithm='lasso_lars'* or *algorithm='lasso_cd'*, *alpha* is the penalty applied to the L1 norm. If *algorithm='threshold'*, *alpha* is the absolute value of the threshold below which coefficients will be squashed to zero. If *algorithm='omp'*, *alpha* is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides *n_nonzero_coefs*.

init : array of shape (n_samples, n_components)

Initialization value of the sparse codes. Only used if *algorithm='lasso_cd'*.

max_iter : int, 1000 by default

Maximum number of iterations to perform if *algorithm='lasso_cd'*.

copy_cov : boolean, optional

Whether to copy the precomputed covariance matrix; if False, it may be overwritten.

n_jobs : int, optional

Number of parallel jobs to run.

check_input : boolean, optional

If False, the input arrays X and dictionary will not be checked.

verbose : int, optional

Controls the verbosity; the higher, the more messages. Defaults to 0.

Returns **code** : array of shape (n_samples, n_components)

The sparse codes

29.8 sklearn.dummy: Dummy estimators

User guide: See the *Model evaluation: quantifying the quality of predictions* section for further details.

dummy.DummyClassifier([strategy, ...])	DummyClassifier is a classifier that makes predictions using simple rules.
dummy.DummyRegressor([strategy, constant, ...])	DummyRegressor is a regressor that makes predictions using simple rules.

29.8.1 sklearn.dummy.DummyClassifier

class sklearn.dummy.**DummyClassifier**(*strategy='stratified'*, *random_state=None*, *constant=None*)

DummyClassifier is a classifier that makes predictions using simple rules.

This classifier is useful as a simple baseline to compare with other (real) classifiers. Do not use it for real problems.

Read more in the *User Guide*.

Parameters **strategy** : str, default="stratified"

Strategy to use to generate predictions.

- "stratified": generates predictions by respecting the training set's class distribution.
- "most_frequent": always predicts the most frequent label in the training set.
- "prior": always predicts the class that maximizes the class prior (like "most_frequent") and `predict_proba` returns the class prior.
- "uniform": generates predictions uniformly at random.
- "constant": always predicts a constant label that is provided by the user. This is useful for metrics that evaluate a non-majority class

  New in version 0.17: Dummy Classifier now supports prior fitting strategy using parameter *prior*.

random_state : int, RandomState instance or None, optional, default=None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

constant : int or str or array of shape = [n_outputs]

The explicit constant as predicted by the "constant" strategy. This parameter is useful only for the "constant" strategy.

Attributes **classes_** : array or list of array of shape = [n_classes]

Class labels for each output.

n_classes_ : array or list of array of shape = [n_classes]

Number of label for each output.

class_prior_ : array or list of array of shape = [n_classes]

Probability of each class for each output.

n_outputs_ : int,

Number of outputs.

outputs_2d_ : bool,

True if the output at fit is 2d, else false.

sparse_output_ : bool,

True if the array returned from predict is to be in sparse CSC format. Is automatically set to True if the input y is passed in sparse format.

Methods

fit(X, y[, sample_weight])	Fit the random classifier.
get_params([deep])	Get parameters for this estimator.
predict(X)	Perform classification on test vectors X.
predict_log_proba(X)	Return log probability estimates for the test vectors X.
predict_proba(X)	Return probability estimates for the test vectors X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*strategy='stratified'*, *random_state=None*, *constant=None*)

fit (*X*, *y*, *sample_weight=None*)
Fit the random classifier.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training vectors, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples] or [n_samples, n_outputs]

Target values.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **self** : object

Returns self.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Perform classification on test vectors X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Input vectors, where n_samples is the number of samples and n_features is the number of features.

Returns **y** : array, shape = [n_samples] or [n_samples, n_outputs]

Predicted target values for X.

predict_log_proba(*X*)

Return log probability estimates for the test vectors X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Input vectors, where n_samples is the number of samples and n_features is the number of features.

Returns **P** : array-like or list of array-like of shape = [n_samples, n_classes]

Returns the log probability of the sample for each class in the model, where classes are ordered arithmetically for each output.

predict_proba(*X*)

Return probability estimates for the test vectors X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Input vectors, where n_samples is the number of samples and n_features is the number of features.

Returns **P** : array-like or list of array-lke of shape = [n_samples, n_classes]

Returns the probability of the sample for each class in the model, where classes are ordered arithmetically, for each output.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.8.2 sklearn.dummy.DummyRegressor

class sklearn.dummy.**DummyRegressor**(*strategy='mean'*, *constant=None*, *quantile=None*)

DummyRegressor is a regressor that makes predictions using simple rules.

This regressor is useful as a simple baseline to compare with other (real) regressors. Do not use it for real problems.

Read more in the *User Guide*.

Parameters **strategy** : str

Strategy to use to generate predictions.

- "mean": always predicts the mean of the training set
- "median": always predicts the median of the training set
- "quantile": always predicts a specified quantile of the training set, provided with the quantile parameter.
- "constant": always predicts a constant value that is provided by the user.

constant : int or float or array of shape = [n_outputs]

The explicit constant as predicted by the "constant" strategy. This parameter is useful only for the "constant" strategy.

quantile : float in [0.0, 1.0]

The quantile to predict using the "quantile" strategy. A quantile of 0.5 corresponds to the median, while 0.0 to the minimum and 1.0 to the maximum.

Attributes **constant_** : float or array of shape [n_outputs]

Mean or median or quantile of the training targets or constant value given by the user.

n_outputs_ : int,

Number of outputs.

outputs_2d_ : bool,

True if the output at fit is 2d, else false.

Methods

fit(X, y[, sample_weight])	Fit the random regressor.
get_params([deep])	Get parameters for this estimator.
predict(X)	Perform classification on test vectors X.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*strategy='mean'*, *constant=None*, *quantile=None*)

fit (*X*, *y*, *sample_weight=None*)
Fit the random regressor.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training vectors, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples] or [n_samples, n_outputs]

Target values.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **self** : object

Returns self.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*)
Perform classification on test vectors X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Input vectors, where n_samples is the number of samples and n_features is the number of features.

Returns **y** : array, shape = [n_samples] or [n_samples, n_outputs]

Predicted target values for X.

score (*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

—

29.9 sklearn.ensemble: Ensemble Methods

The *sklearn.ensemble* module includes ensemble-based methods for classification, regression and anomaly detection.

User guide: See the *Ensemble methods* section for further details.

ensemble.AdaBoostClassifier([...])	An AdaBoost classifier.
ensemble.AdaBoostRegressor([base_estimator, ...])	An AdaBoost regressor.
ensemble.BaggingClassifier([base_estimator, ...])	A Bagging classifier.
ensemble.BaggingRegressor([base_estimator, ...])	A Bagging regressor.
ensemble.ExtraTreesClassifier([...])	An extra-trees classifier.
ensemble.ExtraTreesRegressor([n_estimators, ...])	An extra-trees regressor.
ensemble.GradientBoostingClassifier([loss, ...])	Gradient Boosting for classification.
ensemble.GradientBoostingRegressor([loss, ...])	Gradient Boosting for regression.
ensemble.IsolationForest([n_estimators, ...])	Isolation Forest Algorithm
ensemble.RandomForestClassifier([...])	A random forest classifier.
ensemble.RandomTreesEmbedding([...])	An ensemble of totally random trees.
ensemble.RandomForestRegressor([...])	A random forest regressor.
ensemble.VotingClassifier(estimators[, ...])	Soft Voting/Majority Rule classifier for unfitted estimators.

29.9.1 sklearn.ensemble.AdaBoostClassifier

class sklearn.ensemble.**AdaBoostClassifier**(*base_estimator=None*, *n_estimators=50*, *learning_rate=1.0*, *algorithm='SAMME.R'*, *random_state=None*)

An AdaBoost classifier.

An AdaBoost [1] classifier is a meta-estimator that begins by fitting a classifier on the original dataset and then fits additional copies of the classifier on the same dataset but where the weights of incorrectly classified instances are adjusted such that subsequent classifiers focus more on difficult cases.

This class implements the algorithm known as AdaBoost-SAMME [2].

Read more in the *User Guide*.

Parameters **base_estimator** : object, optional (default=DecisionTreeClassifier)

The base estimator from which the boosted ensemble is built. Support for sample weighting is required, as well as proper *classes_* and *n_classes_* attributes.

n_estimators : integer, optional (default=50)

The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.

learning_rate : float, optional (default=1.)

Learning rate shrinks the contribution of each classifier by `learning_rate`. There is a trade-off between `learning_rate` and `n_estimators`.

algorithm : {'SAMME', 'SAMME.R'}, optional (default='SAMME.R')

If 'SAMME.R' then use the SAMME.R real boosting algorithm. `base_estimator` must support calculation of class probabilities. If 'SAMME' then use the SAMME discrete boosting algorithm. The SAMME.R algorithm typically converges faster than SAMME, achieving a lower test error with fewer boosting iterations.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **estimators_** : list of classifiers

The collection of fitted sub-estimators.

classes_ : array of shape = [n_classes]

The classes labels.

n_classes_ : int

The number of classes.

estimator_weights_ : array of floats

Weights for each estimator in the boosted ensemble.

estimator_errors_ : array of floats

Classification error for each estimator in the boosted ensemble.

feature_importances_ : array of shape = [n_features]

The feature importances if supported by the `base_estimator`.

Methods

decision_function(X)	Compute the decision function of `X`.

Continued on next page

Table 29.75 – continued from previous page

fit(X, y[, sample_weight])	Build a boosted classifier from the training set (X, y).
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict classes for X.
predict_log_proba(X)	Predict class log-probabilities for X.
predict_proba(X)	Predict class probabilities for X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.
staged_decision_function(X)	Compute decision function of X for each boosting iteration.
staged_predict(X)	Return staged predictions for X.
staged_predict_proba(X)	Predict class probabilities for X.
staged_score(X, y[, sample_weight])	Return staged scores for X, y.

__init__ (*base_estimator=None*, *n_estimators=50*, *learning_rate=1.0*, *algorithm='SAMME.R'*, *random_state=None*)

decision_function (*X*)

Compute the decision function of X.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns **score** : array, shape = [n_samples, k]

The decision function of the input samples. The order of outputs is the same of that of the *classes_* attribute. Binary classification is a special cases with `k == 1`, otherwise `k==n_classes`. For binary classification, values closer to -1 or 1 mean more like the first or second class in `classes_`, respectively.

feature_importances_

Return the feature importances (the higher, the more important the feature).

Returns **feature_importances_** : array, shape = [n_features]

fit (*X*, *y*, *sample_weight=None*)

Build a boosted classifier from the training set (X, y).

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

y : array-like of shape = [n_samples]

The target values (class labels).

sample_weight : array-like of shape = [n_samples], optional

Sample weights. If None, the sample weights are initialized to `1 / n_samples`.

Returns **self** : object

Returns self.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Predict classes for X.

The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns **y** : array of shape = [n_samples]

The predicted classes.

predict_log_proba(*X*)

Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the weighted mean predicted class log-probabilities of the classifiers in the ensemble.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns **p** : array of shape = [n_samples]

The class probabilities of the input samples. The order of outputs is the same of that of the *classes_* attribute.

predict_proba(*X*)

Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns **p** : array of shape = [n_samples]

The class probabilities of the input samples. The order of outputs is the same of that of the *classes_* attribute.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

staged_decision_function(*X*)

Compute decision function of `X` for each boosting iteration.

This method allows monitoring (i.e. determine error on testing set) after each boosting iteration.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns **score** : generator of array, shape = [n_samples, k]

The decision function of the input samples. The order of outputs is the same of that of the *classes_* attribute. Binary classification is a special cases with `k == 1`, otherwise `k==n_classes`. For binary classification, values closer to -1 or 1 mean more like the first or second class in `classes_`, respectively.

staged_predict(*X*)

Return staged predictions for X.

The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble.

This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring, such as to determine the prediction on a test set after each boost.

Parameters **X** : array-like of shape = [n_samples, n_features]

The input samples.

Returns **y** : generator of array, shape = [n_samples]

The predicted classes.

staged_predict_proba(*X*)

Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble.

This generator method yields the ensemble predicted class probabilities after each iteration of boosting and therefore allows monitoring, such as to determine the predicted class probabilities on a test set after each boost.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns **p** : generator of array, shape = [n_samples]

The class probabilities of the input samples. The order of outputs is the same of that of the *classes_* attribute.

staged_score(*X*, *y*, *sample_weight=None*)

Return staged scores for X, y.

This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

y : array-like, shape = [n_samples]

Labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **z** : float

Examples using sklearn.ensemble.AdaBoostClassifier

- *Classifier comparison*
- *Discrete versus Real AdaBoost*
- *Multi-class AdaBoosted Decision Trees*
- *Two-class AdaBoost*
- *Plot the decision surfaces of ensembles of trees on the iris dataset*

29.9.2 sklearn.ensemble.AdaBoostRegressor

class sklearn.ensemble.**AdaBoostRegressor**(*base_estimator=None*, *n_estimators=50*, *learning_rate=1.0*, *loss='linear'*, *random_state=None*)

An AdaBoost regressor.

An AdaBoost [1] regressor is a meta-estimator that begins by fitting a regressor on the original dataset and then fits additional copies of the regressor on the same dataset but where the weights of instances are adjusted according to the error of the current prediction. As such, subsequent regressors focus more on difficult cases.

This class implements the algorithm known as AdaBoost.R2 [2].

Read more in the *User Guide*.

Parameters **base_estimator** : object, optional (default=DecisionTreeRegressor)

The base estimator from which the boosted ensemble is built. Support for sample weighting is required.

n_estimators : integer, optional (default=50)

The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.

learning_rate : float, optional (default=1.)

Learning rate shrinks the contribution of each regressor by `learning_rate`. There is a trade-off between `learning_rate` and `n_estimators`.

loss : {'linear', 'square', 'exponential'}, optional (default='linear')

The loss function to use when updating the weights after each boosting iteration.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **estimators_** : list of classifiers

The collection of fitted sub-estimators.

estimator_weights_ : array of floats

Weights for each estimator in the boosted ensemble.

estimator_errors_ : array of floats

Regression error for each estimator in the boosted ensemble.

feature_importances_ : array of shape = [n_features]

The feature importances if supported by the `base_estimator`.

Methods

fit(X, y[, sample_weight])	Build a boosted regressor from the training set (X, y).
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict regression value for X.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.
staged_predict(X)	Return staged predictions for X.
staged_score(X, y[, sample_weight])	Return staged scores for X, y.

__init__(*base_estimator=None*, *n_estimators=50*, *learning_rate=1.0*, *loss='linear'*, *random_state=None*)

feature_importances_

Return the feature importances (the higher, the more important the feature).

Returns **feature_importances_** : array, shape = [n_features]

fit (*X*, *y*, *sample_weight=None*)
Build a boosted regressor from the training set (X, y).

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

y : array-like of shape = [n_samples]

The target values (real numbers).

sample_weight : array-like of shape = [n_samples], optional

Sample weights. If None, the sample weights are initialized to 1 / n_samples.

Returns **self** : object

Returns self.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*)
Predict regression value for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns **y** : array of shape = [n_samples]

The predicted regression values.

score (*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

staged_predict(*X*)
Return staged predictions for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring, such as to determine the prediction on a test set after each boost.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns **y** : generator of array, shape = [n_samples]

The predicted regression values.

staged_score(*X*, *y*, *sample_weight=None*)
Return staged scores for X, y.

This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

y : array-like, shape = [n_samples]

Labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **z** : float

Examples using `sklearn.ensemble.AdaBoostRegressor`

- *Decision Tree Regression with AdaBoost*

29.9.3 `sklearn.ensemble`.BaggingClassifier

class `sklearn.ensemble.`**BaggingClassifier**(*base_estimator=None*, *n_estimators=10*, *max_samples=1.0*, *max_features=1.0*, *bootstrap=True*, *bootstrap_features=False*, *oob_score=False*, *warm_start=False*, *n_jobs=1*, *random_state=None*, *verbose=0*)

A Bagging classifier.

A Bagging classifier is an ensemble meta-estimator that fits base classifiers each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting *[R157]*. If samples are drawn with replacement, then the method is known as Bagging *[R158]*. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces *[R159]*. Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches *[R160]*.

Read more in the *User Guide*.

Parameters **base_estimator** : object or None, optional (default=None)

The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a decision tree.

n_estimators : int, optional (default=10)

The number of base estimators in the ensemble.

max_samples : int or float, optional (default=1.0)

The number of samples to draw from X to train each base estimator.

- If int, then draw *max_samples* samples.
- If float, then draw *max_samples * X.shape[0]* samples.

max_features : int or float, optional (default=1.0)

The number of features to draw from X to train each base estimator.

- If int, then draw *max_features* features.
- If float, then draw *max_features * X.shape[1]* features.

bootstrap : boolean, optional (default=True)

Whether samples are drawn with replacement.

bootstrap_features : boolean, optional (default=False)

Whether features are drawn with replacement.

oob_score : bool

Whether to use out-of-bag samples to estimate the generalization error.

warm_start : bool, optional (default=False)

When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble.

New in version 0.17: *warm_start* constructor parameter.

n_jobs : int, optional (default=1)

The number of jobs to run in parallel for both *fit* and *predict*. If -1, then the number of jobs is set to the number of cores.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

verbose : int, optional (default=0)

Controls the verbosity of the building process.

Attributes **base_estimator_** : estimator

The base estimator from which the ensemble is grown.

estimators_ : list of estimators

The collection of fitted base estimators.

estimators_samples_ : list of arrays

The subset of drawn samples (i.e., the in-bag samples) for each base estimator. Each subset is defined by a boolean mask.

estimators_features_ : list of arrays

The subset of drawn features for each base estimator.

classes_ : array of shape = [n_classes]

The classes labels.

n_classes_ : int or list

The number of classes.

oob_score_ : float

Score of the training dataset obtained using an out-of-bag estimate.

oob_decision_function_ : array of shape = [n_samples, n_classes]

Decision function computed with out-of-bag estimate on the training set. If n_estimators is small it might be possible that a data point was never left out during the bootstrap. In this case, *oob_decision_function_* might contain NaN.

Methods

decision_function(X)	Average of the decision functions of the base classifiers.
fit(X, y[, sample_weight])	Build a Bagging ensemble of estimators from the training set (X, y).
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict class for X.
predict_log_proba(X)	Predict class log-probabilities for X.
predict_proba(X)	Predict class probabilities for X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__(*base_estimator=None*, *n_estimators=10*, *max_samples=1.0*, *max_features=1.0*, *bootstrap=True*, *bootstrap_features=False*, *oob_score=False*, *warm_start=False*, *n_jobs=1*, *random_state=None*, *verbose=0*)

decision_function(*X*)

Average of the decision functions of the base classifiers.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns **score** : array, shape = [n_samples, k]

The decision function of the input samples. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`. Regression and binary classification are special cases with `k == 1`, otherwise `k==n_classes`.

estimators_samples_

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of boolean masks identifying the samples used for for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

fit(*X*, *y*, *sample_weight=None*)

Build a Bagging ensemble of estimators from the training set (X, y).

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

y : array-like, shape = [n_samples]

The target values (class labels in classification, real numbers in regression).

sample_weight : array-like, shape = [n_samples] or None

Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

Returns **self** : object

Returns self.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Predict class for X.

The predicted class of an input sample is computed as the class with the highest mean predicted probability. If base estimators do not implement a `predict_proba` method, then it resorts to voting.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns **y** : array of shape = [n_samples]

The predicted classes.

predict_log_proba(*X*)

Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the log of the mean predicted class probabilities of the base estimators in the ensemble.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns **p** : array of shape = [n_samples, n_classes]

The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

predict_proba(*X*)

Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the mean predicted class probabilities of the base estimators in the ensemble. If base estimators do not implement a `predict_proba` method, then it resorts to voting and the predicted class probabilities of an input sample represents the proportion of estimators predicting each class.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns **p** : array of shape = [n_samples, n_classes]

The class probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.9.4 sklearn.ensemble.BaggingRegressor

class sklearn.ensemble.**BaggingRegressor**(*base_estimator=None*, *n_estimators=10*, *max_samples=1.0*, *max_features=1.0*, *bootstrap=True*, *bootstrap_features=False*, *oob_score=False*, *warm_start=False*, *n_jobs=1*, *random_state=None*, *verbose=0*)

A Bagging regressor.

A Bagging regressor is an ensemble meta-estimator that fits base regressors each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting *[R15]*. If samples are drawn with replacement, then the method is known as Bagging *[R16]*. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces *[R17]*. Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches *[R18]*.

Read more in the *User Guide*.

Parameters **base_estimator** : object or None, optional (default=None)

The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a decision tree.

n_estimators : int, optional (default=10)

The number of base estimators in the ensemble.

max_samples : int or float, optional (default=1.0)

The number of samples to draw from X to train each base estimator.

- If int, then draw *max_samples* samples.
- If float, then draw *max_samples * X.shape[0]* samples.

max_features : int or float, optional (default=1.0)

The number of features to draw from X to train each base estimator.

- If int, then draw *max_features* features.
- If float, then draw *max_features * X.shape[1]* features.

bootstrap : boolean, optional (default=True)

Whether samples are drawn with replacement.

bootstrap_features : boolean, optional (default=False)

Whether features are drawn with replacement.

oob_score : bool

Whether to use out-of-bag samples to estimate the generalization error.

warm_start : bool, optional (default=False)

When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble.

n_jobs : int, optional (default=1)

The number of jobs to run in parallel for both *fit* and *predict*. If -1, then the number of jobs is set to the number of cores.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

verbose : int, optional (default=0)

Controls the verbosity of the building process.

Attributes **estimators_** : list of estimators

The collection of fitted sub-estimators.

estimators_samples_ : list of arrays

The subset of drawn samples (i.e., the in-bag samples) for each base estimator. Each subset is defined by a boolean mask.

estimators_features_ : list of arrays

The subset of drawn features for each base estimator.

oob_score_ : float

Score of the training dataset obtained using an out-of-bag estimate.

oob_prediction_ : array of shape = [n_samples]

Prediction computed with out-of-bag estimate on the training set. If n_estimators is small it might be possible that a data point was never left out during the bootstrap. In this case, *oob_prediction_* might contain NaN.

Methods

fit(X, y[, sample_weight])	Build a Bagging ensemble of estimators from the training set (X, y).
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict regression target for X.

Continued on next page

Table 29.78 – continued from previous page

score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*base_estimator=None*, *n_estimators=10*, *max_samples=1.0*, *max_features=1.0*, *bootstrap=True*, *bootstrap_features=False*, *oob_score=False*, *warm_start=False*, *n_jobs=1*, *random_state=None*, *verbose=0*)

estimators_samples_
The subset of drawn samples for each base estimator.

Returns a dynamically generated list of boolean masks identifying the samples used for for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

fit (*X*, *y*, *sample_weight=None*)

Build a Bagging ensemble of estimators from the training set (X, y).

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

y : array-like, shape = [n_samples]

The target values (class labels in classification, real numbers in regression).

sample_weight : array-like, shape = [n_samples] or None

Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

Returns **self** : object

Returns self.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*)
Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the estimators in the ensemble.

Parameters **X** : {array-like, sparse matrix} of shape = [n_samples, n_features]

The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns **y** : array of shape = [n_samples]

The predicted values.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.ensemble.BaggingRegressor`

- *Single estimator versus bagging: bias-variance decomposition*

29.9.5 `sklearn.ensemble`.IsolationForest

class `sklearn.ensemble.`**IsolationForest**(*n_estimators=100*, *max_samples='auto'*, *contamination=0.1*, *max_features=1.0*, *bootstrap=False*, *n_jobs=1*, *random_state=None*, *verbose=0*)

Isolation Forest Algorithm

Return the anomaly score of each sample using the IsolationForest algorithm

The IsolationForest 'isolates' observations by randomly selecting a feature and then randomly selecting a split value between the maximum and minimum values of the selected feature.

Since recursive partitioning can be represented by a tree structure, the number of splittings required to isolate a sample is equivalent to the path length from the root node to the terminating node.

This path length, averaged over a forest of such random trees, is a measure of normality and our decision function.

Random partitioning produces noticeably shorter paths for anomalies. Hence, when a forest of random trees collectively produce shorter path lengths for particular samples, they are highly likely to be anomalies.

Read more in the *User Guide*.

New in version 0.18.

Parameters **n_estimators** : int, optional (default=100)

The number of base estimators in the ensemble.

max_samples : int or float, optional (default="auto")

The number of samples to draw from X to train each base estimator.

- If int, then draw *max_samples* samples.
- If float, then draw *max_samples * X.shape[0]* samples.
- If "auto", then *max_samples=min(256, n_samples)*.

If max_samples is larger than the number of samples provided, all samples will be used for all trees (no sampling).

contamination : float in (0., 0.5), optional (default=0.1)

The amount of contamination of the data set, i.e. the proportion of outliers in the data set. Used when fitting to define the threshold on the decision function.

max_features : int or float, optional (default=1.0)

The number of features to draw from X to train each base estimator.

- If int, then draw *max_features* features.
- If float, then draw *max_features * X.shape[1]* features.

bootstrap : boolean, optional (default=False)

If True, individual trees are fit on random subsets of the training data sampled with replacement. If False, sampling without replacement is performed.

n_jobs : integer, optional (default=1)

The number of jobs to run in parallel for both *fit* and *predict*. If -1, then the number of jobs is set to the number of cores.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

verbose : int, optional (default=0)

Controls the verbosity of the tree building process.

Attributes **estimators_** : list of DecisionTreeClassifier

The collection of fitted sub-estimators.

estimators_samples_ : list of arrays

The subset of drawn samples (i.e., the in-bag samples) for each base estimator.

max_samples_ : integer

The actual number of samples

References

[R21], *[R22]*

Methods

decision_function(X)	Average anomaly score of X of the base classifiers.
fit(X[, y, sample_weight])	Fit estimator.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict if a particular sample is an outlier or not.
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_estimators=100*, *max_samples='auto'*, *contamination=0.1*, *max_features=1.0*, *bootstrap=False*, *n_jobs=1*, *random_state=None*, *verbose=0*)

decision_function (*X*)
Average anomaly score of X of the base classifiers.

The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest.

The measure of normality of an observation given a tree is the depth of the leaf containing this observation, which is equivalent to the number of splittings required to isolate this point. In case of several observations n_left in the leaf, the average path length of a n_left samples isolation tree is added.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns **scores** : array of shape (n_samples,)

The anomaly score of the input samples. The lower, the more abnormal.

estimators_samples_
The subset of drawn samples for each base estimator.

Returns a dynamically generated list of boolean masks identifying the samples used for for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

fit (*X*, *y=None*, *sample_weight=None*)
Fit estimator.

Parameters **X** : array-like or sparse matrix, shape (n_samples, n_features)

The input samples. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use sparse `csc_matrix` for maximum efficiency.

Returns **self** : object

Returns self.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)
Predict if a particular sample is an outlier or not.

Parameters **X** : array-like or sparse matrix, shape (n_samples, n_features)

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

Returns **is_inlier** : array, shape (n_samples,)

For each observations, tells whether or not (+1 or -1) it should be considered as an inlier according to the fitted model.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.ensemble.IsolationForest`

- *Outlier detection with several methods.*
- *IsolationForest example*

29.9.6 `sklearn.ensemble`.RandomTreesEmbedding

class `sklearn.ensemble.`**RandomTreesEmbedding**(*n_estimators=10*, *max_depth=5*, *min_samples_split=2*, *min_samples_leaf=1*, *min_weight_fraction_leaf=0.0*, *max_leaf_nodes=None*, *min_impurity_decrease=0.0*, *min_impurity_split=None*, *sparse_output=True*, *n_jobs=1*, *random_state=None*, *verbose=0*, *warm_start=False*)

An ensemble of totally random trees.

An unsupervised transformation of a dataset to a high-dimensional sparse representation. A datapoint is coded according to which leaf of each tree it is sorted into. Using a one-hot encoding of the leaves, this leads to a binary coding with as many ones as there are trees in the forest.

The dimensionality of the resulting representation is `n_out <= n_estimators * max_leaf_nodes`. If `max_leaf_nodes == None`, the number of leaf nodes is at most `n_estimators * 2 ** max_depth`.

Read more in the *User Guide*.

Parameters **n_estimators** : integer, optional (default=10)

Number of trees in the forest.

max_depth : integer, optional (default=5)

The maximum depth of each tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

min_samples_split : int, float, optional (default=2)

The minimum number of samples required to split an internal node:

- If int, then consider *min_samples_split* as the minimum number.
- If float, then *min_samples_split* is a percentage and *ceil(min_samples_split * n_samples)* is the minimum number of samples for each split.

Changed in version 0.18: Added float values for percentages.

min_samples_leaf : int, float, optional (default=1)

The minimum number of samples required to be at a leaf node:

- If int, then consider *min_samples_leaf* as the minimum number.
- If float, then *min_samples_leaf* is a percentage and *ceil(min_samples_leaf * n_samples)* is the minimum number of samples for each node.

Changed in version 0.18: Added float values for percentages.

min_weight_fraction_leaf : float, optional (default=0.)

The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

max_leaf_nodes : int or None, optional (default=None)

Grow trees with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

min_impurity_split : float,

Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19 and will be removed in 0.21. Use `min_impurity_decrease` instead.

min_impurity_decrease : float, optional (default=0.)

A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

```
N_t / N * (impurity - N_t_R / N_t * right_impurity
                    - N_t_L / N_t * left_impurity)
```

where `N` is the total number of samples, `N_t` is the number of samples at the current node, `N_t_L` is the number of samples in the left child, and `N_t_R` is the number of samples in the right child.

`N`, `N_t`, `N_t_R` and `N_t_L` all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

bootstrap : boolean, optional (default=True)

Whether bootstrap samples are used when building trees.

sparse_output : bool, optional (default=True)

Whether or not to return a sparse CSR matrix, as default behavior, or to return a dense array compatible with dense pipeline operators.

n_jobs : integer, optional (default=1)

The number of jobs to run in parallel for both *fit* and *predict*. If -1, then the number of jobs is set to the number of cores.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

verbose : int, optional (default=0)

Controls the verbosity of the tree building process.

warm_start : bool, optional (default=False)

When set to `True`, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest.

Attributes **estimators_** : list of DecisionTreeClassifier

The collection of fitted sub-estimators.

Methods

apply(X)	Apply trees in the forest to X, return leaf indices.
decision_path(X)	Return the decision path in the forest
fit(X[, y, sample_weight])	Fit estimator.
fit_transform(X[, y, sample_weight])	Fit estimator and transform dataset.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Transform dataset.

__init__ (*n_estimators=10*, *max_depth=5*, *min_samples_split=2*, *min_samples_leaf=1*, *min_weight_fraction_leaf=0.0*, *max_leaf_nodes=None*, *min_impurity_decrease=0.0*, *min_impurity_split=None*, *sparse_output=True*, *n_jobs=1*, *random_state=None*, *verbose=0*, *warm_start=False*)

apply (*X*)

Apply trees in the forest to X, return leaf indices.

Parameters **X** : array-like or sparse matrix, shape = [n_samples, n_features]

The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

Returns **X_leaves** : array_like, shape = [n_samples, n_estimators]

For each datapoint x in X and for each tree in the forest, return the index of the leaf x ends up in.

decision_path(*X*)
Return the decision path in the forest

New in version 0.18.

Parameters **X** : array-like or sparse matrix, shape = [n_samples, n_features]

The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

Returns **indicator** : sparse csr array, shape = [n_samples, n_nodes]

Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

n_nodes_ptr : array of size (n_estimators + 1,)

The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

feature_importances_

Return the feature importances (the higher, the more important the feature).

Returns **feature_importances_** : array, shape = [n_features]

fit(*X*, *y=None*, *sample_weight=None*)
Fit estimator.

Parameters **X** : array-like or sparse matrix, shape=(n_samples, n_features)

The input samples. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use sparse `csc_matrix` for maximum efficiency.

Returns **self** : object

Returns self.

fit_transform(*X*, *y=None*, *sample_weight=None*)
Fit estimator and transform dataset.

Parameters **X** : array-like or sparse matrix, shape=(n_samples, n_features)

Input data used to build forests. Use `dtype=np.float32` for maximum efficiency.

Returns **X_transformed** : sparse matrix, shape=(n_samples, n_out)

Transformed dataset.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Transform dataset.

Parameters **X** : array-like or sparse matrix, shape=(n_samples, n_features)

Input data to be transformed. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use sparse `csr_matrix` for maximum efficiency.

Returns **X_transformed** : sparse matrix, shape=(n_samples, n_out)

Transformed dataset.

Examples using `sklearn.ensemble.RandomTreesEmbedding`

- *Feature transformations with ensembles of trees*
- *Hashing feature transformation using Totally Random Trees*

29.9.7 `sklearn.ensemble`.VotingClassifier

class `sklearn.ensemble.`**VotingClassifier**(*estimators*, *voting='hard'*, *weights=None*, *n_jobs=1*)
Soft Voting/Majority Rule classifier for unfitted estimators.

New in version 0.17.

Read more in the *User Guide*.

Parameters **estimators** : list of (string, estimator) tuples

Invoking the `fit` method on the `VotingClassifier` will fit clones of those original estimators that will be stored in the class attribute `self.estimators_`. An estimator can be set to *None* using `set_params`.

voting : str, {'hard', 'soft'} (default='hard')

If 'hard', uses predicted class labels for majority rule voting. Else if 'soft', predicts the class label based on the argmax of the sums of the predicted probabilities, which is recommended for an ensemble of well-calibrated classifiers.

weights : array-like, shape = [n_classifiers], optional (default='None')

Sequence of weights (*float* or *int*) to weight the occurrences of predicted class labels (*hard* voting) or class probabilities before averaging (*soft* voting). Uses uniform weights if *None*.

n_jobs : int, optional (default=1)

The number of jobs to run in parallel for `fit`. If -1, then the number of jobs is set to the number of cores.

Attributes **estimators_** : list of classifiers

The collection of fitted sub-estimators as defined in `estimators` that are not *None*.

classes_ : array-like, shape = [n_predictions]

The classes labels.

Examples

```
>>> import numpy as np
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.ensemble import RandomForestClassifier, VotingClassifier
>>> clf1 = LogisticRegression(random_state=1)
>>> clf2 = RandomForestClassifier(random_state=1)
>>> clf3 = GaussianNB()
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> eclf1 = VotingClassifier(estimators=[
...         ('lr', clf1), ('rf', clf2), ('gnb', clf3)], voting='hard')
>>> eclf1 = eclf1.fit(X, y)
>>> print(eclf1.predict(X))
[1 1 1 2 2 2]
>>> eclf2 = VotingClassifier(estimators=[
...         ('lr', clf1), ('rf', clf2), ('gnb', clf3)],
...         voting='soft')
>>> eclf2 = eclf2.fit(X, y)
>>> print(eclf2.predict(X))
[1 1 1 2 2 2]
>>> eclf3 = VotingClassifier(estimators=[
...        ('lr', clf1), ('rf', clf2), ('gnb', clf3)],
...        voting='soft', weights=[2,1,1])
>>> eclf3 = eclf3.fit(X, y)
>>> print(eclf3.predict(X))
[1 1 1 2 2 2]
>>>
```

Methods

fit(X, y[, sample_weight])	Fit the estimators.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get the parameters of the VotingClassifier
predict(X)	Predict class labels for X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Setting the parameters for the voting classifier
transform(X)	Return class labels or probabilities for X for each estimator.

__init__ (*estimators*, *voting='hard'*, *weights=None*, *n_jobs=1*)

fit (*X*, *y*, *sample_weight=None*)

Fit the estimators.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training vectors, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples]

Target values.

sample_weight : array-like, shape = [n_samples] or None

Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

Returns **self** : object

fit_transform(*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)

Get the parameters of the VotingClassifier

Parameters **deep: bool** :

Setting it to True gets the various classifiers and the parameters of the classifiers as well

predict(*X*)

Predict class labels for X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns **maj** : array-like, shape = [n_samples]

Predicted class labels.

predict_proba

Compute probabilities of possible outcomes for samples in X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns **avg** : array-like, shape = [n_samples, n_classes]

Weighted average probability for each class per sample.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)

Setting the parameters for the voting classifier

Valid parameter keys can be listed with get_params().

Parameters **params: keyword arguments** :

Specific parameters using e.g. set_params(parameter_name=new_value) In addition, to setting the parameters of the `VotingClassifier`, the individual classifiers of the `VotingClassifier` can also be set or replaced by setting them to None.

Examples

In this example, the RandomForestClassifier is removed clf1 = LogisticRegression() clf2 = RandomForestClassifier() eclf = VotingClassifier(estimators=[('lr', clf1), ('rf', clf2)] eclf.set_params(rf=None)

transform(*X*)

Return class labels or probabilities for X for each estimator.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns **If 'voting='soft'':** :

array-like = [n_classifiers, n_samples, n_classes] Class probabilities calculated by each classifier.

If 'voting='hard'': :

array-like = [n_samples, n_classifiers] Class labels predicted by each classifier.

Examples using `sklearn.ensemble.VotingClassifier`

- *Plot the decision boundaries of a VotingClassifier*
- *Plot class probabilities calculated by the VotingClassifier*

29.9.8 partial dependence

Partial dependence plots for tree ensembles.

ensemble.partial_dependence.partial_dependence(...)	Partial dependence of `target_variables`.

Continued on next page

Table 29.83 – continued from previous page

ensemble.partial_dependence.plot_partial_dependence(...)	Partial dependence plots for `features`.

sklearn.ensemble.partial_dependence.partial_dependence

sklearn.ensemble.partial_dependence.**partial_dependence**(*gbrt*, *target_variables*, *grid=None*, *X=None*, *percentiles=(0.05*, *0.95)*, *grid_resolution=100*)

Partial dependence of `target_variables`.

Partial dependence plots show the dependence between the joint values of the `target_variables` and the function represented by the `gbrt`.

Read more in the *User Guide*.

Parameters **gbrt** : BaseGradientBoosting

A fitted gradient boosting model.

target_variables : array-like, dtype=int

The target features for which the partial dependecy should be computed (size should be smaller than 3 for visual renderings).

grid : array-like, shape=(n_points, len(target_variables))

The grid of `target_variables` values for which the partial dependecy should be evaluated (either `grid` or `X` must be specified).

X : array-like, shape=(n_samples, n_features)

The data on which `gbrt` was trained. It is used to generate a `grid` for the `target_variables`. The `grid` comprises `grid_resolution` equally spaced points between the two `percentiles`.

percentiles : (low, high), default=(0.05, 0.95)

The lower and upper percentile used create the extreme values for the `grid`. Only if `X` is not None.

grid_resolution : int, default=100

The number of equally spaced points on the `grid`.

Returns **pdp** : array, shape=(n_classes, n_points)

The partial dependence function evaluated on the `grid`. For regression and binary classification `n_classes==1`.

axes : seq of ndarray or None

The axes with which the grid has been created or None if the grid has been given.

Examples

```
>>> samples = [[0, 0, 2], [1, 0, 0]]
>>> labels = [0, 1]
>>> from sklearn.ensemble import GradientBoostingClassifier
>>> gb = GradientBoostingClassifier(random_state=0).fit(samples, labels)
```

```
>>> kwargs = dict(X=samples, percentiles=(0, 1), grid_resolution=2)
>>> partial_dependence(gb, [0], **kwargs)
(array([[-4.52...,  4.52...]]), [array([ 0.,  1.])])
```

sklearn.ensemble.partial_dependence.plot_partial_dependence

sklearn.ensemble.partial_dependence.**plot_partial_dependence**(*gbrt*, *X*, *features*, *feature_names=None*, *label=None*, *n_cols=3*, *grid_resolution=100*, *percentiles=(0.05, 0.95)*, *n_jobs=1*, *verbose=0*, *ax=None*, *line_kw=None*, *contour_kw=None*, ***fig_kw*)

Partial dependence plots for `features`.

The `len(features)` plots are arranged in a grid with `n_cols` columns. Two-way partial dependence plots are plotted as contour plots.

Read more in the *User Guide*.

Parameters **gbrt** : BaseGradientBoosting

A fitted gradient boosting model.

X : array-like, shape=(n_samples, n_features)

The data on which `gbrt` was trained.

features : seq of ints, strings, or tuples of ints or strings

If seq[i] is an int or a tuple with one int value, a one-way PDP is created; if seq[i] is a tuple of two ints, a two-way PDP is created. If feature_names is specified and seq[i] is an int, seq[i] must be < len(feature_names). If seq[i] is a string, feature_names must be specified, and seq[i] must be in feature_names.

feature_names : seq of str

Name of each feature; feature_names[i] holds the name of the feature with index i.

label : object

The class label for which the PDPs should be computed. Only if gbrt is a multi-class model. Must be in `gbrt.classes_`.

n_cols : int

The number of columns in the grid plot (default: 3).

percentiles : (low, high), default=(0.05, 0.95)

The lower and upper percentile used to create the extreme values for the PDP axes.

grid_resolution : int, default=100

The number of equally spaced points on the axes.

n_jobs : int

The number of CPUs to use to compute the PDs. -1 means 'all CPUs'. Defaults to 1.

verbose : int

Verbose output during PD computations. Defaults to 0.

ax : Matplotlib axis object, default None

An axis object onto which the plots will be drawn.

line_kw : dict

Dict with keywords passed to the `matplotlib.pyplot.plot` call. For one-way partial dependence plots.

contour_kw : dict

Dict with keywords passed to the `matplotlib.pyplot.plot` call. For two-way partial dependence plots.

fig_kw : dict

Dict with keywords passed to the figure() call. Note that all keywords not recognized above will be automatically included here.

Returns **fig** : figure

The Matplotlib Figure object.

axs : seq of Axis objects

A seq of Axis objects, one for each subplot.

Examples

```
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.ensemble import GradientBoostingRegressor
>>> X, y = make_friedman1()
>>> clf = GradientBoostingRegressor(n_estimators=10).fit(X, y)
>>> fig, axs = plot_partial_dependence(clf, X, [0, (0, 1)])
...
```

Examples using `sklearn.ensemble.partial_dependence.plot_partial_dependence`

- *Partial Dependence Plots*

29.10 `sklearn.exceptions`: Exceptions and warnings

The *`sklearn.exceptions`* module includes all custom warnings and error classes used across scikit-learn.

`exceptions.NotFittedError`	Exception class to raise if estimator is used before fitting.
`exceptions.ChangedBehaviorWarning`	Warning class used to notify the user of any change in the behavior.
`exceptions.ConvergenceWarning`	Custom warning to capture convergence problems
`exceptions.DataConversionWarning`	Warning used to notify implicit data conversions happening in the code.

Continued on next page

Table 29.84 – continued from previous page

exceptions.DataDimensionalityWarning	Custom warning to notify potential issues with data dimensionality.
exceptions.EfficiencyWarning	Warning used to notify the user of inefficient computation.
exceptions.FitFailedWarning	Warning class used if there is an error while fitting the estimator.
exceptions.NonBLASDotWarning	Warning used when the dot operation does not use BLAS.
exceptions.UndefinedMetricWarning	Warning used when the metric is invalid

29.10.1 sklearn.exceptions.NotFittedError

class sklearn.exceptions.**NotFittedError**

Exception class to raise if estimator is used before fitting.

This class inherits from both ValueError and AttributeError to help with exception handling and backward compatibility.

Examples

```
>>> from sklearn.svm import LinearSVC
>>> from sklearn.exceptions import NotFittedError
>>> try:
...     LinearSVC().predict([[1, 2], [2, 3], [3, 4]])
... except NotFittedError as e:
...     print(repr(e))
...
NotFittedError('This LinearSVC instance is not fitted yet',)
```

Changed in version 0.18: Moved from sklearn.utils.validation.

Methods

with_traceback	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

29.10.2 sklearn.exceptions.ChangedBehaviorWarning

class sklearn.exceptions.**ChangedBehaviorWarning**

Warning class used to notify the user of any change in the behavior.

Changed in version 0.18: Moved from sklearn.base.

Methods

with_traceback	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

29.10.3 sklearn.exceptions.ConvergenceWarning

class sklearn.exceptions.**ConvergenceWarning**
Custom warning to capture convergence problems

Changed in version 0.18: Moved from sklearn.utils.

Methods

with_traceback	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

Examples using sklearn.exceptions.ConvergenceWarning

- *Sparse recovery: feature selection for sparse linear models*

29.10.4 sklearn.exceptions.DataConversionWarning

class sklearn.exceptions.**DataConversionWarning**
Warning used to notify implicit data conversions happening in the code.

This warning occurs when some input data needs to be converted or interpreted in a way that may not match the user's expectations.

For example, this warning may occur when the user

- passes an integer array to a function which expects float input and will convert the input
- requests a non-copying operation, but a copy is required to meet the implementation's data-type expectations;
- passes an input whose shape can be interpreted ambiguously.

Changed in version 0.18: Moved from sklearn.utils.validation.

Methods

with_traceback	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

29.10.5 sklearn.exceptions.DataDimensionalityWarning

class sklearn.exceptions.**DataDimensionalityWarning**
Custom warning to notify potential issues with data dimensionality.

For example, in random projection, this warning is raised when the number of components, which quantifies the dimensionality of the target projection space, is higher than the number of features, which quantifies the dimensionality of the original source space, to imply that the dimensionality of the problem will not be reduced.

Changed in version 0.18: Moved from sklearn.utils.

Methods

with_traceback	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

29.10.6 sklearn.exceptions.EfficiencyWarning

class sklearn.exceptions.**EfficiencyWarning**
Warning used to notify the user of inefficient computation.

This warning notifies the user that the efficiency may not be optimal due to some reason which may be included as a part of the warning message. This may be subclassed into a more specific Warning class.

New in version 0.18.

Methods

with_traceback	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

29.10.7 sklearn.exceptions.FitFailedWarning

class sklearn.exceptions.**FitFailedWarning**
Warning class used if there is an error while fitting the estimator.

This Warning is used in meta estimators GridSearchCV and RandomizedSearchCV and the cross-validation helper function cross_val_score to warn when there is an error while fitting the estimator.

Examples

```
>>> from sklearn.model_selection import GridSearchCV
>>> from sklearn.svm import LinearSVC
>>> from sklearn.exceptions import FitFailedWarning
>>> import warnings
>>> warnings.simplefilter('always', FitFailedWarning)
>>> gs = GridSearchCV(LinearSVC(), {'C': [-1, -2]}, error_score=0)
>>> X, y = [[1, 2], [3, 4], [5, 6], [7, 8], [8, 9]], [0, 0, 0, 1, 1]
>>> with warnings.catch_warnings(record=True) as w:
...     try:
...         gs.fit(X, y)   # This will raise a ValueError since C is < 0
...     except ValueError:
...         pass
...     print(repr(w[-1].message))
...
FitFailedWarning("Classifier fit failed. The score on this train-test
partition for these parameters will be set to 0.000000. Details:
\nValueError('Penalty term must be positive; got (C=-2)',)",)
```

Changed in version 0.18: Moved from sklearn.cross_validation.

Methods

with_traceback	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

29.10.8 sklearn.exceptions.NonBLASDotWarning

class sklearn.exceptions.**NonBLASDotWarning**
Warning used when the dot operation does not use BLAS.

This warning is used to notify the user that BLAS was not used for dot operation and hence the efficiency may be affected.

Changed in version 0.18: Moved from sklearn.utils.validation, extends EfficiencyWarning.

Methods

with_traceback	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

29.10.9 sklearn.exceptions.UndefinedMetricWarning

class sklearn.exceptions.**UndefinedMetricWarning**
Warning used when the metric is invalid

Changed in version 0.18: Moved from sklearn.base.

Methods

with_traceback	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

29.11 sklearn.feature_extraction: Feature Extraction

The *sklearn.feature_extraction* module deals with feature extraction from raw data. It currently includes methods to extract features from text and images.

User guide: See the *Feature extraction* section for further details.

feature_extraction.DictVectorizer([dtype, ...])	Transforms lists of feature-value mappings to vectors.
feature_extraction.FeatureHasher([...])	Implements feature hashing, aka the hashing trick.

29.11.1 sklearn.feature_extraction.DictVectorizer

class sklearn.feature_extraction.**DictVectorizer**(*dtype=<class 'numpy.float64'>*, *separator='='*, *sparse=True*, *sort=True*)
Transforms lists of feature-value mappings to vectors.

This transformer turns lists of mappings (dict-like objects) of feature names to feature values into Numpy arrays or scipy.sparse matrices for use with scikit-learn estimators.

When feature values are strings, this transformer will do a binary one-hot (aka one-of-K) coding: one boolean-valued feature is constructed for each of the possible string values that the feature can take on. For instance, a feature "f" that can take on the values "ham" and "spam" will become two features in the output, one signifying "f=ham", the other "f=spam".

However, note that this transformer will only do a binary one-hot encoding when feature values are of type string. If categorical features are represented as numeric values such as int, the DictVectorizer can be followed by OneHotEncoder to complete binary one-hot encoding.

Features that do not occur in a sample (mapping) will have a zero value in the resulting array/matrix.

Read more in the *User Guide*.

Parameters **dtype** : callable, optional

The type of feature values. Passed to Numpy array/scipy.sparse matrix constructors as the dtype argument.

separator : string, optional

Separator string used when constructing new features for one-hot coding.

sparse : boolean, optional.

Whether transform should produce scipy.sparse matrices. True by default.

sort : boolean, optional.

Whether `feature_names_` and `vocabulary_` should be sorted when fitting. True by default.

Attributes **vocabulary_** : dict

A dictionary mapping feature names to feature indices.

feature_names_ : list

A list of length n_features containing the feature names (e.g., "f=ham" and "f=spam").

See also:

FeatureHasher performs vectorization using only a hash function.

sklearn.preprocessing.OneHotEncoder handles nominal/categorical features encoded as columns of integers.

Examples

```
>>> from sklearn.feature_extraction import DictVectorizer
>>> v = DictVectorizer(sparse=False)
>>> D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]
>>> X = v.fit_transform(D)
>>> X
array([[ 2.,  0.,  1.],
       [ 0.,  1.,  3.]])
>>> v.inverse_transform(X) ==         [{'bar': 2.0, 'foo': 1.0}, {'baz': 1.0, 'foo
↪': 3.0}]
True
>>> v.transform({'foo': 4, 'unseen_feature': 3})
array([[ 0.,  0.,  4.]])
```

Methods

fit(X[, y])	Learn a list of feature name -> indices mappings.
fit_transform(X[, y])	Learn a list of feature name -> indices mappings and transform X.
get_feature_names()	Returns a list of feature names, ordered by their indices.
get_params([deep])	Get parameters for this estimator.
inverse_transform(X[, dict_type])	Transform array or sparse matrix X back to feature mappings.
restrict(support[, indices])	Restrict the features to those in support using feature selection.
set_params(**params)	Set the parameters of this estimator.
transform(X[, y])	Transform feature->value dicts to array or sparse matrix.

__init__ (*dtype=<class 'numpy.float64'>*, *separator='='*, *sparse=True*, *sort=True*)

fit (*X*, *y=None*)
Learn a list of feature name -> indices mappings.

Parameters **X** : Mapping or iterable over Mappings

Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).

y : (ignored)

Returns **self** :

fit_transform (*X*, *y=None*)
Learn a list of feature name -> indices mappings and transform X.

Like fit(X) followed by transform(X), but does not require materializing X in memory.

Parameters **X** : Mapping or iterable over Mappings

Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).

y : (ignored)

Returns **Xa** : {array, sparse matrix}

Feature vectors; always 2-d.

get_feature_names ()
Returns a list of feature names, ordered by their indices.

If one-of-K coding is applied to categorical features, this will include the constructed feature names but not the original ones.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform (*X*, *dict_type=<class 'dict'>*)
Transform array or sparse matrix X back to feature mappings.

X must have been produced by this DictVectorizer's transform or fit_transform method; it may only have passed through transformers that preserve the number of features and their order.

In the case of one-hot/one-of-K coding, the constructed feature names and values are returned rather than the original ones.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Sample matrix.

dict_type : callable, optional

Constructor for feature mappings. Must conform to the collections.Mapping API.

Returns **D** : list of dict_type objects, length = n_samples

Feature mappings for the samples in X.

restrict(*support*, *indices=False*)
Restrict the features to those in support using feature selection.

This function modifies the estimator in-place.

Parameters **support** : array-like

Boolean mask or list of indices (as returned by the get_support member of feature selectors).

indices : boolean, optional

Whether support is a list of indices.

Returns **self** :

Examples

```
>>> from sklearn.feature_extraction import DictVectorizer
>>> from sklearn.feature_selection import SelectKBest, chi2
>>> v = DictVectorizer()
>>> D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]
>>> X = v.fit_transform(D)
>>> support = SelectKBest(chi2, k=2).fit(X, [0, 1])
>>> v.get_feature_names()
['bar', 'baz', 'foo']
>>> v.restrict(support.get_support())
DictVectorizer(dtype=..., separator='=', sort=True,
        sparse=True)
>>> v.get_feature_names()
['bar', 'foo']
```

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *y=None*)
Transform feature->value dicts to array or sparse matrix.

Named features not encountered during fit or fit_transform will be silently ignored.

Parameters **X** : Mapping or iterable over Mappings, length = n_samples

Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).

y : (ignored)

Returns **Xa** : {array, sparse matrix}

Feature vectors; always 2-d.

Examples using `sklearn.feature_extraction.DictVectorizer`

- *Feature Union with Heterogeneous Data Sources*

- *FeatureHasher and DictVectorizer Comparison*

29.11.2 sklearn.feature_extraction.FeatureHasher

class sklearn.feature_extraction.**FeatureHasher**(*n_features=1048576*, *input_type='dict'*, *dtype=<class 'numpy.float64'>*, *alternate_sign=True*, *non_negative=False*)

Implements feature hashing, aka the hashing trick.

This class turns sequences of symbolic feature names (strings) into scipy.sparse matrices, using a hash function to compute the matrix column corresponding to a name. The hash function employed is the signed 32-bit version of Murmurhash3.

Feature names of type byte string are used as-is. Unicode strings are converted to UTF-8 first, but no Unicode normalization is done. Feature values must be (finite) numbers.

This class is a low-memory alternative to DictVectorizer and CountVectorizer, intended for large-scale (online) learning and situations where memory is tight, e.g. when running prediction code on embedded devices.

Read more in the *User Guide*.

Parameters **n_features** : integer, optional

The number of features (columns) in the output matrices. Small numbers of features are likely to cause hash collisions, but large numbers will cause larger coefficient dimensions in linear learners.

dtype : numpy type, optional, default np.float64

The type of feature values. Passed to scipy.sparse matrix constructors as the dtype argument. Do not set this to bool, np.boolean or any unsigned integer type.

input_type : string, optional, default "dict"

Either "dict" (the default) to accept dictionaries over (feature_name, value); "pair" to accept pairs of (feature_name, value); or "string" to accept single strings. feature_name should be a string, while value should be a number. In the case of "string", a value of 1 is implied. The feature_name is hashed to find the appropriate column for the feature. The value's sign might be flipped in the output (but see non_negative, below).

alternate_sign : boolean, optional, default True

When True, an alternating sign is added to the features as to approximately conserve the inner product in the hashed space even for small n_features. This approach is similar to sparse random projection.

non_negative : boolean, optional, default False

When True, an absolute value is applied to the features matrix prior to returning it. When used in conjunction with alternate_sign=True, this significantly reduces the inner product preservation property. .. deprecated:: 0.19

This option will be removed in 0.21.

See also:

DictVectorizer vectorizes string-valued features using a hash table.

sklearn.preprocessing.OneHotEncoder handles nominal/categorical features encoded as columns of integers.

Examples

```
>>> from sklearn.feature_extraction import FeatureHasher
>>> h = FeatureHasher(n_features=10)
>>> D = [{'dog': 1, 'cat':2, 'elephant':4},{'dog': 2, 'run': 5}]
>>> f = h.transform(D)
>>> f.toarray()
array([[ 0.,  0., -4., -1.,  0.,  0.,  0.,  0.,  0.,  2.],
       [ 0.,  0.,  0., -2., -5.,  0.,  0.,  0.,  0.,  0.]])
```

Methods

fit([X, y])	No-op.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(raw_X[, y])	Transform a sequence of instances to a scipy.sparse matrix.

__init__ (*n_features=1048576*, *input_type='dict'*, *dtype=<class 'numpy.float64'>*, *alternate_sign=True*, *non_negative=False*)

fit (*X=None*, *y=None*)
No-op.

This method doesn't do anything. It exists purely for compatibility with the scikit-learn transformer API.

Returns **self** : FeatureHasher

fit_transform (*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*raw_X*, *y=None*)
Transform a sequence of instances to a scipy.sparse matrix.

Parameters **raw_X** : iterable over iterable over raw features, length = n_samples

Samples. Each sample must be iterable an (e.g., a list or tuple) containing/generating feature names (and optionally values, see the input_type constructor argument) which will be hashed. raw_X need not support the len function, so it can be the result of a generator; n_samples is determined on the fly.

y : (ignored)

Returns **X** : scipy.sparse matrix, shape = (n_samples, self.n_features)

Feature matrix, for use with estimators or further transformers.

Examples using `sklearn.feature_extraction.FeatureHasher`

- *FeatureHasher and DictVectorizer Comparison*

29.11.3 From images

The *sklearn.feature_extraction.image* submodule gathers utilities to extract features from images.

feature_extraction.image.img_to_graph(img[, ...])	Graph of the pixel-to-pixel gradient connections
feature_extraction.image.grid_to_graph(n_x, n_y)	Graph of the pixel-to-pixel connections
feature_extraction.image.extract_patches_2d(...)	Reshape a 2D image into a collection of patches
feature_extraction.image.reconstruct_from_patches_2d(...)	Reconstruct the image from all of its patches.
feature_extraction.image.PatchExtractor([...])	Extracts patches from a collection of images

sklearn.feature_extraction.image.img_to_graph

sklearn.feature_extraction.image.**img_to_graph**(*img*, *mask=None*, *return_as=<class 'scipy.sparse.coo.coo_matrix'>*, *dtype=None*)

Graph of the pixel-to-pixel gradient connections

Edges are weighted with the gradient values.

Read more in the *User Guide*.

Parameters **img** : ndarray, 2D or 3D

2D or 3D image

mask : ndarray of booleans, optional

An optional mask of the image, to consider only part of the pixels.

return_as : np.ndarray or a sparse matrix class, optional

The class to use to build the returned adjacency matrix.

dtype : None or dtype, optional

The data of the returned sparse matrix. By default it is the dtype of img

Notes

For scikit-learn versions 0.14.1 and prior, return_as=np.ndarray was handled by returning a dense np.matrix instance. Going forward, np.ndarray returns an np.ndarray, as expected.

For compatibility, user code relying on this method should wrap its calls in `np.asarray` to avoid type issues.

sklearn.feature_extraction.image.grid_to_graph

sklearn.feature_extraction.image.**grid_to_graph**(*n_x*, *n_y*, *n_z=1*, *mask=None*, *return_as=<class 'scipy.sparse.coo.coo_matrix'>*, *dtype=<class 'int'>*)

Graph of the pixel-to-pixel connections

Edges exist if 2 voxels are connected.

Parameters **n_x** : int

Dimension in x axis

n_y : int

Dimension in y axis

n_z : int, optional, default 1

Dimension in z axis

mask : ndarray of booleans, optional

An optional mask of the image, to consider only part of the pixels.

return_as : np.ndarray or a sparse matrix class, optional

The class to use to build the returned adjacency matrix.

dtype : dtype, optional, default int

The data of the returned sparse matrix. By default it is int

Notes

For scikit-learn versions 0.14.1 and prior, return_as=np.ndarray was handled by returning a dense np.matrix instance. Going forward, np.ndarray returns an np.ndarray, as expected.

For compatibility, user code relying on this method should wrap its calls in `np.asarray` to avoid type issues.

sklearn.feature_extraction.image.extract_patches_2d

sklearn.feature_extraction.image.**extract_patches_2d**(*image*, *patch_size*, *max_patches=None*, *random_state=None*)

Reshape a 2D image into a collection of patches

The resulting patches are allocated in a dedicated array.

Read more in the *User Guide*.

Parameters **image** : array, shape = (image_height, image_width) or

(image_height, image_width, n_channels) The original image data. For color images, the last dimension specifies the channel: a RGB image would have *n_channels=3*.

patch_size : tuple of ints (patch_height, patch_width)

the dimensions of one patch

max_patches : integer or float, optional default is None

The maximum number of patches to extract. If max_patches is a float between 0 and 1, it is taken to be a proportion of the total number of patches.

random_state : int, RandomState instance or None, optional (default=None)

Pseudo number generator state used for random sampling to use if *max_patches* is not None. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **patches** : array, shape = (n_patches, patch_height, patch_width) or

(n_patches, patch_height, patch_width, n_channels) The collection of patches extracted from the image, where *n_patches* is either *max_patches* or the total number of patches that can be extracted.

Examples

```
>>> from sklearn.feature_extraction import image
>>> one_image = np.arange(16).reshape((4, 4))
>>> one_image
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15]])
>>> patches = image.extract_patches_2d(one_image, (2, 2))
>>> print(patches.shape)
(9, 2, 2)
>>> patches[0]
array([[0, 1],
       [4, 5]])
>>> patches[1]
array([[1, 2],
       [5, 6]])
>>> patches[8]
array([[10, 11],
       [14, 15]])
```

Examples using sklearn.feature_extraction.image.extract_patches_2d

- *Online learning of a dictionary of parts of faces*
- *Image denoising using dictionary learning*

sklearn.feature_extraction.image.reconstruct_from_patches_2d

sklearn.feature_extraction.image.**reconstruct_from_patches_2d**(*patches*, *image_size*)

Reconstruct the image from all of its patches.

Patches are assumed to overlap and the image is constructed by filling in the patches from left to right, top to bottom, averaging the overlapping regions.

Read more in the *User Guide*.

Parameters **patches** : array, shape = (n_patches, patch_height, patch_width) or

(n_patches, patch_height, patch_width, n_channels) The complete set of patches. If the patches contain colour information, channels are indexed along the last dimension: RGB patches would have *n_channels=3*.

image_size : tuple of ints (image_height, image_width) or

(image_height, image_width, n_channels) the size of the image that will be reconstructed

Returns **image** : array, shape = image_size

the reconstructed image

Examples using sklearn.feature_extraction.image.reconstruct_from_patches_2d

- *Image denoising using dictionary learning*

sklearn.feature_extraction.image.PatchExtractor

class sklearn.feature_extraction.image.**PatchExtractor**(*patch_size=None*, *max_patches=None*, *random_state=None*)

Extracts patches from a collection of images

Read more in the *User Guide*.

Parameters **patch_size** : tuple of ints (patch_height, patch_width)

the dimensions of one patch

max_patches : integer or float, optional default is None

The maximum number of patches per image to extract. If max_patches is a float in (0, 1), it is taken to mean a proportion of the total number of patches.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Methods

fit(X[, y])	Do nothing and return the estimator unchanged
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Transforms the image samples in X into a matrix of patch data.

__init__ (*patch_size=None*, *max_patches=None*, *random_state=None*)

fit (*X*, *y=None*)
Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform (*X*)
Transforms the image samples in X into a matrix of patch data.

Parameters **X** : array, shape = (n_samples, image_height, image_width) or

(n_samples, image_height, image_width, n_channels) Array of images from which to extract patches. For color images, the last dimension specifies the channel: a RGB image would have *n_channels=3*.

Returns **patches** : array, shape = (n_patches, patch_height, patch_width) or

(n_patches, patch_height, patch_width, n_channels) The collection of patches extracted from the images, where *n_patches* is either *n_samples * max_patches* or the total number of patches that can be extracted.

29.11.4 From text

The *sklearn.feature_extraction.text* submodule gathers utilities to build feature vectors from text documents.

feature_extraction.text.CountVectorizer([...])	Convert a collection of text documents to a matrix of token counts

Continued on next page

Table 29.99 – continued from previous page

feature_extraction.text.HashingVectorizer([...])	Convert a collection of text documents to a matrix of token occurrences
feature_extraction.text.TfidfTransformer([...])	Transform a count matrix to a normalized tf or tf-idf representation
feature_extraction.text.TfidfVectorizer([...])	Convert a collection of raw documents to a matrix of TF-IDF features.

sklearn.feature_extraction.text.CountVectorizer

class sklearn.feature_extraction.text.**CountVectorizer**(*input='content'*, *encoding='utf-8'*, *decode_error='strict'*, *strip_accents=None*, *lowercase=True*, *preprocessor=None*, *tokenizer=None*, *stop_words=None*, *token_pattern='(?u)\b\w\w+\b'*, *ngram_range=(1, 1)*, *analyzer='word'*, *max_df=1.0*, *min_df=1*, *max_features=None*, *vocabulary=None*, *binary=False*, *dtype=<class 'numpy.int64'>*)

Convert a collection of text documents to a matrix of token counts

This implementation produces a sparse representation of the counts using scipy.sparse.csr_matrix.

If you do not provide an a-priori dictionary and you do not use an analyzer that does some kind of feature selection then the number of features will be equal to the vocabulary size found by analyzing the data.

Read more in the *User Guide*.

Parameters **input** : string {'filename', 'file', 'content'}

If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be the sequence strings or bytes items are expected to be analyzed directly.

encoding : string, 'utf-8' by default.

If bytes or files are given to analyze, this encoding is used to decode.

decode_error : {'strict', 'ignore', 'replace'}

Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given *encoding*. By default, it is 'strict', meaning that a UnicodeDecodeError will be raised. Other values are 'ignore' and 'replace'.

strip_accents : {'ascii', 'unicode', None}

Remove accents during the preprocessing step. 'ascii' is a fast method that only works on characters that have an direct ASCII mapping. 'unicode' is a slightly slower method that works on any characters. None (default) does nothing.

analyzer : string, {'word', 'char', 'char_wb'} or callable

Whether the feature should be made of word or character n-grams. Option 'char_wb' creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

preprocessor : callable or None (default)

Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps.

tokenizer : callable or None (default)

Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if `analyzer == 'word'`.

ngram_range : tuple (min_n, max_n)

The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used.

stop_words : string {'english'}, list, or None (default)

If 'english', a built-in stop word list for English is used.

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer == 'word'`.

If None, no stop words will be used. max_df can be set to a value in the range [0.7, 1.0) to automatically detect and filter stop words based on intra corpus document frequency of terms.

lowercase : boolean, True by default

Convert all characters to lowercase before tokenizing.

token_pattern : string

Regular expression denoting what constitutes a "token", only used if `analyzer == 'word'`. The default regexp select tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

max_df : float in range [0.0, 1.0] or int, default=1.0

When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop words). If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

min_df : float in range [0.0, 1.0] or int, default=1

When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

max_features : int or None, default=None

If not None, build a vocabulary that only consider the top max_features ordered by term frequency across the corpus.

This parameter is ignored if vocabulary is not None.

vocabulary : Mapping or iterable, optional

Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents. Indices in the mapping should not be repeated and should not have any gap between 0 and the largest index.

binary : boolean, default=False

If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

dtype : type, optional

Type of the matrix returned by fit_transform() or transform().

Attributes **vocabulary_** : dict

A mapping of terms to feature indices.

stop_words_ : set

Terms that were ignored because they either:

- occurred in too many documents (*max_df*)
- occurred in too few documents (*min_df*)
- were cut off by feature selection (*max_features*).

This is only available if no vocabulary was given.

See also:

HashingVectorizer, *TfidfVectorizer*

Notes

The `stop_words_` attribute can get large and increase the model size when pickling. This attribute is provided only for introspection and can be safely removed using delattr or set to None before pickling.

Methods

build_analyzer()	Return a callable that handles preprocessing and tokenization
build_preprocessor()	Return a function to preprocess the text before tokenization
build_tokenizer()	Return a function that splits a string into a sequence of tokens
decode(doc)	Decode the input into a string of unicode symbols
fit(raw_documents[, y])	Learn a vocabulary dictionary of all tokens in the raw documents.
fit_transform(raw_documents[, y])	Learn the vocabulary dictionary and return term-document matrix.
get_feature_names()	Array mapping from feature integer indices to feature name
get_params([deep])	Get parameters for this estimator.
get_stop_words()	Build or fetch the effective stop words list
inverse_transform(X)	Return terms per document with nonzero entries in X.

Continued on next page

Table 29.100 – continued from previous page

set_params(**params)	Set the parameters of this estimator.
transform(raw_documents)	Transform documents to document-term matrix.

__init__(*input='content'*, *encoding='utf-8'*, *decode_error='strict'*, *strip_accents=None*, *lowercase=True*, *preprocessor=None*, *tokenizer=None*, *stop_words=None*, *token_pattern='(?u)\\b\\w\\w+\\b'*, *ngram_range=(1, 1)*, *analyzer='word'*, *max_df=1.0*, *min_df=1*, *max_features=None*, *vocabulary=None*, *binary=False*, *dtype=<class 'numpy.int64'>*)

build_analyzer()
Return a callable that handles preprocessing and tokenization

build_preprocessor()
Return a function to preprocess the text before tokenization

build_tokenizer()
Return a function that splits a string into a sequence of tokens

decode(*doc*)
Decode the input into a string of unicode symbols

The decoding strategy depends on the vectorizer parameters.

fit(*raw_documents*, *y=None*)
Learn a vocabulary dictionary of all tokens in the raw documents.

Parameters **raw_documents** : iterable

An iterable which yields either str, unicode or file objects.

Returns **self** :

fit_transform(*raw_documents*, *y=None*)
Learn the vocabulary dictionary and return term-document matrix.

This is equivalent to fit followed by transform, but more efficiently implemented.

Parameters **raw_documents** : iterable

An iterable which yields either str, unicode or file objects.

Returns **X** : array, [n_samples, n_features]

Document-term matrix.

get_feature_names()
Array mapping from feature integer indices to feature name

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_stop_words()
Build or fetch the effective stop words list

inverse_transform(*X*)
Return terms per document with nonzero entries in X.

Parameters **X** : {array, sparse matrix}, shape = [n_samples, n_features]

Returns **X_inv** : list of arrays, len = n_samples

List of arrays of terms.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*raw_documents*)
Transform documents to document-term matrix.

Extract token counts out of raw text documents using the vocabulary fitted with fit or the one provided to the constructor.

Parameters **raw_documents** : iterable

An iterable which yields either str, unicode or file objects.

Returns **X** : sparse matrix, [n_samples, n_features]

Document-term matrix.

Examples using `sklearn.feature_extraction.text.CountVectorizer`

- *Topic extraction with Non-negative Matrix Factorizationand Latent Dirichlet Allocation*
- *Sample pipeline for text feature extraction and evaluation*

`sklearn.feature_extraction.text`.HashingVectorizer

class sklearn.feature_extraction.text.**HashingVectorizer**(*input='content', encoding='utf-8', decode_error='strict', strip_accents=None, lowercase=True, preprocessor=None, tokenizer=None, stop_words=None, token_pattern='(?u)\b\w\w+\b', ngram_range=(1, 1), analyzer='word', n_features=1048576, binary=False, norm='l2', alternate_sign=True, non_negative=False, dtype=<class 'numpy.float64'>*)
Convert a collection of text documents to a matrix of token occurrences

It turns a collection of text documents into a scipy.sparse matrix holding token occurrence counts (or binary occurrence information), possibly normalized as token frequencies if norm='l1' or projected on the euclidean unit sphere if norm='l2'.

This text vectorizer implementation uses the hashing trick to find the token string name to feature integer index mapping.

This strategy has several advantages:

- it is very low memory scalable to large datasets as there is no need to store a vocabulary dictionary in memory
- it is fast to pickle and un-pickle as it holds no state besides the constructor parameters
- it can be used in a streaming (partial fit) or parallel pipeline as there is no state computed during fit.

There are also a couple of cons (vs using a CountVectorizer with an in-memory vocabulary):

- there is no way to compute the inverse transform (from feature indices to string feature names) which can be a problem when trying to introspect which features are most important to a model.
- there can be collisions: distinct tokens can be mapped to the same feature index. However in practice this is rarely an issue if n_features is large enough (e.g. 2 ** 18 for text classification problems).
- no IDF weighting as this would render the transformer stateful.

The hash function employed is the signed 32-bit version of Murmurhash3.

Read more in the *User Guide*.

Parameters **input** : string {'filename', 'file', 'content'}

If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be the sequence strings or bytes items are expected to be analyzed directly.

encoding : string, default='utf-8'

If bytes or files are given to analyze, this encoding is used to decode.

decode_error : {'strict', 'ignore', 'replace'}

Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given *encoding*. By default, it is 'strict', meaning that a UnicodeDecodeError will be raised. Other values are 'ignore' and 'replace'.

strip_accents : {'ascii', 'unicode', None}

Remove accents during the preprocessing step. 'ascii' is a fast method that only works on characters that have an direct ASCII mapping. 'unicode' is a slightly slower method that works on any characters. None (default) does nothing.

analyzer : string, {'word', 'char', 'char_wb'} or callable

Whether the feature should be made of word or character n-grams. Option 'char_wb' creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

preprocessor : callable or None (default)

Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps.

tokenizer : callable or None (default)

Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if `analyzer == 'word'`.

ngram_range : tuple (min_n, max_n), default=(1, 1)

The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used.

stop_words : string {'english'}, list, or None (default)

If 'english', a built-in stop word list for English is used.

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer == 'word'`.

lowercase : boolean, default=True

Convert all characters to lowercase before tokenizing.

token_pattern : string

Regular expression denoting what constitutes a "token", only used if `analyzer == 'word'`. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

n_features : integer, default=(2 ** 20)

The number of features (columns) in the output matrices. Small numbers of features are likely to cause hash collisions, but large numbers will cause larger coefficient dimensions in linear learners.

norm : 'l1', 'l2' or None, optional

Norm used to normalize term vectors. None for no normalization.

binary : boolean, default=False.

If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

dtype : type, optional

Type of the matrix returned by fit_transform() or transform().

alternate_sign : boolean, optional, default True

When True, an alternating sign is added to the features as to approximately conserve the inner product in the hashed space even for small n_features. This approach is similar to sparse random projection.

New in version 0.19.

non_negative : boolean, optional, default False

When True, an absolute value is applied to the features matrix prior to returning it. When used in conjunction with alternate_sign=True, this significantly reduces the inner product preservation property.

Deprecated since version 0.19: This option will be removed in 0.21.

CountVectorizer, *TfidfVectorizer*

Methods

build_analyzer()	Return a callable that handles preprocessing and tokenization
build_preprocessor()	Return a function to preprocess the text before tokenization
build_tokenizer()	Return a function that splits a string into a sequence of tokens
decode(doc)	Decode the input into a string of unicode symbols
fit(X[, y])	Does nothing: this transformer is stateless.
fit_transform(X)	Transform a sequence of documents to a document-term matrix.
get_params([deep])	Get parameters for this estimator.
get_stop_words()	Build or fetch the effective stop words list
partial_fit(X[, y])	Does nothing: this transformer is stateless.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Transform a sequence of documents to a document-term matrix.

__init__(*input='content'*, *encoding='utf-8'*, *decode_error='strict'*, *strip_accents=None*, *lowercase=True*, *preprocessor=None*, *tokenizer=None*, *stop_words=None*, *token_pattern='(?u)\\b\\w\\w+\\b'*, *ngram_range=(1, 1)*, *analyzer='word'*, *n_features=1048576*, *binary=False*, *norm='l2'*, *alternate_sign=True*, *non_negative=False*, *dtype=<class 'numpy.float64'>*)

build_analyzer()
Return a callable that handles preprocessing and tokenization

build_preprocessor()
Return a function to preprocess the text before tokenization

build_tokenizer()
Return a function that splits a string into a sequence of tokens

decode(*doc*)
Decode the input into a string of unicode symbols

The decoding strategy depends on the vectorizer parameters.

fit(*X*, *y=None*)
Does nothing: this transformer is stateless.

fit_transform(*X*)
Transform a sequence of documents to a document-term matrix.

Parameters **X** : iterable over raw text documents, length = n_samples

Samples. Each sample must be a text document (either bytes or unicode strings, file name or file object depending on the constructor argument) which will be tokenized and hashed.

Returns **X** : scipy.sparse matrix, shape = (n_samples, self.n_features)

Document-term matrix.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_stop_words()
Build or fetch the effective stop words list

partial_fit(*X*, *y=None*)
Does nothing: this transformer is stateless.

This method is just there to mark the fact that this transformer can work in a streaming setup.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Transform a sequence of documents to a document-term matrix.

Parameters **X** : iterable over raw text documents, length = n_samples

Samples. Each sample must be a text document (either bytes or unicode strings, file name or file object depending on the constructor argument) which will be tokenized and hashed.

Returns **X** : scipy.sparse matrix, shape = (n_samples, self.n_features)

Document-term matrix.

Examples using `sklearn.feature_extraction.text.HashingVectorizer`

- *Out-of-core classification of text documents*
- *Classification of text documents using sparse features*
- *Clustering text documents using k-means*

`sklearn.feature_extraction.text`.TfidfTransformer

class `sklearn.feature_extraction.text.`**TfidfTransformer**(*norm='l2'*, *use_idf=True*, *smooth_idf=True*, *sublinear_tf=False*)
Transform a count matrix to a normalized tf or tf-idf representation

Tf means term-frequency while tf-idf means term-frequency times inverse document-frequency. This is a common term weighting scheme in information retrieval, that has also found good use in document classification.

The goal of using tf-idf instead of the raw frequencies of occurrence of a token in a given document is to scale down the impact of tokens that occur very frequently in a given corpus and that are hence empirically less informative than features that occur in a small fraction of the training corpus.

The formula that is used to compute the tf-idf of term t is tf-idf(d, t) = tf(t) * idf(d, t), and the idf is computed as idf(d, t) = log [n / df(d, t)] + 1 (if `smooth_idf=False`), where n is the total number of documents and df(d, t) is the document frequency; the document frequency is the number of documents d that contain term t. The effect of adding "1" to the idf in the equation above is that terms with zero idf, i.e., terms that occur in all documents in a training set, will not be entirely ignored. (Note that the idf formula above differs from the standard textbook notation that defines the idf as idf(d, t) = log [n / (df(d, t) + 1)]).

If `smooth_idf=True` (the default), the constant "1" is added to the numerator and denominator of the idf as if an extra document was seen containing every term in the collection exactly once, which prevents zero divisions: idf(d, t) = log [(1 + n) / (1 + df(d, t))] + 1.

Furthermore, the formulas used to compute tf and idf depend on parameter settings that correspond to the SMART notation used in IR as follows:

Tf is "n" (natural) by default, "l" (logarithmic) when `sublinear_tf=True`. Idf is "t" when use_idf is given, "n" (none) otherwise. Normalization is "c" (cosine) when `norm='l2'`, "n" (none) when `norm=None`.

Read more in the *User Guide*.

Parameters **norm** : 'l1', 'l2' or None, optional

Norm used to normalize term vectors. None for no normalization.

use_idf : boolean, default=True

Enable inverse-document-frequency reweighting.

smooth_idf : boolean, default=True

Smooth idf weights by adding one to document frequencies, as if an extra document was seen containing every term in the collection exactly once. Prevents zero divisions.

sublinear_tf : boolean, default=False

Apply sublinear tf scaling, i.e. replace tf with 1 + log(tf).

Methods

fit(X[, y])	Learn the idf vector (global term weights)
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X[, copy])	Transform a count matrix to a tf or tf-idf representation

__init__ (*norm='l2'*, *use_idf=True*, *smooth_idf=True*, *sublinear_tf=False*)

fit (*X*, *y=None*)

Learn the idf vector (global term weights)

Parameters **X** : sparse matrix, [n_samples, n_features]

a matrix of term/token counts

fit_transform(*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *copy=True*)
Transform a count matrix to a tf or tf-idf representation

Parameters **X** : sparse matrix, [n_samples, n_features]

a matrix of term/token counts

copy : boolean, default True

Whether to copy X and operate on the copy or perform in-place operations.

Returns **vectors** : sparse matrix, [n_samples, n_features]

Examples using `sklearn.feature_extraction.text.TfidfTransformer`

- *Sample pipeline for text feature extraction and evaluation*
- *Clustering text documents using k-means*

sklearn.feature_extraction.text.TfidfVectorizer

class sklearn.feature_extraction.text.**TfidfVectorizer**(*input='content'*, *encoding='utf-8'*, *decode_error='strict'*, *strip_accents=None*, *lowercase=True*, *preprocessor=None*, *tokenizer=None*, *analyzer='word'*, *stop_words=None*, *token_pattern='(?u)\b\w\w+\b'*, *ngram_range=(1, 1)*, *max_df=1.0*, *min_df=1*, *max_features=None*, *vocabulary=None*, *binary=False*, *dtype=<class 'numpy.int64'>*, *norm='l2'*, *use_idf=True*, *smooth_idf=True*, *sublinear_tf=False*)

Convert a collection of raw documents to a matrix of TF-IDF features.

Equivalent to CountVectorizer followed by TfidfTransformer.

Read more in the *User Guide*.

Parameters **input** : string {'filename', 'file', 'content'}

If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be the sequence strings or bytes items are expected to be analyzed directly.

encoding : string, 'utf-8' by default.

If bytes or files are given to analyze, this encoding is used to decode.

decode_error : {'strict', 'ignore', 'replace'}

Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given *encoding*. By default, it is 'strict', meaning that a UnicodeDecodeError will be raised. Other values are 'ignore' and 'replace'.

strip_accents : {'ascii', 'unicode', None}

Remove accents during the preprocessing step. 'ascii' is a fast method that only works on characters that have an direct ASCII mapping. 'unicode' is a slightly slower method that works on any characters. None (default) does nothing.

analyzer : string, {'word', 'char'} or callable

Whether the feature should be made of word or character n-grams.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

preprocessor : callable or None (default)

Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps.

tokenizer : callable or None (default)

Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if `analyzer == 'word'`.

ngram_range : tuple (min_n, max_n)

The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used.

stop_words : string {'english'}, list, or None (default)

If a string, it is passed to _check_stop_list and the appropriate stop list is returned. 'english' is currently the only supported string value.

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer == 'word'`.

If None, no stop words will be used. max_df can be set to a value in the range [0.7, 1.0) to automatically detect and filter stop words based on intra corpus document frequency of terms.

lowercase : boolean, default True

Convert all characters to lowercase before tokenizing.

token_pattern : string

Regular expression denoting what constitutes a "token", only used if `analyzer == 'word'`. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

max_df : float in range [0.0, 1.0] or int, default=1.0

When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop words). If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

min_df : float in range [0.0, 1.0] or int, default=1

When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

max_features : int or None, default=None

If not None, build a vocabulary that only consider the top max_features ordered by term frequency across the corpus.

This parameter is ignored if vocabulary is not None.

vocabulary : Mapping or iterable, optional

Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents.

binary : boolean, default=False

If True, all non-zero term counts are set to 1. This does not mean outputs will have only 0/1 values, only that the tf term in tf-idf is binary. (Set idf and normalization to False to get 0/1 outputs.)

dtype : type, optional

Type of the matrix returned by fit_transform() or transform().

norm : 'l1', 'l2' or None, optional

Norm used to normalize term vectors. None for no normalization.

use_idf : boolean, default=True

Enable inverse-document-frequency reweighting.

smooth_idf : boolean, default=True

Smooth idf weights by adding one to document frequencies, as if an extra document was seen containing every term in the collection exactly once. Prevents zero divisions.

sublinear_tf : boolean, default=False

Apply sublinear tf scaling, i.e. replace tf with 1 + log(tf).

Attributes **vocabulary_** : dict

A mapping of terms to feature indices.

idf_ : array, shape = [n_features], or None

The learned idf vector (global term weights) when `use_idf` is set to True, None otherwise.

stop_words_ : set

Terms that were ignored because they either:

- occurred in too many documents (*max_df*)
- occurred in too few documents (*min_df*)
- were cut off by feature selection (*max_features*).

This is only available if no vocabulary was given.

See also:

CountVectorizer Tokenize the documents and count the occurrences of token and return them as a sparse matrix

TfidfTransformer Apply Term Frequency Inverse Document Frequency normalization to a sparse matrix of occurrence counts.

Notes

The `stop_words_` attribute can get large and increase the model size when pickling. This attribute is provided only for introspection and can be safely removed using delattr or set to None before pickling.

Methods

build_analyzer()	Return a callable that handles preprocessing and tokenization
build_preprocessor()	Return a function to preprocess the text before tokenization

Continued on next page

Table 29.103 – continued from previous page

build_tokenizer()	Return a function that splits a string into a sequence of tokens
decode(doc)	Decode the input into a string of unicode symbols
fit(raw_documents[, y])	Learn vocabulary and idf from training set.
fit_transform(raw_documents[, y])	Learn vocabulary and idf, return term-document matrix.
get_feature_names()	Array mapping from feature integer indices to feature name
get_params([deep])	Get parameters for this estimator.
get_stop_words()	Build or fetch the effective stop words list
inverse_transform(X)	Return terms per document with nonzero entries in X.
set_params(**params)	Set the parameters of this estimator.
transform(raw_documents[, copy])	Transform documents to document-term matrix.

__init__(*input='content'*, *encoding='utf-8'*, *decode_error='strict'*, *strip_accents=None*, *lowercase=True*, *preprocessor=None*, *tokenizer=None*, *analyzer='word'*, *stop_words=None*, *token_pattern='(?u)\\b\\w\\w+\\b'*, *ngram_range=(1, 1)*, *max_df=1.0*, *min_df=1*, *max_features=None*, *vocabulary=None*, *binary=False*, *dtype=<class 'numpy.int64'>*, *norm='l2'*, *use_idf=True*, *smooth_idf=True*, *sublinear_tf=False*)

build_analyzer()
Return a callable that handles preprocessing and tokenization

build_preprocessor()
Return a function to preprocess the text before tokenization

build_tokenizer()
Return a function that splits a string into a sequence of tokens

decode(*doc*)
Decode the input into a string of unicode symbols

The decoding strategy depends on the vectorizer parameters.

fit(*raw_documents*, *y=None*)
Learn vocabulary and idf from training set.

Parameters **raw_documents** : iterable

an iterable which yields either str, unicode or file objects

Returns **self** : TfidfVectorizer

fit_transform(*raw_documents*, *y=None*)
Learn vocabulary and idf, return term-document matrix.

This is equivalent to fit followed by transform, but more efficiently implemented.

Parameters **raw_documents** : iterable

an iterable which yields either str, unicode or file objects

Returns **X** : sparse matrix, [n_samples, n_features]

Tf-idf-weighted document-term matrix.

get_feature_names()
Array mapping from feature integer indices to feature name

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_stop_words()
Build or fetch the effective stop words list

inverse_transform(*X*)
Return terms per document with nonzero entries in X.

Parameters **X** : {array, sparse matrix}, shape = [n_samples, n_features]

Returns **X_inv** : list of arrays, len = n_samples

List of arrays of terms.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*raw_documents*, *copy=True*)
Transform documents to document-term matrix.

Uses the vocabulary and document frequencies (df) learned by fit (or fit_transform).

Parameters **raw_documents** : iterable

an iterable which yields either str, unicode or file objects

copy : boolean, default True

Whether to copy X and operate on the copy or perform in-place operations.

Returns **X** : sparse matrix, [n_samples, n_features]

Tf-idf-weighted document-term matrix.

Examples using `sklearn.feature_extraction.text.TfidfVectorizer`

- *Feature Union with Heterogeneous Data Sources*
- *Topic extraction with Non-negative Matrix Factorizationand Latent Dirichlet Allocation*
- *Biclustering documents with the Spectral Co-clustering algorithm*
- *Classification of text documents using sparse features*
- *Clustering text documents using k-means*

29.12 `sklearn.feature_selection`: Feature Selection

The *`sklearn.feature_selection`* module implements feature selection algorithms. It currently includes univariate filter selection methods and the recursive feature elimination algorithm.

User guide: See the *Feature selection* section for further details.

feature_selection.GenericUnivariateSelect([...])	Univariate feature selector with configurable strategy.
feature_selection.SelectPercentile([...])	Select features according to a percentile of the highest scores.
feature_selection.SelectKBest([score_func, k])	Select features according to the k highest scores.
feature_selection.SelectFpr([score_func, alpha])	Filter: Select the pvalues below alpha based on a FPR test.
feature_selection.SelectFdr([score_func, alpha])	Filter: Select the p-values for an estimated false discovery rate
feature_selection.SelectFromModel(estimator)	Meta-transformer for selecting features based on importance weights.
feature_selection.SelectFwe([score_func, alpha])	Filter: Select the p-values corresponding to Family-wise error rate
feature_selection.RFE(estimator[, ...])	Feature ranking with recursive feature elimination.
feature_selection.RFECV(estimator[, step, ...])	Feature ranking with recursive feature elimination and cross-validated selection of the best number of features.
feature_selection.VarianceThreshold([threshold])	Feature selector that removes all low-variance features.

29.12.1 sklearn.feature_selection.GenericUnivariateSelect

class sklearn.feature_selection.**GenericUnivariateSelect**(*score_func=<function f_classif>*, *mode='percentile'*, *param=1e-05*)

Univariate feature selector with configurable strategy.

Read more in the *User Guide*.

Parameters **score_func** : callable

Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). For modes 'percentile' or 'kbest' it can return a single array scores.

mode : {'percentile', 'k_best', 'fpr', 'fdr', 'fwe'}

Feature selection mode.

param : float or int depending on the feature selection mode

Parameter of the corresponding mode.

Attributes **scores_** : array-like, shape=(n_features,)

Scores of features.

pvalues_ : array-like, shape=(n_features,)

p-values of feature scores, None if *score_func* returned scores only.

f_classif ANOVA F-value between label/feature for classification tasks.

mutual_info_classif Mutual information for a discrete target.

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

mutual_info_regression Mutual information for a continuous target.

SelectPercentile Select features based on percentile of the highest scores.

SelectKBest Select features based on the k highest scores.

SelectFpr Select features based on a false positive rate test.

SelectFdr Select features based on an estimated false discovery rate.

SelectFwe Select features based on family-wise error rate.

Methods

fit(X, y)	Run score function on (X, y) and get the appropriate features.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
get_support([indices])	Get a mask, or integer index, of the features selected
inverse_transform(X)	Reverse the transformation operation
set_params(**params)	Set the parameters of this estimator.
transform(X)	Reduce X to the selected features.

__init__ (*score_func=<function f_classif>*, *mode='percentile'*, *param=1e-05*)

fit (*X*, *y*)
Run score function on (X, y) and get the appropriate features.

Parameters **X** : array-like, shape = [n_samples, n_features]

The training input samples.

y : array-like, shape = [n_samples]

The target values (class labels in classification, real numbers in regression).

Returns **self** : object

Returns self.

fit_transform (*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_support(*indices=False*)
Get a mask, or integer index, of the features selected

Parameters **indices** : boolean (default False)

If True, the return value will be an array of integers, rather than a boolean mask.

Returns **support** : array

An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*X*)
Reverse the transformation operation

Parameters **X** : array of shape [n_samples, n_selected_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_original_features]

X with columns of zeros inserted where features would have been removed by *transform*.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Reduce X to the selected features.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_selected_features]

The input samples with only the selected features.

29.12.2 sklearn.feature_selection.SelectPercentile

class sklearn.feature_selection.**SelectPercentile**(*score_func=<function f_classif>*, *percentile=10*)
Select features according to a percentile of the highest scores.

Read more in the *User Guide*.

Parameters **score_func** : callable

Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues) or a single array with scores. Default is f_classif (see below "See also"). The default function only works with classification tasks.

percentile : int, optional, default=10

Percent of features to keep.

Attributes **scores_** : array-like, shape=(n_features,)

Scores of features.

pvalues_ : array-like, shape=(n_features,)

p-values of feature scores, None if *score_func* returned only scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

mutual_info_classif Mutual information for a discrete target.

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

mutual_info_regression Mutual information for a continuous target.

SelectKBest Select features based on the k highest scores.

SelectFpr Select features based on a false positive rate test.

SelectFdr Select features based on an estimated false discovery rate.

SelectFwe Select features based on family-wise error rate.

GenericUnivariateSelect Univariate feature selector with configurable mode.

Notes

Ties between features with equal scores will be broken in an unspecified way.

Methods

fit(X, y)	Run score function on (X, y) and get the appropriate features.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
get_support([indices])	Get a mask, or integer index, of the features selected
inverse_transform(X)	Reverse the transformation operation
set_params(**params)	Set the parameters of this estimator.
transform(X)	Reduce X to the selected features.

__init__ (*score_func=<function f_classif>*, *percentile=10*)

fit (*X*, *y*)

Run score function on (X, y) and get the appropriate features.

Parameters **X** : array-like, shape = [n_samples, n_features]

The training input samples.

y : array-like, shape = [n_samples]

The target values (class labels in classification, real numbers in regression).

Returns **self** : object

Returns self.

fit_transform(*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_support(*indices=False*)
Get a mask, or integer index, of the features selected

Parameters **indices** : boolean (default False)

If True, the return value will be an array of integers, rather than a boolean mask.

Returns **support** : array

An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*X*)
Reverse the transformation operation

Parameters **X** : array of shape [n_samples, n_selected_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_original_features]

X with columns of zeros inserted where features would have been removed by *transform*.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)

Reduce X to the selected features.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_selected_features]

The input samples with only the selected features.

Examples using sklearn.feature_selection.SelectPercentile

- *Feature agglomeration vs. univariate selection*
- *Univariate Feature Selection*
- *SVM-Anova: SVM with univariate feature selection*

29.12.3 sklearn.feature_selection.SelectKBest

class sklearn.feature_selection.**SelectKBest**(*score_func=<function f_classif>*, *k=10*)

Select features according to the k highest scores.

Read more in the *User Guide*.

Parameters **score_func** : callable

Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues) or a single array with scores. Default is f_classif (see below "See also"). The default function only works with classification tasks.

k : int or "all", optional, default=10

Number of top features to select. The "all" option bypasses selection, for use in a parameter search.

Attributes **scores_** : array-like, shape=(n_features,)

Scores of features.

pvalues_ : array-like, shape=(n_features,)

p-values of feature scores, None if *score_func* returned only scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

mutual_info_classif Mutual information for a discrete target.

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

mutual_info_regression Mutual information for a continuous target.

SelectPercentile Select features based on percentile of the highest scores.

SelectFpr Select features based on a false positive rate test.

SelectFdr Select features based on an estimated false discovery rate.

SelectFwe Select features based on family-wise error rate.

GenericUnivariateSelect Univariate feature selector with configurable mode.

Notes

Ties between features with equal scores will be broken in an unspecified way.

Methods

fit(X, y)	Run score function on (X, y) and get the appropriate features.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
get_support([indices])	Get a mask, or integer index, of the features selected
inverse_transform(X)	Reverse the transformation operation
set_params(**params)	Set the parameters of this estimator.
transform(X)	Reduce X to the selected features.

__init__ (*score_func=<function f_classif>*, *k=10*)

fit (*X*, *y*)

Run score function on (X, y) and get the appropriate features.

Parameters **X** : array-like, shape = [n_samples, n_features]

The training input samples.

y : array-like, shape = [n_samples]

The target values (class labels in classification, real numbers in regression).

Returns **self** : object

Returns self.

fit_transform (*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_support(*indices=False*)
Get a mask, or integer index, of the features selected

Parameters **indices** : boolean (default False)

If True, the return value will be an array of integers, rather than a boolean mask.

Returns **support** : array

An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*X*)
Reverse the transformation operation

Parameters **X** : array of shape [n_samples, n_selected_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_original_features]

X with columns of zeros inserted where features would have been removed by *transform*.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Reduce X to the selected features.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_selected_features]

The input samples with only the selected features.

Examples using `sklearn.feature_selection.SelectKBest`

- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *Concatenating multiple feature extraction methods*
- *Pipeline Anova SVM*
- *Classification of text documents using sparse features*

29.12.4 sklearn.feature_selection.SelectFpr

class sklearn.feature_selection.**SelectFpr**(*score_func=<function f_classif>*, *alpha=0.05*)

Filter: Select the pvalues below alpha based on a FPR test.

FPR test stands for False Positive Rate test. It controls the total amount of false detections.

Read more in the *User Guide*.

Parameters **score_func** : callable

Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below "See also"). The default function only works with classification tasks.

alpha : float, optional

The highest p-value for features to be kept.

Attributes **scores_** : array-like, shape=(n_features,)

Scores of features.

pvalues_ : array-like, shape=(n_features,)

p-values of feature scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

chi2 Chi-squared stats of non-negative features for classification tasks.

mutual_info_classif

f_regression F-value between label/feature for regression tasks.

mutual_info_regression Mutual information between features and the target.

SelectPercentile Select features based on percentile of the highest scores.

SelectKBest Select features based on the k highest scores.

SelectFdr Select features based on an estimated false discovery rate.

SelectFwe Select features based on family-wise error rate.

GenericUnivariateSelect Univariate feature selector with configurable mode.

Methods

fit(X, y)	Run score function on (X, y) and get the appropriate features.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
get_support([indices])	Get a mask, or integer index, of the features selected
inverse_transform(X)	Reverse the transformation operation
set_params(**params)	Set the parameters of this estimator.
transform(X)	Reduce X to the selected features.

__init__(*score_func=<function f_classif>*, *alpha=0.05*)

fit(*X*, *y*)
Run score function on (X, y) and get the appropriate features.

Parameters **X** : array-like, shape = [n_samples, n_features]

The training input samples.

y : array-like, shape = [n_samples]

The target values (class labels in classification, real numbers in regression).

Returns **self** : object

Returns self.

fit_transform(*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_support(*indices=False*)
Get a mask, or integer index, of the features selected

Parameters **indices** : boolean (default False)

If True, the return value will be an array of integers, rather than a boolean mask.

Returns **support** : array

An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*X*)
Reverse the transformation operation

Parameters **X** : array of shape [n_samples, n_selected_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_original_features]

X with columns of zeros inserted where features would have been removed by *transform*.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Reduce X to the selected features.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_selected_features]

The input samples with only the selected features.

29.12.5 sklearn.feature_selection.SelectFdr

class sklearn.feature_selection.**SelectFdr**(*score_func=<function f_classif>*, *alpha=0.05*)
Filter: Select the p-values for an estimated false discovery rate

This uses the Benjamini-Hochberg procedure. `alpha` is an upper bound on the expected false discovery rate.

Read more in the *User Guide*.

Parameters **score_func** : callable

Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below "See also"). The default function only works with classification tasks.

alpha : float, optional

The highest uncorrected p-value for features to keep.

Attributes **scores_** : array-like, shape=(n_features,)

Scores of features.

pvalues_ : array-like, shape=(n_features,)

p-values of feature scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

mutual_info_classif Mutual information for a discrete target.

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

mutual_info_regression Mutual information for a contnuous target.

SelectPercentile Select features based on percentile of the highest scores.

SelectKBest Select features based on the k highest scores.

SelectFpr Select features based on a false positive rate test.

SelectFwe Select features based on family-wise error rate.

GenericUnivariateSelect Univariate feature selector with configurable mode.

Methods

fit(X, y)	Run score function on (X, y) and get the appropriate features.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
get_support([indices])	Get a mask, or integer index, of the features selected
inverse_transform(X)	Reverse the transformation operation
set_params(**params)	Set the parameters of this estimator.
transform(X)	Reduce X to the selected features.

__init__ (*score_func=<function f_classif>*, *alpha=0.05*)

fit (*X*, *y*)

Run score function on (X, y) and get the appropriate features.

Parameters **X** : array-like, shape = [n_samples, n_features]

The training input samples.

y : array-like, shape = [n_samples]

The target values (class labels in classification, real numbers in regression).

Returns **self** : object

Returns self.

fit_transform (*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_support(*indices=False*)
Get a mask, or integer index, of the features selected

Parameters **indices** : boolean (default False)

If True, the return value will be an array of integers, rather than a boolean mask.

Returns **support** : array

An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*X*)
Reverse the transformation operation

Parameters **X** : array of shape [n_samples, n_selected_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_original_features]

X with columns of zeros inserted where features would have been removed by *transform*.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Reduce X to the selected features.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_selected_features]

The input samples with only the selected features.

29.12.6 sklearn.feature_selection.SelectFromModel

class sklearn.feature_selection.**SelectFromModel**(*estimator*, *threshold=None*, *prefit=False*, *norm_order=1*)
Meta-transformer for selecting features based on importance weights.

New in version 0.17.

Parameters **estimator** : object

The base estimator from which the transformer is built. This can be both a fitted (if `prefit` is set to True) or a non-fitted estimator.

threshold : string, float, optional default None

The threshold value to use for feature selection. Features whose importance is greater or equal are kept while the others are discarded. If "median" (resp. "mean"), then the `threshold` value is the median (resp. the mean) of the feature importances. A scaling factor (e.g., "1.25*mean") may also be used. If None and if the estimator has a parameter penalty set to l1, either explicitly or implicitly (e.g, Lasso), the threshold used is 1e-5. Otherwise, "mean" is used by default.

prefit : bool, default False

Whether a prefit model is expected to be passed into the constructor directly or not. If True, `transform` must be called directly and SelectFromModel cannot be used with `cross_val_score`, `GridSearchCV` and similar utilities that clone the estimator. Otherwise train the model using `fit` and then `transform` to do feature selection.

norm_order : non-zero int, inf, -inf, default 1

Order of the norm used to filter the vectors of coefficients below `threshold` in the case where the `coef_` attribute of the estimator is of dimension 2.

Attributes **estimator_** : an estimator

The base estimator from which the transformer is built. This is stored only when a non-fitted estimator is passed to the `SelectFromModel`, i.e when prefit is False.

threshold_ : float

The threshold value used for feature selection.

Methods

fit(X[, y])	Fit the SelectFromModel meta-transformer.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
get_support([indices])	Get a mask, or integer index, of the features selected
inverse_transform(X)	Reverse the transformation operation
partial_fit(X[, y])	Fit the SelectFromModel meta-transformer only once.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Reduce X to the selected features.

__init__ (*estimator*, *threshold=None*, *prefit=False*, *norm_order=1*)

fit (*X*, *y=None*, ***fit_params*)

Fit the SelectFromModel meta-transformer.

Parameters **X** : array-like of shape (n_samples, n_features)

The training input samples.

y : array-like, shape (n_samples,)

The target values (integers that correspond to classes in classification, real numbers in regression).

****fit_params** : Other estimator specific parameters

Returns **self** : object

Returns self.

fit_transform(*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_support(*indices=False*)
Get a mask, or integer index, of the features selected

Parameters **indices** : boolean (default False)

If True, the return value will be an array of integers, rather than a boolean mask.

Returns **support** : array

An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*X*)
Reverse the transformation operation

Parameters **X** : array of shape [n_samples, n_selected_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_original_features]

X with columns of zeros inserted where features would have been removed by *transform*.

partial_fit(*X*, *y=None*, ***fit_params*)
Fit the SelectFromModel meta-transformer only once.

Parameters **X** : array-like of shape (n_samples, n_features)

The training input samples.

y : array-like, shape (n_samples,)

The target values (integers that correspond to classes in classification, real numbers in regression).

****fit_params** : Other estimator specific parameters

Returns **self** : object

Returns self.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Reduce X to the selected features.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_selected_features]

The input samples with only the selected features.

Examples using `sklearn.feature_selection.SelectFromModel`

- *Feature selection using SelectFromModel and LassoCV*
- *Classification of text documents using sparse features*

29.12.7 sklearn.feature_selection.SelectFwe

class sklearn.feature_selection.**SelectFwe**(*score_func=<function f_classif>*, *alpha=0.05*)
Filter: Select the p-values corresponding to Family-wise error rate

Read more in the *User Guide*.

Parameters **score_func** : callable

Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below "See also"). The default function only works with classification tasks.

alpha : float, optional

The highest uncorrected p-value for features to keep.

Attributes **scores_** : array-like, shape=(n_features,)

Scores of features.

pvalues_ : array-like, shape=(n_features,)

p-values of feature scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

SelectPercentile Select features based on percentile of the highest scores.

SelectKBest Select features based on the k highest scores.

SelectFpr Select features based on a false positive rate test.

SelectFdr Select features based on an estimated false discovery rate.

GenericUnivariateSelect Univariate feature selector with configurable mode.

Methods

fit(X, y)	Run score function on (X, y) and get the appropriate features.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
get_support([indices])	Get a mask, or integer index, of the features selected
inverse_transform(X)	Reverse the transformation operation
set_params(**params)	Set the parameters of this estimator.
transform(X)	Reduce X to the selected features.

__init__ (*score_func=<function f_classif>*, *alpha=0.05*)

fit (*X*, *y*)

Run score function on (X, y) and get the appropriate features.

Parameters **X** : array-like, shape = [n_samples, n_features]

The training input samples.

y : array-like, shape = [n_samples]

The target values (class labels in classification, real numbers in regression).

Returns **self** : object

Returns self.

fit_transform (*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_support(*indices=False*)
Get a mask, or integer index, of the features selected

Parameters **indices** : boolean (default False)

If True, the return value will be an array of integers, rather than a boolean mask.

Returns **support** : array

An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*X*)
Reverse the transformation operation

Parameters **X** : array of shape [n_samples, n_selected_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_original_features]

X with columns of zeros inserted where features would have been removed by *transform*.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Reduce X to the selected features.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_selected_features]

The input samples with only the selected features.

29.12.8 sklearn.feature_selection.RFE

class sklearn.feature_selection.**RFE**(*estimator*, *n_features_to_select=None*, *step=1*, *verbose=0*)
Feature ranking with recursive feature elimination.

Given an external estimator that assigns weights to features (e.g., the coefficients of a linear model), the goal of recursive feature elimination (RFE) is to select features by recursively considering smaller and smaller sets of features. First, the estimator is trained on the initial set of features and weights are assigned to each one of them. Then, features whose absolute weights are the smallest are pruned from the current set features. That procedure is recursively repeated on the pruned set until the desired number of features to select is eventually reached.

Read more in the *User Guide*.

Parameters **estimator** : object

A supervised learning estimator with a *fit* method that updates a *coef_* attribute that holds the fitted parameters. Important features must correspond to high absolute values in the *coef_* array.

For instance, this is the case for most supervised learning algorithms such as Support Vector Classifiers and Generalized Linear Models from the *svm* and *linear_model* modules.

n_features_to_select : int or None (default=None)

The number of features to select. If *None*, half of the features are selected.

step : int or float, optional (default=1)

If greater than or equal to 1, then *step* corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then *step* corresponds to the percentage (rounded down) of features to remove at each iteration.

verbose : int, default=0

Controls verbosity of output.

Attributes **n_features_** : int

The number of selected features.

support_ : array of shape [n_features]

The mask of selected features.

ranking_ : array of shape [n_features]

The feature ranking, such that `ranking_[i]` corresponds to the ranking position of the i-th feature. Selected (i.e., estimated best) features are assigned rank 1.

estimator_ : object

The external estimator fit on the reduced dataset.

References

[R27]

Examples

The following example shows how to retrieve the 5 right informative features in the Friedman #1 dataset.

```
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.feature_selection import RFE
>>> from sklearn.svm import SVR
>>> X, y = make_friedman1(n_samples=50, n_features=10, random_state=0)
>>> estimator = SVR(kernel="linear")
>>> selector = RFE(estimator, 5, step=1)
>>> selector = selector.fit(X, y)
>>> selector.support_
array([ True,  True,  True,  True,  True,
        False, False, False, False, False], dtype=bool)
>>> selector.ranking_
array([1, 1, 1, 1, 1, 6, 4, 3, 2, 5])
```

Methods

decision_function(X)	
fit(X, y)	Fit the RFE model and then the underlying estimator on the selected features.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
get_support([indices])	Get a mask, or integer index, of the features selected
inverse_transform(X)	Reverse the transformation operation
predict(X)	Reduce X to the selected features and then predict using the underlying estimator.
predict_log_proba(X)	
predict_proba(X)	
score(X, y)	Reduce X to the selected features and then return the score of the underlying estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Reduce X to the selected features.

__init__ (*estimator*, *n_features_to_select=None*, *step=1*, *verbose=0*)

fit (*X*, *y*)

Fit the RFE model and then the underlying estimator on the selected features.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

The training input samples.

y : array-like, shape = [n_samples]

The target values.

fit_transform (*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_support(*indices=False*)
Get a mask, or integer index, of the features selected

Parameters **indices** : boolean (default False)

If True, the return value will be an array of integers, rather than a boolean mask.

Returns **support** : array

An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*X*)
Reverse the transformation operation

Parameters **X** : array of shape [n_samples, n_selected_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_original_features]

X with columns of zeros inserted where features would have been removed by *transform*.

predict(*X*)

Reduce X to the selected features and then predict using the underlying estimator.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **y** : array of shape [n_samples]

The predicted target values.

score(*X*, *y*)

Reduce X to the selected features and then return the score of the underlying estimator.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

y : array of shape [n_samples]

The target values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Reduce X to the selected features.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_selected_features]

The input samples with only the selected features.

Examples using `sklearn.feature_selection.RFE`

- *Recursive feature elimination*

29.12.9 `sklearn.feature_selection.RFECV`

class `sklearn.feature_selection.`**`RFECV`**(*estimator*, *step=1*, *cv=None*, *scoring=None*, *verbose=0*, *n_jobs=1*)

Feature ranking with recursive feature elimination and cross-validated selection of the best number of features.

Read more in the *User Guide*.

