Release Information

The following releases of this document have been made.

Release history

Date	Issue	Confidentiality	Change
30 April 2013	A.a-1	Confidential-Beta Draft	Beta draft of first issue, limited circulation
12 June 2013	A.a-2	Confidential-Beta Draft	Second beta draft of first issue, limited circulation
04 September 2013	A.a	Non-Confidential Beta	Beta release.
24 December 2013	A.b	Non-Confidential Beta	Second beta release.
18 July 2014	A.c	Non-Confidential Beta	Third beta release.
09 October 2014	A.d	Non-Confidential Beta	Fourth beta release.
17 December 2014	A.e	Non-Confidential Beta	Fifth beta release.
25 March 2015	A.f	Non-Confidential Beta	Sixth beta release.
10 July 2015	A.g	Non-Confidential Beta	Seventh beta release.
30 September 2015	A.h	Non-Confidential Beta	Eighth beta release.
28 January 2016	A.i	Non-Confidential Beta	Ninth beta release.
03 June 2016	A.j	Non-Confidential EAC	EAC release.
30 September 2016	A.k	Non-Confidential v8.0 EAC	Updated EAC release.
31 March 2017	B.a	Non-Confidential v8.1 EAC, v8.2 Beta	Initial release incorporating ARMv8.1 and ARMv8.2.
26 September 2017	B.b	Non-Confidential v8.2 EAC	Initial v8.2 EAC release, incorporating SPE.
20 December 2017	C.a	Non-Confidential v8.3 EAC	Initial v8.3 EAC release.

Arm Limited. Company 02557590 registered in England.
110 Fulbourn Road, Cambridge, England CB1 9NJ.

LES-PRE-20349

In this document, where the term ARM is used to refer to the company it means “Arm or any of its subsidiaries as appropriate”.

Note

- The term ARM can refer to versions of the ARM architecture, for example ARMv8 refers to version 8 of the ARM architecture. The context makes it clear when the term is used in this way.
- This document describes only the ARMv8-A architecture profile. For the behaviors required by the previous version of this architecture profile, ARMv7-A, see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

Confidentiality Status

This document is Non-Confidential. The right to use, copy and disclose this document may be subject to license restrictions in accordance with the terms of the agreement entered into by ARM and the party that ARM delivered this document to.

Product Status

The information in this document is final, that is for a developed product.

Web Address

`http://www.arm.com`

Limitations of this issue

This issue of the ARMv8 Architecture Reference Manual contains many improvements and corrections. Validation of this document has identified the following issues that ARM will address in future issues:

- Appendix K12 *ARM Pseudocode Definition* requires further review and update. Since this appendix is informative, rather than being part of the architecture specification, this does not affect the quality status of this release.

Contents
ARM Architecture Reference Manual ARMv8, for ARMv8-A architecture profile

Preface
About this manual xvi
Using this manual xviii
Conventions xxiv
Additional reading xxvi
Feedback xxvii

Part A ARMv8 Architecture Introduction and Overview

Chapter A1 Introduction to the ARMv8 Architecture
A1.1 About the ARM architecture A1-32
A1.2 Architecture profiles A1-34
A1.3 ARMv8 architectural concepts A1-36
A1.4 Supported data types A1-40
A1.5 Advanced SIMD and floating-point support A1-50
A1.6 The ARM memory model A1-56
A1.7 ARMv8 architecture extensions A1-57

Part B The AArch64 Application Level Architecture

Chapter B1 The AArch64 Application Level Programmers' Model
B1.1 About the Application level programmers' model B1-76
B1.2 Registers in AArch64 Execution state B1-77
B1.3 Software control features and EL0 ..... B1-82

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Chapter B2 **The AArch64 Application Level Memory Model**
B2.1 About the ARM memory model B2-86
B2.2 Atomicity in the ARM architecture B2-88
B2.3 Definition of the ARMv8 memory model B2-92
B2.4 Caches and memory hierarchy B2-104
B2.5 Alignment support B2-109
B2.6 Endian support B2-111
B2.7 Memory types and attributes B2-114
B2.8 Mismatched memory attributes B2-125
B2.9 Synchronization and semaphores B2-128

Part C The AArch64 Instruction Set

Chapter C1 **The A64 Instruction Set**
C1.1 About the A64 instruction set C1-142
C1.2 Structure of the A64 assembler language C1-143
C1.3 Address generation C1-149
C1.4 Instruction aliases C1-152

Chapter C2 **About the A64 Instruction Descriptions**
C2.1 Understanding the A64 instruction descriptions C2-154
C2.2 General information about the A64 instruction descriptions C2-157

Chapter C3 **A64 Instruction Set Overview**
C3.1 Branches, Exception generating, and System instructions C3-162
C3.2 Loads and stores C3-169
C3.3 Data processing - immediate C3-185
C3.4 Data processing - register C3-190
C3.5 Data processing - SIMD and floating-point C3-198

Chapter C4 **A64 Instruction Set Encoding**
C4.1 A64 instruction set encoding C4-224

Chapter C5 **The A64 System Instruction Class**
C5.1 The System instruction class encoding space C5-328
C5.2 Special-purpose registers C5-339
C5.3 A64 System instructions for cache maintenance C5-409
C5.4 A64 system instructions for address translation C5-432
C5.5 A64 System instructions for TLB maintenance C5-459

Chapter C6 **A64 Base Instruction Descriptions**
C6.1 About the A64 base instructions C6-524
C6.2 Alphabetical list of A64 base instructions C6-526

Chapter C7 **A64 Advanced SIMD and Floating-point Instruction Descriptions**
C7.1 About the A64 SIMD and floating-point instructions C7-1006
C7.2 Alphabetical list of A64 Advanced SIMD and floating-point instructions C7-1008

Part D The AArch64 System Level Architecture

Chapter D1 **The AArch64 System Level Programmers' Model**
D1.1 Exception levels D1-1850
D1.2 Exception terminology D1-1851
D1.3 Execution state D1-1853
D1.4 Security state D1-1854

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

D1.5 Virtualization D1-1856
D1.6 Registers for instruction processing and exception handling D1-1859
D1.7 Process state, PSTATE D1-1865
D1.8 Program counter and stack pointer alignment D1-1868
D1.9 Reset D1-1870
D1.10 Exception entry D1-1874
D1.11 Exception return D1-1883
D1.12 The Exception level hierarchy D1-1887
D1.13 Synchronous exception types, routing and priorities D1-1894
D1.14 Asynchronous exception types, routing, masking and priorities D1-1902
D1.15 Configurable instruction enables and disables, and trap controls D1-1910
D1.16 System calls D1-1953
D1.17 Mechanisms for entering a low-power state D1-1954
D1.18 Self-hosted debug D1-1959
D1.19 The Performance Monitors Extension D1-1961
D1.20 Interprocessing D1-1962
D1.21 The effect of implementation choices on the programmers' model D1-1974

Chapter D2 AArch64 Self-hosted Debug

D2.1 About self-hosted debug D2-1980
D2.2 The debug exception enable controls D2-1984
D2.3 Routing debug exceptions D2-1985
D2.4 Enabling debug exceptions from the current Exception level and Security state D2-1987
D2.5 The effect of powerdown on debug exceptions D2-1989
D2.6 Summary of the routing and enabling of debug exceptions D2-1990
D2.7 Pseudocode description of debug exceptions D2-1992
D2.8 Breakpoint Instruction exceptions D2-1993
D2.9 Breakpoint exceptions D2-1995
D2.10 Watchpoint exceptions D2-2016
D2.11 Vector Catch exceptions D2-2031
D2.12 Software Step exceptions D2-2032
D2.13 Synchronization and debug exceptions D2-2046

Chapter D3 The AArch64 System Level Memory Model

D3.1 About the memory system architecture D3-2048
D3.2 Address space D3-2049
D3.3 Mixed-endian support D3-2050
D3.4 Cache support D3-2051
D3.5 External aborts D3-2074
D3.6 Memory barrier instructions D3-2076
D3.7 Pseudocode description of general memory system instructions D3-2077

Chapter D4 The AArch64 Virtual Memory System Architecture

D4.1 About the Virtual Memory System Architecture (VMSA) D4-2082
D4.2 The VMSAv8-64 address translation system D4-2091
D4.3 VMSAv8-64 translation table format descriptors D4-2143
D4.4 Memory access control D4-2155
D4.5 Memory region attributes D4-2174
D4.6 Virtualization Host Extensions D4-2183
D4.7 Nested virtualization D4-2188
D4.8 VMSAv8-64 memory aborts D4-2191
D4.9 Translation Lookaside Buffers (TLBs) D4-2201
D4.10 TLB maintenance requirements and the TLB maintenance instructions D4-2207
D4.11 Caches in a VMSAv8-64 implementation D4-2221

Chapter D5 The Performance Monitors Extension

D5.1 About the Performance Monitors D5-2226

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

D5.2 Accuracy of the Performance Monitors D5-2228
D5.3 Behavior on overflow D5-2230
D5.4 Attributability D5-2232
D5.5 Effect of EL3 and EL2 ..... D5-2233
D5.6 Event filtering D5-2235
D5.7 Performance Monitors and Debug state D5-2237
D5.8 Counter enables D5-2238
D5.9 Counter access D5-2239
D5.10 PMU events and event numbers D5-2240
D5.11 Performance Monitors Extension registers D5-2268

Chapter D6 The Statistical Profiling Extension
D6.1 Statistical Profiling D6-2272
D6.2 Programmers' Model D6-2280
D6.3 Enable and Filtering controls D6-2283
D6.4 Profiling Buffer management interrupt D6-2289

Chapter D7 Statistical Profiling Extension Sample Record Specification
D7.1 About the Statistical Profiling Extension Sample Records D7-2296
D7.2 Alphabetical list of Statistical Profiling Extension packets D7-2299

Chapter D8 The Generic Timer in AArch64 state
D8.1 About the Generic Timer D8-2322
D8.2 The AArch64 view of the Generic Timer D8-2326

Chapter D9 AArch64 System Register Encoding
D9.1 The System register encoding space D9-2332
D9.2 op0==0b10, Moves to and from debug and trace System registers D9-2333
D9.3 op0==0b11, Moves to and from non-debug System registers, Special-purpose registers D9-2335

Chapter D10 AArch64 System Register Descriptions
D10.1 About the AArch64 System registers D10-2348
D10.2 General system control registers D10-2357
D10.3 Debug registers D10-2765
D10.4 Performance Monitors registers D10-2840
D10.5 Statistical Profiling Extension registers D10-2885
D10.6 Generic Timer registers D10-2917

Part E The AArch32 Application Level Architecture

Chapter E1 The AArch32 Application Level Programmers' Model
E1.1 About the Application level programmers' model E1-2978
E1.2 The Application level programmers' model in AArch32 state E1-2979
E1.3 Advanced SIMD and floating-point instructions E1-2990
E1.4 About the AArch32 System register interface E1-3001
E1.5 Exceptions E1-3002

Chapter E2 The AArch32 Application Level Memory Model
E2.1 About the ARM memory model E2-3004
E2.2 Atomicity in the ARM architecture E2-3006
E2.3 Definition of the ARMv8 memory model E2-3011
E2.4 Caches and memory hierarchy E2-3022
E2.5 Alignment support E2-3027
E2.6 Endian support E2-3029
E2.7 Memory types and attributes E2-3032
E2.8 Mismatched memory attributes E2-3042

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

E2.9 Synchronization and semaphores E2-3045

Part F The AArch32 Instruction Sets

Chapter F1 The AArch32 Instruction Sets Overview

F1.1 Support for instructions in different versions of the ARM architecture F1-3058
F1.2 Unified Assembler Language F1-3059
F1.3 Branch instructions F1-3061
F1.4 Data-processing instructions F1-3062
F1.5 PSTATE and banked register access instructions F1-3070
F1.6 Load/store instructions F1-3071
F1.7 Load/store multiple instructions F1-3074
F1.8 Miscellaneous instructions F1-3075
F1.9 Exception-generating and exception-handling instructions F1-3077
F1.10 System register access instructions F1-3079
F1.11 Advanced SIMD and floating-point load/store instructions F1-3080
F1.12 Advanced SIMD and floating-point register transfer instructions F1-3082
F1.13 Advanced SIMD data-processing instructions F1-3083
F1.14 Floating-point data-processing instructions F1-3093

Chapter F2 About the T32 and A32 Instruction Descriptions

F2.1 Format of instruction descriptions F2-3096
F2.2 Standard assembler syntax fields F2-3100
F2.3 Conditional execution F2-3101
F2.4 Shifts applied to a register F2-3104
F2.5 Memory accesses F2-3106
F2.6 Encoding of lists of general-purpose registers and the PC F2-3107
F2.7 General information about the T32 and A32 instruction descriptions F2-3108
F2.8 Additional pseudocode support for instruction descriptions F2-3121
F2.9 Additional information about Advanced SIMD and floating-point instructions .. F2-3122

Chapter F3 T32 Instruction Set Encoding

F3.1 T32 instruction set encoding F3-3130
F3.2 About the T32 Advanced SIMD and floating-point instructions and their encoding F3-3196

Chapter F4 A32 Instruction Set Encoding

F4.1 A32 instruction set encoding F4-3198
F4.2 About the A32 Advanced SIMD and floating-point instructions and their encoding F4-3256

Chapter F5 T32 and A32 Base Instruction Set Instruction Descriptions

F5.1 Alphabetical list of T32 and A32 base instruction set instructions F5-3258
F5.2 Encoding and use of banked register transfer instructions F5-3928

Chapter F6 T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions

F6.1 Alphabetical list of Advanced SIMD and floating-point instructions F6-3934

Part G The AArch32 System Level Architecture

Chapter G1 The AArch32 System Level Programmers' Model

G1.1 About the AArch32 System level programmers' model G1-4590
G1.2 Exception levels G1-4591
G1.3 Exception terminology G1-4592
G1.4 Execution state G1-4594
G1.5 Instruction Set state G1-4596

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

G1.6 Security state G1-4597
G1.7 Security state, Exception levels, and AArch32 execution privilege G1-4600
G1.8 Virtualization G1-4602
G1.9 AArch32 PE modes, and general-purpose and Special-purpose registers G1-4604
G1.10 Process state, PSTATE G1-4614
G1.11 Instruction set states G1-4620
G1.12 Handling exceptions that are taken to an Exception level using AArch32 ..... G1-4622
G1.13 Routing of aborts taken to AArch32 state G1-4642
G1.14 Exception return to an Exception level using AArch32 ..... G1-4645
G1.15 Asynchronous exception behavior for exceptions taken from AArch32 state . G1-4650
G1.16 AArch32 state exception descriptions G1-4661
G1.17 Reset into AArch32 state G1-4684
G1.18 Mechanisms for entering a low-power state G1-4688
G1.19 The AArch32 System register interface G1-4693
G1.20 Advanced SIMD and floating-point support G1-4696
G1.21 Configurable instruction enables and disables, and trap controls G1-4702

Chapter G2 AArch32 Self-hosted Debug

G2.1 About self-hosted debug G2-4738
G2.2 The debug exception enable controls G2-4742
G2.3 Routing debug exceptions G2-4743
G2.4 Enabling debug exceptions from the current Privilege level and Security state G2-4745
G2.5 The effect of powerdown on debug exceptions G2-4747
G2.6 Summary of permitted routing and enabling of debug exceptions G2-4748
G2.7 Pseudocode description of debug exceptions G2-4750
G2.8 Breakpoint Instruction exceptions G2-4751
G2.9 Breakpoint exceptions G2-4754
G2.10 Watchpoint exceptions G2-4781
G2.11 Vector Catch exceptions G2-4795
G2.12 Synchronization and debug exceptions G2-4803

Chapter G3 The AArch32 System Level Memory Model

G3.1 About the memory system architecture G3-4806
G3.2 Address space G3-4807
G3.3 Mixed-endian support G3-4808
G3.4 AArch32 cache and branch predictor support G3-4809
G3.5 System register support for IMPLEMENTATION DEFINED memory features G3-4834
G3.6 External aborts G3-4835
G3.7 Memory barrier instructions G3-4837
G3.8 Pseudocode description of general memory system instructions G3-4838

Chapter G4 The AArch32 Virtual Memory System Architecture

G4.1 About VMSAv8-32 ..... G4-4842
G4.2 The effects of disabling address translation stages on VMSAv8-32 behavior G4-4850
G4.3 Translation tables G4-4854
G4.4 The VMSAv8-32 Short-descriptor translation table format G4-4859
G4.5 The VMSAv8-32 Long-descriptor translation table format G4-4868
G4.6 Memory access control G4-4888
G4.7 Memory region attributes G4-4899
G4.8 Translation Lookaside Buffers (TLBs) G4-4911
G4.9 TLB maintenance requirements G4-4915
G4.10 Caches in VMSAv8-32 ..... G4-4929
G4.11 VMSAv8-32 memory aborts G4-4932
G4.12 Exception reporting in a VMSAv8-32 implementation G4-4944
G4.13 Address translation instructions G4-4963
G4.14 Pseudocode description of VMSAv8-32 memory system operations G4-4970
G4.15 About the System registers for VMSAv8-32 ..... G4-4972
G4.16 Functional grouping of VMSAv8-32 System registers G4-4977

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Chapter G5 **The Generic Timer in AArch32 state**
G5.1 About the Generic Timer in AArch32 state G5-4980
G5.2 The AArch32 view of the Generic Timer G5-4984

Chapter G6 **AArch32 System Register Encoding**
G6.1 The AArch32 System register encoding space G6-4992
G6.2 VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space G6-4993
G6.3 VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space G6-4996

Chapter G7 **AArch32 System Register Descriptions**
G7.1 About the AArch32 System registers G7-5012
G7.2 General system control registers G7-5027
G7.3 Debug registers G7-5502
G7.4 Performance Monitors registers G7-5594
G7.5 Generic Timer registers G7-5646

Part H External Debug

Chapter H1 **About External Debug**
H1.1 Introduction to external debug H1-5692
H1.2 External debug H1-5693
H1.3 Required debug authentication H1-5694

Chapter H2 **Debug State**
H2.1 About Debug state H2-5696
H2.2 Halting the PE on debug events H2-5697
H2.3 Entering Debug state H2-5704
H2.4 Behavior in Debug state H2-5707
H2.5 Exiting Debug state H2-5733

Chapter H3 **Halting Debug Events**
H3.1 Introduction to Halting debug events H3-5736
H3.2 Halting Step debug events H3-5738
H3.3 Halt Instruction debug event H3-5748
H3.4 Exception Catch debug event H3-5749
H3.5 External Debug Request debug event H3-5752
H3.6 OS Unlock Catch debug event H3-5753
H3.7 Reset Catch debug events H3-5754
H3.8 Software Access debug event H3-5755
H3.9 Synchronization and Halting debug events H3-5756

Chapter H4 **The Debug Communication Channel and Instruction Transfer Register**
H4.1 Introduction H4-5760
H4.2 DCC and ITR registers H4-5761
H4.3 DCC and ITR access modes H4-5764
H4.4 Flow control of the DCC and ITR registers H4-5768
H4.5 Synchronization of DCC and ITR accesses H4-5772
H4.6 Interrupt-driven use of the DCC H4-5778
H4.7 Pseudocode description of the operation of the DCC and ITR registers H4-5779

Chapter H5 **The Embedded Cross-Trigger Interface**
H5.1 About the Embedded Cross-Trigger (ECT) H5-5782
H5.2 Basic operation on the ECT H5-5784
H5.3 Cross-triggers on a PE in an ARMv8 implementation H5-5788

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

H5.4 Description and allocation of CTI triggers H5-5789
H5.5 CTI registers programmers' model H5-5793
H5.6 Examples H5-5794

Chapter H6 Debug Reset and Powerdown Support
H6.1 About Debug over powerdown H6-5798
H6.2 Power domains and debug H6-5799
H6.3 Core power domain power states H6-5800
H6.4 Emulating low-power states H6-5803
H6.5 Debug OS Save and Restore sequences H6-5805
H6.6 Reset and debug H6-5809

Chapter H7 The PC Sample-based Profiling Extension
H7.1 About the PC Sample-based Profiling Extension H7-5812

Chapter H8 About the External Debug Registers
H8.1 Relationship between external debug and System registers H8-5816
H8.2 Endianness and supported access sizes H8-5817
H8.3 Synchronization of changes to the external debug registers H8-5818
H8.4 Memory-mapped accesses to the external debug interface H8-5822
H8.5 External debug interface register access permissions H8-5824
H8.6 External debug interface registers H8-5828
H8.7 Cross-trigger interface registers H8-5833
H8.8 External debug register resets H8-5835

Chapter H9 External Debug Register Descriptions
H9.1 About the debug registers H9-5840
H9.2 External debug registers H9-5841
H9.3 Cross-Trigger Interface registers H9-5942

Part I Memory-mapped Components of the ARMv8 Architecture

Chapter I1 Requirements for Memory-mapped Components
I1.1 Supported access sizes I1-5988
I1.2 Synchronization of memory-mapped registers I1-5990

Chapter I2 System Level Implementation of the Generic Timer
I2.1 About the Generic Timer specification I2-5994
I2.2 Memory-mapped counter module I2-5996
I2.3 Memory-mapped timer components I2-6000

Chapter I3 Recommended External Interface to the Performance Monitors
I3.1 About the external interface to the Performance Monitors registers I3-6006

Chapter I4 External System Control Register Descriptions
I4.1 About the external system control register descriptions I4-6014
I4.2 External Performance Monitors registers summary I4-6015

Preface

This preface introduces the *ARM Architecture Reference Manual, ARMv8, for ARMv8-A architecture profile*. It contains the following sections:

- *About this manual* on page xvi.
- *Using this manual* on page xviii.
- *Conventions* on page xxiv.
- *Additional reading* on page xxvi.
- *Feedback* on page xxvii.

Note

This document describes only the ARMv8-A architecture profile. For the behaviors required by the ARMv7-A and ARMv7-R architecture profiles, see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

Non-Confidential

About this manual

This manual describes the ARM® architecture v8, ARMv8. The architecture describes the operation of an ARMv8-A *Processing element (PE)*, and this manual includes descriptions of:

- The two Execution states, AArch64 and AArch32.
- The instruction sets:
  - In AArch32 state, the A32 and T32 instruction sets, that are compatible with earlier versions of the ARM architecture.
  - In AArch64 state, the A64 instruction set.
- The states that determine how a PE operates, including the current Exception level and Security state, and in AArch32 state the PE mode.
- The Exception model.
- The interprocessing model, that supports transitioning between AArch64 state and AArch32 state.
- The memory model, that defines memory ordering and memory management. This manual covers a single architecture profile, ARMv8-A, that defines a *Virtual Memory System Architecture* (VMSA).
- The programmers' model, and its interfaces to System registers that control most PE and memory system features, and provide status information.
- The Advanced SIMD and floating-point instructions, that provide high-performance:
  - Single-precision, half-precision, and double-precision floating-point operations.
  - Conversions between double-precision, single-precision, and half-precision floating-point values.
  - Integer, single-precision floating-point, half-precision floating-point, and in A64, double-precision vector operations in all instruction sets.
  - Single-precision, half-precision, and double-precision floating-point vector operations in the A64 instruction set.
- The security model, that provides two security states to support secure applications.
- The virtualization model, that support the virtualization of Non-secure operation.
- The Debug architecture, that provides software access to debug features.

This manual gives the assembler syntax for the instructions it describes, meaning that it describes instructions in textual form. However, this manual is not a tutorial for ARM assembler language, nor does it describe ARM assembler language, except at a very basic level. To make effective use of ARM assembler language, read the documentation supplied with the assembler being used.

This manual is organized into parts:

Part A Provides an introduction to the ARMv8-A architecture, and an overview of the AArch64 and AArch32 Execution states.

Part B Describes the application level view of the AArch64 Execution state, meaning the view from EL0. It describes the application level view of the programmers' model and the memory model.

Part C Describes the A64 instruction set, that is available in the AArch64 Execution state. The descriptions for each instruction also include the precise effects of each instruction when executed at EL0, described as *unprivileged* execution, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate ARM machine code.

Part D Describes the system level view of the AArch64 Execution state. It includes details of the System registers, most of which are not accessible from EL0, and the system level view of the programmers' model and the memory model. This part includes the description of self-hosted debug.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Part E Describes the application level view of the AArch32 Execution state, meaning the view from the EL0. It describes the application level view of the programmers' model and the memory model.

Note

In AArch32 state, execution at EL0 is execution in User mode.

Part F Describes the T32 and A32 instruction sets, that are available in the AArch32 Execution state. These instruction sets are backwards-compatible with earlier versions of the ARM architecture. This part describes the precise effects of each instruction when executed in User mode, described as *unprivileged* execution or execution at EL0, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate ARM machine code.

Note

User mode is the only mode where software execution is unprivileged.

Part G Describes the system level view of the AArch32 Execution state, that is generally compatible with earlier versions of the ARM architecture. This part includes details of the System registers, most of which are not accessible from EL0, and the instruction interface to those registers. It also describes the system level view of the programmers' model and the memory model.

Part H Describes the Debug architecture for external debug. This provides configuration, breakpoint and watchpoint support, and a *Debug Communications Channel* (DCC) to a debug host.

Part I Describes additional features of the architecture that are not closely coupled to a *processing element* (PE), and therefore are accessed through memory-mapped interfaces. Some of these features are OPTIONAL.

Part J Provides pseudocode that describes various features of the ARMv8 architecture.

Part K, Appendixes

Provide additional information. Some appendixes give information that is not part of the ARMv8 architectural requirements. The cover page of each appendix indicates its status.

Glossary Defines terms used in this document that have a specialized meaning.

Note

Terms that are generally well understood in the microelectronics industry are not included in the Glossary.

Using this manual

The information in this manual is organized into parts, as described in this section.

Part A, Introduction and Architecture Overview

Part A gives an overview of the ARMv8-A architecture profile, including its relationship to the other ARM PE architectures. It introduces the terminology used to describe the architecture, and gives an overview of the Executions states, AArch64 and AArch32. It contains the following chapter:

Chapter A1 ***Introduction to the ARMv8 Architecture***

Read this for an introduction to the ARMv8 architecture.

Part B, The AArch64 Application Level Architecture

Part B describes the AArch64 state application level view of the architecture. It contains the following chapters:

Chapter B1 ***The AArch64 Application Level Programmers' Model***

Read this for an application level description of the programmers' model for software executing in AArch64 state. It describes execution at EL0 when EL0 is using AArch64 state.

Chapter B2 ***The AArch64 Application Level Memory Model***

Read this for an application level description of the memory model for software executing in AArch64 state. It describes the memory model for execution in EL0 when EL0 is using AArch64 state. It includes information about ARM memory types, attributes, and memory access controls.

Part C, The A64 Instruction Set

Part C describes the A64 instruction set, that is used in AArch64 state. It contains the following chapters:

Chapter C1 ***The A64 Instruction Set***

Read this for a description of the A64 instruction set and common instruction operation details.

Chapter C2 ***About the A64 Instruction Descriptions***

Read this to understand the format of the A64 instruction descriptions.

Chapter C3 ***A64 Instruction Set Overview***

Read this for an overview of the individual A64 instructions, that are divided into five functional groups.

Chapter C4 ***A64 Instruction Set Encoding***

Read this for a description of the A64 instruction set encoding.

Chapter C5 ***The A64 System Instruction Class***

Read this for a description of the AArch64 system instructions and register descriptions, and the system instruction class encoding space.

Chapter C6 ***A64 Base Instruction Descriptions***

Read this for information on key aspects of the A64 base instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Chapter C7 ***A64 Advanced SIMD and Floating-point Instruction Descriptions***

Read this for information on key aspects of the A64 Advanced SIMD and floating-point instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Part D, The AArch64 System Level Architecture

Part D describes the AArch64 state system level view of the architecture. It contains the following chapters:

Chapter D1 ***The AArch64 System Level Programmers' Model***

Read this for a description of the AArch64 state system level view of the programmers' model.

Chapter D2 ***AArch64 Self-hosted Debug***

Read this for an introduction to, and a description of, self-hosted debug in AArch64 state.

Chapter D3 ***The AArch64 System Level Memory Model***

Read this for a description of the AArch64 state system level view of the general features of the memory system.

Chapter D4 ***The AArch64 Virtual Memory System Architecture***

Read this for a system level view of the AArch64 Virtual Memory System Architecture (VMSA), the memory system architecture of an ARMv8 implementation that is executing in AArch64 state.

Chapter D5 ***The Performance Monitors Extension***

Read this for a description of an implementation of the ARM Performance Monitors, that are an optional non-invasive debug component.

Chapter D6 ***The Statistical Profiling Extension***

Read this for a description of an implementation of the Statistical Profiling Extension, that is an optional AArch64 state non-invasive debug component.

Chapter D7 ***Statistical Profiling Extension Sample Record Specification***

Read this for a description the sample records generated by the Statistical Profiling Extension.

Chapter D8 ***The Generic Timer in AArch64 state***

Read this for a description of the AArch64 view of an implementation of the ARM Generic Timer.

Chapter D9 ***AArch64 System Register Encoding***

Read this for a description of the description of the encoding of the AArch64 System registers, and the other uses of the AArch64 System registers encoding space.

Chapter D10 ***AArch64 System Register Descriptions***

Read this for an introduction to, and description of, each of the AArch64 System registers.

Part E, The AArch32 Application Level Architecture

Part E describes the AArch32 state application level view of the architecture. It contains the following chapters:

Chapter E1 ***The AArch32 Application Level Programmers' Model***

Read this for an application level description of the programmers' model for software executing in AArch32 state. It describes execution at EL0 when EL0 is using AArch32 state.

Chapter E2 ***The AArch32 Application Level Memory Model***

Read this for an application level description of the memory model for software executing in AArch32 state. It describes the memory model for execution in EL0 when EL0 is using AArch32 state. It includes information about ARM memory types, attributes, and memory access controls.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Part F, The AArch32 Instruction Sets

Part F describes the T32 and A32 instruction sets, that are used in AArch32 state. It contains the following chapters:

Chapter F1 ***The AArch32 Instruction Sets Overview***

Read this for an overview of the T32 and A32 instruction sets.

Chapter F2 ***About the T32 and A32 Instruction Descriptions***

Read this to understand the format of the T32 and A32 instruction descriptions.

Chapter F3 ***T32 Instruction Set Encoding***

Read this for a description of the T32 instruction set encoding. This includes the T32 encoding of the Advanced SIMD and floating-point instructions.

Chapter F4 ***A32 Instruction Set Encoding***

Read this for a description of the A32 instruction set encoding. This includes the A32 encoding of the Advanced SIMD and floating-point instructions.

Chapter F5 ***T32 and A32 Base Instruction Set Instruction Descriptions***

Read this for a description of each of the T32 and A32 base instructions.

Chapter F6 ***T32 and A32 Advanced SIMD and Floating-point Instruction Descriptions***

Read this for a description of each of the T32 and A32 Advanced SIMD and floating-point instructions.

Part G, The AArch32 System Level Architecture

Part G describes the AArch32 state system level view of the architecture. It contains the following chapters:

Chapter G1 ***The AArch32 System Level Programmers' Model***

Read this for a description of the AArch32 state system level view of the programmers' model for execution in an Exception level that is using AArch32.

Chapter G2 ***AArch32 Self-hosted Debug***

Read this for an introduction to, and a description of, self-hosted debug in AArch64 state.

Chapter G3 ***The AArch32 System Level Memory Model***

Read this for a system level view of the general features of the memory system.

Chapter G4 ***The AArch32 Virtual Memory System Architecture***

Read this for a description of the AArch32 Virtual Memory System Architecture (VMSA).

Chapter G5 ***The Generic Timer in AArch32 state***

Read this for a description of the AArch32 view of an implementation of the ARM Generic Timer.

Chapter G6 ***AArch32 System Register Encoding***

Read this for a description of the description of the encoding of the AArch32 System registers, including the System instructions that are part of the the AArch32 System registers encoding space.

Chapter G7 ***AArch32 System Register Descriptions***

Read this for a description of each of the AArch32 System registers.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Part H, External Debug

Part H describes the architecture for external debug. It contains the following chapters:

Chapter H1 ***About External Debug***

Read this for an introduction to external debug, and a definition of the scope of this part of the manual.

Chapter H2 ***Debug State***

Read this for a description of debug state, which the PE might enter as the result of a Halting debug event.

Chapter H3 ***Halting Debug Events***

Read this for a description of the external debug events referred to as Halting debug events.

Chapter H4 ***The Debug Communication Channel and Instruction Transfer Register***

Read this for a description of the communication between a debugger and the PE debug logic using the Debug Communications Channel and the Instruction Transfer register.

Chapter H5 ***The Embedded Cross-Trigger Interface***

Read this for a description of the embedded cross-trigger interface.

Chapter H6 ***Debug Reset and Powerdown Support***

Read this for a description of reset and powerdown support in the Debug architecture.

Chapter H7 ***The PC Sample-based Profiling Extension***

Read this for a description of the PC Sample-based Profiling Extension that is an OPTIONAL extension to an ARMv8 implementation.

Chapter H8 ***About the External Debug Registers***

Read this for some additional information about the external debug registers.

Chapter H9 ***External Debug Register Descriptions***

Read this for a description of each external debug register.

Part I, Memory-mapped Components of the ARMv8 Architecture

Part I describes the memory-mapped components in the architecture. It contains the following chapters:

Chapter I1 ***Requirements for Memory-mapped Components***

Read this for descriptions of some general requirements for memory-mapped components within a system that complies with the ARMv8 Architecture.

Chapter I2 ***System Level Implementation of the Generic Timer***

Read this for a definition of a system level implementation of the Generic Timer.

Chapter I3 ***Recommended External Interface to the Performance Monitors***

Read this for a description of the recommended memory-mapped and external debug interfaces to the Performance Monitors.

Chapter I4 ***External System Control Register Descriptions***

Read this for a description of each memory-mapped system control register.

Part J, Architectural Pseudocode

Part J contains pseudocode that describes various features of the ARM architecture. It contains the following chapter:

Chapter J1 *ARMv8 Pseudocode*

Read this for the pseudocode definitions that describe various features of the ARMv8 architecture, for operation in AArch64 state and in AArch32 state.

Part K, Appendixes

This manual contains the following appendixes:

Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*

Read this for a description of the architecturally-required constraints on UNPREDICTABLE behaviors in the ARMv8 architecture, including AArch32 behaviors that were UNPREDICTABLE in previous versions of the architecture.

Appendix K2 *Recommended External Debug Interface*

Read this for a description of the recommended external debug interface.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix K3 *Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events*

Read this for a description of ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix K4 *Recommendations for reporting memory attributes on an interconnect*

Read this for the ARM recommendations about how the architectural memory attributes are reported on an interconnect.

Appendix K5 *Additional Information for Implementations of the Generic Timer*

Read this for additional information about implementations of the ARM Generic Timer. This information does not form part of the architectural definition of the Generic Timer.

Appendix K6 *Legacy Instruction Syntax for AArch32 Instruction Sets*

Read this for information about the pre-UAL syntax of the AArch32 instruction sets, which can still be valid for the A32 instruction set.

Appendix K7 *Address translation examples*

Read this for examples of translation table lookups using the translation regimes described in Chapter D4 *The AArch64 Virtual Memory System Architecture* and Chapter G4 *The AArch32 Virtual Memory System Architecture*.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Appendix K8 ***Example OS Save and Restore Sequences***

Read this for software examples that perform the OS Save and Restore sequences for an ARMv8 debug implementation.

Note

Chapter H6 *Debug Reset and Powerdown Support* describes the OS Save and Restore mechanism.

Appendix K9 ***Recommended Upload and Download Processes for External Debug***

Read this for information about implementing and using the ARM architecture.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix K10 ***Software Usage Examples***

Read this for software examples that help understanding of some aspects of the Arm architecture.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix K11 ***Barrier Litmus Tests***

Read this for examples of the use of barrier instructions provided by the ARMv8 architecture.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix K12 ***ARM Pseudocode Definition***

Read this for definitions of the AArch32 pseudocode.

Appendix K13 ***Registers Index***

Read this for an alphabetic and functional index of AArch32 and AArch64 registers, and memory-mapped registers.

Glossary

Defines terms used in this document that have a specialized meaning.

Note

Terms that are generally well understood in the microelectronics industry are not included in the Glossary.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Conventions

The following sections describe conventions that this book can use:

- *Typographic conventions*.
- *Signals* on page xxv.
- *Numbers* on page xxv.
- *Pseudocode descriptions* on page xxv.
- *Assembler syntax descriptions* on page xxv.

Typographic conventions

The typographical conventions are:

italic Introduces special terminology, and denotes citations.

bold Denotes signal names, and is used for terms in descriptive lists, where appropriate.

`monospace` Used for assembler syntax descriptions, pseudocode, and source code examples.

Also used in the main text for instruction mnemonics and for references to other items appearing in assembler syntax descriptions, pseudocode, and source code examples.

SMALL CAPITALS

Used in body text for a few terms that have specific technical meanings, and are defined in the *Glossary*.

Colored text Indicates a link. This can be:

- A URL, for example `http://infocenter.arm.com`.
- A cross-reference, that includes the page number of the referenced information if it is not on the current page, for example, *Assembler syntax descriptions* on page xxv.
- A link, to a chapter or appendix, or to a glossary entry, or to the section of the document that defines the colored term, for example *Simple sequential execution* or SCTLR.

{ and } Braces, { and }, have two distinct uses:

Optional items

In syntax descriptions braces enclose optional items. In the following example they indicate that the `<shift>` parameter is optional:

```
ADD <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

Similarly they can be used in generalized field descriptions, for example TCR_ELx.{I}PS refers to a field in the TCR_ELx registers that is called either IPS or PS.

Sets of items

Braces can be used to enclose sets. For example, HCR_EL2.{E2H, TGE} refers to a set of two register fields, HCR_EL2.E2H and HCR_EL2.TGE

Notes Notes are formatted as:

Note

This is a Note.

In this Manual, Notes are used only to provide additional information, usually to help understanding of the text. While a Note may repeat architectural information given elsewhere in the Manual, a Note never provides any part of the definition of the architecture.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Signals

In general this specification does not define hardware signals, but it does include some signal examples and recommendations. The signal conventions are:

Signal level The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means:

- HIGH for active-HIGH signals.
- LOW for active-LOW signals.

Lower-case n At the start or end of a signal name denotes an active-LOW signal.

Numbers

Numbers are normally written in decimal. Binary numbers are preceded by `0b`, and hexadecimal numbers by `0x`. In both cases, the prefix and the associated value are written in a `monospace` font, for example `0xFFFF0000`. To improve readability, long numbers can be written with an underscore separator between every four characters, for example `0xFFFF_0000_0000_0000`. Ignore any underscores when interpreting the value of a number.

Pseudocode descriptions

This manual uses a form of pseudocode to provide precise descriptions of the specified functionality. This pseudocode is written in `monospace` font, and is described in Appendix K12 *ARM Pseudocode Definition*.

Assembler syntax descriptions

This manual contains numerous syntax descriptions for assembler instructions and for components of assembler instructions. These are shown in a `monospace` font, and use the conventions described in *Structure of the A64 assembler language* on page C1-143, Appendix K12 *ARM Pseudocode Definition*, and *Pseudocode operators and keywords on page K12-5648*.

Part A

ARMv8 Architecture Introduction and Overview

Chapter A1
Introduction to the ARMv8 Architecture

This chapter introduces the ARM architecture. It contains the following sections:

- *About the ARM architecture* on page A1-32.
- *Architecture profiles* on page A1-34.
- *ARMv8 architectural concepts* on page A1-36.
- *Supported data types* on page A1-40.
- *Advanced SIMD and floating-point support* on page A1-50.
- *The ARM memory model* on page A1-56.
- *ARMv8 architecture extensions* on page A1-57.

A1.1 About the ARM architecture

The ARM architecture described in this Architecture Reference Manual defines the behavior of an abstract machine, referred to as a *processing element*, often abbreviated to *PE*. Implementations compliant with the ARM architecture must conform to the described behavior of the processing element. It is not intended to describe how to build an implementation of the PE, nor to limit the scope of such implementations beyond the defined behaviors.

Except where the architecture specifies differently, the programmer-visible behavior of an implementation that is compliant with the ARM architecture must be the same as a simple sequential execution of the program on the processing element. This programmer-visible behavior does not include the execution time of the program.

The ARM Architecture Reference Manual also describes rules for software to use the processing element.

The ARM architecture includes definitions of:

- An associated debug architecture, see:
  - Chapter D2 *AArch64 Self-hosted Debug*.
  - Chapter G2 *AArch32 Self-hosted Debug*.
  - Part H of this manual, *External Debug* on page 5689.
- Associated trace architectures that define trace macrocells that implementers can implement with the associated processor hardware. For more information, see the *Embedded Trace Macrocell Architecture Specification.*

The ARM architecture is a *Reduced Instruction Set Computer* (RISC) architecture with the following RISC architecture features:

- A large uniform register file.
- A *load/store* architecture, where data-processing operations only operate on register contents, not directly on memory contents.
- Simple addressing modes, with all load/store addresses determined from register contents and instruction fields only.

The architecture defines the interaction of the PE with memory, including caches, and includes a memory translation system. It also describes how multiple PEs interact with each other and with other observers in a system.

This document defines the ARMv8-A architecture *profile*. See *Architecture profiles* on page A1-34 for more information.

The ARM architecture supports implementations across a wide range of performance points. Implementation size, performance, and very low power consumption are key attributes of the ARM architecture.

An important feature of the ARMv8 architecture is backwards compatibility, combined with the freedom for optimal implementation in a wide range of standard and more specialized use cases. The ARMv8 architecture supports:

- A 64-bit Execution state, AArch64.
- A 32-bit Execution state, AArch32, that is compatible with previous versions of the ARM architecture.

Note

- The AArch32 Execution state is compatible with the ARMv7-A architecture profile, and enhances that profile to support some features included in the AArch64 Execution state.
- This document describes only the ARMv8-A architecture profile. For the behaviors required by the ARMv7-A and ARMv7-R architecture profiles, see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

Features that are optional are explicitly defined as such in this Manual.

Note

The presence of an ID register field for a feature does not imply that the feature is optional.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Both Execution states support SIMD and floating-point instructions:

- AArch32 state provides:
  - SIMD instructions in the base instruction sets that operate on the 32-bit general-purpose registers.
  - Advanced SIMD instructions that operate on registers in the *SIMD and floating-point register* (SIMD&FP register) file.
  - Floating-point instructions that operate on registers in the SIMD&FP register file.
- AArch64 state provides:
  - Advanced SIMD instructions that operate on registers in the SIMD&FP register file.
  - Floating-point instructions that operate on registers in the SIMD&FP register file.

Note

See *Conventions* on page xxiv for information about conventions used in this manual, including the use of SMALL CAPITALS for particular terms that have ARM-specific meanings that are defined in the *Glossary*.

A1.2 Architecture profiles

The ARM architecture has evolved significantly since its introduction, and ARM continues to develop it. Eight major versions of the architecture have been defined to date, denoted by the version numbers 1 to 8. Of these, the first three versions are now obsolete.

The generic names AArch64 and AArch32 describe the 64-bit and 32-bit Execution states:

AArch64 Is the 64-bit Execution state, meaning addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

AArch32 Is the 32-bit Execution state, meaning addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets.

Note

The *Base instruction set* comprises the supported instructions other than the Advanced SIMD and floating-point instructions.

See sections *Execution state* on page A1-36 and *The ARM instruction sets* on page A1-37 for more information.

ARM defines three architecture profiles:

A Application profile, described in this manual:

- Supports a *Virtual Memory System Architecture* (VMSA) based on a *Memory Management Unit* (MMU).

  Note

  An ARMv8-A implementation can be called an AArchv8-A implementation.

- Supports the A64, A32, and T32 instruction sets.

R Real-time profile:

- Supports a *Protected Memory System Architecture* (PMSA) based on a *Memory Protection Unit* (MPU).
- Supports the A32 and T32 instruction sets.

M Microcontroller profile:

- Implements a programmers' model designed for low-latency interrupt processing, with hardware stacking of registers and support for writing interrupt handlers in high-level languages.
- Implements a variant of the R-profile PMSA.
- Supports a variant of the T32 instruction set.

Note

This Architecture Reference Manual describes only the ARMv8-A profile.

For information about the R and M architecture profiles, and earlier ARM architecture versions see:

- The *ARM® Architecture Reference Manual Supplement, ARMv8, for the ARMv8-R AArch32 architecture profile.*
- The *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.
- The *ARM®v8-M Architecture Reference Manual*.
- The *ARM®v7-M Architecture Reference Manual*.
- The *ARM®v6-M Architecture Reference Manual*.

A1.3 ARMv8 architectural concepts

ARMv8 introduces major changes to the ARM architecture, while maintaining a high level of consistency with previous versions of the architecture. The ARMv8 Architecture Reference Manual includes significant changes in the terminology used to describe the architecture, and this section introduces both the ARMv8 architectural concepts and the associated terminology.

The following subsections describe key ARMv8 architectural concepts. Each section introduces the corresponding terms that are used to describe the architecture:

- *Execution state*.
- *The ARM instruction sets* on page A1-37.
- *System registers* on page A1-37.
- *ARMv8 Debug* on page A1-38.

A1.3.1 Execution state

The Execution state defines the PE execution environment, including:

- The supported register widths.
- The supported instruction sets.
- Significant aspects of:
  - The exception model.
  - The *Virtual Memory System Architecture* (VMSA).
  - The programmers' model.

The Execution states are:

AArch64 The 64-bit Execution state. This Execution state:

- Provides 31 64-bit general-purpose registers, of which X30 is used as the procedure link register.
- Provides a 64-bit *program counter* (PC), *stack pointer*s (SPs), and *exception link registers* (ELRs).
- Provides 32 128-bit registers for SIMD vector and scalar floating-point support.
- Provides a single instruction set, A64. For more information, see *The ARM instruction sets* on page A1-37.
- Defines the ARMv8 Exception model, with up to four Exception levels, EL0 - EL3, that provide an *execution privilege* hierarchy, see *Exception levels* on page D1-1850.
- Provides support for 64-bit *virtual addressing*. For more information, including the limits on address ranges, see Chapter D4 *The AArch64 Virtual Memory System Architecture*.
- Defines a number of *Process state* (PSTATE) elements that hold PE state. The A64 instruction set includes instructions that operate directly on various PSTATE elements.
- Names each System register using a suffix that indicates the lowest Exception level at which the register can be accessed.

AArch32 The 32-bit Execution state. This Execution state:

- Provides 13 32-bit general-purpose registers, and a 32-bit PC, SP, and *link register* (LR). The LR is used as both an ELR and a procedure link register.
  Some of these registers have multiple *banked* instances for use in different PE *modes*.
- Provides a single ELR, for exception returns from Hyp mode.
- Provides 32 64-bit registers for Advanced SIMD vector and scalar floating-point support.
- Provides two instruction sets, A32 and T32. For more information, see *The ARM instruction sets* on page A1-37.
- Supports the ARMv7-A exception model, based on *PE modes*, and maps this onto the ARMv8 Exception model, that is based on the Exception levels.
- Provides support for 32-bit virtual addressing.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- Defines a number of *Process state* (PSTATE) elements that hold PE state. The A32 and T32 instruction sets include instructions that operate directly on various PSTATE elements, and instructions that access PSTATE by using the *Application Program Status Register* (APSR) or the *Current Program Status Register* (CPSR).

Later subsections give more information about the different properties of the Execution states.

Transferring control between the AArch64 and AArch32 Execution states is known as *interprocessing*. The PE can move between Execution states only on a change of Exception level, and subject to the rules given in *Interprocessing* on page D1-1962. This means different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.

A1.3.2 The ARM instruction sets

In ARMv8 the possible instruction sets depend on the Execution state:

AArch64 AArch64 state supports only a single instruction set, called A64. This is a fixed-length instruction set that uses 32-bit instruction encodings.

For information on the A64 instruction set, see Chapter C3 *A64 Instruction Set Overview*.

AArch32 AArch32 state supports the following instruction sets:

A32 This is a fixed-length instruction set that uses 32-bit instruction encodings.

T32 This is a variable-length instruction set that uses both 16-bit and 32-bit instruction encodings.

In previous documentation, these instruction sets were called the ARM and Thumb instruction sets. ARMv8 extends each of these instruction sets. In AArch32 state, the Instruction set state determines the instruction set that the PE executes.

For information on the A32 and T32 instruction sets, see Chapter F1 *The AArch32 Instruction Sets Overview*.

The ARMv8 instruction sets support SIMD and scalar floating-point instructions. See *Advanced SIMD and floating-point support* on page A1-50.

A1.3.3 System registers

System registers provide control and status information of architected features.

The System registers use a standard naming format: <register_name>.<bit_field_name> to identify specific registers as well as control and status bits within a register.

Bits can also be described by their numerical position in the form <register_name>[x:y] or the generic form bits[x:y].

In addition, in AArch64 state, most register names include the lowest Exception level that can access the register as a suffix to the register name:

- <register_name>_ELx, where x is 0, 1, 2, or 3.

For information about Exception levels, see *Exception levels* on page D1-1850.

The System registers comprise:

- The following registers that are described in this manual:
  - General system control registers.
  - Debug registers.
  - Generic Timer registers.
  - Optionally, Performance Monitor registers.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- Optionally, one or more of the following groups of registers that are defined in other ARM architecture specifications:
  - Trace System registers, as defined in the *Embedded Trace Macrocell Architecture Specification, ETMv4*.
  - Scalable Vector Extension System registers, as defined in the ARM® *Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for ARMv8-A*.
  - Statistical Profiling Extension System registers, as defined in the *ARM® Architecture Reference Manual Supplement, The Statistical Profiling Extension, for ARMv8-A*.
  - *Generic Interrupt Controller* (GIC) System registers, see *The ARM Generic Interrupt Controller System registers*.
- RAS Extension System registers, as defined in the *ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile*. The RAS Extension is a mandatory extension to the ARMv8.2 architecture, and an optional extension to the ARMv8.0 and the ARMv8.1 architectures.

For information about the AArch64 System registers, see Chapter D10 *AArch64 System Register Descriptions*.

For information about the AArch32 System registers, see Chapter G7 *AArch32 System Register Descriptions*.

The ARM Generic Interrupt Controller System registers

From version 3 of the ARM Generic Interrupt Controller architecture, GICv3, the GIC architecture specification defines a System register interface to some of its functionality. The System register summaries in this manual include these registers, see:

- *About the GIC System registers* on page D9-2345, for more information about the AArch64 GIC System registers.
- *About the GIC System registers* on page G6-5009, for more information about the AArch32 GIC System registers.

These sections give only short overviews of the GIC System registers. For more information, including descriptions of the registers, see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* (ARM IHI 0069).

Note

The programmers' model for earlier versions of the GIC architecture is wholly memory-mapped.

A1.3.4 ARMv8 Debug

ARMv8 supports the following:

Self-hosted debug

In this model, the PE generates *debug exceptions*. Debug exceptions are part of the ARMv8 Exception model.

External debug

In this model, *debug events* cause the PE to enter *Debug state*. In Debug state, the PE is controlled by an external debugger.

All ARMv8 implementations support both models. The model chosen by a particular user depends on the debug requirements during different stages of the design and development life cycle of the product. For example, external debug might be used during debugging of the hardware implementation and OS bring-up, and self-hosted debug might be used during application development.

For more information about self-hosted debug:

- In AArch64 state, see Chapter D2 *AArch64 Self-hosted Debug*.
- In AArch32 state, see Chapter G2 *AArch32 Self-hosted Debug*.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

A1.4 Supported data types

The ARMv8 architecture supports the following integer data types:

Byte 8 bits.
Halfword 16 bits.
Word 32 bits.
Doubleword 64 bits.
Quadword 128 bits.

The architecture also supports the following floating-point data types:

- Half-precision, see *Half-precision floating-point formats* on page A1-44 for details.
- Single-precision, see *Single-precision floating-point format* on page A1-46 for details.
- Double-precision, see *Double-precision floating-point format* on page A1-47 for details.

It also supports:

- Fixed-point interpretation of words and doublewords. See *Fixed-point format* on page A1-48.
- Vectors, where a register holds multiple elements, each of the same data type. See *Vector formats* on page A1-41 for details.

The ARMv8 architecture provides two register files:

- A general-purpose register file.
- A SIMD&FP register file.

In each of these, the possible register widths depend on the Execution state.

In AArch64 state:

- A general-purpose register file contains 64-bit registers:
  - Many instructions can access these registers as 64-bit registers or as 32-bit registers, using only the bottom 32 bits.
- A SIMD&FP register file contains 128-bit registers:
  - The quadword integer data types only apply to the SIMD&FP register file.
  - The floating-point data types only apply to the SIMD&FP register file.
  - While the AArch64 vector registers support 128-bit vectors, the effective vector length can be 64-bits or 128-bits depending on the A64 instruction encoding used, see *Instruction Mnemonics* on page C1-144.

For more information on the register files in AArch64 state, see *Registers in AArch64 Execution state* on page B1-77.

In AArch32 state:

- A general-purpose register file contains 32-bit registers:
  - Two 32-bit registers can support a doubleword.
  - Vector formatting is supported, see Figure A1-4 on page A1-44.
- A SIMD&FP register file contains 64-bit registers:
  - AArch32 state does not support quadword integer or floating-point data types.

Note

Two consecutive 64-bit registers can be used as a 128-bit register.

For more information on the register files in AArch32 state, see *The general-purpose registers, and the PC, in AArch32 state* on page E1-2981.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

A1.4.1 Vector formats

In an implementation that includes the SIMD instructions that operate on the SIMD&FP register file, a register can hold one or more packed elements, all of the same size and type. The combination of a register and a data type describes a vector of elements. The vector is considered to be an array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the size of the register.

Vector indices are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant end of the vector.

Vector formats in AArch64 state

In AArch64 state, the SIMD&FP registers can be referred to as V*n*, where *n* is a value from 0 to 31.

The SIMD&FP registers support three data formats for loads, stores, and data-processing operations:

- A single, scalar, element in the least significant bits of the register.
- A 64-bit vector of byte, halfword, or word elements.
- A 128-bit vector of byte, halfword, word, or doubleword elements.

The element sizes are defined in Table A1-1 with the vector format described as:

- For a 128-bit vector: Vn{.2D, .4S, .8H, .16B}.
- For a 64-bit vector: Vn{.1D, .2S, .4H, .8B}.

Table A1-1 SIMD elements in AArch64 state

Mnemonic	Size
B	8 bits
H	16 bits
S	32 bits
D	64 bits

Figure A1-1 on page A1-42 shows the SIMD vectors in AArch64 state.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

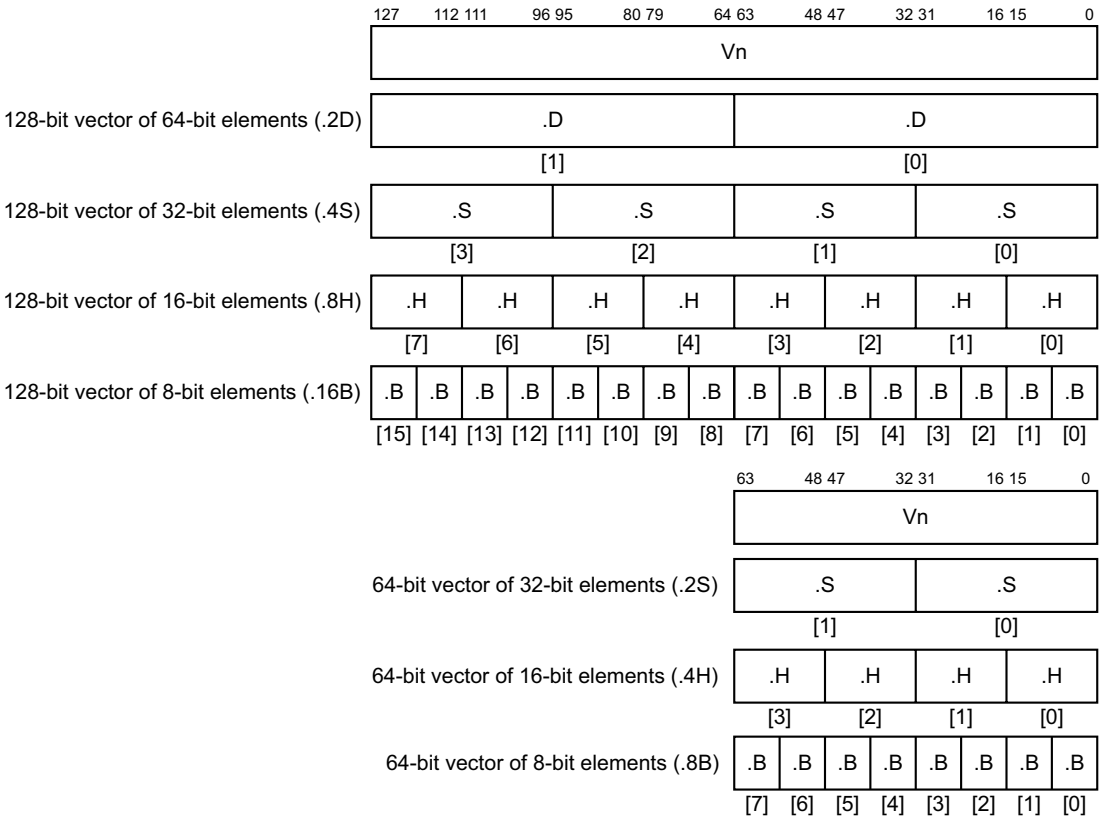

Figure A1-1 SIMD vectors in AArch64 state

Vector formats in AArch32 state

Table A1-2 shows the available formats. Each instruction description specifies the data types that the instruction supports.

Table A1-2 Advanced SIMD data types in AArch32 state

Data type specifier	Meaning
`.<size>`	Any element of <size> bits
`.F<size>`	Floating-point number of <size> bits
`.I<size>`	Signed or unsigned integer of <size> bits
`.P<size>`	Polynomial over {0, 1} of degree less than <size>
`.S<size>`	Signed integer of <size> bits
`.U<size>`	Unsigned integer of <size> bits

Polynomial arithmetic over {0, 1} on page A1-49 describes the polynomial data type.

The `.F16` data type is the half-precision data type selected by the FPSCR.AHP bit, see *Half-precision floating-point formats* on page A1-44.

The `.F32` data type is the ARM standard single-precision floating-point data type, see *Single-precision floating-point format* on page A1-46.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

The instruction definitions use a data type specifier to define the data types appropriate to the operation. Figure A1-2 shows the hierarchy of the Advanced SIMD data types.

‡ Available only if the Cyptographic Extension is implemented. See VMULL instruction description.

Figure A1-2 Advanced SIMD data type hierarchy in AArch32 state

For example, a multiply instruction must distinguish between integer and floating-point data types.

An integer multiply instruction that generates a double-width (long) result must specify the input data types as signed or unsigned. However, some integer multiply instructions use modulo arithmetic, and therefore do not have to distinguish between signed and unsigned inputs.

Figure A1-3 on page A1-44 shows the Advanced SIMD vectors in AArch32 state.

Note

In AArch32 state, a pair of even and following odd numbered doubleword registers can be concatenated and treated as a single quadword register.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

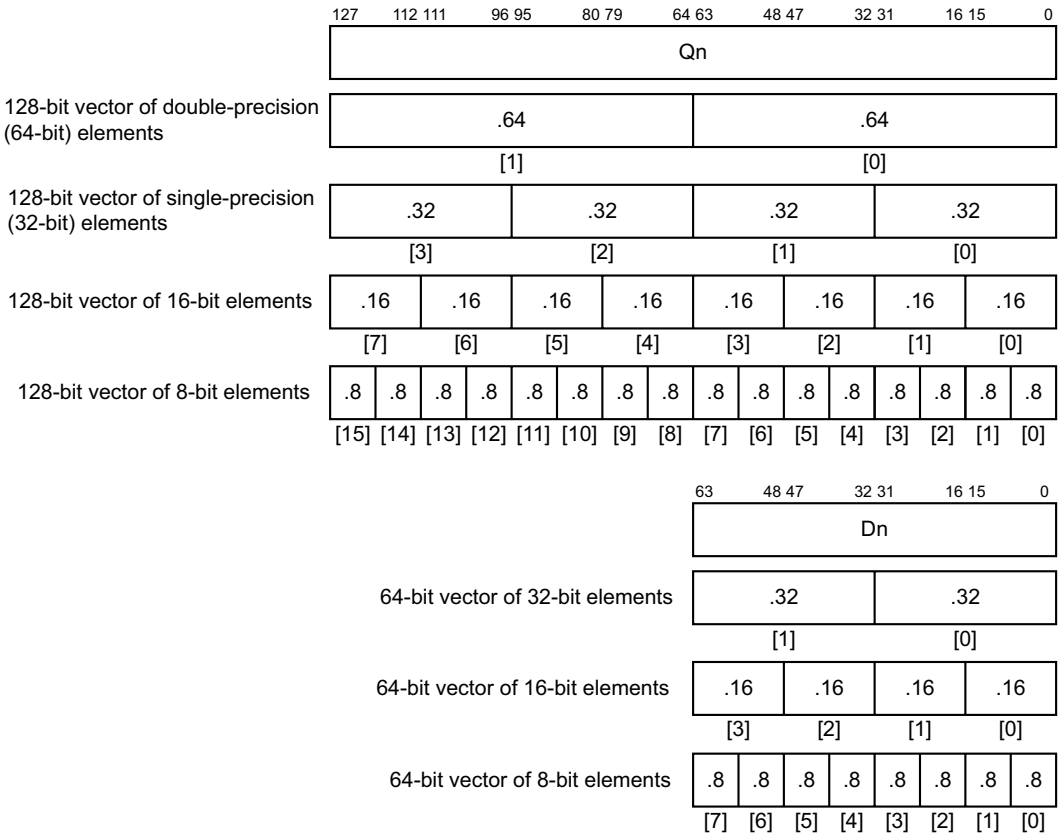

Figure A1-3 Advanced SIMD vectors in AArch32 state

The AArch32 general-purpose registers support vectors formats for use by the SIMD instructions in the Base instruction set. Figure A1-4 shows these formats, that means that a general-purpose register can be treated as either 2 halfwords or 4 bytes.

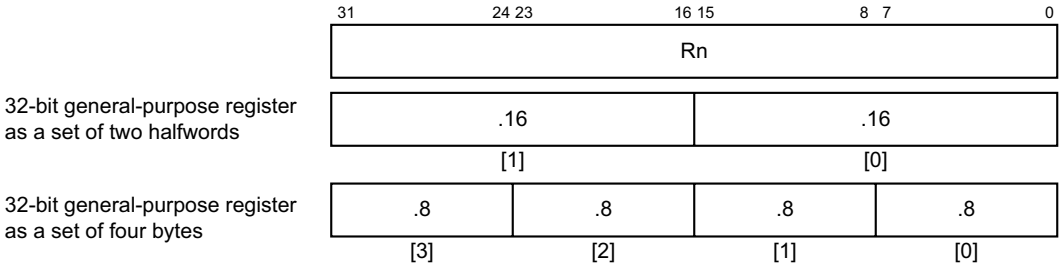

Figure A1-4 Vector formatting in AArch32 state

A1.4.2 Half-precision floating-point formats