Parameters **estimator** : object

A supervised learning estimator with a *fit* method that updates a *coef_* attribute that holds the fitted parameters. Important features must correspond to high absolute values in the *coef_* array.

For instance, this is the case for most supervised learning algorithms such as Support Vector Classifiers and Generalized Linear Models from the *svm* and *linear_model* modules.

step : int or float, optional (default=1)

If greater than or equal to 1, then *step* corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then *step* corresponds to the percentage (rounded down) of features to remove at each iteration.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if `y` is binary or multiclass, *`sklearn.model_selection.StratifiedKFold`* is used. If the estimator is a classifier or if `y` is neither binary nor multiclass, *`sklearn.model_selection.KFold`* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

scoring : string, callable or None, optional, default: None

A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

verbose : int, default=0

Controls verbosity of output.

n_jobs : int, default 1

Number of cores to run in parallel while fitting across folds. Defaults to 1 core. If *n_jobs=-1*, then number of jobs is set to number of cores.

Attributes **n_features_** : int

The number of selected features with cross-validation.

support_ : array of shape [n_features]

The mask of selected features.

ranking_ : array of shape [n_features]

The feature ranking, such that *ranking_[i]* corresponds to the ranking position of the i-th feature. Selected (i.e., estimated best) features are assigned rank 1.

grid_scores_ : array of shape [n_subsets_of_features]

The cross-validation scores such that `grid_scores_[i]` corresponds to the CV score of the i-th subset of features.

estimator_ : object

The external estimator fit on the reduced dataset.

Notes

The size of `grid_scores_` is equal to ceil((n_features - 1) / step) + 1, where step is the number of features removed at each iteration.

[R28]

Examples

The following example shows how to retrieve the a-priori not known 5 informative features in the Friedman #1 dataset.

```
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.feature_selection import RFECV
>>> from sklearn.svm import SVR
>>> X, y = make_friedman1(n_samples=50, n_features=10, random_state=0)
>>> estimator = SVR(kernel="linear")
>>> selector = RFECV(estimator, step=1, cv=5)
>>> selector = selector.fit(X, y)
>>> selector.support_
array([ True,  True,  True,  True,  True,
        False, False, False, False, False], dtype=bool)
>>> selector.ranking_
array([1, 1, 1, 1, 1, 6, 4, 3, 2, 5])
```

Methods

decision_function(X)	
fit(X, y)	Fit the RFE model and automatically tune the number of selected features.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
get_support([indices])	Get a mask, or integer index, of the features selected
inverse_transform(X)	Reverse the transformation operation
predict(X)	Reduce X to the selected features and then predict using the underlying estimator.
predict_log_proba(X)	
predict_proba(X)	
score(X, y)	Reduce X to the selected features and then return the score of the underlying estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Reduce X to the selected features.

__init__(*estimator*, *step=1*, *cv=None*, *scoring=None*, *verbose=0*, *n_jobs=1*)

fit(*X*, *y*)

Fit the RFE model and automatically tune the number of selected features.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training vector, where *n_samples* is the number of samples and *n_features* is the total number of features.

y : array-like, shape = [n_samples]

Target values (integers for classification, real numbers for regression).

fit_transform(*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_support(*indices=False*)
Get a mask, or integer index, of the features selected

Parameters **indices** : boolean (default False)

If True, the return value will be an array of integers, rather than a boolean mask.

Returns **support** : array

An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*X*)
Reverse the transformation operation

Parameters **X** : array of shape [n_samples, n_selected_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_original_features]

X with columns of zeros inserted where features would have been removed by *transform*.

predict(*X*)

Reduce X to the selected features and then predict using the underlying estimator.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **y** : array of shape [n_samples]

The predicted target values.

score(*X*, *y*)

Reduce X to the selected features and then return the score of the underlying estimator.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

y : array of shape [n_samples]

The target values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Reduce X to the selected features.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_selected_features]

The input samples with only the selected features.

Examples using `sklearn.feature_selection.RFECV`

- *Recursive feature elimination with cross-validation*

29.12.10 `sklearn.feature_selection`.VarianceThreshold

class `sklearn.feature_selection.`**`VarianceThreshold`**(*threshold=0.0*)

Feature selector that removes all low-variance features.

This feature selection algorithm looks only at the features (X), not the desired outputs (y), and can thus be used for unsupervised learning.

Read more in the *User Guide*.

Parameters **threshold** : float, optional

Features with a training-set variance lower than this threshold will be removed. The default is to keep all features with non-zero variance, i.e. remove the features that have the same value in all samples.

Attributes **variances_** : array, shape (n_features,)

Variances of individual features.

Examples

The following dataset has integer features, two of which are the same in every sample. These are removed with the default setting for threshold:

```
>>> X = [[0, 2, 0, 3], [0, 1, 4, 3], [0, 1, 1, 3]]
>>> selector = VarianceThreshold()
>>> selector.fit_transform(X)
array([[2, 0],
       [1, 4],
       [1, 1]])
```

Methods

fit(X[, y])	Learn empirical variances from X.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
get_support([indices])	Get a mask, or integer index, of the features selected
inverse_transform(X)	Reverse the transformation operation
set_params(**params)	Set the parameters of this estimator.
transform(X)	Reduce X to the selected features.

`__init__`(*threshold=0.0*)

`fit`(*X*, *y=None*)

Learn empirical variances from X.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Sample vectors from which to compute variances.

y : any

Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

Returns **self** :

fit_transform(*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_support(*indices=False*)
Get a mask, or integer index, of the features selected

Parameters **indices** : boolean (default False)

If True, the return value will be an array of integers, rather than a boolean mask.

Returns **support** : array

An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*X*)
Reverse the transformation operation

Parameters **X** : array of shape [n_samples, n_selected_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_original_features]

X with columns of zeros inserted where features would have been removed by *transform*.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Reduce X to the selected features.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_selected_features]

The input samples with only the selected features.

feature_selection.chi2(X, y)	Compute chi-squared stats between each non-negative feature and class.
feature_selection.f_classif(X, y)	Compute the ANOVA F-value for the provided sample.
feature_selection.f_regression(X, y[, center])	Univariate linear regression tests.
feature_selection.mutual_info_classif(X, y)	Estimate mutual information for a discrete target variable.
feature_selection.mutual_info_regression(X, y)	Estimate mutual information for a continuous target variable.

29.12.11 sklearn.feature_selection.chi2

sklearn.feature_selection.**chi2**(*X*, *y*)
Compute chi-squared stats between each non-negative feature and class.

This score can be used to select the n_features features with the highest values for the test chi-squared statistic from X, which must contain only non-negative features such as booleans or frequencies (e.g., term counts in document classification), relative to the classes.

Recall that the chi-square test measures dependence between stochastic variables, so using this function "weeds out" the features that are the most likely to be independent of class and therefore irrelevant for classification.

Read more in the *User Guide*.

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features_in)

Sample vectors.

y : array-like, shape = (n_samples,)

Target vector (class labels).

Returns **chi2** : array, shape = (n_features,)

chi2 statistics of each feature.

pval : array, shape = (n_features,)

p-values of each feature.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

f_regression F-value between label/feature for regression tasks.

Notes

Complexity of this algorithm is O(n_classes * n_features).

Examples using `sklearn.feature_selection.chi2`

- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *Classification of text documents using sparse features*

29.12.12 `sklearn.feature_selection.f_classif`

`sklearn.feature_selection.f_classif`(*X*, *y*)

Compute the ANOVA F-value for the provided sample.

Read more in the *User Guide*.

Parameters **X** : {array-like, sparse matrix} shape = [n_samples, n_features]

The set of regressors that will be tested sequentially.

y : array of shape(n_samples)

The data matrix.

Returns **F** : array, shape = [n_features,]

The set of F values.

pval : array, shape = [n_features,]

The set of p-values.

See also:

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

Examples using `sklearn.feature_selection.f_classif`

- *Univariate Feature Selection*
- *SVM-Anova: SVM with univariate feature selection*

29.12.13 `sklearn.feature_selection.f_regression`

`sklearn.feature_selection.f_regression`(*X*, *y*, *center=True*)

Univariate linear regression tests.

Linear model for testing the individual effect of each of many regressors. This is a scoring function to be used in a feature seletion procedure, not a free standing feature selection procedure.

This is done in 2 steps:

1. The correlation between each regressor and the target is computed, that is, ((X[:, i] - mean(X[:, i])) * (y - mean_y)) / (std(X[:, i]) * std(y)).
2. It is converted to an F score then to a p-value.

For more on usage see the *User Guide*.

Parameters **X** : {array-like, sparse matrix} shape = (n_samples, n_features)

The set of regressors that will be tested sequentially.

y : array of shape(n_samples).

The data matrix

center : True, bool,

If true, X and y will be centered.

Returns **F** : array, shape=(n_features,)

F values of features.

pval : array, shape=(n_features,)

p-values of F-scores.

See also:

mutual_info_regression Mutual information for a continuous target.

f_classif ANOVA F-value between label/feature for classification tasks.

chi2 Chi-squared stats of non-negative features for classification tasks.

SelectKBest Select features based on the k highest scores.

SelectFpr Select features based on a false positive rate test.

SelectFdr Select features based on an estimated false discovery rate.

SelectFwe Select features based on family-wise error rate.

SelectPercentile Select features based on percentile of the highest scores.

Examples using `sklearn.feature_selection.f_regression`

- *Feature agglomeration vs. univariate selection*
- *Comparison of F-test and mutual information*
- *Pipeline Anova SVM*
- *Sparse recovery: feature selection for sparse linear models*

29.12.14 `sklearn.feature_selection`.mutual_info_classif

`sklearn.feature_selection.`**`mutual_info_classif`**(*X*, *y*, *discrete_features='auto'*, *n_neighbors=3*, *copy=True*, *random_state=None*)

Estimate mutual information for a discrete target variable.

Mutual information (MI) *[R175]* between two random variables is a non-negative value, which measures the dependency between the variables. It is equal to zero if and only if two random variables are independent, and higher values mean higher dependency.

The function relies on nonparametric methods based on entropy estimation from k-nearest neighbors distances as described in *[R176]* and *[R177]*. Both methods are based on the idea originally proposed in *[R178]*.

It can be used for univariate features selection, read more in the *User Guide*.

Parameters **X** : array_like or sparse matrix, shape (n_samples, n_features)

Feature matrix.

y : array_like, shape (n_samples,)

Target vector.

discrete_features : {'auto', bool, array_like}, default 'auto'

If bool, then determines whether to consider all features discrete or continuous. If array, then it should be either a boolean mask with shape (n_features,) or array with indices of discrete features. If 'auto', it is assigned to False for dense *X* and to True for sparse *X*.

n_neighbors : int, default 3

Number of neighbors to use for MI estimation for continuous variables, see *[R176]* and *[R177]*. Higher values reduce variance of the estimation, but could introduce a bias.

copy : bool, default True

Whether to make a copy of the given data. If set to False, the initial data will be overwritten.

random_state : int, RandomState instance or None, optional, default None

The seed of the pseudo random number generator for adding small noise to continuous variables in order to remove repeated values. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **mi** : ndarray, shape (n_features,)

Estimated mutual information between each feature and the target.

Notes

1. The term "discrete features" is used instead of naming them "categorical", because it describes the essence more accurately. For example, pixel intensities of an image are discrete features (but hardly categorical) and you will get better results if mark them as such. Also note, that treating a continuous variable as discrete and vice versa will usually give incorrect results, so be attentive about that.
2. True mutual information can't be negative. If its estimate turns out to be negative, it is replaced by zero.

References

29.12.15 sklearn.feature_selection.mutual_info_regression

sklearn.feature_selection.**mutual_info_regression**(*X*, *y*, *discrete_features='auto'*, *n_neighbors=3*, *copy=True*, *random_state=None*)

Estimate mutual information for a continuous target variable.

Mutual information (MI) *[R29]* between two random variables is a non-negative value, which measures the dependency between the variables. It is equal to zero if and only if two random variables are independent, and higher values mean higher dependency.

The function relies on nonparametric methods based on entropy estimation from k-nearest neighbors distances as described in *[R30]* and *[R31]*. Both methods are based on the idea originally proposed in *[R32]*.

It can be used for univariate features selection, read more in the *User Guide*.

Parameters **X** : array_like or sparse matrix, shape (n_samples, n_features)

Feature matrix.

y : array_like, shape (n_samples,)

Target vector.

discrete_features : {'auto', bool, array_like}, default 'auto'

If bool, then determines whether to consider all features discrete or continuous. If array, then it should be either a boolean mask with shape (n_features,) or array with indices of discrete features. If 'auto', it is assigned to False for dense *X* and to True for sparse *X*.

n_neighbors : int, default 3

Number of neighbors to use for MI estimation for continuous variables, see *[R30]* and *[R31]*. Higher values reduce variance of the estimation, but could introduce a bias.

copy : bool, default True

Whether to make a copy of the given data. If set to False, the initial data will be overwritten.

random_state : int, RandomState instance or None, optional, default None

The seed of the pseudo random number generator for adding small noise to continuous variables in order to remove repeated values. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **mi** : ndarray, shape (n_features,)

Estimated mutual information between each feature and the target.

Notes

1. The term "discrete features" is used instead of naming them "categorical", because it describes the essence more accurately. For example, pixel intensities of an image are discrete features (but hardly categorical) and you will get better results if mark them as such. Also note, that treating a continuous variable as discrete and vice versa will usually give incorrect results, so be attentive about that.
2. True mutual information can't be negative. If its estimate turns out to be negative, it is replaced by zero.

29.13 `sklearn.gaussian_process`: Gaussian Processes

The `sklearn.gaussian_process` module implements Gaussian Process based regression and classification.

User guide: See the *Gaussian Processes* section for further details.

`gaussian_process.GaussianProcessRegressor([...])`	Gaussian process regression (GPR).
`gaussian_process.GaussianProcessClassifier([...])`	Gaussian process classification (GPC) based on Laplace approximation.

29.13.1 `sklearn.gaussian_process.GaussianProcessRegressor`

class `sklearn.gaussian_process.`**`GaussianProcessRegressor`**(*kernel=None*, *alpha=1e-10*, *optimizer='fmin_l_bfgs_b'*, *n_restarts_optimizer=0*, *normalize_y=False*, *copy_X_train=True*, *random_state=None*)

Gaussian process regression (GPR).

The implementation is based on Algorithm 2.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.

In addition to standard scikit-learn estimator API, GaussianProcessRegressor:

- allows prediction without prior fitting (based on the GP prior)
- provides an additional method sample_y(X), which evaluates samples drawn from the GPR (prior or posterior) at given inputs
- exposes a method log_marginal_likelihood(theta), which can be used externally for other ways of selecting hyperparameters, e.g., via Markov chain Monte Carlo.

Read more in the *User Guide*.

New in version 0.18.

Parameters **kernel** : kernel object

The kernel specifying the covariance function of the GP. If None is passed, the kernel "1.0 * RBF(1.0)" is used as default. Note that the kernel's hyperparameters are optimized during fitting.

alpha : float or array-like, optional (default: 1e-10)

Value added to the diagonal of the kernel matrix during fitting. Larger values correspond to increased noise level in the observations. This can also prevent a potential numerical issue during fitting, by ensuring that the calculated values form a positive definite

matrix. If an array is passed, it must have the same number of entries as the data used for fitting and is used as datapoint-dependent noise level. Note that this is equivalent to adding a WhiteKernel with c=alpha. Allowing to specify the noise level directly as a parameter is mainly for convenience and for consistency with Ridge.

optimizer : string or callable, optional (default: "fmin_l_bfgs_b")

Can either be one of the internally supported optimizers for optimizing the kernel's parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:

```
def optimizer(obj_func, initial_theta, bounds):
    # * 'obj_func' is the objective function to be maximized, which
    #   takes the hyperparameters theta as parameter and an
    #   optional flag eval_gradient, which determines if the
    #   gradient is returned additionally to the function value
    # * 'initial_theta': the initial value for theta, which can be
    #   used by local optimizers
    # * 'bounds': the bounds on the values of theta
    ....
    # Returned are the best found hyperparameters theta and
    # the corresponding value of the target function.
    return theta_opt, func_min
```

Per default, the 'fmin_l_bfgs_b' algorithm from scipy.optimize is used. If None is passed, the kernel's parameters are kept fixed. Available internal optimizers are:

```
'fmin_l_bfgs_b'
```

n_restarts_optimizer : int, optional (default: 0)

The number of restarts of the optimizer for finding the kernel's parameters which maximize the log-marginal likelihood. The first run of the optimizer is performed from the kernel's initial parameters, the remaining ones (if any) from thetas sampled log-uniform randomly from the space of allowed theta-values. If greater than 0, all bounds must be finite. Note that n_restarts_optimizer == 0 implies that one run is performed.

normalize_y : boolean, optional (default: False)

Whether the target values y are normalized, i.e., the mean of the observed target values become zero. This parameter should be set to True if the target values' mean is expected to differ considerable from zero. When enabled, the normalization effectively modifies the GP's prior based on the data, which contradicts the likelihood principle; normalization is thus disabled per default.

copy_X_train : bool, optional (default: True)

If True, a persistent copy of the training data is stored in the object. Otherwise, just a reference to the training data is stored, which might cause predictions to change if the data is modified externally.

random_state : int, RandomState instance or None, optional (default: None)

The generator used to initialize the centers. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **X_train_** : array-like, shape = (n_samples, n_features)

Feature values in training data (also required for prediction)

y_train_ : array-like, shape = (n_samples, [n_output_dims])

Target values in training data (also required for prediction)

kernel_ : kernel object

The kernel used for prediction. The structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters

L_ : array-like, shape = (n_samples, n_samples)

Lower-triangular Cholesky decomposition of the kernel in `X_train_`

alpha_ : array-like, shape = (n_samples,)

Dual coefficients of training data points in kernel space

log_marginal_likelihood_value_ : float

The log-marginal-likelihood of `self.kernel_.theta`

Methods

fit(X, y)	Fit Gaussian process regression model.
get_params([deep])	Get parameters for this estimator.
log_marginal_likelihood([theta, eval_gradient])	Returns log-marginal likelihood of theta for training data.
predict(X[, return_std, return_cov])	Predict using the Gaussian process regression model
sample_y(X[, n_samples, random_state])	Draw samples from Gaussian process and evaluate at X.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*kernel=None*, *alpha=1e-10*, *optimizer='fmin_l_bfgs_b'*, *n_restarts_optimizer=0*, *normalize_y=False*, *copy_X_train=True*, *random_state=None*)

fit (*X*, *y*)

Fit Gaussian process regression model.

Parameters **X** : array-like, shape = (n_samples, n_features)

Training data

y : array-like, shape = (n_samples, [n_output_dims])

Target values

Returns **self** : returns an instance of self.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

log_marginal_likelihood(*theta=None*, *eval_gradient=False*)
Returns log-marginal likelihood of theta for training data.

Parameters **theta** : array-like, shape = (n_kernel_params,) or None

Kernel hyperparameters for which the log-marginal likelihood is evaluated. If None, the precomputed log_marginal_likelihood of `self.kernel_.theta` is returned.

eval_gradient : bool, default: False

If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. If True, theta must not be None.

Returns **log_likelihood** : float

Log-marginal likelihood of theta for training data.

log_likelihood_gradient : array, shape = (n_kernel_params,), optional

Gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta. Only returned when eval_gradient is True.

predict(*X*, *return_std=False*, *return_cov=False*)
Predict using the Gaussian process regression model

We can also predict based on an unfitted model by using the GP prior. In addition to the mean of the predictive distribution, also its standard deviation (return_std=True) or covariance (return_cov=True). Note that at most one of the two can be requested.

Parameters **X** : array-like, shape = (n_samples, n_features)

Query points where the GP is evaluated

return_std : bool, default: False

If True, the standard-deviation of the predictive distribution at the query points is returned along with the mean.

return_cov : bool, default: False

If True, the covariance of the joint predictive distribution at the query points is returned along with the mean

Returns **y_mean** : array, shape = (n_samples, [n_output_dims])

Mean of predictive distribution a query points

y_std : array, shape = (n_samples,), optional

Standard deviation of predictive distribution at query points. Only returned when return_std is True.

y_cov : array, shape = (n_samples, n_samples), optional

Covariance of joint predictive distribution a query points. Only returned when return_cov is True.

rng
DEPRECATED: Attribute rng was deprecated in version 0.19 and will be removed in 0.21.

sample_y(*X*, *n_samples=1*, *random_state=0*)
Draw samples from Gaussian process and evaluate at X.

Parameters **X** : array-like, shape = (n_samples_X, n_features)

Query points where the GP samples are evaluated

n_samples : int, default: 1

The number of samples drawn from the Gaussian process

random_state : int, RandomState instance or None, optional (default=0)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **y_samples** : array, shape = (n_samples_X, [n_output_dims], n_samples)

Values of n_samples samples drawn from Gaussian process and evaluated at query points.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

y_train_mean

DEPRECATED: Attribute y_train_mean was deprecated in version 0.19 and will be removed in 0.21.

29.13.2 sklearn.gaussian_process.GaussianProcessClassifier

class sklearn.gaussian_process.**GaussianProcessClassifier**(*kernel=None*, *optimizer='fmin_l_bfgs_b'*, *n_restarts_optimizer=0*, *max_iter_predict=100*, *warm_start=False*, *copy_X_train=True*, *random_state=None*, *multi_class='one_vs_rest'*, *n_jobs=1*)

Gaussian process classification (GPC) based on Laplace approximation.

The implementation is based on Algorithm 3.1, 3.2, and 5.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.

Internally, the Laplace approximation is used for approximating the non-Gaussian posterior by a Gaussian.

Currently, the implementation is restricted to using the logistic link function. For multi-class classification, several binary one-versus rest classifiers are fitted. Note that this class thus does not implement a true multi-class Laplace approximation.

Parameters **kernel** : kernel object

The kernel specifying the covariance function of the GP. If None is passed, the kernel "1.0 * RBF(1.0)" is used as default. Note that the kernel's hyperparameters are optimized during fitting.

optimizer : string or callable, optional (default: "fmin_l_bfgs_b")

Can either be one of the internally supported optimizers for optimizing the kernel's parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:

```
def optimizer(obj_func, initial_theta, bounds):
    # * 'obj_func' is the objective function to be maximized, which
    #   takes the hyperparameters theta as parameter and an
    #   optional flag eval_gradient, which determines if the
    #   gradient is returned additionally to the function value
    # * 'initial_theta': the initial value for theta, which can be
    #   used by local optimizers
    # * 'bounds': the bounds on the values of theta
    ....
    # Returned are the best found hyperparameters theta and
    # the corresponding value of the target function.
    return theta_opt, func_min
```

Per default, the 'fmin_l_bfgs_b' algorithm from scipy.optimize is used. If None is passed, the kernel's parameters are kept fixed. Available internal optimizers are:

```
'fmin_l_bfgs_b'
```

n_restarts_optimizer : int, optional (default: 0)

The number of restarts of the optimizer for finding the kernel's parameters which maximize the log-marginal likelihood. The first run of the optimizer is performed from the kernel's initial parameters, the remaining ones (if any) from thetas sampled log-uniform

randomly from the space of allowed theta-values. If greater than 0, all bounds must be finite. Note that n_restarts_optimizer=0 implies that one run is performed.

max_iter_predict : int, optional (default: 100)

The maximum number of iterations in Newton's method for approximating the posterior during predict. Smaller values will reduce computation time at the cost of worse results.

warm_start : bool, optional (default: False)

If warm-starts are enabled, the solution of the last Newton iteration on the Laplace approximation of the posterior mode is used as initialization for the next call of _posterior_mode(). This can speed up convergence when _posterior_mode is called several times on similar problems as in hyperparameter optimization.

copy_X_train : bool, optional (default: True)

If True, a persistent copy of the training data is stored in the object. Otherwise, just a reference to the training data is stored, which might cause predictions to change if the data is modified externally.

random_state : int, RandomState instance or None, optional (default: None)

The generator used to initialize the centers. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

multi_class : string, default

Specifies how multi-class classification problems are handled. Supported are "one_vs_rest" and "one_vs_one". In "one_vs_rest", one binary Gaussian process classifier is fitted for each class, which is trained to separate this class from the rest. In "one_vs_one", one binary Gaussian process classifier is fitted for each pair of classes, which is trained to separate these two classes. The predictions of these binary predictors are combined into multi-class predictions. Note that "one_vs_one" does not support predicting probability estimates.

n_jobs : int, optional, default: 1

The number of jobs to use for the computation. If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

Attributes **kernel_** : kernel object

The kernel used for prediction. In case of binary classification, the structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters. In case of multi-class classification, a CompoundKernel is returned which consists of the different kernels used in the one-versus-rest classifiers.

log_marginal_likelihood_value_ : float

The log-marginal-likelihood of `self.kernel_.theta`

classes_ : array-like, shape = (n_classes,)

Unique class labels.

n_classes_ : int

The number of classes in the training data

.. versionadded:: 0.18 :

Methods

fit(X, y)	Fit Gaussian process classification model
get_params([deep])	Get parameters for this estimator.
log_marginal_likelihood([theta, eval_gradient])	Returns log-marginal likelihood of theta for training data.
predict(X)	Perform classification on an array of test vectors X.
predict_proba(X)	Return probability estimates for the test vector X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*kernel=None*, *optimizer='fmin_l_bfgs_b'*, *n_restarts_optimizer=0*, *max_iter_predict=100*, *warm_start=False*, *copy_X_train=True*, *random_state=None*, *multi_class='one_vs_rest'*, *n_jobs=1*)

fit (*X*, *y*)
Fit Gaussian process classification model

Parameters **X** : array-like, shape = (n_samples, n_features)

Training data

y : array-like, shape = (n_samples,)

Target values, must be binary

Returns **self** : returns an instance of self.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

log_marginal_likelihood (*theta=None*, *eval_gradient=False*)
Returns log-marginal likelihood of theta for training data.

In the case of multi-class classification, the mean log-marginal likelihood of the one-versus-rest classifiers are returned.

Parameters **theta** : array-like, shape = (n_kernel_params,) or none

Kernel hyperparameters for which the log-marginal likelihood is evaluated. In the case of multi-class classification, theta may be the hyperparameters of the compound kernel or of an individual kernel. In the latter case, all individual kernel get assigned the same theta values. If None, the precomputed log_marginal_likelihood of `self.kernel_.theta` is returned.

eval_gradient : bool, default: False

If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. Note that gradient computation is not supported for non-binary classification. If True, theta must not be None.

Returns **log_likelihood** : float

Log-marginal likelihood of theta for training data.

log_likelihood_gradient : array, shape = (n_kernel_params,), optional

Gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta. Only returned when eval_gradient is True.

predict(*X*)

Perform classification on an array of test vectors X.

Parameters **X** : array-like, shape = (n_samples, n_features)

Returns **C** : array, shape = (n_samples,)

Predicted target values for X, values are from `classes_`

predict_proba(*X*)

Return probability estimates for the test vector X.

Parameters **X** : array-like, shape = (n_samples, n_features)

Returns **C** : array-like, shape = (n_samples, n_classes)

Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.gaussian_process.GaussianProcessClassifier`

- *Plot classification probability*
- *Classifier comparison*
- *Probabilistic predictions with Gaussian process classification (GPC)*

- *Gaussian process classification (GPC) on iris dataset*
- *Iso-probability lines for Gaussian Processes classification (GPC)*
- *Illustration of Gaussian process classification (GPC) on the XOR dataset*

Kernels:

gaussian_process.kernels.Kernel	Base class for all kernels.
gaussian_process.kernels.Sum(k1, k2)	Sum-kernel k1 + k2 of two kernels k1 and k2.
gaussian_process.kernels.Product(k1, k2)	Product-kernel k1 * k2 of two kernels k1 and k2.
gaussian_process.kernels.Exponentiation(...)	Exponentiate kernel by given exponent.
gaussian_process.kernels.ConstantKernel([...])	Constant kernel.
gaussian_process.kernels.WhiteKernel([...])	White kernel.
gaussian_process.kernels.RBF([length_scale, ...])	Radial-basis function kernel (aka squared-exponential kernel).
gaussian_process.kernels.Matern([...])	Matern kernel.
gaussian_process.kernels.RationalQuadratic([...])	Rational Quadratic kernel.
gaussian_process.kernels.ExpSineSquared([...])	Exp-Sine-Squared kernel.
gaussian_process.kernels.DotProduct([...])	Dot-Product kernel.
gaussian_process.kernels.PairwiseKernel([...])	Wrapper for kernels in sklearn.metrics.pairwise.
gaussian_process.kernels.CompoundKernel(kernels)	Kernel which is composed of a set of other kernels.
gaussian_process.kernels.Hyperparameter	A kernel hyperparameter's specification in form of a namedtuple.

29.13.3 sklearn.gaussian_process.kernels.Kernel

class sklearn.gaussian_process.kernels.**Kernel**

Base class for all kernels.

New in version 0.18.

Methods

clone_with_theta(theta)	Returns a clone of self with given hyperparameters theta.
diag(X)	Returns the diagonal of the kernel k(X, X).
get_params([deep])	Get parameters of this kernel.
is_stationary()	Returns whether the kernel is stationary.
set_params(**params)	Set the parameters of this kernel.

__init__()

Initialize self. See help(type(self)) for accurate signature.

__call__(*X*, *Y=None*, *eval_gradient=False*)

Evaluate the kernel.

bounds
Returns the log-transformed bounds on the theta.

Returns bounds : array, shape (n_dims, 2)

The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta(*theta*)
Returns a clone of self with given hyperparameters theta.

diag(*X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters X : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Returns K_diag : array, shape (n_samples_X,)

Diagonal of kernel k(X, X)

get_params(*deep=True*)
Get parameters of this kernel.

Parameters deep : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns params : mapping of string to any

Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params(***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns self :

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns theta : array, shape (n_dims,)

The non-fixed, log-transformed hyperparameters of the kernel

29.13.4 sklearn.gaussian_process.kernels.Sum

class sklearn.gaussian_process.kernels.**Sum**(*k1*, *k2*)

Sum-kernel k1 + k2 of two kernels k1 and k2.

The resulting kernel is defined as k_sum(X, Y) = k1(X, Y) + k2(X, Y)

New in version 0.18.

Parameters **k1** : Kernel object

The first base-kernel of the sum-kernel

k2 : Kernel object

The second base-kernel of the sum-kernel

Methods

clone_with_theta(theta)	Returns a clone of self with given hyperparameters theta.
diag(X)	Returns the diagonal of the kernel k(X, X).
get_params([deep])	Get parameters of this kernel.
is_stationary()	Returns whether the kernel is stationary.
set_params(**params)	Set the parameters of this kernel.

__init__(*k1*, *k2*)

__call__(*X*, *Y=None*, *eval_gradient=False*)

Return the kernel k(X, Y) and optionally its gradient.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Y : array, shape (n_samples_Y, n_features), (optional, default=None)

Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient : bool (optional, default=False)

Determines whether the gradient with respect to the kernel hyperparameter is determined.

Returns **K** : array, shape (n_samples_X, n_samples_Y)

Kernel k(X, Y)

K_gradient : array (opt.), shape (n_samples_X, n_samples_X, n_dims)

The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds

Returns the log-transformed bounds on the theta.

Returns **bounds** : array, shape (n_dims, 2)

The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta(*theta*)

Returns a clone of self with given hyperparameters theta.

diag(*X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Returns **K_diag** : array, shape (n_samples_X,)

Diagonal of kernel k(X, X)

get_params(*deep=True*)
Get parameters of this kernel.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter.

is_stationary()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params(***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns **theta** : array, shape (n_dims,)

The non-fixed, log-transformed hyperparameters of the kernel

29.13.5 sklearn.gaussian_process.kernels.Product

class sklearn.gaussian_process.kernels.**Product**(*k1*, *k2*)
Product-kernel k1 * k2 of two kernels k1 and k2.

The resulting kernel is defined as k_prod(X, Y) = k1(X, Y) * k2(X, Y)

New in version 0.18.

Parameters **k1** : Kernel object

The first base-kernel of the product-kernel

k2 : Kernel object

The second base-kernel of the product-kernel

Methods

clone_with_theta(theta)	Returns a clone of self with given hyperparameters theta.
diag(X)	Returns the diagonal of the kernel k(X, X).
get_params([deep])	Get parameters of this kernel.
is_stationary()	Returns whether the kernel is stationary.
set_params(**params)	Set the parameters of this kernel.

__init__ (*k1*, *k2*)

__call__ (*X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Y : array, shape (n_samples_Y, n_features), (optional, default=None)

Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient : bool (optional, default=False)

Determines whether the gradient with respect to the kernel hyperparameter is determined.

Returns **K** : array, shape (n_samples_X, n_samples_Y)

Kernel k(X, Y)

K_gradient : array (opt.), shape (n_samples_X, n_samples_X, n_dims)

The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds
Returns the log-transformed bounds on the theta.

Returns **bounds** : array, shape (n_dims, 2)

The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta (*theta*)
Returns a clone of self with given hyperparameters theta.

diag (*X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Returns **K_diag** : array, shape (n_samples_X,)

Diagonal of kernel k(X, X)

get_params(*deep=True*)
Get parameters of this kernel.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter.

is_stationary()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params(***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns **theta** : array, shape (n_dims,)

The non-fixed, log-transformed hyperparameters of the kernel

29.13.6 sklearn.gaussian_process.kernels.Exponentiation

class sklearn.gaussian_process.kernels.**Exponentiation**(*kernel*, *exponent*)
Exponentiate kernel by given exponent.

The resulting kernel is defined as k_exp(X, Y) = k(X, Y) ** exponent

New in version 0.18.

Parameters **kernel** : Kernel object

The base kernel

exponent : float

The exponent for the base kernel

Methods

clone_with_theta(theta)	Returns a clone of self with given hyperparameters theta.
diag(X)	Returns the diagonal of the kernel k(X, X).
get_params([deep])	Get parameters of this kernel.
is_stationary()	Returns whether the kernel is stationary.
set_params(**params)	Set the parameters of this kernel.

__init__ (*kernel*, *exponent*)

__call__ (*X*, *Y=None*, *eval_gradient=False*)

Return the kernel k(X, Y) and optionally its gradient.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Y : array, shape (n_samples_Y, n_features), (optional, default=None)

Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient : bool (optional, default=False)

Determines whether the gradient with respect to the kernel hyperparameter is determined.

Returns **K** : array, shape (n_samples_X, n_samples_Y)

Kernel k(X, Y)

K_gradient : array (opt.), shape (n_samples_X, n_samples_X, n_dims)

The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds

Returns the log-transformed bounds on the theta.

Returns **bounds** : array, shape (n_dims, 2)

The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta (*theta*)

Returns a clone of self with given hyperparameters theta.

diag (*X*)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Returns **K_diag** : array, shape (n_samples_X,)

Diagonal of kernel k(X, X)

get_params (*deep=True*)

Get parameters of this kernel.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter.

is_stationary()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params(***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns **theta** : array, shape (n_dims,)

The non-fixed, log-transformed hyperparameters of the kernel

29.13.7 sklearn.gaussian_process.kernels.ConstantKernel

class sklearn.gaussian_process.kernels.**ConstantKernel**(*constant_value=1.0*, *constant_value_bounds=(1e-05, 100000.0)*)

Constant kernel.

Can be used as part of a product-kernel where it scales the magnitude of the other factor (kernel) or as part of a sum-kernel, where it modifies the mean of the Gaussian process.

k(x_1, x_2) = constant_value for all x_1, x_2

New in version 0.18.

Parameters **constant_value** : float, default: 1.0

The constant value which defines the covariance: k(x_1, x_2) = constant_value

constant_value_bounds : pair of floats >= 0, default: (1e-5, 1e5)

The lower and upper bound on constant_value

Methods

clone_with_theta(theta)	Returns a clone of self with given hyperparameters theta.
diag(X)	Returns the diagonal of the kernel k(X, X).
get_params([deep])	Get parameters of this kernel.
is_stationary()	Returns whether the kernel is stationary.
set_params(**params)	Set the parameters of this kernel.

__init__ (*constant_value=1.0*, *constant_value_bounds=(1e-05*, *100000.0)*)

__call__ (*X*, *Y=None*, *eval_gradient=False*)

Return the kernel k(X, Y) and optionally its gradient.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Y : array, shape (n_samples_Y, n_features), (optional, default=None)

Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient : bool (optional, default=False)

Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns **K** : array, shape (n_samples_X, n_samples_Y)

Kernel k(X, Y)

K_gradient : array (opt.), shape (n_samples_X, n_samples_X, n_dims)

The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds

Returns the log-transformed bounds on the theta.

Returns **bounds** : array, shape (n_dims, 2)

The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta (*theta*)

Returns a clone of self with given hyperparameters theta.

diag (*X*)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Returns **K_diag** : array, shape (n_samples_X,)

Diagonal of kernel k(X, X)

get_params (*deep=True*)

Get parameters of this kernel.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params(***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns **theta** : array, shape (n_dims,)

The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.ConstantKernel`

- *Iso-probability lines for Gaussian Processes classification (GPC)*
- *Gaussian Processes regression: basic introductory example*
- *Illustration of prior and posterior Gaussian process for different kernels*

29.13.8 `sklearn.gaussian_process.kernels`.WhiteKernel

class `sklearn.gaussian_process.kernels.`**WhiteKernel**(*noise_level=1.0*, *noise_level_bounds=(1e-05*, *100000.0)*)

White kernel.

The main use-case of this kernel is as part of a sum-kernel where it explains the noise-component of the signal. Tuning its parameter corresponds to estimating the noise-level.

k(x_1, x_2) = noise_level if x_1 == x_2 else 0

New in version 0.18.

Parameters **noise_level** : float, default: 1.0

Parameter controlling the noise level

noise_level_bounds : pair of floats >= 0, default: (1e-5, 1e5)

The lower and upper bound on noise_level

Methods

clone_with_theta(theta)	Returns a clone of self with given hyperparameters theta.
diag(X)	Returns the diagonal of the kernel k(X, X).
get_params([deep])	Get parameters of this kernel.
is_stationary()	Returns whether the kernel is stationary.
set_params(**params)	Set the parameters of this kernel.

__init__ (*noise_level=1.0*, *noise_level_bounds=(1e-05*, *100000.0)*)

__call__ (*X*, *Y=None*, *eval_gradient=False*)

Return the kernel k(X, Y) and optionally its gradient.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Y : array, shape (n_samples_Y, n_features), (optional, default=None)

Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient : bool (optional, default=False)

Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns **K** : array, shape (n_samples_X, n_samples_Y)

Kernel k(X, Y)

K_gradient : array (opt.), shape (n_samples_X, n_samples_X, n_dims)

The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds

Returns the log-transformed bounds on the theta.

Returns **bounds** : array, shape (n_dims, 2)

The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta (*theta*)

Returns a clone of self with given hyperparameters theta.

diag (*X*)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Returns **K_diag** : array, shape (n_samples_X,)

Diagonal of kernel k(X, X)

get_params(*deep=True*)
Get parameters of this kernel.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params(***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns **theta** : array, shape (n_dims,)

The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.WhiteKernel`

- *Comparison of kernel ridge and Gaussian process regression*
- *Gaussian process regression (GPR) on Mauna Loa CO2 data.*
- *Gaussian process regression (GPR) with noise-level estimation*

29.13.9 `sklearn.gaussian_process.kernels.RBF`

class `sklearn.gaussian_process.kernels.`**RBF**(*length_scale=1.0*, *length_scale_bounds=(1e-05, 100000.0)*)
Radial-basis function kernel (aka squared-exponential kernel).

The RBF kernel is a stationary kernel. It is also known as the "squared exponential" kernel. It is parameterized by a length-scale parameter length_scale>0, which can either be a scalar (isotropic variant of the kernel) or a vector with the same number of dimensions as the inputs X (anisotropic variant of the kernel). The kernel is given by:

k(x_i, x_j) = exp(-1 / 2 d(x_i / length_scale, x_j / length_scale)^2)

This kernel is infinitely differentiable, which implies that GPs with this kernel as covariance function have mean square derivatives of all orders, and are thus very smooth.

New in version 0.18.

Parameters **length_scale** : float or array with shape (n_features,), default: 1.0

The length scale of the kernel. If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of l defines the length-scale of the respective feature dimension.

length_scale_bounds : pair of floats >= 0, default: (1e-5, 1e5)

The lower and upper bound on length_scale

Methods

clone_with_theta(theta)	Returns a clone of self with given hyperparameters theta.
diag(X)	Returns the diagonal of the kernel k(X, X).
get_params([deep])	Get parameters of this kernel.
is_stationary()	Returns whether the kernel is stationary.
set_params(**params)	Set the parameters of this kernel.

__init__ (*length_scale=1.0*, *length_scale_bounds=(1e-05*, *100000.0)*)

__call__ (*X*, *Y=None*, *eval_gradient=False*)

Return the kernel k(X, Y) and optionally its gradient.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Y : array, shape (n_samples_Y, n_features), (optional, default=None)

Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient : bool (optional, default=False)

Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns **K** : array, shape (n_samples_X, n_samples_Y)

Kernel k(X, Y)

K_gradient : array (opt.), shape (n_samples_X, n_samples_X, n_dims)

The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds

Returns the log-transformed bounds on the theta.

Returns **bounds** : array, shape (n_dims, 2)

The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta (*theta*)

Returns a clone of self with given hyperparameters theta.

diag(*X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Returns **K_diag** : array, shape (n_samples_X,)

Diagonal of kernel k(X, X)

get_params(*deep=True*)
Get parameters of this kernel.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params(***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns **theta** : array, shape (n_dims,)

The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.RBF`

- *Plot classification probability*
- *Classifier comparison*
- *Probabilistic predictions with Gaussian process classification (GPC)*
- *Gaussian process classification (GPC) on iris dataset*
- *Illustration of Gaussian process classification (GPC) on the XOR dataset*

- *Gaussian process regression (GPR) on Mauna Loa CO2 data.*
- *Gaussian process regression (GPR) with noise-level estimation*
- *Gaussian Processes regression: basic introductory example*
- *Illustration of prior and posterior Gaussian process for different kernels*

29.13.10 sklearn.gaussian_process.kernels.Matern

class sklearn.gaussian_process.kernels.**Matern**(*length_scale=1.0*, *length_scale_bounds=(1e-05*, *100000.0)*, *nu=1.5*)

Matern kernel.

The class of Matern kernels is a generalization of the RBF and the absolute exponential kernel parameterized by an additional parameter nu. The smaller nu, the less smooth the approximated function is. For nu=inf, the kernel becomes equivalent to the RBF kernel and for nu=0.5 to the absolute exponential kernel. Important intermediate values are nu=1.5 (once differentiable functions) and nu=2.5 (twice differentiable functions).

See Rasmussen and Williams 2006, pp84 for details regarding the different variants of the Matern kernel.

New in version 0.18.

Parameters **length_scale** : float or array with shape (n_features,), default: 1.0

The length scale of the kernel. If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of l defines the length-scale of the respective feature dimension.

length_scale_bounds : pair of floats >= 0, default: (1e-5, 1e5)

The lower and upper bound on length_scale

nu: float, default: 1.5 :

The parameter nu controlling the smoothness of the learned function. The smaller nu, the less smooth the approximated function is. For nu=inf, the kernel becomes equivalent to the RBF kernel and for nu=0.5 to the absolute exponential kernel. Important intermediate values are nu=1.5 (once differentiable functions) and nu=2.5 (twice differentiable functions). Note that values of nu not in [0.5, 1.5, 2.5, inf] incur a considerably higher computational cost (appr. 10 times higher) since they require to evaluate the modified Bessel function. Furthermore, in contrast to l, nu is kept fixed to its initial value and not optimized.

Methods

clone_with_theta(theta)	Returns a clone of self with given hyperparameters theta.
diag(X)	Returns the diagonal of the kernel k(X, X).
get_params([deep])	Get parameters of this kernel.
is_stationary()	Returns whether the kernel is stationary.
set_params(**params)	Set the parameters of this kernel.

__init__(*length_scale=1.0*, *length_scale_bounds=(1e-05*, *100000.0)*, *nu=1.5*)

__call__(*X*, *Y=None*, *eval_gradient=False*)

Return the kernel k(X, Y) and optionally its gradient.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Y : array, shape (n_samples_Y, n_features), (optional, default=None)

Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient : bool (optional, default=False)

Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns **K** : array, shape (n_samples_X, n_samples_Y)

Kernel k(X, Y)

K_gradient : array (opt.), shape (n_samples_X, n_samples_X, n_dims)

The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds

Returns the log-transformed bounds on the theta.

Returns **bounds** : array, shape (n_dims, 2)

The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta(*theta*)

Returns a clone of self with given hyperparameters theta.

diag(*X*)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Returns **K_diag** : array, shape (n_samples_X,)

Diagonal of kernel k(X, X)

get_params(*deep=True*)

Get parameters of this kernel.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

hyperparameters

Returns a list of all hyperparameter specifications.

is_stationary()

Returns whether the kernel is stationary.

n_dims

Returns the number of non-fixed hyperparameters of the kernel.

set_params (***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns **theta** : array, shape (n_dims,)

The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.Matern`

- *Illustration of prior and posterior Gaussian process for different kernels*

29.13.11 sklearn.gaussian_process.kernels.RationalQuadratic

class sklearn.gaussian_process.kernels.**RationalQuadratic**(*length_scale=1.0*, *alpha=1.0*, *length_scale_bounds=(1e-05, 100000.0)*, *alpha_bounds=(1e-05, 100000.0)*)

Rational Quadratic kernel.

The RationalQuadratic kernel can be seen as a scale mixture (an infinite sum) of RBF kernels with different characteristic length-scales. It is parameterized by a length-scale parameter length_scale>0 and a scale mixture parameter alpha>0. Only the isotropic variant where length_scale is a scalar is supported at the moment. The kernel given by:

k(x_i, x_j) = (1 + d(x_i, x_j)^2 / (2*alpha * length_scale^2))^-alpha

New in version 0.18.

Parameters **length_scale** : float > 0, default: 1.0

The length scale of the kernel.

alpha : float > 0, default: 1.0

Scale mixture parameter

length_scale_bounds : pair of floats >= 0, default: (1e-5, 1e5)

The lower and upper bound on length_scale

alpha_bounds : pair of floats >= 0, default: (1e-5, 1e5)

The lower and upper bound on alpha

Methods

clone_with_theta(theta)	Returns a clone of self with given hyperparameters theta.
diag(X)	Returns the diagonal of the kernel k(X, X).
get_params([deep])	Get parameters of this kernel.
is_stationary()	Returns whether the kernel is stationary.
set_params(**params)	Set the parameters of this kernel.

__init__ (*length_scale=1.0*, *alpha=1.0*, *length_scale_bounds=(1e-05*, *100000.0)*, *alpha_bounds=(1e-05*, *100000.0)*)

__call__ (*X*, *Y=None*, *eval_gradient=False*)

Return the kernel k(X, Y) and optionally its gradient.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Y : array, shape (n_samples_Y, n_features), (optional, default=None)

Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient : bool (optional, default=False)

Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns **K** : array, shape (n_samples_X, n_samples_Y)

Kernel k(X, Y)

K_gradient : array (opt.), shape (n_samples_X, n_samples_X, n_dims)

The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds

Returns the log-transformed bounds on the theta.

Returns **bounds** : array, shape (n_dims, 2)

The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta (*theta*)

Returns a clone of self with given hyperparameters theta.

diag (*X*)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Returns **K_diag** : array, shape (n_samples_X,)

Diagonal of kernel k(X, X)

get_params (*deep=True*)

Get parameters of this kernel.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params(***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns **theta** : array, shape (n_dims,)

The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.RationalQuadratic`

- *Gaussian process regression (GPR) on Mauna Loa CO2 data.*
- *Illustration of prior and posterior Gaussian process for different kernels*

29.13.12 `sklearn.gaussian_process.kernels`.ExpSineSquared

class `sklearn.gaussian_process.kernels.`**ExpSineSquared**(*length_scale=1.0*, *periodicity=1.0*, *length_scale_bounds=(1e-05, 100000.0)*, *periodicity_bounds=(1e-05, 100000.0)*)

Exp-Sine-Squared kernel.

The ExpSineSquared kernel allows modeling periodic functions. It is parameterized by a length-scale parameter length_scale>0 and a periodicity parameter periodicity>0. Only the isotropic variant where l is a scalar is supported at the moment. The kernel given by:

k(x_i, x_j) = exp(-2 sin(pi / periodicity * d(x_i, x_j)) / length_scale)^2

New in version 0.18.

Parameters **length_scale** : float > 0, default: 1.0

The length scale of the kernel.

periodicity : float > 0, default: 1.0

The periodicity of the kernel.

length_scale_bounds : pair of floats >= 0, default: (1e-5, 1e5)

The lower and upper bound on length_scale

periodicity_bounds : pair of floats >= 0, default: (1e-5, 1e5)

The lower and upper bound on periodicity

Methods

clone_with_theta(theta)	Returns a clone of self with given hyperparameters theta.
diag(X)	Returns the diagonal of the kernel k(X, X).
get_params([deep])	Get parameters of this kernel.
is_stationary()	Returns whether the kernel is stationary.
set_params(**params)	Set the parameters of this kernel.

__init__ (*length_scale=1.0*, *periodicity=1.0*, *length_scale_bounds=(1e-05*, *100000.0)*, *periodicity_bounds=(1e-05*, *100000.0)*)

__call__ (*X*, *Y=None*, *eval_gradient=False*)

Return the kernel k(X, Y) and optionally its gradient.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Y : array, shape (n_samples_Y, n_features), (optional, default=None)

Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient : bool (optional, default=False)

Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns **K** : array, shape (n_samples_X, n_samples_Y)

Kernel k(X, Y)

K_gradient : array (opt.), shape (n_samples_X, n_samples_X, n_dims)

The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds

Returns the log-transformed bounds on the theta.

Returns **bounds** : array, shape (n_dims, 2)

The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta (*theta*)

Returns a clone of self with given hyperparameters theta.

diag (*X*)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Returns **K_diag** : array, shape (n_samples_X,)

Diagonal of kernel k(X, X)

get_params(*deep=True*)
Get parameters of this kernel.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params(***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns **theta** : array, shape (n_dims,)

The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.ExpSineSquared`

- *Comparison of kernel ridge and Gaussian process regression*
- *Gaussian process regression (GPR) on Mauna Loa CO2 data.*
- *Illustration of prior and posterior Gaussian process for different kernels*

29.13.13 sklearn.gaussian_process.kernels.DotProduct

class sklearn.gaussian_process.kernels.**DotProduct**(*sigma_0=1.0*, *sigma_0_bounds=(1e-05, 100000.0)*)

Dot-Product kernel.

The DotProduct kernel is non-stationary and can be obtained from linear regression by putting N(0, 1) priors on the coefficients of x_d (d = 1, . . . , D) and a prior of N(0, sigma_0^2) on the bias. The DotProduct kernel is invariant to a rotation of the coordinates about the origin, but not translations. It is parameterized by a parameter sigma_0^2. For sigma_0^2 =0, the kernel is called the homogeneous linear kernel, otherwise it is inhomogeneous. The kernel is given by

k(x_i, x_j) = sigma_0 ^ 2 + x_i cdot x_j

The DotProduct kernel is commonly combined with exponentiation.

New in version 0.18.

Parameters **sigma_0** : float >= 0, default: 1.0

Parameter controlling the inhomogenity of the kernel. If sigma_0=0, the kernel is homogenous.

sigma_0_bounds : pair of floats >= 0, default: (1e-5, 1e5)

The lower and upper bound on l

Methods

clone_with_theta(theta)	Returns a clone of self with given hyperparameters theta.
diag(X)	Returns the diagonal of the kernel k(X, X).
get_params([deep])	Get parameters of this kernel.
is_stationary()	Returns whether the kernel is stationary.
set_params(**params)	Set the parameters of this kernel.

__init__(*sigma_0=1.0*, *sigma_0_bounds=(1e-05, 100000.0)*)

__call__(*X*, *Y=None*, *eval_gradient=False*)

Return the kernel k(X, Y) and optionally its gradient.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Y : array, shape (n_samples_Y, n_features), (optional, default=None)

Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient : bool (optional, default=False)

Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns **K** : array, shape (n_samples_X, n_samples_Y)

Kernel k(X, Y)

K_gradient : array (opt.), shape (n_samples_X, n_samples_X, n_dims)

The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds
Returns the log-transformed bounds on the theta.

Returns bounds : array, shape (n_dims, 2)

The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta(*theta*)
Returns a clone of self with given hyperparameters theta.

diag(*X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters X : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Returns K_diag : array, shape (n_samples_X,)

Diagonal of kernel k(X, X)

get_params(*deep=True*)
Get parameters of this kernel.

Parameters deep : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns params : mapping of string to any

Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params(***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns self :

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns theta : array, shape (n_dims,)

The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.DotProduct`

- *Iso-probability lines for Gaussian Processes classification (GPC)*
- *Illustration of Gaussian process classification (GPC) on the XOR dataset*
- *Illustration of prior and posterior Gaussian process for different kernels*

29.13.14 `sklearn.gaussian_process.kernels.PairwiseKernel`

class `sklearn.gaussian_process.kernels.`**`PairwiseKernel`**(*gamma=1.0*, *gamma_bounds=(1e-05, 100000.0)*, *metric='linear'*, *pairwise_kernels_kwargs=None*)

Wrapper for kernels in sklearn.metrics.pairwise.

A thin wrapper around the functionality of the kernels in sklearn.metrics.pairwise.

Note: Evaluation of eval_gradient is not analytic but numeric and all kernels support only isotropic distances. The parameter gamma is considered to be a hyperparameter and may be optimized. The other kernel parameters are set directly at initialization and are kept fixed.

New in version 0.18.

Parameters **gamma: float >= 0, default: 1.0** :

Parameter gamma of the pairwise kernel specified by metric

gamma_bounds : pair of floats >= 0, default: (1e-5, 1e5)

The lower and upper bound on gamma

metric : string, or callable, default: "linear"

The metric to use when calculating kernel between instances in a feature array. If metric is a string, it must be one of the metrics in pairwise.PAIRWISE_KERNEL_FUNCTIONS. If metric is "precomputed", X is assumed to be a kernel matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

pairwise_kernels_kwargs : dict, default: None

All entries of this dict (if any) are passed as keyword arguments to the pairwise kernel function.

Methods

clone_with_theta(theta)	Returns a clone of self with given hyperparameters theta.
diag(X)	Returns the diagonal of the kernel k(X, X).
get_params([deep])	Get parameters of this kernel.
is_stationary()	Returns whether the kernel is stationary.
set_params(**params)	Set the parameters of this kernel.

`__init__`(*gamma=1.0*, *gamma_bounds=(1e-05, 100000.0)*, *metric='linear'*, *pairwise_kernels_kwargs=None*)

__call__(*X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Y : array, shape (n_samples_Y, n_features), (optional, default=None)

Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient : bool (optional, default=False)

Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns **K** : array, shape (n_samples_X, n_samples_Y)

Kernel k(X, Y)

K_gradient : array (opt.), shape (n_samples_X, n_samples_X, n_dims)

The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds
Returns the log-transformed bounds on the theta.

Returns **bounds** : array, shape (n_dims, 2)

The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta(*theta*)
Returns a clone of self with given hyperparameters theta.

diag(*X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Returns **K_diag** : array, shape (n_samples_X,)

Diagonal of kernel k(X, X)

get_params(*deep=True*)
Get parameters of this kernel.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params(***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns **theta** : array, shape (n_dims,)

The non-fixed, log-transformed hyperparameters of the kernel

29.13.15 sklearn.gaussian_process.kernels.CompoundKernel

class sklearn.gaussian_process.kernels.**CompoundKernel**(*kernels*)
Kernel which is composed of a set of other kernels.

New in version 0.18.

Methods

clone_with_theta(theta)	Returns a clone of self with given hyperparameters theta.
diag(X)	Returns the diagonal of the kernel k(X, X).
get_params([deep])	Get parameters of this kernel.
is_stationary()	Returns whether the kernel is stationary.
set_params(**params)	Set the parameters of this kernel.

__init__(*kernels*)

__call__(*X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Note that this compound kernel returns the results of all simple kernel stacked along an additional axis.

Parameters **X** : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Y : array, shape (n_samples_Y, n_features), (optional, default=None)

Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient : bool (optional, default=False)

Determines whether the gradient with respect to the kernel hyperparameter is determined.

Returns **K** : array, shape (n_samples_X, n_samples_Y, n_kernels)

Kernel k(X, Y)

K_gradient : array, shape (n_samples_X, n_samples_X, n_dims, n_kernels)

The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds
Returns the log-transformed bounds on the theta.

Returns bounds : array, shape (n_dims, 2)

The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta(*theta*)
Returns a clone of self with given hyperparameters theta.

diag(*X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters X : array, shape (n_samples_X, n_features)

Left argument of the returned kernel k(X, Y)

Returns K_diag : array, shape (n_samples_X, n_kernels)

Diagonal of kernel k(X, X)

get_params(*deep=True*)
Get parameters of this kernel.

Parameters deep : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns params : mapping of string to any

Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params(***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns self :

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns **theta** : array, shape (n_dims,)

The non-fixed, log-transformed hyperparameters of the kernel

29.13.16 sklearn.gaussian_process.kernels.Hyperparameter

class sklearn.gaussian_process.kernels.**Hyperparameter**

A kernel hyperparameter's specification in form of a namedtuple.

New in version 0.18.

Attributes **name** : string

The name of the hyperparameter. Note that a kernel using a hyperparameter with name "x" must have the attributes self.x and self.x_bounds

value_type : string

The type of the hyperparameter. Currently, only "numeric" hyperparameters are supported.

bounds : pair of floats >= 0 or "fixed"

The lower and upper bound on the parameter. If n_elements>1, a pair of 1d array with n_elements each may be given alternatively. If the string "fixed" is passed as bounds, the hyperparameter's value cannot be changed.

n_elements : int, default=1

The number of elements of the hyperparameter value. Defaults to 1, which corresponds to a scalar hyperparameter. n_elements > 1 corresponds to a hyperparameter which is vector-valued, such as, e.g., anisotropic length-scales.

fixed : bool, default: None

Whether the value of this hyperparameter is fixed, i.e., cannot be changed during hyperparameter tuning. If None is passed, the "fixed" is derived based on the given bounds.

Methods

count(...)	
index((value, [start, ...)	Raises ValueError if the value is not present.

__init__()
Initialize self. See help(type(self)) for accurate signature.

__call__()
Call self as a function.

bounds
Alias for field number 2

count(*value*) → integer – return number of occurrences of value

fixed
Alias for field number 4

index(*value*[, *start*[, *stop*]]) → integer – return first index of value.
Raises ValueError if the value is not present.

n_elements
Alias for field number 3

name
Alias for field number 0

value_type
Alias for field number 1

29.14 sklearn.isotonic: Isotonic regression

User guide: See the *Isotonic regression* section for further details.

isotonic.IsotonicRegression([y_min, y_max, ...])	Isotonic regression model.

29.14.1 sklearn.isotonic.IsotonicRegression

class sklearn.isotonic.**IsotonicRegression**(*y_min=None*, *y_max=None*, *increasing=True*, *out_of_bounds='nan'*)

Isotonic regression model.

The isotonic regression optimization problem is defined by:

```
min sum w_i (y[i] - y_[i]) ** 2

subject to y_[i] <= y_[j] whenever X[i] <= X[j]
and min(y_) = y_min, max(y_) = y_max
```

where:

- `y[i]` are inputs (real numbers)
- `y_[i]` are fitted
- `X` specifies the order. If `X` is non-decreasing then `y_` is non-decreasing.
- `w[i]` are optional strictly positive weights (default to 1.0)

Read more in the *User Guide*.

Parameters **y_min** : optional, default: None

If not None, set the lowest value of the fit to y_min.

y_max : optional, default: None

If not None, set the highest value of the fit to y_max.

increasing : boolean or string, optional, default: True

If boolean, whether or not to fit the isotonic regression with y increasing or decreasing.

The string value "auto" determines whether y should increase or decrease based on the Spearman correlation estimate's sign.

out_of_bounds : string, optional, default: "nan"

The `out_of_bounds` parameter handles how x-values outside of the training domain are handled. When set to "nan", predicted y-values will be NaN. When set to "clip", predicted y-values will be set to the value corresponding to the nearest train interval endpoint. When set to "raise", allow `interp1d` to throw ValueError.

Attributes **X_min_** : float

Minimum value of input array *X_* for left bound.

X_max_ : float

Maximum value of input array *X_* for right bound.

f_ : function

The stepwise interpolating function that covers the domain *X_*.

Notes

Ties are broken using the secondary method from Leeuw, 1977.

References

Isotonic Median Regression: A Linear Programming Approach Nilotpal Chakravarti Mathematics of Operations Research Vol. 14, No. 2 (May, 1989), pp. 303-308

Correctness of Kruskal's algorithms for monotone regression with ties Leeuw, Psychometrica, 1977

Methods

fit(X, y[, sample_weight])	Fit the model using X, y as training data.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
predict(T)	Predict new data by linear interpolation.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.
transform(T)	Transform new data by linear interpolation

__init__ (*y_min=None*, *y_max=None*, *increasing=True*, *out_of_bounds='nan'*)

X_
DEPRECATED: Attribute `X_` is deprecated in version 0.18 and will be removed in version 0.20.

fit (*X*, *y*, *sample_weight=None*)
Fit the model using X, y as training data.

Parameters **X** : array-like, shape=(n_samples,)

Training data.

y : array-like, shape=(n_samples,)

Training target.

sample_weight : array-like, shape=(n_samples,), optional, default: None

Weights. If set to None, all weights will be set to 1 (equal weights).

Returns **self** : object

Returns an instance of self.

Notes

X is stored for future use, as *transform* needs X to interpolate new input data.

fit_transform(*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*T*)
Predict new data by linear interpolation.

Parameters **T** : array-like, shape=(n_samples,)

Data to transform.

Returns **T_** : array, shape=(n_samples,)

Transformed data.

score(*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*T*)

Transform new data by linear interpolation

Parameters **T** : array-like, shape=(n_samples,)

Data to transform.

Returns **T_** : array, shape=(n_samples,)

The transformed data

y_

DEPRECATED: Attribute `y_` is deprecated in version 0.18 and will be removed in version 0.20.

Examples using `sklearn.isotonic.IsotonicRegression`

- *Isotonic Regression*

isotonic.isotonic_regression(y[, ...])	Solve the isotonic regression model:
isotonic.check_increasing(x, y)	Determine whether y is monotonically correlated with x.

29.14.2 `sklearn.isotonic`.isotonic_regression

sklearn.isotonic.**isotonic_regression**(*y*, *sample_weight=None*, *y_min=None*, *y_max=None*, *increasing=True*)

Solve the isotonic regression model:

```
min sum w[i] (y[i] - y_[i]) ** 2

subject to y_min = y_[1] <= y_[2] ... <= y_[n] = y_max
```

where:

- y[i] are inputs (real numbers)
- y_[i] are fitted
- w[i] are optional strictly positive weights (default to 1.0)

Read more in the *User Guide*.

Parameters **y** : iterable of floating-point values

The data.

sample_weight : iterable of floating-point values, optional, default: None

Weights on each point of the regression. If None, weight is set to 1 (equal weights).

y_min : optional, default: None

If not None, set the lowest value of the fit to y_min.

y_max : optional, default: None

If not None, set the highest value of the fit to y_max.

increasing : boolean, optional, default: True

Whether to compute `y_` is increasing (if set to True) or decreasing (if set to False)

Returns **y_** : list of floating-point values

Isotonic fit of y.

References

"Active set algorithms for isotonic regression; A unifying framework" by Michael J. Best and Nilotpal Chakravarti, section 3.

29.14.3 sklearn.isotonic.check_increasing

sklearn.isotonic.**check_increasing**(*x*, *y*)

Determine whether y is monotonically correlated with x.

y is found increasing or decreasing with respect to x based on a Spearman correlation test.

Parameters **x** : array-like, shape=(n_samples,)

Training data.

y : array-like, shape=(n_samples,)

Training target.

Returns **increasing_bool** : boolean

Whether the relationship is increasing or decreasing.

Notes

The Spearman correlation coefficient is estimated from the data, and the sign of the resulting estimate is used as the result.

In the event that the 95% confidence interval based on Fisher transform spans zero, a warning is raised.

29.15 sklearn.kernel_approximation Kernel Approximation

The *sklearn.kernel_approximation* module implements several approximate kernel feature maps base on Fourier transforms.

User guide: See the *Kernel Approximation* section for further details.

kernel_approximation.AdditiveChi2Sampler([...])	Approximate feature map for additive chi2 kernel.
kernel_approximation.Nystroem([kernel, ...])	Approximate a kernel map using a subset of the training data.
kernel_approximation.RBFSampler([gamma, ...])	Approximates feature map of an RBF kernel by Monte Carlo approximation of its Fourier transform.
kernel_approximation.SkewedChi2Sampler([...])	Approximates feature map of the "skewed chi-squared" kernel by Monte Carlo approximation of its Fourier transform.

29.15.1 sklearn.kernel_approximation.AdditiveChi2Sampler

class sklearn.kernel_approximation.**AdditiveChi2Sampler**(*sample_steps=2*, *sample_interval=None*)

Approximate feature map for additive chi2 kernel.

Uses sampling the fourier transform of the kernel characteristic at regular intervals.

Since the kernel that is to be approximated is additive, the components of the input vectors can be treated separately. Each entry in the original space is transformed into 2*sample_steps+1 features, where sample_steps is a parameter of the method. Typical values of sample_steps include 1, 2 and 3.

Optimal choices for the sampling interval for certain data ranges can be computed (see the reference). The default values should be reasonable.

Read more in the *User Guide*.

Parameters **sample_steps** : int, optional

Gives the number of (complex) sampling points.

sample_interval : float, optional

Sampling interval. Must be specified when sample_steps not in {1,2,3}.

See also:

SkewedChi2Sampler A Fourier-approximation to a non-additive variant of the chi squared kernel.

sklearn.metrics.pairwise.chi2_kernel The exact chi squared kernel.

sklearn.metrics.pairwise.additive_chi2_kernel The exact additive chi squared kernel.

Notes

This estimator approximates a slightly different version of the additive chi squared kernel then metric.additive_chi2 computes.

Methods

fit(X[, y])	Set parameters.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X[, y])	Apply approximate feature map to X.

__init__ (*sample_steps=2*, *sample_interval=None*)

fit (*X*, *y=None*)
Set parameters.

fit_transform (*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform (*X*, *y=None*)
Apply approximate feature map to X.

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Returns **X_new** : {array, sparse matrix}, shape = (n_samples, n_features * (2*sample_steps + 1))

Whether the return value is an array of sparse matrix depends on the type of the input X.

29.15.2 sklearn.kernel_approximation.Nystroem

class sklearn.kernel_approximation.**Nystroem**(*kernel='rbf'*, *gamma=None*, *coef0=1*, *degree=3*, *kernel_params=None*, *n_components=100*, *random_state=None*)

Approximate a kernel map using a subset of the training data.

Constructs an approximate feature map for an arbitrary kernel using a subset of the data as basis.

Read more in the *User Guide*.

Parameters **kernel** : string or callable, default="rbf"

Kernel map to be approximated. A callable should accept two arguments and the keyword arguments passed to this object as kernel_params, and should return a floating point number.

n_components : int

Number of features to construct. How many data points will be used to construct the mapping.

gamma : float, default=None

Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for sklearn.metrics.pairwise. Ignored by other kernels.

degree : float, default=3

Degree of the polynomial kernel. Ignored by other kernels.

coef0 : float, default=1

Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

kernel_params : mapping of string to any, optional

Additional parameters (keyword arguments) for kernel function passed as callable object.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **components_** : array, shape (n_components, n_features)

Subset of training points used to construct the feature map.

component_indices_ : array, shape (n_components)

Indices of `components_` in the training set.

normalization_ : array, shape (n_components, n_components)

Normalization matrix needed for embedding. Square root of the kernel matrix on `components_`.

See also:

RBFSampler An approximation to the RBF kernel using random Fourier features.

sklearn.metrics.pairwise.kernel_metrics List of built-in kernels.

Methods

fit(X[, y])	Fit estimator to data.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Apply feature map to X.

__init__ (*kernel='rbf'*, *gamma=None*, *coef0=1*, *degree=3*, *kernel_params=None*, *n_components=100*, *random_state=None*)

fit (*X*, *y=None*)
Fit estimator to data.

Samples a subset of training points, computes kernel on these and computes normalization matrix.

Parameters **X** : array-like, shape=(n_samples, n_feature)

Training data.

fit_transform (*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Apply feature map to X.

Computes an approximate feature map using the kernel between some training points and X.

Parameters **X** : array-like, shape=(n_samples, n_features)

Data to transform.

Returns **X_transformed** : array, shape=(n_samples, n_components)

Transformed data.

Examples using `sklearn.kernel_approximation.Nystroem`

- *Explicit feature map approximation for RBF kernels*

29.15.3 `sklearn.kernel_approximation`.RBFSampler

class `sklearn.kernel_approximation.`**RBFSampler**(*gamma=1.0*, *n_components=100*, *random_state=None*)
Approximates feature map of an RBF kernel by Monte Carlo approximation of its Fourier transform.

It implements a variant of Random Kitchen Sinks.[1]

Read more in the *User Guide*.

Parameters **gamma** : float

Parameter of RBF kernel: exp(-gamma * x^2)

n_components : int

Number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Notes

Methods

fit(X[, y])	Fit the model with X.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X[, y])	Apply the approximate feature map to X.

__init__ (*gamma=1.0*, *n_components=100*, *random_state=None*)

fit (*X*, *y=None*)
Fit the model with X.

Samples random projection according to n_features.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Training data, where n_samples in the number of samples and n_features is the number of features.

Returns **self** : object

Returns the transformer.

fit_transform (*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform (*X*, *y=None*)
Apply the approximate feature map to X.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

New data, where n_samples in the number of samples and n_features is the number of features.

Returns **X_new** : array-like, shape (n_samples, n_components)

Examples using `sklearn.kernel_approximation.RBFSampler`

- *Explicit feature map approximation for RBF kernels*

29.15.4 `sklearn.kernel_approximation`.SkewedChi2Sampler

class `sklearn.kernel_approximation.`**`SkewedChi2Sampler`**(*skewedness=1.0*, *n_components=100*, *random_state=None*)

Approximates feature map of the "skewed chi-squared" kernel by Monte Carlo approximation of its Fourier transform.

Read more in the *User Guide*.

Parameters **skewedness** : float

"skewedness" parameter of the kernel. Needs to be cross-validated.

n_components : int

number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

See also:

AdditiveChi2Sampler A different approach for approximating an additive variant of the chi squared kernel.

sklearn.metrics.pairwise.chi2_kernel The exact chi squared kernel.

References

See "Random Fourier Approximations for Skewed Multiplicative Histogram Kernels" by Fuxin Li, Catalin Ionescu and Cristian Sminchisescu.

Methods

fit(X[, y])	Fit the model with X.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X[, y])	Apply the approximate feature map to X.

__init__(*skewedness=1.0*, *n_components=100*, *random_state=None*)

fit(*X*, *y=None*)
Fit the model with X.

Samples random projection according to n_features.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples in the number of samples and n_features is the number of features.

Returns **self** : object

Returns the transformer.

fit_transform(*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *y=None*)
Apply the approximate feature map to X.

Parameters **X** : array-like, shape (n_samples, n_features)

New data, where n_samples in the number of samples and n_features is the number of features. All values of X must be strictly greater than "-skewedness".

Returns **X_new** : array-like, shape (n_samples, n_components)

29.16 sklearn.kernel_ridge Kernel Ridge Regression

Module *sklearn.kernel_ridge* implements kernel ridge regression.

User guide: See the *Kernel ridge regression* section for further details.

kernel_ridge.KernelRidge([alpha, kernel, ...])	Kernel ridge regression.

29.16.1 sklearn.kernel_ridge.KernelRidge

class sklearn.kernel_ridge.**KernelRidge**(*alpha=1*, *kernel='linear'*, *gamma=None*, *degree=3*, *coef0=1*, *kernel_params=None*)

Kernel ridge regression.

Kernel ridge regression (KRR) combines ridge regression (linear least squares with l2-norm regularization) with the kernel trick. It thus learns a linear function in the space induced by the respective kernel and the data. For non-linear kernels, this corresponds to a non-linear function in the original space.

The form of the model learned by KRR is identical to support vector regression (SVR). However, different loss functions are used: KRR uses squared error loss while support vector regression uses epsilon-insensitive loss, both combined with l2 regularization. In contrast to SVR, fitting a KRR model can be done in closed-form and is typically faster for medium-sized datasets. On the other hand, the learned model is non-sparse and thus slower than SVR, which learns a sparse model for epsilon > 0, at prediction-time.

This estimator has built-in support for multi-variate regression (i.e., when y is a 2d-array of shape [n_samples, n_targets]).

Read more in the *User Guide*.

Parameters **alpha** : {float, array-like}, shape = [n_targets]

Small positive values of alpha improve the conditioning of the problem and reduce the variance of the estimates. Alpha corresponds to `(2*C)^-1` in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

kernel : string or callable, default="linear"

Kernel mapping used internally. A callable should accept two arguments and the keyword arguments passed to this object as kernel_params, and should return a floating point number.

gamma : float, default=None

Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for sklearn.metrics.pairwise. Ignored by other kernels.

degree : float, default=3

Degree of the polynomial kernel. Ignored by other kernels.

coef0 : float, default=1

Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

kernel_params : mapping of string to any, optional

Additional parameters (keyword arguments) for kernel function passed as callable object.

Attributes **dual_coef_** : array, shape = [n_samples] or [n_samples, n_targets]

Representation of weight vector(s) in kernel space

X_fit_ : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training data, which is also required for prediction

See also:

Ridge Linear ridge regression.

SVR Support Vector Regression implemented using libsvm.

Examples

```
>>> from sklearn.kernel_ridge import KernelRidge
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = KernelRidge(alpha=1.0)
>>> clf.fit(X, y)
KernelRidge(alpha=1.0, coef0=1, degree=3, gamma=None, kernel='linear',
            kernel_params=None)
```

Methods

fit(X[, y, sample_weight])	Fit Kernel Ridge regression model
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict using the kernel ridge model
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*alpha=1*, *kernel='linear'*, *gamma=None*, *degree=3*, *coef0=1*, *kernel_params=None*)

fit (*X*, *y=None*, *sample_weight=None*)

Fit Kernel Ridge regression model

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training data

y : array-like, shape = [n_samples] or [n_samples, n_targets]

Target values

sample_weight : float or array-like of shape [n_samples]

Individual weights for each sample, ignored if None is passed.

Returns **self** : returns an instance of self.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)
Predict using the kernel ridge model

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Samples.

Returns **C** : array, shape = [n_samples] or [n_samples, n_targets]

Returns predicted values.

score(*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.17 sklearn.discriminant_analysis: Discriminant Analysis

Linear Discriminant Analysis and Quadratic Discriminant Analysis

User guide: See the *Linear and Quadratic Discriminant Analysis* section for further details.

discriminant_analysis.LinearDiscriminantAnalysis([...])	Linear Discriminant Analysis
discriminant_analysis.QuadraticDiscriminantAnalysis([...])	Quadratic Discriminant Analysis

29.17.1 sklearn.discriminant_analysis.LinearDiscriminantAnalysis

class sklearn.discriminant_analysis.**LinearDiscriminantAnalysis**(*solver='svd'*, *shrinkage=None*, *priors=None*, *n_components=None*, *store_covariance=False*, *tol=0.0001*)

Linear Discriminant Analysis

A classifier with a linear decision boundary, generated by fitting class conditional densities to the data and using Bayes' rule.

The model fits a Gaussian density to each class, assuming that all classes share the same covariance matrix.

The fitted model can also be used to reduce the dimensionality of the input by projecting it to the most discriminative directions.

New in version 0.17: *LinearDiscriminantAnalysis*.

Read more in the *User Guide*.

Parameters **solver** : string, optional

Solver to use, possible values:

- 'svd': Singular value decomposition (default). Does not compute the covariance matrix, therefore this solver is recommended for data with a large number of features.
- 'lsqr': Least squares solution, can be combined with shrinkage.
- 'eigen': Eigenvalue decomposition, can be combined with shrinkage.

shrinkage : string or float, optional

Shrinkage parameter, possible values:

- None: no shrinkage (default).
- 'auto': automatic shrinkage using the Ledoit-Wolf lemma.
- float between 0 and 1: fixed shrinkage parameter.

Note that shrinkage works only with 'lsqr' and 'eigen' solvers.

priors : array, optional, shape (n_classes,)

Class priors.

n_components : int, optional

Number of components (< n_classes - 1) for dimensionality reduction.

store_covariance : bool, optional

Additionally compute class covariance matrix (default False).

New in version 0.17.

tol : float, optional

Threshold used for rank estimation in SVD solver.

New in version 0.17.

Attributes **coef_** : array, shape (n_features,) or (n_classes, n_features)

Weight vector(s).

intercept_ : array, shape (n_features,)

Intercept term.

covariance_ : array-like, shape (n_features, n_features)

Covariance matrix (shared by all classes).

explained_variance_ratio_ : array, shape (n_components,)

Percentage of variance explained by each of the selected components. If `n_components` is not set then all components are stored and the sum of explained variances is equal to 1.0. Only available when eigen or svd solver is used.

means_ : array-like, shape (n_classes, n_features)

Class means.

priors_ : array-like, shape (n_classes,)

Class priors (sum to 1).

scalings_ : array-like, shape (rank, n_classes - 1)

Scaling of the features in the space spanned by the class centroids.

xbar_ : array-like, shape (n_features,)

Overall mean.

classes_ : array-like, shape (n_classes,)

Unique class labels.

See also:

sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis Quadratic Discriminant Analysis

Notes

The default solver is 'svd'. It can perform both classification and transform, and it does not rely on the calculation of the covariance matrix. This can be an advantage in situations where the number of features is large. However, the 'svd' solver cannot be used with shrinkage.

The 'lsqr' solver is an efficient algorithm that only works for classification. It supports shrinkage.

The 'eigen' solver is based on the optimization of the between class scatter to within class scatter ratio. It can be used for both classification and transform, and it supports shrinkage. However, the 'eigen' solver needs to compute the covariance matrix, so it might not be suitable for situations with a high number of features.

Examples

```
>>> import numpy as np
>>> from sklearn.discriminant_analysis import LinearDiscriminantAnalysis
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = LinearDiscriminantAnalysis()
>>> clf.fit(X, y)
LinearDiscriminantAnalysis(n_components=None, priors=None, shrinkage=None,
              solver='svd', store_covariance=False, tol=0.0001)
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

Methods

decision_function(X)	Predict confidence scores for samples.
fit(X, y)	Fit LinearDiscriminantAnalysis model according to the given training data and parameters.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict class labels for samples in X.
predict_log_proba(X)	Estimate log probability.
predict_proba(X)	Estimate probability.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Project data to maximize class separation.

__init__ (*solver='svd'*, *shrinkage=None*, *priors=None*, *n_components=None*, *store_covariance=False*, *tol=0.0001*)

decision_function (*X*)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)** :

Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

fit (*X*, *y*)

Fit LinearDiscriminantAnalysis model according to the given training data and parameters.

Changed in version 0.19: *store_covariance* has been moved to main constructor.

Changed in version 0.19: *tol* has been moved to main constructor.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data.

y : array, shape (n_samples,)

Target values.

fit_transform(*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Predict class labels for samples in X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Samples.

Returns **C** : array, shape = [n_samples]

Predicted class label per sample.

predict_log_proba(*X*)

Estimate log probability.

Parameters **X** : array-like, shape (n_samples, n_features)

Input data.

Returns **C** : array, shape (n_samples, n_classes)

Estimated log probabilities.

predict_proba(*X*)

Estimate probability.

Parameters **X** : array-like, shape (n_samples, n_features)

Input data.

Returns **C** : array, shape (n_samples, n_classes)

Estimated probabilities.

score(*X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Project data to maximize class separation.

Parameters **X** : array-like, shape (n_samples, n_features)

Input data.

Returns **X_new** : array, shape (n_samples, n_components)

Transformed data.

Examples using `sklearn.discriminant_analysis.LinearDiscriminantAnalysis`

- *Normal and Shrinkage Linear Discriminant Analysis for classification*
- *Linear and Quadratic Discriminant Analysis with covariance ellipsoid*
- *Comparison of LDA and PCA 2D projection of Iris dataset*

29.17.2 `sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis`

class sklearn.discriminant_analysis.**QuadraticDiscriminantAnalysis**(*priors=None*, *reg_param=0.0*, *store_covariances=False*, *tol=0.0001*)

Quadratic Discriminant Analysis

A classifier with a quadratic decision boundary, generated by fitting class conditional densities to the data and using Bayes' rule.

The model fits a Gaussian density to each class.

New in version 0.17: *QuadraticDiscriminantAnalysis*

Read more in the *User Guide*.

Parameters **priors** : array, optional, shape = [n_classes]

Priors on classes

reg_param : float, optional

Regularizes the covariance estimate as `(1-reg_param)*Sigma + reg_param*np.eye(n_features)`

Attributes **covariances_** : list of array-like, shape = [n_features, n_features]

Covariance matrices of each class.

means_ : array-like, shape = [n_classes, n_features]

Class means.

priors_ : array-like, shape = [n_classes]

Class priors (sum to 1).

rotations_ : list of arrays

For each class k an array of shape [n_features, n_k], with `n_k = min(n_features, number of elements in class k)` It is the rotation of the Gaussian distribution, i.e. its principal axis.

scalings_ : list of arrays

For each class k an array of shape [n_k]. It contains the scaling of the Gaussian distributions along its principal axes, i.e. the variance in the rotated coordinate system.

store_covariances : boolean

If True the covariance matrices are computed and stored in the *self.covariances_* attribute.

New in version 0.17.

tol : float, optional, default 1.0e-4

Threshold used for rank estimation.

New in version 0.17.

Examples

```
>>> from sklearn.discriminant_analysis import QuadraticDiscriminantAnalysis
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = QuadraticDiscriminantAnalysis()
>>> clf.fit(X, y)
...
QuadraticDiscriminantAnalysis(priors=None, reg_param=0.0,
```

```
                               store_covariances=False, tol=0.0001)
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

Methods

decision_function(X)	Apply decision function to an array of samples.
fit(X, y)	Fit the model according to the given training data and parameters.
get_params([deep])	Get parameters for this estimator.
predict(X)	Perform classification on an array of test vectors X.
predict_log_proba(X)	Return posterior probabilities of classification.
predict_proba(X)	Return posterior probabilities of classification.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*priors=None*, *reg_param=0.0*, *store_covariances=False*, *tol=0.0001*)

decision_function (*X*)

Apply decision function to an array of samples.

Parameters **X** : array-like, shape = [n_samples, n_features]

Array of samples (test vectors).

Returns **C** : array, shape = [n_samples, n_classes] or [n_samples,]

Decision function values related to each class, per sample. In the two-class case, the shape is [n_samples,], giving the log likelihood ratio of the positive class.

fit (*X*, *y*)

Fit the model according to the given training data and parameters.

Changed in version 0.19: *store_covariance* has been moved to main constructor.

Changed in version 0.19: *tol* has been moved to main constructor.

Parameters **X** : array-like, shape = [n_samples, n_features]

Training vector, where n_samples in the number of samples and n_features is the number of features.

y : array, shape = [n_samples]

Target values (integers)

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)
Perform classification on an array of test vectors X.

The predicted class C for each sample in X is returned.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array, shape = [n_samples]

predict_log_proba(*X*)
Return posterior probabilities of classification.

Parameters **X** : array-like, shape = [n_samples, n_features]

Array of samples/test vectors.

Returns **C** : array, shape = [n_samples, n_classes]

Posterior log-probabilities of classification per class.

predict_proba(*X*)
Return posterior probabilities of classification.

Parameters **X** : array-like, shape = [n_samples, n_features]

Array of samples/test vectors.

Returns **C** : array, shape = [n_samples, n_classes]

Posterior probabilities of classification per class.

score(*X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.18 sklearn.linear_model: Generalized Linear Models

The *sklearn.linear_model* module implements generalized linear models. It includes Ridge regression, Bayesian Regression, Lasso and Elastic Net estimators computed with Least Angle Regression and coordinate descent. It also implements Stochastic Gradient Descent related algorithms.

User guide: See the *Generalized Linear Models* section for further details.

linear_model.ARDRegression([n_iter, tol, ...])	Bayesian ARD regression.
linear_model.BayesianRidge([n_iter, tol, ...])	Bayesian ridge regression
linear_model.ElasticNet([alpha, l1_ratio, ...])	Linear regression with combined L1 and L2 priors as regularizer.
linear_model.ElasticNetCV([l1_ratio, eps, ...])	Elastic Net model with iterative fitting along a regularization path
linear_model.HuberRegressor([epsilon, ...])	Linear regression model that is robust to outliers.
linear_model.Lars([fit_intercept, verbose, ...])	Least Angle Regression model a.k.a.
linear_model.LarsCV([fit_intercept, ...])	Cross-validated Least Angle Regression model
linear_model.Lasso([alpha, fit_intercept, ...])	Linear Model trained with L1 prior as regularizer (aka the Lasso)
linear_model.LassoCV([eps, n_alphas, ...])	Lasso linear model with iterative fitting along a regularization path
linear_model.LassoLars([alpha, ...])	Lasso model fit with Least Angle Regression a.k.a.
linear_model.LassoLarsCV([fit_intercept, ...])	Cross-validated Lasso, using the LARS algorithm
linear_model.LassoLarsIC([criterion, ...])	Lasso model fit with Lars using BIC or AIC for model selection
linear_model.LinearRegression([...])	Ordinary least squares Linear Regression.
linear_model.LogisticRegression([penalty, ...])	Logistic Regression (aka logit, MaxEnt) classifier.
linear_model.LogisticRegressionCV([Cs, ...])	Logistic Regression CV (aka logit, MaxEnt) classifier.
linear_model.MultiTaskLasso([alpha, ...])	Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer
linear_model.MultiTaskElasticNet([alpha, ...])	Multi-task ElasticNet model trained with L1/L2 mixed-norm as regularizer
linear_model.MultiTaskLassoCV([eps, ...])	Multi-task L1/L2 Lasso with built-in cross-validation.
linear_model.MultiTaskElasticNetCV([...])	Multi-task L1/L2 ElasticNet with built-in cross-validation.
linear_model.OrthogonalMatchingPursuit([...])	Orthogonal Matching Pursuit model (OMP)
linear_model.OrthogonalMatchingPursuitCV([...])	Cross-validated Orthogonal Matching Pursuit model (OMP)
linear_model.PassiveAggressiveClassifier([C, ...])	Passive Aggressive Classifier
linear_model.PassiveAggressiveRegressor([C, ...])	Passive Aggressive Regressor
linear_model.Perceptron([penalty, alpha, ...])	Read more in the *User Guide*.
linear_model.RandomizedLasso([alpha, ...])	Randomized Lasso.
linear_model.RandomizedLogisticRegression([...])	Randomized Logistic Regression
linear_model.RANSACRegressor([...])	RANSAC (RANdom SAmple Consensus) algorithm.
linear_model.Ridge([alpha, fit_intercept, ...])	Linear least squares with l2 regularization.
linear_model.RidgeClassifier([alpha, ...])	Classifier using Ridge regression.
linear_model.RidgeClassifierCV([alphas, ...])	Ridge classifier with built-in cross-validation.
linear_model.RidgeCV([alphas, ...])	Ridge regression with built-in cross-validation.
linear_model.SGDClassifier([loss, penalty, ...])	Linear classifiers (SVM, logistic regression, a.o.) with SGD training.

Continued on next page

Table 29.147 – continued from previous page

linear_model.SGDRegressor([loss, penalty, ...])	Linear model fitted by minimizing a regularized empirical loss with SGD
linear_model.TheilSenRegressor([...])	Theil-Sen Estimator: robust multivariate regression model.

29.18.1 sklearn.linear_model.ARDRegression

class sklearn.linear_model.**ARDRegression**(*n_iter=300*, *tol=0.001*, *alpha_1=1e-06*, *alpha_2=1e-06*, *lambda_1=1e-06*, *lambda_2=1e-06*, *compute_score=False*, *threshold_lambda=10000.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *verbose=False*)

Bayesian ARD regression.

Fit the weights of a regression model, using an ARD prior. The weights of the regression model are assumed to be in Gaussian distributions. Also estimate the parameters lambda (precisions of the distributions of the weights) and alpha (precision of the distribution of the noise). The estimation is done by an iterative procedures (Evidence Maximization)

Read more in the *User Guide*.

Parameters **n_iter** : int, optional

Maximum number of iterations. Default is 300

tol : float, optional

Stop the algorithm if w has converged. Default is 1.e-3.

alpha_1 : float, optional

Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter. Default is 1.e-6.

alpha_2 : float, optional

Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter. Default is 1.e-6.

lambda_1 : float, optional

Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter. Default is 1.e-6.

lambda_2 : float, optional

Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter. Default is 1.e-6.

compute_score : boolean, optional

If True, compute the objective function at each step of the model. Default is False.

threshold_lambda : float, optional

threshold for removing (pruning) weights with high precision from the computation. Default is 1.e+4.

fit_intercept : boolean, optional

whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered). Default is True.

normalize : boolean, optional, default False

This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *`sklearn.preprocessing.StandardScaler`* before calling `fit` on an estimator with `normalize=False`.

copy_X : boolean, optional, default True.

If True, X will be copied; else, it may be overwritten.

verbose : boolean, optional, default False

Verbose mode when fitting the model.

Attributes **coef_** : array, shape = (n_features)

Coefficients of the regression model (mean of distribution)

alpha_ : float

estimated precision of the noise.

lambda_ : array, shape = (n_features)

estimated precisions of the weights.

sigma_ : array, shape = (n_features, n_features)

estimated variance-covariance matrix of the weights

scores_ : float

if computed, value of the objective function (to be maximized)

Notes

For an example, see *examples/linear_model/plot_ard.py*.

Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.ARDRegression()
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
...
ARDRegression(alpha_1=1e-06, alpha_2=1e-06, compute_score=False,
        copy_X=True, fit_intercept=True, lambda_1=1e-06, lambda_2=1e-06,
        n_iter=300, normalize=False, threshold_lambda=10000.0, tol=0.001,
        verbose=False)
```

```
>>> clf.predict([[1, 1]])
array([ 1.])
```

Methods

fit(X, y)	Fit the ARDRegression model according to the given training data and parameters.
get_params([deep])	Get parameters for this estimator.
predict(X[, return_std])	Predict using the linear model.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_iter=300*, *tol=0.001*, *alpha_1=1e-06*, *alpha_2=1e-06*, *lambda_1=1e-06*, *lambda_2=1e-06*, *compute_score=False*, *threshold_lambda=10000.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *verbose=False*)

fit (*X*, *y*)

Fit the ARDRegression model according to the given training data and parameters.

Iterative procedure to maximize the evidence

Parameters **X** : array-like, shape = [n_samples, n_features]

Training vector, where n_samples in the number of samples and n_features is the number of features.

y : array, shape = [n_samples]

Target values (integers)

Returns **self** : returns an instance of self.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*, *return_std=False*)

Predict using the linear model.

In addition to the mean of the predictive distribution, also its standard deviation can be returned.

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

return_std : boolean, optional

Whether to return the standard deviation of posterior prediction.

Returns **y_mean** : array, shape = (n_samples,)

Mean of predictive distribution of query points.

y_std : array, shape = (n_samples,)

Standard deviation of predictive distribution of query points.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.linear_model.ARDRegression`

- *Automatic Relevance Determination Regression (ARD)*

29.18.2 `sklearn.linear_model`.BayesianRidge

class `sklearn.linear_model.`**BayesianRidge**(*n_iter=300*, *tol=0.001*, *alpha_1=1e-06*, *alpha_2=1e-06*, *lambda_1=1e-06*, *lambda_2=1e-06*, *compute_score=False*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *verbose=False*)

Bayesian ridge regression

Fit a Bayesian ridge model and optimize the regularization parameters lambda (precision of the weights) and alpha (precision of the noise).

Read more in the *User Guide*.

Parameters **n_iter** : int, optional

Maximum number of iterations. Default is 300.

tol : float, optional

Stop the algorithm if w has converged. Default is 1.e-3.

alpha_1 : float, optional

Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter. Default is 1.e-6

alpha_2 : float, optional

Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter. Default is 1.e-6.

lambda_1 : float, optional

Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter. Default is 1.e-6.

lambda_2 : float, optional

Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter. Default is 1.e-6

compute_score : boolean, optional

If True, compute the objective function at each step of the model. Default is False

fit_intercept : boolean, optional

whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered). Default is True.

normalize : boolean, optional, default False

This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *`sklearn.preprocessing.StandardScaler`* before calling `fit` on an estimator with `normalize=False`.

copy_X : boolean, optional, default True

If True, X will be copied; else, it may be overwritten.

verbose : boolean, optional, default False

Verbose mode when fitting the model.

Attributes **coef_** : array, shape = (n_features)

Coefficients of the regression model (mean of distribution)

alpha_ : float

estimated precision of the noise.

lambda_ : float

estimated precision of the weights.

sigma_ : array, shape = (n_features, n_features)

estimated variance-covariance matrix of the weights

scores_ : float

if computed, value of the objective function (to be maximized)

Notes

For an example, see *examples/linear_model/plot_bayesian_ridge.py*.

Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.BayesianRidge()
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
...
BayesianRidge(alpha_1=1e-06, alpha_2=1e-06, compute_score=False,
        copy_X=True, fit_intercept=True, lambda_1=1e-06, lambda_2=1e-06,
        n_iter=300, normalize=False, tol=0.001, verbose=False)
>>> clf.predict([[1, 1]])
array([ 1.])
```

Methods

fit(X, y)	Fit the model
get_params([deep])	Get parameters for this estimator.
predict(X[, return_std])	Predict using the linear model.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_iter=300*, *tol=0.001*, *alpha_1=1e-06*, *alpha_2=1e-06*, *lambda_1=1e-06*, *lambda_2=1e-06*, *compute_score=False*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *verbose=False*)

fit (*X*, *y*)
Fit the model

Parameters **X** : numpy array of shape [n_samples,n_features]

Training data

y : numpy array of shape [n_samples]

Target values

Returns **self** : returns an instance of self.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*, *return_std=False*)
Predict using the linear model.

In addition to the mean of the predictive distribution, also its standard deviation can be returned.

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

return_std : boolean, optional

Whether to return the standard deviation of posterior prediction.

Returns **y_mean** : array, shape = (n_samples,)

Mean of predictive distribution of query points.

y_std : array, shape = (n_samples,)

Standard deviation of predictive distribution of query points.

score(*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.linear_model.BayesianRidge`

- *Feature agglomeration vs. univariate selection*
- *Bayesian Ridge Regression*

29.18.3 sklearn.linear_model.ElasticNet

class sklearn.linear_model.**ElasticNet**(*alpha=1.0*, *l1_ratio=0.5*, *fit_intercept=True*, *normalize=False*, *precompute=False*, *max_iter=1000*, *copy_X=True*, *tol=0.0001*, *warm_start=False*, *positive=False*, *random_state=None*, *selection='cyclic'*)

Linear regression with combined L1 and L2 priors as regularizer.

Minimizes the objective function:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

If you are interested in controlling the L1 and L2 penalty separately, keep in mind that this is equivalent to:

```
a * L1 + b * L2
```

where:

```
alpha = a + b and l1_ratio = a / (a + b)
```

The parameter l1_ratio corresponds to alpha in the glmnet R package while alpha corresponds to the lambda parameter in glmnet. Specifically, l1_ratio = 1 is the lasso penalty. Currently, l1_ratio <= 0.01 is not reliable, unless you supply your own sequence of alpha.

Read more in the *User Guide*.

Parameters **alpha** : float, optional

Constant that multiplies the penalty terms. Defaults to 1.0. See the notes for the exact mathematical meaning of this parameter.‘‘alpha = 0‘‘ is equivalent to an ordinary least square, solved by the *LinearRegression* object. For numerical reasons, using `alpha = 0` with the `Lasso` object is not advised. Given this, you should use the *LinearRegression* object.

l1_ratio : float

The ElasticNet mixing parameter, with `0 <= l1_ratio <= 1`. For `l1_ratio = 0` the penalty is an L2 penalty. `For l1_ratio = 1` it is an L1 penalty. For `0 < l1_ratio < 1`, the penalty is a combination of L1 and L2.

fit_intercept : bool

Whether the intercept should be estimated or not. If `False`, the data is assumed to be already centered.

normalize : boolean, optional, default False

This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

precompute : True | False | array-like

Whether to use a precomputed Gram matrix to speed up calculations. The Gram matrix can also be passed as argument. For sparse input this option is always `True` to preserve sparsity.

max_iter : int, optional

The maximum number of iterations

copy_X : boolean, optional, default True

If `True`, X will be copied; else, it may be overwritten.

tol : float, optional

The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.

warm_start : bool, optional

When set to `True`, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

positive : bool, optional

When set to `True`, forces the coefficients to be positive.

selection : str, default 'cyclic'

If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when tol is higher than 1e-4.

random_state : int, RandomState instance or None, optional, default None

The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `selection` == 'random'.

Attributes **coef_** : array, shape (n_features,) | (n_targets, n_features)

parameter vector (w in the cost function formula)

sparse_coef_ : scipy.sparse matrix, shape (n_features, 1) | (n_targets, n_features)

`sparse_coef_` is a readonly property derived from `coef_`

intercept_ : float | array, shape (n_targets,)

independent term in decision function.

n_iter_ : array-like, shape (n_targets,)

number of iterations run by the coordinate descent solver to reach the specified tolerance.

See also:

SGDRegressor implements elastic net regression with incremental training.

SGDClassifier implements logistic regression with elastic net penalty (`SGDClassifier(loss="log", penalty="elasticnet")`).

Notes

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Methods

fit(X, y[, check_input])	Fit model with coordinate descent.
get_params([deep])	Get parameters for this estimator.
path(X, y[, l1_ratio, eps, n_alphas, ...])	Compute elastic net path with coordinate descent
predict(X)	Predict using the linear model
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*alpha=1.0*, *l1_ratio=0.5*, *fit_intercept=True*, *normalize=False*, *precompute=False*, *max_iter=1000*, *copy_X=True*, *tol=0.0001*, *warm_start=False*, *positive=False*, *random_state=None*, *selection='cyclic'*)

fit (*X*, *y*, *check_input=True*)

Fit model with coordinate descent.

Parameters **X** : ndarray or scipy.sparse matrix, (n_samples, n_features)

Data

y : ndarray, shape (n_samples,) or (n_samples, n_targets)

Target

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

static path (*X*, *y*, *l1_ratio=0.5*, *eps=0.001*, *n_alphas=100*, *alphas=None*, *precompute='auto'*, *Xy=None*, *copy_X=True*, *coef_init=None*, *verbose=False*, *return_n_iter=False*, *positive=False*, *check_input=True*, ***params*)

Compute elastic net path with coordinate descent

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

For multi-output tasks it is:

```
(1 / (2 * n_samples)) * ||Y - XW||^Fro_2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

```
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

Parameters **X** : {array-like}, shape (n_samples, n_features)

Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If `y` is mono-output then `X` can be sparse.

y : ndarray, shape (n_samples,) or (n_samples, n_outputs)

Target values

l1_ratio : float, optional

float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). `l1_ratio=1` corresponds to the Lasso

eps : float

Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`

n_alphas : int, optional

Number of alphas along the regularization path

alphas : ndarray, optional

List of alphas where to compute the models. If None alphas are set automatically

precompute : True | False | 'auto' | array-like

Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument.

Xy : array-like, optional

Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X : boolean, optional, default True

If `True`, X will be copied; else, it may be overwritten.

coef_init : array, shape (n_features,) | None

The initial values of the coefficients.

verbose : bool or integer

Amount of verbosity.

params : kwargs

keyword arguments passed to the coordinate descent solver.

return_n_iter : bool

whether to return the number of iterations or not.

positive : bool, default False

If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

check_input : bool, default True

Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

Returns **alphas** : array, shape (n_alphas,)

The alphas along the path where models are computed.

coefs : array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)

Coefficients along the path.

dual_gaps : array, shape (n_alphas,)

The dual gaps at the end of the optimization for each alpha.

n_iters : array-like, shape (n_alphas,)

The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

See also:

MultiTaskElasticNet, *MultiTaskElasticNetCV*, *ElasticNet*, *ElasticNetCV*

Notes

For an example, see *examples/linear_model/plot_lasso_coordinate_descent_path.py*.

predict(*X*)

Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **C** : array, shape = (n_samples,)

Returns predicted values.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

sparse_coef_
sparse representation of the fitted `coef_`

Examples using `sklearn.linear_model.ElasticNet`

- *Lasso and Elastic Net for Sparse Signals*
- *Train error vs Test error*

29.18.4 `sklearn.linear_model`.HuberRegressor

class `sklearn.linear_model.`**HuberRegressor**(*epsilon=1.35*, *max_iter=100*, *alpha=0.0001*, *warm_start=False*, *fit_intercept=True*, *tol=1e-05*)
Linear regression model that is robust to outliers.

The Huber Regressor optimizes the squared loss for the samples where `|(y - X'w) / sigma| < epsilon` and the absolute loss for the samples where `|(y - X'w) / sigma| > epsilon`, where w and sigma are parameters to be optimized. The parameter sigma makes sure that if y is scaled up or down by a certain factor, one does not need to rescale epsilon to achieve the same robustness. Note that this does not take into account the fact that the different features of X may be of different scales.

This makes sure that the loss function is not heavily influenced by the outliers while not completely ignoring their effect.

Read more in the *User Guide*

New in version 0.18.

Parameters **epsilon** : float, greater than 1.0, default 1.35

The parameter epsilon controls the number of samples that should be classified as outliers. The smaller the epsilon, the more robust it is to outliers.

max_iter : int, default 100

Maximum number of iterations that scipy.optimize.fmin_l_bfgs_b should run for.

alpha : float, default 0.0001

Regularization parameter.

warm_start : bool, default False

This is useful if the stored attributes of a previously used model has to be reused. If set to False, then the coefficients will be rewritten for every call to fit.

fit_intercept : bool, default True

Whether or not to fit the intercept. This can be set to False if the data is already centered around the origin.

tol : float, default 1e-5

The iteration will stop when `max{|proj g_i | i = 1, ..., n} <= tol` where pg_i is the i-th component of the projected gradient.

Attributes **coef_** : array, shape (n_features,)

Features got by optimizing the Huber loss.

intercept_ : float

Bias.

scale_ : float

The value by which `|y - X'w - c|` is scaled down.

n_iter_ : int

Number of iterations that fmin_l_bfgs_b has run for. Not available if SciPy version is 0.9 and below.

outliers_ : array, shape (n_samples,)

A boolean mask which is set to True where the samples are identified as outliers.

__init__ (*epsilon=1.35*, *max_iter=100*, *alpha=0.0001*, *warm_start=False*, *fit_intercept=True*, *tol=1e-05*)

fit (*X*, *y*, *sample_weight=None*)

Fit the model according to the given training data.

Parameters **X** : array-like, shape (n_samples, n_features)

Training vector, where n_samples in the number of samples and n_features is the number of features.

y : array-like, shape (n_samples,)

Target vector relative to X.

sample_weight : array-like, shape (n_samples,)

Weight given to each sample.

Returns **self** : object

Returns self.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **C** : array, shape = (n_samples,)

Returns predicted values.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.linear_model.HuberRegressor`

- *HuberRegressor vs Ridge on dataset with strong outliers*
- *Robust linear estimator fitting*

29.18.5 `sklearn.linear_model.Lars`

class `sklearn.linear_model.`**`Lars`**(*fit_intercept=True*, *verbose=False*, *normalize=True*, *precompute='auto'*, *n_nonzero_coefs=500*, *eps=2.2204460492503131e-16*, *copy_X=True*, *fit_path=True*, *positive=False*)

Least Angle Regression model a.k.a. LAR

Read more in the *User Guide*.

Parameters **n_nonzero_coefs** : int, optional

Target number of non-zero coefficients. Use `np.inf` for no limit.

fit_intercept : boolean

Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

positive : boolean (default=False)

Restrict coefficients to be >= 0. Be aware that you might want to remove fit_intercept which is set True by default.

verbose : boolean or integer, optional

Sets the verbosity amount

normalize : boolean, optional, default True

This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *`sklearn.preprocessing.StandardScaler`* before calling `fit` on an estimator with `normalize=False`.

precompute : True | False | 'auto' | array-like

Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument.

copy_X : boolean, optional, default True

If `True`, X will be copied; else, it may be overwritten.

eps : float, optional

The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the `tol` parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

fit_path : boolean

If True the full path is stored in the `coef_path_` attribute. If you compute the solution for a large problem or many targets, setting `fit_path` to `False` will lead to a speedup, especially with a small alpha.

Attributes **alphas_** : array, shape (n_alphas + 1,) | list of n_targets such arrays

Maximum of covariances (in absolute value) at each iteration. `n_alphas` is either `n_nonzero_coefs` or `n_features`, whichever is smaller.

active_ : list, length = n_alphas | list of n_targets such lists

Indices of active variables at the end of the path.

coef_path_ : array, shape (n_features, n_alphas + 1) | list of n_targets such arrays

The varying values of the coefficients along the path. It is not present if the `fit_path` parameter is `False`.

coef_ : array, shape (n_features,) or (n_targets, n_features)

Parameter vector (w in the formulation formula).

intercept_ : float | array, shape (n_targets,)

Independent term in decision function.

n_iter_ : array-like or int

The number of iterations taken by lars_path to find the grid of alphas for each target.

See also:

lars_path, *LarsCV*, *sklearn.decomposition.sparse_encode*

Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.Lars(n_nonzero_coefs=1)
>>> clf.fit([[-1, 1], [0, 0], [1, 1]], [-1.1111, 0, -1.1111])
...
Lars(copy_X=True, eps=..., fit_intercept=True, fit_path=True,
   n_nonzero_coefs=1, normalize=True, positive=False, precompute='auto',
   verbose=False)
>>> print(clf.coef_)
[ 0. -1.11...]
```

Methods

fit(X, y[, Xy])	Fit the model using X, y as training data.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict using the linear model
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*fit_intercept=True*, *verbose=False*, *normalize=True*, *precompute='auto'*, *n_nonzero_coefs=500*, *eps=2.2204460492503131e-16*, *copy_X=True*, *fit_path=True*, *positive=False*)

fit (*X*, *y*, *Xy=None*)

Fit the model using X, y as training data.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data.

y : array-like, shape (n_samples,) or (n_samples, n_targets)

Target values.

Xy : array-like, shape (n_samples,) or (n_samples, n_targets), optional

Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

Returns **self** : object

returns an instance of self.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **C** : array, shape = (n_samples,)

Returns predicted values.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.18.6 sklearn.linear_model.Lasso

class sklearn.linear_model.**Lasso**(*alpha=1.0*, *fit_intercept=True*, *normalize=False*, *precompute=False*, *copy_X=True*, *max_iter=1000*, *tol=0.0001*, *warm_start=False*, *positive=False*, *random_state=None*, *selection='cyclic'*)

Linear Model trained with L1 prior as regularizer (aka the Lasso)

The optimization objective for Lasso is:

```
(1 / (2 * n_samples)) * ||y - Xw||^2_2 + alpha * ||w||_1
```

Technically the Lasso model is optimizing the same objective function as the Elastic Net with `l1_ratio=1.0` (no L2 penalty).

Read more in the *User Guide*.

Parameters **alpha** : float, optional

Constant that multiplies the L1 term. Defaults to 1.0. `alpha = 0` is equivalent to an ordinary least square, solved by the *LinearRegression* object. For numerical reasons, using `alpha = 0` with the `Lasso` object is not advised. Given this, you should use the *LinearRegression* object.

fit_intercept : boolean

whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

normalize : boolean, optional, default False

This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

copy_X : boolean, optional, default True

If `True`, X will be copied; else, it may be overwritten.

precompute : True | False | array-like, default=False

Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument. For sparse input this option is always `True` to preserve sparsity.

max_iter : int, optional

The maximum number of iterations

tol : float, optional

The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.

warm_start : bool, optional

When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

positive : bool, optional

When set to `True`, forces the coefficients to be positive.

selection : str, default 'cyclic'

If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when tol is higher than 1e-4.

random_state : int, RandomState instance or None, optional, default None

The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `selection` == 'random'.

Attributes **coef_** : array, shape (n_features,) | (n_targets, n_features)

parameter vector (w in the cost function formula)

sparse_coef_ : scipy.sparse matrix, shape (n_features, 1) | (n_targets, n_features)

`sparse_coef_` is a readonly property derived from `coef_`

intercept_ : float | array, shape (n_targets,)

independent term in decision function.

n_iter_ : int | array-like, shape (n_targets,)

number of iterations run by the coordinate descent solver to reach the specified tolerance.

See also:

lars_path, *lasso_path*, *LassoLars*, *LassoCV*, *LassoLarsCV*, *sklearn.decomposition.sparse_encode*

Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.Lasso(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
Lasso(alpha=0.1, copy_X=True, fit_intercept=True, max_iter=1000,
   normalize=False, positive=False, precompute=False, random_state=None,
   selection='cyclic', tol=0.0001, warm_start=False)
>>> print(clf.coef_)
[ 0.85  0.  ]
>>> print(clf.intercept_)
0.15
```

Methods

fit(X, y[, check_input])	Fit model with coordinate descent.
get_params([deep])	Get parameters for this estimator.
path(X, y[, l1_ratio, eps, n_alphas, ...])	Compute elastic net path with coordinate descent
predict(X)	Predict using the linear model
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*alpha=1.0*, *fit_intercept=True*, *normalize=False*, *precompute=False*, *copy_X=True*, *max_iter=1000*, *tol=0.0001*, *warm_start=False*, *positive=False*, *random_state=None*, *selection='cyclic'*)

fit (*X*, *y*, *check_input=True*)
Fit model with coordinate descent.