ARMv8 supports two half-precision floating-point formats:

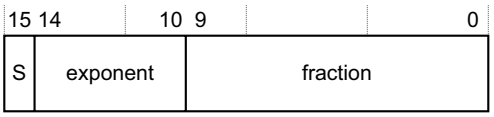
- IEEE half-precision, as described in the IEEE 754-2008 standard.
- ARM *alternative half-precision* format.

Both formats can be used for conversions to and from other floating-point formats. FPCR.AHP controls the format in AArch64 state and FPSCR.AHP controls the format in AArch32 state. ARMv8.2-FP16 adds half-precision data-processing instructions, which always use the IEEE format. These instructions ignore the value of the relevant AHP field, and behave as if it has an *Effective value* of 0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

The description of IEEE half-precision includes ARM-specific details that are left open by the standard, and is only an introduction to the formats and to the values they can contain. For more information, especially on the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

For both half-precision floating-point formats, the layout of the 16-bit format is the same. The format is:



The interpretation of the format depends on the value of the exponent field, bits[14:10] and on which half-precision format is being used.

0 < exponent < `0x1F`

The value is a normalized number and is equal to:

$(-1)^S \times 2^{(\text{exponent}-15)} \times (1.\text{fraction})$

The minimum positive normalized number is 2^{-14}, or approximately 6.104×10^{-5}.

The maximum positive normalized number is $(2 - 2^{-10}) \times 2^{15}$, or 65504.

Larger normalized numbers can be expressed using the alternative format when the exponent == `0x1F`.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 when S==0

–0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-14} \times (0.\text{fraction})$

The minimum positive denormalized number is 2^{-24}, or approximately 5.960×10^{-8}.

Half-precision denormalized numbers are not flushed to zero by default. When ARMv8.2-FP16 is implemented, the FPCR.FZ16 bit controls whether Flush-to-Zero mode is enabled for half-precision data-processing instructions. For details, see *Flush-to-zero* on page A1-53.

exponent == `0x1F`

The value depends on which half-precision format is being used:

IEEE half-precision

The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.

-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[9]:

bit[9] == 0 The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

bit[9] == 1 The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

Alternative half-precision

The value is a normalized number and is equal to:

$-1^S \times 2^{16} \times (1.\text{fraction})$

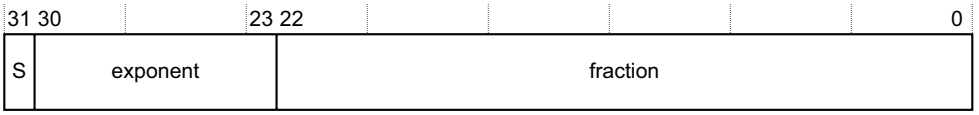
The maximum positive normalized number is $(2-2^{-10}) \times 2^{16}$ or 131008.

A1.4.3 Single-precision floating-point format

The single-precision floating-point format is as defined by the IEEE 754 standard.

This description includes ARM-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

A single-precision value is a 32-bit word with the format:



The interpretation of the format depends on the value of the exponent field, bits[30:23]:

0 < exponent < `0xFF`

The value is a *normalized number* and is equal to:

$(-1)^S \times 2^{(\text{exponent} - 127)} \times (1.\text{fraction})$

The minimum positive normalized number is 2^{-126}, or approximately 1.175×10^{-38}.

The maximum positive normalized number is $(2 - 2^{-23}) \times 2^{127}$, or approximately 3.403×10^{38}.

exponent == 0

The value is either a zero or a *denormalized number*, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 When S==0.

–0 When S==1.

These usually behave identically. In particular, the result is *equal* if +0 and –0 are compared as floating-point numbers. However, they yield different results in some circumstances. For example, the sign of the infinity produced as the result of dividing by zero depends on the sign of the zero. The two zeros can be distinguished from each other by performing an integer comparison of the two words.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-126} \times (0.\text{fraction})$

The minimum positive denormalized number is 2^{-149}, or approximately 1.401×10^{-45}.

Denormalized numbers are always flushed to zero in Advanced SIMD processing in AArch32 state. They are optionally flushed to zero in floating-point processing and in Advanced SIMD processing in AArch64 state. For details, see *Flush-to-zero* on page A1-53.

exponent == `0xFF`

The value is either an *infinity* or a *Not a Number* (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[22]:

bit[22] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[22] == 1

The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

For details of the *default NaN*, see *NaN handling and the Default NaN* on page A1-54.

Note

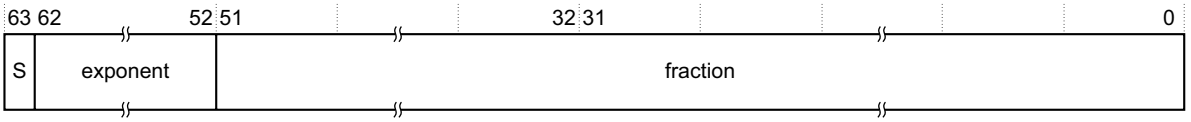
NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

A1.4.4 Double-precision floating-point format

The double-precision floating-point format is as defined by the IEEE 754 standard. Double-precision floating-point is supported by both SIMD and floating-point instructions in AArch64 state, and only by floating-point instructions in AArch32 state.

This description includes implementation-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs, and signed zeros, see the IEEE 754 standard.

A double-precision value is a 64-bit doubleword, with the format:



Double-precision values represent numbers, infinities, and NaNs in a similar way to single-precision values, with the interpretation of the format depending on the value of the exponent:

0 < exponent < `0x7FF`

The value is a normalized number and is equal to:

$(-1)^S \times 2^{(\text{exponent}-1023)} \times (1.\text{fraction})$

The minimum positive normalized number is 2^{-1022}, or approximately 2.225×10^{-308}.

The maximum positive normalized number is $(2 - 2^{-52}) \times 2^{1023}$, or approximately 1.798×10^{308}.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros that behave in the same way as the two single-precision zeros:

+0 when S==0

–0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-1022} \times (0.\text{fraction})$

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

The minimum positive denormalized number is 2^{-1074}, or approximately 4.941×10^{-324}.

Optionally, denormalized numbers are flushed to zero in floating-point calculations. For details, see *Flush-to-zero* on page A1-53.

exponent == `0x7FF`

The value is either an infinity or a NaN, depending on the fraction bits:

fraction == 0

The value is an infinity. As for single-precision, there are two infinities:

+infinity When S==0.

-infinity When S==1.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[51] of the doubleword:

bit[51] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[51] == 1

The NaN is a quiet NaN. The sign bit and the remaining fraction bits can take any value.

For details of the *default NaN*, see *NaN handling and the Default NaN* on page A1-54.

Note

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

A1.4.5 Fixed-point format

Fixed-point formats are used only for conversions between floating-point and fixed-point values. They apply to general-purpose registers.

Fixed-point values can be signed or unsigned, and can be 16-bit or 32-bit. Conversion instructions take an argument that specifies the number of fraction bits in the fixed-point number. That is, it specifies the position of the binary point.

A1.4.6 Conversion between floating-point and fixed-point values

ARMv8 supports the conversion of a scalar floating-point to or from a signed or unsigned fixed-point value in a general-purpose register.

The instruction argument #fbits indicates that the general-purpose register holds a fixed-point number with fbits bits after the binary point, where fbits is in the range 1 to 64 for a 64-bit general-purpose register, or 1 to 32 for a 32-bit general-purpose register.

More specifically:

- For a 64-bit register X_d:
  - The integer part is X_d[63:#fbits].
  - The fractional part is X_d[(#fbits-1):0].
- For a 32-bit register W_d or R_d:
  - The integer part is W_d[31:#fbits] or R_d[31:#fbits].
  - The fractional part is W_d[(#fbits-1):0] or R_d[(#fbits-1):0].

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

These instructions can cause the following floating-point exceptions:

Invalid Operation When the floating-point input is NaN or Infinity or when a numerical value cannot be represented within the destination register.

Inexact When the numeric result differs from the input value.

Input Denormal When Flush-to-zero mode is enabled and the denormal input is replaced by a zero.

Note

An out of range fixed-point result is saturated to the destination size.

For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

A1.4.7 Polynomial arithmetic over {0, 1}

Some SIMD instructions that operate on SIMD&FP registers can operate on polynomials over {0, 1}, see *Supported data types* on page A1-40. The polynomial data type represents a polynomial in x of the form $b_{n-1}x^{n-1} + \ldots + b_1x + b_0$ where b_k is bit[k] of the value.

The coefficients 0 and 1 are manipulated using the rules of Boolean arithmetic:

- $0 + 0 = 1 + 1 = 0$
- $0 + 1 = 1 + 0 = 1$
- $0 \times 0 = 0 \times 1 = 1 \times 0 = 0$
- $1 \times 1 = 1$.

That is:

- Adding two polynomials over {0, 1} is the same as a bitwise exclusive OR.
- Multiplying two polynomials over {0, 1} is the same as integer multiplication except that partial products are exclusive-ORed instead of being added.

A64, A32, and T32 provide instructions for performing polynomial multiplication of 8-bit values.

- For AArch32, see *VMUL (integer and polynomial)* on page F6-4300 and *VMULL (integer and polynomial)* on page F6-4305.
- For AArch64, see *PMUL* on page C7-1449 and *PMULL, PMULL2* on page C7-1451.

The Cryptographic Extension adds the ability to perform long polynomial multiplies of 64-bit values. See *PMULL, PMULL2* on page C7-1451.

Pseudocode description of polynomial multiplication

In pseudocode, polynomial addition is described by the EOR operation on bitstrings.

Polynomial multiplication is described by the `PolynomialMult()` function defined in Chapter J1 *ARMv8 Pseudocode*.

A1.5 Advanced SIMD and floating-point support

Note

In AArch32 state, the SIMD instructions that operate on SIMD&FP registers are always described as the Advanced SIMD instructions, to distinguish them from the SIMD instructions in the base instruction sets, that operate on the 32-bit general-purpose registers. The A64 instruction set does not provide any SIMD instructions that operate on the general-purpose registers, and therefore some AArch64 state descriptions use SIMD as a synonym for Advanced SIMD. Unless the context clearly indicates otherwise, this section describes the support for SIMD instructions that operate on SIMD&FP registers.

ARMv8 can support the following levels of support for Advanced SIMD and floating-point instructions:

- Full SIMD and floating-point support without exception trapping.
- Full SIMD and floating-point support with exception trapping.
- No floating-point or SIMD support. This option is licensed only for implementations targeting specialized markets.

  Note

  All systems that support standard operating systems with rich application environments provide hardware support for Advanced SIMD and floating-point. It is a requirement of the ARM Procedure Call Standard for AArch64, see *Procedure Call Standard for the ARM 64-bit Architecture*.

ARMv8 supports single-precision (32-bit) and double-precision (64-bit) floating-point data types and arithmetic as defined by the IEEE 754 floating-point standard. It also supports the half-precision (16-bit) floating-point data type for data storage, by supporting conversions between single-precision and half-precision data types and double-precision and half-precision data types. When ARMv8.2-FP16 is implemented, it also supports the half-precision floating-point data type for data-processing operations.

The SIMD instructions provide packed *Single Instruction Multiple Data (SIMD)* and single-element scalar operations, and support:

- Single-precision and double-precision arithmetic in AArch64 state.
- Single-precision arithmetic only in AArch32 state.
- When ARMv8.2-FP16 is implemented, half-precision arithmetic is supported in AArch64 and AArch32 states.

Floating-point support in AArch64 state SIMD is IEEE 754-2008 compliant with:

- Configurable rounding modes.
- Configurable Default NaN behavior.
- Configurable Flush-to-zero behavior.

Floating-point computation using AArch32 Advanced SIMD instructions remains unchanged from ARMv7. A32 and T32 Advanced SIMD floating-point always uses ARM standard floating-point arithmetic and performs IEEE 754 floating-point arithmetic with the following restrictions:

- Denormalized numbers are flushed to zero, see *Flush-to-zero* on page A1-53.
- Only default NaNs are supported, see *NaN handling and the Default NaN* on page A1-54.
- The Round to Nearest rounding mode is used.
- Untrapped floating-point exception handling is used for all floating-point exceptions.

If floating-point exception trapping is supported, floating-point exceptions, such as Overflow or Divide by Zero, can be handled without trapping. This applies to both SIMD and floating-point operations. When handled in this way, a floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation. For more information about floating-point exceptions, see *Floating-point exceptions and exception traps* on page D1-1899.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

In AArch64 state, the following registers control floating-point operation and return floating-point status information:

- The Floating-Point Control Register, FPCR, controls:
  - The half-precision format where applicable, FPCR.AHP bit.
  - Default NaN behavior, FPCR.DN bit.
  - Flush-to-zero behavior, FPCR.{FZ, FZ16} bits. If ARMv8.2-FP16 is not implemented, FPCR.FZ16 is RES0.
  - Rounding mode support, FPCR.Rmode field.
  - Len and Stride fields associated with execution in AArch32 state, and only supported for a context save and restore from AArch64 state. These fields are obsolete in ARMv8 and can be implemented as RAZ/WI. If they are implemented as RW and are programmed to a nonzero value, they make some AArch32 floating-point instructions UNDEFINED.
  - Floating-point exception trap controls, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits, see *Floating-point exceptions and exception traps* on page D1-1899.
- The Floating-Point Status Register, FPSR, provides:
  - Cumulative floating-point exceptions flags, FPSR.{IDC, IXC, UFC, OFC, DZC, IOC and QC}.
  - The AArch32 floating-point comparison flags {N,Z,C,V}. These bits are RES0 if AArch32 floating-point is not implemented.

    Note

    In AArch64 state, the process state flags, PSTATE.{N,Z,C,V} are used for all data-processing compares and any associated conditional execution.

AArch32 state provides a single Floating-Point Status and Control Register, FPSCR, combining the FPCR and FPSR fields.

For system level information about the SIMD and floating-point support, see *Advanced SIMD and floating-point support* on page G1-4696.

A1.5.1 Instruction support

The Advanced SIMD and floating-point instructions support:

- Load and store for single elements and vectors of multiple elements.

  Note

  Single elements are also referred to as scalar elements.

- Data processing on single and multiple elements for both integer and floating-point data types.
- When ARMv8.3-CompNum is implemented, complex number arithmetic.
- Floating-point conversion between different levels of precision.
- Conversion between floating-point, fixed-point integer, and integer data types.
- Floating-point rounding.

For more information on the SIMD and floating-point instructions in AArch64 state, see Chapter C3 *A64 Instruction Set Overview*.

For more information on the Advanced SIMD and floating-point instructions in AArch32 state, see Chapter F1 *The AArch32 Instruction Sets Overview*.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

A1.5.2 Floating-point standards, and terminology

The ARM includes support for all the required features of ANSI/IEEE Std 754-2008, *IEEE Standard for Binary Floating-Point Arithmetic*, referred to as IEEE 754-2008. However, some terms in this manual are based on the 1985 version of this standard, referred to as IEEE 754-1985:

- ARM floating-point terminology generally uses the IEEE 754-1985 terms. This section summarizes how IEEE 754-2008 changes these terms.
- References to IEEE 754 that do not include the issue year apply to either issue of the standard.

Table A1-3 shows how the terminology in this manual differs from that used in IEEE 754-2008.

Table A1-3 Floating-point terminology

This manual	IEEE 754-2008
Normalized [a]	Normal
Denormal, or denormalized	Subnormal
Round towards Minus Infinity (RM)	roundTowardsNegative
Round towards Plus Infinity (RP)	roundTowardsPositive
Round towards Zero (RZ)	roundTowardZero
Round to Nearest (RN)	roundTiesToEven
Round to Nearest with Ties to Away	roundTiesToAway
Rounding mode	Rounding-direction attribute

a. *Normalized number* is used in preference to *normal number*, because of the other specific uses of *normal* in this manual.

A1.5.3 ARM standard floating-point input and output values

ARMv8 provides full IEEE 754 floating-point arithmetic support. In AArch32 state, floating-point operations performed using Advanced SIMD instructions are limited to *ARM standard floating-point operation*, regardless of the selected rounding mode in the FPSCR. Unlike AArch32, AArch64 SIMD floating point arithmetic is performed using the rounding mode selected by the FPCR.

ARM standard floating-point arithmetic supports the following input formats defined by the IEEE 754 floating-point standard:

- Zeros.
- Normalized numbers.
- Denormalized numbers are flushed to 0 before floating-point operations, see *Flush-to-zero* on page A1-53.
- NaNs.
- Infinities.

ARM standard floating-point arithmetic supports the Round to Nearest (roundTiesToEven) rounding mode defined by the IEEE 754 standard.

ARM standard floating-point arithmetic supports the following output result formats defined by the IEEE 754 standard:

- Zeros.
- Normalized numbers.
- Results that are less than the minimum normalized number are flushed to zero, see *Flush-to-zero* on page A1-53.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- NaNs produced in floating-point operations are always the default NaN, see *NaN handling and the Default NaN* on page A1-54.
- Infinities.

A1.5.4 Flush-to-zero

The performance of floating-point processing can be reduced when doing calculations involving denormalized numbers and Underflow exceptions. In many algorithms, this performance can be recovered, without significantly affecting the accuracy of the final result, by replacing the denormalized operands and intermediate results with zeros. To permit this optimization, ARM floating-point implementations have a processing mode called *Flush-to-zero* mode. Single-precision and double-precision AArch32 Advanced SIMD floating-point instructions always use Flush-to-zero mode. When ARMv8.2-FP16 is implemented, Flush-to-Zero mode can be enabled for all half-precision data-processing instructions using the FPCR.FZ16 bit in AArch64 state and the FPSCR.FZ16 bit in AArch32 state.

Behavior in Flush-to-zero mode differs from standard IEEE 754 arithmetic in the following ways:

- All inputs to floating-point operations that are double-precision denormalized numbers or single-precision denormalized numbers are treated as though they were zero. This causes an Input Denormal floating-point exception, but does not cause an Inexact floating-point exception.

  The Input Denormal floating-point exception occurs only in Flush-to-zero mode.

  Note

  When ARMv8.2-FP16 is implemented, when in Flush-to-zero mode, a half-precision floating-point number that is flushed to zero does not generate an Input Denormal floating-point exception. This is because this situation is much less exceptional than for double-precision or single-precision denormalized numbers.

  In AArch32 state, the FPSCR contains a cumulative exception bit FPSCR.IDC and optional trap enable bit FPSCR.IDE corresponding to the Input Denormal floating-point exception.

  In AArch64 state, the FPSR contains a cumulative exception bit FPSR.IDC and optional trap enable bit FPCR.IDE corresponding to the Input Denormal floating-point exception.

  The occurrence of all floating-point exceptions except Input Denormal is determined using the input values after flush-to-zero processing has occurred.

- The result of a floating-point operation is flushed to zero if the result of the operation before rounding satisfies the condition:

  $0 < \texttt{Abs(result)} <$ MinNorm, where:

  — MinNorm is 2^{-14} for half-precision.

  — MinNorm is 2^{-126} for single-precision.

  — MinNorm is 2^{-1022} for double-precision.

  This causes the FPSR.UFC bit to be set to 1, and prevents any Inexact floating-point exception from occurring for the operation.

  Underflow floating-point exceptions occur only when a result is flushed to zero.

  In all implementations Underflow floating-point exceptions that occur in Flush-to-zero mode are always treated as untrapped, even when the Underflow trap enable bit, FPCR.UFE, is set to 1.

- An Inexact floating-point exception does not occur if the result is flushed to zero, even though the final result of zero is not equivalent to the value that would be produced if the operation were performed with unbounded precision and exponent range.

When an input or a result is flushed to zero, the value of the sign bit of the zero is preserved. That is, the sign bit of the zero matches the sign bit of the input or result that is being flushed to zero.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Flush-to-zero mode has no effect on half-precision numbers that are inputs to floating-point operations, or results from floating-point operations. When ARMv8.2-FP16 is implemented and when Flush-to-zero mode is enabled, Flush-to-zero mode affects half-precision data-processing instructions, but has no effect on conversions between half-precision and single-precision or double-precision.

Note

Flush-to-zero mode is incompatible with the IEEE 754 standard, and must not be used when IEEE 754 compatibility is a requirement. Flush-to-zero mode must be used with care. Although it can improve performance on some algorithms, there are significant limitations on its use. These are application dependent:

- On many algorithms, it has no noticeable effect, because the algorithm does not normally use denormalized numbers.
- On other algorithms, it can cause exceptions to occur or seriously reduce the accuracy of the results of the algorithm.

A1.5.5 NaN handling and the Default NaN

The IEEE 754 standard specifies that:

- An operation that causes an Invalid Operation floating-point exception generates a quiet NaN as its result if that exception is untrapped.
- An operation involving a quiet NaN operand, but not a signaling NaN operand, returns an input NaN as its result.

The floating-point processing behavior when Default NaN mode is disabled adheres to this, with the following additions:

- If an untrapped Invalid Operation floating-point exception occurs, the quiet NaN result is derived from:
  - The first signaling NaN operand, if the exception occurs because at least one of the operands is a signaling NaN.
  - Otherwise, the default NaN.
- If an untrapped Invalid Operation floating-point exception does not occur, but at least one of the operands is a quiet NaN, the result is derived from the first quiet NaN operand.

Depending on the operation, the exact value of a derived quiet NaN result may differ in both sign and number of fraction bits from its source. For a quiet NaN result derived from signaling NaN operand, the most-significant fraction bit is set to 1.

Note

- In these descriptions, *first operand* relates to the left-to-right ordering of the arguments to the pseudocode function that describes the operation.
- The IEEE 754 standard specifies that the sign bit of a NaN has no significance.

The SIMD and floating-point processing behavior when Default NaN mode is enabled is that the Default NaN is the result of all floating-point operations that either:

- Cause untrapped Invalid Operation floating-point exceptions.
- Have one or more quiet NaN inputs, but no signaling NaN inputs.

Table A1-4 on page A1-55 shows the format of the default NaN for ARM floating-point operations.

Default NaN mode is selected for the floating-point processing by setting the FPCR.DN bit to 1.

Other aspects of the functionality of the Invalid Operation floating-point exception are not affected by Default NaN mode. These are that:

- If untrapped, it causes the FPSR.IOC bit to be set to 1.
- If trapped, it causes a user trap handler to be invoked.

A1.6 The ARM memory model

The ARM memory model supports:

- Generating an exception on an unaligned memory access.
- Restricting access by applications to specified areas of memory.
- Translating *virtual addresses* (VAs) provided by executing instructions to *physical addresses* (PAs).
- Altering the interpretation of multi-byte data between big-endian and little-endian.
- Controlling the order of accesses to memory.
- Controlling caches and address translation structures.
- Synchronizing access to shared memory by multiple PEs.

VA support depends on the Execution state, as follows:

AArch64 state

Supports 64-bit virtual addressing, with the Translation Control Register determining the supported VA range. Execution at EL1 and EL0 supports two independent VA ranges, each with its own translation controls.

AArch32 state

Supports 32-bit virtual addressing, with the Translation Control Register determining the supported VA range. For execution at EL1 and EL0, system software can split the VA range into two subranges, each with its own translation controls.

The supported PA space is IMPLEMENTATION DEFINED, and can be discovered by system software.

Regardless of the Execution state, the *Virtual Memory System Architecture* (VMSA) can translate VAs to blocks or pages of memory anywhere within the supported PA space.

For more information, see:

For execution in AArch64 state

- Chapter B2 *The AArch64 Application Level Memory Model*.
- Chapter D3 *The AArch64 System Level Memory Model*.
- Chapter D4 *The AArch64 Virtual Memory System Architecture*.

For execution in AArch32 state

- Chapter E2 *The AArch32 Application Level Memory Model*.
- Chapter G3 *The AArch32 System Level Memory Model*.
- Chapter G4 *The AArch32 Virtual Memory System Architecture*.

A1.7 ARMv8 architecture extensions

The original ARMv8-A architecture is called ARMv8.0. The following sections of this manual describe or summarize permitted extensions to ARMv8.0:

- *The ARMv8 Cryptographic Extension* on page A1-58.
- *The Reliability, Availability, and Serviceability (RAS) Extension* on page A1-70.
- *The Performance Monitors Extension* on page D1-1961.
- *The IVIPT Extension* on page D4-2223.
- Chapter H7 *The PC Sample-based Profiling Extension*.

In addition to describing ARMv8.0, this manual describes the following architectural extensions:

The ARMv8.1 architectural extension

The ARMv8.1 architecture extension adds both:

- Architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.
- Architectural requirements. These are mandatory.

An implementation is ARMv8.1 compliant when all of the following apply:

- It includes all of the ARMv8.1 architectural features that are mandatory. See *Architectural features added by ARMv8.1* on page A1-59 for all of the ARMv8.1 architectural features.
- It includes all of the ARMv8.1 architectural requirements. *Additional requirements of ARMv8.1* on page A1-61 lists these requirements.

For more information, see *The ARMv8.1 architecture extension* on page A1-59.

The ARMv8.2 architectural extension

The ARMv8.2 architecture extension is an extension to ARMv8.1. It adds both:

- Architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.
- Architectural requirements. These are mandatory.

An implementation is ARMv8.2 compliant if all of the following apply:

- It is ARMv8.1 compliant.
- It includes all of the ARMv8.2 architectural features that are mandatory. See *Architectural features added by ARMv8.2* on page A1-62 for all of the ARMv8.2 architectural features.
- It includes all of the ARMv8.2 architectural requirements. *Additional requirements of ARMv8.2* on page A1-68 lists these requirements.

For more information, see *The ARMv8.2 architecture extension* on page A1-62.

The ARMv8.3 architectural extension

The ARMv8.3 architecture extension is an extension to ARMv8.2. It adds architectural features. Some of these are mandatory, others are optional. Some features must be implemented together.

An implementation is ARMv8.3 compliant if all of the following apply:

- It is ARMv8.2 compliant.
- It includes all of the ARMv8.3 architectural features that are mandatory.

For more information, see *The ARMv8.3 architecture extension* on page A1-68.

The Statistical Profiling Extension

SPE is an optional extension to ARMv8.2. That is, SPE requires the implementation of ARMv8.2.

For more information see *The Statistical Profiling Extension* on page A1-72.

The Scalable Vector Extension (SVE)

SVE is an optional extension to ARMv8.2. That is, SVE requires the implementation of ARMv8.2.

For more information see *The Scalable Vector Extension (SVE)* on page A1-72.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

See also *Permitted implementation of subsets of ARMv8.x and ARMv8.(x+1) architectural features*.

A1.7.1 Permitted implementation of subsets of ARMv8.x and ARMv8.(x+1) architectural features

An ARMv8.*x* compliant implementation can include any arbitrary subset of the architectural features of ARMv8.(*x*+1), subject only to those constraints that require that certain features be implemented together.

An ARMv8.*x* compliant implementation cannot include any features of ARMv8.(*x*+2).

Note

The addition of ARMv8.(*x*+1) features to an ARMv8.*x* compliant implementation is only permitted if the implementer has a licence to ARMv8.(*x*+1) in addition to the licence to ARMv8.*x*.

A1.7.2 The ARMv8 Cryptographic Extension

The presence of the ARMv8.0 Cryptographic Extension in an implementation is subject to export license controls. The Cryptographic Extension is an extension of the SIMD support and operates on the vector register file. The ARMv8.0 implementation of the Extension provides instructions for the acceleration of encryption and decryption to support the following:

- AES.
- SHA1.
- SHA2-256 (SHA256).

The Cryptographic Extension also provides multiply instructions that operate on long polynomials.

The ARMv8.0 Cryptographic Extension provides this functionality in AArch64 state and AArch32 state, and an implementation that supports both AArch64 state and AArch32 state provides the same ARMv8.0 Cryptographic Extension functionality in both states. For more information see *The Cryptographic Extension* on page C3-218 or *The Cryptographic Extension in AArch32 state* on page F1-3091.

ARMv8.2 extensions to the Cryptographic Extension

From ARMv8.2, an implementation of the ARMv8.0 Cryptographic Extension can include either or both of:

- The AES functionality, including support for multiplication of 64-bit polynomials. The ID_AA64ISAR0_EL1.AES field indicates whether this functionality is supported.
- The SHA1 and SHA2-256 functionality. The ID_AA64ISAR0_EL1.{SHA2, SHA1} fields indicate whether this functionality is supported.

In addition, ARMv8.2 adds two optional extensions to the ARMv8 Cryptographic Extension, that provide cryptographic functionality in AArch64 state only. These two optional features are:

ARMv8.2-SHA, SHA2-512 and SHA3 functionality

In the A64 instruction set only, ARMv8.2-SHA adds Advanced SIMD instructions that support:

- SHA2-512 (SHA512).
- SHA3.

Implementation of ARMv8.2-SHA requires implementation of the ARMv8.0 Cryptographic Extension SHA-1 and SHA256 functionality.

The ID_AA64ISAR0_EL1.{SHA2, SHA3} fields identify the presence of ARMv8.2-SHA.

For more information see *ARMv8.2-SHA, SHA2-512 and SHA3* on page C3-219.

ARMv8.2-SM, SM3 and SM4 functionality

In the A64 instruction set only, ARMv8.2-SM adds Advanced SIMD instructions that support the Chinese cryptography algorithms SM3 and SM4.

Implementation of ARMv8.2-SM is independent of the implementation of any SHA functionality.

The ID_AA64ISAR0_EL1.{SM3, SM4} fields identify the presence of ARMv8.2-SM.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This means ARMv8.2-SM can be implemented without any other Cryptographic Extension features.

For more information see *ARMv8.2-SM, SM3 and SM4* on page C3-220.

A1.7.3 The ARMv8.1 architecture extension

The ARMv8.1 architecture extension adds both architectural features and architectural requirements.

Architectural features added by ARMv8.1

An implementation of the ARMv8.1 extension must include all of the features that this section describes as mandatory. Such an implementation, when combined with the additional requirements of ARMv8.1, is also called an implementation of the ARMv8.1 architecture.

The ARMv8.1 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

ARMv8.1-Atomics, ARMv8.1 Atomic instructions

ARMv8.1-Atomics introduces a set of atomic instructions:

- Compare and Swap instructions, `CAS` and `CASP`.
- Atomic memory operation instructions, `LD<OP>` and `ST<OP>`, where `<OP>` is one of `ADD`, `CLR`, `EOR`, `SET`, `SMAX`, `SMIN`, `UMAX`, and `UMIN`.
- Swap instruction, `SWP`.

These instructions are only added to the A64 instruction set.

This feature is mandatory in ARMv8.1 implementations.

Implementations of ARMv8.1-VHE require the implementation of ARMv8.1-Atomics.

The ID_AA64ISAR0_EL1.Atomic field identifies the presence of ARMv8.1-Atomics.

For more information, see:

- *Compare and Swap* on page C3-181.
- *Atomic memory operations* on page C3-182.
- *Swap* on page C3-184.

ARMv8.1-SIMD, ARMv8.1 Advanced SIMD instructions

ARMv8.1-SIMD introduces Rounding Double Multiply Add/Subtract Advanced SIMD instructions. For more information, see:

For the A64 instruction set

- *SQRDMLAH (by element)* on page C7-1598.
- *SQRDMLAH (vector)* on page C7-1601.
- *SQRDMLSH (by element)* on page C7-1603.
- *SQRDMLSH (vector)* on page C7-1606.

For the T32 and A32 instruction sets

- *VQRDMLAH* on page F6-4378.
- *VQRDMLSH* on page F6-4382.

This feature is mandatory in ARMv8.1 implementations.

The following fields identify the presence of ARMv8.1-SIMD:

- ID_AA64ISAR0_EL1.RDM.
- ID_ISAR5_EL1.RDM.
- ID_ISAR5.RDM.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

ARMv8.1-LOR, Limited ordering regions

Limited ordering regions allow large systems to perform special load-acquire and store-release instructions that provide order between the memory accesses to a region of the PA map as observed by a limited set of observers.

This feature is mandatory in ARMv8.1 implementations.

This feature is supported in AArch64 state only.

The ID_AA64MMFR1_EL1.LO field identifies the support for ARMv8.1-LOR.

For more information, see:

- *Limited ordering regions* on page B2-103.

ARMv8.1-HPD, Hierarchical permission disables

ARMv8.1-HPD introduces the facility to disable the hierarchical attributes, APTable, PXNTable, and UXNTable, in the translation tables. This disable has no effect on the NSTable bit.

This feature is mandatory in ARMv8.1 implementations.

This feature is added only to the VMSAv8-64 translation regimes. ARMv8.2 extends this to the AArch32 translation regimes, see ARMv8.2-AA32HPD.

The ID_AA64MMFR1_EL1.HPDS field identifies the support for ARMv8.1-HPD.

ARMv8.1-TTHM, Hardware management of the Access flag and dirty state

In ARMv8.0, all updates to the translation tables are performed by software. From ARMv8.1, for the VMSAv8-64 translation regimes only, hardware can perform updates to the translation tables in two contexts:

- Hardware management of the Access flag.
- Hardware management of dirty state, with updates to a dirty state bit in the translation tables.

The dirty state bit is introduced in ARMv8.1.

Hardware management of dirty state can only be enabled when hardware management of the Access flag is also enabled.

This feature is optional in ARMv8.1 implementations. It is IMPLEMENTATION DEFINED whether this is implemented.

The ID_AA64MMFR1_EL1.HAFDBS field identifies the support for ARMv8.1-TTHM.

For more information, see:

- *The dirty state bit* on page D4-2165.
- *Hardware management of the Access flag and dirty state* on page D4-2165.

ARMv8.1-PAN, Privileged access never

ARMv8.1-PAN adds a new bit to PSTATE. When the value of this PAN state bit is 1, any privileged data access from EL1 or EL2 to a virtual memory address that is accessible at EL0 generates a Permission fault.

This feature is mandatory in ARMv8.1 implementations.

This feature is supported in AArch64 and AArch32 states.

The following fields identify the support for ARMv8.1-PAN:

- ID_AA64MMFR1_EL1.PAN.
- ID_MMFR3_EL1.PAN.
- ID_MMFR3.PAN.

For more information, see:

- *About PSTATE.PAN* on page D4-2156.
- *About the PAN bit* on page G4-4891.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

ARMv8.1-VMID16, 16-bit VMID

In an ARMv8.1 implementation, when EL2 is using AArch64, the VMID size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits.

This feature is optional in ARMv8.1 implementations. It is IMPLEMENTATION DEFINED whether this is implemented.

When implemented, this feature is supported only when EL2 is using AArch64.

The ID_AA64MMFR1_EL1.VMIDBits field identifies the supported VMID size.

For more information, see:

- *VMID size* on page D4-2203.

ARMv8.1-VHE, Virtualization Host Extensions

ARMv8.1 introduces the *Virtualization Host Extensions* (VHE) that provide enhanced support for Type 2 hypervisors in Non-secure state.

This feature is mandatory in ARMv8.1 implementations.

An implementation that includes ARMv8.1-VHE requires ARMv8.1-Atomics to be implemented.

The ID_AA64MMFR1_EL1.VH field identifies the support for ARMv8.1-VHE.

The following fields indicate the presence of the Virtualization Host Extensions for debug, including the changes for the PC Sample-based Profiling Extension and the Performance Monitors Extension:

- ID_AA64DFR0_EL1.DebugVer.
- ID_DFR0_EL1.{CopSDbg, CopDbg}.

For more information, see:

- *Virtualization Host Extensions* on page D4-2183.

ARMv8.1-PMU, ARMv8.1 PMU Extension

ARMv8.1 makes the following enhancements to the Performance Monitors Extension:

- The event number space is extended to 16 bits to allow additional IMPLEMENTATION DEFINED event types, and the reserved space for future additions to the architecturally-defined event types is extended.
- The HPMD bit is added to MDCR_EL2. This bit disables event counting at EL2.
- The STALL_FRONTEND and STALL_BACKEND events are required to be implemented. For more information, see *Required events* on page D5-2266.

The Performance Monitors Extension is an OPTIONAL feature of an implementation, but ARM strongly recommends that ARMv8.1 implementations include either:

- Version 3 of the Performance Monitors Extension, PMUv3, with a 16-bit evtCount field.
- An IMPLEMENTATION DEFINED form of performance monitors.

The following fields identify the ARMv8.1-PMU:

- ID_AA64DFR0_EL1.PMUVer.
- ID_DFR0_EL1.PerfMon.
- ID_DFR0.PerfMon.

Additional requirements of ARMv8.1

The ARMv8.1 architecture includes some mandatory changes that are not associated with a feature. These are:

Changes to CRC32 instructions

All implementations of the ARMv8.1 architecture are required to implement the `CRC32*` instructions. These are optional in ARMv8.0.

The following fields identify the support for the `CRC32*` instructions:

- ID_AA64ISAR0_EL1.CRC32.
- ID_ISAR5_EL1.CRC32.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_ISAR5.CRC32.

An implementation of the ARMv8.1 extension must comply with all of the additional requirements. Such an implementation, when combined with the mandatory architectural features of ARMv8.1, is also called an implementation of the ARMv8.1 architecture.

A1.7.4 The ARMv8.2 architecture extension

The ARMv8.2 architecture extension adds both architectural features and architectural requirements.

Architectural features added by ARMv8.2

An implementation of the ARMv8.2 extension must include all of the features that this section describes as mandatory. Such an implementation, when combined with the additional requirements of ARMv8.2, is also called an implementation of the ARMv8.2 architecture.

The ARMv8.2 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

ARMv8.2-A64ISA, ARMv8.2 changes to the A64 ISA

ARMv8.2-A64ISA adds the `BFC` instruction to the A64 instruction set as an alias of `BFM`. It also requires that the new `BFC` instruction and the A64 pseudo-instruction `REV64` are implemented by assemblers.

Note

- In ARMv8.0 and ARMv8.1, the A64 pseudo-instruction `REV64` is optional.
- Because this feature relates to support for an instruction alias and for a pseudo-instruction there are no corresponding feature ID register fields.

This change to the instruction set and assembler requirements is mandatory in an ARMv8.2 implementation.

For more information, see:

- *BFC* on page C6-563.
- *REV64* on page C6-848.

ARMv8.2-ATS1E1, `AT S1E1R` and `AT S1E1W` instruction variants, taking account of PSTATE.PAN

ARMv8.2-ATS1E1 adds new variants of the AArch64 `AT S1E1R` and `AT S1E1W` instructions and the AArch32 `ATS1CPR` and `ATS1CPW` instructions. These new instructions factor in the PSTATE.PAN bit when determining whether or not the location will generate a permission fault for a privileged access, as is reported in the PAR. For more information, see:

For the AArch64 System instructions

- *AT S1E1RP, Address Translate Stage 1 EL1 Read PAN* on page C5-447.
- *AT S1E1WP, Address Translate Stage 1 EL1 Write PAN* on page C5-451.

For the AArch32 System instructions

- *ATS1CPRP, Address Translate Stage 1 Current state PL1 Read PAN* on page G7-5054.
- *ATS1CPWP, Address Translate Stage 1 Current state PL1 Write PAN* on page G7-5058.

This feature is mandatory in ARMv8.2 implementations.

These instructions are added to the A64 and A32/T32 instruction sets.

The following fields identify the presence of ARMv8.2-ATS1E1:

- ID_AA64MMFR1_EL1.PAN.
- ID_MMFR3_EL1.PAN.
- ID_MMFR3.PAN.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

For more information, see:

- *Address translation instructions* on page D4-2139.
- *ATS1C**, Address translation stage 1, current security state* on page G4-4964.
- *Encoding and availability of the address translation instructions* on page G4-4965.

ARMv8.2-FP16, Half-precision floating-point data processing

ARMv8.2-FP16 supports:

- Half-precision data-processing instructions for Advanced SIMD and floating-point in both AArch64 and AArch32 states.
- The FPCR.FZ16 and FPSCR.FZ16 bits, that enable a Flush-to-zero mode for half-precision data-processing instructions.

This feature is optional in ARMv8.2 implementations, unless SVE is implemented, in which case ARMv8.2-FP16 is mandatory. When this feature is implemented it is implemented in both Advanced SIMD and floating-point, and in AArch64 and AArch32 states.

The following fields identify the presence of ARMv8.2-FP16:

- ID_AA64PFR0_EL1.{FP, AdvSIMD}.
- MVFR1_EL1.{FPHP, SIMDHP}.
- MVFR1.{FPHP, SIMDHP}.

For more information, see:

- *Half-precision floating-point formats* on page A1-44.
- *Flush-to-zero* on page A1-53.
- *Modified immediate constants in A64 instructions* on page C2-158.

ARMv8.2-DotProd, SIMD Dot Product

ARMv8.2-DotProd provides instructions to perform the dot product of two 32-bit vectors, accumulating the result in a third 32-bit vector. This can be performed using signed or unsigned arithmetic.

This feature is optional in ARMv8.2 implementations.

These instructions are added to the A64 and A32/T32 instruction sets.

The following fields identify the presence of ARMv8.2-DotProd:

- ID_AA64ISAR0_EL1.DP.
- ID_ISAR6_EL1.DP.
- ID_ISAR6.DP.

For more information, see:

- *SIMD dot product* on page C3-217.
- *Advanced SIMD dot product instructions* on page F1-3089.

ARMv8.2-FHM, Floating-point multiplication variant

ARMv8.2-FHM adds new floating-point multiplication instructions.

These instructions are added to the A64 and A32/T32 instruction sets.

This feature is optional in ARMv8.2 implementations, and can only be implemented when ARMv8.2-FP16 is implemented.

The following fields identify the presence of ARMv8.2-FHM:

- ID_AA64ISAR0_EL1.FHM.
- ID_ISAR6_EL1.FHM.
- ID_ISAR6.FHM.

For more information, see:

- *SIMD arithmetic* on page C3-205.
- *SIMD by element arithmetic* on page C3-212.
- *Advanced SIMD multiply instructions* on page F1-3088.

Non-Confidential

ARMv8.2-LSMAOC, Load/Store Multiple atomicity and ordering controls

ARMv8.2-LSMAOC adds controls that disable legacy behavior of AArch32 Load Multiple and Store Multiple instructions, and provide a trap of one aspect of this legacy behavior.

Implementation of ARMv8.2-LSMAOC is optional. When implemented it provides:

- LSMAOE fields in the SCTLR_EL1, SCTLR_EL2, HSCTLR, and SCTLR registers. These fields can have the following effects on the behavior of AArch32 Load Multiple and Store Multiple instructions:
  - An interrupt can be taken between two memory accesses made by a single Load Multiple or Store Multiple instruction.
  - The memory accesses made by a single Load Multiple or Store Multiple instruction to Device memory with the non-Reordering attribute can be reordered.
- nTLSMD fields in the SCTLR_EL1, SCTLR_EL2, HSCTLR, and SCTLR registers. These fields can cause an access to Device-nGRE, Device-nGnRE, or Device-nGnRnE memory by an AArch32 Load Multiple and Store Multiple instruction to generate an Alignment fault.

Note

ARMv8.2 deprecates software dependence on the legacy behavior of AArch32 Load Multiple and Store Multiple instructions, and these fields disable this behavior.

The following fields identify the support for ARMv8.2-LSMAOC:

- ID_AA64MMFR2_EL1.LSM
- ID_MMFR4_EL1.LSM
- ID_MMFR4.LSM.

For more information, see the register field descriptions and:

- *Generation of Alignment faults by Load/store multiple accesses to Device memory* on page E2-3028.
- *Multi-register loads and stores that access Device memory* on page E2-3040.
- *Taking an interrupt or other exception during a multiple-register load or store* on page G1-4660.

ARMv8.2-UAO, PSTATE override of Unprivileged Load/Store

ARMv8.2 adds a new bit to PSTATE. When the value of PSTATE.UAO is 1, and when executed at EL1 or at EL2 with HCR_EL2.{E2H, TGE} == {1, 1}, the memory accesses made by the Load/Store unprivileged instructions behave as if they were made by the Load/Store register instructions. See *Load/Store unprivileged* on page C3-173 and *Load/Store register* on page C3-169.

This feature is mandatory in ARMv8.2 implementations.

This feature is supported in AArch64 state only.

The ID_AA64MMFR2_EL1.UAO field identifies the support for ARMv8.2-UAO.

For more information, see:

- *About PSTATE.UAO* on page D4-2157.

ARMv8.2-DCPoP, Data cache clean to Point of Persistence

ARMv8.2-DCPoP introduces a mechanism to identify and manage persistent memory locations in a shared memory hierarchy, including adding the `DC CVAP` instruction.

This feature is mandatory in ARMv8.2 implementations.

This feature is supported in AArch64 state only.

The ID_AA64ISAR1_EL1.DPB field identifies the support for ARMv8.2-DCPoP.