Parameters **X** : ndarray or scipy.sparse matrix, (n_samples, n_features)

Data

y : ndarray, shape (n_samples,) or (n_samples, n_targets)

Target

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

static path (*X*, *y*, *l1_ratio=0.5*, *eps=0.001*, *n_alphas=100*, *alphas=None*, *precompute='auto'*, *Xy=None*, *copy_X=True*, *coef_init=None*, *verbose=False*, *return_n_iter=False*, *positive=False*, *check_input=True*, ***params*)
Compute elastic net path with coordinate descent

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

For multi-output tasks it is:

```
(1 / (2 * n_samples)) * ||Y - XW||^Fro_2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

```
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

Parameters **X** : {array-like}, shape (n_samples, n_features)

Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If `y` is mono-output then `X` can be sparse.

y : ndarray, shape (n_samples,) or (n_samples, n_outputs)

Target values

l1_ratio : float, optional

float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). `l1_ratio=1` corresponds to the Lasso

eps : float

Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`

n_alphas : int, optional

Number of alphas along the regularization path

alphas : ndarray, optional

List of alphas where to compute the models. If None alphas are set automatically

precompute : True | False | 'auto' | array-like

Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument.

Xy : array-like, optional

Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X : boolean, optional, default True

If `True`, X will be copied; else, it may be overwritten.

coef_init : array, shape (n_features,) | None

The initial values of the coefficients.

verbose : bool or integer

Amount of verbosity.

params : kwargs

keyword arguments passed to the coordinate descent solver.

return_n_iter : bool

whether to return the number of iterations or not.

positive : bool, default False

If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

check_input : bool, default True

Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

Returns **alphas** : array, shape (n_alphas,)

The alphas along the path where models are computed.

coefs : array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)

Coefficients along the path.

dual_gaps : array, shape (n_alphas,)

The dual gaps at the end of the optimization for each alpha.

n_iters : array-like, shape (n_alphas,)

The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

See also:

MultiTaskElasticNet, *MultiTaskElasticNetCV*, *ElasticNet*, *ElasticNetCV*

Notes

For an example, see *examples/linear_model/plot_lasso_coordinate_descent_path.py*.

predict(*X*)

Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **C** : array, shape = (n_samples,)

Returns predicted values.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

sparse_coef_
sparse representation of the fitted `coef_`

Examples using `sklearn.linear_model.Lasso`

- *Compressive sensing: tomography reconstruction with L1 prior (Lasso)*
- *Cross-validation on diabetes Dataset Exercise*
- *Lasso and Elastic Net for Sparse Signals*
- *Lasso on dense and sparse data*
- *Joint feature selection with multi-task Lasso*

29.18.7 `sklearn.linear_model`.LassoLars

class `sklearn.linear_model.`**LassoLars**(*alpha=1.0*, *fit_intercept=True*, *verbose=False*, *normalize=True*, *precompute='auto'*, *max_iter=500*, *eps=2.2204460492503131e-16*, *copy_X=True*, *fit_path=True*, *positive=False*)

Lasso model fit with Least Angle Regression a.k.a. Lars

It is a Linear Model trained with an L1 prior as regularizer.

The optimization objective for Lasso is:

```
(1 / (2 * n_samples)) * ||y - Xw||^2_2 + alpha * ||w||_1
```

Read more in the *User Guide*.

Parameters **alpha** : float

Constant that multiplies the penalty term. Defaults to 1.0. `alpha = 0` is equivalent to an ordinary least square, solved by *LinearRegression*. For numerical reasons, using `alpha = 0` with the LassoLars object is not advised and you should prefer the LinearRegression object.

fit_intercept : boolean

whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

positive : boolean (default=False)

Restrict coefficients to be >= 0. Be aware that you might want to remove fit_intercept which is set True by default. Under the positive restriction the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (`alphas_[alphas_ > 0.].min()` when fit_path=True) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator.

verbose : boolean or integer, optional

Sets the verbosity amount

normalize : boolean, optional, default True

This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

copy_X : boolean, optional, default True

If True, X will be copied; else, it may be overwritten.

precompute : True | False | 'auto' | array-like

Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument.

max_iter : integer, optional

Maximum number of iterations to perform.

eps : float, optional

The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the `tol` parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

fit_path : boolean

If `True` the full path is stored in the `coef_path_` attribute. If you compute the solution for a large problem or many targets, setting `fit_path` to `False` will lead to a speedup, especially with a small alpha.

Attributes **alphas_** : array, shape (n_alphas + 1,) | list of n_targets such arrays

Maximum of covariances (in absolute value) at each iteration. `n_alphas` is either `max_iter`, `n_features`, or the number of nodes in the path with correlation greater than `alpha`, whichever is smaller.

active_ : list, length = n_alphas | list of n_targets such lists

Indices of active variables at the end of the path.

coef_path_ : array, shape (n_features, n_alphas + 1) or list

If a list is passed it's expected to be one of n_targets such arrays. The varying values of the coefficients along the path. It is not present if the `fit_path` parameter is `False`.

coef_ : array, shape (n_features,) or (n_targets, n_features)

Parameter vector (w in the formulation formula).

intercept_ : float | array, shape (n_targets,)

Independent term in decision function.

n_iter_ : array-like or int.

The number of iterations taken by lars_path to find the grid of alphas for each target.

lars_path, *lasso_path*, *Lasso*, *LassoCV*, *LassoLarsCV*, *sklearn.decomposition.sparse_encode*

Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.LassoLars(alpha=0.01)
>>> clf.fit([[-1, 1], [0, 0], [1, 1]], [-1, 0, -1])
...
LassoLars(alpha=0.01, copy_X=True, eps=..., fit_intercept=True,
     fit_path=True, max_iter=500, normalize=True, positive=False,
     precompute='auto', verbose=False)
>>> print(clf.coef_)
[ 0.         -0.963257...]
```

Methods

fit(X, y[, Xy])	Fit the model using X, y as training data.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict using the linear model
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*alpha=1.0*, *fit_intercept=True*, *verbose=False*, *normalize=True*, *precompute='auto'*, *max_iter=500*, *eps=2.2204460492503131e-16*, *copy_X=True*, *fit_path=True*, *positive=False*)

fit (*X*, *y*, *Xy=None*)

Fit the model using X, y as training data.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data.

y : array-like, shape (n_samples,) or (n_samples, n_targets)

Target values.

Xy : array-like, shape (n_samples,) or (n_samples, n_targets), optional

Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

Returns **self** : object

returns an instance of self.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **C** : array, shape = (n_samples,)

Returns predicted values.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.18.8 sklearn.linear_model.LinearRegression

class sklearn.linear_model.**LinearRegression**(*fit_intercept=True*, *normalize=False*, *copy_X=True*, *n_jobs=1*)

Ordinary least squares Linear Regression.

Parameters **fit_intercept** : boolean, optional, default True

whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (e.g. data is expected to be already centered).

normalize : boolean, optional, default False

This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

copy_X : boolean, optional, default True

If True, X will be copied; else, it may be overwritten.

n_jobs : int, optional, default 1

The number of jobs to use for the computation. If -1 all CPUs are used. This will only provide speedup for n_targets > 1 and sufficient large problems.

Attributes **coef_** : array, shape (n_features,) or (n_targets, n_features)

Estimated coefficients for the linear regression problem. If multiple targets are passed during the fit (y 2D), this is a 2D array of shape (n_targets, n_features), while if only one target is passed, this is a 1D array of length n_features.

intercept_ : array

Independent term in the linear model.

Notes

From the implementation point of view, this is just plain Ordinary Least Squares (scipy.linalg.lstsq) wrapped as a predictor object.

Methods

fit(X, y[, sample_weight])	Fit linear model.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict using the linear model
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*fit_intercept=True*, *normalize=False*, *copy_X=True*, *n_jobs=1*)

fit (*X*, *y*, *sample_weight=None*)

Fit linear model.

Parameters **X** : numpy array or sparse matrix of shape [n_samples,n_features]

Training data

y : numpy array of shape [n_samples, n_targets]

Target values

sample_weight : numpy array of shape [n_samples]

Individual weights for each sample

New in version 0.17: parameter *sample_weight* support to LinearRegression.

Returns **self** : returns an instance of self.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)
Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **C** : array, shape = (n_samples,)

Returns predicted values.

score(*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.linear_model.LinearRegression`

- *Underfitting vs. Overfitting*

29.18.9 sklearn.linear_model.LogisticRegression

class sklearn.linear_model.**LogisticRegression**(*penalty='l2'*, *dual=False*, *tol=0.0001*, *C=1.0*, *fit_intercept=True*, *intercept_scaling=1*, *class_weight=None*, *random_state=None*, *solver='liblinear'*, *max_iter=100*, *multi_class='ovr'*, *verbose=0*, *warm_start=False*, *n_jobs=1*)

Logistic Regression (aka logit, MaxEnt) classifier.

In the multiclass case, the training algorithm uses the one-vs-rest (OvR) scheme if the 'multi_class' option is set to 'ovr', and uses the cross- entropy loss if the 'multi_class' option is set to 'multinomial'. (Currently the 'multinomial' option is supported only by the 'lbfgs', 'sag' and 'newton-cg' solvers.)

This class implements regularized logistic regression using the 'liblinear' library, 'newton-cg', 'sag' and 'lbfgs' solvers. It can handle both dense and sparse input. Use C-ordered arrays or CSR matrices containing 64-bit floats for optimal performance; any other input format will be converted (and copied).

The 'newton-cg', 'sag', and 'lbfgs' solvers support only L2 regularization with primal formulation. The 'liblinear' solver supports both L1 and L2 regularization, with a dual formulation only for the L2 penalty.

Read more in the *User Guide*.

Parameters **penalty** : str, 'l1' or 'l2', default: 'l2'

Used to specify the norm used in the penalization. The 'newton-cg', 'sag' and 'lbfgs' solvers support only l2 penalties.

New in version 0.19: l1 penalty with SAGA solver (allowing 'multinomial' + L1)

dual : bool, default: False

Dual or primal formulation. Dual formulation is only implemented for l2 penalty with liblinear solver. Prefer dual=False when n_samples > n_features.

C : float, default: 1.0

Inverse of regularization strength; must be a positive float. Like in support vector machines, smaller values specify stronger regularization.

fit_intercept : bool, default: True

Specifies if a constant (a.k.a. bias or intercept) should be added to the decision function.

intercept_scaling : float, default 1.

Useful only when the solver 'liblinear' is used and self.fit_intercept is set to True. In this case, x becomes [x, self.intercept_scaling], i.e. a "synthetic" feature with constant value equal to intercept_scaling is appended to the instance vector. The intercept becomes `intercept_scaling * synthetic_feature_weight`.

Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

class_weight : dict or 'balanced', default: None

Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one.

The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`.

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

New in version 0.17: *class_weight='balanced'*

max_iter : int, default: 100

Useful only for the newton-cg, sag and lbfgs solvers. Maximum number of iterations taken for the solvers to converge.

random_state : int, RandomState instance or None, optional, default: None

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `solver` == 'sag' or 'liblinear'.

solver : {'newton-cg', 'lbfgs', 'liblinear', 'sag', 'saga'},

default: 'liblinear' Algorithm to use in the optimization problem.

- **For small datasets, 'liblinear' is a good choice, whereas 'sag' and** 'saga' are faster for large ones.
- **For multiclass problems, only 'newton-cg', 'sag', 'saga' and 'lbfgs'** handle multinomial loss; 'liblinear' is limited to one-versus-rest schemes.
- **'newton-cg', 'lbfgs' and 'sag' only handle L2 penalty, whereas** 'liblinear' and 'saga' handle L1 penalty.

Note that 'sag' and 'saga' fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

tol : float, default: 1e-4

Tolerance for stopping criteria.

multi_class : str, {'ovr', 'multinomial'}, default: 'ovr'

Multiclass option can be either 'ovr' or 'multinomial'. If the option chosen is 'ovr', then a binary problem is fit for each label. Else the loss minimised is the multinomial loss fit across the entire probability distribution. Does not work for liblinear solver.

New in version 0.18: Stochastic Average Gradient descent solver for 'multinomial' case.

verbose : int, default: 0

For the liblinear and lbfgs solvers set verbose to any positive number for verbosity.

warm_start : bool, default: False

When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. Useless for liblinear solver.

New in version 0.17: *warm_start* to support *lbfgs*, *newton-cg*, *sag*, *saga* solvers.

n_jobs : int, default: 1

Number of CPU cores used when parallelizing over classes if multi_class='ovr'". This parameter is ignored when the ''solver''is set to 'liblinear' regardless of whether 'multi_class' is specified or not. If given a value of -1, all cores are used.

Attributes **coef_** : array, shape (1, n_features) or (n_classes, n_features)

Coefficient of the features in the decision function.

*coef_* is of shape (1, n_features) when the given problem is binary.

intercept_ : array, shape (1,) or (n_classes,)

Intercept (a.k.a. bias) added to the decision function.

If *fit_intercept* is set to False, the intercept is set to zero. *intercept_* is of shape(1,) when the problem is binary.

n_iter_ : array, shape (n_classes,) or (1,)

Actual number of iterations for all classes. If binary or multinomial, it returns only 1 element. For liblinear solver, only the maximum number of iteration across all classes is given.

See also:

SGDClassifier incrementally trained logistic regression (when given the parameter `loss="log"`).

sklearn.svm.LinearSVC learns SVM models using the same algorithm.

Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon, to have slightly different results for the same input data. If that happens, try with a smaller tol parameter.

Predict output may not match that of standalone liblinear in certain cases. See *differences from liblinear* in the narrative documentation.

Methods

decision_function(X)	Predict confidence scores for samples.
densify()	Convert coefficient matrix to dense array format.
fit(X, y[, sample_weight])	Fit the model according to the given training data.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict class labels for samples in X.
predict_log_proba(X)	Log of probability estimates.
predict_proba(X)	Probability estimates.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.
sparsify()	Convert coefficient matrix to sparse format.

__init__ (*penalty='l2'*, *dual=False*, *tol=0.0001*, *C=1.0*, *fit_intercept=True*, *intercept_scaling=1*, *class_weight=None*, *random_state=None*, *solver='liblinear'*, *max_iter=100*, *multi_class='ovr'*, *verbose=0*, *warm_start=False*, *n_jobs=1*)

decision_function (*X*)
Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)** :

Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify ()
Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns **self** : estimator

fit (*X*, *y*, *sample_weight=None*)
Fit the model according to the given training data.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Training vector, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape (n_samples,)

Target vector relative to X.

sample_weight : array-like, shape (n_samples,) optional

Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

New in version 0.17: *sample_weight* support to LogisticRegression.

Returns **self** : object

Returns self.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Predict class labels for samples in X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Samples.

Returns **C** : array, shape = [n_samples]

Predicted class label per sample.

predict_log_proba(*X*)

Log of probability estimates.

The returned estimates for all classes are ordered by the label of classes.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **T** : array-like, shape = [n_samples, n_classes]

Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

predict_proba(*X*)

Probability estimates.

The returned estimates for all classes are ordered by the label of classes.

For a multi_class problem, if multi_class is set to be "multinomial" the softmax function is used to find the predicted probability of each class. Else use a one-vs-rest approach, i.e calculate the probability of each class assuming it to be positive using the logistic function. and normalize these values across all the classes.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **T** : array-like, shape = [n_samples, n_classes]

Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

score(*X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

sparsify()
Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

Returns **self** : estimator

Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

29.18.10 sklearn.linear_model.MultiTaskLasso

class sklearn.linear_model.**MultiTaskLasso**(*alpha=1.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=1000*, *tol=0.0001*, *warm_start=False*, *random_state=None*, *selection='cyclic'*)

Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer

The optimization objective for Lasso is:

```
(1 / (2 * n_samples)) * ||Y - XW||^2_Fro + alpha * ||W||_21
```

Where:

```
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

Parameters **alpha** : float, optional

Constant that multiplies the L1/L2 term. Defaults to 1.0

fit_intercept : boolean

whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

normalize : boolean, optional, default False

This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *`sklearn.preprocessing.StandardScaler`* before calling `fit` on an estimator with `normalize=False`.

copy_X : boolean, optional, default True

If `True`, X will be copied; else, it may be overwritten.

max_iter : int, optional

The maximum number of iterations

tol : float, optional

The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.

warm_start : bool, optional

When set to `True`, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

selection : str, default 'cyclic'

If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when tol is higher than 1e-4

random_state : int, RandomState instance or None, optional, default None

The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `selection` == 'random'.

Attributes **coef_** : array, shape (n_tasks, n_features)

Parameter vector (W in the cost function formula). Note that `coef_` stores the transpose of `W`, `W.T`.

intercept_ : array, shape (n_tasks,)

independent term in decision function.

n_iter_ : int

number of iterations run by the coordinate descent solver to reach the specified tolerance.

See also:

Lasso, *MultiTaskElasticNet*

Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.MultiTaskLasso(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [[0, 0], [1, 1], [2, 2]])
MultiTaskLasso(alpha=0.1, copy_X=True, fit_intercept=True, max_iter=1000,
        normalize=False, random_state=None, selection='cyclic', tol=0.0001,
        warm_start=False)
>>> print(clf.coef_)
[[ 0.89393398  0.        ]
 [ 0.89393398  0.        ]]
>>> print(clf.intercept_)
[ 0.10606602  0.10606602]
```

Methods

fit(X, y)	Fit MultiTaskElasticNet model with coordinate descent
get_params([deep])	Get parameters for this estimator.
path(X, y[, l1_ratio, eps, n_alphas, ...])	Compute elastic net path with coordinate descent
predict(X)	Predict using the linear model
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__(*alpha=1.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=1000*, *tol=0.0001*, *warm_start=False*, *random_state=None*, *selection='cyclic'*)

fit(*X*, *y*)

Fit MultiTaskElasticNet model with coordinate descent

Parameters **X** : ndarray, shape (n_samples, n_features)

Data

y : ndarray, shape (n_samples, n_tasks)

Target

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

path(*X*, *y*, *l1_ratio=0.5*, *eps=0.001*, *n_alphas=100*, *alphas=None*, *precompute='auto'*, *Xy=None*, *copy_X=True*, *coef_init=None*, *verbose=False*, *return_n_iter=False*, *positive=False*, *check_input=True*, ***params*)

Compute elastic net path with coordinate descent

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

For multi-output tasks it is:

```
(1 / (2 * n_samples)) * ||Y - XW||^Fro_2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

```
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

Parameters **X** : {array-like}, shape (n_samples, n_features)

Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If `y` is mono-output then `X` can be sparse.

y : ndarray, shape (n_samples,) or (n_samples, n_outputs)

Target values

l1_ratio : float, optional

float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). `l1_ratio=1` corresponds to the Lasso

eps : float

Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`

n_alphas : int, optional

Number of alphas along the regularization path

alphas : ndarray, optional

List of alphas where to compute the models. If None alphas are set automatically

precompute : True | False | 'auto' | array-like

Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument.

Xy : array-like, optional

Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X : boolean, optional, default True

If `True`, X will be copied; else, it may be overwritten.

coef_init : array, shape (n_features,) | None

The initial values of the coefficients.

verbose : bool or integer

Amount of verbosity.

params : kwargs

keyword arguments passed to the coordinate descent solver.

return_n_iter : bool

whether to return the number of iterations or not.

positive : bool, default False

If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

check_input : bool, default True

Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

Returns **alphas** : array, shape (n_alphas,)

The alphas along the path where models are computed.

coefs : array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)

Coefficients along the path.

dual_gaps : array, shape (n_alphas,)

The dual gaps at the end of the optimization for each alpha.

n_iters : array-like, shape (n_alphas,)

The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

See also:

MultiTaskElasticNet, *MultiTaskElasticNetCV*, *ElasticNet*, *ElasticNetCV*

Notes

For an example, see *examples/linear_model/plot_lasso_coordinate_descent_path.py*.

predict(*X*)

Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **C** : array, shape = (n_samples,)

Returns predicted values.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

sparse_coef_
sparse representation of the fitted `coef_`

Examples using `sklearn.linear_model.MultiTaskLasso`

- *Joint feature selection with multi-task Lasso*

29.18.11 `sklearn.linear_model`.MultiTaskElasticNet

class `sklearn.linear_model.`**MultiTaskElasticNet**(*alpha=1.0*, *l1_ratio=0.5*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=1000*, *tol=0.0001*, *warm_start=False*, *random_state=None*, *selection='cyclic'*)

Multi-task ElasticNet model trained with L1/L2 mixed-norm as regularizer

The optimization objective for MultiTaskElasticNet is:

```
(1 / (2 * n_samples)) * ||Y - XW||^Fro_2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

```
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

Parameters **alpha** : float, optional

Constant that multiplies the L1/L2 term. Defaults to 1.0

l1_ratio : float

The ElasticNet mixing parameter, with 0 < l1_ratio <= 1. For l1_ratio = 1 the penalty is an L1/L2 penalty. For l1_ratio = 0 it is an L2 penalty. For `0 < l1_ratio < 1`, the penalty is a combination of L1/L2 and L2.

fit_intercept : boolean

whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

normalize : boolean, optional, default False

This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

copy_X : boolean, optional, default True

If `True`, X will be copied; else, it may be overwritten.

max_iter : int, optional

The maximum number of iterations

tol : float, optional

The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.

warm_start : bool, optional

When set to `True`, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

selection : str, default 'cyclic'

If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when tol is higher than 1e-4.

random_state : int, RandomState instance or None, optional, default None

The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `selection` == 'random'.

Attributes **intercept_** : array, shape (n_tasks,)

Independent term in decision function.

coef_ : array, shape (n_tasks, n_features)

Parameter vector (W in the cost function formula). If a 1D y is passed in at fit (non multi-task usage), `coef_` is then a 1D array. Note that `coef_` stores the transpose of `W`, `W.T`.

n_iter_ : int

number of iterations run by the coordinate descent solver to reach the specified tolerance.

See also:

ElasticNet, *MultiTaskLasso*

Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.MultiTaskElasticNet(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [[0, 0], [1, 1], [2, 2]])
...
MultiTaskElasticNet(alpha=0.1, copy_X=True, fit_intercept=True,
        l1_ratio=0.5, max_iter=1000, normalize=False, random_state=None,
        selection='cyclic', tol=0.0001, warm_start=False)
>>> print(clf.coef_)
[[ 0.45663524  0.45612256]
 [ 0.45663524  0.45612256]]
>>> print(clf.intercept_)
[ 0.0872422  0.0872422]
```

Methods

fit(X, y)	Fit MultiTaskElasticNet model with coordinate descent
get_params([deep])	Get parameters for this estimator.
path(X, y[, l1_ratio, eps, n_alphas, ...])	Compute elastic net path with coordinate descent
predict(X)	Predict using the linear model
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*alpha=1.0*, *l1_ratio=0.5*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=1000*, *tol=0.0001*, *warm_start=False*, *random_state=None*, *selection='cyclic'*)

fit (*X*, *y*)

Fit MultiTaskElasticNet model with coordinate descent

Parameters **X** : ndarray, shape (n_samples, n_features)

Data

y : ndarray, shape (n_samples, n_tasks)

Target

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

path(*X*, *y*, *l1_ratio=0.5*, *eps=0.001*, *n_alphas=100*, *alphas=None*, *precompute='auto'*, *Xy=None*, *copy_X=True*, *coef_init=None*, *verbose=False*, *return_n_iter=False*, *positive=False*, *check_input=True*, ***params*)

Compute elastic net path with coordinate descent

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

For multi-output tasks it is:

```
(1 / (2 * n_samples)) * ||Y - XW||^Fro_2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

```
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

Parameters **X** : {array-like}, shape (n_samples, n_features)

Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If `y` is mono-output then `X` can be sparse.

y : ndarray, shape (n_samples,) or (n_samples, n_outputs)

Target values

l1_ratio : float, optional

float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). `l1_ratio=1` corresponds to the Lasso

eps : float

Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`

n_alphas : int, optional

Number of alphas along the regularization path

alphas : ndarray, optional

List of alphas where to compute the models. If None alphas are set automatically

precompute : True | False | 'auto' | array-like

Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument.

Xy : array-like, optional

Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X : boolean, optional, default True

If `True`, X will be copied; else, it may be overwritten.

coef_init : array, shape (n_features,) | None

The initial values of the coefficients.

verbose : bool or integer

Amount of verbosity.

params : kwargs

keyword arguments passed to the coordinate descent solver.

return_n_iter : bool

whether to return the number of iterations or not.

positive : bool, default False

If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

check_input : bool, default True

Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

Returns **alphas** : array, shape (n_alphas,)

The alphas along the path where models are computed.

coefs : array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)

Coefficients along the path.

dual_gaps : array, shape (n_alphas,)

The dual gaps at the end of the optimization for each alpha.

n_iters : array-like, shape (n_alphas,)

The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

See also:

MultiTaskElasticNet, *MultiTaskElasticNetCV*, *ElasticNet*, *ElasticNetCV*

Notes

For an example, see *examples/linear_model/plot_lasso_coordinate_descent_path.py*.

predict(*X*)

Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **C** : array, shape = (n_samples,)

Returns predicted values.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

sparse_coef_

sparse representation of the fitted `coef_`

29.18.12 sklearn.linear_model.OrthogonalMatchingPursuit

class sklearn.linear_model.**OrthogonalMatchingPursuit**(*n_nonzero_coefs=None*, *tol=None*, *fit_intercept=True*, *normalize=True*, *precompute='auto'*)

Orthogonal Matching Pursuit model (OMP)

Parameters **n_nonzero_coefs** : int, optional

Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.

tol : float, optional

Maximum norm of the residual. If not None, overrides n_nonzero_coefs.

fit_intercept : boolean, optional

whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

normalize : boolean, optional, default True

This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

precompute : {True, False, 'auto'}, default 'auto'

Whether to use a precomputed Gram and Xy matrix to speed up calculations. Improves performance when *n_targets* or *n_samples* is very large. Note that if you already have such matrices, you can pass them directly to the fit method.

Read more in the :ref:'User Guide <omp>'. :

Attributes **coef_** : array, shape (n_features,) or (n_targets, n_features)

parameter vector (w in the formula)

intercept_ : float or array, shape (n_targets,)

independent term in decision function.

n_iter_ : int or array-like

Number of active features across every target.

Notes

Orthogonal matching pursuit was introduced in G. Mallat, Z. Zhang, Matching pursuits with time-frequency dictionaries, IEEE Transactions on Signal Processing, Vol. 41, No. 12. (December 1993), pp. 3397-3415. (http://blanche.polytechnique.fr/~mallat/papiers/MallatPursuit93.pdf)

This implementation is based on Rubinstein, R., Zibulevsky, M. and Elad, M., Efficient Implementation of the K-SVD Algorithm using Batch Orthogonal Matching Pursuit Technical Report - CS Technion, April 2008. http://www.cs.technion.ac.il/~ronrubin/Publications/KSVD-OMP-v2.pdf

Methods

fit(X, y)	Fit the model using X, y as training data.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict using the linear model
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_nonzero_coefs=None*, *tol=None*, *fit_intercept=True*, *normalize=True*, *precompute='auto'*)

fit (*X*, *y*)

Fit the model using X, y as training data.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data.

y : array-like, shape (n_samples,) or (n_samples, n_targets)

Target values.

Returns **self** : object

returns an instance of self.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)
Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **C** : array, shape = (n_samples,)

Returns predicted values.

score(*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.linear_model.OrthogonalMatchingPursuit`

- *Orthogonal Matching Pursuit*

29.18.13 sklearn.linear_model.PassiveAggressiveClassifier

class sklearn.linear_model.**PassiveAggressiveClassifier**(*C=1.0*, *fit_intercept=True*, *n_iter=5*, *shuffle=True*, *verbose=0*, *loss='hinge'*, *n_jobs=1*, *random_state=None*, *warm_start=False*, *class_weight=None*, *average=False*)

Passive Aggressive Classifier

Read more in the *User Guide*.

Parameters **C** : float

Maximum step size (regularization). Defaults to 1.0.

fit_intercept : bool, default=False

Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

n_iter : int, optional

The number of passes over the training data (aka epochs). Defaults to 5.

shuffle : bool, default=True

Whether or not the training data should be shuffled after each epoch.

random_state : int, RandomState instance or None, optional, default=None

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

verbose : integer, optional

The verbosity level

n_jobs : integer, optional

The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. -1 means 'all CPUs'. Defaults to 1.

loss : string, optional

The loss function to be used: hinge: equivalent to PA-I in the reference paper. squared_hinge: equivalent to PA-II in the reference paper.

warm_start : bool, optional

When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

class_weight : dict, {class_label: weight} or "balanced" or None, optional

Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

New in version 0.17: parameter *class_weight* to automatically weight samples.

average : bool or int, optional

When set to True, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

New in version 0.19: parameter *average* to use weights averaging in SGD

Attributes **coef_** : array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]

Weights assigned to the features.

intercept_ : array, shape = [1] if n_classes == 2 else [n_classes]

Constants in decision function.

Online Passive-Aggressive Algorithms <http://jmlr.csail.mit.edu/papers/volume7/crammer06a/crammer06a.pdf> K. Crammer, O. Dekel, J. Keshat, S. Shalev-Shwartz, Y. Singer - JMLR (2006)

Methods

decision_function(X)	Predict confidence scores for samples.
densify()	Convert coefficient matrix to dense array format.
fit(X, y[, coef_init, intercept_init])	Fit linear model with Passive Aggressive algorithm.
get_params([deep])	Get parameters for this estimator.
partial_fit(X, y[, classes])	Fit linear model with Passive Aggressive algorithm.
predict(X)	Predict class labels for samples in X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(*args, **kwargs)	
sparsify()	Convert coefficient matrix to sparse format.

__init__(*C=1.0*, *fit_intercept=True*, *n_iter=5*, *shuffle=True*, *verbose=0*, *loss='hinge'*, *n_jobs=1*, *random_state=None*, *warm_start=False*, *class_weight=None*, *average=False*)

decision_function(*X*)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)** :

Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify()
Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns **self** : estimator

fit(*X*, *y*, *coef_init=None*, *intercept_init=None*)
Fit linear model with Passive Aggressive algorithm.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training data

y : numpy array of shape [n_samples]

Target values

coef_init : array, shape = [n_classes,n_features]

The initial coefficients to warm-start the optimization.

intercept_init : array, shape = [n_classes]

The initial intercept to warm-start the optimization.

Returns **self** : returns an instance of self.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

loss_function
DEPRECATED: Attribute loss_function was deprecated in version 0.19 and will be removed in 0.21. Use '**loss_function_**' instead

partial_fit(*X*, *y*, *classes=None*)
Fit linear model with Passive Aggressive algorithm.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Subset of the training data

y : numpy array of shape [n_samples]

Subset of the target values

classes : array, shape = [n_classes]

Classes across all calls to partial_fit. Can be obtained by via *np.unique(y_all)*, where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn't need to contain all labels in *classes*.

Returns **self** : returns an instance of self.

predict(*X*)
Predict class labels for samples in X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Samples.

Returns **C** : array, shape = [n_samples]

Predicted class label per sample.

score(*X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

sparsify()
Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

Returns **self** : estimator

Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using `sklearn.linear_model.PassiveAggressiveClassifier`

- *Out-of-core classification of text documents*
- *Comparing various online solvers*
- *Classification of text documents using sparse features*

29.18.14 sklearn.linear_model.PassiveAggressiveRegressor

class sklearn.linear_model.**PassiveAggressiveRegressor**(*C=1.0*, *fit_intercept=True*, *n_iter=5*, *shuffle=True*, *verbose=0*, *loss='epsilon_insensitive'*, *epsilon=0.1*, *random_state=None*, *warm_start=False*, *average=False*)

Passive Aggressive Regressor

Read more in the *User Guide*.

Parameters **C** : float

Maximum step size (regularization). Defaults to 1.0.

epsilon : float

If the difference between the current prediction and the correct label is below this threshold, the model is not updated.

fit_intercept : bool

Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.

n_iter : int, optional

The number of passes over the training data (aka epochs). Defaults to 5.

shuffle : bool, default=True

Whether or not the training data should be shuffled after each epoch.

random_state : int, RandomState instance or None, optional, default=None

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

verbose : integer, optional

The verbosity level

loss : string, optional

The loss function to be used: epsilon_insensitive: equivalent to PA-I in the reference paper. squared_epsilon_insensitive: equivalent to PA-II in the reference paper.

warm_start : bool, optional

When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

average : bool or int, optional

When set to True, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

New in version 0.19: parameter *average* to use weights averaging in SGD

Attributes **coef_** : array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]

Weights assigned to the features.

intercept_ : array, shape = [1] if n_classes == 2 else [n_classes]

Constants in decision function.

densify()

Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns **self** : estimator

fit(*X*, *y*, *coef_init=None*, *intercept_init=None*)

Fit linear model with Passive Aggressive algorithm.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training data

y : numpy array of shape [n_samples]

Target values

coef_init : array, shape = [n_features]

The initial coefficients to warm-start the optimization.

intercept_init : array, shape = [1]

The initial intercept to warm-start the optimization.

Returns **self** : returns an instance of self.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

partial_fit(*X*, *y*)
Fit linear model with Passive Aggressive algorithm.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Subset of training data

y : numpy array of shape [n_samples]

Subset of target values

Returns **self** : returns an instance of self.

predict(*X*)
Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Returns **array, shape (n_samples,)** :

Predicted target values per element in X.

score(*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

sparsify()
Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

Returns **self** : estimator

Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

29.18.15 sklearn.linear_model.Perceptron

class sklearn.linear_model.**Perceptron**(*penalty=None*, *alpha=0.0001*, *fit_intercept=True*, *n_iter=5*, *shuffle=True*, *verbose=0*, *eta0=1.0*, *n_jobs=1*, *random_state=0*, *class_weight=None*, *warm_start=False*)

Read more in the *User Guide*.

Parameters **penalty** : None, 'l2' or 'l1' or 'elasticnet'

The penalty (aka regularization term) to be used. Defaults to None.

alpha : float

Constant that multiplies the regularization term if regularization is used. Defaults to 0.0001

fit_intercept : bool

Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.

n_iter : int, optional

The number of passes over the training data (aka epochs). Defaults to 5.

shuffle : bool, optional, default True

Whether or not the training data should be shuffled after each epoch.

random_state : int, RandomState instance or None, optional, default None

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

verbose : integer, optional

The verbosity level

n_jobs : integer, optional

The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. -1 means 'all CPUs'. Defaults to 1.

eta0 : double

Constant by which the updates are multiplied. Defaults to 1.

class_weight : dict, {class_label: weight} or "balanced" or None, optional

Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

warm_start : bool, optional

When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

Attributes **coef_** : array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]

Weights assigned to the features.

intercept_ : array, shape = [1] if n_classes == 2 else [n_classes]

Constants in decision function.

score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(*args, **kwargs)	
sparsify()	Convert coefficient matrix to sparse format.

__init__ (*penalty=None*, *alpha=0.0001*, *fit_intercept=True*, *n_iter=5*, *shuffle=True*, *verbose=0*, *eta0=1.0*, *n_jobs=1*, *random_state=0*, *class_weight=None*, *warm_start=False*)

decision_function (*X*)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)** :

Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify()

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns **self** : estimator

fit(*X*, *y*, *coef_init=None*, *intercept_init=None*, *sample_weight=None*)

Fit linear model with Stochastic Gradient Descent.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Training data

y : numpy array, shape (n_samples,)

Target values

coef_init : array, shape (n_classes, n_features)

The initial coefficients to warm-start the optimization.

intercept_init : array, shape (n_classes,)

The initial intercept to warm-start the optimization.

sample_weight : array-like, shape (n_samples,), optional

Weights applied to individual samples. If not provided, uniform weights are assumed. These weights will be multiplied with class_weight (passed through the constructor) if class_weight is specified

Returns **self** : returns an instance of self.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

loss_function

DEPRECATED: Attribute loss_function was deprecated in version 0.19 and will be removed in 0.21. Use '**loss_function_**' instead

partial_fit(*X*, *y*, *classes=None*, *sample_weight=None*)

Fit linear model with Stochastic Gradient Descent.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Subset of the training data

y : numpy array, shape (n_samples,)

Subset of the target values

classes : array, shape (n_classes,)

Classes across all calls to partial_fit. Can be obtained by via *np.unique(y_all)*, where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn't need to contain all labels in *classes*.

sample_weight : array-like, shape (n_samples,), optional

Weights applied to individual samples. If not provided, uniform weights are assumed.

Returns **self** : returns an instance of self.

predict(*X*)

Predict class labels for samples in X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Samples.

Returns **C** : array, shape = [n_samples]

Predicted class label per sample.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

sparsify()

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

Returns **self** : estimator

Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using `sklearn.linear_model.Perceptron`

- *Out-of-core classification of text documents*
- *Comparing various online solvers*
- *Classification of text documents using sparse features*

29.18.16 `sklearn.linear_model`.RandomizedLasso

class `sklearn.linear_model.`**`RandomizedLasso`**(*alpha='aic'*, *scaling=0.5*, *sample_fraction=0.75*, *n_resampling=200*, *selection_threshold=0.25*, *fit_intercept=True*, *verbose=False*, *normalize=True*, *precompute='auto'*, *max_iter=500*, *eps=2.2204460492503131e-16*, *random_state=None*, *n_jobs=1*, *pre_dispatch='3*n_jobs'*, *memory=None*)

Randomized Lasso.

Randomized Lasso works by subsampling the training data and computing a Lasso estimate where the penalty of a random subset of coefficients has been scaled. By performing this double randomization several times, the method assigns high scores to features that are repeatedly selected across randomizations. This is known as stability selection. In short, features selected more often are considered good features.

Read more in the *User Guide*.

Parameters **alpha** : float, 'aic', or 'bic', optional

The regularization parameter alpha parameter in the Lasso. Warning: this is not the alpha parameter in the stability selection article which is scaling.

scaling : float, optional

The s parameter used to randomly scale the penalty of different features (See *User Guide* for details). Should be between 0 and 1.

sample_fraction : float, optional

The fraction of samples to be used in each randomized design. Should be between 0 and 1. If 1, all samples are used.

n_resampling : int, optional

Number of randomized models.

selection_threshold : float, optional

The score above which features should be selected.

fit_intercept : boolean, optional

whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

verbose : boolean or integer, optional

Sets the verbosity amount

normalize : boolean, optional, default True

If True, the regressors X will be normalized before regression. This parameter is ignored when *fit_intercept* is set to False. When the regressors are normalized, note that this makes the hyperparameters learned more robust and almost independent of the number of samples. The same property is not valid for standardized data. However, if you wish to standardize, please use *preprocessing.StandardScaler* before calling *fit* on an estimator with *normalize=False*.

precompute : True | False | 'auto' | array-like

Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument, but it will be used only for the selection of parameter alpha, if alpha is 'aic' or 'bic'.

max_iter : integer, optional

Maximum number of iterations to perform in the Lars algorithm.

eps : float, optional

The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the 'tol' parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

n_jobs : integer, optional

Number of CPUs to use during the resampling. If '-1', use all the CPUs

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

pre_dispatch : int, or string, optional

Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in '2*n_jobs'

memory : Instance of sklearn.externals.joblib.Memory or string, optional (default=None)

Used for internal caching. By default, no caching is done. If a string is given, it is the path to the caching directory.

Attributes **scores_** : array, shape = [n_features]

Feature scores between 0 and 1.

all_scores_ : array, shape = [n_features, n_reg_parameter]

Feature scores between 0 and 1 for all values of the regularization parameter. The reference article suggests `scores_` is the max of `all_scores_`.

Examples

```
>>> from sklearn.linear_model import RandomizedLasso
>>> randomized_lasso = RandomizedLasso()
```

Methods

fit(X, y)	Fit the model using X, y as training data.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
get_support([indices])	Get a mask, or integer index, of the features selected
inverse_transform(X)	Reverse the transformation operation
set_params(**params)	Set the parameters of this estimator.
transform(X)	Reduce X to the selected features.

__init__ (*alpha='aic'*, *scaling=0.5*, *sample_fraction=0.75*, *n_resampling=200*, *selection_threshold=0.25*, *fit_intercept=True*, *verbose=False*, *normalize=True*, *precompute='auto'*, *max_iter=500*, *eps=2.2204460492503131e-16*, *random_state=None*, *n_jobs=1*, *pre_dispatch='3*n_jobs'*, *memory=None*)

fit (*X*, *y*)

Fit the model using X, y as training data.

Parameters **X** : array-like, shape = [n_samples, n_features]

Training data.

y : array-like, shape = [n_samples]

Target values.

Returns **self** : object

Returns an instance of self.

fit_transform (*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

get_support(*indices=False*)
Get a mask, or integer index, of the features selected

Parameters **indices** : boolean (default False)

If True, the return value will be an array of integers, rather than a boolean mask.

Returns **support** : array

An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*X*)
Reverse the transformation operation

Parameters **X** : array of shape [n_samples, n_selected_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_original_features]

X with columns of zeros inserted where features would have been removed by *transform*.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Reduce X to the selected features.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_selected_features]

The input samples with only the selected features.

Examples using `sklearn.linear_model.RandomizedLasso`

- *Sparse recovery: feature selection for sparse linear models*

29.18.17 `sklearn.linear_model`.RandomizedLogisticRegression

class `sklearn.linear_model.`**RandomizedLogisticRegression**(*C=1*, *scaling=0.5*, *sample_fraction=0.75*, *n_resampling=200*, *selection_threshold=0.25*, *tol=0.001*, *fit_intercept=True*, *verbose=False*, *normalize=True*, *random_state=None*, *n_jobs=1*, *pre_dispatch='3*n_jobs'*, *memory=None*)

Randomized Logistic Regression

Randomized Logistic Regression works by subsampling the training data and fitting a L1-penalized LogisticRegression model where the penalty of a random subset of coefficients has been scaled. By performing this double randomization several times, the method assigns high scores to features that are repeatedly selected across randomizations. This is known as stability selection. In short, features selected more often are considered good features.

Read more in the *User Guide*.

Parameters **C** : float or array-like of shape [n_reg_parameter], optional, default=1

The regularization parameter C in the LogisticRegression. When C is an array, fit will take each regularization parameter in C one by one for LogisticRegression and store results for each one in `all_scores_`, where columns and rows represent corresponding reg_parameters and features.

scaling : float, optional, default=0.5

The s parameter used to randomly scale the penalty of different features (See *User Guide* for details). Should be between 0 and 1.

sample_fraction : float, optional, default=0.75

The fraction of samples to be used in each randomized design. Should be between 0 and 1. If 1, all samples are used.

n_resampling : int, optional, default=200

Number of randomized models.

selection_threshold : float, optional, default=0.25

The score above which features should be selected.

fit_intercept : boolean, optional, default=True

whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

verbose : boolean or integer, optional

Sets the verbosity amount

normalize : boolean, optional, default True

If True, the regressors X will be normalized before regression. This parameter is ignored when *fit_intercept* is set to False. When the regressors are normalized, note that this makes the hyperparameters learnt more robust and almost independent of the number of samples. The same property is not valid for standardized data. However, if you wish to standardize, please use *preprocessing.StandardScaler* before calling *fit* on an estimator with *normalize=False*.

tol : float, optional, default=1e-3

tolerance for stopping criteria of LogisticRegression

n_jobs : integer, optional

Number of CPUs to use during the resampling. If '-1', use all the CPUs

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

pre_dispatch : int, or string, optional

Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in '2*n_jobs'

memory : Instance of sklearn.externals.joblib.Memory or string, optional (default=None)

Used for internal caching. By default, no caching is done. If a string is given, it is the path to the caching directory.

Attributes **scores_** : array, shape = [n_features]

Feature scores between 0 and 1.

all_scores_ : array, shape = [n_features, n_reg_parameter]

Feature scores between 0 and 1 for all values of the regularization parameter. The reference article suggests `scores_` is the max of `all_scores_`.

The input samples.

Returns **X_r** : array of shape [n_samples, n_original_features]

X with columns of zeros inserted where features would have been removed by *transform*.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Reduce X to the selected features.

Parameters **X** : array of shape [n_samples, n_features]

The input samples.

Returns **X_r** : array of shape [n_samples, n_selected_features]

The input samples with only the selected features.

29.18.18 sklearn.linear_model.RANSACRegressor

class sklearn.linear_model.**RANSACRegressor**(*base_estimator=None*, *min_samples=None*, *residual_threshold=None*, *is_data_valid=None*, *is_model_valid=None*, *max_trials=100*, *max_skips=inf*, *stop_n_inliers=inf*, *stop_score=inf*, *stop_probability=0.99*, *residual_metric=None*, *loss='absolute_loss'*, *random_state=None*)
RANSAC (RANdom SAmple Consensus) algorithm.

RANSAC is an iterative algorithm for the robust estimation of parameters from a subset of inliers from the complete data set. More information can be found in the general documentation of linear models.

A detailed description of the algorithm can be found in the documentation of the `linear_model` sub-package.

Read more in the *User Guide*.

Parameters **base_estimator** : object, optional

Base estimator object which implements the following methods:

- *fit(X, y)*: Fit model to given training data and target values.
- *score(X, y)*: Returns the mean accuracy on the given test data, which is used for the stop criterion defined by *stop_score*. Additionally, the score is used to decide which of two equally large consensus sets is chosen as the better one.

If *base_estimator* is None, then `base_estimator=sklearn.linear_model.LinearRegression()` is used for target values of dtype float.

Note that the current implementation only supports regression estimators.

min_samples : int (>= 1) or float ([0, 1]), optional

Minimum number of samples chosen randomly from original data. Treated as an absolute number of samples for *min_samples >= 1*, treated as a relative number *ceil(min_samples * X.shape[0])* for *min_samples < 1*. This is typically chosen as the minimal number of samples necessary to estimate the given *base_estimator*. By default a `sklearn.linear_model.LinearRegression()` estimator is assumed and *min_samples* is chosen as `X.shape[1] + 1`.

residual_threshold : float, optional

Maximum residual for a data sample to be classified as an inlier. By default the threshold is chosen as the MAD (median absolute deviation) of the target values *y*.

is_data_valid : callable, optional

This function is called with the randomly selected data before the model is fitted to it: *is_data_valid(X, y)*. If its return value is False the current randomly chosen sub-sample is skipped.

is_model_valid : callable, optional

This function is called with the estimated model and the randomly selected data: *is_model_valid(model, X, y)*. If its return value is False the current randomly chosen sub-sample is skipped. Rejecting samples with this function is computationally costlier than with *is_data_valid*. *is_model_valid* should therefore only be used if the estimated model is needed for making the rejection decision.

max_trials : int, optional

Maximum number of iterations for random sample selection.

max_skips : int, optional

Maximum number of iterations that can be skipped due to finding zero inliers or invalid data defined by `is_data_valid` or invalid models defined by `is_model_valid`.

New in version 0.19.

stop_n_inliers : int, optional

Stop iteration if at least this number of inliers are found.

stop_score : float, optional

Stop iteration if score is greater equal than this threshold.

stop_probability : float in range [0, 1], optional

RANSAC iteration stops if at least one outlier-free set of the training data is sampled in RANSAC. This requires to generate at least N samples (iterations):

```
N >= log(1 - probability) / log(1 - e**m)
```

where the probability (confidence) is typically set to high value such as 0.99 (the default) and e is the current fraction of inliers w.r.t. the total number of samples.

residual_metric : callable, optional

Metric to reduce the dimensionality of the residuals to 1 for multi-dimensional target values `y.shape[1] > 1`. By default the sum of absolute differences is used:

```
lambda dy: np.sum(np.abs(dy), axis=1)
```

Deprecated since version 0.18: `residual_metric` is deprecated from 0.18 and will be removed in 0.20. Use `loss` instead.

loss : string, callable, optional, default "absolute_loss"

String inputs, "absolute_loss" and "squared_loss" are supported which find the absolute loss and squared loss per sample respectively.

If `loss` is a callable, then it should be a function that takes two arrays as inputs, the true and predicted value and returns a 1-D array with the "i"th value of the array corresponding to the loss on *X[i]*.

If the loss on a sample is greater than the `residual_threshold`, then this sample is classified as an outlier.

random_state : int, RandomState instance or None, optional, default None

The generator used to initialize the centers. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **estimator_** : object

Best fitted model (copy of the *base_estimator* object).

n_trials_ : int

Number of random selection trials until one of the stop criteria is met. It is always <= `max_trials`.

inlier_mask_ : bool array of shape [n_samples]

Boolean mask of inliers classified as `True`.

n_skips_no_inliers_ : int

Number of iterations skipped due to finding zero inliers.

New in version 0.19.

n_skips_invalid_data_ : int

Number of iterations skipped due to invalid data defined by `is_data_valid`.

New in version 0.19.

n_skips_invalid_model_ : int

Number of iterations skipped due to an invalid model defined by `is_model_valid`.

New in version 0.19.

Methods

fit(X, y[, sample_weight])	Fit estimator using RANSAC algorithm.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict using the estimated model.
score(X, y)	Returns the score of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*base_estimator=None*, *min_samples=None*, *residual_threshold=None*, *is_data_valid=None*, *is_model_valid=None*, *max_trials=100*, *max_skips=inf*, *stop_n_inliers=inf*, *stop_score=inf*, *stop_probability=0.99*, *residual_metric=None*, *loss='absolute_loss'*, *random_state=None*)

fit (*X*, *y*, *sample_weight=None*)

Fit estimator using RANSAC algorithm.

Parameters **X** : array-like or sparse matrix, shape [n_samples, n_features]

Training data.

y : array-like, shape = [n_samples] or [n_samples, n_targets]

Target values.

sample_weight : array-like, shape = [n_samples]

Individual weights for each sample raises error if sample_weight is passed and base_estimator fit method does not support it.

Raises **ValueError** :

If no valid consensus set could be found. This occurs if *is_data_valid* and *is_model_valid* return False for all *max_trials* randomly chosen sub-samples.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*)

Predict using the estimated model.

This is a wrapper for *estimator_.predict(X)*.

Parameters **X** : numpy array of shape [n_samples, n_features]

Returns **y** : array, shape = [n_samples] or [n_samples, n_targets]

Returns predicted values.

score(*X*, *y*)

Returns the score of the prediction.

This is a wrapper for *estimator_.score(X, y)*.

Parameters **X** : numpy array or sparse matrix of shape [n_samples, n_features]

Training data.

y : array, shape = [n_samples] or [n_samples, n_targets]

Target values.

Returns **z** : float

Score of the prediction.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.linear_model.RANSACRegressor`

- *Robust linear model estimation using RANSAC*
- *Robust linear estimator fitting*
- *Theil-Sen Regression*

29.18.19 `sklearn.linear_model`.Ridge

class `sklearn.linear_model.`**Ridge**(*alpha=1.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=None*, *tol=0.001*, *solver='auto'*, *random_state=None*)

Linear least squares with l2 regularization.

This model solves a regression model where the loss function is the linear least squares function and regularization is given by the l2-norm. Also known as Ridge Regression or Tikhonov regularization. This estimator has built-in support for multi-variate regression (i.e., when y is a 2d-array of shape [n_samples, n_targets]).

Read more in the *User Guide*.

Parameters **alpha** : {float, array-like}, shape (n_targets)

Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to `C^-1` in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

copy_X : boolean, optional, default True

If True, X will be copied; else, it may be overwritten.

fit_intercept : boolean

Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

max_iter : int, optional

Maximum number of iterations for conjugate gradient solver. For 'sparse_cg' and 'lsqr' solvers, the default value is determined by scipy.sparse.linalg. For 'sag' solver, the default value is 1000.

normalize : boolean, optional, default False

This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

solver : {'auto', 'svd', 'cholesky', 'lsqr', 'sparse_cg', 'sag', 'saga'}

Solver to use in the computational routines:

- 'auto' chooses the solver automatically based on the type of data.
- 'svd' uses a Singular Value Decomposition of X to compute the Ridge coefficients. More stable for singular matrices than 'cholesky'.
- 'cholesky' uses the standard scipy.linalg.solve function to obtain a closed-form solution.
- 'sparse_cg' uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than 'cholesky' for large-scale data (possibility to set *tol* and *max_iter*).
- 'lsqr' uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest but may not be available in old scipy versions. It also uses an iterative procedure.
- 'sag' uses a Stochastic Average Gradient descent, and 'saga' uses its improved, unbiased version named SAGA. Both methods also use an iterative procedure, and are often faster than other solvers when both n_samples and n_features are large. Note that 'sag' and 'saga' fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

All last five solvers support both dense and sparse data. However, only 'sag' and 'saga' supports sparse input when *fit_intercept* is True.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

tol : float

Precision of the solution.

random_state : int, RandomState instance or None, optional, default None

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `solver` == 'sag'.

New in version 0.17: *random_state* to support Stochastic Average Gradient.

Attributes **coef_** : array, shape (n_features,) or (n_targets, n_features)

Weight vector(s).

intercept_ : float | array, shape = (n_targets,)

Independent term in decision function. Set to 0.0 if `fit_intercept = False`.

n_iter_ : array or None, shape (n_targets,)

Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

New in version 0.17.

Examples

```
>>> from sklearn.linear_model import Ridge
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> np.random.seed(0)
>>> y = np.random.randn(n_samples)
>>> X = np.random.randn(n_samples, n_features)
>>> clf = Ridge(alpha=1.0)
>>> clf.fit(X, y)
Ridge(alpha=1.0, copy_X=True, fit_intercept=True, max_iter=None,
      normalize=False, random_state=None, solver='auto', tol=0.001)
```

Methods

fit(X, y[, sample_weight])	Fit Ridge regression model
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict using the linear model
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*alpha=1.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=None*, *tol=0.001*, *solver='auto'*, *random_state=None*)

fit (*X*, *y*, *sample_weight=None*)

Fit Ridge regression model

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training data

y : array-like, shape = [n_samples] or [n_samples, n_targets]

Target values

sample_weight : float or numpy array of shape [n_samples]

Individual weights for each sample

Returns **self** : returns an instance of self.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)
Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **C** : array, shape = (n_samples,)

Returns predicted values.

score(*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.linear_model.Ridge`

- *Prediction Latency*
- *Compressive sensing: tomography reconstruction with L1 prior (Lasso)*
- *HuberRegressor vs Ridge on dataset with strong outliers*

- *Ordinary Least Squares and Ridge Regression Variance*
- *Polynomial interpolation*
- *Plot Ridge coefficients as a function of the L2 regularization*
- *Plot Ridge coefficients as a function of the regularization*

29.18.20 sklearn.linear_model.RidgeClassifier

class sklearn.linear_model.**RidgeClassifier**(*alpha=1.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=None*, *tol=0.001*, *class_weight=None*, *solver='auto'*, *random_state=None*)

Classifier using Ridge regression.

Read more in the *User Guide*.

Parameters **alpha** : float

Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to `C^-1` in other linear models such as LogisticRegression or LinearSVC.

class_weight : dict or 'balanced', optional

Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one.

The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

copy_X : boolean, optional, default True

If True, X will be copied; else, it may be overwritten.

fit_intercept : boolean

Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

max_iter : int, optional

Maximum number of iterations for conjugate gradient solver. The default value is determined by scipy.sparse.linalg.

normalize : boolean, optional, default False

This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *`sklearn.preprocessing.StandardScaler`* before calling `fit` on an estimator with `normalize=False`.

solver : {'auto', 'svd', 'cholesky', 'lsqr', 'sparse_cg', 'sag', 'saga'}

Solver to use in the computational routines:

- 'auto' chooses the solver automatically based on the type of data.
- 'svd' uses a Singular Value Decomposition of X to compute the Ridge coefficients. More stable for singular matrices than 'cholesky'.

- 'cholesky' uses the standard scipy.linalg.solve function to obtain a closed-form solution.
- 'sparse_cg' uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than 'cholesky' for large-scale data (possibility to set *tol* and *max_iter*).
- 'lsqr' uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest but may not be available in old scipy versions. It also uses an iterative procedure.
- 'sag' uses a Stochastic Average Gradient descent, and 'saga' uses its unbiased and more flexible version named SAGA. Both methods use an iterative procedure, and are often faster than other solvers when both n_samples and n_features are large. Note that 'sag' and 'saga' fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

  New in version 0.17: Stochastic Average Gradient descent solver.

  New in version 0.19: SAGA solver.

tol : float

Precision of the solution.

random_state : int, RandomState instance or None, optional, default None

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `solver` == 'sag'.

Attributes **coef_** : array, shape (n_features,) or (n_classes, n_features)

Weight vector(s).

intercept_ : float | array, shape = (n_targets,)

Independent term in decision function. Set to 0.0 if `fit_intercept = False`.

n_iter_ : array or None, shape (n_targets,)

Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

Ridge, *RidgeClassifierCV*

Notes

For multi-class classification, n_class classifiers are trained in a one-versus-all approach. Concretely, this is implemented by taking advantage of the multi-variate response support in Ridge.

Methods

decision_function(X)	Predict confidence scores for samples.

Continued on next page

Table 29.167 – continued from previous page

fit(X, y[, sample_weight])	Fit Ridge regression model.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict class labels for samples in X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*alpha=1.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=None*, *tol=0.001*, *class_weight=None*, *solver='auto'*, *random_state=None*)

decision_function (*X*)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)** :

Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

fit (*X*, *y*, *sample_weight=None*)

Fit Ridge regression model.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples,n_features]

Training data

y : array-like, shape = [n_samples]

Target values

sample_weight : float or numpy array of shape (n_samples,)

Sample weight.

New in version 0.17: *sample_weight* support to Classifier.

Returns **self** : returns an instance of self.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*)

Predict class labels for samples in X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Samples.

Returns **C** : array, shape = [n_samples]

Predicted class label per sample.

score(*X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.linear_model.RidgeClassifier`

- *Classification of text documents using sparse features*

29.18.21 `sklearn.linear_model`.SGDClassifier

class `sklearn.linear_model.`**SGDClassifier**(*loss='hinge'*, *penalty='l2'*, *alpha=0.0001*, *l1_ratio=0.15*, *fit_intercept=True*, *n_iter=5*, *shuffle=True*, *verbose=0*, *epsilon=0.1*, *n_jobs=1*, *random_state=None*, *learning_rate='optimal'*, *eta0=0.0*, *power_t=0.5*, *class_weight=None*, *warm_start=False*, *average=False*)
Linear classifiers (SVM, logistic regression, a.o.) with SGD training.

This estimator implements regularized linear models with stochastic gradient descent (SGD) learning: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate). SGD allows minibatch (online/out-of-core) learning, see the partial_fit method. For best results using the default learning rate schedule, the data should have zero mean and unit variance.

This implementation works with data represented as dense or sparse arrays of floating point values for the features. The model it fits can be controlled with the loss parameter; by default, it fits a linear support vector machine (SVM).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

Read more in the *User Guide*.

Parameters **loss** : str, 'hinge', 'log', 'modified_huber', 'squared_hinge', 'perceptron', or a regression loss: 'squared_loss', 'huber', 'epsilon_insensitive', or 'squared_epsilon_insensitive'

The loss function to be used. Defaults to 'hinge', which gives a linear SVM. The 'log' loss gives logistic regression, a probabilistic classifier. 'modified_huber' is another smooth loss that brings tolerance to outliers as well as probability estimates. 'squared_hinge' is like hinge but is quadratically penalized. 'perceptron' is the linear loss used by the perceptron algorithm. The other losses are designed for regression but can be useful in classification as well; see SGDRegressor for a description.

penalty : str, 'none', 'l2', 'l1', or 'elasticnet'

The penalty (aka regularization term) to be used. Defaults to 'l2' which is the standard regularizer for linear SVM models. 'l1' and 'elasticnet' might bring sparsity to the model (feature selection) not achievable with 'l2'.

alpha : float

Constant that multiplies the regularization term. Defaults to 0.0001 Also used to compute learning_rate when set to 'optimal'.

l1_ratio : float

The Elastic Net mixing parameter, with 0 <= l1_ratio <= 1. l1_ratio=0 corresponds to L2 penalty, l1_ratio=1 to L1. Defaults to 0.15.

fit_intercept : bool

Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.

n_iter : int, optional

The number of passes over the training data (aka epochs). The number of iterations is set to 1 if using partial_fit. Defaults to 5.

shuffle : bool, optional

Whether or not the training data should be shuffled after each epoch. Defaults to True.

random_state : int, RandomState instance or None, optional (default=None)

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

verbose : integer, optional

The verbosity level

epsilon : float

Epsilon in the epsilon-insensitive loss functions; only if *loss* is 'huber', 'epsilon_insensitive', or 'squared_epsilon_insensitive'. For 'huber', determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

n_jobs : integer, optional

The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. -1 means 'all CPUs'. Defaults to 1.

learning_rate : string, optional

The learning rate schedule:

- 'constant': eta = eta0
- 'optimal': eta = 1.0 / (alpha * (t + t0)) [default]
- 'invscaling': eta = eta0 / pow(t, power_t)

where t0 is chosen by a heuristic proposed by Leon Bottou.

eta0 : double

The initial learning rate for the 'constant' or 'invscaling' schedules. The default value is 0.0 as eta0 is not used by the default schedule 'optimal'.

power_t : double

The exponent for inverse scaling learning rate [default 0.5].

class_weight : dict, {class_label: weight} or "balanced" or None, optional

Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

warm_start : bool, optional

When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

average : bool or int, optional

When set to True, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So `average=10` will begin averaging after seeing 10 samples.

Attributes **coef_** : array, shape (1, n_features) if n_classes == 2 else (n_classes, n_features)

Weights assigned to the features.

intercept_ : array, shape (1,) if n_classes == 2 else (n_classes,)

Constants in decision function.

loss_function_ : concrete `LossFunction`

Examples

```
>>> import numpy as np
>>> from sklearn import linear_model
>>> X = np.array([[-1, -1], [-2, -1], [1, 1], [2, 1]])
>>> Y = np.array([1, 1, 2, 2])
>>> clf = linear_model.SGDClassifier()
>>> clf.fit(X, Y)
```

```
...
SGDClassifier(alpha=0.0001, average=False, class_weight=None, epsilon=0.1,
        eta0=0.0, fit_intercept=True, l1_ratio=0.15,
        learning_rate='optimal', loss='hinge', n_iter=5, n_jobs=1,
        penalty='l2', power_t=0.5, random_state=None, shuffle=True,
        verbose=0, warm_start=False)
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

Methods

decision_function(X)	Predict confidence scores for samples.
densify()	Convert coefficient matrix to dense array format.
fit(X, y[, coef_init, intercept_init, ...])	Fit linear model with Stochastic Gradient Descent.
get_params([deep])	Get parameters for this estimator.
partial_fit(X, y[, classes, sample_weight])	Fit linear model with Stochastic Gradient Descent.
predict(X)	Predict class labels for samples in X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(*args, **kwargs)	
sparsify()	Convert coefficient matrix to sparse format.

__init__(*loss='hinge'*, *penalty='l2'*, *alpha=0.0001*, *l1_ratio=0.15*, *fit_intercept=True*, *n_iter=5*, *shuffle=True*, *verbose=0*, *epsilon=0.1*, *n_jobs=1*, *random_state=None*, *learning_rate='optimal'*, *eta0=0.0*, *power_t=0.5*, *class_weight=None*, *warm_start=False*, *average=False*)

decision_function(*X*)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)** :

Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify()

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns **self** : estimator

fit(*X*, *y*, *coef_init=None*, *intercept_init=None*, *sample_weight=None*)

Fit linear model with Stochastic Gradient Descent.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Training data

y : numpy array, shape (n_samples,)

Target values

coef_init : array, shape (n_classes, n_features)

The initial coefficients to warm-start the optimization.

intercept_init : array, shape (n_classes,)

The initial intercept to warm-start the optimization.

sample_weight : array-like, shape (n_samples,), optional

Weights applied to individual samples. If not provided, uniform weights are assumed. These weights will be multiplied with class_weight (passed through the constructor) if class_weight is specified

Returns **self** : returns an instance of self.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

loss_function

DEPRECATED: Attribute loss_function was deprecated in version 0.19 and will be removed in 0.21. Use '**loss_function_**' instead

partial_fit (*X*, *y*, *classes=None*, *sample_weight=None*)

Fit linear model with Stochastic Gradient Descent.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Subset of the training data

y : numpy array, shape (n_samples,)

Subset of the target values

classes : array, shape (n_classes,)

Classes across all calls to partial_fit. Can be obtained by via *np.unique(y_all)*, where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn't need to contain all labels in *classes*.

sample_weight : array-like, shape (n_samples,), optional

Weights applied to individual samples. If not provided, uniform weights are assumed.

Returns **self** : returns an instance of self.

predict (*X*)

Predict class labels for samples in X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Samples.

Returns **C** : array, shape = [n_samples]

Predicted class label per sample.

predict_log_proba
Log of probability estimates.

This method is only available for log loss and modified Huber loss.

When loss="modified_huber", probability estimates may be hard zeros and ones, so taking the logarithm is not possible.

See `predict_proba` for details.

Parameters **X** : array-like, shape (n_samples, n_features)

Returns **T** : array-like, shape (n_samples, n_classes)

Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in *self.classes_*.

predict_proba
Probability estimates.

This method is only available for log loss and modified Huber loss.

Multiclass probability estimates are derived from binary (one-vs.-rest) estimates by simple normalization, as recommended by Zadrozny and Elkan.

Binary probability estimates for loss="modified_huber" are given by (clip(decision_function(X), -1, 1) + 1) / 2. For other loss functions it is necessary to perform proper probability calibration by wrapping the classifier with *`sklearn.calibration.CalibratedClassifierCV`* instead.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Returns **array, shape (n_samples, n_classes)** :

Returns the probability of the sample for each class in the model, where classes are ordered as they are in *self.classes_*.

References

Zadrozny and Elkan, "Transforming classifier scores into multiclass probability estimates", SIGKDD'02, http://www.research.ibm.com/people/z/zadrozny/kdd2002-Transf.pdf

The justification for the formula in the loss="modified_huber" case is in the appendix B in: http://jmlr.csail.mit.edu/papers/volume2/zhang02c/zhang02c.pdf

score(*X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

sparsify()

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

Returns **self** : estimator

Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using `sklearn.linear_model.SGDClassifier`

- *Model Complexity Influence*
- *Out-of-core classification of text documents*
- *Comparing various online solvers*
- *Plot multi-class SGD on the iris dataset*
- *SGD: Maximum margin separating hyperplane*
- *SGD: Weighted samples*
- *Sample pipeline for text feature extraction and evaluation*
- *Classification of text documents using sparse features*

29.18.22 `sklearn.linear_model`.SGDRegressor

class `sklearn.linear_model.`**SGDRegressor**(*loss='squared_loss'*, *penalty='l2'*, *alpha=0.0001*, *l1_ratio=0.15*, *fit_intercept=True*, *n_iter=5*, *shuffle=True*, *verbose=0*, *epsilon=0.1*, *random_state=None*, *learning_rate='invscaling'*, *eta0=0.01*, *power_t=0.25*, *warm_start=False*, *average=False*)

Linear model fitted by minimizing a regularized empirical loss with SGD

SGD stands for Stochastic Gradient Descent: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

This implementation works with data represented as dense numpy arrays of floating point values for the features.

Read more in the *User Guide*.

Parameters loss : str, 'squared_loss', 'huber', 'epsilon_insensitive', or 'squared_epsilon_insensitive'

The loss function to be used. Defaults to 'squared_loss' which refers to the ordinary least squares fit. 'huber' modifies 'squared_loss' to focus less on getting outliers correct by switching from squared to linear loss past a distance of epsilon. 'epsilon_insensitive' ignores errors less than epsilon and is linear past that; this is the loss function used in SVR. 'squared_epsilon_insensitive' is the same but becomes squared loss past a tolerance of epsilon.

penalty : str, 'none', 'l2', 'l1', or 'elasticnet'

The penalty (aka regularization term) to be used. Defaults to 'l2' which is the standard regularizer for linear SVM models. 'l1' and 'elasticnet' might bring sparsity to the model (feature selection) not achievable with 'l2'.

alpha : float

Constant that multiplies the regularization term. Defaults to 0.0001 Also used to compute learning_rate when set to 'optimal'.

l1_ratio : float

The Elastic Net mixing parameter, with 0 <= l1_ratio <= 1. l1_ratio=0 corresponds to L2 penalty, l1_ratio=1 to L1. Defaults to 0.15.

fit_intercept : bool

Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.

n_iter : int, optional

The number of passes over the training data (aka epochs). The number of iterations is set to 1 if using partial_fit. Defaults to 5.

shuffle : bool, optional

Whether or not the training data should be shuffled after each epoch. Defaults to True.

random_state : int, RandomState instance or None, optional (default=None)

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

verbose : integer, optional

The verbosity level.

epsilon : float

Epsilon in the epsilon-insensitive loss functions; only if *loss* is 'huber', 'epsilon_insensitive', or 'squared_epsilon_insensitive'. For 'huber', determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

learning_rate : string, optional

The learning rate schedule:

- 'constant': eta = eta0

- 'optimal': eta = 1.0 / (alpha * (t + t0)) [default]
- 'invscaling': eta = eta0 / pow(t, power_t)

where t0 is chosen by a heuristic proposed by Leon Bottou.

eta0 : double, optional

The initial learning rate [default 0.01].

power_t : double, optional

The exponent for inverse scaling learning rate [default 0.25].

warm_start : bool, optional

When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

average : bool or int, optional

When set to True, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So `average=10` will begin averaging after seeing 10 samples.

Attributes **coef_** : array, shape (n_features,)

Weights assigned to the features.

intercept_ : array, shape (1,)

The intercept term.

average_coef_ : array, shape (n_features,)

Averaged weights assigned to the features.

average_intercept_ : array, shape (1,)

The averaged intercept term.

Examples

```
>>> import numpy as np
>>> from sklearn import linear_model
>>> n_samples, n_features = 10, 5
>>> np.random.seed(0)
>>> y = np.random.randn(n_samples)
>>> X = np.random.randn(n_samples, n_features)
>>> clf = linear_model.SGDRegressor()
>>> clf.fit(X, y)
...
SGDRegressor(alpha=0.0001, average=False, epsilon=0.1, eta0=0.01,
             fit_intercept=True, l1_ratio=0.15, learning_rate='invscaling',
             loss='squared_loss', n_iter=5, penalty='l2', power_t=0.25,
             random_state=None, shuffle=True, verbose=0, warm_start=False)
```

Methods

densify()	Convert coefficient matrix to dense array format.
fit(X, y[, coef_init, intercept_init, ...])	Fit linear model with Stochastic Gradient Descent.
get_params([deep])	Get parameters for this estimator.
partial_fit(X, y[, sample_weight])	Fit linear model with Stochastic Gradient Descent.
predict(X)	Predict using the linear model
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(*args, **kwargs)	
sparsify()	Convert coefficient matrix to sparse format.

__init__(*loss='squared_loss'*, *penalty='l2'*, *alpha=0.0001*, *l1_ratio=0.15*, *fit_intercept=True*, *n_iter=5*, *shuffle=True*, *verbose=0*, *epsilon=0.1*, *random_state=None*, *learning_rate='invscaling'*, *eta0=0.01*, *power_t=0.25*, *warm_start=False*, *average=False*)

densify()

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns **self** : estimator

fit(*X*, *y*, *coef_init=None*, *intercept_init=None*, *sample_weight=None*)

Fit linear model with Stochastic Gradient Descent.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Training data

y : numpy array, shape (n_samples,)

Target values

coef_init : array, shape (n_features,)

The initial coefficients to warm-start the optimization.

intercept_init : array, shape (1,)

The initial intercept to warm-start the optimization.

sample_weight : array-like, shape (n_samples,), optional

Weights applied to individual samples (1. for unweighted).

Returns **self** : returns an instance of self.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

partial_fit(*X*, *y*, *sample_weight=None*)
Fit linear model with Stochastic Gradient Descent.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Subset of training data

y : numpy array of shape (n_samples,)

Subset of target values

sample_weight : array-like, shape (n_samples,), optional

Weights applied to individual samples. If not provided, uniform weights are assumed.

Returns **self** : returns an instance of self.

predict(*X*)
Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Returns **array, shape (n_samples,)** :

Predicted target values per element in X.

score(*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

sparsify()
Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

Returns **self** : estimator

Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using `sklearn.linear_model.SGDRegressor`

- *Prediction Latency*

29.18.23 `sklearn.linear_model`.TheilSenRegressor

class `sklearn.linear_model.`**`TheilSenRegressor`**(*fit_intercept=True*, *copy_X=True*, *max_subpopulation=10000.0*, *n_subsamples=None*, *max_iter=300*, *tol=0.001*, *random_state=None*, *n_jobs=1*, *verbose=False*)

Theil-Sen Estimator: robust multivariate regression model.

The algorithm calculates least square solutions on subsets with size n_subsamples of the samples in X. Any value of n_subsamples between the number of features and samples leads to an estimator with a compromise between robustness and efficiency. Since the number of least square solutions is "n_samples choose n_subsamples", it can be extremely large and can therefore be limited with max_subpopulation. If this limit is reached, the subsets are chosen randomly. In a final step, the spatial median (or L1 median) is calculated of all least square solutions.

Read more in the *User Guide*.

Parameters **fit_intercept** : boolean, optional, default True

Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations.

copy_X : boolean, optional, default True

If True, X will be copied; else, it may be overwritten.

max_subpopulation : int, optional, default 1e4

Instead of computing with a set of cardinality 'n choose k', where n is the number of samples and k is the number of subsamples (at least number of features), consider only a stochastic subpopulation of a given maximal size if 'n choose k' is larger than max_subpopulation. For other than small problem sizes this parameter will determine memory usage and runtime if n_subsamples is not changed.

n_subsamples : int, optional, default None

Number of samples to calculate the parameters. This is at least the number of features (plus 1 if fit_intercept=True) and the number of samples as a maximum. A lower number leads to a higher breakdown point and a low efficiency while a high number leads to a low breakdown point and a high efficiency. If None, take the minimum number of subsamples leading to maximal robustness. If n_subsamples is set to n_samples, Theil-Sen is identical to least squares.

max_iter : int, optional, default 300

Maximum number of iterations for the calculation of spatial median.

tol : float, optional, default 1.e-3

Tolerance when calculating spatial median.

random_state : int, RandomState instance or None, optional, default None

A random number generator instance to define the state of the random permutations generator. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

n_jobs : integer, optional, default 1

Number of CPUs to use during the cross validation. If `-1`, use all the CPUs.

verbose : boolean, optional, default False

Verbose mode when fitting the model.

Attributes **coef_** : array, shape = (n_features)

Coefficients of the regression model (median of distribution).

intercept_ : float

Estimated intercept of regression model.

breakdown_ : float

Approximated breakdown point.

n_iter_ : int

Number of iterations needed for the spatial median.

n_subpopulation_ : int

Number of combinations taken into account from 'n choose k', where n is the number of samples and k is the number of subsamples.

Methods

fit(X, y)	Fit linear model.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict using the linear model
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*fit_intercept=True*, *copy_X=True*, *max_subpopulation=10000.0*, *n_subsamples=None*, *max_iter=300*, *tol=0.001*, *random_state=None*, *n_jobs=1*, *verbose=False*)

fit (*X*, *y*)

Fit linear model.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training data

y : numpy array of shape [n_samples]

Target values

Returns **self** : returns an instance of self.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*)
Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **C** : array, shape = (n_samples,)

Returns predicted values.

score (*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.linear_model.TheilSenRegressor`

- *Robust linear estimator fitting*
- *Theil-Sen Regression*

linear_model.lars_path(X, y[, Xy, Gram, ...])	Compute Least Angle Regression or Lasso path using LARS algorithm [1]
linear_model.lasso_path(X, y[, eps, ...])	Compute Lasso path with coordinate descent
linear_model.lasso_stability_path(X, y[, ...])	Stability path based on randomized Lasso estimates
linear_model.logistic_regression_path(X, y)	Compute a Logistic Regression model for a list of regularization parameters.
linear_model.orthogonal_mp(X, y[, ...])	Orthogonal Matching Pursuit (OMP)
linear_model.orthogonal_mp_gram(Gram, Xy[, ...])	Gram Orthogonal Matching Pursuit (OMP)

29.18.24 sklearn.linear_model.lars_path

sklearn.linear_model.**lars_path**(*X*, *y*, *Xy=None*, *Gram=None*, *max_iter=500*, *alpha_min=0*, *method='lar'*, *copy_X=True*, *eps=2.2204460492503131e-16*, *copy_Gram=True*, *verbose=0*, *return_path=True*, *return_n_iter=False*, *positive=False*)

Compute Least Angle Regression or Lasso path using LARS algorithm [1]

The optimization objective for the case method='lasso' is:

```
(1 / (2 * n_samples)) * ||y - Xw||^2_2 + alpha * ||w||_1
```

in the case of method='lars', the objective function is only known in the form of an implicit equation (see discussion in [1])

Read more in the *User Guide*.

Parameters **X** : array, shape: (n_samples, n_features)

Input data.

y : array, shape: (n_samples)

Input targets.

positive : boolean (default=False)

Restrict coefficients to be >= 0. When using this option together with method 'lasso' the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha (neither will they when using method 'lar' ..). Only coefficients up to the smallest alpha value (`alphas_[alphas_ > 0.].min()` when fit_path=True) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent lasso_path function.

max_iter : integer, optional (default=500)

Maximum number of iterations to perform, set to infinity for no limit.

Gram : None, 'auto', array, shape: (n_features, n_features), optional

Precomputed Gram matrix (X' * X), if `'auto'`, the Gram matrix is precomputed from the given X, if there are more samples than features.

alpha_min : float, optional (default=0)

Minimum correlation along the path. It corresponds to the regularization parameter alpha parameter in the Lasso.

method : {'lar', 'lasso'}, optional (default='lar')

Specifies the returned model. Select `'lar'` for Least Angle Regression, `'lasso'` for the Lasso.

eps : float, optional (default=‘‘np.finfo(np.float).eps‘‘)

The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems.

copy_X : bool, optional (default=True)

If `False`, `X` is overwritten.

copy_Gram : bool, optional (default=True)

If `False`, `Gram` is overwritten.

verbose : int (default=0)

Controls output verbosity.

return_path : bool, optional (default=True)

If `return_path==True` returns the entire path, else returns only the last point of the path.

return_n_iter : bool, optional (default=False)

Whether to return the number of iterations.

Returns **alphas** : array, shape: [n_alphas + 1]

Maximum of covariances (in absolute value) at each iteration. `n_alphas` is either `max_iter`, `n_features` or the number of nodes in the path with `alpha >= alpha_min`, whichever is smaller.

active : array, shape [n_alphas]

Indices of active variables at the end of the path.

coefs : array, shape (n_features, n_alphas + 1)

Coefficients along the path

n_iter : int

Number of iterations run. Returned only if return_n_iter is set to True.

See also:

lasso_path, *LassoLars*, *Lars*, *LassoLarsCV*, *LarsCV*, *sklearn.decomposition.sparse_encode*

References

[R38], *[R39]*, *[R40]*

Examples using `sklearn.linear_model.lars_path`

- *Lasso path using LARS*

29.18.25 sklearn.linear_model.lasso_path

sklearn.linear_model.**lasso_path**(*X*, *y*, *eps=0.001*, *n_alphas=100*, *alphas=None*, *precompute='auto'*, *Xy=None*, *copy_X=True*, *coef_init=None*, *verbose=False*, *return_n_iter=False*, *positive=False*, ***params*)

Compute Lasso path with coordinate descent

The Lasso optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
(1 / (2 * n_samples)) * ||y - Xw||^2_2 + alpha * ||w||_1
```

For multi-output tasks it is:

```
(1 / (2 * n_samples)) * ||Y - XW||^2_Fro + alpha * ||W||_21
```

Where:

```
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If `y` is mono-output then `X` can be sparse.

y : ndarray, shape (n_samples,), or (n_samples, n_outputs)

Target values

eps : float, optional

Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`

n_alphas : int, optional

Number of alphas along the regularization path

alphas : ndarray, optional

List of alphas where to compute the models. If `None` alphas are set automatically

precompute : True | False | 'auto' | array-like

Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument.

Xy : array-like, optional

Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X : boolean, optional, default True

If `True`, X will be copied; else, it may be overwritten.

coef_init : array, shape (n_features,) | None

The initial values of the coefficients.

verbose : bool or integer

Amount of verbosity.

params : kwargs

keyword arguments passed to the coordinate descent solver.

positive : bool, default False

If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

return_n_iter : bool

whether to return the number of iterations or not.

Returns **alphas** : array, shape (n_alphas,)

The alphas along the path where models are computed.

coefs : array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)

Coefficients along the path.

dual_gaps : array, shape (n_alphas,)

The dual gaps at the end of the optimization for each alpha.

n_iters : array-like, shape (n_alphas,)

The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha.

See also:

lars_path, *Lasso*, *LassoLars*, *LassoCV*, *LassoLarsCV*, *sklearn.decomposition.sparse_encode*

Notes

For an example, see *examples/linear_model/plot_lasso_coordinate_descent_path.py*.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Note that in certain cases, the Lars solver may be significantly faster to implement this functionality. In particular, linear interpolation can be used to retrieve model coefficients between the values output by lars_path

Examples

Comparing lasso_path and lars_path with interpolation:

```
>>> X = np.array([[1, 2, 3.1], [2.3, 5.4, 4.3]]).T
>>> y = np.array([1, 2, 3.1])
>>> # Use lasso_path to compute a coefficient path
>>> _, coef_path, _ = lasso_path(X, y, alphas=[5., 1., .5])
>>> print(coef_path)
[[ 0.          0.          0.46874778]
 [ 0.2159048   0.4425765   0.23689075]]
```

```
>>> # Now use lars_path and 1D linear interpolation to compute the
>>> # same path
>>> from sklearn.linear_model import lars_path
```

```
>>> alphas, active, coef_path_lars = lars_path(X, y, method='lasso')
>>> from scipy import interpolate
>>> coef_path_continuous = interpolate.interp1d(alphas[::-1],
...                                             coef_path_lars[:, ::-1])
>>> print(coef_path_continuous([5., 1., .5]))
[[ 0.          0.          0.46915237]
 [ 0.2159048   0.4425765   0.23668876]]
```

Examples using `sklearn.linear_model.lasso_path`

- *Lasso and Elastic Net*

29.18.26 `sklearn.linear_model`.lasso_stability_path

`sklearn.linear_model.`**`lasso_stability_path`**(*X*, *y*, *scaling=0.5*, *random_state=None*, *n_resampling=200*, *n_grid=100*, *sample_fraction=0.75*, *eps=8.8817841970012523e-16*, *n_jobs=1*, *verbose=False*)

Stability path based on randomized Lasso estimates

Read more in the *User Guide*.

Parameters **X** : array-like, shape = [n_samples, n_features]

training data.

y : array-like, shape = [n_samples]

target values.

scaling : float, optional, default=0.5

The alpha parameter in the stability selection article used to randomly scale the features. Should be between 0 and 1.

random_state : int, RandomState instance or None, optional, default=None

The generator used to randomize the design. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

n_resampling : int, optional, default=200

Number of randomized models.

n_grid : int, optional, default=100

Number of grid points. The path is linearly reinterpolated on a grid between 0 and 1 before computing the scores.

sample_fraction : float, optional, default=0.75

The fraction of samples to be used in each randomized design. Should be between 0 and 1. If 1, all samples are used.

eps : float, optional

Smallest value of alpha / alpha_max considered

n_jobs : integer, optional

Number of CPUs to use during the resampling. If '-1', use all the CPUs

verbose : boolean or integer, optional

Sets the verbosity amount

Returns **alphas_grid** : array, shape ~ [n_grid]

The grid points between 0 and 1: alpha/alpha_max

scores_path : array, shape = [n_features, n_grid]

The scores for each feature along the path.

Notes

For an example, see *examples/linear_model/plot_sparse_recovery.py*.

Examples using `sklearn.linear_model.lasso_stability_path`

- *Sparse recovery: feature selection for sparse linear models*

29.18.27 `sklearn.linear_model`.logistic_regression_path

`sklearn.linear_model.`**`logistic_regression_path`**(*X*, *y*, *pos_class=None*, *Cs=10*, *fit_intercept=True*, *max_iter=100*, *tol=0.0001*, *verbose=0*, *solver='lbfgs'*, *coef=None*, *class_weight=None*, *dual=False*, *penalty='l2'*, *intercept_scaling=1.0*, *multi_class='ovr'*, *random_state=None*, *check_input=True*, *max_squared_sum=None*, *sample_weight=None*)

Compute a Logistic Regression model for a list of regularization parameters.

This is an implementation that uses the result of the previous model to speed up computations along the set of solutions, making it faster than sequentially calling LogisticRegression for the different parameters. Note that there will be no speedup with liblinear solver, since it does not handle warm-starting.

Read more in the *User Guide*.

Parameters **X** : array-like or sparse matrix, shape (n_samples, n_features)

Input data.

y : array-like, shape (n_samples,)

Input data, target values.

Cs : int | array-like, shape (n_cs,)

List of values for the regularization parameter or integer specifying the number of regularization parameters that should be used. In this case, the parameters will be chosen in a logarithmic scale between 1e-4 and 1e4.

pos_class : int, None

The class with respect to which we perform a one-vs-all fit. If None, then it is assumed that the given problem is binary.

fit_intercept : bool

Whether to fit an intercept for the model. In this case the shape of the returned array is (n_cs, n_features + 1).

max_iter : int

Maximum number of iterations for the solver.

tol : float

Stopping criterion. For the newton-cg and lbfgs solvers, the iteration will stop when `max{|g_i | i = 1, ..., n} <= tol` where `g_i` is the i-th component of the gradient.

verbose : int

For the liblinear and lbfgs solvers set verbose to any positive number for verbosity.

solver : {'lbfgs', 'newton-cg', 'liblinear', 'sag', 'saga'}

Numerical solver to use.

coef : array-like, shape (n_features,), default None

Initialization value for coefficients of logistic regression. Useless for liblinear solver.

class_weight : dict or 'balanced', optional

Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one.

The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`.

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

dual : bool

Dual or primal formulation. Dual formulation is only implemented for l2 penalty with liblinear solver. Prefer dual=False when n_samples > n_features.

penalty : str, 'l1' or 'l2'

Used to specify the norm used in the penalization. The 'newton-cg', 'sag' and 'lbfgs' solvers support only l2 penalties.

intercept_scaling : float, default 1.

Useful only when the solver 'liblinear' is used and self.fit_intercept is set to True. In this case, x becomes [x, self.intercept_scaling], i.e. a "synthetic" feature with constant value equal to intercept_scaling is appended to the instance vector. The intercept becomes `intercept_scaling * synthetic_feature_weight`.

Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

multi_class : str, {'ovr', 'multinomial'}

Multiclass option can be either 'ovr' or 'multinomial'. If the option chosen is 'ovr', then a binary problem is fit for each label. Else the loss minimised is the multinomial loss fit across the entire probability distribution. Works only for the 'lbfgs' and 'newton-cg' solvers.

random_state : int, RandomState instance or None, optional, default None

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `solver` == 'sag' or 'liblinear'.

check_input : bool, default True

If False, the input arrays X and y will not be checked.

max_squared_sum : float, default None

Maximum squared sum of X over samples. Used only in SAG solver. If None, it will be computed, going through all the samples. The value should be precomputed to speed up cross validation.

sample_weight : array-like, shape(n_samples,) optional

Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

Returns **coefs** : ndarray, shape (n_cs, n_features) or (n_cs, n_features + 1)

List of coefficients for the Logistic Regression model. If fit_intercept is set to True then the second dimension will be n_features + 1, where the last item represents the intercept.

Cs : ndarray

Grid of Cs used for cross-validation.

n_iter : array, shape (n_cs,)

Actual number of iteration for each Cs.

Notes

You might get slightly different results with the solver liblinear than with the others since this uses LIBLINEAR which penalizes the intercept.

Changed in version 0.19: The "copy" parameter was removed.

29.18.28 `sklearn.linear_model`.orthogonal_mp

`sklearn.linear_model.`**`orthogonal_mp`**(*X*, *y*, *n_nonzero_coefs=None*, *tol=None*, *precompute=False*, *copy_X=True*, *return_path=False*, *return_n_iter=False*)

Orthogonal Matching Pursuit (OMP)

Solves n_targets Orthogonal Matching Pursuit problems. An instance of the problem has the form:

When parametrized by the number of non-zero coefficients using *n_nonzero_coefs*: argmin ||y - Xgamma||^2 subject to ||gamma||_0 <= n_{nonzero coefs}

When parametrized by error using the parameter *tol*: argmin ||gamma||_0 subject to ||y - Xgamma||^2 <= tol

Read more in the *User Guide*.

Parameters **X** : array, shape (n_samples, n_features)

Input data. Columns are assumed to have unit norm.

y : array, shape (n_samples,) or (n_samples, n_targets)

Input targets

n_nonzero_coefs : int

Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.

tol : float

Maximum norm of the residual. If not None, overrides n_nonzero_coefs.

precompute : {True, False, 'auto'},

Whether to perform precomputations. Improves performance when n_targets or n_samples is very large.

copy_X : bool, optional

Whether the design matrix X must be copied by the algorithm. A false value is only helpful if X is already Fortran-ordered, otherwise a copy is made anyway.

return_path : bool, optional. Default: False

Whether to return every value of the nonzero coefficients along the forward path. Useful for cross-validation.

return_n_iter : bool, optional default False

Whether or not to return the number of iterations.

Returns **coef** : array, shape (n_features,) or (n_features, n_targets)

Coefficients of the OMP solution. If *return_path=True*, this contains the whole coefficient path. In this case its shape is (n_features, n_features) or (n_features, n_targets, n_features) and iterating over the last axis yields coefficients in increasing order of active features.

n_iters : array-like or int

Number of active features across every target. Returned only if *return_n_iter* is set to True.

Notes

Orthogonal matching pursuit was introduced in S. Mallat, Z. Zhang, Matching pursuits with time-frequency dictionaries, IEEE Transactions on Signal Processing, Vol. 41, No. 12. (December 1993), pp. 3397-3415. (http://blanche.polytechnique.fr/~mallat/papiers/MallatPursuit93.pdf)

This implementation is based on Rubinstein, R., Zibulevsky, M. and Elad, M., Efficient Implementation of the K-SVD Algorithm using Batch Orthogonal Matching Pursuit Technical Report - CS Technion, April 2008. http://www.cs.technion.ac.il/~ronrubin/Publications/KSVD-OMP-v2.pdf

29.18.29 sklearn.linear_model.orthogonal_mp_gram

sklearn.linear_model.**orthogonal_mp_gram**(*Gram*, *Xy*, *n_nonzero_coefs=None*, *tol=None*, *norms_squared=None*, *copy_Gram=True*, *copy_Xy=True*, *return_path=False*, *return_n_iter=False*)

Gram Orthogonal Matching Pursuit (OMP)

Solves n_targets Orthogonal Matching Pursuit problems using only the Gram matrix X.T * X and the product X.T * y.

Read more in the *User Guide*.

Parameters **Gram** : array, shape (n_features, n_features)

Gram matrix of the input data: X.T * X

Xy : array, shape (n_features,) or (n_features, n_targets)

Input targets multiplied by X: X.T * y

n_nonzero_coefs : int

Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.

tol : float

Maximum norm of the residual. If not None, overrides n_nonzero_coefs.

norms_squared : array-like, shape (n_targets,)

Squared L2 norms of the lines of y. Required if tol is not None.

copy_Gram : bool, optional

Whether the gram matrix must be copied by the algorithm. A false value is only helpful if it is already Fortran-ordered, otherwise a copy is made anyway.

copy_Xy : bool, optional

Whether the covariance vector Xy must be copied by the algorithm. If False, it may be overwritten.

return_path : bool, optional. Default: False

Whether to return every value of the nonzero coefficients along the forward path. Useful for cross-validation.

return_n_iter : bool, optional default False

Whether or not to return the number of iterations.

Returns **coef** : array, shape (n_features,) or (n_features, n_targets)

Coefficients of the OMP solution. If *return_path=True*, this contains the whole coefficient path. In this case its shape is (n_features, n_features) or (n_features, n_targets, n_features) and iterating over the last axis yields coefficients in increasing order of active features.

n_iters : array-like or int

Number of active features across every target. Returned only if *return_n_iter* is set to True.

29.19 `sklearn.manifold`: Manifold Learning

The *sklearn.manifold* module implements data embedding techniques.

User guide: See the *Manifold learning* section for further details.

manifold.LocallyLinearEmbedding([...])	Locally Linear Embedding
manifold.Isomap([n_neighbors, n_components, ...])	Isomap Embedding
manifold.MDS([n_components, metric, n_init, ...])	Multidimensional scaling
manifold.SpectralEmbedding([n_components, ...])	Spectral embedding for non-linear dimensionality reduction.
manifold.TSNE([n_components, perplexity, ...])	t-distributed Stochastic Neighbor Embedding.

29.19.1 `sklearn.manifold`.LocallyLinearEmbedding

class `sklearn.manifold.`**`LocallyLinearEmbedding`**(*n_neighbors=5*, *n_components=2*, *reg=0.001*, *eigen_solver='auto'*, *tol=1e-06*, *max_iter=100*, *method='standard'*, *hessian_tol=0.0001*, *modified_tol=1e-12*, *neighbors_algorithm='auto'*, *random_state=None*, *n_jobs=1*)

Locally Linear Embedding

Read more in the *User Guide*.

Parameters **n_neighbors** : integer

number of neighbors to consider for each point.

n_components : integer

number of coordinates for the manifold

reg : float

regularization constant, multiplies the trace of the local covariance matrix of the distances.

eigen_solver : string, {'auto', 'arpack', 'dense'}

auto : algorithm will attempt to choose the best method for input data

arpack [use arnoldi iteration in shift-invert mode.] For this method, M may be a dense matrix, sparse matrix, or general linear operator. Warning: ARPACK can be unstable for some problems. It is best to try several random seeds in order to check results.

dense [use standard dense matrix operations for the eigenvalue] decomposition. For this method, M must be an array or matrix type. This method should be avoided for large problems.

tol : float, optional

Tolerance for 'arpack' method Not used if eigen_solver=='dense'.

max_iter : integer

maximum number of iterations for the arpack solver. Not used if eigen_solver=='dense'.

method : string ('standard', 'hessian', 'modified' or 'ltsa')

standard [use the standard locally linear embedding algorithm. see] reference [1]

hessian [use the Hessian eigenmap method. This method requires] `n_neighbors > n_components * (1 + (n_components + 1) / 2` see reference [2]

modified [use the modified locally linear embedding algorithm.] see reference [3]

ltsa [use local tangent space alignment algorithm] see reference [4]

hessian_tol : float, optional

Tolerance for Hessian eigenmapping method. Only used if `method == 'hessian'`

modified_tol : float, optional

Tolerance for modified LLE method. Only used if `method == 'modified'`

neighbors_algorithm : string ['auto'|'brute'|'kd_tree'|'ball_tree']

algorithm to use for nearest neighbors search, passed to neighbors.NearestNeighbors instance

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `eigen_solver` == 'arpack'.

n_jobs : int, optional (default = 1)

The number of parallel jobs to run. If `-1`, then the number of jobs is set to the number of CPU cores.

Attributes **embedding_vectors_** : array-like, shape [n_components, n_samples]

Stores the embedding vectors

reconstruction_error_ : float

Reconstruction error associated with *embedding_vectors_*

nbrs_ : NearestNeighbors object

Stores nearest neighbors instance, including BallTree or KDtree if applicable.

References

[R42], *[R43]*, *[R44]*, *[R45]*

Methods

fit(X[, y])	Compute the embedding vectors for data X
fit_transform(X[, y])	Compute the embedding vectors for data X and transform X.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Transform new points into embedding space.

__init__(*n_neighbors=5*, *n_components=2*, *reg=0.001*, *eigen_solver='auto'*, *tol=1e-06*, *max_iter=100*, *method='standard'*, *hessian_tol=0.0001*, *modified_tol=1e-12*, *neighbors_algorithm='auto'*, *random_state=None*, *n_jobs=1*)

fit(*X*, *y=None*)

Compute the embedding vectors for data X

Parameters **X** : array-like of shape [n_samples, n_features]

training set.

Returns **self** : returns an instance of self.

fit_transform(*X*, *y=None*)

Compute the embedding vectors for data X and transform X.

Parameters **X** : array-like of shape [n_samples, n_features]

training set.

Returns **X_new** : array-like, shape (n_samples, n_components)

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)

Transform new points into embedding space.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **X_new** : array, shape = [n_samples, n_components]

Notes

Because of scaling performed by this method, it is discouraged to use it together with methods that are not scale-invariant (like SVMs)

Examples using `sklearn.manifold.LocallyLinearEmbedding`

29.19.2 `sklearn.manifold`.Isomap

class `sklearn.manifold.`**`Isomap`**(*n_neighbors=5*, *n_components=2*, *eigen_solver='auto'*, *tol=0*, *max_iter=None*, *path_method='auto'*, *neighbors_algorithm='auto'*, *n_jobs=1*)

Isomap Embedding

Non-linear dimensionality reduction through Isometric Mapping

Read more in the *User Guide*.

Parameters **n_neighbors** : integer

number of neighbors to consider for each point.

n_components : integer

number of coordinates for the manifold

eigen_solver : ['auto'|'arpack'|'dense']

'auto' : Attempt to choose the most efficient solver for the given problem.

'arpack' : Use Arnoldi decomposition to find the eigenvalues and eigenvectors.

'dense' : Use a direct solver (i.e. LAPACK) for the eigenvalue decomposition.

tol : float

Convergence tolerance passed to arpack or lobpcg. not used if eigen_solver == 'dense'.

max_iter : integer

Maximum number of iterations for the arpack solver. not used if eigen_solver == 'dense'.

path_method : string ['auto'|'FW'|'D']

Method to use in finding shortest path.

'auto' : attempt to choose the best algorithm automatically.

'FW' : Floyd-Warshall algorithm.

'D' : Dijkstra's algorithm.

neighbors_algorithm : string ['auto'|'brute'|'kd_tree'|'ball_tree']

Algorithm to use for nearest neighbors search, passed to neighbors.NearestNeighbors instance.

n_jobs : int, optional (default = 1)

The number of parallel jobs to run. If `-1`, then the number of jobs is set to the number of CPU cores.

Attributes **embedding_** : array-like, shape (n_samples, n_components)

Stores the embedding vectors.

kernel_pca_ : object

KernelPCA object used to implement the embedding.

training_data_ : array-like, shape (n_samples, n_features)

Stores the training data.

nbrs_ : sklearn.neighbors.NearestNeighbors instance

Stores nearest neighbors instance, including BallTree or KDtree if applicable.

dist_matrix_ : array-like, shape (n_samples, n_samples)

Stores the geodesic distance matrix of training data.

[R41]

Methods

`fit`(X[, y])	Compute the embedding vectors for data X
`fit_transform`(X[, y])	Fit the model from data in X and transform X.
`get_params`([deep])	Get parameters for this estimator.
`reconstruction_error`()	Compute the reconstruction error for the embedding.
`set_params`(**params)	Set the parameters of this estimator.
`transform`(X)	Transform X.

__init__(*n_neighbors=5*, *n_components=2*, *eigen_solver='auto'*, *tol=0*, *max_iter=None*, *path_method='auto'*, *neighbors_algorithm='auto'*, *n_jobs=1*)

fit(*X*, *y=None*)

Compute the embedding vectors for data X

Parameters **X** : {array-like, sparse matrix, BallTree, KDTree, NearestNeighbors}

Sample data, shape = (n_samples, n_features), in the form of a numpy array, precomputed tree, or NearestNeighbors object.

Returns **self** : returns an instance of self.

fit_transform(*X*, *y=None*)

Fit the model from data in X and transform X.

Parameters **X** : {array-like, sparse matrix, BallTree, KDTree}

Training vector, where n_samples in the number of samples and n_features is the number of features.

Returns **X_new** : array-like, shape (n_samples, n_components)

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

reconstruction_error()
Compute the reconstruction error for the embedding.

Returns **reconstruction_error** : float

Notes

The cost function of an isomap embedding is

```
E = frobenius_norm[K(D) - K(D_fit)] / n_samples
```

Where D is the matrix of distances for the input data X, D_fit is the matrix of distances for the output embedding X_fit, and K is the isomap kernel:

```
K(D) = -0.5 * (I - 1/n_samples) * D^2 * (I - 1/n_samples)
```

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Transform X.

This is implemented by linking the points X into the graph of geodesic distances of the training data. First the *n_neighbors* nearest neighbors of X are found in the training data, and from these the shortest geodesic distances from each point in X to each point in the training data are computed in order to construct the kernel. The embedding of X is the projection of this kernel onto the embedding vectors of the training set.

Parameters **X** : array-like, shape (n_samples, n_features)

Returns **X_new** : array-like, shape (n_samples, n_components)

Examples using `sklearn.manifold.Isomap`

- *Comparison of Manifold Learning methods*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*
- *Manifold Learning methods on a severed sphere*

29.19.3 sklearn.manifold.MDS

class sklearn.manifold.**MDS**(*n_components=2*, *metric=True*, *n_init=4*, *max_iter=300*, *verbose=0*, *eps=0.001*, *n_jobs=1*, *random_state=None*, *dissimilarity='euclidean'*)

Multidimensional scaling

Read more in the *User Guide*.

Parameters **n_components** : int, optional, default: 2

Number of dimensions in which to immerse the dissimilarities.

metric : boolean, optional, default: True

If `True`, perform metric MDS; otherwise, perform nonmetric MDS.

n_init : int, optional, default: 4

Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress.

max_iter : int, optional, default: 300

Maximum number of iterations of the SMACOF algorithm for a single run.

verbose : int, optional, default: 0

Level of verbosity.

eps : float, optional, default: 1e-3

Relative tolerance with respect to stress at which to declare convergence.

n_jobs : int, optional, default: 1

The number of jobs to use for the computation. If multiple initializations are used (`n_init`), each run of the algorithm is computed in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For `n_jobs` below -1, (`n_cpus + 1 + n_jobs`) are used. Thus for `n_jobs = -2`, all CPUs but one are used.

random_state : int, RandomState instance or None, optional, default: None

The generator used to initialize the centers. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

dissimilarity : 'euclidean' | 'precomputed', optional, default: 'euclidean'

Dissimilarity measure to use:

- **'euclidean':** Pairwise Euclidean distances between points in the dataset.
- **'precomputed':** Pre-computed dissimilarities are passed directly to `fit` and `fit_transform`.

Attributes **embedding_** : array-like, shape (n_components, n_samples)

Stores the position of the dataset in the embedding space.

stress_ : float

The final value of the stress (sum of squared distance of the disparities and the distances for all constrained points).

Methods

fit(X[, y, init])	Computes the position of the points in the embedding space
fit_transform(X[, y, init])	Fit the data from X, and returns the embedded coordinates
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_components=2*, *metric=True*, *n_init=4*, *max_iter=300*, *verbose=0*, *eps=0.001*, *n_jobs=1*, *random_state=None*, *dissimilarity='euclidean'*)

fit (*X*, *y=None*, *init=None*)
Computes the position of the points in the embedding space

Parameters **X** : array, shape (n_samples, n_features) or (n_samples, n_samples)

Input data. If `dissimilarity=='precomputed'`, the input should be the dissimilarity matrix.

init : ndarray, shape (n_samples,), optional, default: None

Starting configuration of the embedding to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.

fit_transform (*X*, *y=None*, *init=None*)
Fit the data from X, and returns the embedded coordinates

Parameters **X** : array, shape (n_samples, n_features) or (n_samples, n_samples)

Input data. If `dissimilarity=='precomputed'`, the input should be the dissimilarity matrix.

init : ndarray, shape (n_samples,), optional, default: None

Starting configuration of the embedding to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.manifold.MDS`

- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*
- *Manifold Learning methods on a severed sphere*
- *Multi-dimensional scaling*

29.19.4 `sklearn.manifold`.SpectralEmbedding

class `sklearn.manifold.`**SpectralEmbedding**(*n_components=2*, *affinity='nearest_neighbors'*, *gamma=None*, *random_state=None*, *eigen_solver=None*, *n_neighbors=None*, *n_jobs=1*)
Spectral embedding for non-linear dimensionality reduction.

Forms an affinity matrix given by the specified function and applies spectral decomposition to the corresponding graph laplacian. The resulting transformation is given by the value of the eigenvectors for each data point.

Note : Laplacian Eigenmaps is the actual algorithm implemented here.

Read more in the *User Guide*.

Parameters **n_components** : integer, default: 2

The dimension of the projected subspace.

eigen_solver : {None, 'arpack', 'lobpcg', or 'amg'}

The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities.

random_state : int, RandomState instance or None, optional, default: None

A pseudo random number generator used for the initialization of the lobpcg eigenvectors. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `solver` == 'amg'.

affinity : string or callable, default

How to construct the affinity matrix.

- 'nearest_neighbors' : construct affinity matrix by knn graph
- 'rbf' : construct affinity matrix by rbf kernel
- 'precomputed' : interpret X as precomputed affinity matrix
- callable : use passed in function as affinity the function takes in data matrix (n_samples, n_features) and return affinity matrix (n_samples, n_samples).

gamma : float, optional, default

Kernel coefficient for rbf kernel.

n_neighbors : int, default

Number of nearest neighbors for nearest_neighbors graph building.

n_jobs : int, optional (default = 1)

The number of parallel jobs to run. If `-1`, then the number of jobs is set to the number of CPU cores.

Attributes **embedding_** : array, shape = (n_samples, n_components)

Spectral embedding of the training matrix.

affinity_matrix_ : array, shape = (n_samples, n_samples)

Affinity_matrix constructed from samples or precomputed.

Methods

fit(X[, y])	Fit the model from data in X.
fit_transform(X[, y])	Fit the model from data in X and transform X.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_components=2*, *affinity='nearest_neighbors'*, *gamma=None*, *random_state=None*, *eigen_solver=None*, *n_neighbors=None*, *n_jobs=1*)

fit (*X*, *y=None*)

Fit the model from data in X.

Parameters **X** : array-like, shape (n_samples, n_features)

Training vector, where n_samples is the number of samples and n_features is the number of features.

If affinity is "precomputed" X : array-like, shape (n_samples, n_samples), Interpret X as precomputed adjacency graph computed from samples.

Returns **self** : object

Returns the instance itself.

fit_transform (*X*, *y=None*)

Fit the model from data in X and transform X.

Parameters **X** : array-like, shape (n_samples, n_features)

Training vector, where n_samples is the number of samples and n_features is the number of features.

If affinity is "precomputed" X : array-like, shape (n_samples, n_samples), Interpret X as precomputed adjacency graph computed from samples.

Returns **X_new** : array-like, shape (n_samples, n_components)

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.manifold.SpectralEmbedding`

- *Various Agglomerative Clustering on a 2D embedding of digits*
- *Comparison of Manifold Learning methods*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*
- *Manifold Learning methods on a severed sphere*

29.19.5 `sklearn.manifold.TSNE`

class `sklearn.manifold.`**TSNE**(*n_components=2*, *perplexity=30.0*, *early_exaggeration=4.0*, *learning_rate=1000.0*, *n_iter=1000*, *n_iter_without_progress=30*, *min_grad_norm=1e-07*, *metric='euclidean'*, *init='random'*, *verbose=0*, *random_state=None*, *method='barnes_hut'*, *angle=0.5*)
t-distributed Stochastic Neighbor Embedding.

t-SNE [1] is a tool to visualize high-dimensional data. It converts similarities between data points to joint probabilities and tries to minimize the Kullback-Leibler divergence between the joint probabilities of the low-dimensional embedding and the high-dimensional data. t-SNE has a cost function that is not convex, i.e. with different initializations we can get different results.

It is highly recommended to use another dimensionality reduction method (e.g. PCA for dense data or TruncatedSVD for sparse data) to reduce the number of dimensions to a reasonable amount (e.g. 50) if the number of features is very high. This will suppress some noise and speed up the computation of pairwise distances between samples. For more tips see Laurens van der Maaten's FAQ [2].

Read more in the *User Guide*.

Parameters **n_components** : int, optional (default: 2)

Dimension of the embedded space.

perplexity : float, optional (default: 30)

The perplexity is related to the number of nearest neighbors that is used in other manifold learning algorithms. Larger datasets usually require a larger perplexity. Consider selecting a value between 5 and 50. The choice is not extremely critical since t-SNE is quite insensitive to this parameter.

early_exaggeration : float, optional (default: 4.0)

Controls how tight natural clusters in the original space are in the embedded space and how much space will be between them. For larger values, the space between natural clusters will be larger in the embedded space. Again, the choice of this parameter is not very critical. If the cost function increases during initial optimization, the early exaggeration factor or the learning rate might be too high.

learning_rate : float, optional (default: 1000)

The learning rate can be a critical parameter. It should be between 100 and 1000. If the cost function increases during initial optimization, the early exaggeration factor or the learning rate might be too high. If the cost function gets stuck in a bad local minimum increasing the learning rate helps sometimes.

n_iter : int, optional (default: 1000)

Maximum number of iterations for the optimization. Should be at least 200.

n_iter_without_progress : int, optional (default: 30)

Only used if method='exact' Maximum number of iterations without progress before we abort the optimization. If method='barnes_hut' this parameter is fixed to a value of 30 and cannot be changed.

New in version 0.17: parameter *n_iter_without_progress* to control stopping criteria.

min_grad_norm : float, optional (default: 1e-7)

Only used if method='exact' If the gradient norm is below this threshold, the optimization will be aborted. If method='barnes_hut' this parameter is fixed to a value of 1e-3 and cannot be changed.

metric : string or callable, optional

The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is "precomputed", X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them. The default is "euclidean" which is interpreted as squared euclidean distance.

init : string or numpy array, optional (default: "random")

Initialization of embedding. Possible options are 'random', 'pca', and a numpy array of shape (n_samples, n_components). PCA initialization cannot be used with precomputed distances and is usually more globally stable than random initialization.

verbose : int, optional (default: 0)

Verbosity level.

random_state : int, RandomState instance or None, optional (default: None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Note that different initializations might result in different local minima of the cost function.

method : string (default: 'barnes_hut')

By default the gradient calculation algorithm uses Barnes-Hut approximation running in O(NlogN) time. method='exact' will run on the slower, but exact, algorithm in O(N^2) time. The exact algorithm should be used when nearest-neighbor errors need to be better than 3%. However, the exact method cannot scale to millions of examples.

New in version 0.17: Approximate optimization *method* via the Barnes-Hut.

angle : float (default: 0.5)

Only used if method='barnes_hut' This is the trade-off between speed and accuracy for Barnes-Hut T-SNE. 'angle' is the angular size (referred to as theta in [3]) of a distant node as measured from a point. If this size is below 'angle' then it is used as a summary node of all points contained within it. This method is not very sensitive to changes in this parameter in the range of 0.2 - 0.8. Angle less than 0.2 has quickly increasing computation time and angle greater 0.8 has quickly increasing error.

Attributes **embedding_** : array-like, shape (n_samples, n_components)

Stores the embedding vectors.

kl_divergence_ : float

Kullback-Leibler divergence after optimization.

n_iter_ : int

Number of iterations run.

Examples

```
>>> import numpy as np
>>> from sklearn.manifold import TSNE
>>> X = np.array([[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 1]])
>>> model = TSNE(n_components=2, random_state=0)
>>> np.set_printoptions(suppress=True)
>>> model.fit_transform(X)
array([[ 0.00017619,  0.00004014],
       [ 0.00010268,  0.00020546],
       [ 0.00018298, -0.00008335],
       [ 0.00009501, -0.00001388]])
```

Methods

fit(X[, y])	Fit X into an embedded space.
fit_transform(X[, y])	Fit X into an embedded space and return that transformed output.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_components=2*, *perplexity=30.0*, *early_exaggeration=4.0*, *learning_rate=1000.0*, *n_iter=1000*, *n_iter_without_progress=30*, *min_grad_norm=1e-07*, *metric='euclidean'*, *init='random'*, *verbose=0*, *random_state=None*, *method='barnes_hut'*, *angle=0.5*)

fit (*X*, *y=None*)
Fit X into an embedded space.

Parameters **X** : array, shape (n_samples, n_features) or (n_samples, n_samples)

If the metric is 'precomputed' X must be a square distance matrix. Otherwise it contains a sample per row. If the method is 'exact', X may be a sparse matrix of type 'csr', 'csc' or 'coo'.

fit_transform (*X*, *y=None*)
Fit X into an embedded space and return that transformed output.

Parameters **X** : array, shape (n_samples, n_features) or (n_samples, n_samples)

If the metric is 'precomputed' X must be a square distance matrix. Otherwise it contains a sample per row.

Returns **X_new** : array, shape (n_samples, n_components)

Embedding of the training data in low-dimensional space.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

n_iter_final
DEPRECATED: Attribute n_iter_final was deprecated in version 0.19 and will be removed in 0.21. Use '**n_iter_**' instead

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.manifold.TSNE`

- *Comparison of Manifold Learning methods*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*
- *Manifold Learning methods on a severed sphere*

manifold.locally_linear_embedding(X, ...[, ...])	Perform a Locally Linear Embedding analysis on the data.
manifold.spectral_embedding(adjacency[, ...])	Project the sample on the first eigenvectors of the graph Laplacian.
manifold.smacof(dissimilarities[, metric, ...])	Computes multidimensional scaling using the SMACOF algorithm.

29.19.6 `sklearn.manifold`.locally_linear_embedding

`sklearn.manifold.`**`locally_linear_embedding`**(*X*, *n_neighbors*, *n_components*, *reg=0.001*, *eigen_solver='auto'*, *tol=1e-06*, *max_iter=100*, *method='standard'*, *hessian_tol=0.0001*, *modified_tol=1e-12*, *random_state=None*, *n_jobs=1*)

Perform a Locally Linear Embedding analysis on the data.

Read more in the *User Guide*.

Parameters **X** : {array-like, sparse matrix, BallTree, KDTree, NearestNeighbors}

Sample data, shape = (n_samples, n_features), in the form of a numpy array, sparse array, precomputed tree, or NearestNeighbors object.

n_neighbors : integer

number of neighbors to consider for each point.

n_components : integer

number of coordinates for the manifold.

reg : float

regularization constant, multiplies the trace of the local covariance matrix of the distances.

eigen_solver : string, {'auto', 'arpack', 'dense'}

auto : algorithm will attempt to choose the best method for input data

arpack [use arnoldi iteration in shift-invert mode.] For this method, M may be a dense matrix, sparse matrix, or general linear operator. Warning: ARPACK can be unstable for some problems. It is best to try several random seeds in order to check results.

dense [use standard dense matrix operations for the eigenvalue] decomposition. For this method, M must be an array or matrix type. This method should be avoided for large problems.

tol : float, optional

Tolerance for 'arpack' method Not used if eigen_solver=='dense'.

max_iter : integer

maximum number of iterations for the arpack solver.

method : {'standard', 'hessian', 'modified', 'ltsa'}

standard [use the standard locally linear embedding algorithm.] see reference *[R46]*

hessian [use the Hessian eigenmap method. This method requires] n_neighbors > n_components * (1 + (n_components + 1) / 2. see reference *[R47]*

modified [use the modified locally linear embedding algorithm.] see reference *[R48]*

ltsa [use local tangent space alignment algorithm] see reference *[R49]*

hessian_tol : float, optional

Tolerance for Hessian eigenmapping method. Only used if method == 'hessian'

modified_tol : float, optional

Tolerance for modified LLE method. Only used if method == 'modified'

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `solver` == 'arpack'.

n_jobs : int, optional (default = 1)

The number of parallel jobs to run for neighbors search. If `-1`, then the number of jobs is set to the number of CPU cores.

Returns **Y** : array-like, shape [n_samples, n_components]

Embedding vectors.

squared_error : float

Reconstruction error for the embedding vectors. Equivalent to `norm(Y - W Y, 'fro')**2`, where W are the reconstruction weights.

References

[R46], *[R47]*, *[R48]*, *[R49]*

Examples using `sklearn.manifold.locally_linear_embedding`

- *Swiss Roll reduction with LLE*

29.19.7 `sklearn.manifold`.spectral_embedding

`sklearn.manifold.`**`spectral_embedding`**(*adjacency*, *n_components=8*, *eigen_solver=None*, *random_state=None*, *eigen_tol=0.0*, *norm_laplacian=True*, *drop_first=True*)

Project the sample on the first eigenvectors of the graph Laplacian.

The adjacency matrix is used to compute a normalized graph Laplacian whose spectrum (especially the eigenvectors associated to the smallest eigenvalues) has an interpretation in terms of minimal number of cuts necessary to split the graph into comparably sized components.

This embedding can also 'work' even if the `adjacency` variable is not strictly the adjacency matrix of a graph but more generally an affinity or similarity matrix between samples (for instance the heat kernel of a euclidean distance matrix or a k-NN matrix).

However care must taken to always make the affinity matrix symmetric so that the eigenvector decomposition works as expected.

Note : Laplacian Eigenmaps is the actual algorithm implemented here.

Read more in the *User Guide*.

Parameters **adjacency** : array-like or sparse matrix, shape: (n_samples, n_samples)

The adjacency matrix of the graph to embed.

n_components : integer, optional, default 8

The dimension of the projection subspace.

eigen_solver : {None, 'arpack', 'lobpcg', or 'amg'}, default None

The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities.

random_state : int, RandomState instance or None, optional, default: None

A pseudo random number generator used for the initialization of the lobpcg eigenvectors decomposition. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `solver` == 'amg'.

eigen_tol : float, optional, default=0.0

Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen_solver.

drop_first : bool, optional, default=True

Whether to drop the first eigenvector. For spectral embedding, this should be True as the first eigenvector should be constant vector for connected graph, but for spectral clustering, this should be kept as False to retain the first eigenvector.

norm_laplacian : bool, optional, default=True

If True, then compute normalized Laplacian.

Returns **embedding** : array, shape=(n_samples, n_components)

The reduced samples.

Notes

Spectral Embedding (Laplacian Eigenmaps) is most useful when the graph has one connected component. If there graph has many components, the first few eigenvectors will simply uncover the connected components of the graph.

29.19.8 sklearn.manifold.smacof

sklearn.manifold.**smacof**(*dissimilarities*, *metric=True*, *n_components=2*, *init=None*, *n_init=8*, *n_jobs=1*, *max_iter=300*, *verbose=0*, *eps=0.001*, *random_state=None*, *return_n_iter=False*)

Computes multidimensional scaling using the SMACOF algorithm.

The SMACOF (Scaling by MAjorizing a COmplicated Function) algorithm is a multidimensional scaling algorithm which minimizes an objective function (the *stress*) using a majorization technique. Stress majorization, also known as the Guttman Transform, guarantees a monotone convergence of stress, and is more powerful than traditional techniques such as gradient descent.

The SMACOF algorithm for metric MDS can summarized by the following steps:

1. Set an initial start configuration, randomly or not.
2. Compute the stress
3. Compute the Guttman Transform
4. Iterate 2 and 3 until convergence.

The nonmetric algorithm adds a monotonic regression step before computing the stress.

Parameters **dissimilarities** : ndarray, shape (n_samples, n_samples)

Pairwise dissimilarities between the points. Must be symmetric.

metric : boolean, optional, default: True

Compute metric or nonmetric SMACOF algorithm.

n_components : int, optional, default: 2

Number of dimensions in which to immerse the dissimilarities. If an `init` array is provided, this option is overridden and the shape of `init` is used to determine the dimensionality of the embedding space.

init : ndarray, shape (n_samples, n_components), optional, default: None

Starting configuration of the embedding to initialize the algorithm. By default, the algorithm is initialized with a randomly chosen array.

n_init : int, optional, default: 8

Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress. If `init` is provided, this option is overridden and a single run is performed.

n_jobs : int, optional, default: 1

The number of jobs to use for the computation. If multiple initializations are used (`n_init`), each run of the algorithm is computed in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For `n_jobs` below -1, (`n_cpus + 1 + n_jobs`) are used. Thus for `n_jobs = -2`, all CPUs but one are used.

max_iter : int, optional, default: 300

Maximum number of iterations of the SMACOF algorithm for a single run.

verbose : int, optional, default: 0

Level of verbosity.

eps : float, optional, default: 1e-3

Relative tolerance with respect to stress at which to declare convergence.

random_state : int, RandomState instance or None, optional, default: None

The generator used to initialize the centers. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

return_n_iter : bool, optional, default: False

Whether or not to return the number of iterations.

Returns **X** : ndarray, shape (n_samples, n_components)

Coordinates of the points in a `n_components`-space.

stress : float

The final value of the stress (sum of squared distance of the disparities and the distances for all constrained points).

n_iter : int

The number of iterations corresponding to the best stress. Returned only if `return_n_iter` is set to `True`.

29.20 `sklearn.metrics`: Metrics

See the *Model evaluation: quantifying the quality of predictions* section and the *Pairwise metrics, Affinities and Kernels* section of the user guide for further details. The `sklearn.metrics` module includes score functions, performance metrics and pairwise metrics and distance computations.

29.20.1 Model Selection Interface

See the *The scoring parameter: defining model evaluation rules* section of the user guide for further details.

`metrics.make_scorer`(score_func[, ...])	Make a scorer from a performance metric or loss function.
`metrics.get_scorer`(scoring)	

sklearn.metrics.make_scorer

sklearn.metrics.**make_scorer**(*score_func*, *greater_is_better=True*, *needs_proba=False*, *needs_threshold=False*, ***kwargs*)

Make a scorer from a performance metric or loss function.

This factory function wraps scoring functions for use in GridSearchCV and cross_val_score. It takes a score function, such as `accuracy_score`, `mean_squared_error`, `adjusted_rand_index` or `average_precision` and returns a callable that scores an estimator's output.

Read more in the *User Guide*.

Parameters **score_func** : callable,

Score function (or loss function) with signature `score_func(y, y_pred, **kwargs)`.

greater_is_better : boolean, default=True

Whether score_func is a score function (default), meaning high is good, or a loss function, meaning low is good. In the latter case, the scorer object will sign-flip the outcome of the score_func.

needs_proba : boolean, default=False

Whether score_func requires predict_proba to get probability estimates out of a classifier.

needs_threshold : boolean, default=False

Whether score_func takes a continuous decision certainty. This only works for binary classification using estimators that have either a decision_function or predict_proba method.

For example `average_precision` or the area under the roc curve can not be computed using discrete predictions alone.

****kwargs** : additional arguments

Additional parameters to be passed to score_func.

Returns **scorer** : callable

Callable object that returns a scalar score; greater is better.

Examples

```
>>> from sklearn.metrics import fbeta_score, make_scorer
>>> ftwo_scorer = make_scorer(fbeta_score, beta=2)
>>> ftwo_scorer
make_scorer(fbeta_score, beta=2)
>>> from sklearn.model_selection import GridSearchCV
>>> from sklearn.svm import LinearSVC
>>> grid = GridSearchCV(LinearSVC(), param_grid={'C': [1, 10]},
...                     scoring=ftwo_scorer)
```

sklearn.metrics.get_scorer

sklearn.metrics.**get_scorer**(*scoring*)

29.20.2 Classification metrics

See the *Classification metrics* section of the user guide for further details.

metrics.accuracy_score(y_true, y_pred[, ...])	Accuracy classification score.
metrics.auc(x, y[, reorder])	Compute Area Under the Curve (AUC) using the trapezoidal rule
metrics.average_precision_score(y_true, y_score)	Compute average precision (AP) from prediction scores
metrics.brier_score_loss(y_true, y_prob[, ...])	Compute the Brier score.
metrics.classification_report(y_true, y_pred)	Build a text report showing the main classification metrics
metrics.cohen_kappa_score(y1, y2[, labels, ...])	Cohen's kappa: a statistic that measures inter-annotator agreement.
metrics.confusion_matrix(y_true, y_pred[, ...])	Compute confusion matrix to evaluate the accuracy of a classification
metrics.dcg_score(y_true, y_score[, k])	Discounted cumulative gain (DCG) at rank K.
metrics.f1_score(y_true, y_pred[, labels, ...])	Compute the F1 score, also known as balanced F-score or F-measure
metrics.fbeta_score(y_true, y_pred, beta[, ...])	Compute the F-beta score
metrics.hamming_loss(y_true, y_pred[, ...])	Compute the average Hamming loss.
metrics.hinge_loss(y_true, pred_decision[, ...])	Average hinge loss (non-regularized)
metrics.jaccard_similarity_score(y_true, y_pred)	Jaccard similarity coefficient score
metrics.log_loss(y_true, y_pred[, eps, ...])	Log loss, aka logistic loss or cross-entropy loss.
metrics.matthews_corrcoef(y_true, y_pred[, ...])	Compute the Matthews correlation coefficient (MCC)
metrics.ndcg_score(y_true, y_score[, k])	Normalized discounted cumulative gain (NDCG) at rank K.
metrics.precision_recall_curve(y_true, ...)	Compute precision-recall pairs for different probability thresholds
metrics.precision_recall_fscore_support(...)	Compute precision, recall, F-measure and support for each class
metrics.precision_score(y_true, y_pred[, ...])	Compute the precision
metrics.recall_score(y_true, y_pred[, ...])	Compute the recall
metrics.roc_auc_score(y_true, y_score[, ...])	Compute Area Under the Curve (AUC) from prediction scores
metrics.roc_curve(y_true, y_score[, ...])	Compute Receiver operating characteristic (ROC)
metrics.zero_one_loss(y_true, y_pred[, ...])	Zero-one classification loss.

sklearn.metrics.accuracy_score

sklearn.metrics.**accuracy_score**(*y_true*, *y_pred*, *normalize=True*, *sample_weight=None*)

Accuracy classification score.

In multilabel classification, this function computes subset accuracy: the set of labels predicted for a sample must *exactly* match the corresponding set of labels in y_true.

Read more in the *User Guide*.

Parameters **y_true** : 1d array-like, or label indicator array / sparse matrix

Ground truth (correct) labels.

y_pred : 1d array-like, or label indicator array / sparse matrix

Predicted labels, as returned by a classifier.

normalize : bool, optional (default=True)

If `False`, return the number of correctly classified samples. Otherwise, return the fraction of correctly classified samples.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **score** : float

If `normalize == True`, return the correctly classified samples (float), else it returns the number of correctly classified samples (int).

The best performance is 1 with `normalize == True` and the number of samples with `normalize == False`.

See also:

jaccard_similarity_score, *hamming_loss*, *zero_one_loss*

Notes

In binary and multiclass classification, this function is equal to the `jaccard_similarity_score` function.

Examples

```
>>> import numpy as np
>>> from sklearn.metrics import accuracy_score
>>> y_pred = [0, 2, 1, 3]
>>> y_true = [0, 1, 2, 3]
>>> accuracy_score(y_true, y_pred)
0.5
>>> accuracy_score(y_true, y_pred, normalize=False)
2
```

In the multilabel case with binary label indicators: >>> accuracy_score(np.array([[0, 1], [1, 1]]), np.ones((2, 2))) 0.5

Examples using `sklearn.metrics.accuracy_score`

- *Multi-class AdaBoosted Decision Trees*
- *Probabilistic predictions with Gaussian process classification (GPC)*
- *Importance of Feature Scaling*
- *Classification of text documents using sparse features*

`sklearn.metrics.auc`

`sklearn.metrics.`**`auc`**(*x*, *y*, *reorder=False*)

Compute Area Under the Curve (AUC) using the trapezoidal rule

This is a general function, given points on a curve. For computing the area under the ROC-curve, see *roc_auc_score*.

Parameters **x** : array, shape = [n]

x coordinates.

y : array, shape = [n]

y coordinates.

reorder : boolean, optional (default=False)

If True, assume that the curve is ascending in the case of ties, as for an ROC curve. If the curve is non-ascending, the result will be wrong.

Returns **auc** : float

See also:

roc_auc_score Computes the area under the ROC curve

precision_recall_curve Compute precision-recall pairs for different probability thresholds

Examples

```
>>> import numpy as np
>>> from sklearn import metrics
>>> y = np.array([1, 1, 2, 2])
>>> pred = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, pred, pos_label=2)
>>> metrics.auc(fpr, tpr)
0.75
```

Examples using `sklearn.metrics.auc`

- *Species distribution modeling*
- *Sparse recovery: feature selection for sparse linear models*
- *Receiver Operating Characteristic (ROC)*
- *Receiver Operating Characteristic (ROC) with cross validation*

`sklearn.metrics.average_precision_score`

`sklearn.metrics.`**`average_precision_score`**(*y_true*, *y_score*, *average='macro'*, *sample_weight=None*)

Compute average precision (AP) from prediction scores

Note: this implementation is restricted to the binary classification task or multilabel classification task.

Read more in the *User Guide*.

Parameters **y_true** : array, shape = [n_samples] or [n_samples, n_classes]

True binary labels in binary label indicators.

y_score : array, shape = [n_samples] or [n_samples, n_classes]

Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by "decision_function" on some classifiers).

average : string, [None, 'micro', 'macro' (default), 'samples', 'weighted']

If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

`'micro'`: Calculate metrics globally by considering each element of the label indicator matrix as a label.

`'macro'`: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

`'weighted'`: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).

`'samples'`: Calculate metrics for each instance, and find their average.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **average_precision** : float

See also:

`roc_auc_score` Area under the ROC curve

`precision_recall_curve` Compute precision-recall pairs for different probability thresholds

Examples

```
>>> import numpy as np
>>> from sklearn.metrics import average_precision_score
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> average_precision_score(y_true, y_scores)
0.83...
```

Examples using `sklearn.metrics.average_precision_score`

- *Precision-Recall*

`sklearn.metrics`.brier_score_loss

`sklearn.metrics.`**`brier_score_loss`**(*y_true*, *y_prob*, *sample_weight=None*, *pos_label=None*)

Compute the Brier score.

The smaller the Brier score, the better, hence the naming with "loss".

Across all items in a set N predictions, the Brier score measures the mean squared difference between (1) the predicted probability assigned to the possible outcomes for item i, and (2) the actual outcome. Therefore, the lower the Brier score is for a set of predictions, the better the predictions are calibrated. Note that the Brier score always takes on a value between zero and one, since this is the largest possible difference between a predicted probability (which must be between zero and one) and the actual outcome (which can take on values of only 0 and 1).

The Brier score is appropriate for binary and categorical outcomes that can be structured as true or false, but is inappropriate for ordinal variables which can take on three or more values (this is because the Brier score assumes that all possible outcomes are equivalently "distant" from one another). Which label is considered to be the positive label is controlled via the parameter pos_label, which defaults to 1.

Read more in the *User Guide*.

Parameters **y_true** : array, shape (n_samples,)

True targets.

y_prob : array, shape (n_samples,)

Probabilities of the positive class.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

pos_label : int or str, default=None

Label of the positive class. If None, the maximum label is used as positive class

Returns **score** : float

Brier score

References

[R55]

Examples

```
>>> import numpy as np
>>> from sklearn.metrics import brier_score_loss
>>> y_true = np.array([0, 1, 1, 0])
>>> y_true_categorical = np.array(["spam", "ham", "ham", "spam"])
>>> y_prob = np.array([0.1, 0.9, 0.8, 0.3])
>>> brier_score_loss(y_true, y_prob)
0.037...
>>> brier_score_loss(y_true, 1-y_prob, pos_label=0)
0.037...
>>> brier_score_loss(y_true_categorical, y_prob,                                pos_
↪label="ham")
0.037...
>>> brier_score_loss(y_true, np.array(y_prob) > 0.5)
0.0
```

Examples using `sklearn.metrics.brier_score_loss`

- *Probability calibration of classifiers*
- *Probability Calibration curves*

`sklearn.metrics`.classification_report

sklearn.metrics.**classification_report**(*y_true*, *y_pred*, *labels=None*, *target_names=None*, *sample_weight=None*, *digits=2*)

Build a text report showing the main classification metrics

Read more in the *User Guide*.

Parameters **y_true** : 1d array-like, or label indicator array / sparse matrix

Ground truth (correct) target values.

y_pred : 1d array-like, or label indicator array / sparse matrix

Estimated targets as returned by a classifier.

labels : array, shape = [n_labels]

Optional list of label indices to include in the report.

target_names : list of strings

Optional display names matching the labels (same order).

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

digits : int

Number of digits for formatting output floating point values

Returns **report** : string

Text summary of the precision, recall, F1 score for each class.

The reported averages are a prevalence-weighted macro-average across classes (equivalent to *precision_recall_fscore_support* with `average='weighted'`).

Note that in binary classification, recall of the positive class is also known as "sensitivity"; recall of the negative class is "specificity".

Examples

```
>>> from sklearn.metrics import classification_report
>>> y_true = [0, 1, 2, 2, 2]
>>> y_pred = [0, 0, 2, 2, 1]
>>> target_names = ['class 0', 'class 1', 'class 2']
>>> print(classification_report(y_true, y_pred, target_names=target_names))
             precision    recall  f1-score   support

    class 0       0.50      1.00      0.67         1
    class 1       0.00      0.00      0.00         1

`sklearn.metrics.cohen_kappa_score`

`sklearn.metrics.`**`cohen_kappa_score`**(*y1*, *y2*, *labels=None*, *weights=None*, *sample_weight=None*)

Cohen's kappa: a statistic that measures inter-annotator agreement.

This function computes Cohen's kappa *[R207]*, a score that expresses the level of agreement between two annotators on a classification problem. It is defined as

$$\kappa = (p_o - p_e)/(1 - p_e)$$

where p_o is the empirical probability of agreement on the label assigned to any sample (the observed agreement ratio), and p_e is the expected agreement when both annotators assign labels randomly. p_e is estimated using a per-annotator empirical prior over the class labels *[R208]*.

Read more in the *User Guide*.

Parameters **y1** : array, shape = [n_samples]

Labels assigned by the first annotator.

y2 : array, shape = [n_samples]

Labels assigned by the second annotator. The kappa statistic is symmetric, so swapping `y1` and `y2` doesn't change the value.

labels : array, shape = [n_classes], optional

List of labels to index the matrix. This may be used to select a subset of labels. If None, all labels that appear at least once in `y1` or `y2` are used.

weights : str, optional

List of weighting type to calculate the score. None means no weighted; "linear" means linear weighted; "quadratic" means quadratic weighted.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **kappa** : float

The kappa statistic, which is a number between -1 and 1. The maximum value means complete agreement; zero or lower means chance agreement.

[R207], *[R208]*, *[R209]*

sklearn.metrics.confusion_matrix

sklearn.metrics.**confusion_matrix**(*y_true*, *y_pred*, *labels=None*, *sample_weight=None*)

Compute confusion matrix to evaluate the accuracy of a classification

By definition a confusion matrix C is such that $C_{i,j}$ is equal to the number of observations known to be in group i but predicted to be in group j.

Thus in binary classification, the count of true negatives is $C_{0,0}$, false negatives is $C_{1,0}$, true positives is $C_{1,1}$ and false positives is $C_{0,1}$.

Read more in the *User Guide*.

Parameters **y_true** : array, shape = [n_samples]

Ground truth (correct) target values.

y_pred : array, shape = [n_samples]

Estimated targets as returned by a classifier.

labels : array, shape = [n_classes], optional

List of labels to index the matrix. This may be used to reorder or select a subset of labels. If none is given, those that appear at least once in `y_true` or `y_pred` are used in sorted order.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **C** : array, shape = [n_classes, n_classes]

Confusion matrix

References

[R57]

Examples

```
>>> from sklearn.metrics import confusion_matrix
>>> y_true = [2, 0, 2, 2, 0, 1]
>>> y_pred = [0, 0, 2, 2, 0, 2]
>>> confusion_matrix(y_true, y_pred)
array([[2, 0, 0],
       [0, 0, 1],
       [1, 0, 2]])
```

```
>>> y_true = ["cat", "ant", "cat", "cat", "ant", "bird"]
>>> y_pred = ["ant", "ant", "cat", "cat", "ant", "cat"]
>>> confusion_matrix(y_true, y_pred, labels=["ant", "bird", "cat"])
array([[2, 0, 0],
       [0, 0, 1],
       [1, 0, 2]])
```

In the binary case, we can extract true positives, etc as follows:

```
>>> tn, fp, fn, tp = confusion_matrix([0, 1, 0, 1], [1, 1, 1, 0]).ravel()
>>> (tn, fp, fn, tp)
(0, 2, 1, 1)
```

`sklearn.metrics.dcg_score`

`sklearn.metrics.`**`dcg_score`**(*y_true*, *y_score*, *k=5*)

Discounted cumulative gain (DCG) at rank K.

Parameters **y_true** : array, shape = [n_samples]

Ground truth (true relevance labels).

y_score : array, shape = [n_samples]

Predicted scores.

k : int

Rank.

Returns **score** : float

References

[R213]

`sklearn.metrics.f1_score`

`sklearn.metrics.`**`f1_score`**(*y_true*, *y_pred*, *labels=None*, *pos_label=1*, *average='binary'*, *sample_weight=None*)

Compute the F1 score, also known as balanced F-score or F-measure

The F1 score can be interpreted as a weighted average of the precision and recall, where an F1 score reaches its best value at 1 and worst score at 0. The relative contribution of precision and recall to the F1 score are equal. The formula for the F1 score is:

```
F1 = 2 * (precision * recall) / (precision + recall)
```

In the multi-class and multi-label case, this is the weighted average of the F1 score of each class.

Read more in the *User Guide*.

Parameters **y_true** : 1d array-like, or label indicator array / sparse matrix

Ground truth (correct) target values.

y_pred : 1d array-like, or label indicator array / sparse matrix

Estimated targets as returned by a classifier.

labels : list, optional

The set of labels to include when `average != 'binary'`, and their order if `average is None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

Changed in version 0.17: parameter *labels* improved for multiclass problem.

pos_label : str or int, 1 by default

The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

average : string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']

This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

`'binary'`: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true,pred}`) are binary.

`'micro'`: Calculate metrics globally by counting the total true positives, false negatives and false positives.

`'macro'`: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

`'weighted'`: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

`'samples'`: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from *`accuracy_score`*).

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **f1_score** : float or array of float, shape = [n_unique_labels]

F1 score of the positive class in binary classification or weighted average of the F1 scores of each class for the multiclass task.

References

[R58]

Examples

```
>>> from sklearn.metrics import f1_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> f1_score(y_true, y_pred, average='macro')
0.26...
>>> f1_score(y_true, y_pred, average='micro')
0.33...
>>> f1_score(y_true, y_pred, average='weighted')
0.26...
>>> f1_score(y_true, y_pred, average=None)
array([ 0.8,  0. ,  0. ])
```

Examples using `sklearn.metrics.f1_score`

- *Probability Calibration curves*

`sklearn.metrics.fbeta_score`

`sklearn.metrics.`**`fbeta_score`**(*y_true*, *y_pred*, *beta*, *labels=None*, *pos_label=1*, *average='binary'*, *sample_weight=None*)

Compute the F-beta score

The F-beta score is the weighted harmonic mean of precision and recall, reaching its optimal value at 1 and its worst value at 0.

The *beta* parameter determines the weight of precision in the combined score. `beta < 1` lends more weight to precision, while `beta > 1` favors recall (`beta -> 0` considers only precision, `beta -> inf` only recall).

Read more in the *User Guide*.

Parameters **y_true** : 1d array-like, or label indicator array / sparse matrix

Ground truth (correct) target values.

y_pred : 1d array-like, or label indicator array / sparse matrix

Estimated targets as returned by a classifier.

beta : float

Weight of precision in harmonic mean.

labels : list, optional

The set of labels to include when `average != 'binary'`, and their order if `average is None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

Changed in version 0.17: parameter *labels* improved for multiclass problem.

pos_label : str or int, 1 by default

The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

average : string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']

This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

`'binary'`: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true,pred}`) are binary.

`'micro'`: Calculate metrics globally by counting the total true positives, false negatives and false positives.

`'macro'`: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

`'weighted'`: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

`'samples'`: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from *`accuracy_score`*).

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **fbeta_score** : float (if average is not None) or array of float, shape = [n_unique_labels]

F-beta score of the positive class in binary classification or weighted average of the F-beta score of each class for the multiclass task.

References

array([ 0.71...,  0.        ,  0.        ])
```

sklearn.metrics.hamming_loss

sklearn.metrics.**hamming_loss**(*y_true*, *y_pred*, *labels=None*, *sample_weight=None*, *classes=None*)

Compute the average Hamming loss.

The Hamming loss is the fraction of labels that are incorrectly predicted.

Read more in the *User Guide*.

Parameters **y_true** : 1d array-like, or label indicator array / sparse matrix

Ground truth (correct) labels.

y_pred : 1d array-like, or label indicator array / sparse matrix

Predicted labels, as returned by a classifier.

labels : array, shape = [n_labels], optional (default=None)

Integer array of labels. If not provided, labels will be inferred from y_true and y_pred.

New in version 0.18.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

New in version 0.18.

classes : array, shape = [n_labels], optional

Integer array of labels.

Deprecated since version 0.18: This parameter has been deprecated in favor of `labels` in version 0.18 and will be removed in 0.20. Use `labels` instead.

Returns **loss** : float or int,

Return the average Hamming loss between element of `y_true` and `y_pred`.

See also:

accuracy_score, *jaccard_similarity_score*, *zero_one_loss*

Notes

In multiclass classification, the Hamming loss correspond to the Hamming distance between `y_true` and `y_pred` which is equivalent to the subset `zero_one_loss` function.

In multilabel classification, the Hamming loss is different from the subset zero-one loss. The zero-one loss considers the entire set of labels for a given sample incorrect if it does entirely match the true set of labels. Hamming loss is more forgiving in that it penalizes the individual labels.

The Hamming loss is upperbounded by the subset zero-one loss. When normalized over samples, the Hamming loss is always between 0 and 1.

References

[R59], *[R60]*

Examples

```
>>> from sklearn.metrics import hamming_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> hamming_loss(y_true, y_pred)
0.25
```

In the multilabel case with binary label indicators:

```
>>> hamming_loss(np.array([[0, 1], [1, 1]]), np.zeros((2, 2)))
0.75
```

Examples using `sklearn.metrics.hamming_loss`

- *Model Complexity Influence*

`sklearn.metrics.hinge_loss`

`sklearn.metrics.`**`hinge_loss`**(*y_true*, *pred_decision*, *labels=None*, *sample_weight=None*)

Average hinge loss (non-regularized)

In binary class case, assuming labels in y_true are encoded with +1 and -1, when a prediction mistake is made, `margin = y_true * pred_decision` is always negative (since the signs disagree), implying `1 - margin` is always greater than 1. The cumulated hinge loss is therefore an upper bound of the number of mistakes made by the classifier.

In multiclass case, the function expects that either all the labels are included in y_true or an optional labels argument is provided which contains all the labels. The multilabel margin is calculated according to Crammer-Singer's method. As in the binary case, the cumulated hinge loss is an upper bound of the number of mistakes made by the classifier.

Read more in the *User Guide*.

Parameters **y_true** : array, shape = [n_samples]

True target, consisting of integers of two values. The positive label must be greater than the negative label.

pred_decision : array, shape = [n_samples] or [n_samples, n_classes]

Predicted decisions, as output by decision_function (floats).

labels : array, optional, default None

Contains all the labels for the problem. Used in multiclass hinge loss.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **loss** : float

References

[R221], *[R222]*, *[R223]*

Examples

```
>>> from sklearn import svm
>>> from sklearn.metrics import hinge_loss
>>> X = [[0], [1]]
>>> y = [-1, 1]
>>> est = svm.LinearSVC(random_state=0)
>>> est.fit(X, y)
LinearSVC(C=1.0, class_weight=None, dual=True, fit_intercept=True,
     intercept_scaling=1, loss='squared_hinge', max_iter=1000,
     multi_class='ovr', penalty='l2', random_state=0, tol=0.0001,
     verbose=0)
>>> pred_decision = est.decision_function([[-2], [3], [0.5]])
>>> pred_decision
array([-2.18...,  2.36...,  0.09...])
>>> hinge_loss([-1, 1, 1], pred_decision)
0.30...
```

In the multiclass case:

```
>>> X = np.array([[0], [1], [2], [3]])
>>> Y = np.array([0, 1, 2, 3])
>>> labels = np.array([0, 1, 2, 3])
>>> est = svm.LinearSVC()
>>> est.fit(X, Y)
LinearSVC(C=1.0, class_weight=None, dual=True, fit_intercept=True,
     intercept_scaling=1, loss='squared_hinge', max_iter=1000,
     multi_class='ovr', penalty='l2', random_state=None, tol=0.0001,
     verbose=0)
>>> pred_decision = est.decision_function([[-1], [2], [3]])
>>> y_true = [0, 2, 3]
>>> hinge_loss(y_true, pred_decision, labels)
0.56...
```

sklearn.metrics.jaccard_similarity_score

sklearn.metrics.**jaccard_similarity_score**(*y_true*, *y_pred*, *normalize=True*, *sample_weight=None*)

Jaccard similarity coefficient score

The Jaccard index [1], or Jaccard similarity coefficient, defined as the size of the intersection divided by the size of the union of two label sets, is used to compare set of predicted labels for a sample to the corresponding set of labels in `y_true`.

Read more in the *User Guide*.

Parameters **y_true** : 1d array-like, or label indicator array / sparse matrix

Ground truth (correct) labels.

y_pred : 1d array-like, or label indicator array / sparse matrix

Predicted labels, as returned by a classifier.

normalize : bool, optional (default=True)

If `False`, return the sum of the Jaccard similarity coefficient over the sample set. Otherwise, return the average of Jaccard similarity coefficient.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **score** : float

If `normalize == True`, return the average Jaccard similarity coefficient, else it returns the sum of the Jaccard similarity coefficient over the sample set.

The best performance is 1 with `normalize == True` and the number of samples with `normalize == False`.

See also:

accuracy_score, *hamming_loss*, *zero_one_loss*

Notes

In binary and multiclass classification, this function is equivalent to the `accuracy_score`. It differs in the multilabel classification problem.

References

[R225]

Examples

```
>>> import numpy as np
>>> from sklearn.metrics import jaccard_similarity_score
>>> y_pred = [0, 2, 1, 3]
>>> y_true = [0, 1, 2, 3]
>>> jaccard_similarity_score(y_true, y_pred)
0.5
>>> jaccard_similarity_score(y_true, y_pred, normalize=False)
2
```

In the multilabel case with binary label indicators:

```
>>> jaccard_similarity_score(np.array([[0, 1], [1, 1]]),        np.ones((2, 2)))
0.75
```

sklearn.metrics.log_loss

sklearn.metrics.**log_loss**(*y_true*, *y_pred*, *eps=1e-15*, *normalize=True*, *sample_weight=None*, *labels=None*)

Log loss, aka logistic loss or cross-entropy loss.

This is the loss function used in (multinomial) logistic regression and extensions of it such as neural networks, defined as the negative log-likelihood of the true labels given a probabilistic classifier's predictions. The log loss is only defined for two or more labels. For a single sample with true label yt in {0,1} and estimated probability yp that yt = 1, the log loss is

-log P(ytlyp) = -(yt log(yp) + (1 - yt) log(1 - yp))

Read more in the *User Guide*.

Parameters **y_true** : array-like or label indicator matrix

Ground truth (correct) labels for n_samples samples.

y_pred : array-like of float, shape = (n_samples, n_classes) or (n_samples,)

Predicted probabilities, as returned by a classifier's predict_proba method. If `y_pred.shape = (n_samples,)` the probabilities provided are assumed to be that of the positive class. The labels in `y_pred` are assumed to be ordered alphabetically, as done by `preprocessing.LabelBinarizer`.

eps : float

Log loss is undefined for p=0 or p=1, so probabilities are clipped to max(eps, min(1 - eps, p)).

normalize : bool, optional (default=True)

If true, return the mean loss per sample. Otherwise, return the sum of the per-sample losses.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

labels : array-like, optional (default=None)

If not provided, labels will be inferred from y_true. If `labels` is `None` and `y_pred` has shape (n_samples,) the labels are assumed to be binary and are inferred from `y_true`. .. versionadded:: 0.18

Returns **loss** : float

Notes

The logarithm used is the natural logarithm (base-e).

sklearn.metrics.matthews_corrcoef

sklearn.metrics.**matthews_corrcoef**(*y_true*, *y_pred*, *sample_weight=None*)

Compute the Matthews correlation coefficient (MCC)

The Matthews correlation coefficient is used in machine learning as a measure of the quality of binary (two-class) classifications. It takes into account true and false positives and negatives and is generally regarded as a balanced measure which can be used even if the classes are of very different sizes. The MCC is in essence a correlation coefficient value between -1 and +1. A coefficient of +1 represents a perfect prediction, 0 an average random prediction and -1 an inverse prediction. The statistic is also known as the phi coefficient. [source: Wikipedia]

Binary and multiclass labels are supported. Only in the binary case does this relate to information about true and false positives and negatives. See references below.

Read more in the *User Guide*.

Parameters **y_true** : array, shape = [n_samples]

Ground truth (correct) target values.

y_pred : array, shape = [n_samples]

Estimated targets as returned by a classifier.

sample_weight : array-like of shape = [n_samples], default None

Sample weights.

Returns **mcc** : float

The Matthews correlation coefficient (+1 represents a perfect prediction, 0 an average random prediction and -1 and inverse prediction).

[R227], *[R228]*, *[R229]*, *[R230]*

Examples

```
>>> from sklearn.metrics import matthews_corrcoef
>>> y_true = [+1, +1, +1, -1]
>>> y_pred = [+1, -1, +1, +1]
>>> matthews_corrcoef(y_true, y_pred)
-0.33...
```

sklearn.metrics.ndcg_score

sklearn.metrics.**ndcg_score**(*y_true*, *y_score*, *k=5*)

Normalized discounted cumulative gain (NDCG) at rank K.

Normalized Discounted Cumulative Gain (NDCG) measures the performance of a recommendation system based on the graded relevance of the recommended entities. It varies from 0.0 to 1.0, with 1.0 representing the ideal ranking of the entities.

Parameters **y_true** : array, shape = [n_samples]

Ground truth (true labels represended as integers).

y_score : array, shape = [n_samples, n_classes]

Predicted probabilities.

k : int

Rank.

Returns **score** : float

References

[R231]

sklearn.metrics.precision_recall_curve

sklearn.metrics.**precision_recall_curve**(*y_true*, *probas_pred*, *pos_label=None*, *sample_weight=None*)

Compute precision-recall pairs for different probability thresholds

Note: this implementation is restricted to the binary classification task.

The precision is the ratio `tp / (tp + fp)` where `tp` is the number of true positives and `fp` the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The recall is the ratio `tp / (tp + fn)` where `tp` is the number of true positives and `fn` the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The last precision and recall values are 1. and 0. respectively and do not have a corresponding threshold. This ensures that the graph starts on the x axis.

Read more in the *User Guide*.

Parameters **y_true** : array, shape = [n_samples]

True targets of binary classification in range {-1, 1} or {0, 1}.

probas_pred : array, shape = [n_samples]

Estimated probabilities or decision function.

pos_label : int or str, default=None

The label of the positive class

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **precision** : array, shape = [n_thresholds + 1]

Precision values such that element i is the precision of predictions with score >= thresholds[i] and the last element is 1.

recall : array, shape = [n_thresholds + 1]

Decreasing recall values such that element i is the recall of predictions with score >= thresholds[i] and the last element is 0.

thresholds : array, shape = [n_thresholds <= len(np.unique(probas_pred))]

Increasing thresholds on the decision function used to compute precision and recall.

Examples

```
>>> import numpy as np
>>> from sklearn.metrics import precision_recall_curve
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> precision, recall, thresholds = precision_recall_curve(
...     y_true, y_scores)
>>> precision
array([ 0.66...,  0.5       ,  1.        ,  1.        ])
>>> recall
array([ 1. ,  0.5,  0.5,  0. ])
>>> thresholds
array([ 0.35,  0.4 ,  0.8 ])
```

Examples using `sklearn.metrics.precision_recall_curve`

- *Sparse recovery: feature selection for sparse linear models*
- *Precision-Recall*

`sklearn.metrics`.precision_recall_fscore_support

sklearn.metrics.**precision_recall_fscore_support**(*y_true*, *y_pred*, *beta=1.0*, *labels=None*, *pos_label=1*, *average=None*, *warn_for=('precision', 'recall', 'f-score')*, *sample_weight=None*)

Compute precision, recall, F-measure and support for each class

The precision is the ratio `tp / (tp + fp)` where `tp` is the number of true positives and `fp` the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The recall is the ratio `tp / (tp + fn)` where `tp` is the number of true positives and `fn` the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The F-beta score can be interpreted as a weighted harmonic mean of the precision and recall, where an F-beta score reaches its best value at 1 and worst score at 0.

The F-beta score weights recall more than precision by a factor of `beta`. `beta == 1.0` means recall and precision are equally important.

The support is the number of occurrences of each class in `y_true`.

If `pos_label is None` and in binary classification, this function returns the average precision, recall and F-measure if `average` is one of `'micro'`, `'macro'`, `'weighted'` or `'samples'`.

Read more in the *User Guide*.

Parameters **y_true** : 1d array-like, or label indicator array / sparse matrix

Ground truth (correct) target values.

y_pred : 1d array-like, or label indicator array / sparse matrix

Estimated targets as returned by a classifier.

beta : float, 1.0 by default

The strength of recall versus precision in the F-score.

labels : list, optional

The set of labels to include when `average != 'binary'`, and their order if `average is None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

pos_label : str or int, 1 by default

The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

average : string, [None (default), 'binary', 'micro', 'macro', 'samples', 'weighted']

If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

`'binary'`: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true,pred}`) are binary.

`'micro'`: Calculate metrics globally by counting the total true positives, false negatives and false positives.

`'macro'`: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

`'weighted'`: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

`'samples'`: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from *`accuracy_score`*).

warn_for : tuple or set, for internal use

This determines which warnings will be made in the case that this function is being used to return only one of its metrics.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **precision** : float (if average is not None) or array of float, shape = [n_unique_labels]

recall : float (if average is not None) or array of float, , shape = [n_unique_labels]

fbeta_score : float (if average is not None) or array of float, shape = [n_unique_labels]

support : int (if average is not None) or array of int, shape = [n_unique_labels]

The number of occurrences of each label in `y_true`.

References

Examples

```
>>> from sklearn.metrics import precision_recall_fscore_support
>>> y_true = np.array(['cat', 'dog', 'pig', 'cat', 'dog', 'pig'])
>>> y_pred = np.array(['cat', 'pig', 'dog', 'cat', 'cat', 'dog'])
>>> precision_recall_fscore_support(y_true, y_pred, average='macro')
...
(0.22..., 0.33..., 0.26..., None)
>>> precision_recall_fscore_support(y_true, y_pred, average='micro')
...
(0.33..., 0.33..., 0.33..., None)
>>> precision_recall_fscore_support(y_true, y_pred, average='weighted')
...
(0.22..., 0.33..., 0.26..., None)
```

It is possible to compute per-label precisions, recalls, F1-scores and supports instead of averaging: >>> precision_recall_fscore_support(y_true, y_pred, average=None, ... labels=['pig', 'dog', 'cat']) ... # doctest: +ELLIPSIS,+NORMALIZE_WHITESPACE (array([0. , 0. , 0.66...]),

array([0., 0., 1.]), array([0. , 0. , 0.8]), array([2, 2, 2]))

sklearn.metrics.precision_score

sklearn.metrics.**precision_score**(*y_true*, *y_pred*, *labels=None*, *pos_label=1*, *average='binary'*, *sample_weight=None*)

Compute the precision

The precision is the ratio `tp / (tp + fp)` where `tp` is the number of true positives and `fp` the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The best value is 1 and the worst value is 0.

Read more in the *User Guide*.

Parameters **y_true** : 1d array-like, or label indicator array / sparse matrix

Ground truth (correct) target values.

y_pred : 1d array-like, or label indicator array / sparse matrix

Estimated targets as returned by a classifier.

labels : list, optional

The set of labels to include when `average != 'binary'`, and their order if `average is None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

Changed in version 0.17: parameter *labels* improved for multiclass problem.

pos_label : str or int, 1 by default

The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

average : string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']

This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

`'binary'`: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true,pred}`) are binary.

`'micro'`: Calculate metrics globally by counting the total true positives, false negatives and false positives.

`'macro'`: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

`'weighted'`: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

`'samples'`: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from *accuracy_score*).

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **precision** : float (if average is not None) or array of float, shape = [n_unique_labels]

Precision of the positive class in binary classification or weighted average of the precision of each class for the multiclass task.

Examples

```
>>> from sklearn.metrics import precision_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> precision_score(y_true, y_pred, average='macro')
0.22...
>>> precision_score(y_true, y_pred, average='micro')
0.33...
>>> precision_score(y_true, y_pred, average='weighted')
...
0.22...
>>> precision_score(y_true, y_pred, average=None)
array([ 0.66...,  0.        ,  0.        ])
```

Examples using `sklearn.metrics.precision_score`

- *Probability Calibration curves*

`sklearn.metrics`.recall_score

`sklearn.metrics.`**`recall_score`**(*y_true*, *y_pred*, *labels=None*, *pos_label=1*, *average='binary'*, *sample_weight=None*)

Compute the recall

The recall is the ratio `tp / (tp + fn)` where `tp` is the number of true positives and `fn` the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The best value is 1 and the worst value is 0.

Read more in the *User Guide*.

Parameters **y_true** : 1d array-like, or label indicator array / sparse matrix

Ground truth (correct) target values.

y_pred : 1d array-like, or label indicator array / sparse matrix

Estimated targets as returned by a classifier.

labels : list, optional

The set of labels to include when `average != 'binary'`, and their order if `average is None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

Changed in version 0.17: parameter *labels* improved for multiclass problem.

pos_label : str or int, 1 by default

The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

average : string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']

This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

`'binary'`: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true,pred}`) are binary.

`'micro'`: Calculate metrics globally by counting the total true positives, false negatives and false positives.

`'macro'`: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

`'weighted'`: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

`'samples'`: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from *`accuracy_score`*).

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **recall** : float (if average is not None) or array of float, shape = [n_unique_labels]

Recall of the positive class in binary classification or weighted average of the recall of each class for the multiclass task.

Examples

```
>>> from sklearn.metrics import recall_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> recall_score(y_true, y_pred, average='macro')
0.33...
>>> recall_score(y_true, y_pred, average='micro')
0.33...
>>> recall_score(y_true, y_pred, average='weighted')
0.33...
>>> recall_score(y_true, y_pred, average=None)
array([ 1.,  0.,  0.])
```

Examples using `sklearn.metrics.recall_score`

- *Probability Calibration curves*

`sklearn.metrics.roc_auc_score`

sklearn.metrics.**roc_auc_score**(*y_true*, *y_score*, *average='macro'*, *sample_weight=None*)

Compute Area Under the Curve (AUC) from prediction scores

Note: this implementation is restricted to the binary classification task or multilabel classification task in label indicator format.

Read more in the *User Guide*.

Parameters **y_true** : array, shape = [n_samples] or [n_samples, n_classes]

True binary labels in binary label indicators.

y_score : array, shape = [n_samples] or [n_samples, n_classes]

Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by "decision_function" on some classifiers).

average : string, [None, 'micro', 'macro' (default), 'samples', 'weighted']

If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

'micro': Calculate metrics globally by considering each element of the label indicator matrix as a label.

'macro': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

'weighted': Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).

'samples': Calculate metrics for each instance, and find their average.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **auc** : float

See also:

average_precision_score Area under the precision-recall curve

roc_curve Compute Receiver operating characteristic (ROC)

References

[R236]

Examples

```
>>> import numpy as np
>>> from sklearn.metrics import roc_auc_score
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> roc_auc_score(y_true, y_scores)
0.75
```

sklearn.metrics.roc_curve

sklearn.metrics.**roc_curve**(*y_true*, *y_score*, *pos_label=None*, *sample_weight=None*, *drop_intermediate=True*)

Compute Receiver operating characteristic (ROC)

Note: this implementation is restricted to the binary classification task.

Read more in the *User Guide*.

Parameters **y_true** : array, shape = [n_samples]

True binary labels in range {0, 1} or {-1, 1}. If labels are not binary, pos_label should be explicitly given.

y_score : array, shape = [n_samples]

Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by "decision_function" on some classifiers).

pos_label : int or str, default=None

Label considered as positive and others are considered negative.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

drop_intermediate : boolean, optional (default=True)

Whether to drop some suboptimal thresholds which would not appear on a plotted ROC curve. This is useful in order to create lighter ROC curves.

New in version 0.17: parameter *drop_intermediate*.

Returns **fpr** : array, shape = [>2]

Increasing false positive rates such that element i is the false positive rate of predictions with score >= thresholds[i].

tpr : array, shape = [>2]

Increasing true positive rates such that element i is the true positive rate of predictions with score >= thresholds[i].

thresholds : array, shape = [n_thresholds]

Decreasing thresholds on the decision function used to compute fpr and tpr. *thresholds[0]* represents no instances being predicted and is arbitrarily set to *max(y_score) + 1*.

See also:

roc_auc_score Compute Area Under the Curve (AUC) from prediction scores

Notes

Since the thresholds are sorted from low to high values, they are reversed upon returning them to ensure they correspond to both `fpr` and `tpr`, which are sorted in reversed order during their calculation.

References

[R63]

Examples

```
>>> import numpy as np
>>> from sklearn import metrics
>>> y = np.array([1, 1, 2, 2])
>>> scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, scores, pos_label=2)
>>> fpr
array([ 0. ,  0.5,  0.5,  1. ])
>>> tpr
array([ 0.5,  0.5,  1. ,  1. ])
>>> thresholds
array([ 0.8 ,  0.4 ,  0.35,  0.1 ])
```

Examples using `sklearn.metrics.roc_curve`

- *Species distribution modeling*
- *Feature transformations with ensembles of trees*
- *Receiver Operating Characteristic (ROC)*
- *Receiver Operating Characteristic (ROC) with cross validation*

sklearn.metrics.zero_one_loss

sklearn.metrics.**zero_one_loss**(*y_true*, *y_pred*, *normalize=True*, *sample_weight=None*)

Zero-one classification loss.

If normalize is `True`, return the fraction of misclassifications (float), else it returns the number of misclassifications (int). The best performance is 0.

Read more in the *User Guide*.

Parameters **y_true** : 1d array-like, or label indicator array / sparse matrix

Ground truth (correct) labels.

y_pred : 1d array-like, or label indicator array / sparse matrix

Predicted labels, as returned by a classifier.

normalize : bool, optional (default=True)

If `False`, return the number of misclassifications. Otherwise, return the fraction of misclassifications.

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **loss** : float or int,

If `normalize == True`, return the fraction of misclassifications (float), else it returns the number of misclassifications (int).

See also:

accuracy_score, *hamming_loss*, *jaccard_similarity_score*

Notes

In multilabel classification, the zero_one_loss function corresponds to the subset zero-one loss: for each sample, the entire set of labels must be correctly predicted, otherwise the loss for that sample is equal to one.

Examples

```
>>> from sklearn.metrics import zero_one_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> zero_one_loss(y_true, y_pred)
0.25
>>> zero_one_loss(y_true, y_pred, normalize=False)
1
```

In the multilabel case with binary label indicators:

```
>>> zero_one_loss(np.array([[0, 1], [1, 1]]), np.ones((2, 2)))
0.5
```

Examples using `sklearn.metrics.zero_one_loss`

- *Discrete versus Real AdaBoost*

29.20.3 Regression metrics

See the *Regression metrics* section of the user guide for further details.

metrics.explained_variance_score(y_true, y_pred)	Explained variance regression score function
metrics.mean_absolute_error(y_true, y_pred)	Mean absolute error regression loss
metrics.mean_squared_error(y_true, y_pred[, ...])	Mean squared error regression loss
metrics.mean_squared_log_error(y_true, y_pred)	Mean squared logarithmic error regression loss
metrics.median_absolute_error(y_true, y_pred)	Median absolute error regression loss
metrics.r2_score(y_true, y_pred[, ...])	R^2 (coefficient of determination) regression score function.

sklearn.metrics.explained_variance_score

sklearn.metrics.**explained_variance_score**(*y_true*, *y_pred*, *sample_weight=None*, *multioutput='uniform_average'*)

Explained variance regression score function

Best possible score is 1.0, lower values are worse.

Read more in the *User Guide*.

Parameters **y_true** : array-like of shape = (n_samples) or (n_samples, n_outputs)

Ground truth (correct) target values.

y_pred : array-like of shape = (n_samples) or (n_samples, n_outputs)

Estimated target values.

sample_weight : array-like of shape = (n_samples), optional

Sample weights.

multioutput : string in ['raw_values', 'uniform_average', 'variance_weighted'] or array-like of shape (n_outputs)

Defines aggregating of multiple output scores. Array-like value defines weights used to average scores.

'raw_values' : Returns a full set of scores in case of multioutput input.

'uniform_average' : Scores of all outputs are averaged with uniform weight.

'variance_weighted' : Scores of all outputs are averaged, weighted by the variances of each individual output.

Returns **score** : float or ndarray of floats

The explained variance or ndarray if 'multioutput' is 'raw_values'.

Notes

This is not a symmetric function.

Examples

```
>>> from sklearn.metrics import explained_variance_score
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> explained_variance_score(y_true, y_pred)
0.957...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> explained_variance_score(y_true, y_pred, multioutput='uniform_average')
...
0.983...
```

sklearn.metrics.mean_absolute_error

sklearn.metrics.**mean_absolute_error**(*y_true*, *y_pred*, *sample_weight=None*, *multioutput='uniform_average'*)

Mean absolute error regression loss

Read more in the *User Guide*.

Parameters **y_true** : array-like of shape = (n_samples) or (n_samples, n_outputs)

Ground truth (correct) target values.

y_pred : array-like of shape = (n_samples) or (n_samples, n_outputs)

Estimated target values.

sample_weight : array-like of shape = (n_samples), optional

Sample weights.

multioutput : string in ['raw_values', 'uniform_average']

or array-like of shape (n_outputs) Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

'raw_values' : Returns a full set of errors in case of multioutput input.

'uniform_average' : Errors of all outputs are averaged with uniform weight.

Returns **loss** : float or ndarray of floats

If multioutput is 'raw_values', then mean absolute error is returned for each output separately. If multioutput is 'uniform_average' or an ndarray of weights, then the weighted average of all output errors is returned.

MAE output is non-negative floating point. The best value is 0.0.

Examples

```
>>> from sklearn.metrics import mean_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_absolute_error(y_true, y_pred)
0.5
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
```

```
>>> mean_absolute_error(y_true, y_pred)
0.75
>>> mean_absolute_error(y_true, y_pred, multioutput='raw_values')
array([ 0.5,  1. ])
>>> mean_absolute_error(y_true, y_pred, multioutput=[0.3, 0.7])
...
0.849...
```

sklearn.metrics.mean_squared_error

sklearn.metrics.**mean_squared_error**(*y_true*, *y_pred*, *sample_weight=None*, *multioutput='uniform_average'*)

Mean squared error regression loss

Read more in the *User Guide*.

Parameters **y_true** : array-like of shape = (n_samples) or (n_samples, n_outputs)

Ground truth (correct) target values.

y_pred : array-like of shape = (n_samples) or (n_samples, n_outputs)

Estimated target values.

sample_weight : array-like of shape = (n_samples), optional

Sample weights.

multioutput : string in ['raw_values', 'uniform_average']

or array-like of shape (n_outputs) Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

'raw_values' : Returns a full set of errors in case of multioutput input.

'uniform_average' : Errors of all outputs are averaged with uniform weight.

Returns **loss** : float or ndarray of floats

A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

Examples

```
>>> from sklearn.metrics import mean_squared_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_squared_error(y_true, y_pred)
0.375
>>> y_true = [[0.5, 1],[-1, 1],[7, -6]]
>>> y_pred = [[0, 2],[-1, 2],[8, -5]]
>>> mean_squared_error(y_true, y_pred)
0.708...
>>> mean_squared_error(y_true, y_pred, multioutput='raw_values')
...
array([ 0.416...,  1.        ])
>>> mean_squared_error(y_true, y_pred, multioutput=[0.3, 0.7])
...
0.824...
```

Examples using `sklearn.metrics.mean_squared_error`

`sklearn.metrics`.mean_squared_log_error

`sklearn.metrics.`**`mean_squared_log_error`**(*y_true*, *y_pred*, *sample_weight=None*, *multioutput='uniform_average'*)

Mean squared logarithmic error regression loss

Read more in the *User Guide*.

Parameters **y_true** : array-like of shape = (n_samples) or (n_samples, n_outputs)

Ground truth (correct) target values.

y_pred : array-like of shape = (n_samples) or (n_samples, n_outputs)

Estimated target values.

sample_weight : array-like of shape = (n_samples), optional

Sample weights.

multioutput : string in ['raw_values', 'uniform_average'] or array-like of shape = (n_outputs)

Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

'raw_values' : Returns a full set of errors when the input is of multioutput format.

'uniform_average' : Errors of all outputs are averaged with uniform weight.

Returns **loss** : float or ndarray of floats

A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

Examples

```
>>> from sklearn.metrics import mean_squared_log_error
>>> y_true = [3, 5, 2.5, 7]
>>> y_pred = [2.5, 5, 4, 8]
>>> mean_squared_log_error(y_true, y_pred)
0.039...
>>> y_true = [[0.5, 1], [1, 2], [7, 6]]
>>> y_pred = [[0.5, 2], [1, 2.5], [8, 8]]
>>> mean_squared_log_error(y_true, y_pred)
0.044...
>>> mean_squared_log_error(y_true, y_pred, multioutput='raw_values')
...
array([ 0.004...,  0.083...])
>>> mean_squared_log_error(y_true, y_pred, multioutput=[0.3, 0.7])
```

```
...
0.060...
```

sklearn.metrics.median_absolute_error

sklearn.metrics.**median_absolute_error**(*y_true*, *y_pred*)

Median absolute error regression loss

Read more in the *User Guide*.

Parameters **y_true** : array-like of shape = (n_samples)

Ground truth (correct) target values.

y_pred : array-like of shape = (n_samples)

Estimated target values.

Returns **loss** : float

A positive floating point value (the best value is 0.0).

Examples

```
>>> from sklearn.metrics import median_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> median_absolute_error(y_true, y_pred)
0.5
```

sklearn.metrics.r2_score

sklearn.metrics.**r2_score**(*y_true*, *y_pred*, *sample_weight=None*, *multioutput='uniform_average'*)

R^2 (coefficient of determination) regression score function.

Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Read more in the *User Guide*.

Parameters **y_true** : array-like of shape = (n_samples) or (n_samples, n_outputs)

Ground truth (correct) target values.

y_pred : array-like of shape = (n_samples) or (n_samples, n_outputs)

Estimated target values.

sample_weight : array-like of shape = (n_samples), optional

Sample weights.

multioutput : string in ['raw_values', 'uniform_average', 'variance_weighted'] or None or array-like of shape (n_outputs)

Defines aggregating of multiple output scores. Array-like value defines weights used to average scores. Default is "uniform_average".

'raw_values' : Returns a full set of scores in case of multioutput input.

'uniform_average' : Scores of all outputs are averaged with uniform weight.

'variance_weighted' : Scores of all outputs are averaged, weighted by the variances of each individual output.

Changed in version 0.19: Default value of multioutput is 'uniform_average'.

Returns **z** : float or ndarray of floats

The R^2 score or ndarray of scores if 'multioutput' is 'raw_values'.

Notes

This is not a symmetric function.

Unlike most other scores, R^2 score may be negative (it need not actually be the square of a quantity R).

References

[R62]

Examples

```
>>> from sklearn.metrics import r2_score
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> r2_score(y_true, y_pred)
0.948...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> r2_score(y_true, y_pred, multioutput='variance_weighted')
...
0.938...
>>> y_true = [1,2,3]
>>> y_pred = [1,2,3]
>>> r2_score(y_true, y_pred)
1.0
>>> y_true = [1,2,3]
>>> y_pred = [2,2,2]
>>> r2_score(y_true, y_pred)
0.0
>>> y_true = [1,2,3]
>>> y_pred = [3,2,1]
>>> r2_score(y_true, y_pred)
-3.0
```

29.20.4 Multilabel ranking metrics

See the *Multilabel ranking metrics* section of the user guide for further details.

metrics.coverage_error(y_true, y_score[, ...])	Coverage error measure
metrics.label_ranking_average_precision_score(...)	Compute ranking-based average precision
metrics.label_ranking_loss(y_true, y_score)	Compute Ranking loss measure

sklearn.metrics.coverage_error

sklearn.metrics.**coverage_error**(*y_true*, *y_score*, *sample_weight=None*)

Coverage error measure

Compute how far we need to go through the ranked scores to cover all true labels. The best value is equal to the average number of labels in `y_true` per sample.

Ties in `y_scores` are broken by giving maximal rank that would have been assigned to all tied values.

Note: Our implementation's score is 1 greater than the one given in Tsoumakas et al., 2010. This extends it to handle the degenerate case in which an instance has 0 true labels.

Read more in the *User Guide*.

Parameters **y_true** : array, shape = [n_samples, n_labels]

True binary labels in binary indicator format.

y_score : array, shape = [n_samples, n_labels]

Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by "decision_function" on some classifiers).

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **coverage_error** : float

References

[R212]

sklearn.metrics.label_ranking_average_precision_score

sklearn.metrics.**label_ranking_average_precision_score**(*y_true*, *y_score*)

Compute ranking-based average precision

Label ranking average precision (LRAP) is the average over each ground truth label assigned to each sample, of the ratio of true vs. total labels with lower score.

This metric is used in multilabel ranking problem, where the goal is to give better rank to the labels associated to each sample.

The obtained score is always strictly greater than 0 and the best value is 1.

Read more in the *User Guide*.

Parameters **y_true** : array or sparse matrix, shape = [n_samples, n_labels]

True binary labels in binary indicator format.

y_score : array, shape = [n_samples, n_labels]

Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by "decision_function" on some classifiers).

Returns **score** : float

Examples

```
>>> import numpy as np
>>> from sklearn.metrics import label_ranking_average_precision_score
>>> y_true = np.array([[1, 0, 0], [0, 0, 1]])
>>> y_score = np.array([[0.75, 0.5, 1], [1, 0.2, 0.1]])
>>> label_ranking_average_precision_score(y_true, y_score)
0.416...
```

sklearn.metrics.label_ranking_loss

sklearn.metrics.**label_ranking_loss**(*y_true*, *y_score*, *sample_weight=None*)

Compute Ranking loss measure

Compute the average number of label pairs that are incorrectly ordered given y_score weighted by the size of the label set and the number of labels not in the label set.

This is similar to the error set size, but weighted by the number of relevant and irrelevant labels. The best performance is achieved with a ranking loss of zero.

Read more in the *User Guide*.

New in version 0.17: A function *label_ranking_loss*

Parameters **y_true** : array or sparse matrix, shape = [n_samples, n_labels]

True binary labels in binary indicator format.

y_score : array, shape = [n_samples, n_labels]

Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by "decision_function" on some classifiers).

sample_weight : array-like of shape = [n_samples], optional

Sample weights.

Returns **loss** : float

References

[R226]

29.20.5 Clustering metrics

See the *Clustering performance evaluation* section of the user guide for further details. The `sklearn.metrics.cluster` submodule contains evaluation metrics for cluster analysis results. There are two forms of evaluation:

- supervised, which uses a ground truth class values for each sample.
- unsupervised, which does not and measures the 'quality' of the model itself.

`metrics.adjusted_mutual_info_score`(...)	Adjusted Mutual Information between two clusterings.
`metrics.adjusted_rand_score`(labels_true, ...)	Rand index adjusted for chance.
`metrics.calinski_harabaz_score`(X, labels)	Compute the Calinski and Harabaz score.
`metrics.completeness_score`(labels_true, ...)	Completeness metric of a cluster labeling given a ground truth.
`metrics.fowlkes_mallows_score`(labels_true, ...)	Measure the similarity of two clusterings of a set of points.
`metrics.homogeneity_completeness_v_measure`(...)	Compute the homogeneity and completeness and V-Measure scores at once.
`metrics.homogeneity_score`(labels_true, ...)	Homogeneity metric of a cluster labeling given a ground truth.
`metrics.mutual_info_score`(labels_true, ...)	Mutual Information between two clusterings.
`metrics.normalized_mutual_info_score`(...)	Normalized Mutual Information between two clusterings.
`metrics.silhouette_score`(X, labels[, ...])	Compute the mean Silhouette Coefficient of all samples.
`metrics.silhouette_samples`(X, labels[, metric])	Compute the Silhouette Coefficient for each sample.
`metrics.v_measure_score`(labels_true, labels_pred)	V-measure cluster labeling given a ground truth.

sklearn.metrics.adjusted_mutual_info_score

sklearn.metrics.**adjusted_mutual_info_score**(*labels_true*, *labels_pred*)

Adjusted Mutual Information between two clusterings.

Adjusted Mutual Information (AMI) is an adjustment of the Mutual Information (MI) score to account for chance. It accounts for the fact that the MI is generally higher for two clusterings with a larger number of clusters, regardless of whether there is actually more information shared. For two clusterings U and V, the AMI is given as:

```
AMI(U, V) = [MI(U, V) - E(MI(U, V))] / [max(H(U), H(V)) - E(MI(U, V))]
```

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Be mindful that this function is an order of magnitude slower than other metrics, such as the Adjusted Rand Index.

Read more in the *User Guide*.

Parameters **labels_true** : int array, shape = [n_samples]

A clustering of the data into disjoint subsets.

labels_pred : array, shape = [n_samples]

A clustering of the data into disjoint subsets.

Returns **ami: float(upperlimited by 1.0)** :

The AMI returns a value of 1 when the two partitions are identical (ie perfectly matched). Random partitions (independent labellings) have an expected AMI around 0 on average hence can be negative.

adjusted_rand_score Adjusted Rand Index

mutual_information_score Mutual Information (not adjusted for chance)

References

[R50], *[R51]*

Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```
>>> from sklearn.metrics.cluster import adjusted_mutual_info_score
>>> adjusted_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> adjusted_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally in-complete, hence the AMI is null:

```
>>> adjusted_mutual_info_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

Examples using `sklearn.metrics.adjusted_mutual_info_score`

- *Adjustment for chance in clustering performance evaluation*
- *Demo of affinity propagation clustering algorithm*
- *Demo of DBSCAN clustering algorithm*
- *A demo of K-Means clustering on the handwritten digits data*

sklearn.metrics.adjusted_rand_score

sklearn.metrics.**adjusted_rand_score**(*labels_true*, *labels_pred*)

Rand index adjusted for chance.

The Rand Index computes a similarity measure between two clusterings by considering all pairs of samples and counting pairs that are assigned in the same or different clusters in the predicted and true clusterings.

The raw RI score is then "adjusted for chance" into the ARI score using the following scheme:

```
ARI = (RI - Expected_RI) / (max(RI) - Expected_RI)
```

The adjusted Rand index is thus ensured to have a value close to 0.0 for random labeling independently of the number of clusters and samples and exactly 1.0 when the clusterings are identical (up to a permutation).

ARI is a symmetric measure:

```
adjusted_rand_score(a, b) == adjusted_rand_score(b, a)
```

Read more in the *User Guide*.

Parameters **labels_true** : int array, shape = [n_samples]

Ground truth class labels to be used as a reference

labels_pred : array, shape = [n_samples]

Cluster labels to evaluate

Returns **ari** : float

Similarity score between -1.0 and 1.0. Random labelings have an ARI close to 0.0. 1.0 stands for perfect match.

See also:

adjusted_mutual_info_score Adjusted Mutual Information

References

[Hubert1985], *[wk]*

Examples

Perfectly matching labelings have a score of 1 even

```
>>> from sklearn.metrics.cluster import adjusted_rand_score
>>> adjusted_rand_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> adjusted_rand_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Labelings that assign all classes members to the same clusters are complete be not always pure, hence penalized:

```
>>> adjusted_rand_score([0, 0, 1, 2], [0, 0, 1, 1])
0.57...
```

ARI is symmetric, so labelings that have pure clusters with members coming from the same classes but unnecessary splits are penalized:

```
>>> adjusted_rand_score([0, 0, 1, 1], [0, 0, 1, 2])
0.57...
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the ARI is very low:

```
>>> adjusted_rand_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

Examples using sklearn.metrics.adjusted_rand_score

- *Adjustment for chance in clustering performance evaluation*
- *Demo of affinity propagation clustering algorithm*
- *Demo of DBSCAN clustering algorithm*
- *A demo of K-Means clustering on the handwritten digits data*
- *Clustering text documents using k-means*

sklearn.metrics.calinski_harabaz_score

sklearn.metrics.**calinski_harabaz_score**(*X*, *labels*)

Compute the Calinski and Harabaz score.

The score is defined as ratio between the within-cluster dispersion and the between-cluster dispersion.

Read more in the *User Guide*.

Parameters **X** : array-like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

labels : array-like, shape (n_samples,)

Predicted labels for each sample.

Returns **score** : float

The resulting Calinski-Harabaz score.

References

[R206]

sklearn.metrics.completeness_score

sklearn.metrics.**completeness_score**(*labels_true*, *labels_pred*)

Completeness metric of a cluster labeling given a ground truth.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is not symmetric: switching label_true with label_pred will return the *homogeneity_score* which will be different in general.

Read more in the *User Guide*.

Parameters **labels_true** : int array, shape = [n_samples]

ground truth class labels to be used as a reference

labels_pred : array, shape = [n_samples]

cluster labels to evaluate

Returns **completeness** : float

score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

homogeneity_score, *v_measure_score*

References

[R56]

Examples

Perfect labelings are complete:

```
>>> from sklearn.metrics.cluster import completeness_score
>>> completeness_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Non-perfect labelings that assign all classes members to the same clusters are still complete:

```
>>> print(completeness_score([0, 0, 1, 1], [0, 0, 0, 0]))
1.0
>>> print(completeness_score([0, 1, 2, 3], [0, 0, 1, 1]))
1.0
```

If classes members are split across different clusters, the assignment cannot be complete:

```
>>> print(completeness_score([0, 0, 1, 1], [0, 1, 0, 1]))
0.0
>>> print(completeness_score([0, 0, 0, 0], [0, 1, 2, 3]))
0.0
```

Examples using `sklearn.metrics.completeness_score`

- *Demo of affinity propagation clustering algorithm*
- *Demo of DBSCAN clustering algorithm*
- *A demo of K-Means clustering on the handwritten digits data*
- *Clustering text documents using k-means*

`sklearn.metrics.fowlkes_mallows_score`

`sklearn.metrics.fowlkes_mallows_score`(*labels_true*, *labels_pred*, *sparse=False*)

Measure the similarity of two clusterings of a set of points.

The Fowlkes-Mallows index (FMI) is defined as the geometric mean between of the precision and recall:

```
FMI = TP / sqrt((TP + FP) * (TP + FN))
```

Where TP is the number of **True Positive** (i.e. the number of pair of points that belongs in the same clusters in both labels_true and labels_pred), FP is the number of **False Positive** (i.e. the number of pair of points that belongs in the same clusters in labels_true and not in labels_pred) and FN is the number of **False Negative** (i.e the number of pair of points that belongs in the same clusters in labels_pred and not in labels_True).

The score ranges from 0 to 1. A high value indicates a good similarity between two clusters.

Read more in the *User Guide*.

Parameters **labels_true** : int array, shape = (n_samples,)

A clustering of the data into disjoint subsets.

labels_pred : array, shape = (n_samples,)

A clustering of the data into disjoint subsets.

Returns **score** : float

The resulting Fowlkes-Mallows score.

References

[R217], *[R218]*

Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```
>>> from sklearn.metrics.cluster import fowlkes_mallows_score
>>> fowlkes_mallows_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> fowlkes_mallows_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally random, hence the FMI is null:

```
>>> fowlkes_mallows_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

sklearn.metrics.homogeneity_completeness_v_measure

sklearn.metrics.**homogeneity_completeness_v_measure**(*labels_true*, *labels_pred*)

Compute the homogeneity and completeness and V-Measure scores at once.

Those metrics are based on normalized conditional entropy measures of the clustering labeling to evaluate given the knowledge of a Ground Truth class labels of the same samples.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster.

Both scores have positive values between 0.0 and 1.0, larger values being desirable.

Those 3 metrics are independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score values in any way.

V-Measure is furthermore symmetric: swapping `labels_true` and `label_pred` will give the same score. This does not hold for homogeneity and completeness.

Read more in the *User Guide*.

Parameters **labels_true** : int array, shape = [n_samples]

ground truth class labels to be used as a reference

labels_pred : array, shape = [n_samples]

cluster labels to evaluate

Returns **homogeneity** : float

score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling

completeness : float

score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

v_measure : float

harmonic mean of the first two

See also:

homogeneity_score, *completeness_score*, *v_measure_score*

sklearn.metrics.homogeneity_score

sklearn.metrics.**homogeneity_score**(*labels_true*, *labels_pred*)

Homogeneity metric of a cluster labeling given a ground truth.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is not symmetric: switching `label_true` with `label_pred` will return the *completeness_score* which will be different in general.

Read more in the *User Guide*.

Parameters **labels_true** : int array, shape = [n_samples]

ground truth class labels to be used as a reference

labels_pred : array, shape = [n_samples]

cluster labels to evaluate

Returns **homogeneity** : float

score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling

See also:

completeness_score, *v_measure_score*

References

[R61]

Examples

Perfect labelings are homogeneous:

```
>>> from sklearn.metrics.cluster import homogeneity_score
>>> homogeneity_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Non-perfect labelings that further split classes into more clusters can be perfectly homogeneous:

```
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 1, 2]))
...
1.0...
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 2, 3]))
...
1.0...
```

Clusters that include samples from different classes do not make for an homogeneous labeling:

```
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 0, 1]))
...
0.0...
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 0, 0]))
...
0.0...
```

Examples using `sklearn.metrics.homogeneity_score`

- *Demo of affinity propagation clustering algorithm*
- *Demo of DBSCAN clustering algorithm*
- *A demo of K-Means clustering on the handwritten digits data*
- *Clustering text documents using k-means*

`sklearn.metrics`.mutual_info_score

`sklearn.metrics.`**`mutual_info_score`**(*labels_true*, *labels_pred*, *contingency=None*)

Mutual Information between two clusterings.

The Mutual Information is a measure of the similarity between two labels of the same data. Where $|U_i|$ is the number of the samples in cluster U_i and $|V_j|$ is the number of the samples in cluster V_j, the Mutual Information between clusterings U and V is given as:

$$MI(U,V) = \sum_{i=1}^{|} U| \sum_{j=1}^{|} V| \frac{|U_i \cap V_j|}{N} \log \frac{N|U_i \cap V_j|}{|U_i||V_j|}$$

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the *User Guide*.

Parameters **labels_true** : int array, shape = [n_samples]

A clustering of the data into disjoint subsets.

labels_pred : array, shape = [n_samples]

A clustering of the data into disjoint subsets.

contingency : {None, array, sparse matrix},

shape = [n_classes_true, n_classes_pred]

A contingency matrix given by the `contingency_matrix` function. If value is `None`, it will be computed, otherwise the given value is used, with `labels_true` and `labels_pred` ignored.

Returns **mi** : float

Mutual information, a non-negative value

See also:

adjusted_mutual_info_score Adjusted against chance Mutual Information

normalized_mutual_info_score Normalized Mutual Information

Examples using `sklearn.metrics.mutual_info_score`

- *Adjustment for chance in clustering performance evaluation*

`sklearn.metrics`.normalized_mutual_info_score

`sklearn.metrics.`**`normalized_mutual_info_score`**(*labels_true*, *labels_pred*)

Normalized Mutual Information between two clusterings.

Normalized Mutual Information (NMI) is an normalization of the Mutual Information (MI) score to scale the results between 0 (no mutual information) and 1 (perfect correlation). In this function, mutual information is normalized by `sqrt(H(labels_true) * H(labels_pred))`

This measure is not adjusted for chance. Therefore `adjusted_mustual_info_score` might be preferred.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the *User Guide*.

Parameters **labels_true** : int array, shape = [n_samples]

A clustering of the data into disjoint subsets.

labels_pred : array, shape = [n_samples]

A clustering of the data into disjoint subsets.

Returns **nmi** : float

score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

adjusted_rand_score Adjusted Rand Index

adjusted_mutual_info_score Adjusted Mutual Information (adjusted against chance)

Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```
>>> from sklearn.metrics.cluster import normalized_mutual_info_score
>>> normalized_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> normalized_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally in-complete, hence the NMI is null:

```
>>> normalized_mutual_info_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

sklearn.metrics.silhouette_score

sklearn.metrics.**silhouette_score**(*X*, *labels*, *metric='euclidean'*, *sample_size=None*, *random_state=None*, ***kwds*)

Compute the mean Silhouette Coefficient of all samples.

The Silhouette Coefficient is calculated using the mean intra-cluster distance (`a`) and the mean nearest-cluster distance (`b`) for each sample. The Silhouette Coefficient for a sample is `(b - a) / max(a, b)`. To clarify, `b` is the distance between a sample and the nearest cluster that the sample is not a part of. Note that Silhouette Coefficent is only defined if number of labels is 2 <= n_labels <= n_samples - 1.

This function returns the mean Silhouette Coefficient over all samples. To obtain the values for each sample, use *silhouette_samples*.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters. Negative values generally indicate that a sample has been assigned to the wrong cluster, as a different cluster is more similar.

Read more in the *User Guide*.

Parameters **X** : array [n_samples_a, n_samples_a] if metric == "precomputed", or, [n_samples_a, n_features] otherwise

Array of pairwise distances between samples, or a feature array.

labels : array, shape = [n_samples]

Predicted labels for each sample.

metric : string, or callable

The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by *metrics.pairwise.pairwise_distances*. If X is the distance array itself, use `metric="precomputed"`.

sample_size : int or None

The size of the sample to use when computing the Silhouette Coefficient on a random subset of the data. If `sample_size is None`, no sampling is used.

random_state : int, RandomState instance or None, optional (default=None)

The generator used to randomly select a subset of samples. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `sample_size is not None`.

****kwds** : optional keyword parameters

Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

Returns **silhouette** : float

Mean Silhouette Coefficient for all samples.

References

[R66], *[R67]*

Examples using `sklearn.metrics.silhouette_score`

- *Demo of affinity propagation clustering algorithm*
- *Demo of DBSCAN clustering algorithm*
- *A demo of K-Means clustering on the handwritten digits data*
- *Selecting the number of clusters with silhouette analysis on KMeans clustering*
- *Clustering text documents using k-means*

`sklearn.metrics`.silhouette_samples

`sklearn.metrics.`**`silhouette_samples`**(*X*, *labels*, *metric='euclidean'*, ***kwds*)

Compute the Silhouette Coefficient for each sample.

The Silhouette Coefficient is a measure of how well samples are clustered with samples that are similar to themselves. Clustering models with a high Silhouette Coefficient are said to be dense, where samples in the same cluster are similar to each other, and well separated, where samples in different clusters are not very similar to each other.

The Silhouette Coefficient is calculated using the mean intra-cluster distance (`a`) and the mean nearest-cluster distance (`b`) for each sample. The Silhouette Coefficient for a sample is `(b - a) / max(a, b)`. Note that Silhouette Coefficent is only defined if number of labels is 2 <= n_labels <= n_samples - 1.

This function returns the Silhouette Coefficient for each sample.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters.

Read more in the *User Guide*.

Parameters **X** : array [n_samples_a, n_samples_a] if metric == "precomputed", or, [n_samples_a, n_features] otherwise

Array of pairwise distances between samples, or a feature array.

labels : array, shape = [n_samples]

label values for each sample

metric : string, or callable

The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by *sklearn.metrics.pairwise.pairwise_distances*. If X is the distance array itself, use "precomputed" as the metric.

****kwds** : optional keyword parameters

Any further parameters are passed directly to the distance function. If using a `scipy.spatial.distance` metric, the parameters are still metric dependent. See the scipy docs for usage examples.

Returns **silhouette** : array, shape = [n_samples]

Silhouette Coefficient for each samples.

References

[R64], *[R65]*

Examples using `sklearn.metrics.silhouette_samples`

- *Selecting the number of clusters with silhouette analysis on KMeans clustering*

`sklearn.metrics.v_measure_score`

`sklearn.metrics.`**`v_measure_score`**(*labels_true*, *labels_pred*)

V-measure cluster labeling given a ground truth.

This score is identical to *normalized_mutual_info_score*.

The V-measure is the harmonic mean between homogeneity and completeness:

```
v = 2 * (homogeneity * completeness) / (homogeneity + completeness)
```

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the *User Guide*.

Parameters **labels_true** : int array, shape = [n_samples]

ground truth class labels to be used as a reference

labels_pred : array, shape = [n_samples]

cluster labels to evaluate

Returns **v_measure** : float

score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

homogeneity_score, *completeness_score*

References

[R68]

Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```
>>> from sklearn.metrics.cluster import v_measure_score
>>> v_measure_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> v_measure_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Labelings that assign all classes members to the same clusters are complete be not homogeneous, hence penalized:

```
>>> print("%.6f" % v_measure_score([0, 0, 1, 2], [0, 0, 1, 1]))
...
0.8...
>>> print("%.6f" % v_measure_score([0, 1, 2, 3], [0, 0, 1, 1]))
...
0.66...
```

Labelings that have pure clusters with members coming from the same classes are homogeneous but unnecessary splits harms completeness and thus penalize V-measure as well:

```
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 1, 2]))
...
0.8...
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 1, 2, 3]))
...
0.66...
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the V-Measure is null:

```
>>> print("%.6f" % v_measure_score([0, 0, 0, 0], [0, 1, 2, 3]))
...
0.0...
```

Clusters that include samples from totally different classes totally destroy the homogeneity of the labeling, hence:

```
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 0, 0]))
...
0.0...
```

Examples using `sklearn.metrics.v_measure_score`

- *Clustering text documents using k-means*

29.20.6 Biclustering metrics

See the *Biclustering evaluation* section of the user guide for further details.

metrics.consensus_score(a, b[, similarity])	The similarity of two sets of biclusters.

sklearn.metrics.consensus_score

sklearn.metrics.**consensus_score**(*a*, *b*, *similarity='jaccard'*)

The similarity of two sets of biclusters.

Similarity between individual biclusters is computed. Then the best matching between sets is found using the Hungarian algorithm. The final score is the sum of similarities divided by the size of the larger set.

Read more in the *User Guide*.

Parameters **a** : (rows, columns)

Tuple of row and column indicators for a set of biclusters.

b : (rows, columns)

Another set of biclusters like `a`.

similarity : string or function, optional, default: "jaccard"

May be the string "jaccard" to use the Jaccard coefficient, or any function that takes four arguments, each of which is a 1d indicator vector: (a_rows, a_columns, b_rows, b_columns).

29.20.7 Pairwise metrics

See the *Pairwise metrics, Affinities and Kernels* section of the user guide for further details.

metrics.pairwise.additive_chi2_kernel(X[, Y])	Computes the additive chi-squared kernel between observations in X and Y
metrics.pairwise.chi2_kernel(X[, Y, gamma])	Computes the exponential chi-squared kernel X and Y.
metrics.pairwise.distance_metrics()	Valid metrics for pairwise_distances.
metrics.pairwise.euclidean_distances(X[, Y, ...])	Considering the rows of X (and Y=X) as vectors, compute the distance matrix between each pair of vectors.
metrics.pairwise.kernel_metrics()	Valid metrics for pairwise_kernels
metrics.pairwise.linear_kernel(X[, Y])	Compute the linear kernel between X and Y.
metrics.pairwise.manhattan_distances(X[, Y, ...])	Compute the L1 distances between the vectors in X and Y.
metrics.pairwise.pairwise_distances(X[, Y, ...])	Compute the distance matrix from a vector array X and optional Y.
metrics.pairwise.pairwise_kernels(X[, Y, ...])	Compute the kernel between arrays X and optional array Y.
metrics.pairwise.polynomial_kernel(X[, Y, ...])	Compute the polynomial kernel between X and Y:
metrics.pairwise.rbf_kernel(X[, Y, gamma])	Compute the rbf (gaussian) kernel between X and Y:
metrics.pairwise.sigmoid_kernel(X[, Y, ...])	Compute the sigmoid kernel between X and Y:
metrics.pairwise.cosine_similarity(X[, Y, ...])	Compute cosine similarity between samples in X and Y.
metrics.pairwise.cosine_distances(X[, Y])	Compute cosine distance between samples in X and Y.
metrics.pairwise.laplacian_kernel(X[, Y, gamma])	Compute the laplacian kernel between X and Y.
metrics.pairwise_distances(X[, Y, metric, ...])	Compute the distance matrix from a vector array X and optional Y.
metrics.pairwise_distances_argmin(X, Y[, ...])	Compute minimum distances between one point and a set of points.
metrics.pairwise_distances_argmin_min(X, Y)	Compute minimum distances between one point and a set of points.
metrics.pairwise.paired_euclidean_distances(X, Y)	Computes the paired euclidean distances between X and Y
metrics.pairwise.paired_manhattan_distances(X, Y)	Compute the L1 distances between the vectors in X and Y.
metrics.pairwise.paired_cosine_distances(X, Y)	Computes the paired cosine distances between X and Y
metrics.pairwise.paired_distances(X, Y[, metric])	Computes the paired distances between X and Y.

sklearn.metrics.pairwise.additive_chi2_kernel

sklearn.metrics.pairwise.**additive_chi2_kernel**(*X*, *Y=None*)

Computes the additive chi-squared kernel between observations in X and Y

The chi-squared kernel is computed between each pair of rows in X and Y. X and Y have to be non-negative. This kernel is most commonly applied to histograms.

The chi-squared kernel is given by:

```
k(x, y) = -Sum [(x - y)^2 / (x + y)]
```

It can be interpreted as a weighted difference per entry.

Read more in the *User Guide*.

Parameters **X** : array-like of shape (n_samples_X, n_features)

Y : array of shape (n_samples_Y, n_features)

Returns **kernel_matrix** : array of shape (n_samples_X, n_samples_Y)

See also:

chi2_kernel The exponentiated version of the kernel, which is usually preferable.

sklearn.kernel_approximation.AdditiveChi2Sampler A Fourier approximation to this kernel.

Notes

As the negative of a distance, this kernel is only conditionally positive definite.

Local features and kernels for classification of texture and object categories: A comprehensive study International Journal of Computer Vision 2007 http://research.microsoft.com/en-us/um/people/manik/projects/trade-off/papers/ZhangIJCV06.pdf

sklearn.metrics.pairwise.chi2_kernel

sklearn.metrics.pairwise.**chi2_kernel**(*X*, *Y=None*, *gamma=1.0*)

Computes the exponential chi-squared kernel X and Y.

The chi-squared kernel is computed between each pair of rows in X and Y. X and Y have to be non-negative. This kernel is most commonly applied to histograms.

The chi-squared kernel is given by:

```
k(x, y) = exp(-gamma Sum [(x - y)^2 / (x + y)])
```

It can be interpreted as a weighted difference per entry.

Read more in the *User Guide*.

Parameters **X** : array-like of shape (n_samples_X, n_features)

Y : array of shape (n_samples_Y, n_features)

gamma : float, default=1.

Scaling parameter of the chi2 kernel.

Returns **kernel_matrix** : array of shape (n_samples_X, n_samples_Y)

See also:

additive_chi2_kernel The additive version of this kernel

sklearn.kernel_approximation.AdditiveChi2Sampler A Fourier approximation to the additive version of this kernel.

sklearn.metrics.pairwise.distance_metrics

sklearn.metrics.pairwise.**distance_metrics**()

Valid metrics for pairwise_distances.

This function simply returns the valid pairwise distance metrics. It exists to allow for a description of the mapping for each of the valid strings.

The valid distance metrics, and the function they map to, are:

metric	Function
'cityblock'	metrics.pairwise.manhattan_distances
'cosine'	metrics.pairwise.cosine_distances
'euclidean'	metrics.pairwise.euclidean_distances
'l1'	metrics.pairwise.manhattan_distances
'l2'	metrics.pairwise.euclidean_distances
'manhattan'	metrics.pairwise.manhattan_distances

Read more in the *User Guide*.

sklearn.metrics.pairwise.euclidean_distances

sklearn.metrics.pairwise.**euclidean_distances**(*X*, *Y=None*, *Y_norm_squared=None*, *squared=False*, *X_norm_squared=None*)

Considering the rows of X (and Y=X) as vectors, compute the distance matrix between each pair of vectors.

For efficiency reasons, the euclidean distance between a pair of row vector x and y is computed as:

```
dist(x, y) = sqrt(dot(x, x) - 2 * dot(x, y) + dot(y, y))
```

This formulation has two advantages over other ways of computing distances. First, it is computationally efficient when dealing with sparse data. Second, if one argument varies but the other remains unchanged, then *dot(x, x)* and/or *dot(y, y)* can be pre-computed.

However, this is not the most precise way of doing this computation, and the distance matrix returned by this function may not be exactly symmetric as required by, e.g., `scipy.spatial.distance` functions.

Read more in the *User Guide*.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples_1, n_features)

Y : {array-like, sparse matrix}, shape (n_samples_2, n_features)

Y_norm_squared : array-like, shape (n_samples_2,), optional

Pre-computed dot-products of vectors in Y (e.g., `(Y**2).sum(axis=1)`)

squared : boolean, optional

Return squared Euclidean distances.

X_norm_squared : array-like, shape = [n_samples_1], optional

Pre-computed dot-products of vectors in X (e.g., `(X**2).sum(axis=1)`)

Returns **distances** : {array, sparse matrix}, shape (n_samples_1, n_samples_2)

See also:

paired_distances distances betweens pairs of elements of X and Y.

Examples

```
>>> from sklearn.metrics.pairwise import euclidean_distances
>>> X = [[0, 1], [1, 1]]
>>> # distance between rows of X
>>> euclidean_distances(X, X)
array([[ 0.,  1.],
       [ 1.,  0.]])
>>> # get distance to origin
>>> euclidean_distances(X, [[0, 0]])
array([[ 1.        ],
       [ 1.41421356]])
```

sklearn.metrics.pairwise.kernel_metrics

sklearn.metrics.pairwise.**kernel_metrics**()

Valid metrics for pairwise_kernels

This function simply returns the valid pairwise distance metrics. It exists, however, to allow for a verbose description of the mapping for each of the valid strings.

The valid distance metrics, and the function they map to, are:

metric	Function
'additive_chi2'	sklearn.pairwise.additive_chi2_kernel
'chi2'	sklearn.pairwise.chi2_kernel
'linear'	sklearn.pairwise.linear_kernel
'poly'	sklearn.pairwise.polynomial_kernel
'polynomial'	sklearn.pairwise.polynomial_kernel
'rbf'	sklearn.pairwise.rbf_kernel
'laplacian'	sklearn.pairwise.laplacian_kernel
'sigmoid'	sklearn.pairwise.sigmoid_kernel
'cosine'	sklearn.pairwise.cosine_similarity

Read more in the *User Guide*.

sklearn.metrics.pairwise.linear_kernel

sklearn.metrics.pairwise.**linear_kernel**(*X*, *Y=None*)

Compute the linear kernel between X and Y.

Read more in the *User Guide*.

Parameters **X** : array of shape (n_samples_1, n_features)

Y : array of shape (n_samples_2, n_features)

Returns **Gram matrix** : array of shape (n_samples_1, n_samples_2)

sklearn.metrics.pairwise.manhattan_distances

sklearn.metrics.pairwise.**manhattan_distances**(*X*, *Y=None*, *sum_over_features=True*, *size_threshold=500000000.0*)

Compute the L1 distances between the vectors in X and Y.

With sum_over_features equal to False it returns the componentwise distances.

Read more in the *User Guide*.

Parameters **X** : array_like

An array with shape (n_samples_X, n_features).

Y : array_like, optional

An array with shape (n_samples_Y, n_features).

sum_over_features : bool, default=True

If True the function returns the pairwise distance matrix else it returns the componentwise L1 pairwise-distances. Not supported for sparse matrix inputs.

size_threshold : int, default=5e8

Unused parameter.

Returns **D** : array

If sum_over_features is False shape is (n_samples_X * n_samples_Y, n_features) and D contains the componentwise L1 pairwise-distances (ie. absolute difference), else shape is (n_samples_X, n_samples_Y) and D contains the pairwise L1 distances.

Examples

```
>>> from sklearn.metrics.pairwise import manhattan_distances
>>> manhattan_distances([[3]], [[3]])
array([[ 0.]])
>>> manhattan_distances([[3]], [[2]])
array([[ 1.]])
>>> manhattan_distances([[2]], [[3]])
array([[ 1.]])
>>> manhattan_distances([[1, 2], [3, 4]],         [[1, 2], [0, 3]])
array([[ 0.,  2.],
       [ 4.,  4.]])
>>> import numpy as np
>>> X = np.ones((1, 2))
>>> y = 2 * np.ones((2, 2))
>>> manhattan_distances(X, y, sum_over_features=False)
array([[ 1.,  1.],
       [ 1.,  1.]]...)
```

sklearn.metrics.pairwise.pairwise_distances

sklearn.metrics.pairwise.**pairwise_distances**(*X*, *Y=None*, *metric='euclidean'*, *n_jobs=1*, ***kwds*)

Compute the distance matrix from a vector array X and optional Y.

This method takes either a vector array or a distance matrix, and returns a distance matrix. If the input is a vector array, the distances are computed. If the input is a distances matrix, it is returned instead.

This method provides a safe way to take a distance matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If Y is given (default is None), then the returned matrix is the pairwise distance between the arrays from both X and Y.

Valid values for metric are:

- From scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']. These metrics support sparse matrix inputs.
- From scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'] See the documentation for scipy.spatial.distance for details on these metrics. These metrics do not support sparse matrix inputs.

Note that in the case of 'cityblock', 'cosine' and 'euclidean' (which are valid scipy.spatial.distance metrics), the scikit-learn implementation will be used, which is faster and has support for sparse matrices (except for 'cityblock'). For a verbose description of the metrics from scikit-learn, see the __doc__ of the sklearn.pairwise.distance_metrics function.

Read more in the *User Guide*.

Parameters **X** : array [n_samples_a, n_samples_a] if metric == "precomputed", or, [n_samples_a, n_features] otherwise

Array of pairwise distances between samples, or a feature array.

Y : array [n_samples_b, n_features], optional

An optional second feature array. Only allowed if metric != "precomputed".

metric : string, or callable

The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is "precomputed", X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

n_jobs : int

The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

****kwds** : optional keyword parameters

Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

Returns **D** : array [n_samples_a, n_samples_a] or [n_samples_a, n_samples_b]

A distance matrix D such that D_{i, j} is the distance between the ith and jth vectors of the given matrix X, if Y is None. If Y is not None, then D_{i, j} is the distance between the ith array from X and the jth array from Y.

sklearn.metrics.pairwise.pairwise_kernels

sklearn.metrics.pairwise.**pairwise_kernels**(*X*, *Y=None*, *metric='linear'*, *filter_params=False*, *n_jobs=1*, ***kwds*)

Compute the kernel between arrays X and optional array Y.

This method takes either a vector array or a kernel matrix, and returns a kernel matrix. If the input is a vector array, the kernels are computed. If the input is a kernel matrix, it is returned instead.

This method provides a safe way to take a kernel matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If Y is given (default is None), then the returned matrix is the pairwise kernel between the arrays from both X and Y.

Valid values for metric are:: ['rbf', 'sigmoid', 'polynomial', 'poly', 'linear', 'cosine']

Read more in the *User Guide*.

Parameters **X** : array [n_samples_a, n_samples_a] if metric == "precomputed", or, [n_samples_a, n_features] otherwise

Array of pairwise kernels between samples, or a feature array.

Y : array [n_samples_b, n_features]

A second feature array only if X has shape [n_samples_a, n_features].

metric : string, or callable

The metric to use when calculating kernel between instances in a feature array. If metric is a string, it must be one of the metrics in pairwise.PAIRWISE_KERNEL_FUNCTIONS. If metric is "precomputed", X is assumed to be a kernel matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

n_jobs : int

The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

filter_params : boolean

Whether to filter invalid parameters or not.

****kwds** : optional keyword parameters

Any further parameters are passed directly to the kernel function.

Returns **K** : array [n_samples_a, n_samples_a] or [n_samples_a, n_samples_b]

A kernel matrix K such that K_{i, j} is the kernel between the ith and jth vectors of the given matrix X, if Y is None. If Y is not None, then K_{i, j} is the kernel between the ith array from X and the jth array from Y.

Notes

If metric is 'precomputed', Y is ignored and X is returned.

sklearn.metrics.pairwise.polynomial_kernel

sklearn.metrics.pairwise.**polynomial_kernel**(*X*, *Y=None*, *degree=3*, *gamma=None*, *coef0=1*)

Compute the polynomial kernel between X and Y:

```
K(X, Y) = (gamma <X, Y> + coef0)^degree
```

Read more in the *User Guide*.

Parameters **X** : ndarray of shape (n_samples_1, n_features)

Y : ndarray of shape (n_samples_2, n_features)

degree : int, default 3

gamma : float, default None

if None, defaults to 1.0 / n_features

coef0 : int, default 1

Returns **Gram matrix** : array of shape (n_samples_1, n_samples_2)

sklearn.metrics.pairwise.rbf_kernel

sklearn.metrics.pairwise.**rbf_kernel**(*X*, *Y=None*, *gamma=None*)

Compute the rbf (gaussian) kernel between X and Y:

```
K(x, y) = exp(-gamma ||x-y||^2)
```

for each pair of rows x in X and y in Y.

Read more in the *User Guide*.

Parameters **X** : array of shape (n_samples_X, n_features)

Y : array of shape (n_samples_Y, n_features)

gamma : float, default None

If None, defaults to 1.0 / n_features

Returns **kernel_matrix** : array of shape (n_samples_X, n_samples_Y)

sklearn.metrics.pairwise.sigmoid_kernel

sklearn.metrics.pairwise.**sigmoid_kernel**(*X*, *Y=None*, *gamma=None*, *coef0=1*)

Compute the sigmoid kernel between X and Y:

```
K(X, Y) = tanh(gamma <X, Y> + coef0)
```

Read more in the *User Guide*.

Parameters **X** : ndarray of shape (n_samples_1, n_features)

Y : ndarray of shape (n_samples_2, n_features)

gamma : float, default None

If None, defaults to 1.0 / n_features

coef0 : int, default 1

Returns **Gram matrix** : array of shape (n_samples_1, n_samples_2)

sklearn.metrics.pairwise.cosine_similarity

sklearn.metrics.pairwise.**cosine_similarity**(*X*, *Y=None*, *dense_output=True*)

Compute cosine similarity between samples in X and Y.

Cosine similarity, or the cosine kernel, computes similarity as the normalized dot product of X and Y:

K(X, Y) = <X, Y> / (||X||*||Y||)

On L2-normalized data, this function is equivalent to linear_kernel.

Read more in the *User Guide*.

Parameters **X** : ndarray or sparse array, shape: (n_samples_X, n_features)

Input data.

Y : ndarray or sparse array, shape: (n_samples_Y, n_features)

Input data. If `None`, the output will be the pairwise similarities between all samples in `X`.

dense_output : boolean (optional), default True

Whether to return dense output even when the input is sparse. If `False`, the output is sparse if both input arrays are sparse.

New in version 0.17: parameter `dense_output` for dense output.

Returns **kernel matrix** : array

An array with shape (n_samples_X, n_samples_Y).

sklearn.metrics.pairwise.cosine_distances

sklearn.metrics.pairwise.**cosine_distances**(*X*, *Y=None*)

Compute cosine distance between samples in X and Y.

Cosine distance is defined as 1.0 minus the cosine similarity.

Read more in the *User Guide*.

Parameters **X** : array_like, sparse matrix

with shape (n_samples_X, n_features).

Y : array_like, sparse matrix (optional)

with shape (n_samples_Y, n_features).

Returns **distance matrix** : array

An array with shape (n_samples_X, n_samples_Y).

See also:

sklearn.metrics.pairwise.cosine_similarity, scipy.spatial.distance.cosine

sklearn.metrics.pairwise.laplacian_kernel

sklearn.metrics.pairwise.**laplacian_kernel**(*X*, *Y=None*, *gamma=None*)

Compute the laplacian kernel between X and Y.

The laplacian kernel is defined as:

```
K(x, y) = exp(-gamma ||x-y||_1)
```

for each pair of rows x in X and y in Y. Read more in the *User Guide*.

New in version 0.17.

Parameters **X** : array of shape (n_samples_X, n_features)

Y : array of shape (n_samples_Y, n_features)

gamma : float, default None

If None, defaults to 1.0 / n_features

Returns **kernel_matrix** : array of shape (n_samples_X, n_samples_Y)

sklearn.metrics.pairwise_distances

sklearn.metrics.**pairwise_distances**(*X*, *Y=None*, *metric='euclidean'*, *n_jobs=1*, ***kwds*)

Compute the distance matrix from a vector array X and optional Y.

This method takes either a vector array or a distance matrix, and returns a distance matrix. If the input is a vector array, the distances are computed. If the input is a distances matrix, it is returned instead.

This method provides a safe way to take a distance matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If Y is given (default is None), then the returned matrix is the pairwise distance between the arrays from both X and Y.

Valid values for metric are:

- From scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']. These metrics support sparse matrix inputs.
- From scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'] See the documentation for scipy.spatial.distance for details on these metrics. These metrics do not support sparse matrix inputs.

Note that in the case of 'cityblock', 'cosine' and 'euclidean' (which are valid scipy.spatial.distance metrics), the scikit-learn implementation will be used, which is faster and has support for sparse matrices (except for 'cityblock'). For a verbose description of the metrics from scikit-learn, see the __doc__ of the sklearn.pairwise.distance_metrics function.

Read more in the *User Guide*.

Parameters **X** : array [n_samples_a, n_samples_a] if metric == "precomputed", or, [n_samples_a, n_features] otherwise

Array of pairwise distances between samples, or a feature array.

Y : array [n_samples_b, n_features], optional

An optional second feature array. Only allowed if metric != "precomputed".

metric : string, or callable

The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is "precomputed", X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

n_jobs : int

The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

****kwds** : optional keyword parameters

Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

Returns **D** : array [n_samples_a, n_samples_a] or [n_samples_a, n_samples_b]

A distance matrix D such that D_{i, j} is the distance between the ith and jth vectors of the given matrix X, if Y is None. If Y is not None, then D_{i, j} is the distance between the ith array from X and the jth array from Y.

Examples using `sklearn.metrics.pairwise_distances`

- *Agglomerative clustering with different metrics*

`sklearn.metrics.`pairwise_distances_argmin

`sklearn.metrics.`**`pairwise_distances_argmin`**(*X*, *Y*, *axis=1*, *metric='euclidean'*, *batch_size=500*, *metric_kwargs=None*)

Compute minimum distances between one point and a set of points.

This function computes for each row in X, the index of the row of Y which is closest (according to the specified distance).

This is mostly equivalent to calling:

pairwise_distances(X, Y=Y, metric=metric).argmin(axis=axis)

but uses much less memory, and is faster for large arrays.

This function works with dense 2D arrays only.

Parameters **X** : array-like

Arrays containing points. Respective shapes (n_samples1, n_features) and (n_samples2, n_features)

Y : array-like

Arrays containing points. Respective shapes (n_samples1, n_features) and (n_samples2, n_features)

batch_size : integer

To reduce memory consumption over the naive solution, data are processed in batches, comprising batch_size rows of X and batch_size rows of Y. The default value is quite conservative, but can be changed for fine-tuning. The larger the number, the larger the memory usage.

metric : string or callable

metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for metric are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for scipy.spatial.distance for details on these metrics.

metric_kwargs : dict

keyword arguments to pass to specified metric function.

axis : int, optional, default 1

Axis along which the argmin and distances are to be computed.

Returns **argmin** : numpy.ndarray

Y[argmin[i], :] is the row in Y that is closest to X[i, :].

See also:

sklearn.metrics.pairwise_distances, *sklearn.metrics.pairwise_distances_argmin_min*

Examples using `sklearn.metrics.pairwise_distances_argmin`

- *Color Quantization using K-Means*
- *Comparison of the K-Means and MiniBatchKMeans clustering algorithms*

`sklearn.metrics`.pairwise_distances_argmin_min

sklearn.metrics.**pairwise_distances_argmin_min**(*X*, *Y*, *axis=1*, *metric='euclidean'*, *batch_size=500*, *metric_kwargs=None*)

Compute minimum distances between one point and a set of points.

This function computes for each row in X, the index of the row of Y which is closest (according to the specified distance). The minimal distances are also returned.

This is mostly equivalent to calling:

(pairwise_distances(X, Y=Y, metric=metric).argmin(axis=axis), pairwise_distances(X, Y=Y, metric=metric).min(axis=axis))

but uses much less memory, and is faster for large arrays.

Parameters **X, Y** : {array-like, sparse matrix}

Arrays containing points. Respective shapes (n_samples1, n_features) and (n_samples2, n_features)

batch_size : integer

To reduce memory consumption over the naive solution, data are processed in batches, comprising batch_size rows of X and batch_size rows of Y. The default value is quite conservative, but can be changed for fine-tuning. The larger the number, the larger the memory usage.

metric : string or callable, default 'euclidean'

metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for metric are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for scipy.spatial.distance for details on these metrics.

metric_kwargs : dict, optional

Keyword arguments to pass to specified metric function.

axis : int, optional, default 1

Axis along which the argmin and distances are to be computed.

Returns **argmin** : numpy.ndarray

Y[argmin[i], :] is the row in Y that is closest to X[i, :].

distances : numpy.ndarray

distances[i] is the distance between the i-th row in X and the argmin[i]-th row in Y.

sklearn.metrics.pairwise_distances, *sklearn.metrics.pairwise_distances_argmin*

sklearn.metrics.pairwise.paired_euclidean_distances

sklearn.metrics.pairwise.**paired_euclidean_distances**(*X*, *Y*)

Computes the paired euclidean distances between X and Y

Read more in the *User Guide*.