For more information about ARMv8.2-DCPoP, see:

- *Memory hierarchy* on page B2-105.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

ARMv8.2-VPIPT, VMID-aware PIPT instruction cache

ARMv8.2-VPIPT supports a new instruction cache type, described as the *VMID-aware PIPT* (VPIPT) instruction cache.

Note

ARMv8.2 adds VPIPT to the set of supported cache types, meaning an ARMv8.2 implementation is permitted to implement VPIPT caches, but is not required to do so.

This feature is supported in AArch64 and AArch32 states.

The CTR_EL0.L1Ip and CTR.L1Ip fields identify the support for ARMv8.2-VPIPT.

For more information, see:

- *VPIPT (VMID-aware PIPT) instruction caches* on page D4-2222.
- *VPIPT (VMID-aware PIPT) instruction caches* on page G4-4930.

ARMv8.2-AA32HPD, AArch32 Hierarchical permission disables

ARMv8.1-HPD introduced the ability to disable the hierarchical attributes, APTable, PXNTable, and UXNTable, in the VMSAv8-64 translation regimes. ARMv8.2-AA32HPD extends this functionality to the VMSAv8-32 translation regimes when those regimes are using the Long descriptor translation table format.

This feature is optional in ARMv8.2 implementations. It is IMPLEMENTATION DEFINED whether this is implemented.

The ID_MMFR4_EL1.HPDS and ID_MMFR4.HPDS fields identify the support for ARMv8.2-AA32HPD.

For more information, see:

- *Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors* on page G4-4872.

ARMv8.2-TTPBHA, Translation table page-based hardware attributes

ARMv8.2 provides a mechanism to allow operating systems or hypervisors to make up to four bits of translation table final-level descriptors available for IMPLEMENTATION DEFINED hardware use.

This functionality is available for all translation regimes in AArch64 state and for stages of translation in AArch32 state that use the Long descriptor translation table format.

ARMv8.2-TTPBHA is optional in ARMv8.2 implementations, but implementation of ARMv8.2-TTPBHA requires implementation of both:

- ARMv8.1-HPD.
- ARMv8.2-AA32HPD, if any Exception level higher than EL0 can use AArch32.

Note

For stage 1 translations, page-based hardware attributes can only be used for a stage of translation for which the Hierarchical permission disables field has a value of 1.

The following fields identify the support for ARMv8.2-TTPBHA:

- ID_AA64MMFR1_EL1.HPDS
- ID_MMFR4_EL1.HPDS
- ID_MMFR4.HPDS.

For more information, see:

- *Memory attribute fields in the VMSAv8-64 translation table format descriptors* on page D4-2148.
- *Attribute fields in VMSAv8-32 Long-descriptor translation table format descriptors* on page G4-4872.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

ARMv8.2-LPA, Large PA and IPA support

ARMv8.2-LPA:

- Allows a larger *intermediate physical address* (IPA) and PA space of up to 52 bits when using the 64KB translation granule.
- Allows a level 1 block size where the block covers a 4TB address range for the 64KB translation granule if the implementation support 52 bits of PA.

This is an optional feature in ARMv8.2 implementations. It is IMPLEMENTATION DEFINED whether it is implemented.

This feature is supported in AArch64 state only.

The ID_AA64MMFR0_EL1.PARange field identifies the support for ARMv8.2-LPA.

For more information about ARMv8.2-LPA, see:

- *VMSA address types and address spaces* on page D4-2083.
- *Address size configuration* on page D4-2097.
- *Extending addressing above 48 bits* on page D4-2101.
- *VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats* on page D4-2143.
- *ARMv8 translation table level 3 descriptor formats* on page D4-2147.

ARMv8.2-LVA, Large VA support

ARMv8.2-LVA supports a larger VA space for each translation table base register of up to 52 bits when using the 64KB translation granule.

This feature is supported in AArch64 state only.

This is an optional feature in ARMv8.2 implementations. It is IMPLEMENTATION DEFINED whether it is implemented.

If ARMv8.2-LVA is implemented, then any implemented trace macrocell must be at least ETMv4.2.

The ID_AA64MMFR2_EL1.VARange field identifies the support for ARMv8.2-LVA.

For more information about ARMv8.2-LVA, see:

- *VMSA address types and address spaces* on page D4-2083.
- *Address size configuration* on page D4-2097.
- *Extending addressing above 48 bits* on page D4-2101.
- *VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats* on page D4-2143.
- *ARMv8 translation table level 3 descriptor formats* on page D4-2147.

ARMv8.2-TTCNP, Translation table Common not private translations

ARMv8.2-TTCNP permits multiple PEs in the same Inner Shareable domain to use the same translation tables for a given stage of address translation.

This feature is mandatory in ARMv8.2 implementations.

This facility is available for all VMSAv8-64 translation regimes and for VMSAv8-32 translation stages that use the Long descriptor translation table format.

The following fields identify the support for ARMv8.2-TTCNP:

- ID_AA64MMFR2_EL1.CnP.
- ID_MMFR4_EL1.CnP.
- ID_MMFR4.CnP.

For more information, see:

- *Common not private translations* on page D4-2202.
- *Common not private translations in VMSAv8-32* on page G4-4919.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

ARMv8.2-TTS2UXN, Translation table stage 2 Unprivileged Execute-never

ARMv8.2-TTS2UXN extends the stage 2 translation table access permissions to provide control of whether memory is executable at EL0 independent of whether it is executable at EL1.

This feature is mandatory in ARMv8.2 implementations.

This facility is available for stage 2 translation stages in VMSAv8-64 and VMSAv8-32.

The following fields identify the support for ARMv8.2-TTS2UXN:

- ID_AA64MMFR1_EL1.XNX.
- ID_MMFR4_EL1.XNX.
- ID_MMFR4.XNX.

For more information, see:

- *Access permissions for instruction execution* on page D4-2159.
- *Access permissions for instruction execution* on page G4-4892.

ARMv8.2-Debug, ARMv8.2 Debug

ARMv8.2-Debug covers a selection of mandatory changes, including:

- If the core power domain is powered up and `DoubleLockStatus()` == TRUE, EDPRSR.{DLK,SPD,PU} is only permitted to read {UNKNOWN, 0, 0}.
- The definition of External Catch debug events is extended to include reset entry.
- All CONSTRAINED UNPREDICTABLE cases that generate External Catch debug events are removed.
- Controls are added to EDECCR to control Exception Catch debug event generation on exception return.
- All IMPLEMENTATION DEFINED control of external debug accesses to OSLAR_EL1 is removed.
- `ExternalSecureNoninvasiveDebugEnabled()` cannot override software controls of counting attributable events in Secure state.

The fields that identify the support for ARMv8.2-Debug are:

- ID_AA64DFR0_EL1.DebugVer and DBGDIDR.Version.
- ID_DFR0_EL1.{CopSDbg, CopDbg} and ID_DFR0.{CopSDbg, CopDbg}.
- EDDEVARCH.ARCHID.

For more information, see:

- *Exception Catch debug events from ARMv8.2* on page H3-5751.
- *EDPRSR.{DLK, SPD, PU} and the Core power domain* on page H6-5801.
- *Interaction with EL3* on page D5-2233.
- *External access disabled* on page H8-5824.

ARMv8.2-PCSample, PC Sample-based Profiling

In ARMv8.2, the control and implementation of the OPTIONAL PC Sample-based Profiling extension is moved from ED*SR Debug registers to PM*SR registers in the Performance Monitors address space. See Chapter H7 *The PC Sample-based Profiling Extension*.

This is an optional feature in ARMv8.2 implementations. It is IMPLEMENTATION DEFINED whether it is implemented.

The following fields identify the support for ARMv8.2-PCSample:

- EDDEVID.PCSample.
- DBGDEVID.PCSample.
- EDDEVID1.PCSROffset.
- DBGDEVID1.PCSROffset.
- PMDEVID.PCSample.

Non-Confidential

ARMv8.2-IESB, Implicit error synchronization event

ARMv8.2-IESB adds an implicit error synchronization event at exception entry and return, controlled by the added SCTLR_ELx.IESB fields. An IESB field is added to the ESR_ELx syndrome registers.

The implicit error synchronization events affect the same synchronizable asynchronous events that are synchronized by the `ESB` instruction, see *The Reliability, Availability, and Serviceability (RAS) Extension* on page A1-70.

This feature is mandatory in ARMv8.2 implementations.

This feature is supported in AArch64 state only.

The ID_AA64MMFR2_EL1.IESB field identifies the support for ARMv8.2-IESB.

For more information, see:

- The *ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile*.

Extensions to the ARM Cryptographic Extensions

See the description of the ARMv8.2-SHA and ARMv8.2-SM features in *ARMv8.2 extensions to the Cryptographic Extension* on page A1-58.

Additional requirements of ARMv8.2

The ARMv8.2 architecture includes some mandatory changes that are not associated with a feature. These are:

Changes to ACTLR2 and HCTLR2 registers

In AArch32 state, the ACTLR2 and HACTLR2 registers become mandatory.

Implementation of RAS Extension

The RAS Extension must be implemented, see *The Reliability, Availability, and Serviceability (RAS) Extension* on page A1-70.

An implementation of the ARMv8.2 extension must comply with all of the additional requirements. Such an implementation, when combined with the mandatory architectural features of ARMv8.2, is also called an implementation of the ARMv8.2 architecture.

A1.7.5 The ARMv8.3 architecture extension

The ARMv8.3 architecture extension adds architectural features.

Architectural features added by ARMv8.3

An implementation of the ARMv8.3 extension must include all of the features that this section describes as mandatory. Such an implementation is also called an implementation of the ARMv8.2 architecture.

The ARMv8.3 architecture extension adds the following architectural features, which are identified by the architectural feature name and a short description of the feature:

ARMv8.3-CompNum, SIMD complex number support

ARMv8.3-CompNum introduces instructions for floating-point multiplication and addition of complex numbers.

These instructions are added to the A64 and A32/T32 instruction sets.

This feature is mandatory in ARMv8.3 implementations.

The half-precision versions of these instructions are implemented only if ARMv8.2-FP16 is implemented. Otherwise they are UNDEFINED.

The fields that identify the presence of ARMv8.3-CompNum are:

- ID_AA64ISAR1_EL1.FCMA.
- ID_ISAR5_EL1.VCMA.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- ID_ISAR5.VCMA.

For more information, see:

- *SIMD complex number arithmetic* on page C3-218.
- *Advanced SIMD complex number arithmetic instructions* on page F1-3089.

ARMv8.3-JSConv, Javascript conversion instructions

ARMv8.3-JSConv introduces instructions that perform a conversion from a double-precision floating point value to a signed 32-bit integer, with rounding to zero. For more information, see:

For the A64 instruction set

- *FJCVTZS* on page C7-1206.

For the A32/T32 instruction set

- *VJCVT* on page F6-4153.

These instructions are added to the A64 and A32/T32 instruction sets.

The feature is mandatory in ARMv8.3 implementations.

The fields that identify the presence of ARMv8.3-JSConv are:

- ID_AA64ISAR1_EL1.JSCVT
- ID_ISAR6_EL1.JSCVT
- ID_ISAR6.JSCVT.

For more information, see:

- *Floating-point conversion* on page C3-200.
- *About the A64 SIMD and floating-point instructions* on page C7-1006.
- *Advanced SIMD and floating-point instructions* on page E1-2990.
- *Floating-point data-processing instructions* on page F1-3093.

ARMv8.3-RCPC, Weaker release consistency

ARMv8.3-RCPC introduces three instructions to support the weaker *Release Consistency processor consistent* (RCpc) model that enables the reordering of a Store-Release followed by a Load-Acquire to a different address:

- *LDAPR* on page C6-655.
- *LDAPRB* on page C6-657.
- *LDAPRH* on page C6-658.

These instructions are added to the A64 instruction set.

The feature is mandatory in ARMv8.3 implementations.

The ID_AA64ISAR1_EL1.LRCPC field identifies the presence of ARMv8.3-RCPC.

For more information, see:

- *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.
- *Load-Acquire/Store-Release* on page C3-174.

ARMv8.3-NV, Nested Virtualization

ARMv8.3-NV provides support for a Guest Hypervisor to run in Non-secure EL1 and ensures that the Guest Hypervisor is unaware that it is running at that Exception level. A Guest Hypervisor is supported regardless of the value of HCR_EL2.E2H.

This feature is supported in AArch64 state only.

The feature is mandatory in ARMv8.3 implementations.

The ID_AA64MMFR2_EL1.NV field identifies the support for ARMv8.3-NV.

For more information, see *Nested virtualization* on page D4-2188.

ARMv8.3-CCIDX, Cache extended number of sets

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

ARMv8.3-CCIDX introduces the following registers to allow caches to be described with greater numbers of sets and greater associativity:

- A 64-bit format of CCSIDR_EL1.
- CCSIDR2_EL1.
- CCSIDR2.

This feature is supported in AArch64 and AArch32 states.

This feature is optional in ARMv8.3 implementations.

The following fields identify the support for ARMv8.3-CCIDX:

- ID_AA64MMFR2_EL1.CCIDX
- ID_MMFR4_EL1.CCIDX.
- ID_MMFR4.CCIDX.

For more information, see:

- *Possible formats of the Cache Size Identification Register, CCSIDR_EL1* on page D3-2053.
- *Possible formats of the Cache Size Identification Registers, CCSIDR and CCSIDR2* on page G3-4812.

ARMv8.3-PAuth, Pointer Authentication

ARMv8.3-PAuth adds functionality that supports address authentication of the contents of a register before that register is used as the target of an indirect branch, or as a load.

This feature is supported only in AArch64 state.

This feature is mandatory in ARMv8.3 implementations.

The fields that identify the support for ARMv8.3-PAuth are ID_AA64ISAR1_EL1.{GPI, GPA, API, APA}.

For more information, see *Pointer authentication in AArch64 state* on page D4-2086.

A1.7.6 The Reliability, Availability, and Serviceability (RAS) Extension

The RAS Extension is a mandatory extension to the ARMv8.2 architecture, and an optional extension to the ARMv8.0 and the ARMv8.1 architectures.

The RAS Extension improves the dependability of a system by providing:

- Reliability, that is, the continuity of correct service.
- Availability, that is, the readiness for correct service.
- Serviceability, that is, the ability to undergo modifications and repairs.

ID_AA64PFR0_EL1.RAS in AArch64 state, and ID_PFR0.RAS in AArch32 state, indicate whether the RAS Extension is implemented.

The RAS Extension introduces a new barrier instruction, the Error Synchronization Barrier (`ESB`), to the A32, T32, and A64 instruction sets.

The RAS Extension introduces the following System registers:

- In AArch64 state:
  - DISR_EL1, Deferred Interrupt Status Register.
  - ERRIDR_EL1, Error Record ID Register.
  - ERRSELR_EL1, Error Record Select Register.
  - ERXADDR_EL1, Selected Error Record Address Register.
  - ERXCTLR_EL1, Selected Error Record Control Register.
  - ERXFR_EL1, Selected Error Record Feature Register.
  - ERXMISC0_EL1, Selected Error Record Miscellaneous Register 0.
  - ERXMISC1_EL1, Selected Error Record Miscellaneous Register 1.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

  - ERXSTATUS_EL1, Selected Error Record Primary Status Register.
  - VDISR_EL2, Virtual Deferred Interrupt Status Register.
  - VSESR_EL2, Virtual SError Exception Syndrome Register.
- In AArch32 state:
  - DISR, Deferred Interrupt Status Register.
  - ERRIDR, Error Record ID Register.
  - ERRSELR, Error Record Select Register.
  - ERXADDR, Selected Error Record Address Register.
  - ERXADDR2, Selected Error Record Address Register 2.
  - ERXCTLR, Selected Error Record Control Register.
  - ERXCTLR2, Selected Error Record Control Register 2.
  - ERXFR, Selected Error Record Feature Register.
  - ERXFR2, Selected Error Record Feature Register 2.
  - ERXMISC0, Selected Error Record Miscellaneous Register 0.
  - ERXMISC1, Selected Error Record Miscellaneous Register 1.
  - ERXMISC2, Selected Error Record Miscellaneous Register 2.
  - ERXMISC3, Selected Error Record Miscellaneous Register 3.
  - ERXSTATUS, Selected Error Record Primary Status Register.
  - VDFSR, Virtual SError Exception Syndrome Register.
  - VDISR, Virtual Deferred Interrupt Status Register.

In addition, the RAS Extension introduces a number of memory-mapped registers.

All registers that are exclusively associated with the RAS architecture are described in the *ARM® Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for the ARMv8-A architecture profile*.

The RAS Extension modifies the following existing System registers:

- In AArch64 state:
  - HCR_EL2.
  - ID_AA64MMFR1_EL1.
  - ID_AA64PFR0_EL1.
  - ID_MMFR4_EL1.
  - ID_PFR0_EL1.
  - SCR_EL3.
  - ESR_ELx.
  - IFSR32_EL2.
- In AArch32 state:
  - HCR2.
  - ID_MMFR4.
  - ID_PFR0.
  - SCR.
  - DFSR.
  - IFSR.
  - HSR.

A1.7.7 The Statistical Profiling Extension

The Statistical Profiling Extension is an optional extension introduced by the ARMv8.2 architecture. Implementation of the Statistical Profiling Extension requires implementation of at least ARMv8.1 of the ARMv8-A architecture profile. The Statistical Profiling Extension is only supported in AArch64 state.

The Statistical Profiling Extension provides a non-invasive method of sampling software and hardware using randomized sampling of either architectural instructions, as defined by the instruction set architecture, or by microarchitectural operations.

ID_AA64DFR0_EL1.PMSVer indicates whether the Statistical Profiling Extension is implemented.

For more information see Chapter D6 *The Statistical Profiling Extension*.

A1.7.8 The *Scalable Vector Extension* (SVE)

The Scalable Vector Extension is an optional extension introduced by the ARMv8.2 architecture. SVE is supported in AArch64 state only.

The Scalable Vector Extension provides vector instructions that, primarily, support wider vectors than the ARM Advanced SIMD instruction set. The *ARM® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for ARMv8-A* describes the SVE.

ID_AA64PFR0_EL1.SVE indicates whether the Scalable Vector Extension is implemented.

The Scalable Vector Extension affects some AArch64 System registers, and those register changes are included in this issue of this Manual, where they are identified as SVE features. SVE also introduces new AArch64 System registers, however these do not appear in this manual. For more information about the new System registers introduced by SVE, please see the *ARM® Architecture Reference Manual Supplement, The Scalable Vector Extension (SVE), for ARMv8-A*.

The Scalable Vector Extension introduces the following System registers:

- ID_AA64ZFR0_EL1.
- ZCR_EL1, and an EL2 alias of this register, ZCR_EL12.
- ZCR_EL2.
- ZCR_EL3.

The Scalable Vector Extension modifies the following existing System registers:

- CPACR_EL1.
- CPTR_EL2.
- CPTR_EL3.
- ESR_ELx.
- ID_AA64PFR0_EL1.
- TCR_EL1.
- TCR_EL2.

Part B

The AArch64 Application Level Architecture

Chapter B1
The AArch64 Application Level Programmers' Model

This chapter gives an application level view of the ARM programmers' model. It contains the following sections:

- *About the Application level programmers' model* on page B1-76.
- *Registers in AArch64 Execution state* on page B1-77.
- *Software control features and EL0* on page B1-82.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

B1.1 About the Application level programmers' model

This chapter contains the programmers' model information required for application development.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of the system information is needed to put the Application level programmers' model into context.

Depending on the implementation choices, the architecture supports multiple levels of execution privilege, indicated by different *Exception levels* that number upwards from EL0 to EL3. EL0 corresponds to the lowest privilege level and is often described as unprivileged. The Application level programmers' model is the programmers' model for software executing at EL0. For more information see *Exception levels* on page D1-1850.

System software determines the Exception level, and therefore the level of privilege, at which software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged at EL0. This:

- Permits the operating system to allocate system resources to an application in a unique or shared manner.
- Provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some system level understanding is necessary, and where relevant it gives a reference to the system level description.

Execution at any Exception level above EL0 is often referred to as privileged execution.

For more information on the system level view of the architecture refer to Chapter D1 *The AArch64 System Level Programmers' Model*.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

B1.2 Registers in AArch64 Execution state

This section describes the registers and process state visible at EL0 when executing in the AArch64 state. It includes the following:

- *Registers in AArch64 state*
- *Process state, PSTATE* on page B1-79
- *System registers* on page B1-80

B1.2.1 Registers in AArch64 state

In the AArch64 application level view, an ARM processing element has:

R0-R30 31 general-purpose registers, R0 to R30. Each register can be accessed as:

- A 64-bit general-purpose register named X0 to X30.
- A 32-bit general-purpose register named W0 to W30.

See the register name mapping in Figure B1-1.

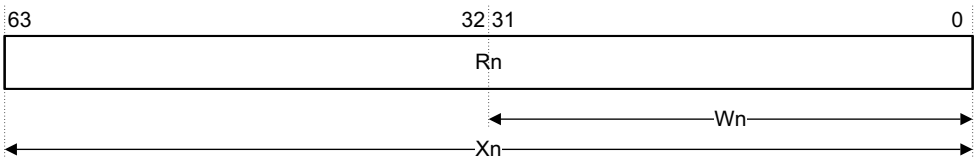

Figure B1-1 General-purpose register naming

The X30 general-purpose register is used as the procedure call link register.

Note

In instruction encodings, the value `0b11111` (31) is used to indicate the ZR (zero register). This indicates that the argument takes the value zero, but does not indicate that the ZR is implemented as a physical register.

SP A 64-bit dedicated Stack Pointer register. The least significant 32 bits of the stack-pointer can be accessed via the register name WSP.

The use of SP as an operand in an instruction, indicates the use of the current stack pointer.

Note

Stack pointer alignment to a 16-byte boundary is configurable at EL1. For more information see the *Procedure Call Standard for the ARM 64-bit Architecture*.

PC A 64-bit Program Counter holding the address of the current instruction.

Software cannot write directly to the PC. It can only be updated on a branch, exception entry or exception return.

Note

Attempting to execute an A64 instruction that is not word-aligned generates a PC alignment fault, see *PC alignment checking* on page D1-1868.

V0-V31 32 SIMD&FP registers, V0 to V31. Each register can be accessed as:

- A 128-bit register named Q0 to Q31.
- A 64-bit register named D0 to D31.
- A 32-bit register named S0 to S31.
- A 16-bit register named H0 to H31.
- An 8-bit register named B0 to B31.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- A 128-bit vector of elements.
- A 64-bit vector of elements.

Where the number of bits described by a register name does not occupy an entire SIMD&FP register, it refers to the least significant bits. See Figure B1-2.

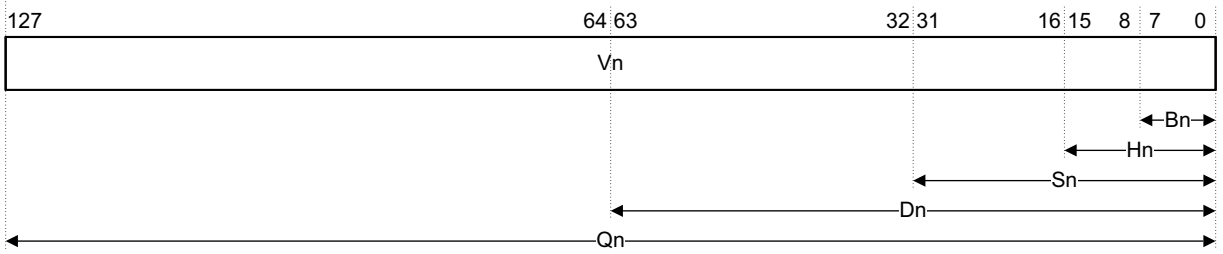

Figure B1-2 SIMD and floating-point register naming

For more information about data types and vector formats, see *Supported data types* on page A1-40.

FPCR, FPSR Two SIMD and floating-point control and status registers, FPCR and FPSR.

See *Registers for instruction processing and exception handling* on page D1-1859 for more information on the registers.

Pseudocode description of registers in AArch64 state

In the pseudocode functions that access registers:

- The assignment form is used for register writes.
- The non-assignment for register reads.

The uses of the `X[]` function are:

- Reading or writing X0-X30, using n to index the required register.
- Reading the zero register ZR, accessed as `X[31]`.

Note