Parameters **X** : array-like, shape (n_samples, n_features)

Y : array-like, shape (n_samples, n_features)

Returns **distances** : ndarray (n_samples,)

sklearn.metrics.pairwise.paired_manhattan_distances

sklearn.metrics.pairwise.**paired_manhattan_distances**(*X*, *Y*)

Compute the L1 distances between the vectors in X and Y.

Read more in the *User Guide*.

Parameters **X** : array-like, shape (n_samples, n_features)

Y : array-like, shape (n_samples, n_features)

Returns **distances** : ndarray (n_samples,)

sklearn.metrics.pairwise.paired_cosine_distances

sklearn.metrics.pairwise.**paired_cosine_distances**(*X*, *Y*)

Computes the paired cosine distances between X and Y

Read more in the *User Guide*.

Parameters **X** : array-like, shape (n_samples, n_features)

Y : array-like, shape (n_samples, n_features)

Returns **distances** : ndarray, shape (n_samples,)

Notes

The cosine distance is equivalent to the half the squared euclidean distance if each sample is normalized to unit norm

sklearn.metrics.pairwise.paired_distances

sklearn.metrics.pairwise.**paired_distances**(*X*, *Y*, *metric='euclidean'*, ***kwds*)

Computes the paired distances between X and Y.

Computes the distances between (X[0], Y[0]), (X[1], Y[1]), etc...

Read more in the *User Guide*.

Parameters **X** : ndarray (n_samples, n_features)

Array 1 for distance computation.

Y : ndarray (n_samples, n_features)

Array 2 for distance computation.

metric : string or callable

The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options specified in PAIRED_DISTANCES, including "euclidean", "manhattan", or "cosine". Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

Returns **distances** : ndarray (n_samples,)

See also:

pairwise_distances pairwise distances.

Examples

```
>>> from sklearn.metrics.pairwise import paired_distances
>>> X = [[0, 1], [1, 1]]
>>> Y = [[0, 1], [2, 1]]
>>> paired_distances(X, Y)
array([ 0.,  1.])
```

29.21 sklearn.mixture: Gaussian Mixture Models

The *sklearn.mixture* module implements mixture modeling algorithms.

User guide: See the *Gaussian mixture models* section for further details.

mixture.GaussianMixture([n_components, ...])	Gaussian Mixture.
mixture.BayesianGaussianMixture([...])	Variational Bayesian estimation of a Gaussian mixture.

29.21.1 sklearn.mixture.GaussianMixture

class sklearn.mixture.**GaussianMixture**(*n_components=1*, *covariance_type='full'*, *tol=0.001*, *reg_covar=1e-06*, *max_iter=100*, *n_init=1*, *init_params='kmeans'*, *weights_init=None*, *means_init=None*, *precisions_init=None*, *random_state=None*, *warm_start=False*, *verbose=0*, *verbose_interval=10*)

Gaussian Mixture.

Representation of a Gaussian mixture model probability distribution. This class allows to estimate the parameters of a Gaussian mixture distribution.

New in version 0.18.

GaussianMixture.

Read more in the *User Guide*.

Parameters **n_components** : int, defaults to 1.

The number of mixture components.

covariance_type : {'full', 'tied', 'diag', 'spherical'},

defaults to 'full'.

String describing the type of covariance parameters to use. Must be one of:

```
'full' (each component has its own general covariance matrix),
'tied' (all components share the same general covariance␣
↪matrix),
'diag' (each component has its own diagonal covariance matrix),
'spherical' (each component has its own single variance).
```

tol : float, defaults to 1e-3.

The convergence threshold. EM iterations will stop when the lower bound average gain is below this threshold.

reg_covar : float, defaults to 1e-6.

Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.

max_iter : int, defaults to 100.

The number of EM iterations to perform.

n_init : int, defaults to 1.

The number of initializations to perform. The best results are kept.

init_params : {'kmeans', 'random'}, defaults to 'kmeans'.

The method used to initialize the weights, the means and the precisions. Must be one of:

```
'kmeans' : responsibilities are initialized using kmeans.
'random' : responsibilities are initialized randomly.
```

weights_init : array-like, shape (n_components,), optional

The user-provided initial weights, defaults to None. If it None, weights are initialized using the *init_params* method.

means_init : array-like, shape (n_components, n_features), optional

The user-provided initial means, defaults to None, If it None, means are initialized using the *init_params* method.

precisions_init : array-like, optional.

The user-provided initial precisions (inverse of the covariance matrices), defaults to None. If it None, precisions are initialized using the 'init_params' method. The shape depends on 'covariance_type':

```
(n_components,)                        if 'spherical',
(n_features, n_features)               if 'tied',
(n_components, n_features)             if 'diag',
(n_components, n_features, n_features) if 'full'
```

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

warm_start : bool, default to False.

If 'warm_start' is True, the solution of the last fitting is used as initialization for the next call of fit(). This can speed up convergence when fit is called several time on similar problems.

verbose : int, default to 0.

Enable verbose output. If 1 then it prints the current initialization and each iteration step. If greater than 1 then it prints also the log probability and the time needed for each step.

verbose_interval : int, default to 10.

Number of iteration done before the next print.

Attributes **weights_** : array-like, shape (n_components,)

The weights of each mixture components.

means_ : array-like, shape (n_components, n_features)

The mean of each mixture component.

covariances_ : array-like

The covariance of each mixture component. The shape depends on *covariance_type*:

```
(n_components,)                        if 'spherical',
(n_features, n_features)               if 'tied',
(n_components, n_features)             if 'diag',
(n_components, n_features, n_features) if 'full'
```

precisions_ : array-like

The precision matrices for each component in the mixture. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on *covariance_type*:

```
(n_components,)                        if 'spherical',
(n_features, n_features)               if 'tied',
(n_components, n_features)             if 'diag',
(n_components, n_features, n_features) if 'full'
```

precisions_cholesky_ : array-like

The cholesky decomposition of the precision matrices of each mixture component. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on *covariance_type*:

```
(n_components,)                        if 'spherical',
(n_features, n_features)               if 'tied',
(n_components, n_features)             if 'diag',
(n_components, n_features, n_features) if 'full'
```

converged_ : bool

True when convergence was reached in fit(), False otherwise.

n_iter_ : int

Number of step used by the best fit of EM to reach the convergence.

lower_bound_ : float

Log-likelihood of the best fit of EM.

See also:

BayesianGaussianMixture Gaussian mixture model fit with a variational inference.

Methods

aic(X)	Akaike information criterion for the current model on the input X.
bic(X)	Bayesian information criterion for the current model on the input X.
fit(X[, y])	Estimate model parameters with the EM algorithm.
get_params([deep])	Get parameters for this estimator.
predict(X[, y])	Predict the labels for the data samples in X using trained model.
predict_proba(X)	Predict posterior probability of each component given the data.
sample([n_samples])	Generate random samples from the fitted Gaussian distribution.
score(X[, y])	Compute the per-sample average log-likelihood of the given data X.
score_samples(X)	Compute the weighted log probabilities for each sample.
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_components=1*, *covariance_type='full'*, *tol=0.001*, *reg_covar=1e-06*, *max_iter=100*, *n_init=1*, *init_params='kmeans'*, *weights_init=None*, *means_init=None*, *precisions_init=None*, *random_state=None*, *warm_start=False*, *verbose=0*, *verbose_interval=10*)

aic (*X*)

Akaike information criterion for the current model on the input X.

Parameters **X** : array of shape (n_samples, n_dimensions)

Returns **aic** : float

The lower the better.

bic (*X*)

Bayesian information criterion for the current model on the input X.

Parameters **X** : array of shape (n_samples, n_dimensions)

Returns **bic** : float

The lower the better.

fit (*X*, *y=None*)

Estimate model parameters with the EM algorithm.

The method fit the model *n_init* times and set the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for *max_iter* times until the change of likelihood or lower bound is less than *tol*, otherwise, a *ConvergenceWarning* is raised.

Parameters **X** : array-like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **self** :

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*, *y=None*)
Predict the labels for the data samples in X using trained model.

Parameters **X** : array-like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **labels** : array, shape (n_samples,)

Component labels.

predict_proba(*X*)
Predict posterior probability of each component given the data.

Parameters **X** : array-like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **resp** : array, shape (n_samples, n_components)

Returns the probability of each Gaussian (state) in the model given each sample.

sample(*n_samples=1*)
Generate random samples from the fitted Gaussian distribution.

Parameters **n_samples** : int, optional

Number of samples to generate. Defaults to 1.

Returns **X** : array, shape (n_samples, n_features)

Randomly generated sample

y : array, shape (nsamples,)

Component labels

score(*X*, *y=None*)
Compute the per-sample average log-likelihood of the given data X.

Parameters **X** : array-like, shape (n_samples, n_dimensions)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **log_likelihood** : float

Log likelihood of the Gaussian mixture given X.

score_samples(*X*)
Compute the weighted log probabilities for each sample.

Parameters **X** : array-like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **log_prob** : array, shape (n_samples,)

Log probabilities of each data point in X.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.mixture.GaussianMixture`

- *Comparing different clustering algorithms on toy datasets*
- *Gaussian Mixture Model Ellipsoids*
- *GMM covariances*
- *Density Estimation for a Gaussian mixture*
- *Gaussian Mixture Model Selection*
- *Gaussian Mixture Model Sine Curve*

29.21.2 `sklearn.mixture`.BayesianGaussianMixture

class sklearn.mixture.**BayesianGaussianMixture**(*n_components=1*, *covariance_type='full'*, *tol=0.001*, *reg_covar=1e-06*, *max_iter=100*, *n_init=1*, *init_params='kmeans'*, *weight_concentration_prior_type='dirichlet_process'*, *weight_concentration_prior=None*, *mean_precision_prior=None*, *mean_prior=None*, *degrees_of_freedom_prior=None*, *covariance_prior=None*, *random_state=None*, *warm_start=False*, *verbose=0*, *verbose_interval=10*)

Variational Bayesian estimation of a Gaussian mixture.

This class allows to infer an approximate posterior distribution over the parameters of a Gaussian mixture distribution. The effective number of components can be inferred from the data.

This class implements two types of prior for the weights distribution: a finite mixture model with Dirichlet distribution and an infinite mixture model with the Dirichlet Process. In practice Dirichlet Process inference algorithm is approximated and uses a truncated distribution with a fixed maximum number of components (called the Stick-breaking representation). The number of components actually used almost always depends on the data.

New in version 0.18.

BayesianGaussianMixture.

Read more in the *User Guide*.

Parameters **n_components** : int, defaults to 1.

The number of mixture components. Depending on the data and the value of the *weight_concentration_prior* the model can decide to not use all the components by setting some component *weights_* to values very close to zero. The number of effective components is therefore smaller than n_components.

covariance_type : {'full', 'tied', 'diag', 'spherical'}, defaults to 'full'

String describing the type of covariance parameters to use. Must be one of:

```
'full' (each component has its own general covariance matrix),
'tied' (all components share the same general covariance␣
↪matrix),
'diag' (each component has its own diagonal covariance matrix),
'spherical' (each component has its own single variance).
```

tol : float, defaults to 1e-3.

The convergence threshold. EM iterations will stop when the lower bound average gain on the likelihood (of the training data with respect to the model) is below this threshold.

reg_covar : float, defaults to 1e-6.

Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.

max_iter : int, defaults to 100.

The number of EM iterations to perform.

n_init : int, defaults to 1.

The number of initializations to perform. The result with the highest lower bound value on the likelihood is kept.

init_params : {'kmeans', 'random'}, defaults to 'kmeans'.

The method used to initialize the weights, the means and the covariances. Must be one of:

```
'kmeans' : responsibilities are initialized using kmeans.
'random' : responsibilities are initialized randomly.
```

weight_concentration_prior_type : str, defaults to 'dirichlet_process'.

String describing the type of the weight concentration prior. Must be one of:

```
'dirichlet_process' (using the Stick-breaking representation),
'dirichlet_distribution' (can favor more uniform weights).
```

weight_concentration_prior : float | None, optional.

The dirichlet concentration of each component on the weight distribution (Dirichlet). The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of the mixture weights simplex. The value of the parameter must be greater than 0. If it is None, it's set to `1. / n_components`.

mean_precision_prior : float | None, optional.

The precision prior on the mean distribution (Gaussian). Controls the extend to where means can be placed. Smaller values concentrate the means of each clusters around *mean_prior*. The value of the parameter must be greater than 0. If it is None, it's set to 1.

mean_prior : array-like, shape (n_features,), optional

The prior on the mean distribution (Gaussian). If it is None, it's set to the mean of X.

degrees_of_freedom_prior : float | None, optional.

The prior of the number of degrees of freedom on the covariance distributions (Wishart). If it is None, it's set to *n_features*.

covariance_prior : float or array-like, optional

The prior on the covariance distribution (Wishart). If it is None, the emiprical covariance prior is initialized using the covariance of X. The shape depends on *covariance_type*:

```
(n_features, n_features) if 'full',
(n_features, n_features) if 'tied',
(n_features)             if 'diag',
float                    if 'spherical'
```

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

warm_start : bool, default to False.

If 'warm_start' is True, the solution of the last fitting is used as initialization for the next call of fit(). This can speed up convergence when fit is called several time on similar problems.

verbose : int, default to 0.

Enable verbose output. If 1 then it prints the current initialization and each iteration step. If greater than 1 then it prints also the log probability and the time needed for each step.

verbose_interval : int, default to 10.

Number of iteration done before the next print.

Attributes **weights_** : array-like, shape (n_components,)

The weights of each mixture components.

means_ : array-like, shape (n_components, n_features)

The mean of each mixture component.

covariances_ : array-like

The covariance of each mixture component. The shape depends on *covariance_type*:

```
(n_components,)                        if 'spherical',
(n_features, n_features)               if 'tied',
(n_components, n_features)             if 'diag',
(n_components, n_features, n_features) if 'full'
```

precisions_ : array-like

The precision matrices for each component in the mixture. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:

```
(n_components,)                        if 'spherical',
(n_features, n_features)               if 'tied',
(n_components, n_features)             if 'diag',
(n_components, n_features, n_features) if 'full'
```

precisions_cholesky_ : array-like

The cholesky decomposition of the precision matrices of each mixture component. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:

```
(n_components,)                        if 'spherical',
(n_features, n_features)               if 'tied',
(n_components, n_features)             if 'diag',
(n_components, n_features, n_features) if 'full'
```

converged_ : bool

True when convergence was reached in fit(), False otherwise.

n_iter_ : int

Number of step used by the best fit of inference to reach the convergence.

lower_bound_ : float

Lower bound value on the likelihood (of the training data with respect to the model) of the best fit of inference.

weight_concentration_prior_ : tuple or float

The dirichlet concentration of each component on the weight distribution (Dirichlet). The type depends on `weight_concentration_prior_type`:

```
(float, float) if 'dirichlet_process' (Beta parameters),
float          if 'dirichlet_distribution' (Dirichlet␣
↪parameters).
```

The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of the simplex.

weight_concentration_ : array-like, shape (n_components,)

The dirichlet concentration of each component on the weight distribution (Dirichlet).

mean_precision_prior : float

The precision prior on the mean distribution (Gaussian). Controls the extend to where means can be placed. Smaller values concentrate the means of each clusters around *mean_prior*.

mean_precision_ : array-like, shape (n_components,)

The precision of each components on the mean distribution (Gaussian).

means_prior_ : array-like, shape (n_features,)

The prior on the mean distribution (Gaussian).

degrees_of_freedom_prior_ : float

The prior of the number of degrees of freedom on the covariance distributions (Wishart).

degrees_of_freedom_ : array-like, shape (n_components,)

The number of degrees of freedom of each components in the model.

covariance_prior_ : float or array-like

The prior on the covariance distribution (Wishart). The shape depends on *covariance_type*:

```
(n_features, n_features) if 'full',
(n_features, n_features) if 'tied',
(n_features)             if 'diag',
float                    if 'spherical'
```

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **self** :

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*, *y=None*)

Predict the labels for the data samples in X using trained model.

Parameters **X** : array-like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **labels** : array, shape (n_samples,)

Component labels.

predict_proba (*X*)

Predict posterior probability of each component given the data.

Parameters **X** : array-like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **resp** : array, shape (n_samples, n_components)

Returns the probability of each Gaussian (state) in the model given each sample.

sample (*n_samples=1*)

Generate random samples from the fitted Gaussian distribution.

Parameters **n_samples** : int, optional

Number of samples to generate. Defaults to 1.

Returns **X** : array, shape (n_samples, n_features)

Randomly generated sample

y : array, shape (nsamples,)

Component labels

score (*X*, *y=None*)
Compute the per-sample average log-likelihood of the given data X.

Parameters **X** : array-like, shape (n_samples, n_dimensions)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **log_likelihood** : float

Log likelihood of the Gaussian mixture given X.

score_samples (*X*)
Compute the weighted log probabilities for each sample.

Parameters **X** : array-like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **log_prob** : array, shape (n_samples,)

Log probabilities of each data point in X.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.mixture.BayesianGaussianMixture`

- *Concentration Prior Type Analysis of Variation Bayesian Gaussian Mixture*
- *Gaussian Mixture Model Ellipsoids*
- *Gaussian Mixture Model Sine Curve*

29.22 `sklearn.multiclass`: Multiclass and multilabel classification

29.22.1 Multiclass and multilabel classification strategies

This module implements multiclass learning algorithms:

- one-vs-the-rest / one-vs-all
- one-vs-one
- error correcting output codes

The estimators provided in this module are meta-estimators: they require a base estimator to be provided in their constructor. For example, it is possible to use these estimators to turn a binary classifier or a regressor into a multiclass classifier. It is also possible to use these estimators with multiclass estimators in the hope that their accuracy or runtime performance improves.

All classifiers in scikit-learn implement multiclass classification; you only need to use this module if you want to experiment with custom multiclass strategies.

The one-vs-the-rest meta-classifier also implements a *predict_proba* method, so long as such a method is implemented by the base classifier. This method returns probabilities of class membership in both the single label and multilabel case. Note that in the multilabel case, probabilities are the marginal probability that a given sample falls in the given class. As such, in the multilabel case the sum of these probabilities over all possible labels for a given sample *will not* sum to unity, as they do in the single label case.

User guide: See the *Multiclass and multilabel algorithms* section for further details.

`multiclass.OneVsRestClassifier`(estimator[, ...])	One-vs-the-rest (OvR) multiclass/multilabel strategy
`multiclass.OneVsOneClassifier`(estimator[, ...])	One-vs-one multiclass strategy
`multiclass.OutputCodeClassifier`(estimator[, ...])	(Error-Correcting) Output-Code multiclass strategy

29.22.2 sklearn.multiclass.OneVsRestClassifier

class sklearn.multiclass.**OneVsRestClassifier**(*estimator*, *n_jobs=1*)

One-vs-the-rest (OvR) multiclass/multilabel strategy

Also known as one-vs-all, this strategy consists in fitting one classifier per class. For each classifier, the class is fitted against all the other classes. In addition to its computational efficiency (only *n_classes* classifiers are needed), one advantage of this approach is its interpretability. Since each class is represented by one and one classifier only, it is possible to gain knowledge about the class by inspecting its corresponding classifier. This is the most commonly used strategy for multiclass classification and is a fair default choice.

This strategy can also be used for multilabel learning, where a classifier is used to predict multiple labels for instance, by fitting on a 2-d matrix in which cell [i, j] is 1 if sample i has label j and 0 otherwise.

In the multilabel learning literature, OvR is also known as the binary relevance method.

Read more in the *User Guide*.

Parameters **estimator** : estimator object

An estimator object implementing *fit* and one of *decision_function* or *predict_proba*.

n_jobs : int, optional, default: 1

The number of jobs to use for the computation. If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

Attributes **estimators_** : list of *n_classes* estimators

Estimators used for predictions.

classes_ : array, shape = [*n_classes*]

Class labels.

label_binarizer_ : LabelBinarizer object

Object used to transform multiclass labels to binary labels and vice-versa.

multilabel_ : boolean

Whether a OneVsRestClassifier is a multilabel classifier.

Methods

decision_function(X)	Returns the distance of each sample from the decision boundary for each class.
fit(X, y)	Fit underlying estimators.
get_params([deep])	Get parameters for this estimator.
partial_fit(X, y[, classes])	Partially fit underlying estimators
predict(X)	Predict multi-class targets using underlying estimators.
predict_proba(X)	Probability estimates.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*estimator*, *n_jobs=1*)

decision_function (*X*)
Returns the distance of each sample from the decision boundary for each class. This can only be used with estimators which implement the decision_function method.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **T** : array-like, shape = [n_samples, n_classes]

fit (*X*, *y*)
Fit underlying estimators.

Parameters **X** : (sparse) array-like, shape = [n_samples, n_features]

Data.

y : (sparse) array-like, shape = [n_samples,], [n_samples, n_classes]

Multi-class targets. An indicator matrix turns on multilabel classification.

Returns **self** :

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

multilabel_
Whether this is a multilabel classifier

partial_fit (*X*, *y*, *classes=None*)
Partially fit underlying estimators

Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration.

Parameters **X** : (sparse) array-like, shape = [n_samples, n_features]

Data.

y : (sparse) array-like, shape = [n_samples,], [n_samples, n_classes]

Multi-class targets. An indicator matrix turns on multilabel classification.

classes : array, shape (n_classes,)

Classes across all calls to partial_fit. Can be obtained via *np.unique(y_all)*, where y_all is the target vector of the entire dataset. This argument is only required in the first call of partial_fit and can be omitted in the subsequent calls.

Returns **self** :

predict(*X*)

Predict multi-class targets using underlying estimators.

Parameters **X** : (sparse) array-like, shape = [n_samples, n_features]

Data.

Returns **y** : (sparse) array-like, shape = [n_samples,], [n_samples, n_classes].

Predicted multi-class targets.

predict_proba(*X*)

Probability estimates.

The returned estimates for all classes are ordered by label of classes.

Note that in the multilabel case, each sample can have any number of labels. This returns the marginal probability that the given sample has the label in question. For example, it is entirely consistent that two labels both have a 90% probability of applying to a given sample.

In the single label multiclass case, the rows of the returned matrix sum to 1.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **T** : (sparse) array-like, shape = [n_samples, n_classes]

Returns the probability of the sample for each class in the model, where classes are ordered as they are in *self.classes_*.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.multiclass.OneVsRestClassifier`

- *Multilabel classification*
- *Precision-Recall*
- *Receiver Operating Characteristic (ROC)*

29.22.3 `sklearn.multiclass.OneVsOneClassifier`

class `sklearn.multiclass.`**`OneVsOneClassifier`**(*estimator*, *n_jobs=1*)

One-vs-one multiclass strategy

This strategy consists in fitting one classifier per class pair. At prediction time, the class which received the most votes is selected. Since it requires to fit *n_classes * (n_classes - 1) / 2* classifiers, this method is usually slower than one-vs-the-rest, due to its O(n_classes^2) complexity. However, this method may be advantageous for algorithms such as kernel algorithms which don't scale well with *n_samples*. This is because each individual learning problem only involves a small subset of the data whereas, with one-vs-the-rest, the complete dataset is used *n_classes* times.

Read more in the *User Guide*.

Parameters **estimator** : estimator object

An estimator object implementing *fit* and one of *decision_function* or *predict_proba*.

n_jobs : int, optional, default: 1

The number of jobs to use for the computation. If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

Attributes **estimators_** : list of *n_classes * (n_classes - 1) / 2* estimators

Estimators used for predictions.

classes_ : numpy array of shape [n_classes]

Array containing labels.

Methods

decision_function(X)	Decision function for the OneVsOneClassifier.
fit(X, y)	Fit underlying estimators.
get_params([deep])	Get parameters for this estimator.
partial_fit(X, y[, classes])	Partially fit underlying estimators
predict(X)	Estimate the best class label for each sample in X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

`__init__`(*estimator*, *n_jobs=1*)

`decision_function`(*X*)

Decision function for the OneVsOneClassifier.

The decision values for the samples are computed by adding the normalized sum of pair-wise classification confidence levels to the votes in order to disambiguate between the decision values when the votes for all

the classes are equal leading to a tie.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **Y** : array-like, shape = [n_samples, n_classes]

fit(*X*, *y*)
Fit underlying estimators.

Parameters **X** : (sparse) array-like, shape = [n_samples, n_features]

Data.

y : array-like, shape = [n_samples]

Multi-class targets.

Returns **self** :

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

partial_fit(*X*, *y*, *classes=None*)
Partially fit underlying estimators

Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration, where the first call should have an array of all target variables.

Parameters **X** : (sparse) array-like, shape = [n_samples, n_features]

Data.

y : array-like, shape = [n_samples]

Multi-class targets.

classes : array, shape (n_classes,)

Classes across all calls to partial_fit. Can be obtained via *np.unique(y_all)*, where y_all is the target vector of the entire dataset. This argument is only required in the first call of partial_fit and can be omitted in the subsequent calls.

Returns **self** :

predict(*X*)
Estimate the best class label for each sample in X.

This is implemented as `argmax(decision_function(X), axis=1)` which will return the label of the class with most votes by estimators predicting the outcome of a decision for each possible class pair.

Parameters **X** : (sparse) array-like, shape = [n_samples, n_features]

Data.

Returns **y** : numpy array of shape [n_samples]

Predicted multi-class targets.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.22.4 sklearn.multiclass.OutputCodeClassifier

class sklearn.multiclass.**OutputCodeClassifier**(*estimator*, *code_size=1.5*, *random_state=None*, *n_jobs=1*)

(Error-Correcting) Output-Code multiclass strategy

Output-code based strategies consist in representing each class with a binary code (an array of 0s and 1s). At fitting time, one binary classifier per bit in the code book is fitted. At prediction time, the classifiers are used to project new points in the class space and the class closest to the points is chosen. The main advantage of these strategies is that the number of classifiers used can be controlled by the user, either for compressing the model (0 < code_size < 1) or for making the model more robust to errors (code_size > 1). See the documentation for more details.

Read more in the *User Guide*.

Parameters **estimator** : estimator object

An estimator object implementing *fit* and one of *decision_function* or *predict_proba*.

code_size : float

Percentage of the number of classes to be used to create the code book. A number between 0 and 1 will require fewer classifiers than one-vs-the-rest. A number greater than 1 will require more classifiers than one-vs-the-rest.

random_state : int, RandomState instance or None, optional, default: None

The generator used to initialize the codebook. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

n_jobs : int, optional, default: 1

The number of jobs to use for the computation. If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

Attributes **estimators_** : list of *int(n_classes * code_size)* estimators

Estimators used for predictions.

classes_ : numpy array of shape [n_classes]

Array containing labels.

code_book_ : numpy array of shape [n_classes, code_size]

Binary array containing the code of each class.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.23 sklearn.multioutput: Multioutput regression and classification

This module implements multioutput regression and classification.

The estimators provided in this module are meta-estimators: they require a base estimator to be provided in their constructor. The meta-estimator extends single output estimators to multioutput estimators.

User guide: See the *Multiclass and multilabel algorithms* section for further details.

multioutput.MultiOutputRegressor(estimator)	Multi target regression
multioutput.MultiOutputClassifier(estimator)	Multi target classification

29.23.1 sklearn.multioutput.MultiOutputRegressor

class sklearn.multioutput.**MultiOutputRegressor**(*estimator*, *n_jobs=1*)

Multi target regression

This strategy consists of fitting one regressor per target. This is a simple strategy for extending regressors that do not natively support multi-target regression.

Parameters **estimator** : estimator object

An estimator object implementing *fit* and *predict*.

n_jobs : int, optional, default=1

The number of jobs to run in parallel for *fit*. If -1, then the number of jobs is set to the number of cores. When individual estimators are fast to train or predict using *n_jobs>1* can result in slower performance due to the overhead of spawning processes.

Methods

fit(X, y[, sample_weight])	Fit the model to data.
get_params([deep])	Get parameters for this estimator.
partial_fit(X, y[, sample_weight])	Incrementally fit the model to data.
predict(X)	Predict multi-output variable using a model trained for each target variable.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*estimator*, *n_jobs=1*)

fit (*X*, *y*, *sample_weight=None*)
Fit the model to data. Fit a separate model for each output variable.

Parameters **X** : (sparse) array-like, shape (n_samples, n_features)

Data.

y : (sparse) array-like, shape (n_samples, n_outputs)

Multi-output targets. An indicator matrix turns on multilabel estimation.

sample_weight : array-like, shape = (n_samples) or None

Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

Returns **self** : object

Returns self.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

partial_fit (*X*, *y*, *sample_weight=None*)
Incrementally fit the model to data. Fit a separate model for each output variable.

Parameters **X** : (sparse) array-like, shape (n_samples, n_features)

Data.

y : (sparse) array-like, shape (n_samples, n_outputs)

Multi-output targets.

sample_weight : array-like, shape = (n_samples) or None

Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

Returns **self** : object

Returns self.

predict(*X*)

Predict multi-output variable using a model trained for each target variable.

Parameters **X** : (sparse) array-like, shape (n_samples, n_features)

Data.

Returns **y** : (sparse) array-like, shape (n_samples, n_outputs)

Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the regression sum of squares ((y_true - y_pred) ** 2).sum() and v is the residual sum of squares ((y_true - y_true.mean()) ** 2).sum(). Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape (n_samples, n_features)

Test samples.

y : array-like, shape (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

Notes

R^2 is calculated by weighting all the targets equally using *multioutput='uniform_average'*.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.multioutput.MultiOutputRegressor`

- *Comparing random forests and the multi-output meta estimator*

29.23.2 `sklearn.multioutput`.MultiOutputClassifier

class `sklearn.multioutput.`**`MultiOutputClassifier`**(*estimator*, *n_jobs=1*)

Multi target classification

This strategy consists of fitting one classifier per target. This is a simple strategy for extending classifiers that do not natively support multi-target classification

Parameters **estimator** : estimator object

An estimator object implementing *fit*, *score* and *predict_proba*.

n_jobs : int, optional, default=1

The number of jobs to use for the computation. If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used. The number of jobs to use for the computation. It does each target variable in y in parallel.

Attributes **estimators_** : list of *n_output* estimators

Estimators used for predictions.

Methods

fit(X, y[, sample_weight])	Fit the model to data.
get_params([deep])	Get parameters for this estimator.
partial_fit(X, y[, classes, sample_weight])	Incrementally fit the model to data.
predict(X)	Predict multi-output variable using a model trained for each target variable.
predict_proba(X)	Probability estimates.
score(X, y)	“Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

`__init__`(*estimator*, *n_jobs=1*)

`fit`(*X*, *y*, *sample_weight=None*)

Fit the model to data. Fit a separate model for each output variable.

Parameters **X** : (sparse) array-like, shape (n_samples, n_features)

Data.

y : (sparse) array-like, shape (n_samples, n_outputs)

Multi-output targets. An indicator matrix turns on multilabel estimation.

sample_weight : array-like, shape = (n_samples) or None

Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

Returns **self** : object

Returns self.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

partial_fit(*X*, *y*, *classes=None*, *sample_weight=None*)

Incrementally fit the model to data. Fit a separate model for each output variable.

Parameters **X** : (sparse) array-like, shape (n_samples, n_features)

Data.

y : (sparse) array-like, shape (n_samples, n_outputs)

Multi-output targets.

classes : list of numpy arrays, shape (n_outputs)

Each array is unique classes for one output in str/int Can be obtained by via `[np.unique(y[:, i]) for i in range(y.shape[1])]`, where y is the target matrix of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn't need to contain all labels in *classes*.

sample_weight : array-like, shape = (n_samples) or None

Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

Returns **self** : object

Returns self.

predict(*X*)

Predict multi-output variable using a model trained for each target variable.

Parameters **X** : (sparse) array-like, shape (n_samples, n_features)

Data.

Returns **y** : (sparse) array-like, shape (n_samples, n_outputs)

Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.

predict_proba(*X*)

Probability estimates. Returns prediction probabilites for each class of each output.

Parameters **X** : array-like, shape (n_samples, n_features)

Data

Returns **p** : array of shape = [n_samples, n_classes], or a list of n_outputs such arrays if n_outputs > 1.

The class probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

score (*X*, *y*)

"Returns the mean accuracy on the given test data and labels.

Parameters **X** : array-like, shape [n_samples, n_features]

Test samples

y : array-like, shape [n_samples, n_outputs]

True values for X

Returns **scores** : float

accuracy_score of self.predict(X) versus y

set_params (***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.24 sklearn.naive_bayes: Naive Bayes

The *sklearn.naive_bayes* module implements Naive Bayes algorithms. These are supervised learning methods based on applying Bayes' theorem with strong (naive) feature independence assumptions.

User guide: See the *Naive Bayes* section for further details.

naive_bayes.GaussianNB([priors])	Gaussian Naive Bayes (GaussianNB)
naive_bayes.MultinomialNB([alpha, ...])	Naive Bayes classifier for multinomial models
naive_bayes.BernoulliNB([alpha, binarize, ...])	Naive Bayes classifier for multivariate Bernoulli models.

29.24.1 sklearn.naive_bayes.GaussianNB

class sklearn.naive_bayes.**GaussianNB** (*priors=None*)

Gaussian Naive Bayes (GaussianNB)

Can perform online updates to model parameters via *partial_fit* method. For details on algorithm used to update feature means and variance online, see Stanford CS tech report STAN-CS-79-773 by Chan, Golub, and LeVeque:

http://i.stanford.edu/pub/cstr/reports/cs/tr/79/773/CS-TR-79-773.pdf

Read more in the *User Guide*.

Parameters **priors** : array-like, shape (n_classes,)

Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

Attributes **class_prior_** : array, shape (n_classes,)

probability of each class.

class_count_ : array, shape (n_classes,)

number of training samples observed in each class.

theta_ : array, shape (n_classes, n_features)

mean of each feature per class

sigma_ : array, shape (n_classes, n_features)

variance of each feature per class

Examples

```
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> Y = np.array([1, 1, 1, 2, 2, 2])
>>> from sklearn.naive_bayes import GaussianNB
>>> clf = GaussianNB()
>>> clf.fit(X, Y)
GaussianNB(priors=None)
>>> print(clf.predict([[-0.8, -1]]))
[1]
>>> clf_pf = GaussianNB()
>>> clf_pf.partial_fit(X, Y, np.unique(Y))
GaussianNB(priors=None)
>>> print(clf_pf.predict([[-0.8, -1]]))
[1]
```

Methods

fit(X, y[, sample_weight])	Fit Gaussian Naive Bayes according to X, y
get_params([deep])	Get parameters for this estimator.
partial_fit(X, y[, classes, sample_weight])	Incremental fit on a batch of samples.
predict(X)	Perform classification on an array of test vectors X.
predict_log_proba(X)	Return log-probability estimates for the test vector X.
predict_proba(X)	Return probability estimates for the test vector X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*priors=None*)

fit (*X*, *y*, *sample_weight=None*)

Fit Gaussian Naive Bayes according to X, y

Parameters **X** : array-like, shape (n_samples, n_features)

Training vectors, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape (n_samples,)

Target values.

sample_weight : array-like, shape (n_samples,), optional (default=None)

Weights applied to individual samples (1. for unweighted).

New in version 0.17: Gaussian Naive Bayes supports fitting with *sample_weight*.

Returns **self** : object

Returns self.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

partial_fit(*X*, *y*, *classes=None*, *sample_weight=None*)
Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance and numerical stability overhead, hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

Parameters **X** : array-like, shape (n_samples, n_features)

Training vectors, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape (n_samples,)

Target values.

classes : array-like, shape (n_classes,), optional (default=None)

List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

sample_weight : array-like, shape (n_samples,), optional (default=None)

Weights applied to individual samples (1. for unweighted).

New in version 0.17.

Returns **self** : object

Returns self.

predict(*X*)
Perform classification on an array of test vectors X.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array, shape = [n_samples]

Predicted target values for X

predict_log_proba(*X*)
Return log-probability estimates for the test vector X.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array-like, shape = [n_samples, n_classes]

Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*.

predict_proba(*X*)
Return probability estimates for the test vector X.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array-like, shape = [n_samples, n_classes]

Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*.

score(*X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.naive_bayes.GaussianNB`

- *Probability calibration of classifiers*
- *Probability Calibration curves*
- *Comparison of Calibration of Classifiers*
- *Classifier comparison*
- *Plot class probabilities calculated by the VotingClassifier*
- *Plotting Learning Curves*
- *Importance of Feature Scaling*

29.24.2 sklearn.naive_bayes.MultinomialNB

class sklearn.naive_bayes.**MultinomialNB**(*alpha=1.0*, *fit_prior=True*, *class_prior=None*)
Naive Bayes classifier for multinomial models

The multinomial Naive Bayes classifier is suitable for classification with discrete features (e.g., word counts for text classification). The multinomial distribution normally requires integer feature counts. However, in practice, fractional counts such as tf-idf may also work.

Read more in the *User Guide*.

Parameters **alpha** : float, optional (default=1.0)

Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

fit_prior : boolean, optional (default=True)

Whether to learn class prior probabilities or not. If false, a uniform prior will be used.

class_prior : array-like, size (n_classes,), optional (default=None)

Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

Attributes **class_log_prior_** : array, shape (n_classes,)

Smoothed empirical log probability for each class.

intercept_ : property

Mirrors `class_log_prior_` for interpreting MultinomialNB as a linear model.

feature_log_prob_ : array, shape (n_classes, n_features)

Empirical log probability of features given a class, `P(x_i|y)`.

coef_ : property

Mirrors `feature_log_prob_` for interpreting MultinomialNB as a linear model.

class_count_ : array, shape (n_classes,)

Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

feature_count_ : array, shape (n_classes, n_features)

Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.

Notes

For the rationale behind the names *coef_* and *intercept_*, i.e. naive Bayes as a linear classifier, see J. Rennie et al. (2003), Tackling the poor assumptions of naive Bayes text classifiers, ICML.

Examples

```
>>> import numpy as np
>>> X = np.random.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import MultinomialNB
>>> clf = MultinomialNB()
>>> clf.fit(X, y)
MultinomialNB(alpha=1.0, class_prior=None, fit_prior=True)
>>> print(clf.predict(X[2:3]))
[3]
```

Methods

fit(X, y[, sample_weight])	Fit Naive Bayes classifier according to X, y
get_params([deep])	Get parameters for this estimator.
partial_fit(X, y[, classes, sample_weight])	Incremental fit on a batch of samples.
predict(X)	Perform classification on an array of test vectors X.
predict_log_proba(X)	Return log-probability estimates for the test vector X.
predict_proba(X)	Return probability estimates for the test vector X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*alpha=1.0*, *fit_prior=True*, *class_prior=None*)

fit (*X*, *y*, *sample_weight=None*)
Fit Naive Bayes classifier according to X, y

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training vectors, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples]

Target values.

sample_weight : array-like, shape = [n_samples], (default=None)

Weights applied to individual samples (1. for unweighted).

Returns **self** : object

Returns self.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

partial_fit(*X*, *y*, *classes=None*, *sample_weight=None*)
Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training vectors, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples]

Target values.

classes : array-like, shape = [n_classes] (default=None)

List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

sample_weight : array-like, shape = [n_samples] (default=None)

Weights applied to individual samples (1. for unweighted).

Returns **self** : object

Returns self.

predict(*X*)
Perform classification on an array of test vectors X.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array, shape = [n_samples]

Predicted target values for X

predict_log_proba(*X*)
Return log-probability estimates for the test vector X.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array-like, shape = [n_samples, n_classes]

Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*.

predict_proba(*X*)
Return probability estimates for the test vector X.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array-like, shape = [n_samples, n_classes]

Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*.

score(*X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.naive_bayes.MultinomialNB`

- *Out-of-core classification of text documents*
- *Classification of text documents using sparse features*

29.24.3 `sklearn.naive_bayes.BernoulliNB`

class `sklearn.naive_bayes.`**BernoulliNB**(*alpha=1.0*, *binarize=0.0*, *fit_prior=True*, *class_prior=None*)

Naive Bayes classifier for multivariate Bernoulli models.

Like MultinomialNB, this classifier is suitable for discrete data. The difference is that while MultinomialNB works with occurrence counts, BernoulliNB is designed for binary/boolean features.

Read more in the *User Guide*.

Parameters **alpha** : float, optional (default=1.0)

Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

binarize : float or None, optional (default=0.0)

Threshold for binarizing (mapping to booleans) of sample features. If None, input is presumed to already consist of binary vectors.

fit_prior : boolean, optional (default=True)

Whether to learn class prior probabilities or not. If false, a uniform prior will be used.

class_prior : array-like, size=[n_classes,], optional (default=None)

Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

Attributes **class_log_prior_** : array, shape = [n_classes]

Log probability of each class (smoothed).

feature_log_prob_ : array, shape = [n_classes, n_features]

Empirical log probability of features given a class, P(x_i|y).

class_count_ : array, shape = [n_classes]

Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

feature_count_ : array, shape = [n_classes, n_features]

Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.

Training vectors, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples]

Target values.

classes : array-like, shape = [n_classes] (default=None)

List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

sample_weight : array-like, shape = [n_samples] (default=None)

Weights applied to individual samples (1. for unweighted).

Returns **self** : object

Returns self.

predict(*X*)

Perform classification on an array of test vectors X.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array, shape = [n_samples]

Predicted target values for X

predict_log_proba(*X*)
Return log-probability estimates for the test vector X.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array-like, shape = [n_samples, n_classes]

Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*.

predict_proba(*X*)
Return probability estimates for the test vector X.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array-like, shape = [n_samples, n_classes]

Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*.

score(*X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.naive_bayes.BernoulliNB`

- *Hashing feature transformation using Totally Random Trees*
- *Classification of text documents using sparse features*

29.25 `sklearn.neighbors`: Nearest Neighbors

The `sklearn.neighbors` module implements the k-nearest neighbors algorithm.

User guide: See the *Nearest Neighbors* section for further details.

neighbors.NearestNeighbors([n_neighbors, ...])	Unsupervised learner for implementing neighbor searches.
neighbors.KNeighborsClassifier([...])	Classifier implementing the k-nearest neighbors vote.
neighbors.RadiusNeighborsClassifier([...])	Classifier implementing a vote among neighbors within a given radius
neighbors.KNeighborsRegressor([n_neighbors, ...])	Regression based on k-nearest neighbors.
neighbors.RadiusNeighborsRegressor([radius, ...])	Regression based on neighbors within a fixed radius.
neighbors.NearestCentroid([metric, ...])	Nearest centroid classifier.
neighbors.BallTree	BallTree for fast generalized N-point problems
neighbors.KDTree	KDTree for fast generalized N-point problems
neighbors.DistanceMetric	DistanceMetric class
neighbors.KernelDensity([bandwidth, ...])	Kernel Density Estimation
neighbors.LocalOutlierFactor([n_neighbors, ...])	Unsupervised Outlier Detection using Local Outlier Factor (LOF)

29.25.1 sklearn.neighbors.NearestNeighbors

class sklearn.neighbors.**NearestNeighbors**(*n_neighbors=5*, *radius=1.0*, *algorithm='auto'*, *leaf_size=30*, *metric='minkowski'*, *p=2*, *metric_params=None*, *n_jobs=1*, ***kwargs*)

Unsupervised learner for implementing neighbor searches.

Read more in the *User Guide*.

Parameters **n_neighbors** : int, optional (default = 5)

Number of neighbors to use by default for *kneighbors* queries.

radius : float, optional (default = 1.0)

Range of parameter space to use by default for *radius_neighbors* queries.

algorithm : {'auto', 'ball_tree', 'kd_tree', 'brute'}, optional

Algorithm used to compute the nearest neighbors:

- 'ball_tree' will use *BallTree*
- 'kd_tree' will use *KDTree*
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size : int, optional (default = 30)

Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p : integer, optional (default = 2)

Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric : string or callable, default 'minkowski'

metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for metric are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for scipy.spatial.distance for details on these metrics.

metric_params : dict, optional (default = None)

Additional keyword arguments for the metric function.

n_jobs : int, optional (default = 1)

The number of parallel jobs to run for neighbors search. If `-1`, then the number of jobs is set to the number of CPU cores. Affects only *kneighbors* and *kneighbors_graph* methods.

See also:

KNeighborsClassifier, *RadiusNeighborsClassifier*, *KNeighborsRegressor*, *RadiusNeighborsRegressor*, *BallTree*

Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of `algorithm` and `leaf_size`.

https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm

Examples

```
>>> import numpy as np
>>> from sklearn.neighbors import NearestNeighbors
>>> samples = [[0, 0, 2], [1, 0, 0], [0, 0, 1]]
```

```
>>> neigh = NearestNeighbors(2, 0.4)
>>> neigh.fit(samples)
NearestNeighbors(...)
```

```
>>> neigh.kneighbors([[0, 0, 1.3]], 2, return_distance=False)
...
array([[2, 0]]...)
```

```
>>> nbrs = neigh.radius_neighbors([[0, 0, 1.3]], 0.4, return_distance=False)
>>> np.asarray(nbrs[0][0])
array(2)
```

Methods

fit(X[, y])	Fit the model using X as training data
get_params([deep])	Get parameters for this estimator.
kneighbors([X, n_neighbors, return_distance])	Finds the K-neighbors of a point.
kneighbors_graph([X, n_neighbors, mode])	Computes the (weighted) graph of k-Neighbors for points in X
radius_neighbors([X, radius, return_distance])	Finds the neighbors within a given radius of a point or points.
radius_neighbors_graph([X, radius, mode])	Computes the (weighted) graph of Neighbors for points in X
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_neighbors=5*, *radius=1.0*, *algorithm='auto'*, *leaf_size=30*, *metric='minkowski'*, *p=2*, *metric_params=None*, *n_jobs=1*, ***kwargs*)

fit (*X*, *y=None*)
Fit the model using X as training data

Parameters **X** : {array-like, sparse matrix, BallTree, KDTree}

Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

kneighbors (*X=None*, *n_neighbors=None*, *return_distance=True*)
Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

Parameters **X** : array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors : int

Number of neighbors to get (default is the value passed to the constructor).

return_distance : boolean, optional. Defaults to True.

If False, distances will not be returned

Returns **dist** : array

Array representing the lengths to points, only present if return_distance=True

ind : array

Indices of the nearest points in the population matrix.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who's the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[ 0.5]]), array([[2]]...))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]]...)
```

kneighbors_graph (*X=None*, *n_neighbors=None*, *mode='connectivity'*)

Computes the (weighted) graph of k-Neighbors for points in X

Parameters **X** : array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors : int

Number of neighbors for each sample. (default is value passed to the constructor).

mode : {'connectivity', 'distance'}, optional

Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

Returns **A** : sparse matrix in CSR format, shape = [n_samples, n_samples_fit]

n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

NearestNeighbors.radius_neighbors_graph

Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[ 1.,  0.,  1.],
       [ 0.,  1.,  1.],
       [ 1.,  0.,  1.]])
```

radius_neighbors(*X=None*, *radius=None*, *return_distance=True*)

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size `radius` around the points of the query array. Points lying on the boundary are included in the results.

The result points are *not* necessarily sorted by distance to their query point.

Parameters **X** : array-like, (n_samples, n_features), optional

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius : float

Limiting distance of neighbors to return. (default is the value passed to the constructor).

return_distance : boolean, optional. Defaults to True.

If False, distances will not be returned

Returns **dist** : array, shape (n_samples,) of arrays

Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the `metric` constructor parameter.

ind : array, shape (n_samples,) of arrays

An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size `radius` around the query points.

Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, *radius_neighbors* returns arrays of objects, where each object is a 1D array of indices or distances.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who's the closest point to [1, 1, 1]:

```
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
```

```
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[ 1.5  0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

radius_neighbors_graph (*X=None*, *radius=None*, *mode='connectivity'*)

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

Parameters **X** : array-like, shape = [n_samples, n_features], optional

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius : float

Radius of neighborhoods. (default is the value passed to the constructor).

mode : {'connectivity', 'distance'}, optional

Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

Returns **A** : sparse matrix in CSR format, shape = [n_samples, n_samples]

A[i, j] is assigned the weight of edge that connects i to j.

kneighbors_graph

Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[ 1.,  0.,  1.],
       [ 0.,  1.,  0.],
       [ 1.,  0.,  1.]])
```

set_params (***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.25.2 sklearn.neighbors.KNeighborsClassifier

class sklearn.neighbors.**KNeighborsClassifier**(*n_neighbors=5*, *weights='uniform'*, *algorithm='auto'*, *leaf_size=30*, *p=2*, *metric='minkowski'*, *metric_params=None*, *n_jobs=1*, ***kwargs*)

Classifier implementing the k-nearest neighbors vote.

Read more in the *User Guide*.

Parameters **n_neighbors** : int, optional (default = 5)

Number of neighbors to use by default for `kneighbors` queries.

weights : str or callable, optional (default = 'uniform')

weight function used in prediction. Possible values:

- 'uniform' : uniform weights. All points in each neighborhood are weighted equally.
- 'distance' : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

algorithm : {'auto', 'ball_tree', 'kd_tree', 'brute'}, optional

Algorithm used to compute the nearest neighbors:

- 'ball_tree' will use `BallTree`
- 'kd_tree' will use `KDTree`
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size : int, optional (default = 30)

Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

metric : string or callable, default 'minkowski'

the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of the DistanceMetric class for a list of available metrics.

p : integer, optional (default = 2)

Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params : dict, optional (default = None)

Additional keyword arguments for the metric function.

n_jobs : int, optional (default = 1)

The number of parallel jobs to run for neighbors search. If `-1`, then the number of jobs is set to the number of CPU cores. Doesn't affect *fit* method.

See also:

RadiusNeighborsClassifier, *KNeighborsRegressor*, *RadiusNeighborsRegressor*, *NearestNeighbors*

Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of `algorithm` and `leaf_size`.

Warning: Regarding the Nearest Neighbors algorithms, if it is found that two neighbors, neighbor *k+1* and *k*, have identical distances but different labels, the results will depend on the ordering of the training data.

https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm

Examples

```
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import KNeighborsClassifier
>>> neigh = KNeighborsClassifier(n_neighbors=3)
>>> neigh.fit(X, y)
KNeighborsClassifier(...)
>>> print(neigh.predict([[1.1]]))
[0]
>>> print(neigh.predict_proba([[0.9]]))
[[ 0.66666667  0.33333333]]
```

Methods

fit(X, y)	Fit the model using X as training data and y as target values
get_params([deep])	Get parameters for this estimator.
kneighbors([X, n_neighbors, return_distance])	Finds the K-neighbors of a point.
kneighbors_graph([X, n_neighbors, mode])	Computes the (weighted) graph of k-Neighbors for points in X
predict(X)	Predict the class labels for the provided data
predict_proba(X)	Return probability estimates for the test data X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_neighbors=5*, *weights='uniform'*, *algorithm='auto'*, *leaf_size=30*, *p=2*, *metric='minkowski'*, *metric_params=None*, *n_jobs=1*, ***kwargs*)

fit (*X*, *y*)

Fit the model using X as training data and y as target values

Parameters **X** : {array-like, sparse matrix, BallTree, KDTree}

Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

y : {array-like, sparse matrix}

Target values of shape = [n_samples] or [n_samples, n_outputs]

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

kneighbors (*X=None*, *n_neighbors=None*, *return_distance=True*)
Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

Parameters **X** : array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors : int

Number of neighbors to get (default is the value passed to the constructor).

return_distance : boolean, optional. Defaults to True.

If False, distances will not be returned

Returns **dist** : array

Array representing the lengths to points, only present if return_distance=True

ind : array

Indices of the nearest points in the population matrix.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who's the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[ 0.5]]), array([[2]]...))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]]...)
```

kneighbors_graph(*X=None*, *n_neighbors=None*, *mode='connectivity'*)

Computes the (weighted) graph of k-Neighbors for points in X

Parameters **X** : array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors : int

Number of neighbors for each sample. (default is value passed to the constructor).

mode : {'connectivity', 'distance'}, optional

Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

Returns **A** : sparse matrix in CSR format, shape = [n_samples, n_samples_fit]

n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

NearestNeighbors.radius_neighbors_graph

Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[ 1.,  0.,  1.],
       [ 0.,  1.,  1.],
       [ 1.,  0.,  1.]])
```

predict(*X*)

Predict the class labels for the provided data

Parameters **X** : array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'

Test samples.

Returns **y** : array of shape [n_samples] or [n_samples, n_outputs]

Class labels for each data sample.

predict_proba(*X*)

Return probability estimates for the test data X.

Parameters **X** : array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'

Test samples.

Returns **p** : array of shape = [n_samples, n_classes], or a list of n_outputs

of such arrays if n_outputs > 1. The class probabilities of the input samples. Classes are ordered by lexicographic order.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.neighbors.KNeighborsClassifier`

- *Classifier comparison*
- *Plot the decision boundaries of a VotingClassifier*
- *Digits Classification Exercise*
- *Nearest Neighbors Classification*
- *Classification of text documents using sparse features*

29.25.3 `sklearn.neighbors`.RadiusNeighborsClassifier

class `sklearn.neighbors.`**RadiusNeighborsClassifier**(*radius=1.0*, *weights='uniform'*, *algorithm='auto'*, *leaf_size=30*, *p=2*, *metric='minkowski'*, *outlier_label=None*, *metric_params=None*, ***kwargs*)

Classifier implementing a vote among neighbors within a given radius

Read more in the *User Guide*.

Parameters **radius** : float, optional (default = 1.0)

Range of parameter space to use by default for *radius_neighbors* queries.

weights : str or callable

weight function used in prediction. Possible values:

- 'uniform' : uniform weights. All points in each neighborhood are weighted equally.
- 'distance' : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

algorithm : {'auto', 'ball_tree', 'kd_tree', 'brute'}, optional

Algorithm used to compute the nearest neighbors:

- 'ball_tree' will use *BallTree*
- 'kd_tree' will use *KDTree*
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size : int, optional (default = 30)

Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

metric : string or callable, default 'minkowski'

the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of the DistanceMetric class for a list of available metrics.

p : integer, optional (default = 2)

Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

outlier_label : int, optional (default = None)

Label, which is given for outlier samples (samples with no neighbors on given radius). If set to None, ValueError is raised, when outlier is detected.

metric_params : dict, optional (default = None)

Additional keyword arguments for the metric function.

See also:

KNeighborsClassifier, *RadiusNeighborsRegressor*, *KNeighborsRegressor*, *NearestNeighbors*

Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of `algorithm` and `leaf_size`.

https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm

Examples

```
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import RadiusNeighborsClassifier
>>> neigh = RadiusNeighborsClassifier(radius=1.0)
>>> neigh.fit(X, y)
RadiusNeighborsClassifier(...)
>>> print(neigh.predict([[1.5]]))
[0]
```

Methods

fit(X, y)	Fit the model using X as training data and y as target values
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict the class labels for the provided data
radius_neighbors([X, radius, return_distance])	Finds the neighbors within a given radius of a point or points.
radius_neighbors_graph([X, radius, mode])	Computes the (weighted) graph of Neighbors for points in X
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*radius=1.0*, *weights='uniform'*, *algorithm='auto'*, *leaf_size=30*, *p=2*, *metric='minkowski'*, *outlier_label=None*, *metric_params=None*, ***kwargs*)

fit (*X*, *y*)

Fit the model using X as training data and y as target values

Parameters **X** : {array-like, sparse matrix, BallTree, KDTree}

Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

y : {array-like, sparse matrix}

Target values of shape = [n_samples] or [n_samples, n_outputs]

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Predict the class labels for the provided data

Parameters **X** : array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'

Test samples.

Returns **y** : array of shape [n_samples] or [n_samples, n_outputs]

Class labels for each data sample.

radius_neighbors(*X=None*, *radius=None*, *return_distance=True*)

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size `radius` around the points of the query array. Points lying on the boundary are included in the results.

The result points are *not* necessarily sorted by distance to their query point.

Parameters **X** : array-like, (n_samples, n_features), optional

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius : float

Limiting distance of neighbors to return. (default is the value passed to the constructor).

return_distance : boolean, optional. Defaults to True.

If False, distances will not be returned

Returns **dist** : array, shape (n_samples,) of arrays

Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the `metric` constructor parameter.

ind : array, shape (n_samples,) of arrays

An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size `radius` around the query points.

Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, *radius_neighbors* returns arrays of objects, where each object is a 1D array of indices or distances.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who's the closest point to [1, 1, 1]:

```
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
```

```
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[ 1.5  0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

radius_neighbors_graph (*X=None*, *radius=None*, *mode='connectivity'*)

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

Parameters **X** : array-like, shape = [n_samples, n_features], optional

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius : float

Radius of neighborhoods. (default is the value passed to the constructor).

mode : {'connectivity', 'distance'}, optional

Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

Returns **A** : sparse matrix in CSR format, shape = [n_samples, n_samples]

A[i, j] is assigned the weight of edge that connects i to j.

See also:

kneighbors_graph

Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[ 1.,  0.,  1.],
       [ 0.,  1.,  0.],
       [ 1.,  0.,  1.]])
```

score (*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.25.4 sklearn.neighbors.KNeighborsRegressor

class sklearn.neighbors.**KNeighborsRegressor**(*n_neighbors=5*, *weights='uniform'*, *algorithm='auto'*, *leaf_size=30*, *p=2*, *metric='minkowski'*, *metric_params=None*, *n_jobs=1*, ***kwargs*)

Regression based on k-nearest neighbors.

The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.

Read more in the *User Guide*.

Parameters **n_neighbors** : int, optional (default = 5)

Number of neighbors to use by default for *kneighbors* queries.

weights : str or callable

weight function used in prediction. Possible values:

- 'uniform' : uniform weights. All points in each neighborhood are weighted equally.
- 'distance' : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

algorithm : {'auto', 'ball_tree', 'kd_tree', 'brute'}, optional

Algorithm used to compute the nearest neighbors:

- 'ball_tree' will use *BallTree*
- 'kd_tree' will use *KDTree*
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size : int, optional (default = 30)

Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

metric : string or callable, default 'minkowski'

the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of the DistanceMetric class for a list of available metrics.

p : integer, optional (default = 2)

Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params : dict, optional (default = None)

Additional keyword arguments for the metric function.

n_jobs : int, optional (default = 1)

The number of parallel jobs to run for neighbors search. If `-1`, then the number of jobs is set to the number of CPU cores. Doesn't affect *fit* method.

NearestNeighbors, *RadiusNeighborsRegressor*, *KNeighborsClassifier*, *RadiusNeighborsClassifier*

Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of `algorithm` and `leaf_size`.

Warning: Regarding the Nearest Neighbors algorithms, if it is found that two neighbors, neighbor *k+1* and *k*, have identical distances but but different labels, the results will depend on the ordering of the training data.

https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm

Examples

```
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import KNeighborsRegressor
>>> neigh = KNeighborsRegressor(n_neighbors=2)
>>> neigh.fit(X, y)
KNeighborsRegressor(...)
>>> print(neigh.predict([[1.5]]))
[ 0.5]
```

Methods

fit(X, y)	Fit the model using X as training data and y as target values
get_params([deep])	Get parameters for this estimator.
kneighbors([X, n_neighbors, return_distance])	Finds the K-neighbors of a point.
kneighbors_graph([X, n_neighbors, mode])	Computes the (weighted) graph of k-Neighbors for points in X
predict(X)	Predict the target for the provided data
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_neighbors=5*, *weights='uniform'*, *algorithm='auto'*, *leaf_size=30*, *p=2*, *metric='minkowski'*, *metric_params=None*, *n_jobs=1*, ***kwargs*)

fit (*X*, *y*)

Fit the model using X as training data and y as target values

Parameters **X** : {array-like, sparse matrix, BallTree, KDTree}

Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

y : {array-like, sparse matrix}

Target values, array of float values, shape = [n_samples] or [n_samples, n_outputs]

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

kneighbors (*X=None*, *n_neighbors=None*, *return_distance=True*)

Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

Parameters **X** : array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors : int

Number of neighbors to get (default is the value passed to the constructor).

return_distance : boolean, optional. Defaults to True.

If False, distances will not be returned

Returns **dist** : array

Array representing the lengths to points, only present if return_distance=True

ind : array

Indices of the nearest points in the population matrix.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who's the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[ 0.5]]), array([[2]]...))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]]...)
```

kneighbors_graph (*X=None*, *n_neighbors=None*, *mode='connectivity'*)
Computes the (weighted) graph of k-Neighbors for points in X

Parameters **X** : array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors : int

Number of neighbors for each sample. (default is value passed to the constructor).

mode : {'connectivity', 'distance'}, optional

Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

Returns **A** : sparse matrix in CSR format, shape = [n_samples, n_samples_fit]

n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

NearestNeighbors.radius_neighbors_graph

Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.kneighbors_graph(X)
```

```
>>> A.toarray()
array([[ 1.,  0.,  1.],
       [ 0.,  1.,  1.],
       [ 1.,  0.,  1.]])
```

predict(*X*)

Predict the target for the provided data

Parameters **X** : array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'

Test samples.

Returns **y** : array of int, shape = [n_samples] or [n_samples, n_outputs]

Target values

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.neighbors.KNeighborsRegressor`

- *Face completion with a multi-output estimators*
- *Nearest Neighbors regression*

29.25.5 sklearn.neighbors.RadiusNeighborsRegressor

class sklearn.neighbors.**RadiusNeighborsRegressor**(*radius=1.0*, *weights='uniform'*, *algorithm='auto'*, *leaf_size=30*, *p=2*, *metric='minkowski'*, *metric_params=None*, ***kwargs*)

Regression based on neighbors within a fixed radius.

The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.

Read more in the *User Guide*.

Parameters **radius** : float, optional (default = 1.0)

Range of parameter space to use by default for `radius_neighbors` queries.

weights : str or callable

weight function used in prediction. Possible values:

- 'uniform' : uniform weights. All points in each neighborhood are weighted equally.
- 'distance' : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

algorithm : {'auto', 'ball_tree', 'kd_tree', 'brute'}, optional

Algorithm used to compute the nearest neighbors:

- 'ball_tree' will use `BallTree`
- 'kd_tree' will use `KDTree`
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size : int, optional (default = 30)

Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

metric : string or callable, default 'minkowski'

the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of the DistanceMetric class for a list of available metrics.

p : integer, optional (default = 2)

Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params : dict, optional (default = None)

Additional keyword arguments for the metric function.

NearestNeighbors, *KNeighborsRegressor*, *KNeighborsClassifier*, *RadiusNeighborsClassifier*

Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of `algorithm` and `leaf_size`.

https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm

Examples

```
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import RadiusNeighborsRegressor
>>> neigh = RadiusNeighborsRegressor(radius=1.0)
>>> neigh.fit(X, y)
RadiusNeighborsRegressor(...)
>>> print(neigh.predict([[1.5]]))
[ 0.5]
```

Methods

fit(X, y)	Fit the model using X as training data and y as target values
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict the target for the provided data
radius_neighbors([X, radius, return_distance])	Finds the neighbors within a given radius of a point or points.
radius_neighbors_graph([X, radius, mode])	Computes the (weighted) graph of Neighbors for points in X
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*radius=1.0*, *weights='uniform'*, *algorithm='auto'*, *leaf_size=30*, *p=2*, *metric='minkowski'*, *metric_params=None*, ***kwargs*)

fit (*X*, *y*)

Fit the model using X as training data and y as target values

Parameters **X** : {array-like, sparse matrix, BallTree, KDTree}

Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

y : {array-like, sparse matrix}

Target values, array of float values, shape = [n_samples] or [n_samples, n_outputs]

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Predict the target for the provided data

Parameters **X** : array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'

Test samples.

Returns **y** : array of int, shape = [n_samples] or [n_samples, n_outputs]

Target values

radius_neighbors(*X=None*, *radius=None*, *return_distance=True*)

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size `radius` around the points of the query array. Points lying on the boundary are included in the results.

The result points are *not* necessarily sorted by distance to their query point.

Parameters **X** : array-like, (n_samples, n_features), optional

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius : float

Limiting distance of neighbors to return. (default is the value passed to the constructor).

return_distance : boolean, optional. Defaults to True.

If False, distances will not be returned

Returns **dist** : array, shape (n_samples,) of arrays

Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the `metric` constructor parameter.

ind : array, shape (n_samples,) of arrays

An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size `radius` around the query points.

Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, *radius_neighbors* returns arrays of objects, where each object is a 1D array of indices or distances.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who's the closest point to [1, 1, 1]:

```
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[ 1.5  0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

radius_neighbors_graph (*X=None*, *radius=None*, *mode='connectivity'*)

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

Parameters **X** : array-like, shape = [n_samples, n_features], optional

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius : float

Radius of neighborhoods. (default is the value passed to the constructor).

mode : {'connectivity', 'distance'}, optional

Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

Returns **A** : sparse matrix in CSR format, shape = [n_samples, n_samples]

A[i, j] is assigned the weight of edge that connects i to j.

See also:

kneighbors_graph

Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[ 1.,  0.,  1.],
       [ 0.,  1.,  0.],
       [ 1.,  0.,  1.]])
```

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.25.6 sklearn.neighbors.NearestCentroid

class sklearn.neighbors.**NearestCentroid**(*metric='euclidean'*, *shrink_threshold=None*)

Nearest centroid classifier.

Each class is represented by its centroid, with test samples classified to the class with the nearest centroid.

Read more in the *User Guide*.

Parameters **metric** : string, or callable

The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by metrics.pairwise.pairwise_distances for its metric parameter. The centroids for the samples corresponding to each class is the point from which the sum of the distances (according to the metric) of all samples that belong to that particular class are minimized. If the "manhattan" metric is provided, this centroid is the median and for all other metrics, the centroid is now set to be the mean.

shrink_threshold : float, optional (default = None)

Threshold for shrinking centroids to remove features.

Attributes **centroids_** : array-like, shape = [n_classes, n_features]

Centroid of each class

See also:

sklearn.neighbors.KNeighborsClassifier nearest neighbors classifier

Notes

When used for text classification with tf-idf vectors, this classifier is also known as the Rocchio classifier.

References

Tibshirani, R., Hastie, T., Narasimhan, B., & Chu, G. (2002). Diagnosis of multiple cancer types by shrunken centroids of gene expression. Proceedings of the National Academy of Sciences of the United States of America, 99(10), 6567-6572. The National Academy of Sciences.

Examples

```
>>> from sklearn.neighbors.nearest_centroid import NearestCentroid
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = NearestCentroid()
>>> clf.fit(X, y)
NearestCentroid(metric='euclidean', shrink_threshold=None)
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

Methods

fit(X, y)	Fit the NearestCentroid model according to the given training data.
get_params([deep])	Get parameters for this estimator.
predict(X)	Perform classification on an array of test vectors X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*metric='euclidean'*, *shrink_threshold=None*)

fit (*X*, *y*)

Fit the NearestCentroid model according to the given training data.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training vector, where n_samples in the number of samples and n_features is the number of features. Note that centroid shrinking cannot be used with sparse matrices.

y : array, shape = [n_samples]

Target values (integers)

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Perform classification on an array of test vectors X.

The predicted class C for each sample in X is returned.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array, shape = [n_samples]

Notes

If the metric constructor parameter is "precomputed", X is assumed to be the distance matrix between the data to be predicted and `self.centroids_`.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.neighbors.NearestCentroid`

- *Nearest Centroid Classification*
- *Classification of text documents using sparse features*

29.25.7 `sklearn.neighbors.BallTree`

class `sklearn.neighbors.`**`BallTree`**

BallTree for fast generalized N-point problems

BallTree(X, leaf_size=40, metric='minkowski', **kwargs)

Parameters **X** : array-like, shape = [n_samples, n_features]

n_samples is the number of points in the data set, and n_features is the dimension of the parameter space. Note: if X is a C-contiguous array of doubles then data will not be copied. Otherwise, an internal copy will be made.

leaf_size : positive integer (default = 40)

Number of points at which to switch to brute-force. Changing leaf_size will not affect the results of a query, but can significantly impact the speed of a query and the memory required to store the constructed tree. The amount of memory needed to store the tree scales as approximately n_samples / leaf_size. For a specified `leaf_size`, a leaf node is guaranteed to satisfy `leaf_size <= n_points <= 2 * leaf_size`, except in the case that `n_samples < leaf_size`.

metric : string or DistanceMetric object

the distance metric to use for the tree. Default='minkowski' with p=2 (that is, a euclidean metric). See the documentation of the DistanceMetric class for a list of available metrics. ball_tree.valid_metrics gives a list of the metrics which are valid for BallTree.

Additional keywords are passed to the distance metric class. :

Attributes **data** : np.ndarray

The training data

Examples

Query for k-nearest neighbors

```
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((10, 3))  # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2)
>>> dist, ind = tree.query([X[0]], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[ 0.          0.19662693  0.29473397]
```

Pickle and Unpickle a tree. Note that the state of the tree is saved in the pickle operation: the tree needs not be rebuilt upon unpickling.

```
>>> import numpy as np
>>> import pickle
>>> np.random.seed(0)
>>> X = np.random.random((10, 3))  # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2)
>>> s = pickle.dumps(tree)
>>> tree_copy = pickle.loads(s)
>>> dist, ind = tree_copy.query(X[0], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[ 0.          0.19662693  0.29473397]
```

Query for neighbors within a given radius

```
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((10, 3))  # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2)
>>> print(tree.query_radius(X[0], r=0.3, count_only=True))
3
>>> ind = tree.query_radius(X[0], r=0.3)
>>> print(ind)  # indices of neighbors within distance 0.3
[3 0 1]
```

Compute a gaussian kernel density estimate:

```
>>> import numpy as np
>>> np.random.seed(1)
>>> X = np.random.random((100, 3))
>>> tree = BallTree(X)
>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([ 6.94114649,  7.83281226,  7.2071716 ])
```

Compute a two-point auto-correlation function

```
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = BallTree(X)
>>> tree.two_point_correlation(X, r)
array([ 30,  62, 278, 580, 820])
```

Methods

get_arrays	
get_n_calls	
get_tree_stats	
kernel_density(self, X, h[, kernel, atol, ...])	Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.
query(X[, k, return_distance, dualtree, ...])	query the tree for the k nearest neighbors
query_radius	query_radius(self, X, r, count_only = False):
reset_n_calls	
two_point_correlation	Compute the two-point correlation function

__init__()
Initialize self. See help(type(self)) for accurate signature.

kernel_density(*self*, *X*, *h*, *kernel='gaussian'*, *atol=0*, *rtol=1E-8*, *breadth_first=True*, *return_log=False*)
Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

Parameters **X** : array_like

An array of points to query. Last dimension should match dimension of training data.

h : float

the bandwidth of the kernel

kernel : string

specify the kernel to use. Options are - 'gaussian' - 'tophat' - 'epanechnikov' - 'exponential' - 'linear' - 'cosine' Default is kernel = 'gaussian'

atol, rtol : float (default = 0)

Specify the desired relative and absolute tolerance of the result. If the true result is K_true, then the returned result K_ret satisfies `abs(K_true - K_ret) < atol + rtol * K_ret` The default is zero (i.e. machine precision) for both.

breadth_first : boolean (default = False)

if True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.

return_log : boolean (default = False)

return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

Returns density : ndarray

The array of (log)-density evaluations, shape = X.shape[:-1]

Examples

Compute a gaussian kernel density estimate:

```
>>> import numpy as np
>>> np.random.seed(1)
>>> X = np.random.random((100, 3))
>>> tree = BinaryTree(X)
>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([ 6.94114649,  7.83281226,  7.2071716 ])
```

query(*X*, *k=1*, *return_distance=True*, *dualtree=False*, *breadth_first=False*)
query the tree for the k nearest neighbors

Parameters X : array-like, last dimension self.dim

An array of points to query

k : integer (default = 1)

The number of nearest neighbors to return

return_distance : boolean (default = True)

if True, return a tuple (d, i) of distances and indices if False, return array i

dualtree : boolean (default = False)

if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.

breadth_first : boolean (default = False)

if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.

sort_results : boolean (default = True)

if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

Returns **i** : if return_distance == False

(d,i) : if return_distance == True

d : array of doubles - shape: x.shape[:-1] + (k,)

each entry gives the list of distances to the neighbors of the corresponding point

i : array of integers - shape: x.shape[:-1] + (k,)

each entry gives the list of indices of neighbors of the corresponding point

Examples

Query for k-nearest neighbors

```
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((10, 3))  # 10 points in 3 dimensions
>>> tree = BinaryTree(X, leaf_size=2)
>>> dist, ind = tree.query(X[0], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[ 0.          0.19662693  0.29473397]
```

query_radius()

query_radius(self, X, r, count_only = False):

query the tree for neighbors within a radius r

Parameters **X** : array-like, last dimension self.dim

An array of points to query

r : distance within which neighbors are returned

r can be a single value, or an array of values of shape x.shape[:-1] if different radii are desired for each point.

return_distance : boolean (default = False)

if True, return distances to neighbors of each point if False, return only neighbors Note that unlike the query() method, setting return_distance=True here adds to the computation time. Not all distances need to be calculated explicitly for return_distance=False. Results are not sorted by default: see `sort_results` keyword.

count_only : boolean (default = False)

if True, return only the count of points within distance r if False, return the indices of all points within distance r If return_distance==True, setting count_only=True will result in an error.

sort_results : boolean (default = False)

if True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return_distance == False, setting sort_results = True will result in an error.

Returns **count** : if count_only == True

ind : if count_only == False and return_distance == False

(ind, dist) : if count_only == False and return_distance == True

count : array of integers, shape = X.shape[:-1]

each entry gives the number of neighbors within a distance r of the corresponding point.

ind : array of objects, shape = X.shape[:-1]

each element is a numpy integer array listing the indices of neighbors of the corresponding point. Note that unlike the results of a k-neighbors query, the returned neighbors are not sorted by distance by default.

dist : array of objects, shape = X.shape[:-1]

each element is a numpy double array listing the distances corresponding to indices in i.

Examples

Query for neighbors in a given radius

```
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((10, 3))  # 10 points in 3 dimensions
>>> tree = BinaryTree(X, leaf_size=2)
>>> print(tree.query_radius(X[0], r=0.3, count_only=True))
3
>>> ind = tree.query_radius(X[0], r=0.3)
>>> print(ind)  # indices of neighbors within distance 0.3
[3 0 1]
```

two_point_correlation()

Compute the two-point correlation function

Parameters **X** : array_like

An array of points to query. Last dimension should match dimension of training data.

r : array_like

A one-dimensional array of distances

dualtree : boolean (default = False)

If true, use a dualtree algorithm. Otherwise, use a single-tree algorithm. Dual tree algorithms can have better scaling for large N.

Returns **counts** : ndarray

counts[i] contains the number of pairs of points with distance less than or equal to r[i]

Examples

Compute the two-point autocorrelation function of X:

```
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = BinaryTree(X)
>>> tree.two_point_correlation(X, r)
array([ 30,  62, 278, 580, 820])
```

29.25.8 sklearn.neighbors.KDTree

class sklearn.neighbors.**KDTree**

KDTree for fast generalized N-point problems

KDTree(X, leaf_size=40, metric='minkowski', **kwargs)

Parameters **X** : array-like, shape = [n_samples, n_features]

n_samples is the number of points in the data set, and n_features is the dimension of the parameter space. Note: if X is a C-contiguous array of doubles then data will not be copied. Otherwise, an internal copy will be made.

leaf_size : positive integer (default = 40)

Number of points at which to switch to brute-force. Changing leaf_size will not affect the results of a query, but can significantly impact the speed of a query and the memory required to store the constructed tree. The amount of memory needed to store the tree scales as approximately n_samples / leaf_size. For a specified `leaf_size`, a leaf node is guaranteed to satisfy `leaf_size <= n_points <= 2 * leaf_size`, except in the case that `n_samples < leaf_size`.

metric : string or DistanceMetric object

the distance metric to use for the tree. Default='minkowski' with p=2 (that is, a euclidean metric). See the documentation of the DistanceMetric class for a list of available metrics. kd_tree.valid_metrics gives a list of the metrics which are valid for KDTree.

Additional keywords are passed to the distance metric class. :

Attributes **data** : np.ndarray

The training data

Examples

Query for k-nearest neighbors

```
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((10, 3))  # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> dist, ind = tree.query([X[0]], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
```

```
>>> print(dist)  # distances to 3 closest neighbors
[ 0.          0.19662693  0.29473397]
```

Pickle and Unpickle a tree. Note that the state of the tree is saved in the pickle operation: the tree needs not be rebuilt upon unpickling.

```
>>> import numpy as np
>>> import pickle
>>> np.random.seed(0)
>>> X = np.random.random((10, 3))  # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> s = pickle.dumps(tree)
>>> tree_copy = pickle.loads(s)
>>> dist, ind = tree_copy.query(X[0], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[ 0.          0.19662693  0.29473397]
```

Query for neighbors within a given radius

```
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((10, 3))  # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> print(tree.query_radius(X[0], r=0.3, count_only=True))
3
>>> ind = tree.query_radius(X[0], r=0.3)
>>> print(ind)  # indices of neighbors within distance 0.3
[3 0 1]
```

Compute a gaussian kernel density estimate:

```
>>> import numpy as np
>>> np.random.seed(1)
>>> X = np.random.random((100, 3))
>>> tree = KDTree(X)
>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([ 6.94114649,  7.83281226,  7.2071716 ])
```

Compute a two-point auto-correlation function

```
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = KDTree(X)
>>> tree.two_point_correlation(X, r)
array([ 30,  62, 278, 580, 820])
```

Methods

get_arrays
get_n_calls

Continued on next page

Table 29.208 – continued from previous page

get_tree_stats	
kernel_density(self, X, h[, kernel, atol, ...])	Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.
query(X[, k, return_distance, dualtree, ...])	query the tree for the k nearest neighbors
query_radius	query_radius(self, X, r, count_only = False):
reset_n_calls	
two_point_correlation	Compute the two-point correlation function

__init__()
Initialize self. See help(type(self)) for accurate signature.

kernel_density(*self*, *X*, *h*, *kernel='gaussian'*, *atol=0*, *rtol=1E-8*, *breadth_first=True*, *return_log=False*)
Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

Parameters **X** : array_like

An array of points to query. Last dimension should match dimension of training data.

h : float

the bandwidth of the kernel

kernel : string

specify the kernel to use. Options are - 'gaussian' - 'tophat' - 'epanechnikov' - 'exponential' - 'linear' - 'cosine' Default is kernel = 'gaussian'

atol, rtol : float (default = 0)

Specify the desired relative and absolute tolerance of the result. If the true result is K_true, then the returned result K_ret satisfies `abs(K_true - K_ret) < atol + rtol * K_ret` The default is zero (i.e. machine precision) for both.

breadth_first : boolean (default = False)

if True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.

return_log : boolean (default = False)

return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

Returns **density** : ndarray

The array of (log)-density evaluations, shape = X.shape[:-1]

Examples

Compute a gaussian kernel density estimate:

```
>>> import numpy as np
>>> np.random.seed(1)
>>> X = np.random.random((100, 3))
>>> tree = BinaryTree(X)
```

```
>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([ 6.94114649,  7.83281226,  7.2071716 ])
```

query(*X*, *k=1*, *return_distance=True*, *dualtree=False*, *breadth_first=False*)
query the tree for the k nearest neighbors

Parameters **X** : array-like, last dimension self.dim

An array of points to query

k : integer (default = 1)

The number of nearest neighbors to return

return_distance : boolean (default = True)

if True, return a tuple (d, i) of distances and indices if False, return array i

dualtree : boolean (default = False)

if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.

breadth_first : boolean (default = False)

if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.

sort_results : boolean (default = True)

if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

Returns **i** : if return_distance == False

(d,i) : if return_distance == True

d : array of doubles - shape: x.shape[:-1] + (k,)

each entry gives the list of distances to the neighbors of the corresponding point

i : array of integers - shape: x.shape[:-1] + (k,)

each entry gives the list of indices of neighbors of the corresponding point

Examples

Query for k-nearest neighbors

```
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((10, 3))  # 10 points in 3 dimensions
>>> tree = BinaryTree(X, leaf_size=2)
>>> dist, ind = tree.query(X[0], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[ 0.          0.19662693  0.29473397]
```

query_radius()

query_radius(self, X, r, count_only = False):

query the tree for neighbors within a radius r

Parameters **X** : array-like, last dimension self.dim

An array of points to query

r : distance within which neighbors are returned

r can be a single value, or an array of values of shape x.shape[:-1] if different radii are desired for each point.

return_distance : boolean (default = False)

if True, return distances to neighbors of each point if False, return only neighbors Note that unlike the query() method, setting return_distance=True here adds to the computation time. Not all distances need to be calculated explicitly for return_distance=False. Results are not sorted by default: see `sort_results` keyword.

count_only : boolean (default = False)

if True, return only the count of points within distance r if False, return the indices of all points within distance r If return_distance==True, setting count_only=True will result in an error.

sort_results : boolean (default = False)

if True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return_distance == False, setting sort_results = True will result in an error.

Returns **count** : if count_only == True

ind : if count_only == False and return_distance == False

(ind, dist) : if count_only == False and return_distance == True

count : array of integers, shape = X.shape[:-1]

each entry gives the number of neighbors within a distance r of the corresponding point.

ind : array of objects, shape = X.shape[:-1]

each element is a numpy integer array listing the indices of neighbors of the corresponding point. Note that unlike the results of a k-neighbors query, the returned neighbors are not sorted by distance by default.

dist : array of objects, shape = X.shape[:-1]

each element is a numpy double array listing the distances corresponding to indices in i.

Examples

Query for neighbors in a given radius

```
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((10, 3))  # 10 points in 3 dimensions
>>> tree = BinaryTree(X, leaf_size=2)
>>> print(tree.query_radius(X[0], r=0.3, count_only=True))
```

```
3
>>> ind = tree.query_radius(X[0], r=0.3)
>>> print(ind)  # indices of neighbors within distance 0.3
[3 0 1]
```

two_point_correlation()
Compute the two-point correlation function

Parameters **X** : array_like

An array of points to query. Last dimension should match dimension of training data.

r : array_like

A one-dimensional array of distances

dualtree : boolean (default = False)

If true, use a dualtree algorithm. Otherwise, use a single-tree algorithm. Dual tree algorithms can have better scaling for large N.

Returns **counts** : ndarray

counts[i] contains the number of pairs of points with distance less than or equal to r[i]

Examples

Compute the two-point autocorrelation function of X:

```
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = BinaryTree(X)
>>> tree.two_point_correlation(X, r)
array([ 30,  62, 278, 580, 820])
```

29.25.9 sklearn.neighbors.DistanceMetric

class sklearn.neighbors.**DistanceMetric**
DistanceMetric class

This class provides a uniform interface to fast distance metric functions. The various metrics can be accessed via the *get_metric* class method and the metric string identifier (see below). For example, to use the Euclidean distance:

```
>>> dist = DistanceMetric.get_metric('euclidean')
>>> X = [[0, 1, 2],
         [3, 4, 5]])
>>> dist.pairwise(X)
array([[ 0.        ,  5.19615242],
       [ 5.19615242,  0.        ]])
```

Available Metrics The following lists the string metric identifiers and the associated distance metric classes:

Metrics intended for real-valued vector spaces:

identifier	class name	args	distance function
“euclidean”	EuclideanDistance	•	`sqrt(sum((x - y)^2))`
“manhattan”	ManhattanDistance	•	`sum(|x - y|)`
“chebyshev”	ChebyshevDistance	•	`max(|x - y|)`
“minkowski”	MinkowskiDistance	p	`sum(|x - y|^p)^(1/p)`
“wminkowski”	WMinkowskiDistance	p, w	`sum(w * |x - y|^p)^(1/p)`
“seuclidean”	SEuclideanDistance	V	`sqrt(sum((x - y)^2 / V))`
“mahalanobis”	MahalanobisDistance	V or VI	`sqrt((x - y)' V^-1 (x - y))`

Metrics intended for two-dimensional vector spaces: Note that the haversine distance metric requires data in the form of [latitude, longitude] and both inputs and outputs are in units of radians.

identifier	class name	distance function
“haversine”	HaversineDistance	**2 arcsin(sqrt(sin^2(0.5*dx)** • cos(x1)cos(x2)sin^2(0.5*dy)))

Metrics intended for integer-valued vector spaces: Though intended for integer-valued vectors, these are also valid metrics in the case of real-valued vectors.

identifier	class name	distance function
“hamming”	HammingDistance	`N_unequal(x, y) / N_tot`
“canberra”	CanberraDistance	`sum(|x - y| / (|x| + |y|))`
“braycurtis”	BrayCurtisDistance	`sum(|x - y|) / (sum(|x|) + sum(|y|))`

Metrics intended for boolean-valued vector spaces: Any nonzero entry is evaluated to “True”. In the listings below, the following abbreviations are used:

- N : number of dimensions
- NTT : number of dims in which both values are True
- NTF : number of dims in which the first value is True, second is False
- NFT : number of dims in which the first value is False, second is True
- NFF : number of dims in which both values are False
- NNEQ : number of non-equal dimensions, NNEQ = NTF + NFT
- NNZ : number of nonzero dimensions, NNZ = NTF + NFT + NTT

identifier	class name	distance function
“jaccard”	JaccardDistance	NNEQ / NNZ
“matching”	MatchingDistance	NNEQ / N
“dice”	DiceDistance	NNEQ / (NTT + NNZ)
“kulsinski”	KulsinskiDistance	(NNEQ + N - NTT) / (NNEQ + N)
“rogerstanimoto”	RogersTanimotoDistance	2 * NNEQ / (N + NNEQ)
“russellrao”	RussellRaoDistance	NNZ / N
“sokalmichener”	SokalMichenerDistance	2 * NNEQ / (N + NNEQ)
“sokalsneath”	SokalSneathDistance	NNEQ / (NNEQ + 0.5 * NTT)

User-defined distance:

identifier	class name	args
“pyfunc”	PyFuncDistance	func

Here `func` is a function which takes two one-dimensional numpy arrays, and returns a distance. Note that in order to be used within the BallTree, the distance must be a true metric: i.e. it must satisfy the following properties

1. Non-negativity: d(x, y) >= 0
2. Identity: d(x, y) = 0 if and only if x == y
3. Symmetry: d(x, y) = d(y, x)
4. Triangle Inequality: d(x, y) + d(y, z) >= d(x, z)

Because of the Python object overhead involved in calling the python function, this will be fairly slow, but it will have the same scaling as other distances.

Methods

dist_to_rdist	Convert the true distance to the reduced distance.
get_metric	Get the given distance metric from the string identifier.
pairwise	Compute the pairwise distances between X and Y
rdist_to_dist	Convert the Reduced distance to the true distance.

__init__()
Initialize self. See help(type(self)) for accurate signature.

dist_to_rdist()
Convert the true distance to the reduced distance.

The reduced distance, defined for some metrics, is a computationally more efficent measure which preserves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is the squared-euclidean distance.

get_metric()
Get the given distance metric from the string identifier.

See the docstring of DistanceMetric for a list of available metrics.

Parameters **metric** : string or class name

The distance metric to use

****kwargs** :

additional arguments will be passed to the requested metric

pairwise()
Compute the pairwise distances between X and Y

This is a convenience routine for the sake of testing. For many metrics, the utilities in scipy.spatial.distance.cdist and scipy.spatial.distance.pdist will be faster.

Parameters **X** : array_like

Array of shape (Nx, D), representing Nx points in D dimensions.

Y : array_like (optional)

Array of shape (Ny, D), representing Ny points in D dimensions. If not specified, then Y=X.

Returns :

———- :

dist : ndarray

The shape (Nx, Ny) array of pairwise distances between points in X and Y.

rdist_to_dist()
Convert the Reduced distance to the true distance.

The reduced distance, defined for some metrics, is a computationally more efficent measure which preserves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is the squared-euclidean distance.

29.25.10 sklearn.neighbors.KernelDensity

class sklearn.neighbors.**KernelDensity**(*bandwidth=1.0*, *algorithm='auto'*, *kernel='gaussian'*, *metric='euclidean'*, *atol=0*, *rtol=0*, *breadth_first=True*, *leaf_size=40*, *metric_params=None*)

Kernel Density Estimation

Read more in the *User Guide*.

Parameters **bandwidth** : float

The bandwidth of the kernel.

algorithm : string

The tree algorithm to use. Valid options are ['kd_tree'|'ball_tree'|'auto']. Default is 'auto'.

kernel : string

The kernel to use. Valid kernels are ['gaussian'|'tophat'|'epanechnikov'|'exponential'|'linear'|'cosine'] Default is 'gaussian'.

metric : string

The distance metric to use. Note that not all metrics are valid with all algorithms. Refer to the documentation of *BallTree* and *KDTree* for a description of available algorithms. Note that the normalization of the density output is correct only for the Euclidean distance metric. Default is 'euclidean'.

atol : float

The desired absolute tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 0.

rtol : float

The desired relative tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 1E-8.

breadth_first : boolean

If true (default), use a breadth-first approach to the problem. Otherwise use a depth-first approach.

leaf_size : int

Specify the leaf size of the underlying tree. See *BallTree* or *KDTree* for details. Default is 40.

metric_params : dict

Additional parameters to be passed to the tree for use with the metric. For more information, see the documentation of *BallTree* or *KDTree*.

Methods

fit(X[, y])	Fit the Kernel Density model on the data.
get_params([deep])	Get parameters for this estimator.
sample([n_samples, random_state])	Generate random samples from the model.
score(X[, y])	Compute the total log probability under the model.
score_samples(X)	Evaluate the density model on the data.
set_params(**params)	Set the parameters of this estimator.

__init__ (*bandwidth=1.0*, *algorithm='auto'*, *kernel='gaussian'*, *metric='euclidean'*, *atol=0*, *rtol=0*, *breadth_first=True*, *leaf_size=40*, *metric_params=None*)

fit (*X*, *y=None*)
Fit the Kernel Density model on the data.

Parameters **X** : array_like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

sample (*n_samples=1*, *random_state=None*)
Generate random samples from the model.

Currently, this is implemented only for gaussian and tophat kernels.

Parameters **n_samples** : int, optional

Number of samples to generate. Defaults to 1.

random_state : int, RandomState instance or None. default to None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **X** : array_like, shape (n_samples, n_features)

List of samples.

score (*X*, *y=None*)
Compute the total log probability under the model.

Parameters **X** : array_like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **logprob** : float

Total log-likelihood of the data in X.

score_samples (*X*)
Evaluate the density model on the data.

Parameters **X** : array_like, shape (n_samples, n_features)

An array of points to query. Last dimension should match dimension of training data (n_features).

Returns **density** : ndarray, shape (n_samples,)

The array of log(density) evaluations.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.neighbors.KernelDensity`

- *Kernel Density Estimation*
- *Simple 1D Kernel Density Estimation*
- *Kernel Density Estimate of Species Distributions*

29.25.11 `sklearn.neighbors`.LocalOutlierFactor

class sklearn.neighbors.**LocalOutlierFactor**(*n_neighbors=20*, *algorithm='auto'*, *leaf_size=30*, *metric='minkowski'*, *p=2*, *metric_params=None*, *contamination=0.1*, *n_jobs=1*)
Unsupervised Outlier Detection using Local Outlier Factor (LOF)

The anomaly score of each sample is called Local Outlier Factor. It measures the local deviation of density of a given sample with respect to its neighbors. It is local in that the anomaly score depends on how isolated the object is with respect to the surrounding neighborhood. More precisely, locality is given by k-nearest neighbors, whose distance is used to estimate the local density. By comparing the local density of a sample to the local densities of its neighbors, one can identify samples that have a substantially lower density than their neighbors. These are considered outliers.

Parameters **n_neighbors** : int, optional (default=20)

Number of neighbors to use by default for *kneighbors* queries. If n_neighbors is larger than the number of samples provided, all samples will be used.

algorithm : {'auto', 'ball_tree', 'kd_tree', 'brute'}, optional

Algorithm used to compute the nearest neighbors:

- 'ball_tree' will use *BallTree*
- 'kd_tree' will use *KDTree*
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size : int, optional (default=30)

Leaf size passed to *BallTree* or *KDTree*. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p : integer, optional (default=2)

Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric : string or callable, default 'minkowski'

metric used for the distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If 'precomputed', the training input X is expected to be a distance matrix.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string.

Valid values for metric are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for scipy.spatial.distance for details on these metrics: http://docs.scipy.org/doc/scipy/reference/spatial.distance.html

metric_params : dict, optional (default=None)

Additional keyword arguments for the metric function.

contamination : float in (0., 0.5), optional (default=0.1)

The amount of contamination of the data set, i.e. the proportion of outliers in the data set. When fitting this is used to define the threshold on the decision function.

n_jobs : int, optional (default=1)

The number of parallel jobs to run for neighbors search. If `-1`, then the number of jobs is set to the number of CPU cores. Affects only *kneighbors* and *kneighbors_graph* methods.

Attributes **negative_outlier_factor_** : numpy array, shape (n_samples,)

The opposite LOF of the training samples. The lower, the more normal. Inliers tend to have a LOF score close to 1, while outliers tend to have a larger LOF score.

The local outlier factor (LOF) of a sample captures its supposed 'degree of abnormality'. It is the average of the ratio of the local reachability density of a sample and those of its k-nearest neighbors.

n_neighbors_ : integer

The actual number of neighbors used for *kneighbors* queries.

References

[R72]

Methods

fit(X[, y])	Fit the model using X as training data.
fit_predict(X[, y])	"Fits the model to the training set X and returns the labels
get_params([deep])	Get parameters for this estimator.
kneighbors([X, n_neighbors, return_distance])	Finds the K-neighbors of a point.
kneighbors_graph([X, n_neighbors, mode])	Computes the (weighted) graph of k-Neighbors for points in X
set_params(**params)	Set the parameters of this estimator.

__init__ (*n_neighbors=20*, *algorithm='auto'*, *leaf_size=30*, *metric='minkowski'*, *p=2*, *metric_params=None*, *contamination=0.1*, *n_jobs=1*)

fit (*X*, *y=None*)

Fit the model using X as training data.

Parameters **X** : {array-like, sparse matrix, BallTree, KDTree}

Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

Returns **self** : object

Returns self.

fit_predict (*X*, *y=None*)

"Fits the model to the training set X and returns the labels (1 inlier, -1 outlier) on the training set according to the LOF score and the contamination parameter.

Parameters **X** : array-like, shape (n_samples, n_features), default=None

The query sample or samples to compute the Local Outlier Factor w.r.t. to the training samples.

Returns **is_inlier** : array, shape (n_samples,)

Returns -1 for anomalies/outliers and 1 for inliers.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

kneighbors (*X=None*, *n_neighbors=None*, *return_distance=True*)
Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

Parameters **X** : array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors : int

Number of neighbors to get (default is the value passed to the constructor).

return_distance : boolean, optional. Defaults to True.

If False, distances will not be returned

Returns **dist** : array

Array representing the lengths to points, only present if return_distance=True

ind : array

Indices of the nearest points in the population matrix.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who's the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[ 0.5]]), array([[2]]...))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]]...)
```

kneighbors_graph(*X=None*, *n_neighbors=None*, *mode='connectivity'*)
Computes the (weighted) graph of k-Neighbors for points in X

Parameters **X** : array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'

The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors : int

Number of neighbors for each sample. (default is value passed to the constructor).

mode : {'connectivity', 'distance'}, optional

Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

Returns **A** : sparse matrix in CSR format, shape = [n_samples, n_samples_fit]

n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

NearestNeighbors.radius_neighbors_graph

Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[ 1.,  0.,  1.],
       [ 0.,  1.,  1.],
       [ 1.,  0.,  1.]])
```

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.neighbors.LocalOutlierFactor`

- *Outlier detection with several methods.*
- *Anomaly detection with Local Outlier Factor (LOF)*

neighbors.kneighbors_graph(X, n_neighbors[, ...])	Computes the (weighted) graph of k-Neighbors for points in X

Continued on next page

Table 29.212 – continued from previous page

neighbors.radius_neighbors_graph(X, radius)	Computes the (weighted) graph of Neighbors for points in X

29.25.12 sklearn.neighbors.kneighbors_graph

sklearn.neighbors.**kneighbors_graph**(*X*, *n_neighbors*, *mode='connectivity'*, *metric='minkowski'*, *p=2*, *metric_params=None*, *include_self=False*, *n_jobs=1*)

Computes the (weighted) graph of k-Neighbors for points in X

Read more in the *User Guide*.

Parameters **X** : array-like or BallTree, shape = [n_samples, n_features]

Sample data, in the form of a numpy array or a precomputed *BallTree*.

n_neighbors : int

Number of neighbors for each sample.

mode : {'connectivity', 'distance'}, optional

Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, and 'distance' will return the distances between neighbors according to the given metric.

metric : string, default 'minkowski'

The distance metric used to calculate the k-Neighbors for each sample point. The DistanceMetric class gives a list of available metrics. The default distance is 'euclidean' ('minkowski' metric with the p param equal to 2.)

include_self : bool, default=False.

Whether or not to mark each sample as the first nearest neighbor to itself. If *None*, then True is used for mode='connectivity' and False for mode='distance' as this will preserve backwards compatibilty.

p : int, default 2

Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params : dict, optional

additional keyword arguments for the metric function.

n_jobs : int, optional (default = 1)

The number of parallel jobs to run for neighbors search. If `-1`, then the number of jobs is set to the number of CPU cores.

Returns **A** : sparse matrix in CSR format, shape = [n_samples, n_samples]

A[i, j] is assigned the weight of edge that connects i to j.

radius_neighbors_graph

Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import kneighbors_graph
>>> A = kneighbors_graph(X, 2, mode='connectivity', include_self=True)
>>> A.toarray()
array([[ 1.,  0.,  1.],
       [ 0.,  1.,  1.],
       [ 1.,  0.,  1.]])
```

Examples using `sklearn.neighbors.kneighbors_graph`

- *Agglomerative clustering with and without structure*
- *Comparing different clustering algorithms on toy datasets*
- *Hierarchical clustering: structured vs unstructured ward*

29.25.13 `sklearn.neighbors`.radius_neighbors_graph

`sklearn.neighbors.`**`radius_neighbors_graph`**(*X*, *radius*, *mode='connectivity'*, *metric='minkowski'*, *p=2*, *metric_params=None*, *include_self=False*, *n_jobs=1*)

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

Read more in the *User Guide*.

Parameters **X** : array-like or BallTree, shape = [n_samples, n_features]

Sample data, in the form of a numpy array or a precomputed *BallTree*.

radius : float

Radius of neighborhoods.

mode : {'connectivity', 'distance'}, optional

Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, and 'distance' will return the distances between neighbors according to the given metric.

metric : string, default 'minkowski'

The distance metric used to calculate the neighbors within a given radius for each sample point. The DistanceMetric class gives a list of available metrics. The default distance is 'euclidean' ('minkowski' metric with the param equal to 2.)

include_self : bool, default=False

Whether or not to mark each sample as the first nearest neighbor to itself. If *None*, then True is used for mode='connectivity' and False for mode='distance' as this will preserve backwards compatibilty.

p : int, default 2

Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params : dict, optional

additional keyword arguments for the metric function.

n_jobs : int, optional (default = 1)

The number of parallel jobs to run for neighbors search. If `-1`, then the number of jobs is set to the number of CPU cores.

Returns **A** : sparse matrix in CSR format, shape = [n_samples, n_samples]

A[i, j] is assigned the weight of edge that connects i to j.

kneighbors_graph

Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import radius_neighbors_graph
>>> A = radius_neighbors_graph(X, 1.5, mode='connectivity', include_self=True)
>>> A.toarray()
array([[ 1.,  0.,  1.],
       [ 0.,  1.,  0.],
       [ 1.,  0.,  1.]])
```

29.26 `sklearn.neural_network`: Neural network models

The *sklearn.neural_network* module includes models based on neural networks.

User guide: See the *Neural network models (supervised)* and *Neural network models (unsupervised)* sections for further details.

neural_network.BernoulliRBM([n_components, ...])	Bernoulli Restricted Boltzmann Machine (RBM).
neural_network.MLPClassifier([...])	Multi-layer Perceptron classifier.
neural_network.MLPRegressor([...])	Multi-layer Perceptron regressor.

29.26.1 `sklearn.neural_network`.BernoulliRBM

class `sklearn.neural_network.`**`BernoulliRBM`**(*n_components=256*, *learning_rate=0.1*, *batch_size=10*, *n_iter=10*, *verbose=0*, *random_state=None*)

Bernoulli Restricted Boltzmann Machine (RBM).

A Restricted Boltzmann Machine with binary visible units and binary hidden units. Parameters are estimated using Stochastic Maximum Likelihood (SML), also known as Persistent Contrastive Divergence (PCD) [2].

The time complexity of this implementation is `O(d ** 2)` assuming d ~ n_features ~ n_components.

Read more in the *User Guide*.

Parameters **n_components** : int, optional

Number of binary hidden units.

learning_rate : float, optional

The learning rate for weight updates. It is *highly* recommended to tune this hyper-parameter. Reasonable values are in the 10**[0., -3.] range.

batch_size : int, optional

Number of examples per minibatch.

n_iter : int, optional

Number of iterations/sweeps over the training dataset to perform during training.

verbose : int, optional

The verbosity level. The default, zero, means silent mode.

random_state : integer or numpy.RandomState, optional

A random number generator instance to define the state of the random permutations generator. If an integer is given, it fixes the seed. Defaults to the global numpy random number generator.

Attributes **intercept_hidden_** : array-like, shape (n_components,)

Biases of the hidden units.

intercept_visible_ : array-like, shape (n_features,)

Biases of the visible units.

components_ : array-like, shape (n_components, n_features)

Weight matrix, where n_features in the number of visible units and n_components is the number of hidden units.

Examples

```
>>> import numpy as np
>>> from sklearn.neural_network import BernoulliRBM
>>> X = np.array([[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 1]])
>>> model = BernoulliRBM(n_components=2)
>>> model.fit(X)
BernoulliRBM(batch_size=10, learning_rate=0.1, n_components=2, n_iter=10,
       random_state=None, verbose=0)
```

Methods

fit(X[, y])	Fit the model to the data X.

Continued on next page

Table 29.214 – continued from previous page

fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
gibbs(v)	Perform one Gibbs sampling step.
partial_fit(X[, y])	Fit the model to the data X which should contain a partial segment of the data.
score_samples(X)	Compute the pseudo-likelihood of X.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Compute the hidden layer activation probabilities, P(h=1|v=X).

__init__(*n_components=256*, *learning_rate=0.1*, *batch_size=10*, *n_iter=10*, *verbose=0*, *random_state=None*)

fit(*X*, *y=None*)

Fit the model to the data X.

Parameters **X** : {array-like, sparse matrix} shape (n_samples, n_features)

Training data.

Returns **self** : BernoulliRBM

The fitted model.

fit_transform(*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

gibbs(*v*)

Perform one Gibbs sampling step.

Parameters **v** : array-like, shape (n_samples, n_features)

Values of the visible layer to start from.

Returns **v_new** : array-like, shape (n_samples, n_features)

Values of the visible layer after one Gibbs step.

partial_fit(*X*, *y=None*)
Fit the model to the data X which should contain a partial segment of the data.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data.

Returns **self** : BernoulliRBM

The fitted model.

score_samples(*X*)
Compute the pseudo-likelihood of X.

Parameters **X** : {array-like, sparse matrix} shape (n_samples, n_features)

Values of the visible layer. Must be all-boolean (not checked).

Returns **pseudo_likelihood** : array-like, shape (n_samples,)

Value of the pseudo-likelihood (proxy for likelihood).

Notes

This method is not deterministic: it computes a quantity called the free energy on X, then on a randomly corrupted version of X, and returns the log of the logistic function of the difference.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Compute the hidden layer activation probabilities, P(h=1|v=X).

Parameters **X** : {array-like, sparse matrix} shape (n_samples, n_features)

The data to be transformed.

Returns **h** : array, shape (n_samples, n_components)

Latent representations of the data.

Examples using `sklearn.neural_network.BernoulliRBM`

- *Restricted Boltzmann Machine features for digit classification*

29.26.2 sklearn.neural_network.MLPClassifier

class sklearn.neural_network.**MLPClassifier**(*hidden_layer_sizes=(100,)*, *activation='relu'*, *solver='adam'*, *alpha=0.0001*, *batch_size='auto'*, *learning_rate='constant'*, *learning_rate_init=0.001*, *power_t=0.5*, *max_iter=200*, *shuffle=True*, *random_state=None*, *tol=0.0001*, *verbose=False*, *warm_start=False*, *momentum=0.9*, *nesterovs_momentum=True*, *early_stopping=False*, *validation_fraction=0.1*, *beta_1=0.9*, *beta_2=0.999*, *epsilon=1e-08*)

Multi-layer Perceptron classifier.

This model optimizes the log-loss function using LBFGS or stochastic gradient descent.

New in version 0.18.

Parameters **hidden_layer_sizes** : tuple, length = n_layers - 2, default (100,)

The ith element represents the number of neurons in the ith hidden layer.

activation : {'identity', 'logistic', 'tanh', 'relu'}, default 'relu'

Activation function for the hidden layer.

- 'identity', no-op activation, useful to implement linear bottleneck, returns f(x) = x
- 'logistic', the logistic sigmoid function, returns f(x) = 1 / (1 + exp(-x)).
- 'tanh', the hyperbolic tan function, returns f(x) = tanh(x).
- 'relu', the rectified linear unit function, returns f(x) = max(0, x)

solver : {'lbfgs', 'sgd', 'adam'}, default 'adam'

The solver for weight optimization.

- 'lbfgs' is an optimizer in the family of quasi-Newton methods.
- 'sgd' refers to stochastic gradient descent.
- 'adam' refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba

Note: The default solver 'adam' works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, 'lbfgs' can converge faster and perform better.

alpha : float, optional, default 0.0001

L2 penalty (regularization term) parameter.

batch_size : int, optional, default 'auto'

Size of minibatches for stochastic optimizers. If the solver is 'lbfgs', the classifier will not use minibatch. When set to "auto", *batch_size=min(200, n_samples)*

learning_rate : {'constant', 'invscaling', 'adaptive'}, default 'constant'

Learning rate schedule for weight updates.

- 'constant' is a constant learning rate given by 'learning_rate_init'.

- 'invscaling' gradually decreases the learning rate `learning_rate_` at each time step 't' using an inverse scaling exponent of 'power_t'. effective_learning_rate = learning_rate_init / pow(t, power_t)
- 'adaptive' keeps the learning rate constant to 'learning_rate_init' as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least tol, or fail to increase validation score by at least tol if 'early_stopping' is on, the current learning rate is divided by 5.

Only used when `solver='sgd'`.

max_iter : int, optional, default 200

Maximum number of iterations. The solver iterates until convergence (determined by 'tol') or this number of iterations. For stochastic solvers ('sgd', 'adam'), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.

random_state : int, RandomState instance or None, optional, default None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

shuffle : bool, optional, default True

Whether to shuffle samples in each iteration. Only used when solver='sgd' or 'adam'.

tol : float, optional, default 1e-4

Tolerance for the optimization. When the loss or score is not improving by at least tol for two consecutive iterations, unless *learning_rate* is set to 'adaptive', convergence is considered to be reached and training stops.

learning_rate_init : double, optional, default 0.001

The initial learning rate used. It controls the step-size in updating the weights. Only used when solver='sgd' or 'adam'.

power_t : double, optional, default 0.5

The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the learning_rate is set to 'invscaling'. Only used when solver='sgd'.

verbose : bool, optional, default False

Whether to print progress messages to stdout.

warm_start : bool, optional, default False

When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

momentum : float, default 0.9

Momentum for gradient descent update. Should be between 0 and 1. Only used when solver='sgd'.

nesterovs_momentum : boolean, default True

Whether to use Nesterov's momentum. Only used when solver='sgd' and momentum > 0.

early_stopping : bool, default False

Whether to use early stopping to terminate training when validation score is not improving. If set to true, it will automatically set aside 10% of training data as validation and terminate training when validation score is not improving by at least tol for two consecutive epochs. Only effective when solver='sgd' or 'adam'

validation_fraction : float, optional, default 0.1

The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True

beta_1 : float, optional, default 0.9

Exponential decay rate for estimates of first moment vector in adam, should be in [0, 1). Only used when solver='adam'

beta_2 : float, optional, default 0.999

Exponential decay rate for estimates of second moment vector in adam, should be in [0, 1). Only used when solver='adam'

epsilon : float, optional, default 1e-8

Value for numerical stability in adam. Only used when solver='adam'

Attributes **classes_** : array or list of array of shape (n_classes,)

Class labels for each output.

loss_ : float

The current loss computed with the loss function.

coefs_ : list, length n_layers - 1

The ith element in the list represents the weight matrix corresponding to layer i.

intercepts_ : list, length n_layers - 1

The ith element in the list represents the bias vector corresponding to layer i + 1.

n_iter_ : int,

The number of iterations the solver has ran.

n_layers_ : int

Number of layers.

n_outputs_ : int

Number of outputs.

out_activation_ : string

Name of the output activation function.

Notes

MLPClassifier trains iteratively since at each time step the partial derivatives of the loss function with respect to the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent overfitting.

This implementation works with data represented as dense numpy arrays or sparse scipy arrays of floating point values.

Methods

fit(X, y)	Fit the model to data matrix X and target(s) y.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict using the multi-layer perceptron classifier
predict_log_proba(X)	Return the log of probability estimates.
predict_proba(X)	Probability estimates.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*hidden_layer_sizes=(100,)*, *activation='relu'*, *solver='adam'*, *alpha=0.0001*, *batch_size='auto'*, *learning_rate='constant'*, *learning_rate_init=0.001*, *power_t=0.5*, *max_iter=200*, *shuffle=True*, *random_state=None*, *tol=0.0001*, *verbose=False*, *warm_start=False*, *momentum=0.9*, *nesterovs_momentum=True*, *early_stopping=False*, *validation_fraction=0.1*, *beta_1=0.9*, *beta_2=0.999*, *epsilon=1e-08*)

fit (*X*, *y*)

Fit the model to data matrix X and target(s) y.

Parameters **X** : array-like or sparse matrix, shape (n_samples, n_features)

The input data.

y : array-like, shape (n_samples,) or (n_samples, n_outputs)

The target values (class labels in classification, real numbers in regression).

Returns **self** : returns a trained MLP model.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

partial_fit

Fit the model to data matrix X and target y.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

The input data.

y : array-like, shape (n_samples,)

The target values.

classes : array, shape (n_classes)

Classes across all calls to partial_fit. Can be obtained via *np.unique(y_all)*, where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn't need to contain all labels in *classes*.

Returns **self** : returns a trained MLP model.

predict(*X*)

Predict using the multi-layer perceptron classifier

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

The input data.

Returns **y** : array-like, shape (n_samples,) or (n_samples, n_classes)

The predicted classes.

predict_log_proba(*X*)

Return the log of probability estimates.

Parameters **X** : array-like, shape (n_samples, n_features)

The input data.

Returns **log_y_prob** : array-like, shape (n_samples, n_classes)

The predicted log-probability of the sample for each class in the model, where classes are ordered as they are in *self.classes_*. Equivalent to log(predict_proba(X))

predict_proba(*X*)

Probability estimates.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

The input data.

Returns **y_prob** : array-like, shape (n_samples, n_classes)

The predicted probability of the sample for each class in the model, where classes are ordered as they are in *self.classes_*.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params (***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.neural_network.MLPClassifier`

- *Classifier comparison*
- *Varying regularization in Multi-layer Perceptron*
- *Compare Stochastic learning strategies for MLPClassifier*
- *Visualization of MLP weights on MNIST*

29.26.3 `sklearn.neural_network`.MLPRegressor

class `sklearn.neural_network.`**MLPRegressor**(*hidden_layer_sizes=(100,)*, *activation='relu'*, *solver='adam'*, *alpha=0.0001*, *batch_size='auto'*, *learning_rate='constant'*, *learning_rate_init=0.001*, *power_t=0.5*, *max_iter=200*, *shuffle=True*, *random_state=None*, *tol=0.0001*, *verbose=False*, *warm_start=False*, *momentum=0.9*, *nesterovs_momentum=True*, *early_stopping=False*, *validation_fraction=0.1*, *beta_1=0.9*, *beta_2=0.999*, *epsilon=1e-08*)

Multi-layer Perceptron regressor.

This model optimizes the squared-loss using LBFGS or stochastic gradient descent.

New in version 0.18.

Parameters **hidden_layer_sizes** : tuple, length = n_layers - 2, default (100,)

The ith element represents the number of neurons in the ith hidden layer.

activation : {'identity', 'logistic', 'tanh', 'relu'}, default 'relu'

Activation function for the hidden layer.

- 'identity', no-op activation, useful to implement linear bottleneck, returns f(x) = x
- 'logistic', the logistic sigmoid function, returns f(x) = 1 / (1 + exp(-x)).
- 'tanh', the hyperbolic tan function, returns f(x) = tanh(x).
- 'relu', the rectified linear unit function, returns f(x) = max(0, x)

solver : {'lbfgs', 'sgd', 'adam'}, default 'adam'

The solver for weight optimization.

- 'lbfgs' is an optimizer in the family of quasi-Newton methods.
- 'sgd' refers to stochastic gradient descent.

- 'adam' refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba

Note: The default solver 'adam' works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, 'lbfgs' can converge faster and perform better.

alpha : float, optional, default 0.0001

L2 penalty (regularization term) parameter.

batch_size : int, optional, default 'auto'

Size of minibatches for stochastic optimizers. If the solver is 'lbfgs', the classifier will not use minibatch. When set to "auto", *batch_size=min(200, n_samples)*

learning_rate : {'constant', 'invscaling', 'adaptive'}, default 'constant'

Learning rate schedule for weight updates.

- 'constant' is a constant learning rate given by 'learning_rate_init'.
- 'invscaling' gradually decreases the learning rate `learning_rate_` at each time step 't' using an inverse scaling exponent of 'power_t'. effective_learning_rate = learning_rate_init / pow(t, power_t)
- 'adaptive' keeps the learning rate constant to 'learning_rate_init' as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least tol, or fail to increase validation score by at least tol if 'early_stopping' is on, the current learning rate is divided by 5.

Only used when solver='sgd'.

max_iter : int, optional, default 200

Maximum number of iterations. The solver iterates until convergence (determined by 'tol') or this number of iterations. For stochastic solvers ('sgd', 'adam'), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.

random_state : int, RandomState instance or None, optional, default None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

shuffle : bool, optional, default True

Whether to shuffle samples in each iteration. Only used when solver='sgd' or 'adam'.

tol : float, optional, default 1e-4

Tolerance for the optimization. When the loss or score is not improving by at least tol for two consecutive iterations, unless *learning_rate* is set to 'adaptive', convergence is considered to be reached and training stops.

learning_rate_init : double, optional, default 0.001

The initial learning rate used. It controls the step-size in updating the weights. Only used when solver='sgd' or 'adam'.

power_t : double, optional, default 0.5

The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the learning_rate is set to 'invscaling'. Only used when solver='sgd'.

verbose : bool, optional, default False

Whether to print progress messages to stdout.

warm_start : bool, optional, default False

When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

momentum : float, default 0.9

Momentum for gradient descent update. Should be between 0 and 1. Only used when solver='sgd'.

nesterovs_momentum : boolean, default True

Whether to use Nesterov's momentum. Only used when solver='sgd' and momentum > 0.

early_stopping : bool, default False

Whether to use early stopping to terminate training when validation score is not improving. If set to true, it will automatically set aside 10% of training data as validation and terminate training when validation score is not improving by at least tol for two consecutive epochs. Only effective when solver='sgd' or 'adam'

validation_fraction : float, optional, default 0.1

The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True

beta_1 : float, optional, default 0.9

Exponential decay rate for estimates of first moment vector in adam, should be in [0, 1). Only used when solver='adam'

beta_2 : float, optional, default 0.999

Exponential decay rate for estimates of second moment vector in adam, should be in [0, 1). Only used when solver='adam'

epsilon : float, optional, default 1e-8

Value for numerical stability in adam. Only used when solver='adam'

Attributes **loss_** : float

The current loss computed with the loss function.

coefs_ : list, length n_layers - 1

The ith element in the list represents the weight matrix corresponding to layer i.

intercepts_ : list, length n_layers - 1

The ith element in the list represents the bias vector corresponding to layer i + 1.

n_iter_ : int,

The number of iterations the solver has ran.

n_layers_ : int

Number of layers.

n_outputs_ : int

Number of outputs.

out_activation_ : string

Name of the output activation function.

Notes

MLPRegressor trains iteratively since at each time step the partial derivatives of the loss function with respect to the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent overfitting.

This implementation works with data represented as dense and sparse numpy arrays of floating point values.

Methods

fit(X, y)	Fit the model to data matrix X and target(s) y.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict using the multi-layer perceptron model.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*hidden_layer_sizes=(100,)*, *activation='relu'*, *solver='adam'*, *alpha=0.0001*, *batch_size='auto'*, *learning_rate='constant'*, *learning_rate_init=0.001*, *power_t=0.5*, *max_iter=200*, *shuffle=True*, *random_state=None*, *tol=0.0001*, *verbose=False*, *warm_start=False*, *momentum=0.9*, *nesterovs_momentum=True*, *early_stopping=False*, *validation_fraction=0.1*, *beta_1=0.9*, *beta_2=0.999*, *epsilon=1e-08*)

fit (*X*, *y*)

Fit the model to data matrix X and target(s) y.

Parameters **X** : array-like or sparse matrix, shape (n_samples, n_features)

The input data.

y : array-like, shape (n_samples,) or (n_samples, n_outputs)

The target values (class labels in classification, real numbers in regression).

Returns **self** : returns a trained MLP model.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

partial_fit
Fit the model to data matrix X and target y.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

The input data.

y : array-like, shape (n_samples,)

The target values.

Returns **self** : returns a trained MLP model.

predict(*X*)
Predict using the multi-layer perceptron model.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

The input data.

Returns **y** : array-like, shape (n_samples, n_outputs)

The predicted values.

score(*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.27 sklearn.calibration: Probability Calibration

Calibration of predicted probabilities.

User guide: See the *Probability calibration* section for further details.

calibration.CalibratedClassifierCV([...])	Probability calibration with isotonic regression or sigmoid.

29.27.1 sklearn.calibration.CalibratedClassifierCV

class sklearn.calibration.**CalibratedClassifierCV**(*base_estimator=None*, *method='sigmoid'*, *cv=3*)

Probability calibration with isotonic regression or sigmoid.

With this class, the base_estimator is fit on the train set of the cross-validation generator and the test set is used for calibration. The probabilities for each of the folds are then averaged for prediction. In case that cv="prefit" is passed to __init__, it is assumed that base_estimator has been fitted already and all data is used for calibration. Note that data for fitting the classifier and for calibrating it must be disjoint.

Read more in the *User Guide*.

Parameters **base_estimator** : instance BaseEstimator

The classifier whose output decision function needs to be calibrated to offer more accurate predict_proba outputs. If cv=prefit, the classifier must have been fit already on data.

method : 'sigmoid' or 'isotonic'

The method to use for calibration. Can be 'sigmoid' which corresponds to Platt's method or 'isotonic' which is a non-parametric approach. It is not advised to use isotonic calibration with too few calibration samples (<<1000) since it tends to overfit. Use sigmoids (Platt's calibration) in this case.

cv : integer, cross-validation generator, iterable or "prefit", optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if y is binary or multiclass, *sklearn.model_selection.StratifiedKFold* is used. If y is neither binary nor multiclass, *sklearn.model_selection.KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

If "prefit" is passed, it is assumed that base_estimator has been fitted already and all data is used for calibration.

Attributes **classes_** : array, shape (n_classes)

The class labels.

calibrated_classifiers_ : list (len() equal to cv or 1 if cv == "prefit")

The list of calibrated classifiers, one for each crossvalidation fold, which has been fitted on all but the validation fold and calibrated on the validation fold.

Methods

fit(X, y[, sample_weight])	Fit the calibrated model
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict the target of new samples.
predict_proba(X)	Posterior probabilities of classification
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*base_estimator=None*, *method='sigmoid'*, *cv=3*)

fit (*X*, *y*, *sample_weight=None*)
Fit the calibrated model

Parameters **X** : array-like, shape (n_samples, n_features)

Training data.

y : array-like, shape (n_samples,)

Target values.

sample_weight : array-like, shape = [n_samples] or None

Sample weights. If None, then samples are equally weighted.

Returns **self** : object

Returns an instance of self.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*)
Predict the target of new samples. Can be different from the prediction of the uncalibrated classifier.

Parameters **X** : array-like, shape (n_samples, n_features)

The samples.

Returns **C** : array, shape (n_samples,)

The predicted class.

predict_proba(*X*)
Posterior probabilities of classification

This function returns posterior probabilities of classification according to each class on an array of test vectors X.

Parameters **X** : array-like, shape (n_samples, n_features)

The samples.

Returns **C** : array, shape (n_samples, n_classes)

The predicted probas.

score(*X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.calibration.CalibratedClassifierCV`

- *Probability calibration of classifiers*
- *Probability Calibration curves*
- *Probability Calibration for 3-class classification*

calibration.calibration_curve(y_true, y_prob)	Compute true and predicted probabilities for a calibration curve.

29.27.2 `sklearn.calibration`.calibration_curve

sklearn.calibration.**calibration_curve**(*y_true*, *y_prob*, *normalize=False*, *n_bins=5*)
Compute true and predicted probabilities for a calibration curve.

Calibration curves may also be referred to as reliability diagrams.

Read more in the *User Guide*.

Parameters **y_true** : array, shape (n_samples,)

True targets.

y_prob : array, shape (n_samples,)

Probabilities of the positive class.

normalize : bool, optional, default=False

Whether y_prob needs to be normalized into the bin [0, 1], i.e. is not a proper probability. If True, the smallest value in y_prob is mapped onto 0 and the largest one onto 1.

n_bins : int

Number of bins. A bigger number requires more data.

Returns **prob_true** : array, shape (n_bins,)

The true probability in each bin (fraction of positives).

prob_pred : array, shape (n_bins,)

The mean predicted probability in each bin.

29.28 `sklearn.cross_decomposition`: Cross decomposition

User guide: See the *Cross decomposition* section for further details.

`cross_decomposition.PLSRegression`([...])	PLS regression
`cross_decomposition.PLSCanonical`([...])	PLSCanonical implements the 2 blocks canonical PLS of the original Wold algorithm [Tenenhaus 1998] p.204, referred as PLS-C2A in [Wegelin 2000].
`cross_decomposition.CCA`([n_components, ...])	CCA Canonical Correlation Analysis.
`cross_decomposition.PLSSVD`([n_components, ...])	Partial Least Square SVD

29.28.1 sklearn.cross_decomposition.PLSRegression

class sklearn.cross_decomposition.**PLSRegression**(*n_components=2*, *scale=True*, *max_iter=500*, *tol=1e-06*, *copy=True*)

PLS regression

PLSRegression implements the PLS 2 blocks regression known as PLS2 or PLS1 in case of one dimensional response. This class inherits from _PLS with mode="A", deflation_mode="regression", norm_y_weights=False and algorithm="nipals".

Read more in the *User Guide*.

Parameters **n_components** : int, (default 2)

Number of components to keep.

scale : boolean, (default True)

whether to scale the data

max_iter : an integer, (default 500)

the maximum number of iterations of the NIPALS inner loop (used only if algorithm="nipals")

tol : non-negative real

Tolerance used in the iterative algorithm default 1e-06.

copy : boolean, default True

Whether the deflation should be done on a copy. Let the default value to True unless you don't care about side effect

Attributes **x_weights_** : array, [p, n_components]

X block weights vectors.

y_weights_ : array, [q, n_components]

Y block weights vectors.

x_loadings_ : array, [p, n_components]

X block loadings vectors.

y_loadings_ : array, [q, n_components]

Y block loadings vectors.

x_scores_ : array, [n_samples, n_components]

X scores.

y_scores_ : array, [n_samples, n_components]

Y scores.

x_rotations_ : array, [p, n_components]

X block to latents rotations.

y_rotations_ : array, [q, n_components]

Y block to latents rotations.

coef_ : array, [p, q]

The coefficients of the linear model: `Y = X coef_ + Err`

n_iter_ : array-like

Number of iterations of the NIPALS inner loop for each component.

Notes

Matrices:

```
T: x_scores_
U: y_scores_
W: x_weights_
C: y_weights_
P: x_loadings_
Q: y_loadings__
```

Are computed such that:

```
X = T P.T + Err and Y = U Q.T + Err
T[:, k] = Xk W[:, k] for k in range(n_components)
U[:, k] = Yk C[:, k] for k in range(n_components)
x_rotations_ = W (P.T W)^(-1)
y_rotations_ = C (Q.T C)^(-1)
```

where Xk and Yk are residual matrices at iteration k.

Slides explaining PLS

For each component k, find weights u, v that optimizes: `max corr(Xk u, Yk v) * std(Xk u) std(Yk u)`, such that `|u| = 1`

Note that it maximizes both the correlations between the scores and the intra-block variances.

The residual matrix of X (Xk+1) block is obtained by the deflation on the current X score: x_score.

The residual matrix of Y (Yk+1) block is obtained by deflation on the current X score. This performs the PLS regression known as PLS2. This mode is prediction oriented.

This implementation provides the same results that 3 PLS packages provided in the R language (R-project):

- "mixOmics" with function pls(X, Y, mode = "regression")
- "plspm " with function plsreg2(X, Y)
- "pls" with function oscorespls.fit(X, Y)

Examples

```
>>> from sklearn.cross_decomposition import PLSRegression
>>> X = [[0., 0., 1.], [1.,0.,0.], [2.,2.,2.], [2.,5.,4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> pls2 = PLSRegression(n_components=2)
>>> pls2.fit(X, Y)
...
PLSRegression(copy=True, max_iter=500, n_components=2, scale=True,
        tol=1e-06)
>>> Y_pred = pls2.predict(X)
```

Methods

fit(X, Y)	Fit model to data.
fit_transform(X[, y])	Learn and apply the dimension reduction on the train data.
get_params([deep])	Get parameters for this estimator.
predict(X[, copy])	Apply the dimension reduction learned on the train data.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.
transform(X[, Y, copy])	Apply the dimension reduction learned on the train data.

__init__ (*n_components=2*, *scale=True*, *max_iter=500*, *tol=1e-06*, *copy=True*)

fit (*X*, *Y*)
Fit model to data.

Parameters **X** : array-like, shape = [n_samples, n_features]

Training vectors, where n_samples in the number of samples and n_features is the number of predictors.

Y : array-like of response, shape = [n_samples, n_targets]

Target vectors, where n_samples in the number of samples and n_targets is the number of response variables.

fit_transform (*X*, *y=None*, ***fit_params*)
Learn and apply the dimension reduction on the train data.

Parameters **X** : array-like of predictors, shape = [n_samples, p]

Training vectors, where n_samples in the number of samples and p is the number of predictors.

Y : array-like of response, shape = [n_samples, q], optional

Training vectors, where n_samples in the number of samples and q is the number of response variables.

copy : boolean, default True

Whether to copy X and Y, or perform in-place normalization.

Returns **x_scores if Y is not given, (x_scores, y_scores) otherwise.** :

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*, *copy=True*)

Apply the dimension reduction learned on the train data.

Parameters **X** : array-like of predictors, shape = [n_samples, p]

Training vectors, where n_samples in the number of samples and p is the number of predictors.

copy : boolean, default True

Whether to copy X and Y, or perform in-place normalization.

Notes

This call requires the estimation of a p x q matrix, which may be an issue in high dimensional space.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *Y=None*, *copy=True*)

Apply the dimension reduction learned on the train data.

Parameters **X** : array-like of predictors, shape = [n_samples, p]

Training vectors, where n_samples in the number of samples and p is the number of predictors.

Y : array-like of response, shape = [n_samples, q], optional

Training vectors, where n_samples in the number of samples and q is the number of response variables.

copy : boolean, default True

Whether to copy X and Y, or perform in-place normalization.

Returns **x_scores if Y is not given, (x_scores, y_scores) otherwise.** :

Examples using `sklearn.cross_decomposition.PLSRegression`

- *Compare cross decomposition methods*

29.28.2 `sklearn.cross_decomposition.`PLSCanonical

class `sklearn.cross_decomposition.`**`PLSCanonical`**(*n_components=2*, *scale=True*, *algorithm='nipals'*, *max_iter=500*, *tol=1e-06*, *copy=True*)

PLSCanonical implements the 2 blocks canonical PLS of the original Wold algorithm [Tenenhaus 1998] p.204, referred as PLS-C2A in [Wegelin 2000].

This class inherits from PLS with mode="A" and deflation_mode="canonical", norm_y_weights=True and algorithm="nipals", but svd should provide similar results up to numerical errors.

Read more in the *User Guide*.

Parameters **scale** : boolean, scale data? (default True)

algorithm : string, "nipals" or "svd"

The algorithm used to estimate the weights. It will be called n_components times, i.e. once for each iteration of the outer loop.

max_iter : an integer, (default 500)

the maximum number of iterations of the NIPALS inner loop (used only if algorithm="nipals")

tol : non-negative real, default 1e-06

the tolerance used in the iterative algorithm

copy : boolean, default True

Whether the deflation should be done on a copy. Let the default value to True unless you don't care about side effect

n_components : int, number of components to keep. (default 2).

Attributes **x_weights_** : array, shape = [p, n_components]

X block weights vectors.

y_weights_ : array, shape = [q, n_components]

Y block weights vectors.

x_loadings_ : array, shape = [p, n_components]

X block loadings vectors.

y_loadings_ : array, shape = [q, n_components]

Y block loadings vectors.

x_scores_ : array, shape = [n_samples, n_components]

X scores.

y_scores_ : array, shape = [n_samples, n_components]

Y scores.

x_rotations_ : array, shape = [p, n_components]

X block to latents rotations.

y_rotations_ : array, shape = [q, n_components]

Y block to latents rotations.

n_iter_ : array-like

Number of iterations of the NIPALS inner loop for each component. Not useful if the algorithm provided is "svd".

See also:

CCA, *PLSSVD*

Notes

Matrices:

```
T: x_scores_
U: y_scores_
W: x_weights_
C: y_weights_
P: x_loadings_
Q: y_loadings__
```

Are computed such that:

```
X = T P.T + Err and Y = U Q.T + Err
T[:, k] = Xk W[:, k] for k in range(n_components)
U[:, k] = Yk C[:, k] for k in range(n_components)
x_rotations_ = W (P.T W)^(-1)
y_rotations_ = C (Q.T C)^(-1)
```

where Xk and Yk are residual matrices at iteration k.

Slides explaining PLS

For each component k, find weights u, v that optimize:

```
max corr(Xk u, Yk v) * std(Xk u) std(Yk u), such that ``|u| = |v| = 1``
```

Note that it maximizes both the correlations between the scores and the intra-block variances.

The residual matrix of X (Xk+1) block is obtained by the deflation on the current X score: x_score.

The residual matrix of Y (Yk+1) block is obtained by deflation on the current Y score. This performs a canonical symmetric version of the PLS regression. But slightly different than the CCA. This is mostly used for modeling.

This implementation provides the same results that the "plspm" package provided in the R language (R-project), using the function plsca(X, Y). Results are equal or collinear with the function `pls(..., mode`

= "canonical") of the "mixOmics" package. The difference relies in the fact that mixOmics implementation does not exactly implement the Wold algorithm since it does not normalize y_weights to one.

Examples

```
>>> from sklearn.cross_decomposition import PLSCanonical
>>> X = [[0., 0., 1.], [1.,0.,0.], [2.,2.,2.], [2.,5.,4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> plsca = PLSCanonical(n_components=2)
>>> plsca.fit(X, Y)
...
PLSCanonical(algorithm='nipals', copy=True, max_iter=500, n_components=2,
             scale=True, tol=1e-06)
>>> X_c, Y_c = plsca.transform(X, Y)
```

Methods

fit(X, Y)	Fit model to data.
fit_transform(X[, y])	Learn and apply the dimension reduction on the train data.
get_params([deep])	Get parameters for this estimator.
predict(X[, copy])	Apply the dimension reduction learned on the train data.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.
transform(X[, Y, copy])	Apply the dimension reduction learned on the train data.

__init__ (*n_components=2*, *scale=True*, *algorithm='nipals'*, *max_iter=500*, *tol=1e-06*, *copy=True*)

fit (*X*, *Y*)
Fit model to data.

Parameters **X** : array-like, shape = [n_samples, n_features]

Training vectors, where n_samples in the number of samples and n_features is the number of predictors.

Y : array-like of response, shape = [n_samples, n_targets]

Target vectors, where n_samples in the number of samples and n_targets is the number of response variables.

fit_transform (*X*, *y=None*, ***fit_params*)
Learn and apply the dimension reduction on the train data.

Parameters **X** : array-like of predictors, shape = [n_samples, p]

Training vectors, where n_samples in the number of samples and p is the number of predictors.

Y : array-like of response, shape = [n_samples, q], optional

Training vectors, where n_samples in the number of samples and q is the number of response variables.

copy : boolean, default True

Whether to copy X and Y, or perform in-place normalization.

Returns x_scores if Y is not given, (x_scores, y_scores) otherwise. :

get_params(*deep=True*)

Get parameters for this estimator.

Parameters deep : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns params : mapping of string to any

Parameter names mapped to their values.

predict(*X*, *copy=True*)

Apply the dimension reduction learned on the train data.

Parameters X : array-like of predictors, shape = [n_samples, p]

Training vectors, where n_samples in the number of samples and p is the number of predictors.

copy : boolean, default True

Whether to copy X and Y, or perform in-place normalization.

Notes

This call requires the estimation of a p x q matrix, which may be an issue in high dimensional space.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters X : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns score : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *Y=None*, *copy=True*)
Apply the dimension reduction learned on the train data.

Parameters **X** : array-like of predictors, shape = [n_samples, p]

Training vectors, where n_samples in the number of samples and p is the number of predictors.

Y : array-like of response, shape = [n_samples, q], optional

Training vectors, where n_samples in the number of samples and q is the number of response variables.

copy : boolean, default True

Whether to copy X and Y, or perform in-place normalization.

Returns **x_scores if Y is not given, (x_scores, y_scores) otherwise.** :

Examples using `sklearn.cross_decomposition.PLSCanonical`

- *Compare cross decomposition methods*

29.28.3 `sklearn.cross_decomposition.CCA`

class `sklearn.cross_decomposition.`**CCA**(*n_components=2*, *scale=True*, *max_iter=500*, *tol=1e-06*, *copy=True*)
CCA Canonical Correlation Analysis.

CCA inherits from PLS with mode="B" and deflation_mode="canonical".

Read more in the *User Guide*.

Parameters **n_components** : int, (default 2).

number of components to keep.

scale : boolean, (default True)

whether to scale the data?

max_iter : an integer, (default 500)

the maximum number of iterations of the NIPALS inner loop

tol : non-negative real, default 1e-06.

the tolerance used in the iterative algorithm

copy : boolean

Whether the deflation be done on a copy. Let the default value to True unless you don't care about side effects

Attributes **x_weights_** : array, [p, n_components]

X block weights vectors.

y_weights_ : array, [q, n_components]

Y block weights vectors.

x_loadings_ : array, [p, n_components]

X block loadings vectors.

y_loadings_ : array, [q, n_components]

Y block loadings vectors.

x_scores_ : array, [n_samples, n_components]

X scores.

y_scores_ : array, [n_samples, n_components]

Y scores.

x_rotations_ : array, [p, n_components]

X block to latents rotations.

y_rotations_ : array, [q, n_components]

Y block to latents rotations.

n_iter_ : array-like

Number of iterations of the NIPALS inner loop for each component.

See also:

PLSCanonical, *PLSSVD*

Notes

For each component k, find the weights u, v that maximizes max corr(Xk u, Yk v), such that `|u| = |v| = 1`

Note that it maximizes only the correlations between the scores.

The residual matrix of X (Xk+1) block is obtained by the deflation on the current X score: x_score.

The residual matrix of Y (Yk+1) block is obtained by deflation on the current Y score.

Examples

```
>>> from sklearn.cross_decomposition import CCA
>>> X = [[0., 0., 1.], [1.,0.,0.], [2.,2.,2.], [3.,5.,4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> cca = CCA(n_components=1)
>>> cca.fit(X, Y)
...
CCA(copy=True, max_iter=500, n_components=1, scale=True, tol=1e-06)
>>> X_c, Y_c = cca.transform(X, Y)
```

Methods

fit(X, Y)	Fit model to data.
fit_transform(X[, y])	Learn and apply the dimension reduction on the train data.
get_params([deep])	Get parameters for this estimator.
predict(X[, copy])	Apply the dimension reduction learned on the train data.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.
transform(X[, Y, copy])	Apply the dimension reduction learned on the train data.

__init__ (*n_components=2*, *scale=True*, *max_iter=500*, *tol=1e-06*, *copy=True*)

fit (*X*, *Y*)
Fit model to data.

Parameters **X** : array-like, shape = [n_samples, n_features]

Training vectors, where n_samples in the number of samples and n_features is the number of predictors.

Y : array-like of response, shape = [n_samples, n_targets]

Target vectors, where n_samples in the number of samples and n_targets is the number of response variables.

fit_transform (*X*, *y=None*, ***fit_params*)
Learn and apply the dimension reduction on the train data.

Parameters **X** : array-like of predictors, shape = [n_samples, p]

Training vectors, where n_samples in the number of samples and p is the number of predictors.

Y : array-like of response, shape = [n_samples, q], optional

Training vectors, where n_samples in the number of samples and q is the number of response variables.

copy : boolean, default True

Whether to copy X and Y, or perform in-place normalization.

Returns **x_scores if Y is not given, (x_scores, y_scores) otherwise.** :

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*, *copy=True*)

Apply the dimension reduction learned on the train data.

Parameters **X** : array-like of predictors, shape = [n_samples, p]

Training vectors, where n_samples in the number of samples and p is the number of predictors.

copy : boolean, default True

Whether to copy X and Y, or perform in-place normalization.

Notes

This call requires the estimation of a p x q matrix, which may be an issue in high dimensional space.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *Y=None*, *copy=True*)

Apply the dimension reduction learned on the train data.

Parameters **X** : array-like of predictors, shape = [n_samples, p]

Training vectors, where n_samples in the number of samples and p is the number of predictors.

Y : array-like of response, shape = [n_samples, q], optional

Training vectors, where n_samples in the number of samples and q is the number of response variables.

copy : boolean, default True

Whether to copy X and Y, or perform in-place normalization.

Returns **x_scores if Y is not given, (x_scores, y_scores) otherwise.** :

Examples using `sklearn.cross_decomposition.CCA`

- *Multilabel classification*
- *Compare cross decomposition methods*

29.28.4 `sklearn.cross_decomposition.PLSSVD`

class `sklearn.cross_decomposition.`**`PLSSVD`**(*n_components=2*, *scale=True*, *copy=True*)

Partial Least Square SVD

Simply perform a svd on the crosscovariance matrix: X'Y There are no iterative deflation here.

Read more in the *User Guide*.

Parameters **n_components** : int, default 2

Number of components to keep.

scale : boolean, default True

Whether to scale X and Y.

copy : boolean, default True

Whether to copy X and Y, or perform in-place computations.

Attributes **x_weights_** : array, [p, n_components]

X block weights vectors.

y_weights_ : array, [q, n_components]

Y block weights vectors.

x_scores_ : array, [n_samples, n_components]

X scores.

y_scores_ : array, [n_samples, n_components]

Y scores.

Methods

`fit`(X, Y)

Continued on next page

Table 29.224 – continued from previous page

fit_transform(X[, y])	Learn and apply the dimension reduction on the train data.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X[, Y])	Apply the dimension reduction learned on the train data.

__init__ (*n_components=2*, *scale=True*, *copy=True*)

fit_transform (*X*, *y=None*, ***fit_params*)
Learn and apply the dimension reduction on the train data.

Parameters **X** : array-like of predictors, shape = [n_samples, p]

Training vectors, where n_samples in the number of samples and p is the number of predictors.

Y : array-like of response, shape = [n_samples, q], optional

Training vectors, where n_samples in the number of samples and q is the number of response variables.

Returns **x_scores if Y is not given, (x_scores, y_scores) otherwise.** :

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform (*X*, *Y=None*)
Apply the dimension reduction learned on the train data.

29.29 sklearn.pipeline: Pipeline

The *sklearn.pipeline* module implements utilities to build a composite estimator, as a chain of transforms and estimators.

pipeline.Pipeline(steps[, memory])	Pipeline of transforms with a final estimator.
pipeline.FeatureUnion(transformer_list[, ...])	Concatenates results of multiple transformer objects.

29.29.1 sklearn.pipeline.Pipeline

class sklearn.pipeline.**Pipeline**(*steps*, *memory=None*)

Pipeline of transforms with a final estimator.

Sequentially apply a list of transforms and a final estimator. Intermediate steps of the pipeline must be 'transforms', that is, they must implement fit and transform methods. The final estimator only needs to implement fit. The transformers in the pipeline can be cached using `memory` argument.

The purpose of the pipeline is to assemble several steps that can be cross-validated together while setting different parameters. For this, it enables setting parameters of the various steps using their names and the parameter name separated by a '__', as in the example below. A step's estimator may be replaced entirely by setting the parameter with its name to another estimator, or a transformer removed by setting to None.

Read more in the *User Guide*.

Parameters **steps** : list

List of (name, transform) tuples (implementing fit/transform) that are chained, in the order in which they are chained, with the last object an estimator.

memory : Instance of sklearn.external.joblib.Memory or string, optional (default=None)

Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute `named_steps` or `steps` to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.

Attributes **named_steps** : bunch object, a dictionary with attribute access

Read-only attribute to access any step parameter by user given name. Keys are step names and values are steps parameters.

Examples

```
>>> from sklearn import svm
>>> from sklearn.datasets import samples_generator
>>> from sklearn.feature_selection import SelectKBest
>>> from sklearn.feature_selection import f_regression
>>> from sklearn.pipeline import Pipeline
>>> # generate some data to play with
>>> X, y = samples_generator.make_classification(
...     n_informative=5, n_redundant=0, random_state=42)
>>> # ANOVA SVM-C
>>> anova_filter = SelectKBest(f_regression, k=5)
>>> clf = svm.SVC(kernel='linear')
>>> anova_svm = Pipeline([('anova', anova_filter), ('svc', clf)])
>>> # You can set the parameters using the names issued
>>> # For instance, fit using a k of 10 in the SelectKBest
>>> # and a parameter 'C' of the svm
>>> anova_svm.set_params(anova__k=10, svc__C=.1).fit(X, y)
...
Pipeline(memory=None,
         steps=[('anova', SelectKBest(...)),
                ('svc', SVC(...))])
>>> prediction = anova_svm.predict(X)
>>> anova_svm.score(X, y)
```

```
0.829...
>>> # getting the selected features chosen by anova_filter
>>> anova_svm.named_steps['anova'].get_support()
...
array([False, False,  True,  True, False, False, True,  True, False,
       True,  False,  True,  True, False, True,  False, True, True,
       False, False], dtype=bool)
>>> # Another way to get selected features chosen by anova_filter
>>> anova_svm.named_steps.anova.get_support()
...
array([False, False,  True,  True, False, False, True,  True, False,
       True,  False,  True,  True, False, True,  False, True, True,
       False, False], dtype=bool)
```

Methods

decision_function(X)	Apply transforms, and decision_function of the final estimator
fit(X[, y])	Fit the model
fit_predict(X[, y])	Applies fit_predict of last step in pipeline after transforms.
fit_transform(X[, y])	Fit the model and transform with the final estimator
get_params([deep])	Get parameters for this estimator.
predict(X)	Apply transforms to the data, and predict with the final estimator
predict_log_proba(X)	Apply transforms, and predict_log_proba of the final estimator
predict_proba(X)	Apply transforms, and predict_proba of the final estimator
score(X[, y, sample_weight])	Apply transforms, and score with the final estimator
set_params(**kwargs)	Set the parameters of this estimator.

__init__ (*steps*, *memory=None*)

decision_function (*X*)

Apply transforms, and decision_function of the final estimator

Parameters **X** : iterable

Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns **y_score** : array-like, shape = [n_samples, n_classes]

fit (*X*, *y=None*, ***fit_params*)

Fit the model

Fit all the transforms one after the other and transform the data, then fit the transformed data using the final estimator.

Parameters **X** : iterable

Training data. Must fulfill input requirements of first step of the pipeline.

y : iterable, default=None

Training targets. Must fulfill label requirements for all steps of the pipeline.

****fit_params** : dict of string -> object

Parameters passed to the `fit` method of each step, where each parameter name is prefixed such that parameter `p` for step `s` has key `s__p`.

Returns **self** : Pipeline

This estimator

fit_predict(*X*, *y=None*, ***fit_params*)

Applies fit_predict of last step in pipeline after transforms.

Applies fit_transforms of a pipeline to the data, followed by the fit_predict method of the final estimator in the pipeline. Valid only if the final estimator implements fit_predict.

Parameters **X** : iterable

Training data. Must fulfill input requirements of first step of the pipeline.

y : iterable, default=None

Training targets. Must fulfill label requirements for all steps of the pipeline.

****fit_params** : dict of string -> object

Parameters passed to the `fit` method of each step, where each parameter name is prefixed such that parameter `p` for step `s` has key `s__p`.

Returns **y_pred** : array-like

fit_transform(*X*, *y=None*, ***fit_params*)

Fit the model and transform with the final estimator

Fits all the transforms one after the other and transforms the data, then uses fit_transform on transformed data with the final estimator.

Parameters **X** : iterable

Training data. Must fulfill input requirements of first step of the pipeline.

y : iterable, default=None

Training targets. Must fulfill label requirements for all steps of the pipeline.

****fit_params** : dict of string -> object

Parameters passed to the `fit` method of each step, where each parameter name is prefixed such that parameter `p` for step `s` has key `s__p`.

Returns **Xt** : array-like, shape = [n_samples, n_transformed_features]

Transformed samples

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform

Apply inverse transformations in reverse order

All estimators in the pipeline must support `inverse_transform`.

Parameters **Xt** : array-like, shape = [n_samples, n_transformed_features]

Data samples, where `n_samples` is the number of samples and `n_features` is the number of features. Must fulfill input requirements of last step of pipeline's `inverse_transform` method.

Returns **Xt** : array-like, shape = [n_samples, n_features]

predict(*X*)

Apply transforms to the data, and predict with the final estimator

Parameters **X** : iterable

Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns **y_pred** : array-like

predict_log_proba(*X*)

Apply transforms, and predict_log_proba of the final estimator

Parameters **X** : iterable

Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns **y_score** : array-like, shape = [n_samples, n_classes]

predict_proba(*X*)

Apply transforms, and predict_proba of the final estimator

Parameters **X** : iterable

Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns **y_proba** : array-like, shape = [n_samples, n_classes]

score(*X*, *y=None*, *sample_weight=None*)

Apply transforms, and score with the final estimator

Parameters **X** : iterable

Data to predict on. Must fulfill input requirements of first step of the pipeline.

y : iterable, default=None

Targets used for scoring. Must fulfill label requirements for all steps of the pipeline.

sample_weight : array-like, default=None

If not None, this argument is passed as `sample_weight` keyword argument to the `score` method of the final estimator.

Returns **score** : float

set_params(***kwargs*)

Set the parameters of this estimator.

Valid parameter keys can be listed with `get_params()`.

Returns **self** :

transform

Apply transforms, and transform with the final estimator

This also works where final estimator is `None`: all prior transformations are applied.

Parameters **X** : iterable

Data to transform. Must fulfill input requirements of first step of the pipeline.

Returns **Xt** : array-like, shape = [n_samples, n_transformed_features]

Examples using `sklearn.pipeline.Pipeline`

- *Feature Union with Heterogeneous Data Sources*
- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *Pipelining: chaining a PCA and a logistic regression*
- *Concatenating multiple feature extraction methods*
- *Explicit feature map approximation for RBF kernels*
- *Imputing missing values before building an estimator*
- *Feature agglomeration vs. univariate selection*
- *Sample pipeline for text feature extraction and evaluation*
- *Underfitting vs. Overfitting*
- *Restricted Boltzmann Machine features for digit classification*
- *SVM-Anova: SVM with univariate feature selection*
- *Classification of text documents using sparse features*

29.29.2 `sklearn.pipeline`.FeatureUnion

class `sklearn.pipeline.`**`FeatureUnion`**(*transformer_list*, *n_jobs=1*, *transformer_weights=None*)

Concatenates results of multiple transformer objects.

This estimator applies a list of transformer objects in parallel to the input data, then concatenates the results. This is useful to combine several feature extraction mechanisms into a single transformer.

Parameters of the transformers may be set using its name and the parameter name separated by a '__'. A transformer may be replaced entirely by setting the parameter with its name to another transformer, or removed by setting to `None`.

Read more in the *User Guide*.

Parameters **transformer_list** : list of (string, transformer) tuples

List of transformer objects to be applied to the data. The first half of each tuple is the name of the transformer.

n_jobs : int, optional

Number of jobs to run in parallel (default 1).

transformer_weights : dict, optional

Multiplicative weights for features per transformer. Keys are transformer names, values the weights.

Continued on next page

Table 29.227 – continued from previous page

Methods

fit(X[, y])	Fit all transformers using X.
fit_transform(X[, y])	Fit all transformers, transform the data and concatenate results.
get_feature_names()	Get feature names from all transformers.
get_params([deep])	Get parameters for this estimator.
set_params(**kwargs)	Set the parameters of this estimator.
transform(X)	Transform X separately by each transformer, concatenate results.

__init__ (*transformer_list*, *n_jobs=1*, *transformer_weights=None*)

fit (*X*, *y=None*)
Fit all transformers using X.

Parameters **X** : iterable or array-like, depending on transformers

Input data, used to fit transformers.

y : array-like, shape (n_samples, ...), optional

Targets for supervised learning.

Returns **self** : FeatureUnion

This estimator

fit_transform (*X*, *y=None*, ***fit_params*)
Fit all transformers, transform the data and concatenate results.

Parameters **X** : iterable or array-like, depending on transformers

Input data to be transformed.

y : array-like, shape (n_samples, ...), optional

Targets for supervised learning.

Returns **X_t** : array-like or sparse matrix, shape (n_samples, sum_n_components)

hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers.

get_feature_names ()
Get feature names from all transformers.

Returns **feature_names** : list of strings

Names of the features produced by transform.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***kwargs*)
Set the parameters of this estimator.

Valid parameter keys can be listed with `get_params()`.

Returns **self** :

transform(*X*)
Transform X separately by each transformer, concatenate results.

Parameters **X** : iterable or array-like, depending on transformers

Input data to be transformed.

Returns **X_t** : array-like or sparse matrix, shape (n_samples, sum_n_components)

hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers.

Examples using `sklearn.pipeline.FeatureUnion`

- *Feature Union with Heterogeneous Data Sources*
- *Concatenating multiple feature extraction methods*

pipeline.make_pipeline(*steps, **kwargs)	Construct a Pipeline from the given estimators.
pipeline.make_union(*transformers, **kwargs)	Construct a FeatureUnion from the given transformers.

29.29.3 `sklearn.pipeline.make_pipeline`

sklearn.pipeline.**make_pipeline**(**steps*, ***kwargs*)
Construct a Pipeline from the given estimators.

This is a shorthand for the Pipeline constructor; it does not require, and does not permit, naming the estimators. Instead, their names will be set to the lowercase of their types automatically.

Parameters ***steps** : list of estimators,

memory : Instance of sklearn.externals.joblib.Memory or string, optional (default=None)

Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute `named_steps` or `steps` to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.

Returns **p** : Pipeline

Examples

```
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.preprocessing import StandardScaler
>>> make_pipeline(StandardScaler(), GaussianNB(priors=None))
...
Pipeline(memory=None,
```

```
        steps=[('standardscaler',
                StandardScaler(copy=True, with_mean=True, with_std=True)),
               ('gaussiannb', GaussianNB(priors=None))])
```

Examples using `sklearn.pipeline.make_pipeline`

- *Feature transformations with ensembles of trees*
- *Pipeline Anova SVM*
- *Polynomial interpolation*
- *Robust linear estimator fitting*
- *Using FunctionTransformer to select columns*
- *Importance of Feature Scaling*
- *Clustering text documents using k-means*

29.29.4 `sklearn.pipeline`.make_union

`sklearn.pipeline.`**`make_union`**(**transformers*, ***kwargs*)

Construct a FeatureUnion from the given transformers.

This is a shorthand for the FeatureUnion constructor; it does not require, and does not permit, naming the transformers. Instead, they will be given names automatically based on their types. It also does not allow weighting.

Parameters ***transformers** : list of estimators

n_jobs : int, optional

Number of jobs to run in parallel (default 1).

Returns **f** : FeatureUnion

Examples

```
>>> from sklearn.decomposition import PCA, TruncatedSVD
>>> from sklearn.pipeline import make_union
>>> make_union(PCA(), TruncatedSVD())
FeatureUnion(n_jobs=1,
       transformer_list=[('pca',
                          PCA(copy=True, iterated_power='auto',
                              n_components=None, random_state=None,
                              svd_solver='auto', tol=0.0, whiten=False)),
                         ('truncatedsvd',
                          TruncatedSVD(algorithm='randomized',
                          n_components=2, n_iter=5,
                          random_state=None, tol=0.0))],
       transformer_weights=None)
```

29.30 sklearn.preprocessing: Preprocessing and Normalization

The *sklearn.preprocessing* module includes scaling, centering, normalization, binarization and imputation methods.

User guide: See the *Preprocessing data* section for further details.

preprocessing.Binarizer([threshold, copy])	Binarize data (set feature values to 0 or 1) according to a threshold
preprocessing.FunctionTransformer([func, ...])	Constructs a transformer from an arbitrary callable.
preprocessing.Imputer([missing_values, ...])	Imputation transformer for completing missing values.
preprocessing.KernelCenterer	Center a kernel matrix
preprocessing.LabelBinarizer([neg_label, ...])	Binarize labels in a one-vs-all fashion
preprocessing.LabelEncoder	Encode labels with value between 0 and n_classes-1.
preprocessing.MultiLabelBinarizer([classes, ...])	Transform between iterable of iterables and a multilabel format
preprocessing.MaxAbsScaler([copy])	Scale each feature by its maximum absolute value.
preprocessing.MinMaxScaler([feature_range, copy])	Transforms features by scaling each feature to a given range.
preprocessing.Normalizer([norm, copy])	Normalize samples individually to unit norm.
preprocessing.OneHotEncoder([n_values, ...])	Encode categorical integer features using a one-hot aka one-of-K scheme.
preprocessing.PolynomialFeatures([degree, ...])	Generate polynomial and interaction features.
preprocessing.QuantileTransformer([...])	Transform features using quantiles information.
preprocessing.RobustScaler([with_centering, ...])	Scale features using statistics that are robust to outliers.
preprocessing.StandardScaler([copy, ...])	Standardize features by removing the mean and scaling to unit variance

29.30.1 sklearn.preprocessing.Binarizer

class sklearn.preprocessing.**Binarizer**(*threshold=0.0*, *copy=True*)

Binarize data (set feature values to 0 or 1) according to a threshold

Values greater than the threshold map to 1, while values less than or equal to the threshold map to 0. With the default threshold of 0, only positive values map to 1.

Binarization is a common operation on text count data where the analyst can decide to only consider the presence or absence of a feature rather than a quantified number of occurrences for instance.

It can also be used as a pre-processing step for estimators that consider boolean random variables (e.g. modelled using the Bernoulli distribution in a Bayesian setting).

Read more in the *User Guide*.

Parameters **threshold** : float, optional (0.0 by default)

Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.

copy : boolean, optional, default True

set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

See also:

`binarize` Equivalent function without the estimator API.

Notes

If the input is a sparse matrix, only the non-zero values are subject to update by the Binarizer class.

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.

Methods

`fit`(X[, y])	Do nothing and return the estimator unchanged
`fit_transform`(X[, y])	Fit to data, then transform it.
`get_params`([deep])	Get parameters for this estimator.
`set_params`(**params)	Set the parameters of this estimator.
`transform`(X[, y, copy])	Binarize each element of X

__init__ (*threshold=0.0*, *copy=True*)

fit (*X*, *y=None*)
Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

fit_transform (*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *y=None*, *copy=None*)

Binarize each element of X

Parameters **X** : {array-like, sparse matrix}, shape [n_samples, n_features]

The data to binarize, element by element. scipy.sparse matrices should be in CSR format to avoid an un-necessary copy.

29.30.2 sklearn.preprocessing.FunctionTransformer

class sklearn.preprocessing.**FunctionTransformer**(*func=None*, *inverse_func=None*, *validate=True*, *accept_sparse=False*, *pass_y=False*, *kw_args=None*, *inv_kw_args=None*)

Constructs a transformer from an arbitrary callable.

A FunctionTransformer forwards its X (and optionally y) arguments to a user-defined function or function object and returns the result of this function. This is useful for stateless transformations such as taking the log of frequencies, doing custom scaling, etc.

A FunctionTransformer will not do any checks on its function's output.

Note: If a lambda is used as the function, then the resulting transformer will not be pickleable.

New in version 0.17.

Read more in the *User Guide*.

Parameters **func** : callable, optional default=None

The callable to use for the transformation. This will be passed the same arguments as transform, with args and kwargs forwarded. If func is None, then func will be the identity function.

inverse_func : callable, optional default=None

The callable to use for the inverse transformation. This will be passed the same arguments as inverse transform, with args and kwargs forwarded. If inverse_func is None, then inverse_func will be the identity function.

validate : bool, optional default=True

Indicate that the input X array should be checked before calling func. If validate is false, there will be no input validation. If it is true, then X will be converted to a 2-dimensional NumPy array or sparse matrix. If this conversion is not possible or X contains NaN or infinity, an exception is raised.

accept_sparse : boolean, optional

Indicate that func accepts a sparse matrix as input. If validate is False, this has no effect. Otherwise, if accept_sparse is false, sparse matrix inputs will cause an exception to be raised.

pass_y : bool, optional default=False

Indicate that transform should forward the y argument to the inner callable.

kw_args : dict, optional

Dictionary of additional keyword arguments to pass to func.

inv_kw_args : dict, optional

Dictionary of additional keyword arguments to pass to inverse_func.

Methods

fit(X[, y])	Fit transformer by checking X.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
inverse_transform(X[, y])	Transform X using the inverse function.
set_params(**params)	Set the parameters of this estimator.
transform(X[, y])	Transform X using the forward function.

__init__ (*func=None*, *inverse_func=None*, *validate=True*, *accept_sparse=False*, *pass_y=False*, *kw_args=None*, *inv_kw_args=None*)

fit (*X*, *y=None*)

Fit transformer by checking X.

If `validate` is `True`, `X` will be checked.

Parameters **X** : array-like, shape (n_samples, n_features)

Input array.

Returns **self** :

fit_transform (*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform (*X*, *y=None*)

Transform X using the inverse function.

Parameters **X** : array-like, shape (n_samples, n_features)

Input array.

Returns **X_out** : array-like, shape (n_samples, n_features)

Transformed input.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform (*X*, *y=None*)
Transform X using the forward function.

Parameters **X** : array-like, shape (n_samples, n_features)

Input array.

Returns **X_out** : array-like, shape (n_samples, n_features)

Transformed input.

Examples using `sklearn.preprocessing.FunctionTransformer`

- *Using FunctionTransformer to select columns*

29.30.3 `sklearn.preprocessing`.Imputer

class `sklearn.preprocessing.`**Imputer** (*missing_values='NaN'*, *strategy='mean'*, *axis=0*, *verbose=0*, *copy=True*)
Imputation transformer for completing missing values.

Read more in the *User Guide*.

Parameters **missing_values** : integer or "NaN", optional (default="NaN")

The placeholder for the missing values. All occurrences of *missing_values* will be imputed. For missing values encoded as np.nan, use the string value "NaN".

strategy : string, optional (default="mean")

The imputation strategy.

- If "mean", then replace missing values using the mean along the axis.
- If "median", then replace missing values using the median along the axis.
- If "most_frequent", then replace missing using the most frequent value along the axis.

axis : integer, optional (default=0)

The axis along which to impute.

- If *axis=0*, then impute along columns.
- If *axis=1*, then impute along rows.

verbose : integer, optional (default=0)

Controls the verbosity of the imputer.

copy : boolean, optional (default=True)

If True, a copy of X will be created. If False, imputation will be done in-place whenever possible. Note that, in the following cases, a new copy will always be made, even if *copy=False*:

- If X is not an array of floating values;
- If X is sparse and *missing_values=0*;
- If *axis=0* and X is encoded as a CSR matrix;
- If *axis=1* and X is encoded as a CSC matrix.

Attributes **statistics_** : array of shape (n_features,)

The imputation fill value for each feature if axis == 0.

Notes

- When `axis=0`, columns which only contained missing values at *fit* are discarded upon *transform*.
- When `axis=1`, an exception is raised if there are rows for which it is not possible to fill in the missing values (e.g., because they only contain missing values).

Methods

fit(X[, y])	Fit the imputer on X.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Impute all missing values in X.

__init__ (*missing_values='NaN'*, *strategy='mean'*, *axis=0*, *verbose=0*, *copy=True*)

fit (*X*, *y=None*)
Fit the imputer on X.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Input data, where `n_samples` is the number of samples and `n_features` is the number of features.

Returns **self** : object

Returns self.

fit_transform (*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Impute all missing values in X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

The input data to complete.

Examples using `sklearn.preprocessing.Imputer`

- *Imputing missing values before building an estimator*

29.30.4 sklearn.preprocessing.KernelCenterer

class sklearn.preprocessing.**KernelCenterer**
Center a kernel matrix

Let K(x, z) be a kernel defined by phi(x)^T phi(z), where phi is a function mapping x to a Hilbert space. KernelCenterer centers (i.e., normalize to have zero mean) the data without explicitly computing phi(x). It is equivalent to centering phi(x) with sklearn.preprocessing.StandardScaler(with_std=False).

Read more in the *User Guide*.

Methods

fit(K[, y])	Fit KernelCenterer
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(K[, y, copy])	Center kernel matrix.

__init__()
Initialize self. See help(type(self)) for accurate signature.

fit(*K*, *y=None*)
Fit KernelCenterer

Parameters **K** : numpy array of shape [n_samples, n_samples]

Kernel matrix.

Returns **self** : returns an instance of self.

fit_transform(*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*K*, *y=None*, *copy=True*)
Center kernel matrix.

Parameters **K** : numpy array of shape [n_samples1, n_samples2]

Kernel matrix.

copy : boolean, optional, default True

Set to False to perform inplace computation.

Returns **K_new** : numpy array of shape [n_samples1, n_samples2]

29.30.5 sklearn.preprocessing.LabelBinarizer

class sklearn.preprocessing.**LabelBinarizer**(*neg_label=0*, *pos_label=1*, *sparse_output=False*)

Binarize labels in a one-vs-all fashion

Several regression and binary classification algorithms are available in the scikit. A simple way to extend these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme.

At learning time, this simply consists in learning one regressor or binary classifier per class. In doing so, one needs to convert multi-class labels to binary labels (belong or does not belong to the class). LabelBinarizer makes this process easy with the transform method.

At prediction time, one assigns the class for which the corresponding model gave the greatest confidence. LabelBinarizer makes this easy with the inverse_transform method.

Read more in the *User Guide*.

Parameters **neg_label** : int (default: 0)

Value with which negative labels must be encoded.

pos_label : int (default: 1)

Value with which positive labels must be encoded.

sparse_output : boolean (default: False)

True if the returned array from transform is desired to be in sparse CSR format.

Attributes **classes_** : array of shape [n_class]

Holds the label for each class.

y_type_ : str,

Represents the type of the target data as evaluated by utils.multiclass.type_of_target. Possible type are 'continuous', 'continuous-multioutput', 'binary', 'multiclass', 'multiclass-multioutput', 'multilabel-indicator', and 'unknown'.

sparse_input_ : boolean,

True if the input data to transform is given as a sparse matrix, False otherwise.

See also:

label_binarize function to perform the transform operation of LabelBinarizer with fixed classes.

sklearn.preprocessing.OneHotEncoder encode categorical integer features using a one-hot aka one-of-K scheme.

Examples

```
>>> from sklearn import preprocessing
>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit([1, 2, 6, 4, 2])
LabelBinarizer(neg_label=0, pos_label=1, sparse_output=False)
>>> lb.classes_
array([1, 2, 4, 6])
>>> lb.transform([1, 6])
array([[1, 0, 0, 0],
       [0, 0, 0, 1]])
```

Binary targets transform to a column vector

```
>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit_transform(['yes', 'no', 'no', 'yes'])
array([[1],
       [0],
       [0],
       [1]])
```

Passing a 2D matrix for multilabel classification

```
>>> import numpy as np
>>> lb.fit(np.array([[0, 1, 1], [1, 0, 0]]))
LabelBinarizer(neg_label=0, pos_label=1, sparse_output=False)
>>> lb.classes_
array([0, 1, 2])
>>> lb.transform([0, 1, 2, 1])
array([[1, 0, 0],
       [0, 1, 0],
       [0, 0, 1],
       [0, 1, 0]])
```

Methods

fit(y)	Fit label binarizer
fit_transform(y)	Fit label binarizer and transform multi-class labels to binary labels.
get_params([deep])	Get parameters for this estimator.
inverse_transform(Y[, threshold])	Transform binary labels back to multi-class labels
set_params(**params)	Set the parameters of this estimator.
transform(y)	Transform multi-class labels to binary labels

__init__ (*neg_label=0*, *pos_label=1*, *sparse_output=False*)

fit (*y*)

Fit label binarizer

Parameters **y** : array of shape [n_samples,] or [n_samples, n_classes]

Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification.

Returns **self** : returns an instance of self.

fit_transform (*y*)

Fit label binarizer and transform multi-class labels to binary labels.

The output of transform is sometimes referred to as the 1-of-K coding scheme.

Parameters **y** : array or sparse matrix of shape [n_samples,] or [n_samples, n_classes]

Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.

Returns **Y** : array or CSR matrix of shape [n_samples, n_classes]

Shape will be [n_samples, 1] for binary problems.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform(*Y*, *threshold=None*)
Transform binary labels back to multi-class labels

Parameters **Y** : numpy array or sparse matrix with shape [n_samples, n_classes]

Target values. All sparse matrices are converted to CSR before inverse transformation.

threshold : float or None

Threshold used in the binary and multi-label cases.

Use 0 when:

- Y contains the output of decision_function (classifier)

Use 0.5 when:

- Y contains the output of predict_proba

If None, the threshold is assumed to be half way between neg_label and pos_label.

Returns **y** : numpy array or CSR matrix of shape [n_samples] Target values.

Notes

In the case when the binary labels are fractional (probabilistic), inverse_transform chooses the class with the greatest value. Typically, this allows to use the output of a linear model's decision_function method directly as the input of inverse_transform.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*y*)
Transform multi-class labels to binary labels

The output of transform is sometimes referred to by some authors as the 1-of-K coding scheme.

Parameters **y** : array or sparse matrix of shape [n_samples,] or [n_samples, n_classes]

Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.

Returns **Y** : numpy array or CSR matrix of shape [n_samples, n_classes]

Shape will be [n_samples, 1] for binary problems.

29.30.6 sklearn.preprocessing.LabelEncoder

class sklearn.preprocessing.**LabelEncoder**

Encode labels with value between 0 and n_classes-1.

Read more in the *User Guide*.

Attributes **classes_** : array of shape (n_class,)

Holds the label for each class.

See also:

sklearn.preprocessing.OneHotEncoder encode categorical integer features using a one-hot aka one-of-K scheme.

Examples

LabelEncoder can be used to normalize labels.

```
>>> from sklearn import preprocessing
>>> le = preprocessing.LabelEncoder()
>>> le.fit([1, 2, 2, 6])
LabelEncoder()
>>> le.classes_
array([1, 2, 6])
>>> le.transform([1, 1, 2, 6])
array([0, 0, 1, 2]...)
>>> le.inverse_transform([0, 0, 1, 2])
array([1, 1, 2, 6])
```

It can also be used to transform non-numerical labels (as long as they are hashable and comparable) to numerical labels.

```
>>> le = preprocessing.LabelEncoder()
>>> le.fit(["paris", "paris", "tokyo", "amsterdam"])
LabelEncoder()
>>> list(le.classes_)
['amsterdam', 'paris', 'tokyo']
>>> le.transform(["tokyo", "tokyo", "paris"])
array([2, 2, 1]...)
>>> list(le.inverse_transform([2, 2, 1]))
['tokyo', 'tokyo', 'paris']
```

Methods

fit(y)	Fit label encoder
fit_transform(y)	Fit label encoder and return encoded labels
get_params([deep])	Get parameters for this estimator.
inverse_transform(y)	Transform labels back to original encoding.
set_params(**params)	Set the parameters of this estimator.
transform(y)	Transform labels to normalized encoding.

__init__()
Initialize self. See help(type(self)) for accurate signature.

fit(*y*)
Fit label encoder

Parameters **y** : array-like of shape (n_samples,)

Target values.

Returns **self** : returns an instance of self.

fit_transform(*y*)
Fit label encoder and return encoded labels

Parameters **y** : array-like of shape [n_samples]

Target values.

Returns **y** : array-like of shape [n_samples]

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform(*y*)
Transform labels back to original encoding.

Parameters **y** : numpy array of shape [n_samples]

Target values.

Returns **y** : numpy array of shape [n_samples]

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*y*)
Transform labels to normalized encoding.

Parameters **y** : array-like of shape [n_samples]

Target values.

Returns **y** : array-like of shape [n_samples]

29.30.7 sklearn.preprocessing.MultiLabelBinarizer

class sklearn.preprocessing.**MultiLabelBinarizer**(*classes=None*, *sparse_output=False*)
Transform between iterable of iterables and a multilabel format

Although a list of sets or tuples is a very intuitive format for multilabel data, it is unwieldy to process. This transformer converts between this intuitive format and the supported multilabel format: a (samples x classes) binary matrix indicating the presence of a class label.

Parameters **classes** : array-like of shape [n_classes] (optional)

Indicates an ordering for the class labels

sparse_output : boolean (default: False),

Set to true if output binary array is desired in CSR sparse format

Attributes **classes_** : array of labels

A copy of the *classes* parameter where provided, or otherwise, the sorted set of classes found when fitting.

See also:

sklearn.preprocessing.OneHotEncoder encode categorical integer features using a one-hot aka one-of-K scheme.

Examples

```
>>> from sklearn.preprocessing import MultiLabelBinarizer
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit_transform([(1, 2), (3,)])
array([[1, 1, 0],
       [0, 0, 1]])
>>> mlb.classes_
array([1, 2, 3])
```

```
>>> mlb.fit_transform([set(['sci-fi', 'thriller']), set(['comedy'])])
array([[0, 1, 1],
       [1, 0, 0]])
>>> list(mlb.classes_)
['comedy', 'sci-fi', 'thriller']
```

Methods

fit(y)	Fit the label sets binarizer, storing *classes_*
fit_transform(y)	Fit the label sets binarizer and transform the given label sets
get_params([deep])	Get parameters for this estimator.
inverse_transform(yt)	Transform the given indicator matrix into label sets
set_params(**params)	Set the parameters of this estimator.
transform(y)	Transform the given label sets

__init__ (*classes=None*, *sparse_output=False*)

fit (*y*)
Fit the label sets binarizer, storing *classes_*

Parameters **y** : iterable of iterables

A set of labels (any orderable and hashable object) for each sample. If the *classes* parameter is set, *y* will not be iterated.

Returns **self** : returns this MultiLabelBinarizer instance

fit_transform(*y*)
Fit the label sets binarizer and transform the given label sets

Parameters **y** : iterable of iterables

A set of labels (any orderable and hashable object) for each sample. If the *classes* parameter is set, *y* will not be iterated.

Returns **y_indicator** : array or CSR matrix, shape (n_samples, n_classes)

A matrix such that *y_indicator[i, j] = 1* iff *classes_[j]* is in *y[i]*, and 0 otherwise.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform(*yt*)
Transform the given indicator matrix into label sets

Parameters **yt** : array or sparse matrix of shape (n_samples, n_classes)

A matrix containing only 1s ands 0s.

Returns **y** : list of tuples

The set of labels for each sample such that *y[i]* consists of *classes_[j]* for each *yt[i, j] == 1*.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*y*)
Transform the given label sets

Parameters **y** : iterable of iterables

A set of labels (any orderable and hashable object) for each sample. If the *classes* parameter is set, *y* will not be iterated.

Returns **y_indicator** : array or CSR matrix, shape (n_samples, n_classes)

A matrix such that *y_indicator[i, j] = 1* iff *classes_[j]* is in *y[i]*, and 0 otherwise.

29.30.8 sklearn.preprocessing.MaxAbsScaler

class sklearn.preprocessing.**MaxAbsScaler**(*copy=True*)

Scale each feature by its maximum absolute value.

This estimator scales and translates each feature individually such that the maximal absolute value of each feature in the training set will be 1.0. It does not shift/center the data, and thus does not destroy any sparsity.

This scaler can also be applied to sparse CSR or CSC matrices.

New in version 0.17.

Parameters **copy** : boolean, optional, default is True

Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

Attributes **scale_** : ndarray, shape (n_features,)

Per feature relative scaling of the data.

New in version 0.17: *scale_* attribute.

max_abs_ : ndarray, shape (n_features,)

Per feature maximum absolute value.

n_samples_seen_ : int

The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across `partial_fit` calls.

See also:

maxabs_scale Equivalent function without the estimator API.

Notes

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot_all_scaling.py*.

Methods

fit(X[, y])	Compute the maximum absolute value to be used for later scaling.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
inverse_transform(X)	Scale back the data to the original representation
partial_fit(X[, y])	Online computation of max absolute value of X for later scaling.
set_params(**params)	Set the parameters of this estimator.
transform(X[, y])	Scale the data

__init__(*copy=True*)

fit(*X*, *y=None*)

Compute the maximum absolute value to be used for later scaling.

Parameters **X** : {array-like, sparse matrix}, shape [n_samples, n_features]

The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.

fit_transform(*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform(*X*)

Scale back the data to the original representation

Parameters **X** : {array-like, sparse matrix}

The data that should be transformed back.

partial_fit(*X*, *y=None*)

Online computation of max absolute value of X for later scaling. All of X is processed as a single batch. This is intended for cases when *fit* is not feasible due to very large number of *n_samples* or because X is read from a continuous stream.

Parameters **X** : {array-like, sparse matrix}, shape [n_samples, n_features]

The data used to compute the mean and standard deviation used for later scaling along the features axis.

y : Passthrough for `Pipeline` compatibility.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *y=None*)

Scale the data

Parameters **X** : {array-like, sparse matrix}

The data that should be scaled.

Examples using `sklearn.preprocessing.MaxAbsScaler`

- *Compare the effect of different scalers on data with outliers*

29.30.9 `sklearn.preprocessing`.MinMaxScaler

class `sklearn.preprocessing.`**`MinMaxScaler`**(*feature_range=(0, 1)*, *copy=True*)

Transforms features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set, i.e. between zero and one.

The transformation is given by:

```
X_std = (X - X.min(axis=0)) / (X.max(axis=0) - X.min(axis=0))
X_scaled = X_std * (max - min) + min
```

where min, max = feature_range.

This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the *User Guide*.

Parameters **feature_range** : tuple (min, max), default=(0, 1)

Desired range of transformed data.

copy : boolean, optional, default True

Set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array).

Attributes **min_** : ndarray, shape (n_features,)

Per feature adjustment for minimum.

scale_ : ndarray, shape (n_features,)

Per feature relative scaling of the data.

New in version 0.17: *scale_* attribute.

data_min_ : ndarray, shape (n_features,)

Per feature minimum seen in the data

New in version 0.17: *data_min_*

data_max_ : ndarray, shape (n_features,)

Per feature maximum seen in the data

New in version 0.17: *data_max_*

data_range_ : ndarray, shape (n_features,)

Per feature range `(data_max_ - data_min_)` seen in the data

New in version 0.17: *data_range_*

See also:

minmax_scale Equivalent function without the estimator API.

Notes

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot_all_scaling.py*.

Methods

fit(X[, y])	Compute the minimum and maximum to be used for later scaling.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
inverse_transform(X)	Undo the scaling of X according to feature_range.
partial_fit(X[, y])	Online computation of min and max on X for later scaling.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Scaling features of X according to feature_range.

__init__ (*feature_range=(0, 1)*, *copy=True*)

fit (*X*, *y=None*)
Compute the minimum and maximum to be used for later scaling.

Parameters **X** : array-like, shape [n_samples, n_features]

The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.

fit_transform (*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform(*X*)
Undo the scaling of X according to feature_range.

Parameters **X** : array-like, shape [n_samples, n_features]

Input data that will be transformed. It cannot be sparse.

partial_fit(*X*, *y=None*)
Online computation of min and max on X for later scaling. All of X is processed as a single batch. This is intended for cases when *fit* is not feasible due to very large number of *n_samples* or because X is read from a continuous stream.

Parameters **X** : array-like, shape [n_samples, n_features]

The data used to compute the mean and standard deviation used for later scaling along the features axis.

y : Passthrough for `Pipeline` compatibility.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Scaling features of X according to feature_range.

Parameters **X** : array-like, shape [n_samples, n_features]

Input data that will be transformed.

Examples using `sklearn.preprocessing.MinMaxScaler`

- *Compare Stochastic learning strategies for MLPClassifier*
- *Compare the effect of different scalers on data with outliers*

29.30.10 `sklearn.preprocessing`.Normalizer

class `sklearn.preprocessing.`**Normalizer**(*norm='l2'*, *copy=True*)
Normalize samples individually to unit norm.

Each sample (i.e. each row of the data matrix) with at least one non zero component is rescaled independently of other samples so that its norm (l1 or l2) equals one.

This transformer is able to work both with dense numpy arrays and scipy.sparse matrix (use CSR format if you want to avoid the burden of a copy / conversion).

Scaling inputs to unit norms is a common operation for text classification or clustering for instance. For instance the dot product of two l2-normalized TF-IDF vectors is the cosine similarity of the vectors and is the base similarity metric for the Vector Space Model commonly used by the Information Retrieval community.

Read more in the *User Guide*.

Parameters **norm** : 'l1', 'l2', or 'max', optional ('l2' by default)

The norm to use to normalize each non zero sample.

copy : boolean, optional, default True

set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

See also:

normalize Equivalent function without the estimator API.

Notes

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot_all_scaling.py*.

Methods

fit(X[, y])	Do nothing and return the estimator unchanged
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X[, y, copy])	Scale each non zero row of X to unit norm

__init__(*norm='l2'*, *copy=True*)

fit(*X*, *y=None*)
Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

fit_transform(*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *y=None*, *copy=None*)
Scale each non zero row of X to unit norm

Parameters **X** : {array-like, sparse matrix}, shape [n_samples, n_features]

The data to normalize, row by row. scipy.sparse matrices should be in CSR format to avoid an un-necessary copy.

Examples using `sklearn.preprocessing.Normalizer`

- *Compare the effect of different scalers on data with outliers*
- *Clustering text documents using k-means*

29.30.11 `sklearn.preprocessing`.OneHotEncoder

class `sklearn.preprocessing.`**OneHotEncoder**(*n_values='auto'*, *categorical_features='all'*, *dtype=<class 'numpy.float64'>*, *sparse=True*, *handle_unknown='error'*)
Encode categorical integer features using a one-hot aka one-of-K scheme.

The input to this transformer should be a matrix of integers, denoting the values taken on by categorical (discrete) features. The output will be a sparse matrix where each column corresponds to one possible value of one feature. It is assumed that input features take on values in the range [0, n_values).

This encoding is needed for feeding categorical data to many scikit-learn estimators, notably linear models and SVMs with the standard kernels.

Note: a one-hot encoding of y labels should use a LabelBinarizer instead.

Read more in the *User Guide*.

Parameters **n_values** : 'auto', int or array of ints

Number of values per feature.

- 'auto' : determine value range from training data.
- **int** [number of categorical values per feature.] Each feature value should be in `range(n_values)`
- **array** [`n_values[i]` is the number of categorical values in] `X[:, i]`. Each feature value should be in `range(n_values[i])`

categorical_features : "all" or array of indices or mask

Specify what features are treated as categorical.

- 'all' (default): All features are treated as categorical.
- array of indices: Array of categorical feature indices.

- mask: Array of length n_features and with dtype=bool.

Non-categorical features are always stacked to the right of the matrix.

dtype : number type, default=np.float

Desired dtype of output.

sparse : boolean, default=True

Will return sparse matrix if set True else will return an array.

handle_unknown : str, 'error' or 'ignore'

Whether to raise an error or ignore if a unknown categorical feature is present during transform.

Attributes active_features_ : array

Indices for active features, meaning values that actually occur in the training set. Only available when n_values is `'auto'`.

feature_indices_ : array of shape (n_features,)

Indices to feature ranges. Feature `i` in the original data is mapped to features from `feature_indices_[i]` to `feature_indices_[i+1]` (and then potentially masked by *active_features_* afterwards)

n_values_ : array of shape (n_features,)

Maximum number of values per feature.

See also:

sklearn.feature_extraction.DictVectorizer performs a one-hot encoding of dictionary items (also handles string-valued features).

sklearn.feature_extraction.FeatureHasher performs an approximate one-hot encoding of dictionary items or strings.

sklearn.preprocessing.LabelBinarizer binarizes labels in a one-vs-all fashion.

sklearn.preprocessing.MultiLabelBinarizer transforms between iterable of iterables and a multilabel format, e.g. a (samples x classes) binary matrix indicating the presence of a class label.

sklearn.preprocessing.LabelEncoder encodes labels with values between 0 and n_classes-1.

Examples

Given a dataset with three features and four samples, we let the encoder find the maximum value per feature and transform the data to a binary one-hot encoding.

```
>>> from sklearn.preprocessing import OneHotEncoder
>>> enc = OneHotEncoder()
>>> enc.fit([[0, 0, 3], [1, 1, 0], [0, 2, 1], [1, 0, 2]])
OneHotEncoder(categorical_features='all', dtype=<... 'numpy.float64'>,
       handle_unknown='error', n_values='auto', sparse=True)
>>> enc.n_values_
array([2, 3, 4])
>>> enc.feature_indices_
array([0, 2, 5, 9])
>>> enc.transform([[0, 1, 1]]).toarray()
array([[ 1.,  0.,  0.,  1.,  0.,  0.,  1.,  0.,  0.]])
```

Methods

fit(X[, y])	Fit OneHotEncoder to X.
fit_transform(X[, y])	Fit OneHotEncoder to X, then transform X.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Transform X using one-hot encoding.

__init__ (*n_values='auto'*, *categorical_features='all'*, *dtype=<class 'numpy.float64'>*, *sparse=True*, *handle_unknown='error'*)

fit (*X*, *y=None*)
Fit OneHotEncoder to X.

Parameters **X** : array-like, shape [n_samples, n_feature]

Input array of type int.

Returns **self** :

fit_transform (*X*, *y=None*)
Fit OneHotEncoder to X, then transform X.

Equivalent to self.fit(X).transform(X), but more convenient and more efficient. See fit for the parameters, transform for the return value.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params (**params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform (*X*)
Transform X using one-hot encoding.

Parameters **X** : array-like, shape [n_samples, n_features]

Input array of type int.

Returns **X_out** : sparse matrix if sparse=True else a 2-d array, dtype=int

Transformed input.

Examples using `sklearn.preprocessing.OneHotEncoder`

- *Feature transformations with ensembles of trees*

29.30.12 sklearn.preprocessing.PolynomialFeatures

class sklearn.preprocessing.**PolynomialFeatures**(*degree=2*, *interaction_only=False*, *include_bias=True*)

Generate polynomial and interaction features.

Generate a new feature matrix consisting of all polynomial combinations of the features with degree less than or equal to the specified degree. For example, if an input sample is two dimensional and of the form [a, b], the degree-2 polynomial features are [1, a, b, a^2, ab, b^2].

Parameters **degree** : integer

The degree of the polynomial features. Default = 2.

interaction_only : boolean, default = False

If true, only interaction features are produced: features that are products of at most `degree` *distinct* input features (so not `x[1] ** 2`, `x[0] * x[2] ** 3`, etc.).

include_bias : boolean

If True (default), then include a bias column, the feature in which all polynomial powers are zero (i.e. a column of ones - acts as an intercept term in a linear model).

Attributes **powers_** : array, shape (n_output_features, n_input_features)

powers_[i, j] is the exponent of the jth input in the ith output.

n_input_features_ : int

The total number of input features.

n_output_features_ : int

The total number of polynomial output features. The number of output features is computed by iterating over all suitably sized combinations of input features.

Notes

Be aware that the number of features in the output array scales polynomially in the number of features of the input array, and exponentially in the degree. High degrees can cause overfitting.

See *examples/linear_model/plot_polynomial_interpolation.py*

Examples

```
>>> X = np.arange(6).reshape(3, 2)
>>> X
array([[0, 1],
       [2, 3],
       [4, 5]])
>>> poly = PolynomialFeatures(2)
>>> poly.fit_transform(X)
array([[  1.,   0.,   1.,   0.,   0.,   1.],
       [  1.,   2.,   3.,   4.,   6.,   9.],
       [  1.,   4.,   5.,  16.,  20.,  25.]])
>>> poly = PolynomialFeatures(interaction_only=True)
>>> poly.fit_transform(X)
array([[  1.,   0.,   1.,   0.],
```

```
       [  1.,   2.,   3.,   6.],
       [  1.,   4.,   5.,  20.]])
```

Methods

fit(X[, y])	Compute number of output features.
fit_transform(X[, y])	Fit to data, then transform it.
get_feature_names([input_features])	Return feature names for output features
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X[, y])	Transform data to polynomial features

__init__ (*degree=2*, *interaction_only=False*, *include_bias=True*)

fit (*X*, *y=None*)
Compute number of output features.

fit_transform (*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_feature_names (*input_features=None*)
Return feature names for output features

Parameters **input_features** : list of string, length n_features, optional

String names for input features if available. By default, “x0”, “x1”, ... “xn_features” is used.

Returns **output_feature_names** : list of string, length n_output_features

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *y=None*)

Transform data to polynomial features

Parameters **X** : array-like, shape [n_samples, n_features]

The data to transform, row by row.

Returns **XP** : np.ndarray shape [n_samples, NP]

The matrix of features, where NP is the number of polynomial features generated from the combination of inputs.

Examples using `sklearn.preprocessing.PolynomialFeatures`

- *Polynomial interpolation*
- *Robust linear estimator fitting*
- *Underfitting vs. Overfitting*

29.30.13 sklearn.preprocessing.QuantileTransformer

class sklearn.preprocessing.**QuantileTransformer**(*n_quantiles=1000*, *output_distribution='uniform'*, *ignore_implicit_zeros=False*, *subsample=100000*, *random_state=None*, *copy=True*)

Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature, this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers: this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. The cumulative density function of a feature is used to project the original values. Features values of new/unseen data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that this transform is non-linear. It may distort linear correlations between variables measured at the same scale but renders variables measured at different scales more directly comparable.

Read more in the *User Guide*.

Parameters **n_quantiles** : int, optional (default=1000)

Number of quantiles to be computed. It corresponds to the number of landmarks used to discretize the cumulative density function.

output_distribution : str, optional (default='uniform')

Marginal distribution for the transformed data. The choices are 'uniform' (default) or 'normal'.

ignore_implicit_zeros : bool, optional (default=False)

Only applies to sparse matrices. If True, the sparse entries of the matrix are discarded to compute the quantile statistics. If False, these entries are treated as zeros.

subsample : int, optional (default=1e5)

Maximum number of samples used to estimate the quantiles for computational efficiency. Note that the subsampling procedure may differ for value-identical sparse and dense matrices.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Note that this is used by subsampling and smoothing noise.

copy : boolean, optional, (default=True)

Set to False to perform inplace transformation and avoid a copy (if the input is already a numpy array).

Attributes **quantiles_** : ndarray, shape (n_quantiles, n_features)

The values corresponding the quantiles of reference.

references_ : ndarray, shape(n_quantiles,)

Quantiles of references.

See also:

quantile_transform Equivalent function without the estimator API.

StandardScaler perform standardization that is faster, but less robust to outliers.

RobustScaler perform robust standardization that removes the influence of outliers but does not put outliers and inliers on the same scale.

Notes

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot_all_scaling.py*.

Examples

```
>>> import numpy as np
>>> from sklearn.preprocessing import QuantileTransformer
>>> rng = np.random.RandomState(0)
>>> X = np.sort(rng.normal(loc=0.5, scale=0.25, size=(25, 1)), axis=0)
>>> qt = QuantileTransformer(n_quantiles=10, random_state=0)
>>> qt.fit_transform(X)
array([...])
```

Methods

fit(X[, y])	Compute the quantiles used for transforming.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.

Continued on next page

Table 29.242 – continued from previous page

inverse_transform(X)	Back-projection to the original space.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Feature-wise transformation of the data.

__init__ (*n_quantiles=1000*, *output_distribution='uniform'*, *ignore_implicit_zeros=False*, *subsample=100000*, *random_state=None*, *copy=True*)

fit (*X*, *y=None*)

Compute the quantiles used for transforming.

Parameters **X** : ndarray or sparse matrix, shape (n_samples, n_features)

The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse `csc_matrix`. Additionally, the sparse matrix needs to be nonnegative if *ignore_implicit_zeros* is False.

Returns **self** : object

Returns self

fit_transform (*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform (*X*)

Back-projection to the original space.

X [ndarray or sparse matrix, shape (n_samples, n_features)] The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse `csc_matrix`. Additionally, the sparse matrix needs to be nonnegative if *ignore_implicit_zeros* is False.

Returns **Xt** : ndarray or sparse matrix, shape (n_samples, n_features)

The projected data.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Feature-wise transformation of the data.

Parameters **X** : ndarray or sparse matrix, shape (n_samples, n_features)

The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse `csc_matrix`. Additionally, the sparse matrix needs to be nonnegative if *ignore_implicit_zeros* is False.

Returns **Xt** : ndarray or sparse matrix, shape (n_samples, n_features)

The projected data.

Examples using `sklearn.preprocessing.QuantileTransformer`

- *Compare the effect of different scalers on data with outliers*

29.30.14 `sklearn.preprocessing`.RobustScaler

class `sklearn.preprocessing.`**RobustScaler**(*with_centering=True*, *with_scaling=True*, *quantile_range=(25.0, 75.0)*, *copy=True*)
Scale features using statistics that are robust to outliers.

This Scaler removes the median and scales the data according to the quantile range (defaults to IQR: Interquartile Range). The IQR is the range between the 1st quartile (25th quantile) and the 3rd quartile (75th quantile).

Centering and scaling happen independently on each feature (or each sample, depending on the *axis* argument) by computing the relevant statistics on the samples in the training set. Median and interquartile range are then stored to be used on later data using the *transform* method.

Standardization of a dataset is a common requirement for many machine learning estimators. Typically this is done by removing the mean and scaling to unit variance. However, outliers can often influence the sample mean / variance in a negative way. In such cases, the median and the interquartile range often give better results.

New in version 0.17.

Read more in the *User Guide*.

Parameters **with_centering** : boolean, True by default

If True, center the data before scaling. This does not work (and will raise an exception) when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.

with_scaling : boolean, True by default

If True, scale the data to interquartile range.

quantile_range : tuple (q_min, q_max), 0.0 < q_min < q_max < 100.0

Default: (25.0, 75.0) = (1st quantile, 3rd quantile) = IQR Quantile range used to calculate `scale_`.

New in version 0.18.

copy : boolean, optional, default is True

If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or scipy.sparse CSR matrix, a copy may still be returned.

Attributes **center_** : array of floats

The median value for each feature in the training set.

scale_ : array of floats

The (scaled) interquartile range for each feature in the training set.

New in version 0.17: *scale_* attribute.

See also:

robust_scale Equivalent function without the estimator API.

sklearn.decomposition.PCA Further removes the linear correlation across features with 'whiten=True'.

Notes

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot_all_scaling.py*.

https://en.wikipedia.org/wiki/Median_(statistics) https://en.wikipedia.org/wiki/Interquartile_range

Methods

fit(X[, y])	Compute the median and quantiles to be used for scaling.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
inverse_transform(X)	Scale back the data to the original representation
set_params(**params)	Set the parameters of this estimator.
transform(X[, y])	Center and scale the data

__init__(*with_centering=True*, *with_scaling=True*, *quantile_range=(25.0*, *75.0)*, *copy=True*)

fit(*X*, *y=None*)
Compute the median and quantiles to be used for scaling.

Parameters **X** : array-like, shape [n_samples, n_features]

The data used to compute the median and quantiles used for later scaling along the features axis.

fit_transform(*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform(*X*)
Scale back the data to the original representation

Parameters **X** : array-like

The data used to scale along the specified axis.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *y=None*)
Center and scale the data

Parameters **X** : array-like

The data used to scale along the specified axis.

Examples using `sklearn.preprocessing.RobustScaler`

- *Compare the effect of different scalers on data with outliers*

29.30.15 sklearn.preprocessing.StandardScaler

class sklearn.preprocessing.**StandardScaler**(*copy=True*, *with_mean=True*, *with_std=True*)
Standardize features by removing the mean and scaling to unit variance

Centering and scaling happen independently on each feature by computing the relevant statistics on the samples in the training set. Mean and standard deviation are then stored to be used on later data using the *transform* method.

Standardization of a dataset is a common requirement for many machine learning estimators: they might behave badly if the individual feature do not more or less look like standard normally distributed data (e.g. Gaussian with 0 mean and unit variance).

For instance many elements used in the objective function of a learning algorithm (such as the RBF kernel of Support Vector Machines or the L1 and L2 regularizers of linear models) assume that all features are centered around 0 and have variance in the same order. If a feature has a variance that is orders of magnitude larger that others, it might dominate the objective function and make the estimator unable to learn from other features correctly as expected.

This scaler can also be applied to sparse CSR or CSC matrices by passing *with_mean=False* to avoid breaking the sparsity structure of the data.

Read more in the *User Guide*.

Parameters **with_mean** : boolean, True by default

If True, center the data before scaling. This does not work (and will raise an exception) when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.

with_std : boolean, True by default

If True, scale the data to unit variance (or equivalently, unit standard deviation).

copy : boolean, optional, default True

If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or scipy.sparse CSR matrix, a copy may still be returned.

Attributes **scale_** : ndarray, shape (n_features,)

Per feature relative scaling of the data.

New in version 0.17: *scale_*

mean_ : array of floats with shape [n_features]

The mean value for each feature in the training set.

var_ : array of floats with shape [n_features]

The variance for each feature in the training set. Used to compute *scale_*

n_samples_seen_ : int

The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across `partial_fit` calls.

See also:

scale Equivalent function without the estimator API.

sklearn.decomposition.PCA Further removes the linear correlation across features with 'whiten=True'.

Notes

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot_all_scaling.py*.

Methods

fit(X[, y])	Compute the mean and std to be used for later scaling.
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
inverse_transform(X[, copy])	Scale back the data to the original representation
partial_fit(X[, y])	Online computation of mean and std on X for later scaling.
set_params(**params)	Set the parameters of this estimator.
transform(X[, y, copy])	Perform standardization by centering and scaling

__init__ (*copy=True*, *with_mean=True*, *with_std=True*)

fit (*X*, *y=None*)
Compute the mean and std to be used for later scaling.

Parameters **X** : {array-like, sparse matrix}, shape [n_samples, n_features]

The data used to compute the mean and standard deviation used for later scaling along the features axis.

y : Passthrough for `Pipeline` compatibility.

fit_transform (*X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform (*X*, *copy=None*)
Scale back the data to the original representation

Parameters **X** : array-like, shape [n_samples, n_features]

The data used to scale along the features axis.

partial_fit (*X*, *y=None*)
Online computation of mean and std on X for later scaling. All of X is processed as a single batch. This is intended for cases when *fit* is not feasible due to very large number of *n_samples* or because X is read from a continuous stream.

The algorithm for incremental mean and std is given in Equation 1.5a,b in Chan, Tony F., Gene H. Golub, and Randall J. LeVeque. "Algorithms for computing the sample variance: Analysis and recommendations." The American Statistician 37.3 (1983): 242-247:

Parameters **X** : {array-like, sparse matrix}, shape [n_samples, n_features]

The data used to compute the mean and standard deviation used for later scaling along the features axis.

y : Passthrough for `Pipeline` compatibility.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*, *y=None*, *copy=None*)

Perform standardization by centering and scaling

Parameters **X** : array-like, shape [n_samples, n_features]

The data used to scale along the features axis.

preprocessing.add_dummy_feature(X[, value])	Augment dataset with an additional dummy feature.
preprocessing.binarize(X[, threshold, copy])	Boolean thresholding of array-like or scipy.sparse matrix
preprocessing.label_binarize(y, classes[, ...])	Binarize labels in a one-vs-all fashion
preprocessing.maxabs_scale(X[, axis, copy])	Scale each feature to the [-1, 1] range without breaking the sparsity.
preprocessing.minmax_scale(X[, ...])	Transforms features by scaling each feature to a given range.
preprocessing.normalize(X[, norm, axis, ...])	Scale input vectors individually to unit norm (vector length).

Continued on next page

Table 29.245 – continued from previous page

preprocessing.quantile_transform(X[, axis, ...])	Transform features using quantiles information.
preprocessing.robust_scale(X[, axis, ...])	Standardize a dataset along any axis
preprocessing.scale(X[, axis, with_mean, ...])	Standardize a dataset along any axis

29.30.16 sklearn.preprocessing.add_dummy_feature

sklearn.preprocessing.**add_dummy_feature**(*X*, *value=1.0*)

Augment dataset with an additional dummy feature.

This is useful for fitting an intercept term with implementations which cannot otherwise fit it directly.

Parameters **X** : {array-like, sparse matrix}, shape [n_samples, n_features]

Data.

value : float

Value to use for the dummy feature.

Returns **X** : {array, sparse matrix}, shape [n_samples, n_features + 1]

Same data with dummy feature added as first column.

Examples

```
>>> from sklearn.preprocessing import add_dummy_feature
>>> add_dummy_feature([[0, 1], [1, 0]])
array([[ 1.,  0.,  1.],
       [ 1.,  1.,  0.]])
```

29.30.17 sklearn.preprocessing.binarize

sklearn.preprocessing.**binarize**(*X*, *threshold=0.0*, *copy=True*)

Boolean thresholding of array-like or scipy.sparse matrix

Read more in the *User Guide*.

Parameters **X** : {array-like, sparse matrix}, shape [n_samples, n_features]

The data to binarize, element by element. scipy.sparse matrices should be in CSR or CSC format to avoid an un-necessary copy.

threshold : float, optional (0.0 by default)

Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.

copy : boolean, optional, default True

set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR / CSC matrix and if axis is 1).

See also:

Binarizer Performs binarization using the `Transformer` API (e.g. as part of a preprocessing *sklearn.pipeline.Pipeline*).

29.30.18 sklearn.preprocessing.label_binarize

sklearn.preprocessing.**label_binarize**(*y*, *classes*, *neg_label=0*, *pos_label=1*, *sparse_output=False*)

Binarize labels in a one-vs-all fashion

Several regression and binary classification algorithms are available in the scikit. A simple way to extend these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme.

This function makes it possible to compute this transformation for a fixed set of class labels known ahead of time.

Parameters **y** : array-like

Sequence of integer labels or multilabel data to encode.

classes : array-like of shape [n_classes]

Uniquely holds the label for each class.

neg_label : int (default: 0)

Value with which negative labels must be encoded.

pos_label : int (default: 1)

Value with which positive labels must be encoded.

sparse_output : boolean (default: False),

Set to true if output binary array is desired in CSR sparse format

Returns **Y** : numpy array or CSR matrix of shape [n_samples, n_classes]

Shape will be [n_samples, 1] for binary problems.

See also:

LabelBinarizer class used to wrap the functionality of label_binarize and allow for fitting to classes independently of the transform operation

Examples

```
>>> from sklearn.preprocessing import label_binarize
>>> label_binarize([1, 6], classes=[1, 2, 4, 6])
array([[1, 0, 0, 0],
       [0, 0, 0, 1]])
```

The class ordering is preserved:

```
>>> label_binarize([1, 6], classes=[1, 6, 4, 2])
array([[1, 0, 0, 0],
       [0, 1, 0, 0]])
```

Binary targets transform to a column vector

```
>>> label_binarize(['yes', 'no', 'no', 'yes'], classes=['no', 'yes'])
array([[1],
       [0],
       [0],
       [1]])
```

Examples using `sklearn.preprocessing.label_binarize`

- *Precision-Recall*
- *Receiver Operating Characteristic (ROC)*

29.30.19 `sklearn.preprocessing`.maxabs_scale

`sklearn.preprocessing.`**`maxabs_scale`**(*X*, *axis=0*, *copy=True*)

Scale each feature to the [-1, 1] range without breaking the sparsity.

This estimator scales each feature individually such that the maximal absolute value of each feature in the training set will be 1.0.

This scaler can also be applied to sparse CSR or CSC matrices.

Parameters **axis** : int (0 by default)

axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.

copy : boolean, optional, default is True

Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

See also:

MaxAbsScaler Performs scaling to the [-1, 1] range using the‘‘Transformer‘‘ API (e.g. as part of a preprocessing *sklearn.pipeline.Pipeline*).

Notes

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot_all_scaling.py*.

29.30.20 `sklearn.preprocessing`.minmax_scale

`sklearn.preprocessing.`**`minmax_scale`**(*X*, *feature_range=(0, 1)*, *axis=0*, *copy=True*)

Transforms features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set, i.e. between zero and one.

The transformation is given by:

```
X_std = (X - X.min(axis=0)) / (X.max(axis=0) - X.min(axis=0))
X_scaled = X_std * (max - min) + min
```

where min, max = feature_range.

This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the *User Guide*.

New in version 0.17: *minmax_scale* function interface to *sklearn.preprocessing.MinMaxScaler*.

Parameters **feature_range** : tuple (min, max), default=(0, 1)

Desired range of transformed data.

axis : int (0 by default)

axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.

copy : boolean, optional, default is True

Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

See also:

MinMaxScaler Performs scaling to a given range using the‘‘Transformer‘‘ API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

Notes

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot_all_scaling.py*.

Examples using `sklearn.preprocessing.minmax_scale`

- *Compare the effect of different scalers on data with outliers*

29.30.21 `sklearn.preprocessing`.normalize

`sklearn.preprocessing.`**`normalize`**(*X*, *norm='l2'*, *axis=1*, *copy=True*, *return_norm=False*)

Scale input vectors individually to unit norm (vector length).

Read more in the *User Guide*.

Parameters **X** : {array-like, sparse matrix}, shape [n_samples, n_features]

The data to normalize, element by element. scipy.sparse matrices should be in CSR format to avoid an un-necessary copy.

norm : ‘l1’, ‘l2’, or ‘max’, optional (‘l2’ by default)

The norm to use to normalize each non zero sample (or each non-zero feature if axis is 0).

axis : 0 or 1, optional (1 by default)

axis used to normalize the data along. If 1, independently normalize each sample, otherwise (if 0) normalize each feature.

copy : boolean, optional, default True

set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix and if axis is 1).

return_norm : boolean, default False

whether to return the computed norms

Returns **X** : {array-like, sparse matrix}, shape [n_samples, n_features]

Normalized input X.

norms : array, shape [n_samples] if axis=1 else [n_features]

An array of norms along given axis for X. When X is sparse, a NotImplementedError will be raised for norm 'l1' or 'l2'.

See also:

Normalizer Performs normalization using the `Transformer` API (e.g. as part of a preprocessing *sklearn.pipeline.Pipeline*).

Notes

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot_all_scaling.py*.

29.30.22 sklearn.preprocessing.quantile_transform

sklearn.preprocessing.**quantile_transform**(*X*, *axis=0*, *n_quantiles=1000*, *output_distribution='uniform'*, *ignore_implicit_zeros=False*, *subsample=100000*, *random_state=None*, *copy=False*)

Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature, this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers: this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. The cumulative density function of a feature is used to project the original values. Features values of new/unseen data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that this transform is non-linear. It may distort linear correlations between variables measured at the same scale but renders variables measured at different scales more directly comparable.

Read more in the *User Guide*.

Parameters **X** : array-like, sparse matrix

The data to transform.

axis : int, (default=0)

Axis used to compute the means and standard deviations along. If 0, transform each feature, otherwise (if 1) transform each sample.

n_quantiles : int, optional (default=1000)

Number of quantiles to be computed. It corresponds to the number of landmarks used to discretize the cumulative density function.

output_distribution : str, optional (default='uniform')

Marginal distribution for the transformed data. The choices are 'uniform' (default) or 'normal'.

ignore_implicit_zeros : bool, optional (default=False)

Only applies to sparse matrices. If True, the sparse entries of the matrix are discarded to compute the quantile statistics. If False, these entries are treated as zeros.

subsample : int, optional (default=1e5)

Maximum number of samples used to estimate the quantiles for computational efficiency. Note that the subsampling procedure may differ for value-identical sparse and dense matrices.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Note that this is used by subsampling and smoothing noise.

copy : boolean, optional, (default=True)

Set to False to perform inplace transformation and avoid a copy (if the input is already a numpy array).

Attributes **quantiles_** : ndarray, shape (n_quantiles, n_features)

The values corresponding the quantiles of reference.

references_ : ndarray, shape(n_quantiles,)

Quantiles of references.

See also:

QuantileTransformer Performs quantile-based scaling using the `Transformer` API (e.g. as part of a preprocessing *sklearn.pipeline.Pipeline*).

scale perform standardization that is faster, but less robust to outliers.

robust_scale perform robust standardization that removes the influence of outliers but does not put outliers and inliers on the same scale.

Notes

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot_all_scaling.py*.

Examples

```
>>> import numpy as np
>>> from sklearn.preprocessing import quantile_transform
>>> rng = np.random.RandomState(0)
>>> X = np.sort(rng.normal(loc=0.5, scale=0.25, size=(25, 1)), axis=0)
>>> quantile_transform(X, n_quantiles=10, random_state=0)
...
array([...])
```

29.30.23 sklearn.preprocessing.robust_scale

sklearn.preprocessing.**robust_scale**(*X*, *axis=0*, *with_centering=True*, *with_scaling=True*, *quantile_range=(25.0, 75.0)*, *copy=True*)

Standardize a dataset along any axis

Center to the median and component wise scale according to the interquartile range.

Read more in the *User Guide*.

Parameters **X** : array-like

The data to center and scale.

axis : int (0 by default)

axis used to compute the medians and IQR along. If 0, independently scale each feature, otherwise (if 1) scale each sample.

with_centering : boolean, True by default

If True, center the data before scaling.

with_scaling : boolean, True by default

If True, scale the data to unit variance (or equivalently, unit standard deviation).

quantile_range : tuple (q_min, q_max), 0.0 < q_min < q_max < 100.0

Default: (25.0, 75.0) = (1st quantile, 3rd quantile) = IQR Quantile range used to calculate `scale_`.

New in version 0.18.

copy : boolean, optional, default is True

set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix and if axis is 1).

See also:

RobustScaler Performs centering and scaling using the `Transformer` API (e.g. as part of a preprocessing *sklearn.pipeline.Pipeline*).

Notes

This implementation will refuse to center scipy.sparse matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly *with_centering=False* (in that case, only variance scaling will be performed on the features of the CSR matrix) or to call *X.toarray()* if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSR matrix.

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot_all_scaling.py*.

29.30.24 sklearn.preprocessing.scale

`sklearn.preprocessing.`**`scale`**(*X*, *axis=0*, *with_mean=True*, *with_std=True*, *copy=True*)

Standardize a dataset along any axis

Center to the mean and component wise scale to unit variance.

Read more in the *User Guide*.

Parameters **X** : {array-like, sparse matrix}

The data to center and scale.

axis : int (0 by default)

axis used to compute the means and standard deviations along. If 0, independently standardize each feature, otherwise (if 1) standardize each sample.

with_mean : boolean, True by default

If True, center the data before scaling.

with_std : boolean, True by default

If True, scale the data to unit variance (or equivalently, unit standard deviation).

copy : boolean, optional, default True

set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSC matrix and if axis is 1).

See also:

`StandardScaler` Performs scaling to unit variance using the‘‘Transformer‘‘ API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

Notes

This implementation will refuse to center scipy.sparse matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly *with_mean=False* (in that case, only variance scaling will be performed on the features of the CSC matrix) or to call *X.toarray()* if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSC matrix.

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot_all_scaling.py*.

29.31 `sklearn.random_projection`: Random projection

Random Projection transformers

Random Projections are a simple and computationally efficient way to reduce the dimensionality of the data by trading a controlled amount of accuracy (as additional variance) for faster processing times and smaller model sizes.

The dimensions and distribution of Random Projections matrices are controlled so as to preserve the pairwise distances between any two samples of the dataset.

The main theoretical result behind the efficiency of random projection is the Johnson-Lindenstrauss lemma (quoting Wikipedia):

> In mathematics, the Johnson-Lindenstrauss lemma is a result concerning low-distortion embeddings of points from high-dimensional into low-dimensional Euclidean space. The lemma states that a small set of points in a high-dimensional space can be embedded into a space of much lower dimension in such a way that distances between the points are nearly preserved. The map used for the embedding is at least Lipschitz, and can even be taken to be an orthogonal projection.

User guide: See the *Random Projection* section for further details.

random_projection.GaussianRandomProjection([...])	Reduce dimensionality through Gaussian random projection
random_projection.SparseRandomProjection([...])	Reduce dimensionality through sparse random projection

29.31.1 sklearn.random_projection.GaussianRandomProjection

class sklearn.random_projection.**GaussianRandomProjection**(*n_components='auto'*, *eps=0.1*, *random_state=None*)

Reduce dimensionality through Gaussian random projection

The components of the random matrix are drawn from N(0, 1 / n_components).

Read more in the *User Guide*.

Parameters **n_components** : int or 'auto', optional (default = 'auto')

Dimensionality of the target projection space.

n_components can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality of the embedding is controlled by the `eps` parameter.

It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

eps : strictly positive float, optional (default=0.1)

Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when n_components is set to 'auto'.

Smaller values lead to better embedding and higher number of dimensions (n_components) in the target projection space.

random_state : int, RandomState instance or None, optional (default=None)

Control the pseudo random number generator used to generate the matrix at fit time. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **n_component_** : int

Concrete number of components computed when n_components="auto".

components_ : numpy array of shape [n_components, n_features]

Random matrix used for the projection.

See also:

SparseRandomProjection

Methods

fit(X[, y])	Generate a sparse random projection matrix
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Project the data by using matrix product with the random matrix

__init__(*n_components='auto'*, *eps=0.1*, *random_state=None*)

fit(*X*, *y=None*)

Generate a sparse random projection matrix

Parameters **X** : numpy array or scipy.sparse of shape [n_samples, n_features]

Training set: only the shape is used to find optimal random matrix dimensions based on the theory referenced in the afore mentioned papers.

y : is not used: placeholder to allow for usage in a Pipeline.

Returns **self** :

fit_transform(*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)

Project the data by using matrix product with the random matrix

Parameters **X** : numpy array or scipy.sparse of shape [n_samples, n_features]

The input data to project into a smaller dimensional space.

Returns **X_new** : numpy array or scipy sparse of shape [n_samples, n_components]

Projected array.

29.31.2 sklearn.random_projection.SparseRandomProjection

class sklearn.random_projection.**SparseRandomProjection**(*n_components='auto'*, *density='auto'*, *eps=0.1*, *dense_output=False*, *random_state=None*)

Reduce dimensionality through sparse random projection

Sparse random matrix is an alternative to dense random projection matrix that guarantees similar embedding quality while being much more memory efficient and allowing faster computation of the projected data.

If we note *s = 1 / density* the components of the random matrix are drawn from:

- -sqrt(s) / sqrt(n_components) with probability 1 / 2s
- 0 with probability 1 - 1 / s
- +sqrt(s) / sqrt(n_components) with probability 1 / 2s

Read more in the *User Guide*.

Parameters **n_components** : int or 'auto', optional (default = 'auto')

Dimensionality of the target projection space.

n_components can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality of the embedding is controlled by the `eps` parameter.

It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

density : float in range]0, 1], optional (default='auto')

Ratio of non-zero component in the random projection matrix.

If density = 'auto', the value is set to the minimum density as recommended by Ping Li et al.: 1 / sqrt(n_features).

Use density = 1 / 3.0 if you want to reproduce the results from Achlioptas, 2001.

eps : strictly positive float, optional, (default=0.1)

Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when n_components is set to 'auto'.

Smaller values lead to better embedding and higher number of dimensions (n_components) in the target projection space.

dense_output : boolean, optional (default=False)

If True, ensure that the output of the random projection is a dense numpy array even if the input and random projection matrix are both sparse. In practice, if the number of components is small the number of zero components in the projected data will be very small and it will be more CPU and memory efficient to use a dense representation.

If False, the projected data uses a sparse representation if the input is sparse.

random_state : int, RandomState instance or None, optional (default=None)

Control the pseudo random number generator used to generate the matrix at fit time. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **n_component_** : int

Concrete number of components computed when n_components="auto".

components_ : CSR matrix with shape [n_components, n_features]

Random matrix used for the projection.

density_ : float in range 0.0 - 1.0

Concrete density computed from when density = "auto".

See also:

GaussianRandomProjection

References

[R73], *[R74]*

Methods

fit(X[, y])	Generate a sparse random projection matrix
fit_transform(X[, y])	Fit to data, then transform it.
get_params([deep])	Get parameters for this estimator.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Project the data by using matrix product with the random matrix

__init__(*n_components='auto'*, *density='auto'*, *eps=0.1*, *dense_output=False*, *random_state=None*)

fit(*X*, *y=None*)

Generate a sparse random projection matrix

Parameters **X** : numpy array or scipy.sparse of shape [n_samples, n_features]

Training set: only the shape is used to find optimal random matrix dimensions based on the theory referenced in the afore mentioned papers.

y : is not used: placeholder to allow for usage in a Pipeline.

Returns **self** :

fit_transform(*X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters **X** : numpy array of shape [n_samples, n_features]

Training set.

y : numpy array of shape [n_samples]

Target values.

Returns **X_new** : numpy array of shape [n_samples, n_features_new]

Transformed array.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Project the data by using matrix product with the random matrix

Parameters **X** : numpy array or scipy.sparse of shape [n_samples, n_features]

The input data to project into a smaller dimensional space.

Returns **X_new** : numpy array or scipy sparse of shape [n_samples, n_components]

Projected array.

Examples using `sklearn.random_projection.SparseRandomProjection`

- *The Johnson-Lindenstrauss bound for embedding with random projections*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*

random_projection.johnson_lindenstrauss_min_dim(...)	Find a 'safe' number of components to randomly project to

29.31.3 sklearn.random_projection.johnson_lindenstrauss_min_dim

sklearn.random_projection.**johnson_lindenstrauss_min_dim**(*n_samples*, *eps=0.1*)
Find a 'safe' number of components to randomly project to

The distortion introduced by a random projection *p* only changes the distance between two points by a factor (1 +- eps) in an euclidean space with good probability. The projection *p* is an eps-embedding as defined by:

(1 - eps) ||u - v||^2 < ||p(u) - p(v)||^2 < (1 + eps) ||u - v||^2

Where u and v are any rows taken from a dataset of shape [n_samples, n_features], eps is in]0, 1[and p is a projection by a random Gaussian N(0, 1) matrix with shape [n_components, n_features] (or a sparse Achlioptas matrix).

The minimum number of components to guarantee the eps-embedding is given by:

n_components >= 4 log(n_samples) / (eps^2 / 2 - eps^3 / 3)

Note that the number of dimensions is independent of the original number of features but instead depends on the size of the dataset: the larger the dataset, the higher is the minimal dimensionality of an eps-embedding.

Read more in the *User Guide*.

Parameters **n_samples** : int or numpy array of int greater than 0,

Number of samples. If an array is given, it will compute a safe number of components array-wise.

eps : float or numpy array of float in]0,1[, optional (default=0.1)

Maximum distortion rate as defined by the Johnson-Lindenstrauss lemma. If an array is given, it will compute a safe number of components array-wise.

Returns **n_components** : int or numpy array of int,

The minimal number of components to guarantee with good probability an eps-embedding with n_samples.

29.32 `sklearn.semi_supervised` Semi-Supervised Learning

The *sklearn.semi_supervised* module implements semi-supervised learning algorithms. These algorithms utilized small amounts of labeled data and large amounts of unlabeled data for classification tasks. This module includes Label Propagation.

User guide: See the *Semi-Supervised* section for further details.

semi_supervised.LabelPropagation([kernel, ...])	Label Propagation classifier

Continued on next page

Table 29.250 – continued from previous page

semi_supervised.LabelSpreading([kernel, ...])	LabelSpreading model for semi-supervised learning

29.32.1 sklearn.semi_supervised.LabelPropagation

class sklearn.semi_supervised.**LabelPropagation**(*kernel='rbf'*, *gamma=20*, *n_neighbors=7*, *alpha=1*, *max_iter=30*, *tol=0.001*, *n_jobs=1*)

Label Propagation classifier

Read more in the *User Guide*.

Parameters **kernel** : {'knn', 'rbf', callable}

String identifier for kernel function to use or the kernel function itself. Only 'rbf' and 'knn' strings are valid inputs. The function passed should take two inputs, each of shape [n_samples, n_features], and return a [n_samples, n_samples] shaped weight matrix.

gamma : float

Parameter for rbf kernel

n_neighbors : integer > 0

Parameter for knn kernel

alpha : float

Clamping factor

max_iter : float

Change maximum number of iterations allowed

tol : float

Convergence tolerance: threshold to consider the system at steady state

Attributes **X_** : array, shape = [n_samples, n_features]

Input array.

classes_ : array, shape = [n_classes]

The distinct labels used in classifying instances.

label_distributions_ : array, shape = [n_samples, n_classes]

Categorical distribution for each item.

transduction_ : array, shape = [n_samples]

Label assigned to each item via the transduction.

n_iter_ : int

Number of iterations run.

Examples

```
>>> from sklearn import datasets
>>> from sklearn.semi_supervised import LabelPropagation
>>> label_prop_model = LabelPropagation()
>>> iris = datasets.load_iris()
>>> random_unlabeled_points = np.where(np.random.randint(0, 2,
...    size=len(iris.target)))
>>> labels = np.copy(iris.target)
>>> labels[random_unlabeled_points] = -1
>>> label_prop_model.fit(iris.data, labels)
...
LabelPropagation(...)
```

Methods

fit(X, y)	Fit a semi-supervised label propagation model based
get_params([deep])	Get parameters for this estimator.
predict(X)	Performs inductive inference across the model.
predict_proba(X)	Predict probability for each possible outcome.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*kernel='rbf'*, *gamma=20*, *n_neighbors=7*, *alpha=1*, *max_iter=30*, *tol=0.001*, *n_jobs=1*)

fit (*X*, *y*)

Fit a semi-supervised label propagation model based

All the input data is provided matrix X (labeled and unlabeled) and corresponding label matrix y with a dedicated marker value for unlabeled samples.

Parameters **X** : array-like, shape = [n_samples, n_features]

A {n_samples by n_samples} size matrix will be created from this

y : array_like, shape = [n_samples]

n_labeled_samples (unlabeled points are marked as -1) All unlabeled samples will be transductively assigned labels

Returns **self** : returns an instance of self.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Performs inductive inference across the model.

Parameters **X** : array_like, shape = [n_samples, n_features]

Returns **y** : array_like, shape = [n_samples]

Predictions for input data

predict_proba(*X*)

Predict probability for each possible outcome.

Compute the probability estimates for each single sample in X and each possible outcome seen during training (categorical distribution).

Parameters **X** : array_like, shape = [n_samples, n_features]

Returns **probabilities** : array, shape = [n_samples, n_classes]

Normalized probability distributions across class labels

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.32.2 sklearn.semi_supervised.LabelSpreading

class sklearn.semi_supervised.**LabelSpreading**(*kernel='rbf'*, *gamma=20*, *n_neighbors=7*, *alpha=0.2*, *max_iter=30*, *tol=0.001*, *n_jobs=1*)

LabelSpreading model for semi-supervised learning

This model is similar to the basic Label Propagation algorithm, but uses affinity matrix based on the normalized graph Laplacian and soft clamping across the labels.

Read more in the *User Guide*.

Parameters **kernel** : {'knn', 'rbf', callable}

String identifier for kernel function to use or the kernel function itself. Only 'rbf' and 'knn' strings are valid inputs. The function passed should take two inputs, each of shape [n_samples, n_features], and return a [n_samples, n_samples] shaped weight matrix

gamma : float

parameter for rbf kernel

n_neighbors : integer > 0

parameter for knn kernel

alpha : float

clamping factor

max_iter : float

maximum number of iterations allowed

tol : float

Convergence tolerance: threshold to consider the system at steady state

n_jobs : int, optional (default = 1)

The number of parallel jobs to run. If `-1`, then the number of jobs is set to the number of CPU cores.

Attributes **X_** : array, shape = [n_samples, n_features]

Input array.

classes_ : array, shape = [n_classes]

The distinct labels used in classifying instances.

label_distributions_ : array, shape = [n_samples, n_classes]

Categorical distribution for each item.

transduction_ : array, shape = [n_samples]

Label assigned to each item via the transduction.

n_iter_ : int

Number of iterations run.

29.33 `sklearn.svm`: Support Vector Machines

The `sklearn.svm` module includes Support Vector Machine algorithms.

User guide: See the *Support Vector Machines* section for further details.

29.33.1 Estimators

svm.SVC([C, kernel, degree, gamma, coef0, ...])	C-Support Vector Classification.
svm.LinearSVC([penalty, loss, dual, tol, C, ...])	Linear Support Vector Classification.
svm.NuSVC([nu, kernel, degree, gamma, ...])	Nu-Support Vector Classification.
svm.SVR([kernel, degree, gamma, coef0, tol, ...])	Epsilon-Support Vector Regression.
svm.LinearSVR([epsilon, tol, C, loss, ...])	Linear Support Vector Regression.
svm.NuSVR([nu, C, kernel, degree, gamma, ...])	Nu Support Vector Regression.
svm.OneClassSVM([kernel, degree, gamma, ...])	Unsupervised Outlier Detection.

sklearn.svm.SVC

class sklearn.svm.**SVC**(*C=1.0*, *kernel='rbf'*, *degree=3*, *gamma='auto'*, *coef0=0.0*, *shrinking=True*, *probability=False*, *tol=0.001*, *cache_size=200*, *class_weight=None*, *verbose=False*, *max_iter=-1*, *decision_function_shape='ovr'*, *random_state=None*)

C-Support Vector Classification.

The implementation is based on libsvm. The fit time complexity is more than quadratic with the number of samples which makes it hard to scale to dataset with more than a couple of 10000 samples.

The multiclass support is handled according to a one-vs-one scheme.

For details on the precise mathematical formulation of the provided kernel functions and how *gamma*, *coef0* and *degree* affect each other, see the corresponding section in the narrative documentation: *Kernel functions*.

Read more in the *User Guide*.

Parameters **C** : float, optional (default=1.0)

Penalty parameter C of the error term.

kernel : string, optional (default='rbf')

Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to pre-compute the kernel matrix from data matrices; that matrix should be an array of shape `(n_samples, n_samples)`.

degree : int, optional (default=3)

Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

gamma : float, optional (default='auto')

Kernel coefficient for 'rbf', 'poly' and 'sigmoid'. If gamma is 'auto' then 1/n_features will be used instead.

coef0 : float, optional (default=0.0)

Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

probability : boolean, optional (default=False)

Whether to enable probability estimates. This must be enabled prior to calling *fit*, and will slow down that method.

shrinking : boolean, optional (default=True)

Whether to use the shrinking heuristic.

tol : float, optional (default=1e-3)

Tolerance for stopping criterion.

cache_size : float, optional

Specify the size of the kernel cache (in MB).

class_weight : {dict, 'balanced'}, optional

Set the parameter C of class i to class_weight[i]*C for SVC. If not given, all classes are supposed to have weight one. The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

verbose : bool, default: False

Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter : int, optional (default=-1)

Hard limit on iterations within solver, or -1 for no limit.

decision_function_shape : 'ovo', 'ovr', default='ovr'

Whether to return a one-vs-rest ('ovr') decision function of shape (n_samples, n_classes) as all other classifiers, or the original one-vs-one ('ovo') decision function of libsvm which has shape (n_samples, n_classes * (n_classes - 1) / 2).

Changed in version 0.19: decision_function_shape is 'ovr' by default.

New in version 0.17: *decision_function_shape='ovr'* is recommended.

Changed in version 0.17: Deprecated *decision_function_shape='ovo' and None*.

random_state : int, RandomState instance or None, optional (default=None)

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **support_** : array-like, shape = [n_SV]

Indices of support vectors.

support_vectors_ : array-like, shape = [n_SV, n_features]

Support vectors.

n_support_ : array-like, dtype=int32, shape = [n_class]

Number of support vectors for each class.

dual_coef_ : array, shape = [n_class-1, n_SV]

Coefficients of the support vector in the decision function. For multiclass, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the section about multi-class classification in the SVM section of the User Guide for details.

coef_ : array, shape = [n_class-1, n_features]

Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

*coef_* is a readonly property derived from *dual_coef_* and *support_vectors_*.

intercept_ : array, shape = [n_class * (n_class-1) / 2]

Constants in decision function.

Examples

```
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [1, 1], [2, 1]])
>>> y = np.array([1, 1, 2, 2])
>>> from sklearn.svm import SVC
>>> clf = SVC()
>>> clf.fit(X, y)
SVC(C=1.0, cache_size=200, class_weight=None, coef0=0.0,
    decision_function_shape='ovr', degree=3, gamma='auto', kernel='rbf',
    max_iter=-1, probability=False, random_state=None, shrinking=True,
    tol=0.001, verbose=False)
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

Methods

decision_function(X)	Distance of the samples X to the separating hyperplane.
fit(X, y[, sample_weight])	Fit the SVM model according to the given training data.
get_params([deep])	Get parameters for this estimator.
predict(X)	Perform classification on samples in X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__ (*C=1.0*, *kernel='rbf'*, *degree=3*, *gamma='auto'*, *coef0=0.0*, *shrinking=True*, *probability=False*, *tol=0.001*, *cache_size=200*, *class_weight=None*, *verbose=False*, *max_iter=-1*, *decision_function_shape='ovr'*, *random_state=None*)

decision_function (*X*)

Distance of the samples X to the separating hyperplane.

Parameters **X** : array-like, shape (n_samples, n_features)

Returns **X** : array-like, shape (n_samples, n_classes * (n_classes-1) / 2)

Returns the decision function of the sample for each class in the model. If decision_function_shape='ovr', the shape is (n_samples, n_classes)

fit (*X*, *y*, *sample_weight=None*)

Fit the SVM model according to the given training data.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).

y : array-like, shape (n_samples,)

Target values (class labels in classification, real numbers in regression)

sample_weight : array-like, shape (n_samples,)

Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

Returns **self** : object

Returns self.

Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)

Perform classification on samples in X.

For an one-class model, +1 or -1 is returned.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]

Returns **y_pred** : array, shape (n_samples,)

Class labels for samples in X.

predict_log_proba

Compute log probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute *probability* set to True.

Parameters **X** : array-like, shape (n_samples, n_features)

For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]

Returns **T** : array-like, shape (n_samples, n_classes)

Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*.

Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

predict_proba
Compute probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute *probability* set to True.

Parameters **X** : array-like, shape (n_samples, n_features)

For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]

Returns **T** : array-like, shape (n_samples, n_classes)

Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*.

Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

score (*X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params (***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

sklearn.svm.LinearSVC

class sklearn.svm.**LinearSVC**(*penalty='l2'*, *loss='squared_hinge'*, *dual=True*, *tol=0.0001*, *C=1.0*, *multi_class='ovr'*, *fit_intercept=True*, *intercept_scaling=1*, *class_weight=None*, *verbose=0*, *random_state=None*, *max_iter=1000*)

Linear Support Vector Classification.

Similar to SVC with parameter kernel='linear', but implemented in terms of liblinear rather than libsvm, so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples.

This class supports both dense and sparse input and the multiclass support is handled according to a one-vs-the-rest scheme.

Read more in the *User Guide*.

Parameters **C** : float, optional (default=1.0)

Penalty parameter C of the error term.

loss : string, 'hinge' or 'squared_hinge' (default='squared_hinge')

Specifies the loss function. 'hinge' is the standard SVM loss (used e.g. by the SVC class) while 'squared_hinge' is the square of the hinge loss.

penalty : string, 'l1' or 'l2' (default='l2')

Specifies the norm used in the penalization. The 'l2' penalty is the standard used in SVC. The 'l1' leads to `coef_` vectors that are sparse.

dual : bool, (default=True)

Select the algorithm to either solve the dual or primal optimization problem. Prefer dual=False when n_samples > n_features.

tol : float, optional (default=1e-4)

Tolerance for stopping criteria.

multi_class : string, 'ovr' or 'crammer_singer' (default='ovr')

Determines the multi-class strategy if *y* contains more than two classes. `"ovr"` trains n_classes one-vs-rest classifiers, while `"crammer_singer"` optimizes a joint objective over all classes. While *crammer_singer* is interesting from a theoretical perspective as it is consistent, it is seldom used in practice as it rarely leads to better accuracy and is more expensive to compute. If `"crammer_singer"` is chosen, the options loss, penalty and dual will be ignored.

fit_intercept : boolean, optional (default=True)

Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be already centered).

intercept_scaling : float, optional (default=1)

When self.fit_intercept is True, instance vector x becomes `[x, self.intercept_scaling]`, i.e. a "synthetic" feature with constant value equals to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic feature weight Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

class_weight : {dict, 'balanced'}, optional

Set the parameter C of class i to `class_weight[i]*C` for SVC. If not given, all classes are supposed to have weight one. The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

verbose : int, (default=0)

Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in liblinear that, if enabled, may not work properly in a multithreaded context.

random_state : int, RandomState instance or None, optional (default=None)

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

max_iter : int, (default=1000)

The maximum number of iterations to be run.

Attributes **coef_** : array, shape = [n_features] if n_classes == 2 else [n_classes, n_features]

Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

`coef_` is a readonly property derived from `raw_coef_` that follows the internal memory layout of liblinear.

intercept_ : array, shape = [1] if n_classes == 2 else [n_classes]

Constants in decision function.

See also:

SVC Implementation of Support Vector Machine classifier using libsvm: the kernel can be non-linear but its SMO algorithm does not scale to large number of samples as LinearSVC does. Furthermore SVC multi-class mode is implemented using one vs one scheme while LinearSVC uses one vs the rest. It is possible to implement one vs the rest with SVC by using the *sklearn.multiclass.OneVsRestClassifier* wrapper. Finally SVC can fit dense data without memory copy if the input is C-contiguous. Sparse data will still incur memory copy though.

sklearn.linear_model.SGDClassifier SGDClassifier can optimize the same cost function as LinearSVC by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon to have slightly different results for the same input data. If that happens, try with a smaller `tol` parameter.

The underlying implementation, liblinear, uses a sparse internal representation for the data that will incur a memory copy.

Predict output may not match that of standalone liblinear in certain cases. See *differences from liblinear* in the narrative documentation.

LIBLINEAR: A Library for Large Linear Classification

Methods

decision_function(X)	Predict confidence scores for samples.
densify()	Convert coefficient matrix to dense array format.
fit(X, y[, sample_weight])	Fit the model according to the given training data.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict class labels for samples in X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.
sparsify()	Convert coefficient matrix to sparse format.

__init__ (*penalty='l2'*, *loss='squared_hinge'*, *dual=True*, *tol=0.0001*, *C=1.0*, *multi_class='ovr'*, *fit_intercept=True*, *intercept_scaling=1*, *class_weight=None*, *verbose=0*, *random_state=None*, *max_iter=1000*)

decision_function (*X*)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)** :

Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify ()

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns **self** : estimator

fit (*X*, *y*, *sample_weight=None*)

Fit the model according to the given training data.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training vector, where n_samples in the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples]

Target vector relative to X

sample_weight : array-like, shape = [n_samples], optional

Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

Returns **self** : object

Returns self.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)
Predict class labels for samples in X.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Samples.

Returns **C** : array, shape = [n_samples]

Predicted class label per sample.

score(*X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

sparsify()
Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

Returns **self** : estimator

Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using `sklearn.svm.LinearSVC`

- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *Explicit feature map approximation for RBF kernels*
- *Probability Calibration curves*
- *Comparison of Calibration of Classifiers*
- *Precision-Recall*
- *Plot different SVM classifiers in the iris dataset*
- *Scaling the regularization parameter for SVCs*
- *Classification of text documents using sparse features*

`sklearn.svm.NuSVC`

class `sklearn.svm.`**`NuSVC`**(*nu=0.5*, *kernel='rbf'*, *degree=3*, *gamma='auto'*, *coef0=0.0*, *shrinking=True*, *probability=False*, *tol=0.001*, *cache_size=200*, *class_weight=None*, *verbose=False*, *max_iter=-1*, *decision_function_shape='ovr'*, *random_state=None*)

Nu-Support Vector Classification.

Similar to SVC but uses a parameter to control the number of support vectors.

The implementation is based on libsvm.

Read more in the *User Guide*.

Parameters **nu** : float, optional (default=0.5)

An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1].

kernel : string, optional (default='rbf')

Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix.

degree : int, optional (default=3)

Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

gamma : float, optional (default='auto')

Kernel coefficient for 'rbf', 'poly' and 'sigmoid'. If gamma is 'auto' then 1/n_features will be used instead.

coef0 : float, optional (default=0.0)

Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

probability : boolean, optional (default=False)

Whether to enable probability estimates. This must be enabled prior to calling *fit*, and will slow down that method.

shrinking : boolean, optional (default=True)

Whether to use the shrinking heuristic.

tol : float, optional (default=1e-3)

Tolerance for stopping criterion.

cache_size : float, optional

Specify the size of the kernel cache (in MB).

class_weight : {dict, 'balanced'}, optional

Set the parameter C of class i to class_weight[i]*C for SVC. If not given, all classes are supposed to have weight one. The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies as `n_samples / (n_classes * np.bincount(y))`

verbose : bool, default: False

Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter : int, optional (default=-1)

Hard limit on iterations within solver, or -1 for no limit.

decision_function_shape : 'ovo', 'ovr', default='ovr'

Whether to return a one-vs-rest ('ovr') decision function of shape (n_samples, n_classes) as all other classifiers, or the original one-vs-one ('ovo') decision function of libsvm which has shape (n_samples, n_classes * (n_classes - 1) / 2).

Changed in version 0.19: decision_function_shape is 'ovr' by default.

New in version 0.17: *decision_function_shape='ovr'* is recommended.

Changed in version 0.17: Deprecated *decision_function_shape='ovo' and None*.

random_state : int, RandomState instance or None, optional (default=None)

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **support_** : array-like, shape = [n_SV]

Indices of support vectors.

support_vectors_ : array-like, shape = [n_SV, n_features]

Support vectors.

n_support_ : array-like, dtype=int32, shape = [n_class]

Number of support vectors for each class.

dual_coef_ : array, shape = [n_class-1, n_SV]

Coefficients of the support vector in the decision function. For multiclass, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the section about multi-class classification in the SVM section of the User Guide for details.

coef_ : array, shape = [n_class-1, n_features]

Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

*coef_* is readonly property derived from *dual_coef_* and *support_vectors_*.

intercept_ : array, shape = [n_class * (n_class-1) / 2]

Constants in decision function.

Examples

```
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [1, 1], [2, 1]])
>>> y = np.array([1, 1, 2, 2])
>>> from sklearn.svm import NuSVC
>>> clf = NuSVC()
>>> clf.fit(X, y)
NuSVC(cache_size=200, class_weight=None, coef0=0.0,
      decision_function_shape='ovr', degree=3, gamma='auto', kernel='rbf',
      max_iter=-1, nu=0.5, probability=False, random_state=None,
      shrinking=True, tol=0.001, verbose=False)
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

Methods

decision_function(X)	Distance of the samples X to the separating hyperplane.
fit(X, y[, sample_weight])	Fit the SVM model according to the given training data.
get_params([deep])	Get parameters for this estimator.
predict(X)	Perform classification on samples in X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__(*nu=0.5*, *kernel='rbf'*, *degree=3*, *gamma='auto'*, *coef0=0.0*, *shrinking=True*, *probability=False*, *tol=0.001*, *cache_size=200*, *class_weight=None*, *verbose=False*, *max_iter=-1*, *decision_function_shape='ovr'*, *random_state=None*)

decision_function(*X*)

Distance of the samples X to the separating hyperplane.

Parameters **X** : array-like, shape (n_samples, n_features)

Returns **X** : array-like, shape (n_samples, n_classes * (n_classes-1) / 2)

Returns the decision function of the sample for each class in the model. If decision_function_shape='ovr', the shape is (n_samples, n_classes)

fit (*X*, *y*, *sample_weight=None*)

Fit the SVM model according to the given training data.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).

y : array-like, shape (n_samples,)

Target values (class labels in classification, real numbers in regression)

sample_weight : array-like, shape (n_samples,)

Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

Returns **self** : object

Returns self.

Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*)

Perform classification on samples in X.

For an one-class model, +1 or -1 is returned.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]

Returns **y_pred** : array, shape (n_samples,)

Class labels for samples in X.

predict_log_proba

Compute log probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute *probability* set to True.

Parameters **X** : array-like, shape (n_samples, n_features)

For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]

Returns **T** : array-like, shape (n_samples, n_classes)

Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*.

Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

predict_proba

Compute probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute *probability* set to True.

Parameters **X** : array-like, shape (n_samples, n_features)

For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]

Returns **T** : array-like, shape (n_samples, n_classes)

Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*.

Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.svm.NuSVC`

- *Non-linear SVM*

`sklearn.svm.SVR`

class `sklearn.svm.`**SVR**(*kernel='rbf'*, *degree=3*, *gamma='auto'*, *coef0=0.0*, *tol=0.001*, *C=1.0*, *epsilon=0.1*, *shrinking=True*, *cache_size=200*, *verbose=False*, *max_iter=-1*)

Epsilon-Support Vector Regression.

The free parameters in the model are C and epsilon.

The implementation is based on libsvm.

Read more in the *User Guide*.

Parameters **C** : float, optional (default=1.0)

Penalty parameter C of the error term.

epsilon : float, optional (default=0.1)

Epsilon in the epsilon-SVR model. It specifies the epsilon-tube within which no penalty is associated in the training loss function with points predicted within a distance epsilon from the actual value.

kernel : string, optional (default='rbf')

Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix.

degree : int, optional (default=3)

Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

gamma : float, optional (default='auto')

Kernel coefficient for 'rbf', 'poly' and 'sigmoid'. If gamma is 'auto' then 1/n_features will be used instead.

coef0 : float, optional (default=0.0)

Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

shrinking : boolean, optional (default=True)

Whether to use the shrinking heuristic.

tol : float, optional (default=1e-3)

Tolerance for stopping criterion.

cache_size : float, optional

Specify the size of the kernel cache (in MB).

verbose : bool, default: False

Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter : int, optional (default=-1)

Hard limit on iterations within solver, or -1 for no limit.

Attributes **support_** : array-like, shape = [n_SV]

Indices of support vectors.

support_vectors_ : array-like, shape = [nSV, n_features]

Support vectors.

dual_coef_ : array, shape = [1, n_SV]

Coefficients of the support vector in the decision function.

coef_ : array, shape = [1, n_features]

Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

*coef_* is readonly property derived from *dual_coef_* and *support_vectors_*.

intercept_ : array, shape = [1]

Constants in decision function.

sample_weight : array-like, shape = [n_samples]

Individual weights for each sample

See also:

NuSVR Support Vector Machine for regression implemented using libsvm using a parameter to control the number of support vectors.

LinearSVR Scalable Linear Support Vector Machine for regression implemented using liblinear.

Examples

```
>>> from sklearn.svm import SVR
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> np.random.seed(0)
>>> y = np.random.randn(n_samples)
>>> X = np.random.randn(n_samples, n_features)
>>> clf = SVR(C=1.0, epsilon=0.2)
>>> clf.fit(X, y)
SVR(C=1.0, cache_size=200, coef0=0.0, degree=3, epsilon=0.2, gamma='auto',
    kernel='rbf', max_iter=-1, shrinking=True, tol=0.001, verbose=False)
```

Methods

fit(X, y[, sample_weight])	Fit the SVM model according to the given training data.
get_params([deep])	Get parameters for this estimator.
predict(X)	Perform regression on samples in X.

Continued on next page

Table 29.257 – continued from previous page

score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*kernel='rbf'*, *degree=3*, *gamma='auto'*, *coef0=0.0*, *tol=0.001*, *C=1.0*, *epsilon=0.1*, *shrinking=True*, *cache_size=200*, *verbose=False*, *max_iter=-1*)

fit (*X*, *y*, *sample_weight=None*)

Fit the SVM model according to the given training data.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).

y : array-like, shape (n_samples,)

Target values (class labels in classification, real numbers in regression)

sample_weight : array-like, shape (n_samples,)

Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

Returns **self** : object

Returns self.

Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*)

Perform regression on samples in X.

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

Returns **y_pred** : array, shape (n_samples,)

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.svm.SVR`

- *Comparison of kernel ridge regression and SVR*
- *Prediction Latency*
- *Support Vector Regression (SVR) using linear and non-linear kernels*

`sklearn.svm`.LinearSVR

class sklearn.svm.**LinearSVR**(*epsilon=0.0*, *tol=0.0001*, *C=1.0*, *loss='epsilon_insensitive'*, *fit_intercept=True*, *intercept_scaling=1.0*, *dual=True*, *verbose=0*, *random_state=None*, *max_iter=1000*)

Linear Support Vector Regression.

Similar to SVR with parameter kernel='linear', but implemented in terms of liblinear rather than libsvm, so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples.

This class supports both dense and sparse input.

Read more in the *User Guide*.

Parameters **C** : float, optional (default=1.0)

Penalty parameter C of the error term. The penalty is a squared l2 penalty. The bigger this parameter, the less regularization is used.

loss : string, 'epsilon_insensitive' or 'squared_epsilon_insensitive' (default='epsilon_insensitive')

Specifies the loss function. 'l1' is the epsilon-insensitive loss (standard SVR) while 'l2' is the squared epsilon-insensitive loss.

epsilon : float, optional (default=0.1)

Epsilon parameter in the epsilon-insensitive loss function. Note that the value of this parameter depends on the scale of the target variable y. If unsure, set `epsilon=0`.

dual : bool, (default=True)

Select the algorithm to either solve the dual or primal optimization problem. Prefer dual=False when n_samples > n_features.

tol : float, optional (default=1e-4)

Tolerance for stopping criteria.

fit_intercept : boolean, optional (default=True)

Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be already centered).

intercept_scaling : float, optional (default=1)

When self.fit_intercept is True, instance vector x becomes [x, self.intercept_scaling], i.e. a "synthetic" feature with constant value equals to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic feature weight Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

verbose : int, (default=0)

Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in liblinear that, if enabled, may not work properly in a multithreaded context.

random_state : int, RandomState instance or None, optional (default=None)

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

max_iter : int, (default=1000)

The maximum number of iterations to be run.

Attributes **coef_** : array, shape = [n_features] if n_classes == 2 else [n_classes, n_features]

Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

*coef_* is a readonly property derived from *raw_coef_* that follows the internal memory layout of liblinear.

intercept_ : array, shape = [1] if n_classes == 2 else [n_classes]

Constants in decision function.

See also:

LinearSVC Implementation of Support Vector Machine classifier using the same library as this class (liblinear).

SVR Implementation of Support Vector Machine regression using libsvm: the kernel can be non-linear but its SMO algorithm does not scale to large number of samples as LinearSVC does.

sklearn.linear_model.SGDRegressor SGDRegressor can optimize the same cost function as LinearSVR by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

Methods

fit(X, y[, sample_weight])	Fit the model according to the given training data.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict using the linear model
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*epsilon=0.0*, *tol=0.0001*, *C=1.0*, *loss='epsilon_insensitive'*, *fit_intercept=True*, *intercept_scaling=1.0*, *dual=True*, *verbose=0*, *random_state=None*, *max_iter=1000*)

fit (*X*, *y*, *sample_weight=None*)
Fit the model according to the given training data.

Parameters **X** : {array-like, sparse matrix}, shape = [n_samples, n_features]

Training vector, where n_samples in the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples]

Target vector relative to X

sample_weight : array-like, shape = [n_samples], optional

Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

Returns **self** : object

Returns self.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*)
Predict using the linear model

Parameters **X** : {array-like, sparse matrix}, shape = (n_samples, n_features)

Samples.

Returns **C** : array, shape = (n_samples,)

Returns predicted values.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

sklearn.svm.NuSVR

class sklearn.svm.**NuSVR**(*nu=0.5*, *C=1.0*, *kernel='rbf'*, *degree=3*, *gamma='auto'*, *coef0=0.0*, *shrinking=True*, *tol=0.001*, *cache_size=200*, *verbose=False*, *max_iter=-1*)

Nu Support Vector Regression.

Similar to NuSVC, for regression, uses a parameter nu to control the number of support vectors. However, unlike NuSVC, where nu replaces C, here nu replaces the parameter epsilon of epsilon-SVR.

The implementation is based on libsvm.

Read more in the *User Guide*.

Parameters **C** : float, optional (default=1.0)

Penalty parameter C of the error term.

nu : float, optional

An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.

kernel : string, optional (default='rbf')

Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix.

degree : int, optional (default=3)

Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

gamma : float, optional (default='auto')

Kernel coefficient for 'rbf', 'poly' and 'sigmoid'. If gamma is 'auto' then 1/n_features will be used instead.

coef0 : float, optional (default=0.0)

Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

shrinking : boolean, optional (default=True)

Whether to use the shrinking heuristic.

tol : float, optional (default=1e-3)

Tolerance for stopping criterion.

cache_size : float, optional

Specify the size of the kernel cache (in MB).

verbose : bool, default: False

Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter : int, optional (default=-1)

Hard limit on iterations within solver, or -1 for no limit.

Attributes **support_** : array-like, shape = [n_SV]

Indices of support vectors.

support_vectors_ : array-like, shape = [nSV, n_features]

Support vectors.

dual_coef_ : array, shape = [1, n_SV]

Coefficients of the support vector in the decision function.

coef_ : array, shape = [1, n_features]

Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

*coef_* is readonly property derived from *dual_coef_* and *support_vectors_*.

intercept_ : array, shape = [1]

Constants in decision function.

See also:

NuSVC Support Vector Machine for classification implemented with libsvm with a parameter to control the number of support vectors.

SVR epsilon Support Vector Machine for regression implemented with libsvm.

Examples

```
>>> from sklearn.svm import NuSVR
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> np.random.seed(0)
>>> y = np.random.randn(n_samples)
>>> X = np.random.randn(n_samples, n_features)
>>> clf = NuSVR(C=1.0, nu=0.1)
>>> clf.fit(X, y)
NuSVR(C=1.0, cache_size=200, coef0=0.0, degree=3, gamma='auto',
      kernel='rbf', max_iter=-1, nu=0.1, shrinking=True, tol=0.001,
      verbose=False)
```

Methods

fit(X, y[, sample_weight])	Fit the SVM model according to the given training data.
get_params([deep])	Get parameters for this estimator.
predict(X)	Perform regression on samples in X.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*nu=0.5*, *C=1.0*, *kernel='rbf'*, *degree=3*, *gamma='auto'*, *coef0=0.0*, *shrinking=True*, *tol=0.001*, *cache_size=200*, *verbose=False*, *max_iter=-1*)

fit (*X*, *y*, *sample_weight=None*)

Fit the SVM model according to the given training data.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).

y : array-like, shape (n_samples,)

Target values (class labels in classification, real numbers in regression)

sample_weight : array-like, shape (n_samples,)

Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

Returns **self** : object

Returns self.

Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)
Perform regression on samples in X.

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

Returns **y_pred** : array, shape (n_samples,)

score(*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.svm.NuSVR`

- *Model Complexity Influence*

sklearn.svm.OneClassSVM

class sklearn.svm.**OneClassSVM**(*kernel='rbf'*, *degree=3*, *gamma='auto'*, *coef0=0.0*, *tol=0.001*, *nu=0.5*, *shrinking=True*, *cache_size=200*, *verbose=False*, *max_iter=-1*, *random_state=None*)

Unsupervised Outlier Detection.

Estimate the support of a high-dimensional distribution.

The implementation is based on libsvm.

Read more in the *User Guide*.

Parameters **kernel** : string, optional (default='rbf')

Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix.

nu : float, optional

An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.

degree : int, optional (default=3)

Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

gamma : float, optional (default='auto')

Kernel coefficient for 'rbf', 'poly' and 'sigmoid'. If gamma is 'auto' then 1/n_features will be used instead.

coef0 : float, optional (default=0.0)

Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

tol : float, optional

Tolerance for stopping criterion.

shrinking : boolean, optional

Whether to use the shrinking heuristic.

cache_size : float, optional

Specify the size of the kernel cache (in MB).

verbose : bool, default: False

Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter : int, optional (default=-1)

Hard limit on iterations within solver, or -1 for no limit.

random_state : int, RandomState instance or None, optional (default=None)

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **support_** : array-like, shape = [n_SV]

Indices of support vectors.

support_vectors_ : array-like, shape = [nSV, n_features]

Support vectors.

dual_coef_ : array, shape = [n_classes-1, n_SV]

Coefficients of the support vectors in the decision function.

coef_ : array, shape = [n_classes-1, n_features]

Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

*coef_* is readonly property derived from *dual_coef_* and *support_vectors_*

intercept_ : array, shape = [n_classes-1]

Constants in decision function.

Methods

decision_function(X)	Signed distance to the separating hyperplane.
fit(X[, y, sample_weight])	Detects the soft boundary of the set of samples X.
get_params([deep])	Get parameters for this estimator.
predict(X)	Perform classification on samples in X.
set_params(**params)	Set the parameters of this estimator.

__init__ (*kernel='rbf'*, *degree=3*, *gamma='auto'*, *coef0=0.0*, *tol=0.001*, *nu=0.5*, *shrinking=True*, *cache_size=200*, *verbose=False*, *max_iter=-1*, *random_state=None*)

decision_function (*X*)

Signed distance to the separating hyperplane.

Signed distance is positive for an inlier and negative for an outlier.

Parameters **X** : array-like, shape (n_samples, n_features)

Returns **X** : array-like, shape (n_samples,)

Returns the decision function of the samples.

fit (*X*, *y=None*, *sample_weight=None*, ***params*)

Detects the soft boundary of the set of samples X.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

Set of samples, where n_samples is the number of samples and n_features is the number of features.

sample_weight : array-like, shape (n_samples,)

Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

Returns **self** : object

Returns self.

Notes

If X is not a C-ordered contiguous array it is copied.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)
Perform classification on samples in X.

For an one-class model, +1 or -1 is returned.

Parameters **X** : {array-like, sparse matrix}, shape (n_samples, n_features)

For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]

Returns **y_pred** : array, shape (n_samples,)

Class labels for samples in X.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.svm.OneClassSVM`

- *Outlier detection on a real data set*
- *Species distribution modeling*
- *Libsvm GUI*
- *Outlier detection with several methods.*
- *One-class SVM with non-linear kernel (RBF)*

svm.l1_min_c(X, y[, loss, fit_intercept, ...])	Return the lowest bound for C such that for C in (l1_min_C, infinity) the model is guaranteed not to be empty.

sklearn.svm.l1_min_c

sklearn.svm.**l1_min_c**(*X*, *y*, *loss='squared_hinge'*, *fit_intercept=True*, *intercept_scaling=1.0*)
Return the lowest bound for C such that for C in (l1_min_C, infinity) the model is guaranteed not to be empty. This applies to l1 penalized classifiers, such as LinearSVC with penalty='l1' and linear_model.LogisticRegression with penalty='l1'.

This value is valid if class_weight parameter in fit() is not set.

Parameters **X** : array-like or sparse matrix, shape = [n_samples, n_features]

Training vector, where n_samples in the number of samples and n_features is the number of features.

y : array, shape = [n_samples]

Target vector relative to X

loss : {'squared_hinge', 'log'}, default 'squared_hinge'

Specifies the loss function. With 'squared_hinge' it is the squared hinge loss (a.k.a. L2 loss). With 'log' it is the loss of logistic regression models. 'l2' is accepted as an alias for 'squared_hinge', for backward compatibility reasons, but should not be used in new code.

fit_intercept : bool, default: True

Specifies if the intercept should be fitted by the model. It must match the fit() method parameter.

intercept_scaling : float, default: 1

when fit_intercept is True, instance vector x becomes [x, intercept_scaling], i.e. a "synthetic" feature with constant value equals to intercept_scaling is appended to the instance vector. It must match the fit() method parameter.

Returns **l1_min_c** : float

minimum value for C

Examples using `sklearn.svm.l1_min_c`

- *Path with L1- Logistic Regression*

29.33.2 Low-level methods

svm.libsvm.fit	Train the model using libsvm (low-level method)
svm.libsvm.decision_function	Predict margin (libsvm name for this is predict_values)
svm.libsvm.predict	Predict target values of X given a model (low-level method)
svm.libsvm.predict_proba	Predict probabilities
svm.libsvm.cross_validation	Binding of the cross-validation routine (low-level routine)

`sklearn.svm.libsvm.fit`

sklearn.svm.libsvm.**fit**()

Train the model using libsvm (low-level method)

Parameters **X** : array-like, dtype=float64, size=[n_samples, n_features]

Y : array, dtype=float64, size=[n_samples]

target vector

svm_type : {0, 1, 2, 3, 4}, optional

Type of SVM: C_SVC, NuSVC, OneClassSVM, EpsilonSVR or NuSVR respectively. 0 by default.

kernel : {'linear', 'rbf', 'poly', 'sigmoid', 'precomputed'}, optional

Kernel to use in the model: linear, polynomial, RBF, sigmoid or precomputed. 'rbf' by default.

degree : int32, optional

Degree of the polynomial kernel (only relevant if kernel is set to polynomial), 3 by default.

gamma : float64, optional

Gamma parameter in rbf, poly and sigmoid kernels. Ignored by other kernels. 0.1 by default.

coef0 : float64, optional

Independent parameter in poly/sigmoid kernel. 0 by default.

tol : float64, optional

Numeric stopping criterion (WRITEME). 1e-3 by default.

C : float64, optional

C parameter in C-Support Vector Classification. 1 by default.

nu : float64, optional

0.5 by default.

epsilon : double, optional

0.1 by default.

class_weight : array, dtype float64, shape (n_classes,), optional

np.empty(0) by default.

sample_weight : array, dtype float64, shape (n_samples,), optional

np.empty(0) by default.

shrinking : int, optional

1 by default.

probability : int, optional

0 by default.

cache_size : float64, optional

Cache size for gram matrix columns (in megabytes). 100 by default.

max_iter : int (-1 for no limit), optional.

Stop solver after this many iterations regardless of accuracy (XXX Currently there is no API to know whether this kicked in.) -1 by default.

random_seed : int, optional

Seed for the random number generator used for probability estimates. 0 by default.

Returns **support** : array, shape=[n_support]

index of support vectors

support_vectors : array, shape=[n_support, n_features]

support vectors (equivalent to X[support]). Will return an empty array in the case of precomputed kernel.

n_class_SV : array

number of support vectors in each class.

sv_coef : array

coefficients of support vectors in decision function.

intercept : array

intercept in decision function

probA, probB : array

probability estimates, empty array for probability=False

sklearn.svm.libsvm.decision_function

sklearn.svm.libsvm.**decision_function**()

Predict margin (libsvm name for this is predict_values)

We have to reconstruct model and parameters to make sure we stay in sync with the python object.

sklearn.svm.libsvm.predict

sklearn.svm.libsvm.**predict**()

Predict target values of X given a model (low-level method)

Parameters **X** : array-like, dtype=float, size=[n_samples, n_features]

svm_type : {0, 1, 2, 3, 4}

Type of SVM: C SVC, nu SVC, one class, epsilon SVR, nu SVR

kernel : {'linear', 'rbf', 'poly', 'sigmoid', 'precomputed'}

Type of kernel.

degree : int

Degree of the polynomial kernel.

gamma : float

Gamma parameter in rbf, poly and sigmoid kernels. Ignored by other kernels. 0.1 by default.

coef0 : float

Independent parameter in poly/sigmoid kernel.

Returns **dec_values** : array

predicted values.

sklearn.svm.libsvm.predict_proba

sklearn.svm.libsvm.**predict_proba**()

Predict probabilities

svm_model stores all parameters needed to predict a given value.

For speed, all real work is done at the C level in function copy_predict (libsvm_helper.c).

We have to reconstruct model and parameters to make sure we stay in sync with the python object.

See sklearn.svm.predict for a complete list of parameters.

Parameters **X** : array-like, dtype=float

kernel : {'linear', 'rbf', 'poly', 'sigmoid', 'precomputed'}

Returns **dec_values** : array

predicted values.

sklearn.svm.libsvm.cross_validation

sklearn.svm.libsvm.**cross_validation**()

Binding of the cross-validation routine (low-level routine)

Parameters **X** : array-like, dtype=float, size=[n_samples, n_features]

Y : array, dtype=float, size=[n_samples]

target vector

svm_type : {0, 1, 2, 3, 4}

Type of SVM: C SVC, nu SVC, one class, epsilon SVR, nu SVR

kernel : {'linear', 'rbf', 'poly', 'sigmoid', 'precomputed'}

Kernel to use in the model: linear, polynomial, RBF, sigmoid or precomputed.

degree : int

Degree of the polynomial kernel (only relevant if kernel is set to polynomial)

gamma : float

Gamma parameter in rbf, poly and sigmoid kernels. Ignored by other kernels. 0.1 by default.

coef0 : float

Independent parameter in poly/sigmoid kernel.

tol : float

Stopping criteria.

C : float

C parameter in C-Support Vector Classification

nu : float

cache_size : float

random_seed : int, optional

Seed for the random number generator used for probability estimates. 0 by default.

Returns **target** : array, float

29.34 sklearn.tree: Decision Trees

The *sklearn.tree* module includes decision tree-based models for classification and regression.

User guide: See the *Decision Trees* section for further details.

tree.DecisionTreeClassifier([criterion, ...])	A decision tree classifier.
tree.DecisionTreeRegressor([criterion, ...])	A decision tree regressor.
tree.ExtraTreeClassifier([criterion, ...])	An extremely randomized tree classifier.
tree.ExtraTreeRegressor([criterion, ...])	An extremely randomized tree regressor.

29.34.1 sklearn.tree.DecisionTreeClassifier

class sklearn.tree.**DecisionTreeClassifier**(*criterion='gini'*, *splitter='best'*, *max_depth=None*, *min_samples_split=2*, *min_samples_leaf=1*, *min_weight_fraction_leaf=0.0*, *max_features=None*, *random_state=None*, *max_leaf_nodes=None*, *min_impurity_decrease=0.0*, *min_impurity_split=None*, *class_weight=None*, *presort=False*)

A decision tree classifier.

Read more in the *User Guide*.

Parameters **criterion** : string, optional (default="gini")

The function to measure the quality of a split. Supported criteria are "gini" for the Gini impurity and "entropy" for the information gain.

splitter : string, optional (default="best")

The strategy used to choose the split at each node. Supported strategies are "best" to choose the best split and "random" to choose the best random split.

max_features : int, float, string or None, optional (default=None)

The number of features to consider when looking for the best split:

- If int, then consider *max_features* features at each split.
- If float, then *max_features* is a percentage and *int(max_features * n_features)* features are considered at each split.
- If "auto", then *max_features=sqrt(n_features)*.
- If "sqrt", then *max_features=sqrt(n_features)*.
- If "log2", then *max_features=log2(n_features)*.
- If None, then *max_features=n_features*.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

max_depth : int or None, optional (default=None)

The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

min_samples_split : int, float, optional (default=2)

The minimum number of samples required to split an internal node:

- If int, then consider *min_samples_split* as the minimum number.
- If float, then *min_samples_split* is a percentage and *ceil(min_samples_split * n_samples)* are the minimum number of samples for each split.

Changed in version 0.18: Added float values for percentages.

min_samples_leaf : int, float, optional (default=1)

The minimum number of samples required to be at a leaf node:

- If int, then consider *min_samples_leaf* as the minimum number.
- If float, then *min_samples_leaf* is a percentage and *ceil(min_samples_leaf * n_samples)* are the minimum number of samples for each node.

Changed in version 0.18: Added float values for percentages.

min_weight_fraction_leaf : float, optional (default=0.)

The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

max_leaf_nodes : int or None, optional (default=None)

Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

class_weight : dict, list of dicts, "balanced" or None, optional (default=None)

Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be [{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}] instead of [{1:1}, {2:5}, {3:1}, {4:1}].

The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

For multi-output, the weights of each column of y will be multiplied.

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

min_impurity_split : float,

Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19 and will be removed in 0.21. Use `min_impurity_decrease` instead.

min_impurity_decrease : float, optional (default=0.)

A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

```
N_t / N * (impurity - N_t_R / N_t * right_impurity
                    - N_t_L / N_t * left_impurity)
```

where `N` is the total number of samples, `N_t` is the number of samples at the current node, `N_t_L` is the number of samples in the left child, and `N_t_R` is the number of samples in the right child.

`N`, `N_t`, `N_t_R` and `N_t_L` all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

presort : bool, optional (default=False)

Whether to presort the data to speed up the finding of best splits in fitting. For the default settings of a decision tree on large datasets, setting this to true may slow down the training process. When using either a smaller dataset or a restricted depth, this may speed up the training.

Attributes **classes_** : array of shape = [n_classes] or a list of such arrays

The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).

feature_importances_ : array of shape = [n_features]

The feature importances. The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance *[R80]*.

max_features_ : int,

The inferred value of max_features.

n_classes_ : int or list

The number of classes (for single output problems), or a list containing the number of classes for each output (for multi-output problems).

n_features_ : int

The number of features when `fit` is performed.

n_outputs_ : int

The number of outputs when `fit` is performed.

tree_ : Tree object

The underlying Tree object.

See also:

DecisionTreeRegressor

Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data and `max_features=n_features`, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, `random_state` has to be fixed.

Examples

```
>>> from sklearn.datasets import load_iris
>>> from sklearn.model_selection import cross_val_score
>>> from sklearn.tree import DecisionTreeClassifier
>>> clf = DecisionTreeClassifier(random_state=0)
>>> iris = load_iris()
>>> cross_val_score(clf, iris.data, iris.target, cv=10)
...
...
array([ 1.     ,  0.93...,  0.86...,  0.93...,  0.93...,
        0.93...,  0.93...,  1.     ,  0.93...,  1.      ])
```

Methods

apply(X[, check_input])	Returns the index of the leaf that each sample is predicted as.
decision_path(X[, check_input])	Return the decision path in the tree
fit(X, y[, sample_weight, check_input, ...])	Build a decision tree classifier from the training set (X, y).
get_params([deep])	Get parameters for this estimator.
predict(X[, check_input])	Predict class or regression value for X.
predict_log_proba(X)	Predict class log-probabilities of the input samples X.
predict_proba(X[, check_input])	Predict class probabilities of the input samples X.
score(X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(**params)	Set the parameters of this estimator.

__init__(*criterion='gini'*, *splitter='best'*, *max_depth=None*, *min_samples_split=2*, *min_samples_leaf=1*, *min_weight_fraction_leaf=0.0*, *max_features=None*, *random_state=None*, *max_leaf_nodes=None*, *min_impurity_decrease=0.0*, *min_impurity_split=None*, *class_weight=None*, *presort=False*)

apply(*X*, *check_input=True*)

Returns the index of the leaf that each sample is predicted as.

New in version 0.17.

Parameters **X** : array_like or sparse matrix, shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Returns **X_leaves** : array_like, shape = [n_samples,]

For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within `[0; self.tree_.node_count)`, possibly with gaps in the numbering.

decision_path (*X*, *check_input=True*)

Return the decision path in the tree

New in version 0.18.

Parameters **X** : array_like or sparse matrix, shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Returns **indicator** : sparse csr array, shape = [n_samples, n_nodes]

Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

feature_importances_

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Returns **feature_importances_** : array, shape = [n_features]

fit (*X*, *y*, *sample_weight=None*, *check_input=True*, *X_idx_sorted=None*)

Build a decision tree classifier from the training set (X, y).

Parameters **X** : array-like or sparse matrix, shape = [n_samples, n_features]

The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

y : array-like, shape = [n_samples] or [n_samples, n_outputs]

The target values (class labels) as integers or strings.

sample_weight : array-like, shape = [n_samples] or None

Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

X_idx_sorted : array-like, shape = [n_samples, n_features], optional

The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don't use this parameter unless you know what to do.

Returns **self** : object

Returns self.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*, *check_input=True*)

Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

Parameters **X** : array-like or sparse matrix of shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Returns **y** : array of shape = [n_samples] or [n_samples, n_outputs]

The predicted classes, or the predict values.

predict_log_proba(*X*)

Predict class log-probabilities of the input samples X.

Parameters **X** : array-like or sparse matrix of shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

Returns **p** : array of shape = [n_samples, n_classes], or a list of n_outputs

such arrays if n_outputs > 1. The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

predict_proba(*X*, *check_input=True*)

Predict class probabilities of the input samples X.

The predicted class probability is the fraction of samples of the same class in a leaf.

check_input [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Parameters **X** : array-like or sparse matrix of shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

Returns **p** : array of shape = [n_samples, n_classes], or a list of n_outputs

such arrays if n_outputs > 1. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

score (*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params (***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.tree.DecisionTreeClassifier`

- *Classifier comparison*
- *Discrete versus Real AdaBoost*
- *Multi-class AdaBoosted Decision Trees*
- *Two-class AdaBoost*
- *Plot the decision surfaces of ensembles of trees on the iris dataset*
- *Plot the decision boundaries of a VotingClassifier*
- *Plot the decision surface of a decision tree on the iris dataset*
- *Understanding the decision tree structure*

29.34.2 sklearn.tree.DecisionTreeRegressor

class sklearn.tree.**DecisionTreeRegressor**(*criterion='mse'*, *splitter='best'*, *max_depth=None*, *min_samples_split=2*, *min_samples_leaf=1*, *min_weight_fraction_leaf=0.0*, *max_features=None*, *random_state=None*, *max_leaf_nodes=None*, *min_impurity_decrease=0.0*, *min_impurity_split=None*, *presort=False*)

A decision tree regressor.

Read more in the *User Guide*.

Parameters **criterion** : string, optional (default="mse")

The function to measure the quality of a split. Supported criteria are "mse" for the mean squared error, which is equal to variance reduction as feature selection criterion, and "mae" for the mean absolute error.

New in version 0.18: Mean Absolute Error (MAE) criterion.

splitter : string, optional (default="best")

The strategy used to choose the split at each node. Supported strategies are "best" to choose the best split and "random" to choose the best random split.

max_features : int, float, string or None, optional (default=None)

The number of features to consider when looking for the best split:

- If int, then consider *max_features* features at each split.
- If float, then *max_features* is a percentage and *int(max_features * n_features)* features are considered at each split.
- If "auto", then *max_features=n_features*.
- If "sqrt", then *max_features=sqrt(n_features)*.
- If "log2", then *max_features=log2(n_features)*.
- If None, then *max_features=n_features*.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

max_depth : int or None, optional (default=None)

The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

min_samples_split : int, float, optional (default=2)

The minimum number of samples required to split an internal node:

- If int, then consider *min_samples_split* as the minimum number.
- If float, then *min_samples_split* is a percentage and *ceil(min_samples_split * n_samples)* are the minimum number of samples for each split.

Changed in version 0.18: Added float values for percentages.

min_samples_leaf : int, float, optional (default=1)

The minimum number of samples required to be at a leaf node:

- If int, then consider *min_samples_leaf* as the minimum number.

- If float, then *min_samples_leaf* is a percentage and *ceil(min_samples_leaf * n_samples)* are the minimum number of samples for each node.

Changed in version 0.18: Added float values for percentages.

min_weight_fraction_leaf : float, optional (default=0.)

The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

max_leaf_nodes : int or None, optional (default=None)

Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

min_impurity_split : float,

Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19 and will be removed in 0.21. Use `min_impurity_decrease` instead.

min_impurity_decrease : float, optional (default=0.)

A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

```
N_t / N * (impurity - N_t_R / N_t * right_impurity
                    - N_t_L / N_t * left_impurity)
```

where `N` is the total number of samples, `N_t` is the number of samples at the current node, `N_t_L` is the number of samples in the left child, and `N_t_R` is the number of samples in the right child.

`N`, `N_t`, `N_t_R` and `N_t_L` all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

presort : bool, optional (default=False)

Whether to presort the data to speed up the finding of best splits in fitting. For the default settings of a decision tree on large datasets, setting this to true may slow down the training process. When using either a smaller dataset or a restricted depth, this may speed up the training.

Attributes **feature_importances_** : array of shape = [n_features]

The feature importances. The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance *[R84]*.

max_features_ : int,

The inferred value of max_features.

n_features_ : int

The number of features when `fit` is performed.

n_outputs_ : int

The number of outputs when `fit` is performed.

tree_ : Tree object

The underlying Tree object.

```

Methods

apply(X[, check_input])	Returns the index of the leaf that each sample is predicted as.
decision_path(X[, check_input])	Return the decision path in the tree

Continued on next page

Table 29.265 – continued from previous page

fit(X, y[, sample_weight, check_input, ...])	Build a decision tree regressor from the training set (X, y).
get_params([deep])	Get parameters for this estimator.
predict(X[, check_input])	Predict class or regression value for X.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*criterion='mse'*, *splitter='best'*, *max_depth=None*, *min_samples_split=2*, *min_samples_leaf=1*, *min_weight_fraction_leaf=0.0*, *max_features=None*, *random_state=None*, *max_leaf_nodes=None*, *min_impurity_decrease=0.0*, *min_impurity_split=None*, *presort=False*)

apply (*X*, *check_input=True*)

Returns the index of the leaf that each sample is predicted as.

New in version 0.17.

Parameters **X** : array_like or sparse matrix, shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Returns **X_leaves** : array_like, shape = [n_samples,]

For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within `[0; self.tree_.node_count)`, possibly with gaps in the numbering.

decision_path (*X*, *check_input=True*)

Return the decision path in the tree

New in version 0.18.

Parameters **X** : array_like or sparse matrix, shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Returns **indicator** : sparse csr array, shape = [n_samples, n_nodes]

Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

feature_importances_

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Returns **feature_importances_** : array, shape = [n_features]

fit (*X*, *y*, *sample_weight=None*, *check_input=True*, *X_idx_sorted=None*)
Build a decision tree regressor from the training set (X, y).

Parameters **X** : array-like or sparse matrix, shape = [n_samples, n_features]

The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

y : array-like, shape = [n_samples] or [n_samples, n_outputs]

The target values (real numbers). Use `dtype=np.float64` and `order='C'` for maximum efficiency.

sample_weight : array-like, shape = [n_samples] or None

Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

X_idx_sorted : array-like, shape = [n_samples, n_features], optional

The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don't use this parameter unless you know what to do.

Returns **self** : object

Returns self.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*, *check_input=True*)
Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

Parameters **X** : array-like or sparse matrix of shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Returns **y** : array of shape = [n_samples] or [n_samples, n_outputs]

The predicted classes, or the predict values.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

Examples using `sklearn.tree.DecisionTreeRegressor`

- *Decision Tree Regression with AdaBoost*
- *Single estimator versus bagging: bias-variance decomposition*
- *Decision Tree Regression*
- *Multi-output Decision Tree Regression*

29.34.3 `sklearn.tree`.ExtraTreeClassifier

class `sklearn.tree.`**ExtraTreeClassifier**(*criterion='gini'*, *splitter='random'*, *max_depth=None*, *min_samples_split=2*, *min_samples_leaf=1*, *min_weight_fraction_leaf=0.0*, *max_features='auto'*, *random_state=None*, *max_leaf_nodes=None*, *min_impurity_decrease=0.0*, *min_impurity_split=None*, *class_weight=None*)

An extremely randomized tree classifier.

Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate the samples of a node into two groups, random splits are drawn for each of the *max_features* randomly selected features and the best split among those is chosen. When *max_features* is set 1, this amounts to building a totally random decision tree.

Warning: Extra-trees should only be used within ensemble methods.

Read more in the *User Guide*.

apply(*X*, *check_input=True*)

Returns the index of the leaf that each sample is predicted as.

New in version 0.17.

Parameters **X** : array_like or sparse matrix, shape = [n_samples, n_features]

The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Returns **X_leaves** : array_like, shape = [n_samples,]

For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within [0; self.tree_.node_count), possibly with gaps in the numbering.

decision_path(*X*, *check_input=True*)
Return the decision path in the tree

New in version 0.18.

Parameters **X** : array_like or sparse matrix, shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Returns **indicator** : sparse csr array, shape = [n_samples, n_nodes]

Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

feature_importances_
Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Returns **feature_importances_** : array, shape = [n_features]

fit(*X*, *y*, *sample_weight=None*, *check_input=True*, *X_idx_sorted=None*)
Build a decision tree classifier from the training set (X, y).

Parameters **X** : array-like or sparse matrix, shape = [n_samples, n_features]

The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

y : array-like, shape = [n_samples] or [n_samples, n_outputs]

The target values (class labels) as integers or strings.

sample_weight : array-like, shape = [n_samples] or None

Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

X_idx_sorted : array-like, shape = [n_samples, n_features], optional

The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don't use this parameter unless you know what to do.

Returns **self** : object

Returns self.

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*, *check_input=True*)

Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

Parameters **X** : array-like or sparse matrix of shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Returns **y** : array of shape = [n_samples] or [n_samples, n_outputs]

The predicted classes, or the predict values.

predict_log_proba(*X*)

Predict class log-probabilities of the input samples X.

Parameters **X** : array-like or sparse matrix of shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

Returns **p** : array of shape = [n_samples, n_classes], or a list of n_outputs

such arrays if n_outputs > 1. The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

predict_proba(*X*, *check_input=True*)

Predict class probabilities of the input samples X.

The predicted class probability is the fraction of samples of the same class in a leaf.

check_input [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Parameters **X** : array-like or sparse matrix of shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

Returns **p** : array of shape = [n_samples, n_classes], or a list of n_outputs

such arrays if n_outputs > 1. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

score(*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True labels for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

Mean accuracy of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

29.34.4 sklearn.tree.ExtraTreeRegressor

class sklearn.tree.**ExtraTreeRegressor**(*criterion='mse'*, *splitter='random'*, *max_depth=None*, *min_samples_split=2*, *min_samples_leaf=1*, *min_weight_fraction_leaf=0.0*, *max_features='auto'*, *random_state=None*, *min_impurity_decrease=0.0*, *min_impurity_split=None*, *max_leaf_nodes=None*)

An extremely randomized tree regressor.

Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate the samples of a node into two groups, random splits are drawn for each of the *max_features* randomly selected features and the best split among those is chosen. When *max_features* is set 1, this amounts to building a totally random decision tree.

Warning: Extra-trees should only be used within ensemble methods.

Read more in the *User Guide*.

See also:

ExtraTreeClassifier, ExtraTreesClassifier, ExtraTreesRegressor

Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

References

[R263]

Methods

apply(X[, check_input])	Returns the index of the leaf that each sample is predicted as.
decision_path(X[, check_input])	Return the decision path in the tree
fit(X, y[, sample_weight, check_input, ...])	Build a decision tree regressor from the training set (X, y).
get_params([deep])	Get parameters for this estimator.
predict(X[, check_input])	Predict class or regression value for X.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (*criterion='mse'*, *splitter='random'*, *max_depth=None*, *min_samples_split=2*, *min_samples_leaf=1*, *min_weight_fraction_leaf=0.0*, *max_features='auto'*, *random_state=None*, *min_impurity_decrease=0.0*, *min_impurity_split=None*, *max_leaf_nodes=None*)

apply (*X*, *check_input=True*)

Returns the index of the leaf that each sample is predicted as.

New in version 0.17.

Parameters **X** : array_like or sparse matrix, shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Returns **X_leaves** : array_like, shape = [n_samples,]

For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within `[0; self.tree_.node_count)`, possibly with gaps in the numbering.

decision_path (*X*, *check_input=True*)

Return the decision path in the tree

New in version 0.18.

Parameters **X** : array_like or sparse matrix, shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Returns **indicator** : sparse csr array, shape = [n_samples, n_nodes]

Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

feature_importances_

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Returns **feature_importances_** : array, shape = [n_features]

fit(*X*, *y*, *sample_weight=None*, *check_input=True*, *X_idx_sorted=None*)

Build a decision tree regressor from the training set (X, y).

Parameters **X** : array-like or sparse matrix, shape = [n_samples, n_features]

The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

y : array-like, shape = [n_samples] or [n_samples, n_outputs]

The target values (real numbers). Use `dtype=np.float64` and `order='C'` for maximum efficiency.

sample_weight : array-like, shape = [n_samples] or None

Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

X_idx_sorted : array-like, shape = [n_samples, n_features], optional

The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don't use this parameter unless you know what to do.

Returns **self** : object

Returns self.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*, *check_input=True*)

Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

Parameters **X** : array-like or sparse matrix of shape = [n_samples, n_features]

The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

check_input : boolean, (default=True)

Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Returns **y** : array of shape = [n_samples] or [n_samples, n_outputs]

The predicted classes, or the predict values.

score(*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

tree.export_graphviz	Export a decision tree in DOT format.

29.34.5 sklearn.tree.export_graphviz

sklearn.tree.**export_graphviz**()

Export a decision tree in DOT format.

This function generates a GraphViz representation of the decision tree, which is then written into *out_file*. Once exported, graphical renderings can be generated using, for example:

```
$ dot -Tps tree.dot -o tree.ps      (PostScript format)
$ dot -Tpng tree.dot -o tree.png    (PNG format)
```

The sample counts that are shown are weighted with any sample_weights that might be present.

Read more in the *User Guide*.

Parameters **decision_tree** : decision tree classifier

The decision tree to be exported to GraphViz.

out_file : file object or string, optional (default='tree.dot')

Handle or name of the output file. If `None`, the result is returned as a string. This will the default from version 0.20.

max_depth : int, optional (default=None)

The maximum depth of the representation. If None, the tree is fully generated.

feature_names : list of strings, optional (default=None)

Names of each of the features.

class_names : list of strings, bool or None, optional (default=None)

Names of each of the target classes in ascending numerical order. Only relevant for classification and not supported for multi-output. If `True`, shows a symbolic representation of the class name.

label : {'all', 'root', 'none'}, optional (default='all')

Whether to show informative labels for impurity, etc. Options include 'all' to show at every node, 'root' to show only at the top root node, or 'none' to not show at any node.

filled : bool, optional (default=False)

When set to `True`, paint nodes to indicate majority class for classification, extremity of values for regression, or purity of node for multi-output.

leaves_parallel : bool, optional (default=False)

When set to `True`, draw all leaf nodes at the bottom of the tree.

impurity : bool, optional (default=True)

When set to `True`, show the impurity at each node.

node_ids : bool, optional (default=False)

When set to `True`, show the ID number on each node.

proportion : bool, optional (default=False)

When set to `True`, change the display of 'values' and/or 'samples' to be proportions and percentages respectively.

rotate : bool, optional (default=False)

When set to `True`, orient tree left to right rather than top-down.

rounded : bool, optional (default=False)

When set to `True`, draw node boxes with rounded corners and use Helvetica fonts instead of Times-Roman.

special_characters : bool, optional (default=False)

When set to `False`, ignore special characters for PostScript compatibility.

precision : int, optional (default=3)

Number of digits of precision for floating point in the values of impurity, threshold and value attributes of each node.

Returns **dot_data** : string

String representation of the input tree in GraphViz dot format. Only returned if `out_file` is None.

New in version 0.18.

Examples

```
>>> from sklearn.datasets import load_iris
>>> from sklearn import tree
```

```
>>> clf = tree.DecisionTreeClassifier()
>>> iris = load_iris()
```

```
>>> clf = clf.fit(iris.data, iris.target)
>>> tree.export_graphviz(clf,
...     out_file='tree.dot')
```

29.35 `sklearn.utils`: Utilities

The *sklearn.utils* module includes various utilities.

Developer guide: See the *Utilities for Developers* page for further details.

utils.assert_all_finite(X)	Throw a ValueError if X contains NaN or infinity.
utils.as_float_array(X[, copy, force_all_finite])	Converts an array-like to an array of floats.
utils.check_X_y(X, y[, accept_sparse, ...])	Input validation for standard estimators.
utils.check_array(array[, accept_sparse, ...])	Input validation on an array, list, sparse matrix or similar.
utils.check_consistent_length(*arrays)	Check that all arrays have consistent first dimensions.
utils.check_random_state(seed)	Turn seed into a np.random.RandomState instance
utils.indexable(*iterables)	Make arrays indexable for cross-validation.
utils.class_weight.compute_class_weight(...)	Estimate class weights for unbalanced datasets.
utils.class_weight.compute_sample_weight(...)	Estimate sample weights by class for unbalanced datasets.
utils.estimator_checks.check_estimator(Estimator)	Check if estimator adheres to scikit-learn conventions.
utils.extmath.safe_sparse_dot(a, b[, ...])	Dot product that handle the sparse matrix case correctly
utils.resample(*arrays, **options)	Resample arrays or sparse matrices in a consistent way
utils.safe_indexing(X, indices)	Return items or rows from X using indices.
utils.shuffle(*arrays, **options)	Shuffle arrays or sparse matrices in a consistent way
utils.sparsefuncs.mean_variance_axis(X, axis)	Compute mean and variance along an axix on a CSR or CSC matrix
utils.sparsefuncs.incr_mean_variance_axis(X, ...)	Compute incremental mean and variance along an axix on a CSR or CSC matrix.
utils.sparsefuncs.inplace_column_scale(X, scale)	Inplace column scaling of a CSC/CSR matrix.
utils.sparsefuncs.inplace_row_scale(X, scale)	Inplace row scaling of a CSR or CSC matrix.
utils.sparsefuncs.inplace_swap_row(X, m, n)	Swaps two rows of a CSC/CSR matrix in-place.
utils.sparsefuncs.inplace_swap_column(X, m, n)	Swaps two columns of a CSC/CSR matrix in-place.
utils.validation.check_is_fitted(estimator, ...)	Perform is_fitted validation for estimator.
utils.validation.check_symmetric(array[, ...])	Make sure that array is 2D, square and symmetric.
utils.validation.column_or_1d(y[, warn])	Ravel column or 1d numpy array, else raises an error
utils.validation.has_fit_parameter(...)	Checks whether the estimator's fit method supports the given parameter.

29.35.1 sklearn.utils.assert_all_finite

sklearn.utils.**assert_all_finite**(*X*)

Throw a ValueError if X contains NaN or infinity.

Parameters **X** : array or sparse matrix

29.35.2 sklearn.utils.as_float_array

sklearn.utils.**as_float_array**(*X*, *copy=True*, *force_all_finite=True*)

Converts an array-like to an array of floats.

The new dtype will be np.float32 or np.float64, depending on the original type. The function can create a copy or modify the argument depending on the argument copy.

Parameters **X** : {array-like, sparse matrix}

copy : bool, optional

If True, a copy of X will be created. If False, a copy may still be returned if X's dtype is not a floating point type.

force_all_finite : boolean (default=True)

Whether to raise an error on np.inf and np.nan in X.

Returns **XT** : {array, sparse matrix}

An array of type np.float

29.35.3 sklearn.utils.check_X_y

sklearn.utils.**check_X_y**(*X*, *y*, *accept_sparse=False*, *dtype='numeric'*, *order=None*, *copy=False*, *force_all_finite=True*, *ensure_2d=True*, *allow_nd=False*, *multi_output=False*, *ensure_min_samples=1*, *ensure_min_features=1*, *y_numeric=False*, *warn_on_dtype=False*, *estimator=None*)

Input validation for standard estimators.

Checks X and y for consistent length, enforces X 2d and y 1d. Standard input checks are only applied to y, such as checking that y does not have np.nan or np.inf targets. For multi-label y, set multi_output=True to allow 2d and sparse y. If the dtype of X is object, attempt converting to float, raising on failure.

Parameters **X** : nd-array, list or sparse matrix

Input data.

y : nd-array, list or sparse matrix

Labels.

accept_sparse : string, boolean or list of string (default=False)

String[s] representing allowed sparse matrix formats, such as 'csc', 'csr', etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.

Deprecated since version 0.19: Passing 'None' to parameter `accept_sparse` in methods is deprecated in version 0.19 "and will be removed in 0.21. Use `accept_sparse=False` instead.

dtype : string, type, list of types or None (default="numeric")

Data type of result. If None, the dtype of the input is preserved. If "numeric", dtype is preserved unless array.dtype is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.

order : 'F', 'C' or None (default=None)

Whether an array will be forced to be fortran or c-style.

copy : boolean (default=False)

Whether a forced copy will be triggered. If copy=False, a copy might be triggered by a conversion.

force_all_finite : boolean (default=True)

Whether to raise an error on np.inf and np.nan in X. This parameter does not influence whether y can have np.inf or np.nan values.

ensure_2d : boolean (default=True)

Whether to make X at least 2d.

allow_nd : boolean (default=False)

Whether to allow X.ndim > 2.

multi_output : boolean (default=False)

Whether to allow 2-d y (array or sparse matrix). If false, y will be validated as a vector. y cannot have np.nan or np.inf values if multi_output=True.

ensure_min_samples : int (default=1)

Make sure that X has a minimum number of samples in its first axis (rows for a 2D array).

ensure_min_features : int (default=1)

Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when X has effectively 2 dimensions or is originally 1D and `ensure_2d` is True. Setting to 0 disables this check.

y_numeric : boolean (default=False)

Whether to ensure that y has a numeric type. If dtype of y is object, it is converted to float64. Should only be used for regression algorithms.

warn_on_dtype : boolean (default=False)

Raise DataConversionWarning if the dtype of the input data structure does not match the requested dtype, causing a memory copy.

estimator : str or estimator instance (default=None)

If passed, include the name of the estimator in warning messages.

Returns **X_converted** : object

The converted and validated X.

y_converted : object

The converted and validated y.

29.35.4 sklearn.utils.check_array

sklearn.utils.**check_array**(*array*, *accept_sparse=False*, *dtype='numeric'*, *order=None*, *copy=False*, *force_all_finite=True*, *ensure_2d=True*, *allow_nd=False*, *ensure_min_samples=1*, *ensure_min_features=1*, *warn_on_dtype=False*, *estimator=None*)

Input validation on an array, list, sparse matrix or similar.

By default, the input is converted to an at least 2D numpy array. If the dtype of the array is object, attempt converting to float, raising on failure.

Parameters **array** : object

Input object to check / convert.

accept_sparse : string, boolean or list/tuple of strings (default=False)

String[s] representing allowed sparse matrix formats, such as 'csc', 'csr', etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.

Deprecated since version 0.19: Passing 'None' to parameter `accept_sparse` in methods is deprecated in version 0.19 "and will be removed in 0.21. Use `accept_sparse=False` instead.

dtype : string, type, list of types or None (default="numeric")

Data type of result. If None, the dtype of the input is preserved. If "numeric", dtype is preserved unless array.dtype is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.

order : 'F', 'C' or None (default=None)

Whether an array will be forced to be fortran or c-style. When order is None (default), then if copy=False, nothing is ensured about the memory layout of the output array; otherwise (copy=True) the memory layout of the returned array is kept as close as possible to the original array.

copy : boolean (default=False)

Whether a forced copy will be triggered. If copy=False, a copy might be triggered by a conversion.

force_all_finite : boolean (default=True)

Whether to raise an error on np.inf and np.nan in X.

ensure_2d : boolean (default=True)

Whether to raise a value error if X is not 2d.

allow_nd : boolean (default=False)

Whether to allow X.ndim > 2.

ensure_min_samples : int (default=1)

Make sure that the array has a minimum number of samples in its first axis (rows for a 2D array). Setting to 0 disables this check.

ensure_min_features : int (default=1)

Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when the input

data has effectively 2 dimensions or is originally 1D and `ensure_2d` is True. Setting to 0 disables this check.

warn_on_dtype : boolean (default=False)

Raise DataConversionWarning if the dtype of the input data structure does not match the requested dtype, causing a memory copy.

estimator : str or estimator instance (default=None)

If passed, include the name of the estimator in warning messages.

Returns **X_converted** : object

The converted and validated X.

29.35.5 sklearn.utils.check_consistent_length

sklearn.utils.**check_consistent_length**(**arrays*)

Check that all arrays have consistent first dimensions.

Checks whether all objects in arrays have the same shape or length.

Parameters ***arrays** : list or tuple of input objects.

Objects that will be checked for consistent length.

29.35.6 sklearn.utils.check_random_state

sklearn.utils.**check_random_state**(*seed*)

Turn seed into a np.random.RandomState instance

If seed is None, return the RandomState singleton used by np.random. If seed is an int, return a new RandomState instance seeded with seed. If seed is already a RandomState instance, return it. Otherwise raise ValueError.

Examples using sklearn.utils.check_random_state

- *Isotonic Regression*
- *Face completion with a multi-output estimators*
- *Empirical evaluation of the impact of k-means initialization*
- *MNIST classfification using multinomial logistic + L1*
- *Manifold Learning methods on a severed sphere*
- *Scaling the regularization parameter for SVCs*

29.35.7 sklearn.utils.indexable

sklearn.utils.**indexable**(**iterables*)

Make arrays indexable for cross-validation.

Checks consistent length, passes through None, and ensures that everything can be indexed by converting sparse matrices to csr and converting non-interable objects to arrays.

Parameters ***iterables** : lists, dataframes, arrays, sparse matrices

List of objects to ensure sliceability.

29.35.8 sklearn.utils.class_weight.compute_class_weight

sklearn.utils.class_weight.**compute_class_weight**(*class_weight*, *classes*, *y*)

Estimate class weights for unbalanced datasets.

Parameters **class_weight** : dict, 'balanced' or None

If 'balanced', class weights will be given by `n_samples / (n_classes * np.bincount(y))`. If a dictionary is given, keys are classes and values are corresponding class weights. If None is given, the class weights will be uniform.

classes : ndarray

Array of the classes occurring in the data, as given by `np.unique(y_org)` with `y_org` the original class labels.

y : array-like, shape (n_samples,)

Array of original class labels per sample;

Returns **class_weight_vect** : ndarray, shape (n_classes,)

Array with class_weight_vect[i] the weight for i-th class

References

The "balanced" heuristic is inspired by Logistic Regression in Rare Events Data, King, Zen, 2001.

29.35.9 sklearn.utils.class_weight.compute_sample_weight

sklearn.utils.class_weight.**compute_sample_weight**(*class_weight*, *y*, *indices=None*)

Estimate sample weights by class for unbalanced datasets.

Parameters **class_weight** : dict, list of dicts, "balanced", or None, optional

Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be [{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}] instead of [{1:1}, {2:5}, {3:1}, {4:1}].

The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data: `n_samples / (n_classes * np.bincount(y))`.

For multi-output, the weights of each column of y will be multiplied.

y : array-like, shape = [n_samples] or [n_samples, n_outputs]

Array of original class labels per sample.

indices : array-like, shape (n_subsample,), or None

Array of indices to be used in a subsample. Can be of length less than n_samples in the case of a subsample, or equal to n_samples in the case of a bootstrap subsample with repeated indices. If None, the sample weight will be calculated over the full sample. Only "balanced" is supported for class_weight if this is provided.

Returns **sample_weight_vect** : ndarray, shape (n_samples,)

Array with sample weights as applied to the original y

29.35.10 sklearn.utils.estimator_checks.check_estimator

sklearn.utils.estimator_checks.**check_estimator**(*Estimator*)

Check if estimator adheres to scikit-learn conventions.

This estimator will run an extensive test-suite for input validation, shapes, etc. Additional tests for classifiers, regressors, clustering or transformers will be run if the Estimator class inherits from the corresponding mixin from sklearn.base.

This test can be applied to classes or instances. Classes currently have some additional tests that related to construction, while passing instances allows the testing of multiple options.

Parameters **estimator** : estimator object or class

Estimator to check. Estimator is a class object or instance.

29.35.11 sklearn.utils.extmath.safe_sparse_dot

sklearn.utils.extmath.**safe_sparse_dot**(*a*, *b*, *dense_output=False*)

Dot product that handle the sparse matrix case correctly

Uses BLAS GEMM as replacement for numpy.dot where possible to avoid unnecessary copies.

Parameters **a** : array or sparse matrix

b : array or sparse matrix

dense_output : boolean, default False

When False, either `a` or `b` being sparse will yield sparse output. When True, output will always be an array.

Returns **dot_product** : array or sparse matrix

sparse if `a` or `b` is sparse and ‘‘dense_output‘‘=False.

29.35.12 sklearn.utils.resample

sklearn.utils.**resample**(**arrays*, ***options*)

Resample arrays or sparse matrices in a consistent way

The default strategy implements one step of the bootstrapping procedure.

Parameters ***arrays** : sequence of indexable data-structures

Indexable data-structures can be arrays, lists, dataframes or scipy sparse matrices with consistent first dimension.

replace : boolean, True by default

Implements resampling with replacement. If False, this will implement (sliced) random permutations.

n_samples : int, None by default

Number of samples to generate. If left to None this is automatically set to the first dimension of the arrays. If replace is False it should not be larger than the length of arrays.

random_state : int, RandomState instance or None, optional (default=None)

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **resampled_arrays** : sequence of indexable data-structures

Sequence of resampled views of the collections. The original arrays are not impacted.

See also:

sklearn.utils.shuffle

Examples

It is possible to mix sparse and dense arrays in the same run:

```
>>> X = np.array([[1., 0.], [2., 1.], [0., 0.]])
>>> y = np.array([0, 1, 2])

>>> from scipy.sparse import coo_matrix
>>> X_sparse = coo_matrix(X)

>>> from sklearn.utils import resample
>>> X, X_sparse, y = resample(X, X_sparse, y, random_state=0)
>>> X
array([[ 1.,  0.],
       [ 2.,  1.],
       [ 1.,  0.]])

>>> X_sparse
<3x2 sparse matrix of type '<... 'numpy.float64'>'
    with 4 stored elements in Compressed Sparse Row format>

>>> X_sparse.toarray()
array([[ 1.,  0.],
       [ 2.,  1.],
       [ 1.,  0.]])

>>> y
array([0, 1, 0])

>>> resample(y, n_samples=2, random_state=0)
array([0, 1])
```

29.35.13 sklearn.utils.safe_indexing

sklearn.utils.**safe_indexing**(*X*, *indices*)

Return items or rows from X using indices.

Allows simple indexing of lists or arrays.

Parameters **X** : array-like, sparse-matrix, list, pandas.DataFrame, pandas.Series.

Data from which to sample rows or items.

indices : array-like of int

Indices according to which X will be subsampled.

Returns **subset** :

Subset of X on first axis

29.35.14 sklearn.utils.shuffle

sklearn.utils.**shuffle**(**arrays*, ***options*)

Shuffle arrays or sparse matrices in a consistent way

This is a convenience alias to `resample(*arrays, replace=False)` to do random permutations of the collections.

Parameters ***arrays** : sequence of indexable data-structures

Indexable data-structures can be arrays, lists, dataframes or scipy sparse matrices with consistent first dimension.

random_state : int, RandomState instance or None, optional (default=None)

The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

n_samples : int, None by default

Number of samples to generate. If left to None this is automatically set to the first dimension of the arrays.

Returns **shuffled_arrays** : sequence of indexable data-structures

Sequence of shuffled views of the collections. The original arrays are not impacted.

See also:

sklearn.utils.resample

Examples

It is possible to mix sparse and dense arrays in the same run:

```
>>> X = np.array([[1., 0.], [2., 1.], [0., 0.]])
>>> y = np.array([0, 1, 2])

>>> from scipy.sparse import coo_matrix
>>> X_sparse = coo_matrix(X)
```

```
>>> from sklearn.utils import shuffle
>>> X, X_sparse, y = shuffle(X, X_sparse, y, random_state=0)
>>> X
array([[ 0.,  0.],
       [ 2.,  1.],
       [ 1.,  0.]])

>>> X_sparse
<3x2 sparse matrix of type '<... 'numpy.float64'>'
    with 3 stored elements in Compressed Sparse Row format>

>>> X_sparse.toarray()
array([[ 0.,  0.],
       [ 2.,  1.],
       [ 1.,  0.]])

>>> y
array([2, 1, 0])

>>> shuffle(y, n_samples=2, random_state=0)
array([0, 1])
```

Examples using `sklearn.utils.shuffle`

- *Model Complexity Influence*
- *Prediction Latency*
- *Color Quantization using K-Means*
- *Empirical evaluation of the impact of k-means initialization*
- *Gradient Boosting regression*

29.35.15 `sklearn.utils.sparsefuncs`.mean_variance_axis

`sklearn.utils.sparsefuncs.`**`mean_variance_axis`**(*X*, *axis*)

Compute mean and variance along an axix on a CSR or CSC matrix

Parameters **X** : CSR or CSC sparse matrix, shape (n_samples, n_features)

Input data.

axis : int (either 0 or 1)

Axis along which the axis should be computed.

Returns **means** : float array with shape (n_features,)

Feature-wise means

variances : float array with shape (n_features,)

Feature-wise variances

29.35.16 sklearn.utils.sparsefuncs.incr_mean_variance_axis

sklearn.utils.sparsefuncs.**incr_mean_variance_axis**(*X*, *axis*, *last_mean*, *last_var*, *last_n*)

Compute incremental mean and variance along an axix on a CSR or CSC matrix.

last_mean, last_var are the statistics computed at the last step by this function. Both must be initilized to 0-arrays of the proper size, i.e. the number of features in X. last_n is the number of samples encountered until now.

Parameters **X** : CSR or CSC sparse matrix, shape (n_samples, n_features)

Input data.

axis : int (either 0 or 1)

Axis along which the axis should be computed.

last_mean : float array with shape (n_features,)

Array of feature-wise means to update with the new data X.

last_var : float array with shape (n_features,)

Array of feature-wise var to update with the new data X.

last_n : int

Number of samples seen so far, excluded X.

Returns **means** : float array with shape (n_features,)

Updated feature-wise means.

variances : float array with shape (n_features,)

Updated feature-wise variances.

n : int

Updated number of seen samples.

29.35.17 sklearn.utils.sparsefuncs.inplace_column_scale

sklearn.utils.sparsefuncs.**inplace_column_scale**(*X*, *scale*)

Inplace column scaling of a CSC/CSR matrix.

Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a (n_samples, n_features) shape.

Parameters **X** : CSC or CSR matrix with shape (n_samples, n_features)

Matrix to normalize using the variance of the features.

scale : float array with shape (n_features,)

Array of precomputed feature-wise values to use for scaling.

29.35.18 sklearn.utils.sparsefuncs.inplace_row_scale

sklearn.utils.sparsefuncs.**inplace_row_scale**(*X*, *scale*)

Inplace row scaling of a CSR or CSC matrix.

Scale each row of the data matrix by multiplying with specific scale provided by the caller assuming a (n_samples, n_features) shape.

Parameters **X** : CSR or CSC sparse matrix, shape (n_samples, n_features)

Matrix to be scaled.

scale : float array with shape (n_features,)

Array of precomputed sample-wise values to use for scaling.

29.35.19 sklearn.utils.sparsefuncs.inplace_swap_row

sklearn.utils.sparsefuncs.**inplace_swap_row**(*X*, *m*, *n*)

Swaps two rows of a CSC/CSR matrix in-place.

Parameters **X** : CSR or CSC sparse matrix, shape=(n_samples, n_features)

Matrix whose two rows are to be swapped.

m : int

Index of the row of X to be swapped.

n : int

Index of the row of X to be swapped.

29.35.20 sklearn.utils.sparsefuncs.inplace_swap_column

sklearn.utils.sparsefuncs.**inplace_swap_column**(*X*, *m*, *n*)

Swaps two columns of a CSC/CSR matrix in-place.

Parameters **X** : CSR or CSC sparse matrix, shape=(n_samples, n_features)

Matrix whose two columns are to be swapped.

m : int

Index of the column of X to be swapped.

n : int

Index of the column of X to be swapped.

29.35.21 sklearn.utils.validation.check_is_fitted

sklearn.utils.validation.**check_is_fitted**(*estimator*, *attributes*, *msg=None*, *all_or_any=<built-in function all>*)

Perform is_fitted validation for estimator.

Checks if the estimator is fitted by verifying the presence of "all_or_any" of the passed attributes and raises a NotFittedError with the given message.

Parameters **estimator** : estimator instance.

estimator instance for which the check is performed.

attributes : attribute name(s) given as string or a list/tuple of strings

Eg. : ["coef_", "estimator_", ...], "coef_"

msg : string

The default error message is, "This %(name)s instance is not fitted yet. Call 'fit' with appropriate arguments before using this method."

For custom messages if "%(name)s" is present in the message string, it is substituted for the estimator name.

Eg. : "Estimator, %(name)s, must be fitted before sparsifying".

all_or_any : callable, {all, any}, default all

Specify whether all or any of the given attributes must exist.

Returns **None** :

Raises **NotFittedError** :

If the attributes are not found.

29.35.22 sklearn.utils.validation.check_symmetric

sklearn.utils.validation.**check_symmetric**(*array*, *tol=1e-10*, *raise_warning=True*, *raise_exception=False*)

Make sure that array is 2D, square and symmetric.

If the array is not symmetric, then a symmetrized version is returned. Optionally, a warning or exception is raised if the matrix is not symmetric.

Parameters **array** : nd-array or sparse matrix

Input object to check / convert. Must be two-dimensional and square, otherwise a ValueError will be raised.

tol : float

Absolute tolerance for equivalence of arrays. Default = 1E-10.

raise_warning : boolean (default=True)

If True then raise a warning if conversion is required.

raise_exception : boolean (default=False)

If True then raise an exception if array is not symmetric.

Returns **array_sym** : ndarray or sparse matrix

Symmetrized version of the input array, i.e. the average of array and array.transpose(). If sparse, then duplicate entries are first summed and zeros are eliminated.

29.35.23 sklearn.utils.validation.column_or_1d

sklearn.utils.validation.**column_or_1d**(*y*, *warn=False*)

Ravel column or 1d numpy array, else raises an error

Parameters **y** : array-like

warn : boolean, default False

To control display of warnings.

Returns **y** : array

29.35.24 sklearn.utils.validation.has_fit_parameter

sklearn.utils.validation.**has_fit_parameter**(*estimator*, *parameter*)

Checks whether the estimator's fit method supports the given parameter.

Parameters **estimator** : object

An estimator to inspect.

parameter: str :

The searched parameter.

Returns **is_parameter: bool** :

Whether the parameter was found to be a a named parameter of the estimator's fit method.

Examples

```
>>> from sklearn.svm import SVC
>>> has_fit_parameter(SVC(), "sample_weight")
True
```

29.36 Recently deprecated

29.36.1 To be removed in 0.20

grid_search.ParameterGrid(param_grid)	Grid of parameters with a discrete number of values for each.
grid_search.ParameterSampler(...[, random_state])	Generator on parameters sampled from given distributions.
grid_search.GridSearchCV(estimator, param_grid)	Exhaustive search over specified parameter values for an estimator.
grid_search.RandomizedSearchCV(estimator, ...)	Randomized search on hyper parameters.
cross_validation.LeaveOneOut(n)	Leave-One-Out cross validation iterator.

sklearn.grid_search.ParameterGrid

Warning: DEPRECATED

class sklearn.grid_search.**ParameterGrid**(*param_grid*)

Grid of parameters with a discrete number of values for each.

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.ParameterGrid* instead.

Can be used to iterate over parameter value combinations with the Python built-in function iter.

Read more in the *User Guide*.

Parameters **param_grid** : dict of string to sequence, or sequence of such

The parameter grid to explore, as a dictionary mapping estimator parameters to sequences of allowed values.

An empty dict signifies default parameters.

A sequence of dicts signifies a sequence of grids to search, and is useful to avoid exploring parameter combinations that make no sense or have no effect. See the examples below.

See also:

GridSearchCV uses ParameterGrid to perform a full parallelized parameter search.

Examples

```
>>> from sklearn.grid_search import ParameterGrid
>>> param_grid = {'a': [1, 2], 'b': [True, False]}
>>> list(ParameterGrid(param_grid)) == (
...    [{'a': 1, 'b': True}, {'a': 1, 'b': False},
...     {'a': 2, 'b': True}, {'a': 2, 'b': False}])
True
```

```
>>> grid = [{'kernel': ['linear']}, {'kernel': ['rbf'], 'gamma': [1, 10]}]
>>> list(ParameterGrid(grid)) == [{'kernel': 'linear'},
...                               {'kernel': 'rbf', 'gamma': 1},
...                               {'kernel': 'rbf', 'gamma': 10}]
True
>>> ParameterGrid(grid)[1] == {'kernel': 'rbf', 'gamma': 1}
True
.. automethod:: __init__
```

sklearn.grid_search.ParameterSampler

Warning: DEPRECATED

class sklearn.grid_search.**ParameterSampler**(*param_distributions*, *n_iter*, *random_state=None*)

Generator on parameters sampled from given distributions.

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.ParameterSampler* instead.

Non-deterministic iterable over random candidate combinations for hyper- parameter search. If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Note that as of SciPy 0.12, the `scipy.stats.distributions` do not accept a custom RNG instance and always use the singleton RNG from `numpy.random`. Hence setting `random_state` will not guarantee a deterministic iteration whenever `scipy.stats` distributions are used to define the parameter search space.

Read more in the *User Guide*.

Parameters **param_distributions** : dict

Dictionary where the keys are parameters and values are distributions from which a parameter is to be sampled. Distributions either have to provide a `rvs` function to sample from them, or can be given as a list of values, where a uniform distribution is assumed.

n_iter : integer

Number of parameter settings that are produced.

random_state : int, RandomState instance or None, optional (default=None)

Pseudo random number generator state used for random uniform sampling from lists of possible values instead of scipy.stats distributions. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Returns **params** : dict of string to any

Yields dictionaries mapping each estimator parameter to as sampled value.

Examples

```
>>> from sklearn.grid_search import ParameterSampler
>>> from scipy.stats.distributions import expon
>>> import numpy as np
>>> np.random.seed(0)
>>> param_grid = {'a':[1, 2], 'b': expon()}
>>> param_list = list(ParameterSampler(param_grid, n_iter=4))
>>> rounded_list = [dict((k, round(v, 6)) for (k, v) in d.items())
...                 for d in param_list]
>>> rounded_list == [{'b': 0.89856, 'a': 1},
...                  {'b': 0.923223, 'a': 1},
...                  {'b': 1.878964, 'a': 2},
```

```
...                   {'b': 1.038159, 'a': 2}]
True
.. automethod:: __init__
```

sklearn.grid_search.GridSearchCV

Warning: DEPRECATED

class sklearn.grid_search.**GridSearchCV**(*estimator*, *param_grid*, *scoring=None*, *fit_params=None*, *n_jobs=1*, *iid=True*, *refit=True*, *cv=None*, *verbose=0*, *pre_dispatch='2*n_jobs'*, *error_score='raise'*)

Exhaustive search over specified parameter values for an estimator.

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.GridSearchCV* instead.

Important members are fit, predict.

GridSearchCV implements a "fit" and a "score" method. It also implements "predict", "predict_proba", "decision_function", "transform" and "inverse_transform" if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated grid-search over a parameter grid.

Read more in the *User Guide*.

Parameters **estimator** : estimator object.

A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

param_grid : dict or list of dictionaries

Dictionary with parameters names (string) as keys and lists of parameter settings to try as values, or a list of such dictionaries, in which case the grids spanned by each dictionary in the list are explored. This enables searching over any sequence of parameter settings.

scoring : string, callable or None, default=None

A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`. If `None`, the `score` method of the estimator is used.

fit_params : dict, optional

Parameters to pass to the fit method.

n_jobs: int, default: 1 : :

The maximum number of estimators fit in parallel.

- If -1 all CPUs are used.
- If 1 is given, no parallel computing code is used at all, which is useful for debugging.
- For `n_jobs` below -1, `(n_cpus + n_jobs + 1)` are used. For example, with `n_jobs = -2` all CPUs but one are used.

Changed in version 0.17: Upgraded to joblib 0.9.3.

pre_dispatch : int, or string, optional

Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in '2*n_jobs'

iid : boolean, default=True

If True, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *`sklearn.model_selection.StratifiedKFold`* is used. In all other cases, *`sklearn.model_selection.KFold`* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

refit : boolean, default=True

Refit the best estimator with the entire dataset. If "False", it is impossible to make predictions using this GridSearchCV instance after fitting.

verbose : integer

Controls the verbosity: the higher, the more messages.

error_score : 'raise' (default) or numeric

Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

Attributes **grid_scores_** : list of named tuples

Contains scores for all parameter combinations in param_grid. Each entry corresponds to one parameter setting. Each named tuple has the attributes:

- `parameters`, a dict of parameter settings
- `mean_validation_score`, the mean score over the cross-validation folds
- `cv_validation_scores`, the list of scores for each fold

best_estimator_ : estimator

Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

best_score_ : float

Score of best_estimator on the left out data.

best_params_ : dict

Parameter setting that gave the best results on the hold out data.

scorer_ : function

Scorer function used on the held out data to choose the best parameters for the model.

See also:

ParameterGrid generates all the combinations of a hyperparameter grid.

sklearn.cross_validation.train_test_split utility function to split the data into a development set usable for fitting a GridSearchCV instance and an evaluation set for its final evaluation.

sklearn.metrics.make_scorer Make a scorer from a performance metric or loss function.

Notes

The parameters selected are those that maximize the score of the left out data, unless an explicit score is passed in which case it is used instead.

If *n_jobs* was set to a value higher than one, the data is copied for each point in the grid (and not *n_jobs* times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set *pre_dispatch*. Then, the memory is copied only *pre_dispatch* many times. A reasonable value for *pre_dispatch* is *2 * n_jobs*.

Examples

```
>>> from sklearn import svm, grid_search, datasets
>>> iris = datasets.load_iris()
>>> parameters = {'kernel':('linear', 'rbf'), 'C':[1, 10]}
>>> svr = svm.SVC()
>>> clf = grid_search.GridSearchCV(svr, parameters)
>>> clf.fit(iris.data, iris.target)
...
GridSearchCV(cv=None, error_score=...,
       estimator=SVC(C=1.0, cache_size=..., class_weight=..., coef0=...,
                     decision_function_shape='ovr', degree=..., gamma=...,
                     kernel='rbf', max_iter=-1, probability=False,
                     random_state=None, shrinking=True, tol=...,
                     verbose=False),
       fit_params={}, iid=..., n_jobs=1,
       param_grid=..., pre_dispatch=..., refit=...,
       scoring=..., verbose=...)
```

Methods

decision_function(X)	Call decision_function on the estimator with the best found parameters.
fit(X[, y])	Run fit with all sets of parameters.
get_params([deep])	Get parameters for this estimator.
inverse_transform(Xt)	Call inverse_transform on the estimator with the best found parameters.
predict(X)	Call predict on the estimator with the best found parameters.
predict_log_proba(X)	Call predict_log_proba on the estimator with the best found parameters.
predict_proba(X)	Call predict_proba on the estimator with the best found parameters.
score(X[, y])	Returns the score on the given data, if the estimator has been refit.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Call transform on the estimator with the best found parameters.

__init__ (*estimator*, *param_grid*, *scoring=None*, *fit_params=None*, *n_jobs=1*, *iid=True*, *refit=True*, *cv=None*, *verbose=0*, *pre_dispatch='2*n_jobs'*, *error_score='raise'*)

decision_function (*X*)

Call decision_function on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `decision_function`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

fit (*X*, *y=None*)

Run fit with all sets of parameters.

Parameters **X** : array-like, shape = [n_samples, n_features]

Training vector, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples] or [n_samples, n_output], optional

Target relative to X for classification or regression; None for unsupervised learning.

get_params (*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform (*Xt*)

Call inverse_transform on the estimator with the best found parameters.

Only available if the underlying estimator implements `inverse_transform` and `refit=True`.

Parameters **Xt** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

predict(*X*)
Call predict on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

predict_log_proba(*X*)
Call predict_log_proba on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_log_proba`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

predict_proba(*X*)
Call predict_proba on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_proba`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

score(*X*, *y=None*)
Returns the score on the given data, if the estimator has been refit.

This uses the score defined by `scoring` where provided, and the `best_estimator_.score` method otherwise.

Parameters **X** : array-like, shape = [n_samples, n_features]

Input data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples] or [n_samples, n_output], optional

Target relative to X for classification or regression; None for unsupervised learning.

Returns **score** : float

Notes

- The long-standing behavior of this method changed in version 0.16.
- It no longer uses the metric provided by `estimator.score` if the `scoring` parameter was set when fitting.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)

Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports `transform` and `refit=True`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

sklearn.grid_search.RandomizedSearchCV

Warning: DEPRECATED

class sklearn.grid_search.**RandomizedSearchCV**(*estimator*, *param_distributions*, *n_iter=10*, *scoring=None*, *fit_params=None*, *n_jobs=1*, *iid=True*, *refit=True*, *cv=None*, *verbose=0*, *pre_dispatch='2*n_jobs'*, *random_state=None*, *error_score='raise'*)

Randomized search on hyper parameters.

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.RandomizedSearchCV* instead.

RandomizedSearchCV implements a "fit" and a "score" method. It also implements "predict", "predict_proba", "decision_function", "transform" and "inverse_transform" if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated search over parameter settings.

In contrast to GridSearchCV, not all parameter values are tried out, but rather a fixed number of parameter settings is sampled from the specified distributions. The number of parameter settings that are tried is given by n_iter.

If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Read more in the *User Guide*.

Parameters **estimator** : estimator object.

A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

param_distributions : dict

Dictionary with parameters names (string) as keys and distributions or lists of parameters to try. Distributions must provide a `rvs` method for sampling (such as those from scipy.stats.distributions). If a list is given, it is sampled uniformly.

n_iter : int, default=10

Number of parameter settings that are sampled. n_iter trades off runtime vs quality of the solution.

scoring : string, callable or None, default=None

A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`. If `None`, the `score` method of the estimator is used.

fit_params : dict, optional

Parameters to pass to the fit method.

n_jobs: int, default: 1 : :

The maximum number of estimators fit in parallel.

- If -1 all CPUs are used.
- If 1 is given, no parallel computing code is used at all, which is useful for debugging.
- For `n_jobs` below -1, `(n_cpus + n_jobs + 1)` are used. For example, with `n_jobs = -2` all CPUs but one are used.

pre_dispatch : int, or string, optional

Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in '2*n_jobs'

iid : boolean, default=True

If True, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *`sklearn.model_selection.StratifiedKFold`* is used. In all other cases, *`sklearn.model_selection.KFold`* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

refit : boolean, default=True

Refit the best estimator with the entire dataset. If "False", it is impossible to make predictions using this RandomizedSearchCV instance after fitting.

verbose : integer

Controls the verbosity: the higher, the more messages.

random_state : int, RandomState instance or None, optional, default=None

Pseudo random number generator state used for random uniform sampling from lists of possible values instead of scipy.stats distributions. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

error_score : 'raise' (default) or numeric

Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

Attributes **grid_scores_** : list of named tuples

Contains scores for all parameter combinations in param_grid. Each entry corresponds to one parameter setting. Each named tuple has the attributes:

- `parameters`, a dict of parameter settings
- `mean_validation_score`, the mean score over the cross-validation folds
- `cv_validation_scores`, the list of scores for each fold

best_estimator_ : estimator

Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

best_score_ : float

Score of best_estimator on the left out data.

best_params_ : dict

Parameter setting that gave the best results on the hold out data.

See also:

GridSearchCV Does exhaustive search over a grid of parameters.

ParameterSampler A generator over parameter settings, constructed from param_distributions.

Notes

The parameters selected are those that maximize the score of the held-out data, according to the scoring parameter.

If *n_jobs* was set to a value higher than one, the data is copied for each parameter setting(and not *n_jobs* times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set *pre_dispatch*. Then, the memory is copied only *pre_dispatch* many times. A reasonable value for *pre_dispatch* is *2 * n_jobs*.

Methods

decision_function(X)	Call decision_function on the estimator with the best found parameters.
fit(X[, y])	Run fit on the estimator with randomly drawn parameters.

Continued on next page

Table 29.272 – continued from previous page

get_params([deep])	Get parameters for this estimator.
inverse_transform(Xt)	Call inverse_transform on the estimator with the best found parameters.
predict(X)	Call predict on the estimator with the best found parameters.
predict_log_proba(X)	Call predict_log_proba on the estimator with the best found parameters.
predict_proba(X)	Call predict_proba on the estimator with the best found parameters.
score(X[, y])	Returns the score on the given data, if the estimator has been refit.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Call transform on the estimator with the best found parameters.

__init__(*estimator*, *param_distributions*, *n_iter=10*, *scoring=None*, *fit_params=None*, *n_jobs=1*, *iid=True*, *refit=True*, *cv=None*, *verbose=0*, *pre_dispatch='2*n_jobs'*, *random_state=None*, *error_score='raise'*)

decision_function(*X*)

Call decision_function on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `decision_function`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

fit(*X*, *y=None*)

Run fit on the estimator with randomly drawn parameters.

Parameters **X** : array-like, shape = [n_samples, n_features]

Training vector, where n_samples in the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples] or [n_samples, n_output], optional

Target relative to X for classification or regression; None for unsupervised learning.

get_params(*deep=True*)

Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform(*Xt*)

Call inverse_transform on the estimator with the best found parameters.

Only available if the underlying estimator implements `inverse_transform` and `refit=True`.

Parameters **Xt** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

predict(*X*)
Call predict on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

predict_log_proba(*X*)
Call predict_log_proba on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_log_proba`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

predict_proba(*X*)
Call predict_proba on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_proba`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

score(*X*, *y=None*)
Returns the score on the given data, if the estimator has been refit.

This uses the score defined by `scoring` where provided, and the `best_estimator_.score` method otherwise.

Parameters **X** : array-like, shape = [n_samples, n_features]

Input data, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape = [n_samples] or [n_samples, n_output], optional

Target relative to X for classification or regression; None for unsupervised learning.

Returns **score** : float

Notes

- The long-standing behavior of this method changed in version 0.16.
- It no longer uses the metric provided by `estimator.score` if the `scoring` parameter was set when fitting.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports `transform` and `refit=True`.

Parameters **X** : indexable, length n_samples

Must fulfill the input assumptions of the underlying estimator.

sklearn.cross_validation.LeaveOneOut

Warning: DEPRECATED

class sklearn.cross_validation.**LeaveOneOut**(*n*)

Leave-One-Out cross validation iterator.

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.LeaveOneOut* instead.

Provides train/test indices to split data in train test sets. Each sample is used once as a test set (singleton) while the remaining samples form the training set.

Note: `LeaveOneOut(n)` is equivalent to `KFold(n, n_folds=n)` and `LeavePOut(n, p=1)`.

Due to the high number of test sets (which is the same as the number of samples) this cross validation method can be very costly. For large datasets one should favor KFold, StratifiedKFold or ShuffleSplit.

Read more in the *User Guide*.

Parameters **n** : int

Total number of elements in dataset.

See also:

LeaveOneLabelOut, domain-specific

Examples

```
>>> from sklearn import cross_validation
>>> X = np.array([[1, 2], [3, 4]])
>>> y = np.array([1, 2])
>>> loo = cross_validation.LeaveOneOut(2)
>>> len(loo)
2
>>> print(loo)
sklearn.cross_validation.LeaveOneOut(n=2)
>>> for train_index, test_index in loo:
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
...    print(X_train, X_test, y_train, y_test)
TRAIN: [1] TEST: [0]
[[3 4]] [[1 2]] [2] [1]
TRAIN: [0] TEST: [1]
[[1 2]] [[3 4]] [1] [2]
.. automethod:: __init__
```

sklearn.cross_validation.LeavePOut

Warning: DEPRECATED

class sklearn.cross_validation.**LeavePOut**(*n*, *p*)

Leave-P-Out cross validation iterator

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.LeavePOut* instead.

Provides train/test indices to split data in train test sets. This results in testing on all distinct samples of size p, while the remaining n - p samples form the training set in each iteration.

Note: `LeavePOut(n, p)` is NOT equivalent to `KFold(n, n_folds=n // p)` which creates non-overlapping test sets.

Due to the high number of iterations which grows combinatorically with the number of samples this cross validation method can be very costly. For large datasets one should favor KFold, StratifiedKFold or ShuffleSplit.

Read more in the *User Guide*.

Parameters **n** : int

Total number of elements in dataset.

p : int

Size of the test sets.

Examples

```
>>> from sklearn import cross_validation
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> lpo = cross_validation.LeavePOut(4, 2)
>>> len(lpo)
6
>>> print(lpo)
sklearn.cross_validation.LeavePOut(n=4, p=2)
>>> for train_index, test_index in lpo:
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
TRAIN: [0 2] TEST: [1 3]
TRAIN: [0 1] TEST: [2 3]
.. automethod:: __init__
```

sklearn.cross_validation.KFold

Warning: DEPRECATED

class sklearn.cross_validation.**KFold**(*n*, *n_folds=3*, *shuffle=False*, *random_state=None*)

K-Folds cross validation iterator.

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.KFold* instead.

Provides train/test indices to split data in train test sets. Split dataset into k consecutive folds (without shuffling by default).

Each fold is then used as a validation set once while the k - 1 remaining fold(s) form the training set.

Read more in the *User Guide*.

Parameters **n** : int

Total number of elements.

n_folds : int, default=3

Number of folds. Must be at least 2.

shuffle : boolean, optional

Whether to shuffle the data before splitting into batches.

random_state : int, RandomState instance or None, optional, default=None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `shuffle` == True.

See also:

StratifiedKFold, `folds`, `classification`

LabelKFold K-fold iterator variant with non-overlapping labels.

Notes

The first n % n_folds folds have size n // n_folds + 1, other folds have size n // n_folds.

Examples

```
>>> from sklearn.cross_validation import KFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4])
>>> kf = KFold(4, n_folds=2)
>>> len(kf)
2
>>> print(kf)
sklearn.cross_validation.KFold(n=4, n_folds=2, shuffle=False,
                               random_state=None)
>>> for train_index, test_index in kf:
```

```
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [0 1] TEST: [2 3]
.. automethod:: __init__
```

sklearn.cross_validation.LabelKFold

Warning: DEPRECATED

class sklearn.cross_validation.**LabelKFold**(*labels*, *n_folds=3*)

K-fold iterator variant with non-overlapping labels.

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.GroupKFold* instead.

The same label will not appear in two different folds (the number of distinct labels has to be at least equal to the number of folds).

The folds are approximately balanced in the sense that the number of distinct labels is approximately the same in each fold.

New in version 0.17.

Parameters **labels** : array-like with shape (n_samples,)

Contains a label for each sample. The folds are built so that the same label does not appear in two different folds.

n_folds : int, default=3

Number of folds. Must be at least 2.

See also:

LeaveOneLabelOut, domain-specific

Examples

```
>>> from sklearn.cross_validation import LabelKFold
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> labels = np.array([0, 0, 2, 2])
>>> label_kfold = LabelKFold(labels, n_folds=2)
>>> len(label_kfold)
2
>>> print(label_kfold)
sklearn.cross_validation.LabelKFold(n_labels=4, n_folds=2)
>>> for train_index, test_index in label_kfold:
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
...
TRAIN: [0 1] TEST: [2 3]
```

```
[[1 2]
 [3 4]] [[5 6]
 [7 8]] [1 2] [3 4]
TRAIN: [2 3] TEST: [0 1]
[[5 6]
 [7 8]] [[1 2]
 [3 4]] [3 4] [1 2]
.. automethod:: __init__
```

sklearn.cross_validation.LeaveOneLabelOut

Warning: DEPRECATED

class sklearn.cross_validation.**LeaveOneLabelOut**(*labels*)

Leave-One-Label_Out cross-validation iterator

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.LeaveOneGroupOut* instead.

Provides train/test indices to split data according to a third-party provided label. This label information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the labels could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

Read more in the *User Guide*.

Parameters **labels** : array-like of int with shape (n_samples,)

Arbitrary domain-specific stratification of the data to be used to draw the splits.

See also:

LabelKFold K-fold iterator variant with non-overlapping labels.

Examples

```
>>> from sklearn import cross_validation
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 1, 2])
>>> labels = np.array([1, 1, 2, 2])
>>> lol = cross_validation.LeaveOneLabelOut(labels)
>>> len(lol)
2
>>> print(lol)
sklearn.cross_validation.LeaveOneLabelOut(labels=[1 1 2 2])
>>> for train_index, test_index in lol:
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
...    print(X_train, X_test, y_train, y_test)
TRAIN: [2 3] TEST: [0 1]
[[5 6]
 [7 8]] [[1 2]
```

```
 [3 4]] [1 2] [1 2]
TRAIN: [0 1] TEST: [2 3]
[[1 2]
 [3 4]] [[5 6]
 [7 8]] [1 2] [1 2]
.. automethod:: __init__
```

sklearn.cross_validation.LeavePLabelOut

Warning: DEPRECATED

class sklearn.cross_validation.**LeavePLabelOut**(*labels*, *p*)

Leave-P-Label_Out cross-validation iterator

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.LeavePGroupsOut* instead.

Provides train/test indices to split data according to a third-party provided label. This label information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the labels could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePLabelOut and LeaveOneLabelOut is that the former builds the test sets with all the samples assigned to `p` different values of the labels while the latter uses samples all assigned the same labels.

Read more in the *User Guide*.

Parameters **labels** : array-like of int with shape (n_samples,)

Arbitrary domain-specific stratification of the data to be used to draw the splits.

p : int

Number of samples to leave out in the test split.

See also:

LabelKFold K-fold iterator variant with non-overlapping labels.

Examples

```
>>> from sklearn import cross_validation
>>> X = np.array([[1, 2], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1])
>>> labels = np.array([1, 2, 3])
>>> lpl = cross_validation.LeavePLabelOut(labels, p=2)
>>> len(lpl)
3
>>> print(lpl)
sklearn.cross_validation.LeavePLabelOut(labels=[1 2 3], p=2)
>>> for train_index, test_index in lpl:
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
```

```
...     print(X_train, X_test, y_train, y_test)
TRAIN: [2] TEST: [0 1]
[[5 6]] [[1 2]
 [3 4]] [1] [1 2]
TRAIN: [1] TEST: [0 2]
[[3 4]] [[1 2]
 [5 6]] [2] [1 1]
TRAIN: [0] TEST: [1 2]
[[1 2]] [[3 4]
 [5 6]] [1] [2 1]
.. automethod:: __init__
```

sklearn.cross_validation.LabelShuffleSplit

Warning: DEPRECATED

class sklearn.cross_validation.**LabelShuffleSplit**(*labels*, *n_iter=5*, *test_size=0.2*, *train_size=None*, *random_state=None*)

Shuffle-Labels-Out cross-validation iterator

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.GroupShuffleSplit* instead.

Provides randomized train/test indices to split data according to a third-party provided label. This label information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the labels could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePLabelOut and LabelShuffleSplit is that the former generates splits using all subsets of size `p` unique labels, whereas LabelShuffleSplit generates a user-determined number of random test splits, each with a user-determined fraction of unique labels.

For example, a less computationally intensive alternative to `LeavePLabelOut(labels, p=10)` would be `LabelShuffleSplit(labels, test_size=10, n_iter=100)`.

Note: The parameters `test_size` and `train_size` refer to labels, and not to samples, as in ShuffleSplit.

New in version 0.17.

Parameters **labels** : array, [n_samples]

Labels of samples

n_iter : int (default 5)

Number of re-shuffling and splitting iterations.

test_size : float (default 0.2), int, or None

If float, should be between 0.0 and 1.0 and represent the proportion of the labels to include in the test split. If int, represents the absolute number of test labels. If None, the value is automatically set to the complement of the train size.

train_size : float, int, or None (default is None)

If float, should be between 0.0 and 1.0 and represent the proportion of the labels to include in the train split. If int, represents the absolute number of train labels. If None, the value is automatically set to the complement of the test size.

random_state : int, RandomState instance or None, optional (default None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

__init__ (*labels*, *n_iter=5*, *test_size=0.2*, *train_size=None*, *random_state=None*)

sklearn.cross_validation.StratifiedKFold

Warning: DEPRECATED

class sklearn.cross_validation.**StratifiedKFold**(*y*, *n_folds=3*, *shuffle=False*, *random_state=None*)

Stratified K-Folds cross validation iterator

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.StratifiedKFold* instead.

Provides train/test indices to split data in train test sets.

This cross-validation object is a variation of KFold that returns stratified folds. The folds are made by preserving the percentage of samples for each class.

Read more in the *User Guide*.

Parameters **y** : array-like, [n_samples]

Samples to split in K folds.

n_folds : int, default=3

Number of folds. Must be at least 2.

shuffle : boolean, optional

Whether to shuffle each stratification of the data before splitting into batches.

random_state : int, RandomState instance or None, optional, default=None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*. Used when `shuffle` == True.

See also:

LabelKFold K-fold iterator variant with non-overlapping labels.

Notes

All the folds have size trunc(n_samples / n_folds), the last one has the complementary.

Examples

```
>>> from sklearn.cross_validation import StratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> skf = StratifiedKFold(y, n_folds=2)
>>> len(skf)
2
>>> print(skf)
sklearn.cross_validation.StratifiedKFold(labels=[0 0 1 1], n_folds=2,
                                         shuffle=False, random_state=None)
>>> for train_index, test_index in skf:
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [0 2] TEST: [1 3]
.. automethod:: __init__
```

sklearn.cross_validation.ShuffleSplit

Warning: DEPRECATED

class sklearn.cross_validation.**ShuffleSplit**(*n*, *n_iter=10*, *test_size=0.1*, *train_size=None*, *random_state=None*)

Random permutation cross-validation iterator.

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.ShuffleSplit* instead.

Yields indices to split data into training and test sets.

Note: contrary to other cross-validation strategies, random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the *User Guide*.

Parameters **n** : int

Total number of elements in the dataset.

n_iter : int (default 10)

Number of re-shuffling & splitting iterations.

test_size : float (default 0.1), int, or None

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is automatically set to the complement of the train size.

train_size : float, int, or None (default is None)

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random_state : int, RandomState instance or None, optional (default None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Examples

```
>>> from sklearn import cross_validation
>>> rs = cross_validation.ShuffleSplit(4, n_iter=3,
...     test_size=.25, random_state=0)
>>> len(rs)
3
>>> print(rs)
...
ShuffleSplit(4, n_iter=3, test_size=0.25, ...)
>>> for train_index, test_index in rs:
...    print("TRAIN:", train_index, "TEST:", test_index)
...
TRAIN: [3 1 0] TEST: [2]
TRAIN: [2 1 3] TEST: [0]
TRAIN: [0 2 1] TEST: [3]
```

```
>>> rs = cross_validation.ShuffleSplit(4, n_iter=3,
...     train_size=0.5, test_size=.25, random_state=0)
>>> for train_index, test_index in rs:
...    print("TRAIN:", train_index, "TEST:", test_index)
...
TRAIN: [3 1] TEST: [2]
TRAIN: [2 1] TEST: [0]
TRAIN: [0 2] TEST: [3]
.. automethod:: __init__
```

sklearn.cross_validation.StratifiedShuffleSplit

Warning: DEPRECATED

class sklearn.cross_validation.**StratifiedShuffleSplit**(*y*, *n_iter=10*, *test_size=0.1*, *train_size=None*, *random_state=None*)

Stratified ShuffleSplit cross validation iterator

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.StratifiedShuffleSplit* instead.

Provides train/test indices to split data in train test sets.

This cross-validation object is a merge of StratifiedKFold and ShuffleSplit, which returns stratified randomized folds. The folds are made by preserving the percentage of samples for each class.

Note: like the ShuffleSplit strategy, stratified random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the *User Guide*.

Parameters **y** : array, [n_samples]

Labels of samples.

n_iter : int (default 10)

Number of re-shuffling & splitting iterations.

test_size : float (default 0.1), int, or None

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is automatically set to the complement of the train size.

train_size : float, int, or None (default is None)

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random_state : int, RandomState instance or None, optional (default None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Examples

```
>>> from sklearn.cross_validation import StratifiedShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> sss = StratifiedShuffleSplit(y, 3, test_size=0.5, random_state=0)
>>> len(sss)
3
>>> print(sss)
StratifiedShuffleSplit(labels=[0 0 1 1], n_iter=3, ...)
>>> for train_index, test_index in sss:
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 2] TEST: [3 0]
TRAIN: [0 2] TEST: [1 3]
TRAIN: [0 2] TEST: [3 1]
.. automethod:: __init__
```

sklearn.cross_validation.PredefinedSplit

Warning: DEPRECATED

class sklearn.cross_validation.**PredefinedSplit**(*test_fold*)

Predefined split cross validation iterator

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.PredefinedSplit* instead.

Splits the data into training/test set folds according to a predefined scheme. Each sample can be assigned to at most one test set fold, as specified by the user through the `test_fold` parameter.

Read more in the *User Guide*.

Parameters **test_fold** : “array-like, shape (n_samples,)

test_fold[i] gives the test set fold of sample i. A value of -1 indicates that the corresponding sample is not part of any test set folds, but will instead always be put into the training fold.

Examples

```
>>> from sklearn.cross_validation import PredefinedSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> ps = PredefinedSplit(test_fold=[0, 1, -1, 1])
>>> len(ps)
2
>>> print(ps)
sklearn.cross_validation.PredefinedSplit(test_fold=[ 0  1 -1  1])
>>> for train_index, test_index in ps:
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 2 3] TEST: [0]
TRAIN: [0 2] TEST: [1 3]
.. automethod:: __init__
```

sklearn.decomposition.RandomizedPCA

Warning: DEPRECATED

class sklearn.decomposition.**RandomizedPCA**(**args*, ***kwargs*)

Principal component analysis (PCA) using randomized SVD

Deprecated since version 0.18: This class will be removed in 0.20. Use *PCA* with parameter svd_solver ‘randomized’ instead. The new implementation DOES NOT store whiten `components_`. Apply transform to get them.

Linear dimensionality reduction using approximated Singular Value Decomposition of the data and keeping only the most significant singular vectors to project the data to a lower dimensional space.

Read more in the *User Guide*.

Parameters **n_components** : int, optional

Maximum number of components to keep. When not given or None, this is set to n_features (the second dimension of the training data).

copy : bool

If False, data passed to fit are overwritten and running fit(X).transform(X) will not yield the expected results, use fit_transform(X) instead.

iterated_power : int, default=2

Number of iterations for the power method.

Changed in version 0.18.

whiten : bool, optional

When True (False by default) the *components_* vectors are multiplied by the square root of (n_samples) and divided by the singular values to ensure uncorrelated outputs with unit component-wise variances.

Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometime improve the predictive accuracy of the downstream estimators by making their data respect some hard-wired assumptions.

random_state : int, RandomState instance or None, optional, default=None

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **components_** : array, shape (n_components, n_features)

Components with maximum variance.

explained_variance_ratio_ : array, shape (n_components,)

Percentage of variance explained by each of the selected components. If k is not set then all components are stored and the sum of explained variances is equal to 1.0.

singular_values_ : array, shape (n_components,)

The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the `n_components` variables in the lower-dimensional space.

mean_ : array, shape (n_features,)

Per-feature empirical mean, estimated from the training set.

See also:

PCA, *TruncatedSVD*

[Halko2009], *[MRT]*

Examples

```
>>> import numpy as np
>>> from sklearn.decomposition import RandomizedPCA
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> pca = RandomizedPCA(n_components=2)
>>> pca.fit(X)
RandomizedPCA(copy=True, iterated_power=2, n_components=2,
       random_state=None, whiten=False)
>>> print(pca.explained_variance_ratio_)
[ 0.99244...  0.00755...]
>>> print(pca.singular_values_)
[ 6.30061...  0.54980...]
```

Methods

fit(X[, y])	Fit the model with X by extracting the first principal components.
fit_transform(X[, y])	Fit the model with X and apply the dimensionality reduction on X.
get_params([deep])	Get parameters for this estimator.
inverse_transform(X[, y])	Transform data back to its original space.
set_params(**params)	Set the parameters of this estimator.
transform(X)	Apply dimensionality reduction on X.

__init__ (**args*, ***kwargs*)
DEPRECATED: RandomizedPCA was deprecated in 0.18 and will be removed in 0.20. Use PCA(svd_solver='randomized') instead. The new implementation DOES NOT store whiten `components_`. Apply transform to get them.

fit (*X*, *y=None*)
Fit the model with X by extracting the first principal components.

Parameters **X** : array-like, shape (n_samples, n_features)

Training data, where n_samples in the number of samples and n_features is the number of features.

Returns **self** : object

Returns the instance itself.

fit_transform (*X*, *y=None*)
Fit the model with X and apply the dimensionality reduction on X.

Parameters **X** : array-like, shape (n_samples, n_features)

New data, where n_samples in the number of samples and n_features is the number of features.

Returns **X_new** : array-like, shape (n_samples, n_components)

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

inverse_transform (*X*, *y=None*)
Transform data back to its original space.

Returns an array X_original whose transform would be X.

Parameters **X** : array-like, shape (n_samples, n_components)

New data, where n_samples in the number of samples and n_components is the number of components.

Returns **X_original array-like, shape (n_samples, n_features)** :

Notes

If whitening is enabled, inverse_transform does not compute the exact inverse operation of transform.

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

transform(*X*)
Apply dimensionality reduction on X.

X is projected on the first principal components previous extracted from a training set.

Parameters **X** : array-like, shape (n_samples, n_features)

New data, where n_samples in the number of samples and n_features is the number of features.

Returns **X_new** : array-like, shape (n_samples, n_components)

sklearn.gaussian_process.GaussianProcess

Warning: DEPRECATED

class sklearn.gaussian_process.**GaussianProcess**(**args*, ***kwargs*)
The legacy Gaussian Process model class.

Deprecated since version 0.18: This class will be removed in 0.20. Use the *GaussianProcessRegressor* instead.

Read more in the *User Guide*.

Parameters **regr** : string or callable, optional

A regression function returning an array of outputs of the linear regression functional basis. The number of observations n_samples should be greater than the size p of this basis. Default assumes a simple constant regression trend. Available built-in regression models are:

```
'constant', 'linear', 'quadratic'
```

corr : string or callable, optional

A stationary autocorrelation function returning the autocorrelation between two points x and x'. Default assumes a squared-exponential autocorrelation model. Built-in correlation models are:

```
'absolute_exponential', 'squared_exponential',
'generalized_exponential', 'cubic', 'linear'
```

beta0 : double array_like, optional

The regression weight vector to perform Ordinary Kriging (OK). Default assumes Universal Kriging (UK) so that the vector beta of regression weights is estimated using the maximum likelihood principle.

storage_mode : string, optional

A string specifying whether the Cholesky decomposition of the correlation matrix should be stored in the class (storage_mode = 'full') or not (storage_mode = 'light'). Default assumes storage_mode = 'full', so that the Cholesky decomposition of the correlation matrix is stored. This might be a useful parameter when one is not interested in the MSE and only plan to estimate the BLUP, for which the correlation matrix is not required.

verbose : boolean, optional

A boolean specifying the verbose level. Default is verbose = False.

theta0 : double array_like, optional

An array with shape (n_features,) or (1,). The parameters in the autocorrelation model. If thetaL and thetaU are also specified, theta0 is considered as the starting point for the maximum likelihood estimation of the best set of parameters. Default assumes isotropic autocorrelation model with theta0 = 1e-1.

thetaL : double array_like, optional

An array with shape matching theta0's. Lower bound on the autocorrelation parameters for maximum likelihood estimation. Default is None, so that it skips maximum likelihood estimation and it uses theta0.

thetaU : double array_like, optional

An array with shape matching theta0's. Upper bound on the autocorrelation parameters for maximum likelihood estimation. Default is None, so that it skips maximum likelihood estimation and it uses theta0.

normalize : boolean, optional

Input X and observations y are centered and reduced wrt means and standard deviations estimated from the n_samples observations provided. Default is normalize = True so that data is normalized to ease maximum likelihood estimation.

nugget : double or ndarray, optional

Introduce a nugget effect to allow smooth predictions from noisy data. If nugget is an ndarray, it must be the same length as the number of data points used for the fit. The nugget is added to the diagonal of the assumed training covariance; in this way it acts as a Tikhonov regularization in the problem. In the special case of the squared exponential correlation function, the nugget mathematically represents the variance of the input values. Default assumes a nugget close to machine precision for the sake of robustness (nugget = 10. * MACHINE_EPSILON).

optimizer : string, optional

A string specifying the optimization algorithm to be used. Default uses 'fmin_cobyla' algorithm from scipy.optimize. Available optimizers are:

```
'fmin_cobyla', 'Welch'
```

'Welch' optimizer is dued to Welch et al., see reference *[WBSWM1992]*. It consists in iterating over several one-dimensional optimizations instead of running one single multi-dimensional optimization.

random_start : int, optional

The number of times the Maximum Likelihood Estimation should be performed from a random starting point. The first MLE always uses the specified starting point (theta0), the next starting points are picked at random according to an exponential distribution (log-uniform on [thetaL, thetaU]). Default does not use random starting point (random_start = 1).

random_state : int, RandomState instance or None, optional (default=None)

The generator used to shuffle the sequence of coordinates of theta in the Welch optimizer. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

Attributes **theta_** : array

Specified theta OR the best set of autocorrelation parameters (the sought maximizer of the reduced likelihood function).

reduced_likelihood_function_value_ : array

The optimal reduced likelihood function value.

Notes

The presentation implementation is based on a translation of the DACE Matlab toolbox, see reference *[NLNS2002]*.

References

[NLNS2002], *[WBSWM1992]*

Examples

```
>>> import numpy as np
>>> from sklearn.gaussian_process import GaussianProcess
>>> X = np.array([[1., 3., 5., 6., 7., 8.]]).T
>>> y = (X * np.sin(X)).ravel()
>>> gp = GaussianProcess(theta0=0.1, thetaL=.001, thetaU=1.)
>>> gp.fit(X, y)
GaussianProcess(beta0=None...
        ...
```

Methods

fit(X, y)	The Gaussian Process model fitting method.
get_params([deep])	Get parameters for this estimator.
predict(X[, eval_MSE, batch_size])	This function evaluates the Gaussian Process model at x.

Continued on next page

Table 29.274 – continued from previous page

reduced_likelihood_function([theta])	This function determines the BLUP parameters and evaluates the reduced likelihood function for the given autocorrelation parameters theta.
score(X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(**params)	Set the parameters of this estimator.

__init__ (**args*, ***kwargs*)
DEPRECATED: GaussianProcess was deprecated in version 0.18 and will be removed in 0.20. Use the GaussianProcessRegressor instead.

fit (*X*, *y*)
The Gaussian Process model fitting method.

Parameters **X** : double array_like

An array with shape (n_samples, n_features) with the input at which observations were made.

y : double array_like

An array with shape (n_samples,) or shape (n_samples, n_targets) with the observations of the output to be predicted.

Returns **gp** : self

A fitted Gaussian Process model object awaiting data to perform predictions.

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict (*X*, *eval_MSE=False*, *batch_size=None*)
This function evaluates the Gaussian Process model at x.

Parameters **X** : array_like

An array with shape (n_eval, n_features) giving the point(s) at which the prediction(s) should be made.

eval_MSE : boolean, optional

A boolean specifying whether the Mean Squared Error should be evaluated or not. Default assumes evalMSE = False and evaluates only the BLUP (mean prediction).

batch_size : integer, optional

An integer giving the maximum number of points that can be evaluated simultaneously (depending on the available memory). Default is None so that all given points are evaluated at the same time.

Returns **y** : array_like, shape (n_samples,) or (n_samples, n_targets)

An array with shape (n_eval,) if the Gaussian Process was trained on an array of shape (n_samples,) or an array with shape (n_eval, n_targets) if the Gaussian Process was trained on an array of shape (n_samples, n_targets) with the Best Linear Unbiased Prediction at x.

MSE : array_like, optional (if eval_MSE == True)

An array with shape (n_eval,) or (n_eval, n_targets) as with y, with the Mean Squared Error at x.

reduced_likelihood_function (*theta=None*)

This function determines the BLUP parameters and evaluates the reduced likelihood function for the given autocorrelation parameters theta.

Maximizing this function wrt the autocorrelation parameters theta is equivalent to maximizing the likelihood of the assumed joint Gaussian distribution of the observations y evaluated onto the design of experiments X.

Parameters **theta** : array_like, optional

An array containing the autocorrelation parameters at which the Gaussian Process model parameters should be determined. Default uses the built-in autocorrelation parameters (ie `theta = self.theta_`).

Returns **reduced_likelihood_function_value** : double

The value of the reduced likelihood function associated to the given autocorrelation parameters theta.

par : dict

A dictionary containing the requested Gaussian Process model parameters:

sigma2 Gaussian Process variance.

beta Generalized least-squares regression weights for Universal Kriging or given beta0 for Ordinary Kriging.

gamma Gaussian Process weights.

C Cholesky decomposition of the correlation matrix [R].

Ft Solution of the linear equation system : [R] x Ft = F

G QR decomposition of the matrix Ft.

score (*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters **X** : array-like, shape = (n_samples, n_features)

Test samples.

y : array-like, shape = (n_samples) or (n_samples, n_outputs)

True values for X.

sample_weight : array-like, shape = [n_samples], optional

Sample weights.

Returns **score** : float

R^2 of self.predict(X) wrt. y.

set_params(***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

sklearn.mixture.GMM

Warning: DEPRECATED

class sklearn.mixture.**GMM**(**args*, ***kwargs*)

Legacy Gaussian Mixture Model

Deprecated since version 0.18: This class will be removed in 0.20. Use *sklearn.mixture.GaussianMixture* instead.

Methods

aic(X)	Akaike information criterion for the current model fit and the proposed data.
bic(X)	Bayesian information criterion for the current model fit and the proposed data.
fit(X[, y])	Estimate model parameters with the EM algorithm.
fit_predict(X[, y])	Fit and then predict labels for data.
get_params([deep])	Get parameters for this estimator.
predict(X)	Predict label for data.
predict_proba(X)	Predict posterior probability of data under each Gaussian in the model.
sample([n_samples, random_state])	Generate random samples from the model.
score(X[, y])	Compute the log probability under the model.
score_samples(X)	Return the per-sample likelihood of the data under the model.
set_params(**params)	Set the parameters of this estimator.

__init__(**args*, ***kwargs*)

DEPRECATED: The class GMM is deprecated in 0.18 and will be removed in 0.20. Use class GaussianMixture instead.

aic(*X*)

Akaike information criterion for the current model fit and the proposed data.

Parameters **X** : array of shape(n_samples, n_dimensions)

Returns **aic** : float (the lower the better)

bic(*X*)

Bayesian information criterion for the current model fit and the proposed data.

Parameters **X** : array of shape(n_samples, n_dimensions)

Returns **bic** : float (the lower the better)

fit(*X*, *y=None*)
Estimate model parameters with the EM algorithm.

A initialization step is performed before entering the expectation-maximization (EM) algorithm. If you want to avoid this step, set the keyword argument init_params to the empty string '' when creating the GMM object. Likewise, if you would like just to do an initialization, set n_iter=0.

Parameters **X** : array_like, shape (n, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **self** :

fit_predict(*X*, *y=None*)
Fit and then predict labels for data.

Warning: Due to the final maximization step in the EM algorithm, with low iterations the prediction may not be 100% accurate.

New in version 0.17: *fit_predict* method in Gaussian Mixture Model.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array, shape = (n_samples,) component memberships

get_params(*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

predict(*X*)
Predict label for data.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array, shape = (n_samples,) component memberships

predict_proba(*X*)
Predict posterior probability of data under each Gaussian in the model.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **responsibilities** : array-like, shape = (n_samples, n_components)

Returns the probability of the sample for each Gaussian (state) in the model.

sample(*n_samples=1*, *random_state=None*)
Generate random samples from the model.

Parameters **n_samples** : int, optional

Number of samples to generate. Defaults to 1.

Returns **X** : array_like, shape (n_samples, n_features)

List of samples

score(*X*, *y=None*)
Compute the log probability under the model.

Parameters **X** : array_like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **logprob** : array_like, shape (n_samples,)

Log probabilities of each data point in X

score_samples(*X*)
Return the per-sample likelihood of the data under the model.

Compute the log probability of X under the model and return the posterior distribution (responsibilities) of each mixture component for each element of X.

Parameters **X** : array_like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **logprob** : array_like, shape (n_samples,)

Log probabilities of each data point in X.

responsibilities : array_like, shape (n_samples, n_components)

Posterior probabilities of each mixture component for each observation

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

sklearn.mixture.DPGMM

Warning: DEPRECATED

class sklearn.mixture.**DPGMM**(**args*, ***kwargs*)
Dirichlet Process Gaussian Mixture Models

Deprecated since version 0.18: This class will be removed in 0.20. Use *sklearn.mixture.BayesianGaussianMixture* with parameter `weight_concentration_prior_type='dirichlet_process'` instead.

Methods

aic(X)	Akaike information criterion for the current model fit and the proposed data.
bic(X)	Bayesian information criterion for the current model fit and the proposed data.

Continued on next page

Table 29.276 – continued from previous page

fit(X[, y])	Estimate model parameters with the EM algorithm.
fit_predict(X[, y])	Fit and then predict labels for data.
get_params([deep])	Get parameters for this estimator.
lower_bound(X, z)	returns a lower bound on model evidence based on X and membership
predict(X)	Predict label for data.
predict_proba(X)	Predict posterior probability of data under each Gaussian in the model.
sample([n_samples, random_state])	Generate random samples from the model.
score(X[, y])	Compute the log probability under the model.
score_samples(X)	Return the likelihood of the data under the model.
set_params(**params)	Set the parameters of this estimator.

__init__ (**args*, ***kwargs*)
DEPRECATED: The *DPGMM* class is not working correctly and it's better to use *sklearn.mixture.BayesianGaussianMixture* class with parameter *weight_concentration_prior_type='dirichlet_process'* instead. DPGMM is deprecated in 0.18 and will be removed in 0.20.

aic (*X*)
Akaike information criterion for the current model fit and the proposed data.

Parameters **X** : array of shape(n_samples, n_dimensions)

Returns **aic** : float (the lower the better)

bic (*X*)
Bayesian information criterion for the current model fit and the proposed data.

Parameters **X** : array of shape(n_samples, n_dimensions)

Returns **bic** : float (the lower the better)

fit (*X*, *y=None*)
Estimate model parameters with the EM algorithm.

A initialization step is performed before entering the expectation-maximization (EM) algorithm. If you want to avoid this step, set the keyword argument init_params to the empty string '' when creating the GMM object. Likewise, if you would like just to do an initialization, set n_iter=0.

Parameters **X** : array_like, shape (n, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **self** :

fit_predict (*X*, *y=None*)
Fit and then predict labels for data.

Warning: Due to the final maximization step in the EM algorithm, with low iterations the prediction may not be 100% accurate.

New in version 0.17: *fit_predict* method in Gaussian Mixture Model.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array, shape = (n_samples,) component memberships

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

lower_bound(*X*, *z*)
returns a lower bound on model evidence based on X and membership

predict(*X*)
Predict label for data.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array, shape = (n_samples,) component memberships

predict_proba(*X*)
Predict posterior probability of data under each Gaussian in the model.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **responsibilities** : array-like, shape = (n_samples, n_components)

Returns the probability of the sample for each Gaussian (state) in the model.

sample(*n_samples=1*, *random_state=None*)
Generate random samples from the model.

Parameters **n_samples** : int, optional

Number of samples to generate. Defaults to 1.

Returns **X** : array_like, shape (n_samples, n_features)

List of samples

score(*X*, *y=None*)
Compute the log probability under the model.

Parameters **X** : array_like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **logprob** : array_like, shape (n_samples,)

Log probabilities of each data point in X

score_samples(*X*)
Return the likelihood of the data under the model.

Compute the bound on log probability of X under the model and return the posterior distribution (responsibilities) of each mixture component for each element of X.

This is done by computing the parameters for the mean-field of z for each observation.

Parameters **X** : array_like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **logprob** : array_like, shape (n_samples,)

Log probabilities of each data point in X

responsibilities : array_like, shape (n_samples, n_components)

Posterior probabilities of each mixture component for each observation

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

sklearn.mixture.VBGMM

Warning: DEPRECATED

class sklearn.mixture.**VBGMM**(**args*, ***kwargs*)
Variational Inference for the Gaussian Mixture Model

Deprecated since version 0.18: This class will be removed in 0.20. Use *sklearn.mixture.BayesianGaussianMixture* with parameter `weight_concentration_prior_type='dirichlet_distribution'` instead.

Variational inference for a Gaussian mixture model probability distribution. This class allows for easy and efficient inference of an approximate posterior distribution over the parameters of a Gaussian mixture model with a fixed number of components.

Initialization is with normally-distributed means and identity covariance, for proper convergence.

Read more in the User Guide.

Parameters **n_components** : int, default 1

Number of mixture components.

covariance_type : string, default 'diag'

String describing the type of covariance parameters to use. Must be one of 'spherical', 'tied', 'diag', 'full'.

alpha : float, default 1

Real number representing the concentration parameter of the dirichlet distribution. Intuitively, the higher the value of alpha the more likely the variational mixture of Gaussians model will use all components it can.

tol : float, default 1e-3

Convergence threshold.

n_iter : int, default 10

Maximum number of iterations to perform before convergence.

params : string, default 'wmc'

Controls which parameters are updated in the training process. Can contain any combination of 'w' for weights, 'm' for means, and 'c' for covars.

init_params : string, default 'wmc'

Controls which parameters are updated in the initialization process. Can contain any combination of 'w' for weights, 'm' for means, and 'c' for covars. Defaults to 'wmc'.

verbose : int, default 0

Controls output verbosity.

Attributes **covariance_type** : string

String describing the type of covariance parameters used by the DP-GMM. Must be one of 'spherical', 'tied', 'diag', 'full'.

n_features : int

Dimensionality of the Gaussians.

n_components : int (read-only)

Number of mixture components.

weights_ : array, shape (*n_components*,)

Mixing weights for each mixture component.

means_ : array, shape (*n_components*, *n_features*)

Mean parameters for each mixture component.

precs_ : array

Precision (inverse covariance) parameters for each mixture component. The shape depends on *covariance_type*:

```
(`n_components`, 'n_features')                if 'spherical',
(`n_features`, `n_features`)                  if 'tied',
(`n_components`, `n_features`)                if 'diag',
(`n_components`, `n_features`, `n_features`)  if 'full'
```

converged_ : bool

True when convergence was reached in fit(), False otherwise.

See also:

GMM Finite Gaussian mixture model fit with EM

DPGMM Infinite Gaussian mixture model, using the dirichlet process, fit with a variational algorithm

Methods

aic(X)	Akaike information criterion for the current model fit and the proposed data.
bic(X)	Bayesian information criterion for the current model fit and the proposed data.
fit(X[, y])	Estimate model parameters with the EM algorithm.
fit_predict(X[, y])	Fit and then predict labels for data.
get_params([deep])	Get parameters for this estimator.
lower_bound(X, z)	returns a lower bound on model evidence based on X and membership
predict(X)	Predict label for data.
predict_proba(X)	Predict posterior probability of data under each Gaussian in the model.
sample([n_samples, random_state])	Generate random samples from the model.
score(X[, y])	Compute the log probability under the model.

Continued on next page

Table 29.277 – continued from previous page

score_samples(X)	Return the likelihood of the data under the model.
set_params(**params)	Set the parameters of this estimator.

__init__ (**args*, ***kwargs*)
DEPRECATED: The *VBGMM* class is not working correctly and it's better to use *sklearn.mixture.BayesianGaussianMixture* class with parameter *weight_concentration_prior_type='dirichlet_distribution'* instead. VBGMM is deprecated in 0.18 and will be removed in 0.20.

aic (*X*)
Akaike information criterion for the current model fit and the proposed data.

Parameters **X** : array of shape(n_samples, n_dimensions)

Returns **aic** : float (the lower the better)

bic (*X*)
Bayesian information criterion for the current model fit and the proposed data.

Parameters **X** : array of shape(n_samples, n_dimensions)

Returns **bic** : float (the lower the better)

fit (*X*, *y=None*)
Estimate model parameters with the EM algorithm.

A initialization step is performed before entering the expectation-maximization (EM) algorithm. If you want to avoid this step, set the keyword argument init_params to the empty string '' when creating the GMM object. Likewise, if you would like just to do an initialization, set n_iter=0.

Parameters **X** : array_like, shape (n, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **self** :

fit_predict (*X*, *y=None*)
Fit and then predict labels for data.

Warning: Due to the final maximization step in the EM algorithm, with low iterations the prediction may not be 100% accurate.

New in version 0.17: *fit_predict* method in Gaussian Mixture Model.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array, shape = (n_samples,) component memberships

get_params (*deep=True*)
Get parameters for this estimator.

Parameters **deep** : boolean, optional

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns **params** : mapping of string to any

Parameter names mapped to their values.

lower_bound (*X*, *z*)
returns a lower bound on model evidence based on X and membership

predict(*X*)
Predict label for data.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **C** : array, shape = (n_samples,) component memberships

predict_proba(*X*)
Predict posterior probability of data under each Gaussian in the model.

Parameters **X** : array-like, shape = [n_samples, n_features]

Returns **responsibilities** : array-like, shape = (n_samples, n_components)

Returns the probability of the sample for each Gaussian (state) in the model.

sample(*n_samples=1*, *random_state=None*)
Generate random samples from the model.

Parameters **n_samples** : int, optional

Number of samples to generate. Defaults to 1.

Returns **X** : array_like, shape (n_samples, n_features)

List of samples

score(*X*, *y=None*)
Compute the log probability under the model.

Parameters **X** : array_like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **logprob** : array_like, shape (n_samples,)

Log probabilities of each data point in X

score_samples(*X*)
Return the likelihood of the data under the model.

Compute the bound on log probability of X under the model and return the posterior distribution (responsibilities) of each mixture component for each element of X.

This is done by computing the parameters for the mean-field of z for each observation.

Parameters **X** : array_like, shape (n_samples, n_features)

List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns **logprob** : array_like, shape (n_samples,)

Log probabilities of each data point in X

responsibilities : array_like, shape (n_samples, n_components)

Posterior probabilities of each mixture component for each observation

set_params(***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns **self** :

grid_search.fit_grid_point(X, y, estimator, ...)	Run fit on one set of parameters.
learning_curve.learning_curve(estimator, X, y)	Learning curve.
learning_curve.validation_curve(estimator, ...)	Validation curve.
cross_validation.cross_val_predict(estimator, X)	Generate cross-validated estimates for each input data point
cross_validation.cross_val_score(estimator, X)	Evaluate a score by cross-validation
cross_validation.check_cv(cv[, X, y, classifier])	Input checker utility for building a CV in a user friendly way.
cross_validation.permutation_test_score(...)	Evaluate the significance of a cross-validated score with permutations
cross_validation.train_test_split(*arrays, ...)	Split arrays or matrices into random train and test subsets

sklearn.grid_search.fit_grid_point

Warning: DEPRECATED

sklearn.grid_search.**fit_grid_point**(*X*, *y*, *estimator*, *parameters*, *train*, *test*, *scorer*, *verbose*, *error_score='raise'*, ***fit_params*)

Run fit on one set of parameters.

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.fit_grid_point* instead.

Parameters **X** : array-like, sparse matrix or list

Input data.

y : array-like or None

Targets for input data.

estimator : estimator object

A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

parameters : dict

Parameters to be set on estimator for this grid point.

train : ndarray, dtype int or bool

Boolean mask or indices for training set.

test : ndarray, dtype int or bool

Boolean mask or indices for test set.

scorer : callable or None.

If provided must be a scorer callable object / function with signature `scorer(estimator, X, y)`.

verbose : int

Verbosity level.

****fit_params** : kwargs

Additional parameter passed to the fit function of the estimator.

error_score : 'raise' (default) or numeric

Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

Returns **score** : float

Score of this parameter setting on given training / test split.

parameters : dict

The parameters that have been evaluated.

n_samples_test : int

Number of test samples in this split.

sklearn.learning_curve.learning_curve

Warning: DEPRECATED

sklearn.learning_curve.**learning_curve**(*estimator*, *X*, *y*, *train_sizes=array([0.1, 0.33, 0.55, 0.78, 1.])*, *cv=None*, *scoring=None*, *exploit_incremental_learning=False*, *n_jobs=1*, *pre_dispatch='all'*, *verbose=0*, *error_score='raise'*)

Learning curve.

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.learning_curve* instead.

Determines cross-validated training and test scores for different training set sizes.

A cross-validation generator splits the whole dataset k times in training and test data. Subsets of the training set with varying sizes will be used to train the estimator and a score for each training subset size and the test set will be computed. Afterwards, the scores will be averaged over all k runs for each training subset size.

Read more in the *User Guide*.

Parameters **estimator** : object type that implements the "fit" and "predict" methods

An object of that type which is cloned for each validation.

X : array-like, shape (n_samples, n_features)

Training vector, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape (n_samples) or (n_samples, n_features), optional

Target relative to X for classification or regression; None for unsupervised learning.

train_sizes : array-like, shape (n_ticks,), dtype float or int

Relative or absolute numbers of training examples that will be used to generate the learning curve. If the dtype is float, it is regarded as a fraction of the maximum size of the training set (that is determined by the selected validation method), i.e. it has to be within (0, 1]. Otherwise it is interpreted as absolute sizes of the training sets. Note that for classification the number of samples usually have to be big enough to contain at least one sample from each class. (default: np.linspace(0.1, 1.0, 5))

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *`sklearn.model_selection.StratifiedKFold`* is used. In all other cases, *`sklearn.model_selection.KFold`* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

scoring : string, callable or None, optional, default: None

A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

exploit_incremental_learning : boolean, optional, default: False

If the estimator supports incremental learning, this will be used to speed up fitting for different training set sizes.

n_jobs : integer, optional

Number of jobs to run in parallel (default 1).

pre_dispatch : integer or string, optional

Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The string can be an expression like '2*n_jobs'.

verbose : integer, optional

Controls the verbosity: the higher, the more messages.

error_score : 'raise' (default) or numeric

Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

Returns **train_sizes_abs** : array, shape = (n_unique_ticks,), dtype int

Numbers of training examples that has been used to generate the learning curve. Note that the number of ticks might be less than n_ticks because duplicate entries will be removed.

train_scores : array, shape (n_ticks, n_cv_folds)

Scores on training sets.

test_scores : array, shape (n_ticks, n_cv_folds)

Scores on test set.

Notes

See *examples/model_selection/plot_learning_curve.py*

sklearn.learning_curve.validation_curve

Warning: DEPRECATED

sklearn.learning_curve.**validation_curve**(*estimator*, *X*, *y*, *param_name*, *param_range*, *cv=None*, *scoring=None*, *n_jobs=1*, *pre_dispatch='all'*, *verbose=0*)

Validation curve.

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.validation_curve* instead.

Determine training and test scores for varying parameter values.

Compute scores for an estimator with different values of a specified parameter. This is similar to grid search with one parameter. However, this will also compute training scores and is merely a utility for plotting the results.

Read more in the *User Guide*.

Parameters **estimator** : object type that implements the "fit" and "predict" methods

An object of that type which is cloned for each validation.

X : array-like, shape (n_samples, n_features)

Training vector, where n_samples is the number of samples and n_features is the number of features.

y : array-like, shape (n_samples) or (n_samples, n_features), optional

Target relative to X for classification or regression; None for unsupervised learning.

param_name : string

Name of the parameter that will be varied.

param_range : array-like, shape (n_values,)

The values of the parameter that will be evaluated.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *sklearn.model_selection.StratifiedKFold* is used. In all other cases, *sklearn.model_selection.KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

scoring : string, callable or None, optional, default: None

A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

n_jobs : integer, optional

Number of jobs to run in parallel (default 1).

pre_dispatch : integer or string, optional

Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The string can be an expression like '2*n_jobs'.

verbose : integer, optional

Controls the verbosity: the higher, the more messages.

Returns **train_scores** : array, shape (n_ticks, n_cv_folds)

Scores on training sets.

test_scores : array, shape (n_ticks, n_cv_folds)

Scores on test set.

Notes

See *examples/model_selection/plot_validation_curve.py*

sklearn.cross_validation.cross_val_predict

Warning: DEPRECATED

sklearn.cross_validation.**cross_val_predict**(*estimator*, *X*, *y=None*, *cv=None*, *n_jobs=1*, *verbose=0*, *fit_params=None*, *pre_dispatch='2*n_jobs'*)

Generate cross-validated estimates for each input data point

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.cross_val_predict* instead.

Read more in the *User Guide*.

Parameters **estimator** : estimator object implementing 'fit' and 'predict'

The object to use to fit the data.

X : array-like

The data to fit. Can be, for example a list, or an array at least 2d.

y : array-like, optional, default: None

The target variable to try to predict in the case of supervised learning.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,

- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

n_jobs : integer, optional

The number of CPUs to use to do the computation. -1 means 'all CPUs'.

verbose : integer, optional

The verbosity level.

fit_params : dict, optional

Parameters to pass to the fit method of the estimator.

pre_dispatch : int, or string, optional

Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in '2*n_jobs'

Returns **preds** : ndarray

This is the result of calling 'predict'

Examples

```
>>> from sklearn import datasets, linear_model
>>> from sklearn.cross_validation import cross_val_predict
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> y_pred = cross_val_predict(lasso, X, y)
```

sklearn.cross_validation.cross_val_score

Warning: DEPRECATED

sklearn.cross_validation.**cross_val_score**(*estimator*, *X*, *y=None*, *scoring=None*, *cv=None*, *n_jobs=1*, *verbose=0*, *fit_params=None*, *pre_dispatch='2*n_jobs'*)

Evaluate a score by cross-validation

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.cross_val_score* instead.

Read more in the *User Guide*.

Parameters **estimator** : estimator object implementing 'fit'

The object to use to fit the data.

X : array-like

The data to fit. Can be, for example a list, or an array at least 2d.

y : array-like, optional, default: None

The target variable to try to predict in the case of supervised learning.

scoring : string, callable or None, optional, default: None

A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

n_jobs : integer, optional

The number of CPUs to use to do the computation. -1 means 'all CPUs'.

verbose : integer, optional

The verbosity level.

fit_params : dict, optional

Parameters to pass to the fit method of the estimator.

pre_dispatch : int, or string, optional

Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in '2*n_jobs'

Returns **scores** : array of float, shape=(len(list(cv)),)

Array of scores of the estimator for each run of the cross validation.

See also:

sklearn.metrics.make_scorer Make a scorer from a performance metric or loss function.

Examples

```
>>> from sklearn import datasets, linear_model
>>> from sklearn.cross_validation import cross_val_score
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> print(cross_val_score(lasso, X, y))
[ 0.33150734  0.08022311  0.03531764]
```

sklearn.cross_validation.check_cv

Warning: DEPRECATED

sklearn.cross_validation.**check_cv**(*cv*, *X=None*, *y=None*, *classifier=False*)

Input checker utility for building a CV in a user friendly way.

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.check_cv* instead.

Parameters **cv** : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if classifier is True and `y` is binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

X : array-like

The data the cross-val object will be applied on.

y : array-like

The target variable for a supervised learning problem.

classifier : boolean optional

Whether the task is a classification task, in which case stratified KFold will be used.

Returns **checked_cv** : a cross-validation generator instance.

The return value is guaranteed to be a cv generator instance, whatever the input type.

sklearn.cross_validation.permutation_test_score

Warning: DEPRECATED

sklearn.cross_validation.**permutation_test_score**(*estimator*, *X*, *y*, *cv=None*, *n_permutations=100*, *n_jobs=1*, *labels=None*, *random_state=0*, *verbose=0*, *scoring=None*)

Evaluate the significance of a cross-validated score with permutations

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.permutation_test_score* instead.

Read more in the *User Guide*.

Parameters **estimator** : estimator object implementing 'fit'

The object to use to fit the data.

X : array-like of shape at least 2D

The data to fit.

y : array-like

The target variable to try to predict in the case of supervised learning.

scoring : string, callable or None, optional, default: None

A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

cv : int, cross-validation generator or an iterable, optional

Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

n_permutations : integer, optional

Number of times to permute `y`.

n_jobs : integer, optional

The number of CPUs to use to do the computation. -1 means 'all CPUs'.

labels : array-like of shape [n_samples] (optional)

Labels constrain the permutation among groups of samples with a same label.

random_state : int, RandomState instance or None, optional (default=0)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

verbose : integer, optional

The verbosity level.

Returns **score** : float

The true score without permuting targets.

permutation_scores : array, shape (n_permutations,)

The scores obtained for each permutations.

pvalue : float

The p-value, which approximates the probability that the score would be obtained by chance. This is calculated as:

(C + 1) / (n_permutations + 1)

Where C is the number of permutations whose score >= the true score.

The best possible p-value is 1/(n_permutations + 1), the worst is 1.0.

Notes

This function implements Test 1 in:

Ojala and Garriga. Permutation Tests for Studying Classifier Performance. The Journal of Machine Learning Research (2010) vol. 11

sklearn.cross_validation.train_test_split

Warning: DEPRECATED

sklearn.cross_validation.**train_test_split**(**arrays*, ***options*)

Split arrays or matrices into random train and test subsets

Deprecated since version 0.18: This module will be removed in 0.20. Use *sklearn.model_selection.train_test_split* instead.

Quick utility that wraps input validation and `next(iter(ShuffleSplit(n_samples)))` and application to input data into a single call for splitting (and optionally subsampling) data in a oneliner.

Read more in the *User Guide*.

Parameters ***arrays** : sequence of indexables with same length / shape[0]

Allowed inputs are lists, numpy arrays, scipy-sparse matrices or pandas dataframes.

test_size : float, int, or None (default is None)

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is automatically set to the complement of the train size. If train size is also None, test size is set to 0.25.

train_size : float, int, or None (default is None)

If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random_state : int, RandomState instance or None, optional (default=None)

If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

stratify : array-like or None (default is None)

If not None, data is split in a stratified fashion, using this as the labels array.

New in version 0.17: *stratify* splitting

Returns **splitting** : list, length = 2 * len(arrays),

List containing train-test split of inputs.

New in version 0.16: If the input is sparse, the output will be a `scipy.sparse.csr_matrix`. Else, output type is the same as the input type.

Examples

```
>>> import numpy as np
>>> from sklearn.cross_validation import train_test_split
>>> X, y = np.arange(10).reshape((5, 2)), range(5)
>>> X
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7],
       [8, 9]])
>>> list(y)
[0, 1, 2, 3, 4]
```

```
>>> X_train, X_test, y_train, y_test = train_test_split(
...     X, y, test_size=0.33, random_state=42)
...
>>> X_train
array([[4, 5],
       [0, 1],
       [6, 7]])
>>> y_train
[2, 0, 3]
>>> X_test
array([[2, 3],
       [8, 9]])
>>> y_test
[1, 4]
```

CHAPTER

THIRTY

DEVELOPER'S GUIDE

30.1 Contributing

This project is a community effort, and everyone is welcome to contribute.

The project is hosted on https://github.com/scikit-learn/scikit-learn

Scikit-learn is somewhat *selective* when it comes to adding new algorithms, and the best way to contribute and to help the project is to start working on known issues. See *Issues for New Contributors* to get started.

Our community, our values

We are a community based on openness and friendly, didactic, discussions.

We aspire to treat everybody equally, and value their contributions.

Decisions are made based on technical merit and consensus.

Code is not the only way to help the project. Reviewing pull requests, answering questions to help others on mailing lists or issues, organizing and teaching tutorials, working on the website, improving the documentation, are all priceless contributions.

We abide by the principles of openness, respect, and consideration of others of the Python Software Foundation: https://www.python.org/psf/codeofconduct/

30.1.1 Submitting a bug report

In case you experience issues using this package, do not hesitate to submit a ticket to the Bug Tracker. You are also welcome to post feature requests or pull requests.

30.1.2 Retrieving the latest code

We use Git for version control and GitHub for hosting our main repository.

You can check out the latest sources with the command:

```
git clone git://github.com/scikit-learn/scikit-learn.git
```

or if you have write privileges:

```
git clone git@github.com:scikit-learn/scikit-learn.git
```

If you run the development version, it is cumbersome to reinstall the package each time you update the sources. It is thus preferred that you add the scikit-learn directory to your `PYTHONPATH` and build the extension in place:

```
python setup.py build_ext --inplace
```

Another option is to install the package in editable mode if you change your code a lot and do not want to have to reinstall every time. This basically builds the extension in place and creates a link to the development directory (see the pip docs):

```
pip install --editable .
```

Note: This is fundamentally similar to using the command `python setup.py develop` (see the setuptool docs). It is however preferred to use pip.

Note: If you decide to do an editable install you have to rerun:

```
python setup.py build_ext --inplace
```

every time the source code of a compiled extension is changed (for instance when switching branches or pulling changes from upstream).

On Unix-like systems, you can simply type `make` in the top-level folder to build in-place and launch all the tests. Have a look at the `Makefile` for additional utilities.

30.1.3 Contributing code

Note: To avoid duplicating work, it is highly advised that you contact the developers on the mailing list before starting work on a non-trivial feature.

https://mail.python.org/mailman/listinfo/scikit-learn

How to contribute

The preferred way to contribute to scikit-learn is to fork the main repository on GitHub, then submit a "pull request" (PR):

1. Create an account on GitHub if you do not already have one.
2. Fork the project repository: click on the 'Fork' button near the top of the page. This creates a copy of the code under your account on the GitHub server. For more details on how to fork a repository see this guide.
3. Clone this copy to your local disk:

   ```
   $ git clone git@github.com:YourLogin/scikit-learn.git
   ```

4. Create a branch to hold your changes:

```
$ git checkout -b my-feature
```

and start making changes. Never work in the `master` branch!

5. Work on this copy, on your computer, using Git to do the version control. When you're done editing, do:

```
$ git add modified_files
$ git commit
```

to record your changes in Git, then push them to GitHub with:

```
$ git push -u origin my-feature
```

Finally, follow these instructions to create a pull request from your fork. This will send an email to the committers. You may want to consider sending an email to the mailing list for more visibility.

Note: In the above setup, your `origin` remote repository points to YourLogin/scikit-learn.git. If you wish to fetch/merge from the main repository instead of your forked one, you will need to add another remote to use instead of `origin`. If we choose the name `upstream` for it, the command will be:

```
$ git remote add upstream https://github.com/scikit-learn/scikit-learn.git
```

If any of the above seems like magic to you, then look up the Git documentation and the Git development workflow on the web.

If some conflicts arise between your branch and the `master` branch, you need to merge `master`. The command will be:

```
$ git merge master
```

with `master` being synchronized with the `upstream`.

Subsequently, you need to solve the conflicts. You can refer to the Git documentation related to resolving merge conflict using the command line.

Note: In the past, the policy to resolve conflicts was to rebase your branch on `master`. GitHub interface deals with merging `master` better than in the past.

Contributing pull requests

It is recommended to check that your contribution complies with the following rules before submitting a pull request:

- Follow the *coding-guidelines* (see below). To make sure that your PR does not add PEP8 violations you can run *./build_tools/travis/flake8_diff.sh* or *make flake8-diff* on a Unix-like system.
- When applicable, use the validation tools and other code in the `sklearn.utils` submodule. A list of utility routines available for developers can be found in the *Utilities for Developers* page.
- If your pull request addresses an issue, please use the title to describe the issue and mention the issue number in the pull request description to ensure a link is created to the original issue.
- All public methods should have informative docstrings with sample usage presented as doctests when appropriate.

- Please prefix the title of your pull request with `[MRG]` if the contribution is complete and should be subjected to a detailed review. Two core developers will review your code and change the prefix of the pull request to `[MRG + 1]` and `[MRG + 2]` on approval, making it eligible for merging. An incomplete contribution – where you expect to do more work before receiving a full review – should be prefixed `[WIP]` (to indicate a work in progress) and changed to `[MRG]` when it matures. WIPs may be useful to: indicate you are working on something to avoid duplicated work, request broad review of functionality or API, or seek collaborators. WIPs often benefit from the inclusion of a task list in the PR description.
- All other tests pass when everything is rebuilt from scratch. On Unix-like systems, check with (from the toplevel source folder):

```
$ make
```

- When adding additional functionality, provide at least one example script in the `examples/` folder. Have a look at other examples for reference. Examples should demonstrate why the new functionality is useful in practice and, if possible, compare it to other methods available in scikit-learn.
- Documentation and high-coverage tests are necessary for enhancements to be accepted. Bug-fixes or new features should be provided with non-regression tests. These tests verify the correct behavior of the fix or feature. In this manner, further modifications on the code base are granted to be consistent with the desired behavior. For the case of bug fixes, at the time of the PR, the non-regression tests should fail for the code base in the master branch and pass for the PR code.
- At least one paragraph of narrative documentation with links to references in the literature (with PDF links when possible) and the example. For more details on writing and building the documentation, see the *Documentation* section.

You can also check for common programming errors with the following tools:

- Code with a good unittest coverage (at least 90%, better 100%), check with:

```
$ pip install nose coverage
$ nosetests --with-coverage path/to/tests_for_package
```

  see also *Testing and improving test coverage*

- No pyflakes warnings, check with:

```
$ pip install pyflakes
$ pyflakes path/to/module.py
```

- No PEP8 warnings, check with:

```
$ pip install pep8
$ pep8 path/to/module.py
```

- AutoPEP8 can help you fix some of the easy redundant errors:

```
$ pip install autopep8
$ autopep8 path/to/pep8.py
```

Bonus points for contributions that include a performance analysis with a benchmark script and profiling output (please report on the mailing list or on the GitHub wiki).

Also check out the *How to optimize for speed* guide for more details on profiling and Cython optimizations.

Note: The current state of the scikit-learn code base is not compliant with all of those guidelines, but we expect that enforcing those constraints on all new contributions will get the overall code base quality in the right direction.

Note: For two very well documented and more detailed guides on development workflow, please pay a visit to the Scipy Development Workflow - and the Astropy Workflow for Developers sections.

Continuous Integration (CI)

- Travis is used for testing on Linux platforms
- Appveyor is used for testing on Windows platforms
- CircleCI is used to build the docs for viewing

Please note that if one of the following markers appear in the latest commit message, the following actions are taken.

Commit Message Marker	Action Taken by CI
[ci skip]	CI is skipped completely
[doc skip]	Docs are not built
[doc quick]	Docs built, but excludes example gallery plots
[doc build]	Docs built including example gallery plots

Filing Bugs

We use Github issues to track all bugs and feature requests; feel free to open an issue if you have found a bug or wish to see a feature implemented.

It is recommended to check that your issue complies with the following rules before submitting:

- Verify that your issue is not being currently addressed by other issues or pull requests.
- If you are submitting an algorithm or feature request, please verify that the algorithm fulfills our new algorithm requirements.
- Please ensure all code snippets and error messages are formatted in appropriate code blocks. See Creating and highlighting code blocks.
- Please include your operating system type and version number, as well as your Python, scikit-learn, numpy, and scipy versions. This information can be found by running the following code snippet:

```
import platform; print(platform.platform())
import sys; print("Python", sys.version)
import numpy; print("NumPy", numpy.__version__)
import scipy; print("SciPy", scipy.__version__)
import sklearn; print("Scikit-Learn", sklearn.__version__)
```

- Please be specific about what estimators and/or functions are involved and the shape of the data, as appropriate; please include a reproducible code snippet or link to a gist. If an exception is raised, please provide the traceback.

Issues for New Contributors

New contributors should look for the following tags when looking for issues. We strongly recommend that new contributors tackle "easy" issues first: this helps the contributor become familiar with the contribution workflow, and for the core devs to become acquainted with the contributor; besides which, we frequently underestimate how easy an issue is to solve!

Easy Tags

A great way to start contributing to scikit-learn is to pick an item from the list of Easy issues in the issue tracker. Resolving these issues allow you to start contributing to the project without much prior knowledge. Your assistance in this area will be greatly appreciated by the more experienced developers as it helps free up their time to concentrate on other issues.

Need Contributor Tags

We often use the Need Contributor tag to mark issues regardless of difficulty. Additionally, we use the Need Contributor tag to mark Pull Requests which have been abandoned by their original contributor and are available for someone to pick up where the original contributor left off. The list of issues with the Need Contributor tag can be found here .

Note that not all issues which need contributors will have this tag.

Documentation

We are glad to accept any sort of documentation: function docstrings, reStructuredText documents (like this one), tutorials, etc. reStructuredText documents live in the source code repository under the doc/ directory.

You can edit the documentation using any text editor, and then generate the HTML output by typing `make html` from the doc/ directory. Alternatively, `make html-noplot` can be used to quickly generate the documentation without the example gallery. The resulting HTML files will be placed in _build/html/ and are viewable in a web browser. See the README file in the doc/ directory for more information.

For building the documentation, you will need sphinx, matplotlib and pillow.

When you are writing documentation, it is important to keep a good compromise between mathematical and algorithmic details, and give intuition to the reader on what the algorithm does.

Basically, to elaborate on the above, it is best to always start with a small paragraph with a hand-waving explanation of what the method does to the data. Then, it is very helpful to point out why the feature is useful and when it should be used - the latter also including "big O" ($O\left(g\left(n\right)\right)$) complexities of the algorithm, as opposed to just *rules of thumb*, as the latter can be very machine-dependent. If those complexities are not available, then rules of thumb may be provided instead.

Secondly, a generated figure from an example (as mentioned in the previous paragraph) should then be included to further provide some intuition.

Next, one or two small code examples to show its use can be added.

Next, any math and equations, followed by references, can be added to further the documentation. Not starting the documentation with the maths makes it more friendly towards users that are just interested in what the feature will do, as opposed to how it works "under the hood".

You may also be asked to show your changes when it's built. When you create a pull request or make changes in an existing one modifying the docs, CircleCI automatically builds them. Thus, you can easily view your changes in the built artifacts using the following URL:

`http://scikit-learn.org/circle?{BUILD_NUMBER}`

We attempt to assemble a more precise set of changed files in the documentation at:

`http://scikit-learn.org/circle?{BUILD_NUMBER}/_changed.html`

Note: When you visit the details page of the CircleCI tests, you can find your BUILD_NUMBER mentioned as 'build #' which is different from your pull request number, which is presented as 'pull/#'.

Finally, follow the formatting rules below to make it consistently good:

- Add "See also" in docstrings for related classes/functions.
- "See also" in docstrings should be one line per reference, with a colon and an explanation, for example:

```
See also
--------
SelectKBest : Select features based on the k highest scores.
SelectFpr : Select features based on a false positive rate test.
```

- For unwritten formatting rules, try to follow existing good works:
  - For "References" in docstrings, see the Silhouette Coefficient (*sklearn.metrics.silhouette_score*).

Warning: Sphinx version

While we do our best to have the documentation build under as many version of Sphinx as possible, the different versions tend to behave slightly differently. To get the best results, you should use version 1.0.

Testing and improving test coverage

High-quality unit testing is a corner-stone of the scikit-learn development process. For this purpose, we use the nose package. The tests are functions appropriately named, located in *tests* subdirectories, that check the validity of the algorithms and the different options of the code.

The full scikit-learn tests can be run using 'make' in the root folder. Alternatively, running 'nosetests' in a folder will run all the tests of the corresponding subpackages.

We expect code coverage of new features to be at least around 90%.

Note: Workflow to improve test coverage

To test code coverage, you need to install the coverage package in addition to nose.

1. Run 'make test-coverage'. The output lists for each file the line numbers that are not tested.
2. Find a low hanging fruit, looking at which lines are not tested, write or adapt a test specifically for these lines.
3. Loop.

Developers web site

More information can be found on the developer's wiki.

Issue Tracker Tags

All issues and pull requests on the Github issue tracker should have (at least) one of the following tags:

Bug / Crash Something is happening that clearly shouldn't happen. Wrong results as well as unexpected errors from estimators go here.

Cleanup / Enhancement Improving performance, usability, consistency.

Documentation Missing, incorrect or sub-standard documentations and examples.

New Feature Feature requests and pull requests implementing a new feature.

There are three other tags to help new contributors:

Easy This issue can be tackled by anyone, no experience needed. Ask for help if the formulation is unclear.

Moderate Might need some knowledge of machine learning or the package, but is still approachable for someone new to the project.

Needs Contributor This tag marks an issue which currently lacks a contributor or a PR that needs another contributor to take over the work. These issues can range in difficulty, and may not be approachable for new contributors. Note that not all issues which need contributors will have this tag.

30.1.4 Other ways to contribute

Code is not the only way to contribute to scikit-learn. For instance, documentation is also a very important part of the project and often doesn't get as much attention as it deserves. If you find a typo in the documentation, or have made improvements, do not hesitate to send an email to the mailing list or submit a GitHub pull request. Full documentation can be found under the doc/ directory.

It also helps us if you spread the word: reference the project from your blog and articles, link to it from your website, or simply say "I use it":

30.1.5 Coding guidelines

The following are some guidelines on how new code should be written. Of course, there are special cases and there will be exceptions to these rules. However, following these rules when submitting new code makes the review easier so new code can be integrated in less time.

Uniformly formatted code makes it easier to share code ownership. The scikit-learn project tries to closely follow the official Python guidelines detailed in PEP8 that detail how code should be formatted and indented. Please read it and follow it.

In addition, we add the following guidelines:

- Use underscores to separate words in non class names: `n_samples` rather than `nsamples`.
- Avoid multiple statements on one line. Prefer a line return after a control flow statement (`if`/`for`).
- Use relative imports for references inside scikit-learn.
- Unit tests are an exception to the previous rule; they should use absolute imports, exactly as client code would. A corollary is that, if `sklearn.foo` exports a class or function that is implemented in `sklearn.foo.bar.baz`, the test should import it from `sklearn.foo`.
- **Please don't use** `import *` **in any case**. It is considered harmful by the official Python recommendations. It makes the code harder to read as the origin of symbols is no longer explicitly referenced, but most important, it prevents using a static analysis tool like pyflakes to automatically find bugs in scikit-learn.
- Use the numpy docstring standard in all your docstrings.

A good example of code that we like can be found here.

Input validation

The module *sklearn.utils* contains various functions for doing input validation and conversion. Sometimes, np.asarray suffices for validation; do *not* use np.asanyarray or np.atleast_2d, since those let NumPy's np.matrix through, which has a different API (e.g., * means dot product on np.matrix, but Hadamard product on np.ndarray).

In other cases, be sure to call *check_array* on any array-like argument passed to a scikit-learn API function. The exact parameters to use depends mainly on whether and which scipy.sparse matrices must be accepted.

For more information, refer to the *Utilities for Developers* page.

Random Numbers

If your code depends on a random number generator, do not use numpy.random.random() or similar routines. To ensure repeatability in error checking, the routine should accept a keyword random_state and use this to construct a numpy.random.RandomState object. See *sklearn.utils.check_random_state* in *Utilities for Developers*.

Here's a simple example of code using some of the above guidelines:

```
from sklearn.utils import check_array, check_random_state

def choose_random_sample(X, random_state=0):
    """
    Choose a random point from X

    Parameters
    ----------
    X : array-like, shape = (n_samples, n_features)
        array representing the data
    random_state : RandomState or an int seed (0 by default)
        A random number generator instance to define the state of the
        random permutations generator.

    Returns
    -------
    x : numpy array, shape = (n_features,)
        A random point selected from X
    """
    X = check_array(X)
    random_state = check_random_state(random_state)
    i = random_state.randint(X.shape[0])
    return X[i]
```

If you use randomness in an estimator instead of a freestanding function, some additional guidelines apply.

First off, the estimator should take a random_state argument to its __init__ with a default value of None. It should store that argument's value, **unmodified**, in an attribute random_state. fit can call check_random_state on that attribute to get an actual random number generator. If, for some reason, randomness is needed after fit, the RNG should be stored in an attribute random_state_. The following example should make this clear:

```
class GaussianNoise(BaseEstimator, TransformerMixin):
    """This estimator ignores its input and returns random Gaussian noise.

    It also does not adhere to all scikit-learn conventions,
    but showcases how to handle randomness.
```

```
    """

    def __init__(self, n_components=100, random_state=None):
        self.random_state = random_state

    # the arguments are ignored anyway, so we make them optional
    def fit(self, X=None, y=None):
        self.random_state_ = check_random_state(self.random_state)

    def transform(self, X):
        n_samples = X.shape[0]
        return self.random_state_.randn(n_samples, n_components)
```

The reason for this setup is reproducibility: when an estimator is `fit` twice to the same data, it should produce an identical model both times, hence the validation in `fit`, not `__init__`.

Deprecation

If any publicly accessible method, function, attribute or parameter is renamed, we still support the old one for two releases and issue a deprecation warning when it is called/passed/accessed. E.g., if the function `zero_one` is renamed to `zero_one_loss`, we add the decorator `deprecated` (from `sklearn.utils`) to `zero_one` and call `zero_one_loss` from that function:

```
from ..utils import deprecated

def zero_one_loss(y_true, y_pred, normalize=True):
    # actual implementation
    pass

@deprecated("Function 'zero_one' was renamed to 'zero_one_loss' "
            "in version 0.13 and will be removed in release 0.15. "
            "Default behavior is changed from 'normalize=False' to "
            "'normalize=True'")
def zero_one(y_true, y_pred, normalize=False):
    return zero_one_loss(y_true, y_pred, normalize)
```

If an attribute is to be deprecated, use the decorator `deprecated` on a property. E.g., renaming an attribute `labels_` to `classes_` can be done as:

```
@property
@deprecated("Attribute labels_ was deprecated in version 0.13 and "
            "will be removed in 0.15. Use 'classes_' instead")
def labels_(self):
    return self.classes_
```

If a parameter has to be deprecated, use `DeprecationWarning` appropriately. In the following example, k is deprecated and renamed to n_clusters:

```
import warnings

def example_function(n_clusters=8, k=None):
    if k is not None:
        warnings.warn("'k' was renamed to n_clusters in version 0.13 and "
                      "will be removed in 0.15.", DeprecationWarning)
        n_clusters = k
```

As in these examples, the warning message should always give both the version in which the deprecation happened and the version in which the old behavior will be removed. If the deprecation happened in version 0.x-dev, the message should say deprecation occurred in version 0.x and the removal will be in 0.(x+2). For example, if the deprecation happened in version 0.18-dev, the message should say it happened in version 0.18 and the old behavior will be removed in version 0.20.

In addition, a deprecation note should be added in the docstring, recalling the same information as the deprecation warning as explained above. Use the `.. deprecated::` directive:

```
.. deprecated:: 0.13
   ``k`` was renamed to ``n_clusters`` in version 0.13 and will be removed
   in 0.15.
```

Python versions supported

All scikit-learn code should work unchanged in both Python 2.7 and 3.4 or newer. Since Python 3.x is not backwards compatible, that may require changes to code and it certainly requires testing on both 2.7 and 3.4 or newer.

For most numerical algorithms, Python 3.x support is easy: just remember that `print` is a function and integer division is written `//`. String handling has been overhauled, though, as have parts of the Python standard library. The six package helps with cross-compatibility and is included in scikit-learn as `sklearn.externals.six`.

30.1.6 APIs of scikit-learn objects

To have a uniform API, we try to have a common basic API for all the objects. In addition, to avoid the proliferation of framework code, we try to adopt simple conventions and limit to a minimum the number of methods an object must implement.

Different objects

The main objects in scikit-learn are (one class can implement multiple interfaces):

Estimator The base object, implements a `fit` method to learn from data, either:

```
estimator = obj.fit(data, targets)
```

or:

```
estimator = obj.fit(data)
```

Predictor For supervised learning, or some unsupervised problems, implements:

```
prediction = obj.predict(data)
```

Classification algorithms usually also offer a way to quantify certainty of a prediction, either using `decision_function` or `predict_proba`:

```
probability = obj.predict_proba(data)
```

Transformer For filtering or modifying the data, in a supervised or unsupervised way, implements:

```
new_data = obj.transform(data)
```

When fitting and transforming can be performed much more efficiently together than separately, implements:

```
new_data = obj.fit_transform(data)
```

Model A model that can give a goodness of fit measure or a likelihood of unseen data, implements (higher is better):

```
score = obj.score(data)
```

Estimators

The API has one predominant object: the estimator. A estimator is an object that fits a model based on some training data and is capable of inferring some properties on new data. It can be, for instance, a classifier or a regressor. All estimators implement the fit method:

```
estimator.fit(X, y)
```

All built-in estimators also have a `set_params` method, which sets data-independent parameters (overriding previous parameter values passed to `__init__`).

All estimators in the main scikit-learn codebase should inherit from `sklearn.base.BaseEstimator`.

Instantiation

This concerns the creation of an object. The object's `__init__` method might accept constants as arguments that determine the estimator's behavior (like the C constant in SVMs). It should not, however, take the actual training data as an argument, as this is left to the `fit()` method:

```
clf2 = SVC(C=2.3)
clf3 = SVC([[1, 2], [2, 3]], [-1, 1]) # WRONG!
```

The arguments accepted by `__init__` should all be keyword arguments with a default value. In other words, a user should be able to instantiate an estimator without passing any arguments to it. The arguments should all correspond to hyperparameters describing the model or the optimisation problem the estimator tries to solve. These initial arguments (or parameters) are always remembered by the estimator. Also note that they should not be documented under the "Attributes" section, but rather under the "Parameters" section for that estimator.

In addition, **every keyword argument accepted by `__init__` should correspond to an attribute on the instance**. Scikit-learn relies on this to find the relevant attributes to set on an estimator when doing model selection.

To summarize, an `__init__` should look like:

```
def __init__(self, param1=1, param2=2):
    self.param1 = param1
    self.param2 = param2
```

There should be no logic, not even input validation, and the parameters should not be changed. The corresponding logic should be put where the parameters are used, typically in `fit`. The following is wrong:

```
def __init__(self, param1=1, param2=2, param3=3):
    # WRONG: parameters should not be modified
    if param1 > 1:
        param2 += 1
    self.param1 = param1
```

```
    # WRONG: the object's attributes should have exactly the name of
    # the argument in the constructor
    self.param3 = param2
```

The reason for postponing the validation is that the same validation would have to be performed in `set_params`, which is used in algorithms like `GridSearchCV`.

Fitting

The next thing you will probably want to do is to estimate some parameters in the model. This is implemented in the `fit()` method.

The `fit()` method takes the training data as arguments, which can be one array in the case of unsupervised learning, or two arrays in the case of supervised learning.

Note that the model is fitted using X and y, but the object holds no reference to X and y. There are, however, some exceptions to this, as in the case of precomputed kernels where this data must be stored for use by the predict method.

Parameters	
X	array-like, with shape = [N, D], where N is the number of samples and D is the number of features.
y	array, with shape = [N], where N is the number of samples.
kwargs	optional data-dependent parameters.

`X.shape[0]` should be the same as `y.shape[0]`. If this requisite is not met, an exception of type `ValueError` should be raised.

`y` might be ignored in the case of unsupervised learning. However, to make it possible to use the estimator as part of a pipeline that can mix both supervised and unsupervised transformers, even unsupervised estimators need to accept a `y=None` keyword argument in the second position that is just ignored by the estimator. For the same reason, `fit_predict`, `fit_transform`, `score` and `partial_fit` methods need to accept a `y` argument in the second place if they are implemented.

The method should return the object (`self`). This pattern is useful to be able to implement quick one liners in an IPython session such as:

```
y_predicted = SVC(C=100).fit(X_train, y_train).predict(X_test)
```

Depending on the nature of the algorithm, `fit` can sometimes also accept additional keywords arguments. However, any parameter that can have a value assigned prior to having access to the data should be an `__init__` keyword argument. **fit parameters should be restricted to directly data dependent variables**. For instance a Gram matrix or an affinity matrix which are precomputed from the data matrix `X` are data dependent. A tolerance stopping criterion `tol` is not directly data dependent (although the optimal value according to some scoring function probably is).

Estimated Attributes

Attributes that have been estimated from the data must always have a name ending with trailing underscore, for example the coefficients of some regression estimator would be stored in a `coef_` attribute after `fit` has been called.

The last-mentioned attributes are expected to be overridden when you call `fit` a second time without taking any previous value into account: **fit should be idempotent**.

Optional Arguments

In iterative algorithms, the number of iterations should be specified by an integer called `n_iter`.

30.1.7 Rolling your own estimator

If you want to implement a new estimator that is scikit-learn-compatible, whether it is just for you or for contributing it to scikit-learn, there are several internals of scikit-learn that you should be aware of in addition to the scikit-learn API outlined above. You can check whether your estimator adheres to the scikit-learn interface and standards by running *utils.estimator_checks.check_estimator* on the class:

```
>>> from sklearn.utils.estimator_checks import check_estimator
>>> from sklearn.svm import LinearSVC
>>> check_estimator(LinearSVC)  # passes
```

The main motivation to make a class compatible to the scikit-learn estimator interface might be that you want to use it together with model evaluation and selection tools such as *model_selection.GridSearchCV* and *pipeline.Pipeline*.

Before detailing the required interface below, we describe two ways to achieve the correct interface more easily.

Project template:

We provide a project template which helps in the creation of Python packages containing scikit-learn compatible estimators. It provides:

- an initial git repository with Python package directory structure
- a template of a scikit-learn estimator
- an initial test suite including use of `check_estimator`
- directory structures and scripts to compile documentation and example galleries
- scripts to manage continuous integration (testing on Linux and Windows)
- instructions from getting started to publishing on PyPi

`BaseEstimator` and mixins:

We tend to use use "duck typing", so building an estimator which follows the API suffices for compatibility, without needing to inherit from or even import any scikit-learn classes.

However, if a dependency on scikit-learn is acceptable in your code, you can prevent a lot of boilerplate code by deriving a class from `BaseEstimator` and optionally the mixin classes in `sklearn.base`. For example, below is a custom classifier, with more examples included in the scikit-learn-contrib project template.

```
>>> import numpy as np
>>> from sklearn.base import BaseEstimator, ClassifierMixin
>>> from sklearn.utils.validation import check_X_y, check_array, check_is_fitted
>>> from sklearn.utils.multiclass import unique_labels
>>> from sklearn.metrics import euclidean_distances
>>> class TemplateClassifier(BaseEstimator, ClassifierMixin):
...
...     def __init__(self, demo_param='demo'):
...         self.demo_param = demo_param
...
...     def fit(self, X, y):
...
...         # Check that X and y have correct shape
...         X, y = check_X_y(X, y)
...         # Store the classes seen during fit
...         self.classes_ = unique_labels(y)
...
...         self.X_ = X
...         self.y_ = y
...         # Return the classifier
...         return self
...
...     def predict(self, X):
...
...         # Check is fit had been called
...         check_is_fitted(self, ['X_', 'y_'])
...
...         # Input validation
...         X = check_array(X)
...
...         closest = np.argmin(euclidean_distances(X, self.X_), axis=1)
...         return self.y_[closest]
```

get_params and set_params

All scikit-learn estimators have `get_params` and `set_params` functions. The `get_params` function takes no arguments and returns a dict of the `__init__` parameters of the estimator, together with their values. It must take one keyword argument, `deep`, which receives a boolean value that determines whether the method should return the parameters of sub-estimators (for most estimators, this can be ignored). The default value for `deep` should be true.

The `set_params` on the other hand takes as input a dict of the form `'parameter': value` and sets the parameter of the estimator using this dict. Return value must be estimator itself.

While the `get_params` mechanism is not essential (see *Cloning* below), the `set_params` function is necessary as it is used to set parameters during grid searches.

The easiest way to implement these functions, and to get a sensible `__repr__` method, is to inherit from `sklearn.base.BaseEstimator`. If you do not want to make your code dependent on scikit-learn, the easiest way to implement the interface is:

```
def get_params(self, deep=True):
    # suppose this estimator has parameters "alpha" and "recursive"
    return {"alpha": self.alpha, "recursive": self.recursive}

def set_params(self, **parameters):
    for parameter, value in parameters.items():
```

```
        self.setattr(parameter, value)
    return self
```

Parameters and init

As *model_selection.GridSearchCV* uses set_params to apply parameter setting to estimators, it is essential that calling set_params has the same effect as setting parameters using the __init__ method. The easiest and recommended way to accomplish this is to **not do any parameter validation in** __init__. All logic behind estimator parameters, like translating string arguments into functions, should be done in fit.

Also it is expected that parameters with trailing _ are **not to be set inside the** __init__ **method**. All and only the public attributes set by fit have a trailing _. As a result the existence of parameters with trailing _ is used to check if the estimator has been fitted.

Cloning

For use with the model_selection module, an estimator must support the base.clone function to replicate an estimator. This can be done by providing a get_params method. If get_params is present, then clone(estimator) will be an instance of type(estimator) on which set_params has been called with clones of the result of estimator.get_params().

Objects that do not provide this method will be deep-copied (using the Python standard function copy.deepcopy) if safe=False is passed to clone.

Pipeline compatibility

For an estimator to be usable together with pipeline.Pipeline in any but the last step, it needs to provide a fit or fit_transform function. To be able to evaluate the pipeline on any data but the training set, it also needs to provide a transform function. There are no special requirements for the last step in a pipeline, except that it has a fit function. All fit and fit_transform functions must take arguments X, y, even if y is not used. Similarly, for score to be usable, the last step of the pipeline needs to have a score function that accepts an optional y.

Estimator types

Some common functionality depends on the kind of estimator passed. For example, cross-validation in *model_selection.GridSearchCV* and *model_selection.cross_val_score* defaults to being stratified when used on a classifier, but not otherwise. Similarly, scorers for average precision that take a continuous prediction need to call decision_function for classifiers, but predict for regressors. This distinction between classifiers and regressors is implemented using the _estimator_type attribute, which takes a string value. It should be "classifier" for classifiers and "regressor" for regressors and "clusterer" for clustering methods, to work as expected. Inheriting from ClassifierMixin, RegressorMixin or ClusterMixin will set the attribute automatically.

Working notes

For unresolved issues, TODOs, and remarks on ongoing work, developers are advised to maintain notes on the GitHub wiki.

Specific models

Classifiers should accept `y` (target) arguments to `fit` that are sequences (lists, arrays) of either strings or integers. They should not assume that the class labels are a contiguous range of integers; instead, they should store a list of classes in a `classes_` attribute or property. The order of class labels in this attribute should match the order in which `predict_proba`, `predict_log_proba` and `decision_function` return their values. The easiest way to achieve this is to put:

```
self.classes_, y = np.unique(y, return_inverse=True)
```

in `fit`. This returns a new `y` that contains class indexes, rather than labels, in the range [0, `n_classes`).

A classifier's `predict` method should return arrays containing class labels from `classes_`. In a classifier that implements `decision_function`, this can be achieved with:

```
def predict(self, X):
    D = self.decision_function(X)
    return self.classes_[np.argmax(D, axis=1)]
```

In linear models, coefficients are stored in an array called `coef_`, and the independent term is stored in `intercept_`. `sklearn.linear_model.base` contains a few base classes and mixins that implement common linear model patterns.

The `sklearn.utils.multiclass` module contains useful functions for working with multiclass and multilabel problems.

30.2 Developers' Tips for Debugging

30.2.1 Memory errors: debugging Cython with valgrind

While python/numpy's built-in memory management is relatively robust, it can lead to performance penalties for some routines. For this reason, much of the high-performance code in scikit-learn in written in cython. This performance gain comes with a tradeoff, however: it is very easy for memory bugs to crop up in cython code, especially in situations where that code relies heavily on pointer arithmetic.

Memory errors can manifest themselves a number of ways. The easiest ones to debug are often segmentation faults and related glibc errors. Uninitialized variables can lead to unexpected behavior that is difficult to track down. A very useful tool when debugging these sorts of errors is valgrind.

Valgrind is a command-line tool that can trace memory errors in a variety of code. Follow these steps:

1. Install valgrind on your system.
2. Download the python valgrind suppression file: valgrind-python.supp.
3. Follow the directions in the README.valgrind file to customize your python suppressions. If you don't, you will have spurious output coming related to the python interpreter instead of your own code.
4. Run valgrind as follows:

```
$> valgrind -v --suppressions=valgrind-python.supp python my_test_script.py
```

The result will be a list of all the memory-related errors, which reference lines in the C-code generated by cython from your .pyx file. If you examine the referenced lines in the .c file, you will see comments which indicate the corresponding location in your .pyx source file. Hopefully the output will give you clues as to the source of your memory error.

For more information on valgrind and the array of options it has, see the tutorials and documentation on the valgrind web site.

30.3 Utilities for Developers

Scikit-learn contains a number of utilities to help with development. These are located in *sklearn.utils*, and include tools in a number of categories. All the following functions and classes are in the module *sklearn.utils*.

Warning: These utilities are meant to be used internally within the scikit-learn package. They are not guaranteed to be stable between versions of scikit-learn. Backports, in particular, will be removed as the scikit-learn dependencies evolve.

30.3.1 Validation Tools

These are tools used to check and validate input. When you write a function which accepts arrays, matrices, or sparse matrices as arguments, the following should be used when applicable.

- *assert_all_finite*: Throw an error if array contains NaNs or Infs.
- *as_float_array*: convert input to an array of floats. If a sparse matrix is passed, a sparse matrix will be returned.
- *check_array*: convert input to 2d array, raise error on sparse matrices. Allowed sparse matrix formats can be given optionally, as well as allowing 1d or nd arrays. Calls *assert_all_finite* by default.
- *check_X_y*: check that X and y have consistent length, calls check_array on X, and column_or_1d on y. For multilabel classification or multitarget regression, specify multi_output=True, in which case check_array will be called on y.
- *indexable*: check that all input arrays have consistent length and can be sliced or indexed using safe_index. This is used to validate input for cross-validation.

If your code relies on a random number generator, it should never use functions like `numpy.random.random` or `numpy.random.normal`. This approach can lead to repeatability issues in unit tests. Instead, a `numpy.random.RandomState` object should be used, which is built from a `random_state` argument passed to the class or function. The function *check_random_state*, below, can then be used to create a random number generator object.

- *check_random_state*: create a `np.random.RandomState` object from a parameter `random_state`.
  - If `random_state` is `None` or `np.random`, then a randomly-initialized `RandomState` object is returned.
  - If `random_state` is an integer, then it is used to seed a new `RandomState` object.
  - If `random_state` is a `RandomState` object, then it is passed through.

For example:

```
>>> from sklearn.utils import check_random_state
>>> random_state = 0
>>> random_state = check_random_state(random_state)
>>> random_state.rand(4)
array([ 0.5488135 ,  0.71518937,  0.60276338,  0.54488318])
```

When developing your own scikit-learn compatible estimator, the following helpers are available.

- *validation.check_is_fitted*: check that the estimator has been fitted before calling transform, predict, or similar methods. This helper allows to raise a standardized error message across estimator.
- *validation.has_fit_parameter*: check that a given parameter is supported in the fit method of a given estimator.

30.3.2 Efficient Linear Algebra & Array Operations

- extmath.randomized_range_finder: construct an orthonormal matrix whose range approximates the range of the input. This is used in extmath.randomized_svd, below.
- extmath.randomized_svd: compute the k-truncated randomized SVD. This algorithm finds the exact truncated singular values decomposition using randomization to speed up the computations. It is particularly fast on large matrices on which you wish to extract only a small number of components.
- arrayfuncs.cholesky_delete: (used in sklearn.linear_model.least_angle.lars_path) Remove an item from a cholesky factorization.
- arrayfuncs.min_pos: (used in sklearn.linear_model.least_angle) Find the minimum of the positive values within an array.
- extmath.fast_logdet: efficiently compute the log of the determinant of a matrix.
- extmath.density: efficiently compute the density of a sparse vector
- *extmath.safe_sparse_dot*: dot product which will correctly handle scipy.sparse inputs. If the inputs are dense, it is equivalent to numpy.dot.
- extmath.weighted_mode: an extension of scipy.stats.mode which allows each item to have a real-valued weight.
- *resample*: Resample arrays or sparse matrices in a consistent way. used in *shuffle*, below.
- *shuffle*: Shuffle arrays or sparse matrices in a consistent way. Used in sklearn.cluster.k_means.

30.3.3 Efficient Random Sampling

- random.sample_without_replacement: implements efficient algorithms for sampling n_samples integers from a population of size n_population without replacement.

30.3.4 Efficient Routines for Sparse Matrices

The sklearn.utils.sparsefuncs cython module hosts compiled extensions to efficiently process scipy.sparse data.

- *sparsefuncs.mean_variance_axis*: compute the means and variances along a specified axis of a CSR matrix. Used for normalizing the tolerance stopping criterion in sklearn.cluster.k_means_.KMeans.
- sparsefuncs.inplace_csr_row_normalize_l1 and sparsefuncs.inplace_csr_row_normalize_l2: can be used to normalize individual sparse samples to unit L1 or L2 norm as done in *sklearn.preprocessing.Normalizer*.
- sparsefuncs.inplace_csr_column_scale: can be used to multiply the columns of a CSR matrix by a constant scale (one scale per column). Used for scaling features to unit standard deviation in *sklearn.preprocessing.StandardScaler*.

30.3.5 Graph Routines

- `graph.single_source_shortest_path_length`: (not currently used in scikit-learn) Return the shortest path from a single source to all connected nodes on a graph. Code is adapted from networkx. If this is ever needed again, it would be far faster to use a single iteration of Dijkstra's algorithm from `graph_shortest_path`.
- `graph_shortest_path.graph_shortest_path`: (used in *`sklearn.manifold.Isomap`*) Return the shortest path between all pairs of connected points on a directed or undirected graph. Both the Floyd-Warshall algorithm and Dijkstra's algorithm are available. The algorithm is most efficient when the connectivity matrix is a `scipy.sparse.csr_matrix`.

Benchmarking

- `bench.total_seconds` (back-ported from `timedelta.total_seconds` in Python 2.7). Used in `benchmarks/bench_glm.py`.

30.3.6 Testing Functions

- `testing.assert_in`, `testing.assert_not_in`: Assertions for container membership. Designed for forward compatibility with Nose 1.0.
- `testing.assert_raise_message`: Assertions for checking the error raise message.
- `testing.mock_mldata_urlopen`: Mocks the urlopen function to fake requests to mldata.org. Used in tests of *`sklearn.datasets`*.
- `testing.all_estimators` : returns a list of all estimators in scikit-learn to test for consistent behavior and interfaces.

30.3.7 Multiclass and multilabel utility function

- `multiclass.is_multilabel`: Helper function to check if the task is a multi-label classification one.
- `multiclass.is_label_indicator_matrix`: Helper function to check if a classification output is in label indicator matrix format.
- `multiclass.unique_labels`: Helper function to extract an ordered array of unique labels from different formats of target.

30.3.8 Helper Functions

- `gen_even_slices`: generator to create `n`-packs of slices going up to `n`. Used in `sklearn.decomposition.dict_learning` and `sklearn.cluster.k_means`.
- `safe_mask`: Helper function to convert a mask to the format expected by the numpy array or scipy sparse matrix on which to use it (sparse matrices support integer indices only while numpy arrays support both boolean masks and integer indices).
- `safe_sqr`: Helper function for unified squaring (`**2`) of array-likes, matrices and sparse matrices.

30.3.9 Hash Functions

- `murmurhash3_32` provides a python wrapper for the `MurmurHash3_x86_32` C++ non cryptographic hash function. This hash function is suitable for implementing lookup tables, Bloom filters, Count Min Sketch, feature hashing and implicitly defined sparse random projections:

```
>>> from sklearn.utils import murmurhash3_32
>>> murmurhash3_32("some feature", seed=0) == -384616559
True

>>> murmurhash3_32("some feature", seed=0, positive=True) == 3910350737
True
```

  The `sklearn.utils.murmurhash` module can also be "cimported" from other cython modules so as to benefit from the high performance of MurmurHash while skipping the overhead of the Python interpreter.

30.3.10 Warnings and Exceptions

- `deprecated`: Decorator to mark a function or class as deprecated.
- *`sklearn.exceptions.ConvergenceWarning`*: Custom warning to catch convergence problems. Used in `sklearn.covariance.graph_lasso`.

30.4 How to optimize for speed

The following gives some practical guidelines to help you write efficient code for the scikit-learn project.

Note: While it is always useful to profile your code so as to **check performance assumptions**, it is also highly recommended to **review the literature** to ensure that the implemented algorithm is the state of the art for the task before investing into costly implementation optimization.

Times and times, hours of efforts invested in optimizing complicated implementation details have been rendered irrelevant by the subsequent discovery of simple **algorithmic tricks**, or by using another algorithm altogether that is better suited to the problem.

The section *A sample algorithmic trick: warm restarts for cross validation* gives an example of such a trick.

30.4.1 Python, Cython or C/C++?

In general, the scikit-learn project emphasizes the **readability** of the source code to make it easy for the project users to dive into the source code so as to understand how the algorithm behaves on their data but also for ease of maintainability (by the developers).

When implementing a new algorithm is thus recommended to **start implementing it in Python using Numpy and Scipy** by taking care of avoiding looping code using the vectorized idioms of those libraries. In practice this means trying to **replace any nested for loops by calls to equivalent Numpy array methods**. The goal is to avoid the CPU wasting time in the Python interpreter rather than crunching numbers to fit your statistical model. It's generally a good idea to consider NumPy and SciPy performance tips: http://scipy.github.io/old-wiki/pages/PerformanceTips

Sometimes however an algorithm cannot be expressed efficiently in simple vectorized Numpy code. In this case, the recommended strategy is the following:

1. **Profile** the Python implementation to find the main bottleneck and isolate it in a **dedicated module level function**. This function will be reimplemented as a compiled extension module.
2. If there exists a well maintained BSD or MIT **C/C++** implementation of the same algorithm that is not too big, you can write a **Cython wrapper** for it and include a copy of the source code of the library in the scikit-learn source tree: this strategy is used for the classes *svm.LinearSVC*, *svm.SVC* and *linear_model.LogisticRegression* (wrappers for liblinear and libsvm).
3. Otherwise, write an optimized version of your Python function using **Cython** directly. This strategy is used for the *linear_model.ElasticNet* and *linear_model.SGDClassifier* classes for instance.
4. **Move the Python version of the function in the tests** and use it to check that the results of the compiled extension are consistent with the gold standard, easy to debug Python version.
5. Once the code is optimized (not simple bottleneck spottable by profiling), check whether it is possible to have **coarse grained parallelism** that is amenable to **multi-processing** by using the `joblib.Parallel` class.

When using Cython, use either

$ python setup.py build_ext -i $ python setup.py install

to generate C files. You are responsible for adding .c/.cpp extensions along with build parameters in each submodule `setup.py`.

C/C++ generated files are embedded in distributed stable packages. The goal is to make it possible to install scikit-learn stable version on any machine with Python, Numpy, Scipy and C/C++ compiler.

30.4.2 Profiling Python code

In order to profile Python code we recommend to write a script that loads and prepare you data and then use the IPython integrated profiler for interactively exploring the relevant part for the code.

Suppose we want to profile the Non Negative Matrix Factorization module of the scikit. Let us setup a new IPython session and load the digits dataset and as in the *Recognizing hand-written digits* example:

```
In [1]: from sklearn.decomposition import NMF

In [2]: from sklearn.datasets import load_digits

In [3]: X = load_digits().data
```

Before starting the profiling session and engaging in tentative optimization iterations, it is important to measure the total execution time of the function we want to optimize without any kind of profiler overhead and save it somewhere for later reference:

```
In [4]: %timeit NMF(n_components=16, tol=1e-2).fit(X)
1 loops, best of 3: 1.7 s per loop
```

To have a look at the overall performance profile using the `%prun` magic command:

```
In [5]: %prun -l nmf.py NMF(n_components=16, tol=1e-2).fit(X)
         14496 function calls in 1.682 CPU seconds

   Ordered by: internal time
   List reduced from 90 to 9 due to restriction <'nmf.py'>

   ncalls  tottime  percall  cumtime  percall filename:lineno(function)
       36    0.609    0.017    1.499    0.042 nmf.py:151(_nls_subproblem)
     1263    0.157    0.000    0.157    0.000 nmf.py:18(_pos)
```

```
      1    0.053    0.053    1.681    1.681 nmf.py:352(fit_transform)
    673    0.008    0.000    0.057    0.000 nmf.py:28(norm)
      1    0.006    0.006    0.047    0.047 nmf.py:42(_initialize_nmf)
     36    0.001    0.000    0.010    0.000 nmf.py:36(_sparseness)
     30    0.001    0.000    0.001    0.000 nmf.py:23(_neg)
      1    0.000    0.000    0.000    0.000 nmf.py:337(__init__)
      1    0.000    0.000    1.681    1.681 nmf.py:461(fit)
```

The `tottime` column is the most interesting: it gives to total time spent executing the code of a given function ignoring the time spent in executing the sub-functions. The real total time (local code + sub-function calls) is given by the `cumtime` column.

Note the use of the `-l nmf.py` that restricts the output to lines that contains the "nmf.py" string. This is useful to have a quick look at the hotspot of the nmf Python module it-self ignoring anything else.

Here is the beginning of the output of the same command without the `-l nmf.py` filter:

```
In [5] %prun NMF(n_components=16, tol=1e-2).fit(X)
         16159 function calls in 1.840 CPU seconds

   Ordered by: internal time

   ncalls  tottime  percall  cumtime  percall filename:lineno(function)
     2833    0.653    0.000    0.653    0.000 {numpy.core._dotblas.dot}
       46    0.651    0.014    1.636    0.036 nmf.py:151(_nls_subproblem)
     1397    0.171    0.000    0.171    0.000 nmf.py:18(_pos)
     2780    0.167    0.000    0.167    0.000 {method 'sum' of 'numpy.ndarray'␣
↪objects}
        1    0.064    0.064    1.840    1.840 nmf.py:352(fit_transform)
     1542    0.043    0.000    0.043    0.000 {method 'flatten' of 'numpy.ndarray'␣
↪objects}
      337    0.019    0.000    0.019    0.000 {method 'all' of 'numpy.ndarray'␣
↪objects}
     2734    0.011    0.000    0.181    0.000 fromnumeric.py:1185(sum)
        2    0.010    0.005    0.010    0.005 {numpy.linalg.lapack_lite.dgesdd}
      748    0.009    0.000    0.065    0.000 nmf.py:28(norm)
...
```

The above results show that the execution is largely dominated by dot products operations (delegated to blas). Hence there is probably no huge gain to expect by rewriting this code in Cython or C/C++: in this case out of the 1.7s total execution time, almost 0.7s are spent in compiled code we can consider optimal. By rewriting the rest of the Python code and assuming we could achieve a 1000% boost on this portion (which is highly unlikely given the shallowness of the Python loops), we would not gain more than a 2.4x speed-up globally.

Hence major improvements can only be achieved by **algorithmic improvements** in this particular example (e.g. trying to find operation that are both costly and useless to avoid computing then rather than trying to optimize their implementation).

It is however still interesting to check what's happening inside the `_nls_subproblem` function which is the hotspot if we only consider Python code: it takes around 100% of the accumulated time of the module. In order to better understand the profile of this specific function, let us install `line_profiler` and wire it to IPython:

```
$ pip install line_profiler
```

- **Under IPython 0.13+**, first create a configuration profile:

  ```
  $ ipython profile create
  ```

Then register the line_profiler extension in `~/.ipython/profile_default/ipython_config.py`:

```
c.TerminalIPythonApp.extensions.append('line_profiler')
c.InteractiveShellApp.extensions.append('line_profiler')
```

This will register the `%lprun` magic command in the IPython terminal application and the other frontends such as qtconsole and notebook.

Now restart IPython and let us use this new toy:

```
In [1]: from sklearn.datasets import load_digits

In [2]: from sklearn.decomposition.nmf import _nls_subproblem, NMF

In [3]: X = load_digits().data

In [4]: %lprun -f _nls_subproblem NMF(n_components=16, tol=1e-2).fit(X)
Timer unit: 1e-06 s

File: sklearn/decomposition/nmf.py
Function: _nls_subproblem at line 137
Total time: 1.73153 s

Line #      Hits         Time  Per Hit   % Time  Line Contents
==============================================================
   137                                           def _nls_subproblem(V, W, H_init,␣
↪tol, max_iter):
   138                                               """Non-negative least square␣
↪solver
   ...
   170                                               """
   171        48         5863    122.1      0.3      if (H_init < 0).any():
   172                                                   raise ValueError("Negative␣
↪values in H_init passed to NLS solver.")
   173
   174        48          139      2.9      0.0      H = H_init
   175        48       112141   2336.3      5.8      WtV = np.dot(W.T, V)
   176        48        16144    336.3      0.8      WtW = np.dot(W.T, W)
   177
   178                                               # values justified in the paper
   179        48          144      3.0      0.0      alpha = 1
   180        48          113      2.4      0.0      beta = 0.1
   181       638         1880      2.9      0.1      for n_iter in xrange(1, max_iter␣
↪+ 1):
   182       638       195133    305.9     10.2          grad = np.dot(WtW, H) - WtV
   183       638       495761    777.1     25.9          proj_gradient = norm(grad[np.
↪logical_or(grad < 0, H > 0)])
   184       638         2449      3.8      0.1          if proj_gradient < tol:
   185        48          130      2.7      0.0              break
   186
   187      1474         4474      3.0      0.2          for inner_iter in xrange(1,␣
↪20):
   188      1474        83833     56.9      4.4              Hn = H - alpha * grad
   189                                                       # Hn = np.where(Hn > 0,␣
↪Hn, 0)
   190      1474       194239    131.8     10.1              Hn = _pos(Hn)
   191      1474        48858     33.1      2.5              d = Hn - H
   192      1474       150407    102.0      7.8              gradd = np.sum(grad * d)
   193      1474       515390    349.7     26.9              dQd = np.sum(np.dot(WtW,␣
↪d) * d)
```

```
   ...
```

By looking at the top values of the `% Time` column it is really easy to pin-point the most expensive expressions that would deserve additional care.

30.4.3 Memory usage profiling

You can analyze in detail the memory usage of any Python code with the help of memory_profiler. First, install the latest version:

```
$ pip install -U memory_profiler
```

Then, setup the magics in a manner similar to `line_profiler`.

- **Under IPython 0.11+**, first create a configuration profile:

  ```
  $ ipython profile create
  ```

  Then register the extension in `~/.ipython/profile_default/ipython_config.py` alongside the line profiler:

  ```
  c.TerminalIPythonApp.extensions.append('memory_profiler')
  c.InteractiveShellApp.extensions.append('memory_profiler')
  ```

  This will register the `%memit` and `%mprun` magic commands in the IPython terminal application and the other frontends such as qtconsole and notebook.

`%mprun` is useful to examine, line-by-line, the memory usage of key functions in your program. It is very similar to `%lprun`, discussed in the previous section. For example, from the `memory_profiler examples` directory:

```
In [1] from example import my_func

In [2] %mprun -f my_func my_func()
Filename: example.py

Line #    Mem usage  Increment   Line Contents
================================================
     3                           @profile
     4      5.97 MB    0.00 MB   def my_func():
     5     13.61 MB    7.64 MB       a = [1] * (10 ** 6)
     6    166.20 MB  152.59 MB       b = [2] * (2 * 10 ** 7)
     7     13.61 MB -152.59 MB       del b
     8     13.61 MB    0.00 MB       return a
```

Another useful magic that `memory_profiler` defines is `%memit`, which is analogous to `%timeit`. It can be used as follows:

```
In [1]: import numpy as np

In [2]: %memit np.zeros(1e7)
maximum of 3: 76.402344 MB per loop
```

For more details, see the docstrings of the magics, using `%memit?` and `%mprun?`.

30.4.4 Performance tips for the Cython developer

If profiling of the Python code reveals that the Python interpreter overhead is larger by one order of magnitude or more than the cost of the actual numerical computation (e.g. `for` loops over vector components, nested evaluation of conditional expression, scalar arithmetic...), it is probably adequate to extract the hotspot portion of the code as a standalone function in a `.pyx` file, add static type declarations and then use Cython to generate a C program suitable to be compiled as a Python extension module.

The official documentation available at http://docs.cython.org/ contains a tutorial and reference guide for developing such a module. In the following we will just highlight a couple of tricks that we found important in practice on the existing cython codebase in the scikit-learn project.

TODO: html report, type declarations, bound checks, division by zero checks, memory alignment, direct blas calls...

- https://www.youtube.com/watch?v=gMvkiQ-gOW8
- http://conference.scipy.org/proceedings/SciPy2009/paper_1/
- http://conference.scipy.org/proceedings/SciPy2009/paper_2/

30.4.5 Profiling compiled extensions

When working with compiled extensions (written in C/C++ with a wrapper or directly as Cython extension), the default Python profiler is useless: we need a dedicated tool to introspect what's happening inside the compiled extension itself.

Using yep and google-perftools

Easy profiling without special compilation options use yep:

- https://pypi.python.org/pypi/yep
- http://fa.bianp.net/blog/2011/a-profiler-for-python-extensions

---

Note: google-perftools provides a nice 'line by line' report mode that can be triggered with the `--lines` option. However this does not seem to work correctly at the time of writing. This issue can be tracked on the project issue tracker.

Using gprof

In order to profile compiled Python extensions one could use `gprof` after having recompiled the project with `gcc -pg` and using the `python-dbg` variant of the interpreter on debian / ubuntu: however this approach requires to also have `numpy` and `scipy` recompiled with `-pg` which is rather complicated to get working.

Fortunately there exist two alternative profilers that don't require you to recompile everything.

Using valgrind / callgrind / kcachegrind

TODO

30.4.6 Multi-core parallelism using `joblib.Parallel`

TODO: give a simple teaser example here.

Checkout the official joblib documentation:

- https://pythonhosted.org/joblib

30.4.7 A sample algorithmic trick: warm restarts for cross validation

TODO: demonstrate the warm restart tricks for cross validation of linear regression with Coordinate Descent.

30.5 Advanced installation instructions

There are different ways to get scikit-learn installed:

- Install the version of scikit-learn provided by your *operating system or Python distribution*. This is the quickest option for those who have operating systems that distribute scikit-learn.
- *Install an official release*. This is the best approach for users who want a stable version number and aren't concerned about running a slightly older version of scikit-learn.
- *Install the latest development version*. This is best for users who want the latest-and-greatest features and aren't afraid of running brand-new code.

Note: If you wish to contribute to the project, you need to *install the latest development version*.

30.5.1 Installing an official release

Scikit-learn requires:

- Python (>= 2.7 or >= 3.3),
- NumPy (>= 1.8.2),
- SciPy (>= 0.13.3).

Mac OSX

Scikit-learn and its dependencies are all available as wheel packages for OSX:

```
pip install -U numpy scipy scikit-learn
```

Linux

At this time scikit-learn does not provide official binary packages for Linux so you have to build from source if you want the latest version. If you don't need the newest version, consider using your package manager to install scikit-learn. It is usually the easiest way, but might not provide the newest version.

Installing build dependencies

Installing from source requires you to have installed the scikit-learn runtime dependencies, Python development headers and a working C/C++ compiler. Under Debian-based operating systems, which include Ubuntu, if you have Python 2 you can install all these requirements by issuing:

```
sudo apt-get install build-essential python-dev python-setuptools \
                     python-numpy python-scipy \
                     libatlas-dev libatlas3gf-base
```

If you have Python 3:

```
sudo apt-get install build-essential python3-dev python3-setuptools \
                     python3-numpy python3-scipy \
                     libatlas-dev libatlas3gf-base
```

On recent Debian and Ubuntu (e.g. Ubuntu 13.04 or later) make sure that ATLAS is used to provide the implementation of the BLAS and LAPACK linear algebra routines:

```
sudo update-alternatives --set libblas.so.3 \
    /usr/lib/atlas-base/atlas/libblas.so.3
sudo update-alternatives --set liblapack.so.3 \
    /usr/lib/atlas-base/atlas/liblapack.so.3
```

Note: In order to build the documentation and run the example code contains in this documentation you will need matplotlib:

```
sudo apt-get install python-matplotlib
```

Note: The above installs the ATLAS implementation of BLAS (the Basic Linear Algebra Subprograms library). Ubuntu 11.10 and later, and recent (testing) versions of Debian, offer an alternative implementation called OpenBLAS.

Using OpenBLAS can give speedups in some scikit-learn modules, but can freeze joblib/multiprocessing prior to OpenBLAS version 0.2.8-4, so using it is not recommended unless you know what you're doing.

If you do want to use OpenBLAS, then replacing ATLAS only requires a couple of commands. ATLAS has to be removed, otherwise NumPy may not work:

```
sudo apt-get remove libatlas3gf-base libatlas-dev
sudo apt-get install libopenblas-dev

sudo update-alternatives  --set libblas.so.3 \
    /usr/lib/openblas-base/libopenblas.so.0
sudo update-alternatives --set liblapack.so.3 \
    /usr/lib/lapack/liblapack.so.3
```

On Red Hat and clones (e.g. CentOS), install the dependencies using:

```
sudo yum -y install gcc gcc-c++ numpy python-devel scipy
```

Building scikit-learn with pip

This is usually the fastest way to install or upgrade to the latest stable release:

```
pip install --user --install-option="--prefix=" -U scikit-learn
```

The `--user` flag asks pip to install scikit-learn in the `$HOME/.local` folder therefore not requiring root permission. This flag should make pip ignore any old version of scikit-learn previously installed on the system while benefiting from system packages for numpy and scipy. Those dependencies can be long and complex to build correctly from source.

The `--install-option="--prefix="` flag is only required if Python has a `distutils.cfg` configuration with a predefined `prefix=` entry.

From source package

download the source package from pypi, unpack the sources and cd into the source directory.

This packages uses distutils, which is the default way of installing python modules. The install command is:

```
python setup.py install
```

or alternatively (also from within the scikit-learn source folder):

```
pip install .
```

Warning: Packages installed with the `python setup.py install` command cannot be uninstalled nor upgraded by `pip` later. To properly uninstall scikit-learn in that case it is necessary to delete the `sklearn` folder from your Python `site-packages` directory.

Windows

First, you need to install numpy and scipy from their own official installers.

Wheel packages (.whl files) for scikit-learn from pypi can be installed with the pip utility. Open a console and type the following to install or upgrade scikit-learn to the latest stable release:

```
pip install -U scikit-learn
```

If there are no binary packages matching your python, version you might to try to install scikit-learn and its dependencies from christoph gohlke unofficial windows installers or from a *python distribution* instead.

30.5.2 Third party distributions of scikit-learn

Some third-party distributions are now providing versions of scikit-learn integrated with their package-management systems.

These can make installation and upgrading much easier for users since the integration includes the ability to automatically install dependencies (numpy, scipy) that scikit-learn requires.

The following is an incomplete list of python and os distributions that provide their own version of scikit-learn.

MacPorts for Mac OSX

The MacPorts package is named `py<XY>-scikits-learn`, where `XY` denotes the Python version. It can be installed by typing the following command:

```
sudo port install py26-scikit-learn
```

or:

```
sudo port install py27-scikit-learn
```

Arch Linux

Arch Linux's package is provided through the official repositories as `python-scikit-learn` for Python 3 and `python2-scikit-learn` for Python 2. It can be installed by typing the following command:

```
# pacman -S python-scikit-learn
```

or:

```
# pacman -S python2-scikit-learn
```

depending on the version of Python you use.

NetBSD

scikit-learn is available via pkgsrc-wip:

http://pkgsrc.se/wip/py-scikit_learn

Fedora

The Fedora package is called `python-scikit-learn` for the Python 2 version and `python3-scikit-learn` for the Python 3 version. Both versions can be installed using `yum`:

```
$ sudo yum install python-scikit-learn
```

or:

```
$ sudo yum install python3-scikit-learn
```

Building on windows

To build scikit-learn on Windows you need a working C/C++ compiler in addition to numpy, scipy and setuptools.

Picking the right compiler depends on the version of Python (2 or 3) and the architecture of the Python interpreter, 32-bit or 64-bit. You can check the Python version by running the following in `cmd` or `powershell` console:

```
python --version
```

and the architecture with:

```
python -c "import struct; print(struct.calcsize('P') * 8)"
```

The above commands assume that you have the Python installation folder in your PATH environment variable.

32-bit Python

For 32-bit python it is possible use the standalone installers for microsoft visual c++ express 2008 for Python 2 or Microsoft Visual C++ Express 2010 for Python 3.

Once installed you should be able to build scikit-learn without any particular configuration by running the following command in the scikit-learn folder:

```
python setup.py install
```

64-bit Python

For the 64-bit architecture, you either need the full Visual Studio or the free Windows SDKs that can be downloaded from the links below.

The Windows SDKs include the MSVC compilers both for 32 and 64-bit architectures. They come as a `GRMSDKX_EN_DVD.iso` file that can be mounted as a new drive with a `setup.exe` installer in it.

- For Python 2 you need SDK **v7.0**: MS Windows SDK for Windows 7 and .NET Framework 3.5 SP1
- For Python 3 you need SDK **v7.1**: MS Windows SDK for Windows 7 and .NET Framework 4

Both SDKs can be installed in parallel on the same host. To use the Windows SDKs, you need to setup the environment of a `cmd` console launched with the following flags (at least for SDK v7.0):

```
cmd /E:ON /V:ON /K
```

Then configure the build environment with:

```
SET DISTUTILS_USE_SDK=1
SET MSSdk=1
"C:\Program Files\Microsoft SDKs\Windows\v7.0\Setup\WindowsSdkVer.exe" -q -version:v7.
↪0
"C:\Program Files\Microsoft SDKs\Windows\v7.0\Bin\SetEnv.cmd" /x64 /release
```

Finally you can build scikit-learn in the same `cmd` console:

```
python setup.py install
```

Replace `v7.0` by the `v7.1` in the above commands to do the same for Python 3 instead of Python 2.

Replace `/x64` by `/x86` to build for 32-bit Python instead of 64-bit Python.

Building binary packages and installers

The `.whl` package and `.exe` installers can be built with:

```
pip install wheel
python setup.py bdist_wheel bdist_wininst -b doc/logos/scikit-learn-logo.bmp
```

The resulting packages are generated in the `dist/` folder.

Using an alternative compiler

It is possible to use MinGW (a port of GCC to Windows OS) as an alternative to MSVC for 32-bit Python. Not that extensions built with mingw32 can be redistributed as reusable packages as they depend on GCC runtime libraries typically not installed on end-users environment.

To force the use of a particular compiler, pass the `--compiler` flag to the build step:

```
python setup.py build --compiler=my_compiler install
```

where `my_compiler` should be one of `mingw32` or `msvc`.

30.5.3 Bleeding Edge

See section *Retrieving the latest code* on how to get the development version. Then follow the previous instructions to build from source depending on your platform. You will also require Cython >=0.23 in order to build the development version.

30.5.4 Testing

Testing scikit-learn once installed

Testing requires having the nose library. After installation, the package can be tested by executing *from outside* the source directory:

```
$ nosetests -v sklearn
```

Under Windows, it is recommended to use the following command (adjust the path to the `python.exe` program) as using the `nosetests.exe` program can badly interact with tests that use `multiprocessing`:

```
C:\Python34\python.exe -c "import nose; nose.main()" -v sklearn
```

This should give you a lot of output (and some warnings) but eventually should finish with a message similar to:

```
Ran 3246 tests in 260.618s
OK (SKIP=20)
```

Otherwise, please consider posting an issue into the bug tracker or to the *Mailing List* including the traceback of the individual failures and errors. Please include your operating system, your version of NumPy, SciPy and scikit-learn, and how you installed scikit-learn.

Testing scikit-learn from within the source folder

Scikit-learn can also be tested without having the package installed. For this you must compile the sources inplace from the source directory:

```
python setup.py build_ext --inplace
```

Test can now be run using nosetests:

```
nosetests -v sklearn/
```

This is automated by the commands:

```
make in
```

and:

```
make test
```

You can also install a symlink named `site-packages/scikit-learn.egg-link` to the development folder of scikit-learn with:

```
pip install --editable .
```

30.6 Maintainer / core-developer information

For more information see https://github.com/scikit-learn/scikit-learn/wiki/How-to-make-a-release

30.6.1 Making a release

1. Update docs:
   - edit the doc/whats_new.rst file to add release title and commit statistics. You can retrieve commit statistics with:

     ```
     $ git shortlog -ns 0.998..
     ```

   - edit the doc/conf.py to increase the version number
   - edit the doc/themes/scikit-learn/layout.html to change the 'News' entry of the front page.
2. Update the version number in sklearn/__init__.py, the __version__ variable
3. Create the tag and push it:

   ```
   $ git tag 0.999

   $ git push origin --tags
   ```

4. create tarballs:
   - Wipe clean your repo:

     ```
     $ git clean -xfd
     ```

   - Register and upload on PyPI:

     ```
     $ python setup.py sdist register upload
     ```

   - Upload manually the tarball on SourceForge: https://sourceforge.net/projects/scikit-learn/files/
5. Push the documentation to the website (see README in doc folder)
6. Build binaries for windows and push them to PyPI:

   ```
   $ python setup.py bdist_wininst upload
   ```

   And upload them also to sourceforge
7. FOR FINAL RELEASE: Update the release date in What's New