The pseudocode use of X[31] to represent the zero register does not indicate that hardware must implement this register.

The AArch64 `SP[]` function is used to read or write the current SP.

The AArch64 `PC[]` function is used to read the PC.

The AArch64 `V[]` function is used to read or write the Advanced SIMD and floating-point registers V0-V31, using a parameter `n` to index the required register.

The AArch64 `Vpart[]` function is used to read or write a part of one of V0-V31, using a parameter `n` to index the required register, and a parameter `part` to indicate the required part of the register, see the function description for more information.

The `SP[]`, `PC[]`, `V[]`, and `Vpart[]` functions are defined in Chapter J1 *ARMv8 Pseudocode*.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

B1.2.2 Process state, PSTATE

Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

The following PSTATE information is accessible at EL0:

The Condition flags

Flag-setting instructions set these. They are:

N Negative Condition flag. If the result of the instruction is regarded as a two's complement signed integer, the PE sets this to:
- 1 if the result is negative.
- 0 if the result is positive or zero.

Z Zero Condition flag. Set to:
- 1 if the result of the instruction is zero.
- 0 otherwise.

A result of zero often indicates an equal result from a comparison.

C Carry Condition flag. Set to:
- 1 if the instruction results in a carry condition, for example an unsigned overflow that is the result of an addition.
- 0 otherwise.

V Overflow Condition flag. Set to:
- 1 if the instruction results in an overflow condition, for example a signed overflow that is the result of an addition.
- 0 otherwise.

Conditional instructions test the N, Z, C and V Condition flags, combining them with the Condition code for the instruction to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution, see *Condition flags and related instructions* on page C6-525.

The exception masking bits

D Debug exception mask bit. When EL0 is enabled to modify the mask bits, this bit is visible and can be modified. However, this bit is architecturally ignored at EL0.

A SError interrupt mask bit.

I IRQ interrupt mask bit.

F FIQ interrupt mask bit.

For each bit, the values are:

0 Exception not masked.

1 Exception masked.

Access at EL0 using AArch64 state depends on SCTLR_EL1.UMA. See *Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks* on page D1-1914.

See *Process state, PSTATE* on page D1-1865 for the system level view of PSTATE.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessing PSTATE fields at EL0

At EL0 using AArch64 state, PSTATE fields can be accessed using Special-purpose registers that can be directly read using the MRS instruction and directly written using the MSR (register) instructions. Table B1-1 shows the Special-purpose registers that access the PSTATE fields that hold AArch64 state when the PE is at EL0 using AArch64. All other PSTATE fields do not have direct read and write access at EL0.

Table B1-1 Accessing PSTATE fields at EL0 using MRS and MSR (register)

Special-purpose register	PSTATE fields
NZCV	N, Z, C, V
DAIF	D, A, I, F

Software can also use the MSR (immediate) instruction to directly write to PSTATE.{D, A, I, F}. Table B1-2 shows the MSR (immediate) operands that can directly write to PSTATE.{D, A, I, F} when the PE is at EL0 using AArch64 state.

Table B1-2 Accessing PSTATE.{D, A, I, F} at EL0 using MSR (immediate)

Operand	PSTATE fields	Notes
DAIFSet	D, A, I, F	Directly sets any of the PSTATE.{D,A, I, F} bits to 1
DAIFClr	D, A, I, F	Directly clears any of the PSTATE.{D, A, I, F} bits to 0

However, access to the PSTATE.{D, A, I, F} fields at EL0 using AArch64 state depends on SCTLR_EL1.UMA. *Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks* on page D1-1914.

Writes to the PSTATE fields have side-effects on various aspects of the PE operation. All of these side-effects, are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

B1.2.3 System registers

System registers provide support for execution control, status and general system configuration. The majority of the System registers are not accessible at EL0.

However, some System registers can be configured to allow access from software executing at EL0. Any access from EL0 to a System register with the access right disabled causes the instruction to behave as UNDEFINED. The registers that can be accessed from EL0 are:

Cache ID registers The CTR_EL0 and DCZID_EL0 registers provide implementation parameters for EL0 cache management support.

Debug registers A debug communications channel is supported by the MDCCSR_EL0, DBGDTR_EL0, DBGDTRRX_EL0 and DBGDTRTX_EL0 registers.

Performance Monitors registers

See *Performance Monitors support* on page B1-81.

Thread ID registers The TPIDR_EL0 and TPIDRRO_EL0 registers are two thread ID registers with different access rights.

Timer registers In ARMv8 the following operations are performed:

- Read access to the system counter clock frequency using CNTFRQ_EL0.
- Physical and virtual timer count registers, CNTPCT_EL0 and CNTVCT_EL0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- Physical up-count comparison, down-count value and timer control registers, CNTP_CVAL_EL0, CNTP_TVAL_EL0, and CNTP_CTL_EL0.
- Virtual up-count comparison, down-count value and timer control registers, CNTV_CVAL_EL0, CNTV_TVAL_EL0, and CNTV_CTL_EL0.

Performance Monitors support

The ARMv8 architecture defines optional Performance Monitors.

The basic form of the Performance Monitors is:

- A 64-bit cycle counter.
- Up to a maximum of 32 IMPLEMENTATION DEFINED event counters, where the number is identified by the PMCR_EL0.N field.
- System register access to the cycle counter and event registers, and related controls for:
  - Enabling and resetting counters.
  - Flagging overflows.
  - Generating interrupts on overflow.

  Software can enable the cycle counter independently of the event counters.

Software executing at EL1 or a higher Exception level, for example an operating system, can enable access to the counters from EL0. This allows an application to monitor its own performance with fine grain control without requiring operating system support. For example, an application might implement per-function performance monitoring.

For details on the features, configuration and control of the Performance Monitors, see Chapter D5 *The Performance Monitors Extension*.

EL0 access to Performance Monitors

To allow application code to make use of the Performance Monitors, software executing at a higher Exception level must set the following bits in the PMUSERENR_EL0 System register:

EN When set to 1, access to all Performance Monitors registers is allowed at EL0, except for writes to PMUSERENR_EL0, and reads/writes of PMINTENSET_EL1 and PMINTENCLR_EL1.

ER When set to 1, read access to event counters is allowed at EL0. This includes read/write access to PMSELR_EL0, so that the event counter to read through PMXEVCNTR_EL0 can be set.

CR When set to 1, read access to PMCCNTR_EL0 is allowed at EL0.

SW When set to 1, write access to PMSWINC_EL0 is allowed at EL0.

Note

Register PMUSERENR_EL0 is always read-only at EL0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

B1.3 Software control features and EL0

The following sections describe the EL0 view of the ARMv8 software control features:

- *Exception handling*
- *Wait for Interrupt and Wait for Event*
- *The YIELD instruction*
- *Application level cache management* on page B1-83
- *Instructions relating to Debug* on page B1-83

B1.3.1 Exception handling

In the ARM architecture, an *exception* causes a change of program flow. Execution of an exception handler starts, at an Exception level higher than EL0, from a defined vector that relates to the exception taken.

Exceptions include:

- Interrupts.
- Memory system aborts.
- Exceptions generated by attempting to execute an instruction that is UNDEFINED.
- System calls.
- Secure monitor or Hypervisor traps.
- Debug exceptions.

Most details of exception handling are not visible to application level software, and are described in Chapter D1 *The AArch64 System Level Programmers' Model*.

The `SVC` instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a system call to an operating system.

The `BRK` instruction generates a Breakpoint Instruction exception. This provides a mechanism for debugging software using debugger executing on the same PE, see *Breakpoint Instruction exceptions* on page D2-1993.

Note

The `BRK` instruction is supported only in the A64 instruction set. The equivalent instruction in the T32 and A32 instruction sets is `BKPT`.

B1.3.2 Wait for Interrupt and Wait for Event

Issuing a `WFI` instruction indicates that no further execution is required until a WFI wake-up event occurs, see *Wait For Interrupt* on page D1-1957. This permits entry to a low-power state.

Issuing a `WFE` instruction indicates that no further execution is required until a WFE wake-up event occurs, see *Wait for Event mechanism and Send event* on page D1-1954. This permits entry to a low-power state.

B1.3.3 The YIELD instruction

The `YIELD` instruction provides a hint that the task performed by a thread is of low importance so that it could yield, see *YIELD* on page C6-1003. This mechanism can be used to improve overall performance in a *Symmetric Multithreading* (SMT) or *Symmetric Multiprocessing* (SMP) system.

Examples of when the `YIELD` instruction might be used include a thread that is sitting in a spin-lock, or where the arbitration priority of the snoop bit in an SMP system is modified. The `YIELD` instruction permits binary compatibility between SMT and SMP systems.

The `YIELD` instruction is a NOP (No Operation) hint instruction.

The `YIELD` instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use for future migration to a multiprocessor or multithreading system. Operating systems can use `YIELD` in places where a yield hint is wanted, knowing that it will be treated as a NOP if there is no implementation benefit.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

B1.3.4 Application level cache management

A small number of cache management instructions can be enabled at EL0 from higher levels of privilege using the SCTLR_EL1 System register. Any access from EL0 to an operation with the access right disabled causes the instruction to behave as UNDEFINED.

About the available operations, see *Application level access to functionality related to caches* on page B2-106.

B1.3.5 Instructions relating to Debug

Exception handling on page B1-82 refers to the BRK instruction, which generates a Breakpoint Instruction exception. In addition, in both AArch64 state and AArch32 state, the HLT instruction causes the PE to halt execution and enter Debug state. This provides a mechanism for debugging software using a debugger that is external to the PE, see Chapter H1 *About External Debug*.

Note

In AArch32 state, previous versions of the architecture defined the DBG instruction, that could provide a hint to the debug system. In ARMv8, this instruction executes as a NOP. ARM deprecates the use of the DBG instruction.

Chapter B2
The AArch64 Application Level Memory Model

This chapter gives an application level view of the memory model. It contains the following sections:

- *About the ARM memory model* on page B2-86.
- *Atomicity in the ARM architecture* on page B2-88.
- *Definition of the ARMv8 memory model* on page B2-92.
- *Caches and memory hierarchy* on page B2-104.
- *Alignment support* on page B2-109.
- *Endian support* on page B2-111.
- *Memory types and attributes* on page B2-114.
- *Mismatched memory attributes* on page B2-125.
- *Synchronization and semaphores* on page B2-128.

Note

In this chapter, System register names usually link to the description of the register in Chapter D10 *AArch64 System Register Descriptions*, for example SCTLR_EL1.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

B2.1 About the ARM memory model

The ARM architecture is a weakly ordered memory architecture that permits the observation and completion of memory accesses in a different order from the program order. The following sections of this chapter provide the complete definition of the ARMv8 memory model, this introduction is not intended to contradict the definition found in those sections. In general, the basic principles of the ARMv8 memory model are:

- To provide a memory model that has similar weaknesses to those found in the memory models used by high-level programming languages such as C or Java. For example, by permitting independent memory accesses to be re-ordered as seen by other observers.
- To avoid the requirement for multi-copy atomicity in the majority of memory types.
- The provision of instructions and memory barriers to compensate for the lack of multi-copy atomicity in the cases where it would be needed.
- The use of address, data, and control dependencies in the creation of order so as to avoid having excessive numbers of barriers or other explicit instructions in common situations where some order is required by the programmer or the compiler.

This section contains:

- *Address space*.
- *Memory type overview*.

B2.1.1 Address space

Address calculations are performed using 64-bit registers. However, supervisory software can configure the top eight address bits for use as a tag, as described in *Address tagging in AArch64 state* on page D4-2084. If this is done, address bits[63:56]:

- Are not considered when determining whether the address is valid.
- Are never propagated to the program counter.

Supervisory software determines the valid address range. Attempting to access an address that is not valid generates an MMU fault.

Simple sequential execution of instructions might overflow the valid address range. For more information, see *Virtual address space overflow* on page D3-2049.

Memory accesses use the `Mem[]` function. This function makes an access of the required type. If supervisory software configures the top eight address bits for use as a tag, the top eight address bits are ignored.

The `AccType{}` enumeration defines the different access types.

Note

- Chapter D3 *The AArch64 System Level Memory Model* and Chapter D4 *The AArch64 Virtual Memory System Architecture* include descriptions of memory system features that are transparent to the application, including memory access, address translation, memory maintenance instructions, and alignment checking and the associated fault handling. These chapters also include pseudocode descriptions of these operations.
- For information on the pseudocode that relates to memory accesses, see *Basic memory access* on page D3-2077, *Unaligned memory access* on page D3-2078, and *Aligned memory access* on page D3-2078.

B2.1.2 Memory type overview

ARMv8 provides the following mutually-exclusive memory types:

Normal This is generally used for bulk memory operations, both read/write and read-only operations.

Device The ARM architecture forbids *Speculative* reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive Locations.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.

Device memory has additional attributes that have the following effects:

- They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See *Gathering* on page B2-121.
- They preserve the access order and synchronization requirements, both for accesses to a single peripheral and where there is a synchronization requirement on the observability of one or more memory write and read accesses. See *Reordering* on page B2-122
- They indicate whether a write can be acknowledged other than at the end point. See *Early Write Acknowledgement* on page B2-123.

For more information on Normal memory and Device memory, see *Memory types and attributes* on page B2-114.

Note

Earlier versions of the ARM architecture defined a single Device memory type and a Strongly-ordered memory type. A *Note* in *Device memory* on page B2-118 describes how these memory types map onto the ARMv8 memory types.

B2.2 Atomicity in the ARM architecture

Atomicity is a feature of memory accesses, described as *atomic* accesses. The ARM architecture description refers to two types of atomicity, *single-copy atomicity* and *multi-copy atomicity*. In the ARMv8 architecture, the atomicity requirements for memory accesses depend on the memory type, and whether the access is explicit or implicit. For more information, see:

- *Requirements for single-copy atomicity*.
- *Properties of single-copy atomic accesses* on page B2-89.
- *Multi-copy atomicity* on page B2-89.
- *Requirements for multi-copy atomicity* on page B2-90.
- *Concurrent modification and execution of instructions* on page B2-90.

For more information about the memory types, see *Memory type overview* on page B2-86.

B2.2.1 Requirements for single-copy atomicity

For explicit memory accesses generated from an Exception level the following rules apply:

- A read that is generated by a load instruction that loads a single general-purpose register and is aligned to the size of the read in the instruction is single-copy atomic.
- A write that is generated by a store instruction that stores a single general-purpose register and is aligned to the size of the write in the instruction is single-copy atomic.
- Reads that are generated by a Load Pair instruction that loads two general-purpose registers and are aligned to the size of the load to each register are treated as two single-copy atomic reads, one for each register being loaded.
- Writes that are generated by a Store pair instruction that stores two general-purpose registers and are aligned to the size of the store of each register are treated as two single-copy atomic writes, one for each register being stored.
- Load-Exclusive Pair instructions of two 32-bit quantities and Store-Exclusive Pair instructions of 32-bit quantities are single-copy atomic.
- When the Store-Exclusive of a Load-Exclusive/Store-Exclusive pair instruction using two 64-bit quantities succeeds, it causes a single-copy atomic update of the entire memory location being updated.

  Note

  To atomically load two 64-bit quantities, perform a Load-Exclusive pair/Store-Exclusive pair sequence of reading and writing the same value for which the Store-Exclusive pair succeeds, and use the read values from the Load-Exclusive pair.

- Where translation table walks generate a read of a translation table entry, this read is single-copy atomic.
- For the atomicity of instruction fetches, see *Concurrent modification and execution of instructions* on page B2-90.
- Reads to SIMD and floating-point registers of a single 64-bit or smaller quantity that is aligned to the size of the quantity being loaded are treated as single-copy atomic reads.
- Writes from SIMD and floating-point registers of a single 64-bit or smaller quantity that is aligned to the size of the quantity being stored are treated as single-copy atomic writes.
- Element or Structure Reads to SIMD and floating-point registers of 64-bit or smaller elements, where each element is aligned to the size of the element being loaded, have each element treated as a single-copy atomic read.
- Element or Structure Writes from SIMD and floating-point registers of 64-bit or smaller elements, where each element is aligned to the size of the element being stored, have each element treated as a single-copy atomic store.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- Reads to SIMD and floating-point registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit reads.
- Writes from SIMD and floating-point registers of a 128-bit value that is 64-bit aligned in memory are treated as a pair of single-copy atomic 64-bit writes.

All other memory accesses are regarded as streams of accesses to bytes, and no atomicity between accesses to different bytes is ensured by the architecture.

All accesses to any byte are single-copy atomic.

Note

In AArch64 state, no memory accesses from a DC ZVA have single-copy atomicity of any quantity greater than individual bytes.

If, according to these rules, an instruction is executed as a sequence of accesses, exceptions, including interrupts, can be taken during that sequence, regardless of the memory type being accessed. If any of these exceptions are returned from using their preferred return address, the instruction that generated the sequence of accesses is re-executed, and so any access performed before the exception was taken is repeated. See also *Taking an interrupt or other exception during a multiple-register load or store* on page D1-1909.

Note

The exception behavior for these multiple access instructions means that they are not suitable for use for writes to memory for the purpose of software synchronization.

B2.2.2 Properties of single-copy atomic accesses

A memory access instruction that is single-copy atomic has the following properties:

1. For a pair of overlapping single-copy atomic store instructions, all of the overlapping writes generated by one of the stores are Coherence-after the corresponding overlapping writes generated by the other store.
2. For a single-copy atomic load instruction L_1 that overlaps a single-copy atomic store instruction S_2, if one of the overlapping reads generated by L_1 Reads-from one of the overlapping writes generated by S_2, then none of the overlapping writes generated by S_2 are Coherence-after the corresponding overlapping reads generated by L_1.

For more information, see *Definition of the ARMv8 memory model* on page B2-92.

B2.2.3 Multi-copy atomicity

In a multiprocessing system, writes to a memory location are *multi-copy atomic* if the following conditions are both true:

- All writes to the same location are *serialized*, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a location does not return the value of a write until all observers observe that write.

Note

Writes that are not coherent are not multi-copy atomic.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

B2.2.4 Requirements for multi-copy atomicity

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory, writes are not required to be multi-copy atomic.

The ARMv8 memory model is Other-multi-copy atomic. For more information, see *Ordering constraints* on page B2-96.

B2.2.5 Concurrent modification and execution of instructions

The ARMv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction performing any behavior that can be achieved by executing any sequence of instructions that can be executed from the same Exception level, except where each of the instruction before modification and the instruction after modification is one of a `B`, `BL`, `BRK`, `HVC`, `ISB`, `NOP`, `SMC`, or `SVC` instruction.

For the `B`, `BL`, `BRK`, `HVC`, `ISB`, `NOP`, `SMC`, and `SVC` instructions the architecture guarantees that, after modification of the instruction, behavior is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the modified instruction.

If one thread of execution changes a conditional branch instruction, such as `B` or `BL`, to another conditional instruction and the change affects both the condition field and the branch target, execution of the changed instruction by another thread of execution before the change is synchronized can lead to either:

- The old condition being associated with the new target address.
- The new condition being associated with the old target address.

These possibilities apply regardless of whether the condition, either before or after the change to the branch instruction, is the *always* condition.

For all other instructions, to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. No PE must be executing an instruction when another PE is modifying that instruction.
2. To ensure that the modified instructions are observable, a PE that is writing the instructions must issue the following sequence of instructions and operations:

```
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Wt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Xn.
        STR Wt, [Xn]
        DC CVAU, Xn         ; Clean data cache by VA to point of unification (PoU)
        DSB ISH             ; Ensure visibility of the data cleaned from cache
        IC IVAU, Xn         ; Invalidate instruction cache by VA to PoU
        DSB ISH             ; Ensure completion of the invalidations
```

Note

- The `DC CVAU` operation is not required if the area of memory is either Non-cacheable or Write-Through Cacheable.
- If the contents of physical memory differ between the mappings, changing the mapping of VAs to PAs can cause the instructions to be concurrently modified by one PE and executed by another PE. If the modifications affect instructions other than those listed as being acceptable for modification, synchronization must be used to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

3. In a multiprocessor system, the `IC IVAU` is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. However, when the modified instructions are observable, each PE that is executing the modified instructions must issue the following instruction to ensure execution of the modified instructions:

```
ISB                             ; Synchronize fetched instruction stream
```

For more information about the required synchronization operation, see *Synchronization and coherency issues between data and instruction accesses* on page B2-107.

Note

For information about memory accesses caused by instruction fetches, see *Ordering relations* on page B2-95.

B2.2.6 Possible implementation restrictions on using atomic instructions

In some implementations, and for some memory types, the properties of atomicity can be met only by functionality outside the PE. Some system implementations might not support atomic instructions for all regions of the memory. In particular, this can apply to:

- Any type of memory in the system that does not support hardware cache coherency.
- Device, Non-cacheable memory, or memory that is treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such implementations, it is defined by the system:

- Whether the atomic instructions are atomic in regard to other agents that access memory.
- If the atomic instructions are atomic in regard to other agents that access memory, which address ranges or memory types this applies to.

An implementation can choose which memory type is treated as Non-cacheable.

The memory types for which it is architecturally guaranteed that the atomic instructions will be atomic are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

If the atomic instructions are not atomic in regard to other agents that access memory, then performing an atomic instruction to such a location can have one or more of the following effects:

- The instruction generates a synchronous External abort.
- The instruction generates a System Error interrupt.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault reported using the Data Abort Fault status code of ESR_ELx.DFSC = `110101`.

  For the Non-secure EL1&0 translation regime, if the atomic instruction is not supported because of the memory type that is defined in the first stage of translation, or the second stage of translation is not enabled, then this exception is a first stage abort and is taken to EL1. Otherwise, the exception is a second stage abort and is taken to EL2.
- The instruction is treated as a `NOP`.
- The instructions are performed, but there is no guarantee that the memory accesses were performed atomically in regard to other agents that access memory. In this case, the instruction might also generate a System Error interrupt.

B2.3 Definition of the ARMv8 memory model

This section describes observation and ordering in the ARMv8 memory model. It contains the following subsections:

- *Locations*.
- *Ordering and observability* on page B2-93.
- *Ordering constraints* on page B2-96.
- *Completion and endpoint ordering* on page B2-97.
- *Memory barriers* on page B2-98.
- *Limited ordering regions* on page B2-103.

For more information about endpoint ordering of memory accesses, see *Reordering* on page B2-122.

In the ARMv8 memory model, the Shareability memory attribute indicates the degree to which hardware must ensure memory coherency between a set of observers, see *Memory types and attributes* on page B2-114.

The ARMv8 architecture defines additional memory attributes and associated behaviors, which are defined in the system level section of this manual. See:

- Chapter D3 *The AArch64 System Level Memory Model*.
- Chapter D4 *The AArch64 Virtual Memory System Architecture*.

See also *Mismatched memory attributes* on page B2-125.

B2.3.1 Locations

The ARMv8 memory model provides a set of definitions that are used to constrain the permitted sequences of accesses to memory. The ARMv8 memory model defines:

- The ordering of observation of memory accesses between different observers.
- The ordering of arrival of memory accesses arriving at an endpoint.
- The mechanisms to control the ordering of observation of memory accesses and the arrival of memory accesses at an endpoint.

Locations, Memory effects, and Observers

The ARMv8 memory model provides the following definition of a *Location* in memory:

Location

A *Location* refers to a single byte in memory.

As part of its execution an instruction might generate a Memory effect. Observers in the system might observe the Memory effects of that instruction on a Location. The ARMv8 memory model provides the following definitions of a Memory effect and an Observer:

Memory effect

The *Memory effects* of an instruction are the read, write, or barrier effects of that instruction. For an instruction that accesses memory:

- A read effect is generated for each Location that is read by the instruction.
- A write effect is generated for each Location that is written by the instruction.

An instruction can generate both read and write effects.

The Memory effects of an instruction I_1 are said to appear in program order before the Memory effects of instruction I_2 if and only if I_1 occurs before I_2 in program order.

For the purposes of describing the ARMv8 memory model, all read and write effects access only Normal memory locations in a Common Shareability Domain. Where this section refers to a read, write, or memory barrier without any qualification, then it is referring to the corresponding Memory effect.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Observer

An *Observer* refers to either a processing element, or some other memory accessing agent that can generate reads from or writes to memory.

Common Shareability Domain

A *Common Shareability Domain* for a program is the smallest Shareability domain that contains all of the active Observers of the Memory effects generated by a program.

B2.3.2 Ordering and observability

The ARMv8 memory model permits reordering of memory accesses. This section defines the constraints placed on the reordering of memory accesses using the following:

- Register value dependencies to establish order between instructions on a PE.
- Ordering constraints to establish order between accesses to a Location.

Register value dependencies

The ARMv8 memory model defines the following dependencies between instructions:

Register dependency

A *Register dependency* from a first data value V_1 to a second data value V_2 exists within a PE if and only if either:

- The register, excluding the AArch64 zero register (XZR or WZR), that is used to hold V_1 is used in the calculation of V_2.
- There is a Register dependency from V_1 to a third data value V_3 and there is a register dependency from V_3 to V_2.

Register data dependency

A *Register data dependency* from a first data value V_1 to a second data value V_2 exists within a PE if and only if either:

- The register, excluding the AArch64 zero register (XZR or WZR) and the AArch32 PC, that is used to hold V_1 and is used in the calculation of V_2, and the calculation between V_1 and the V_2 does not consist of either:
  - A conditional branch whose condition is determined by V_1.
  - A conditional selection, move, or computation whose condition is determined by V_1, where the input data values for the selection, move, or computation do not have a data dependency on V_1.
- There is a Register data dependency from V_1 to a third data value V_3, and there is a Register data dependency from V_3 to V_2.

Address dependency

An *Address dependency* from a read R_1 to a subsequent read R_2 exists if and only if there is a Register data dependency from the data value that is returned by R_1 to the address used by R_2.

An *Address dependency* from a read R_1 to a subsequent write W_2 exists if and only if there is a Register dependency from the data value that is returned by R_1 to the address used by W_2.

Data dependency

A *Data dependency* from a read R_1 to a subsequent write W_2 exists if and only if there is a Register dependency from the data value returned by R_1 to the data value written by W_2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Control dependency

A *Control dependency* from a read R_1 to a subsequent instruction I_2 exists if and only if there is a Register dependency from the data value returned by R_1 to the data value used in the evaluation of a conditional branch or the determination of a synchronous exception on an instruction and I_2 is only executed as a result of one of the possible outcomes of that conditional branch or synchronous exception.

Ordering and observability at a Location

Memory effects on a Location are related by the following relations:

Reads-from

A *Reads-from* relation that couples reads and writes to the same Location such that each read is paired with a single write in the program. A read R_2 of a Location Reads-from a write W_1 to the same Location if and only if R_2 takes its data from W_1.

Note

The Reads-from relation represents a read being satisfied by a write and then returning the written data.

Coherence order

A *Coherence order* relation for each Location in the program that provides a total order on all writes from all coherent Observers to that Location, starting with a notional write of the initial value.

Note

The Coherence order of a Location represents the order in which writes to the Location arrive at memory.

Coherence-after

A write W_2 to a Location is *Coherence-after* another write W_1 to the same Location if and only if W_2 is sequenced after W_1 in the Coherence order of the Location.

A write W_2 to a Location is Coherence-after a read R_1 of the same location if and only if R_1 Reads-from a write W_3 to the same Location and W_2 is Coherence-after W_3.

Overlapping accesses

Two Memory effect overlap if and only if they access the same Location. Two instructions overlap if and only if one or more of their generated Memory effects overlap.

Observed-by

A read or a write RW_1 from an Observer is *Observed-by* a write W_2 from a different Observer if and only if W_2 is coherence-after RW_1.

A write W_1 from an Observer is Observed-by a read R_2 from a different Observer if and only if R_2 Reads-from W_1.

Note

The Observed-by relation only relates accesses generated by different Observers.

`DMB FULL`

A `DMB FULL` is a `DMB` with neither the `LD` or the `ST` qualifier.

Where this section refers to `DMB` without any qualification, then it is referring to all types of `DMB`. Unless a specific shareability domain is defined, a `DMB` applies to the Common Shareability Domain.

All properties that apply to `DMB` also apply to the corresponding `DSB`.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Ordering relations

In addition to the ordering relations for a single Location, the ARMv8 memory model also provides ordering relations to describe the ordering of Memory effects to multiple Locations. These are as follows:

Dependency-ordered-before

A dependency creates externally-visible order between a read and another Memory effect generated by the same Observer. A read R_1 is *Dependency-ordered-before* a read or write RW_2 from the same Observer if and only if R_1 appears in program order before RW_2 and any of the following cases apply:

- There is an Address dependency or a Data dependency from R_1 to RW_2.
- RW_2 is a write W_2 and there is a Control dependency from R_1 to W_2.
- RW_2 is a read R_2 generated by an instruction appearing in program order after an instruction I_3 that generates a Context synchronization event, and there is a Control dependency from R_1 to I_3.
- RW_2 is a write W_2 appearing in program order after a read or a write RW_3 and there is an Address dependency from R_1 to RW_3.
- RW_2 is a write W_2 that is Coherence-after a write W_3 and there is a Control dependency or a Data dependency from R_1 to W_3.
- RW_2 is a read R_2 that Reads-from a write W_3 and there is an Address dependency or a Data dependency from R_1 to W_3.

Atomic-ordered-before

Load-Exclusive and Store-Exclusive instructions provide some ordering guarantees, even in the absence of dependencies. A read or a write RW_1 is *Atomic-ordered-before* a read or a write RW_2 from the same Observer if and only if RW_1 appears in program order before RW_2 and either of the following cases apply:

- RW_1 is a read R_1 and RW_2 is a write W_2 such that R_1 and W_2 are generated by an atomic instruction or a successful Load-Exclusive/Store-Exclusive instruction pair to the same Location.
- RW_1 is a write W_1 generated by an atomic instruction or a successful Store-Exclusive instruction and RW_2 is a read R_2 generated by an instruction with Acquire or AcquirePC semantics such that R_2 Reads-from W_1.

For more information, see *Synchronization and semaphores* on page B2-128.

Barrier-ordered-before

Barrier instructions order prior Memory effects before subsequent Memory effects generated by the same Observer. A read or a write RW_1 is *Barrier-ordered-before* a read or a write RW_2 from the same Observer if and only if RW_1 appears in program order before RW_2 and any of the following cases apply:

- RW_1 appears in program order before a `DMB FULL` or an atomic instruction with both Acquire and Release semantics that appears in program order before RW_2.
- RW_1 is a write W_1 generated by an instruction with Release semantics and RW_2 is a read R_2 generated by an instruction with Acquire semantics.
- RW_1 is a read R_1 and either:
  - R_1 appears in program order before a `DMB LD` that appears in program order before RW_2.
  - R_1 is generated by an instruction with Acquire or AcquirePC semantics.
- RW_2 is a write W_2 and either:
  - RW_1 is a write W_1 appearing in program order before a `DMB ST` that appears in program order before W_2.
  - W_2 is generated by an instruction with Release semantics.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

— RW_1 appears in program order before a write W_3 generated by an instruction with Release semantics and W_2 is Coherence-after W_3.

Ordered-before

An arbitrary pair of Memory effects is ordered if it can be linked by a chain of ordered accesses consistent with external observation. A read or a write RW_1 is *Ordered-before* a read or a write RW_2 if and only if any of the following cases apply:

- RW_1 is Observed-by RW_2.
- RW_1 is Dependency-ordered-before RW_2.
- RW_1 is Atomic-ordered-before RW_2.
- RW_1 is Barrier-ordered-before RW_2.
- RW_1 is Ordered-before a read or a write that is Ordered-before RW_2.

B2.3.3 Ordering constraints

The ARMv8 memory model is described as being Other-multi-copy atomic. The definition of Other-multi-copy atomic is as follows:

Other-multi-copy atomic

In an *Other-multi-copy atomic* system, it is required that a write from an Observer, if observed by a different Observer, is then observed by all other Observers that access the Location coherently. It is, however, permitted for an Observer to observe its own writes prior to making them visible to other observers in the system.

The Other-multi-copy atomic property of the ARMv8 memory model is enforced by placing constraints on the possible executions of a program. Those executions that meet the constraints given by the ordering model are said to be *architecturally well-formed*. An implementation that is executing a program is only permitted to exhibit behavior consistent with an architecturally well-formed execution:

Architecturally well-formed

An architecturally well-formed execution must satisfy both of the following requirements:

Internal visibility requirement

For a read or a write RW_1 that appears in program order before a read or a write RW_2 to the same Location, the internal visibility requirement requires that exactly one of the following statements is true:

- RW_2 is a write W_2 that is Coherence-after RW_1.
- RW_1 is a write W_1 and RW_2 is a read R_2 such that either:
  - R_2 Reads-from W_1.
  - R_2 Reads-from another write that is Coherence-after W_1.
- RW_1 and RW_2 are both reads R_1 and R_2 such that R_1 Reads-from a write W_3 and either:
  - R_2 Reads-from W_3.
  - R_2 Reads-from another write that is Coherence-after W_3.

Note

If a Memory effect M_1 from an Observer appears in program order before a Memory effect M_2 from the same Observer, then M_1 will be seen to occur before M_2 by that Observer.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

External visibility requirement

For a read or a write RW_1 from an Observer that is Ordered-before a read or a write RW_2 from a different Observer, the external visibility constraint requires that RW_2 is not Observed-by RW_1. This means that an Architecturally well-formed execution must not exhibit a cycle in the Ordered-before relation.

Note

If a Memory effect M_1 from an Observer is Ordered-before another Memory effect M_2, from a different Observer, then M_1 will be seen to occur before M_2 by all Observers in the system.

B2.3.4 Completion and endpoint ordering

Interaction between Observers in a system is not restricted to communication via shared variables in coherent memory. For example, an Observer could configure an interrupt controller to raise an interrupt on another Observer as a form of message passing. These interactions typically involve an additional agent, which defines the instruction sequence that is required to establish communication links between different Observers. When these forms of interaction are used in conjunction with shared variables, a `DSB` instruction can be used to enforce ordering between them.

For all memory, the completion rules are defined as:

- A read R_1 to a Location is complete for a shareability domain when all of the following are true:
  - Any write to the same Location by an Observer within the shareability domain will be Coherence-after R_1.
  - Any translation table walks associated with R_1 are complete for that shareability domain.
- A write W_1 to a Location is complete for a shareability domain when all of the following are true:
  - Any write to the same Location by an Observer within the shareability domain will be Coherence-after W_1.
  - Any read to the same Location by an Observer within the shareability domain will either Reads-from W_1 or Reads-from a write that is Coherence-after W_1.
  - Any translation table walks associated with the write are complete for that shareability domain.
- A translation table walk is complete for a shareability domain when the memory accesses, including the updates to translation table entries, associated with the translation table walk are complete for that shareability domain, and the TLB is updated.
- A cache maintenance instruction is complete for a shareability domain when the memory effects of the instruction are complete for that shareability domain, and any translation table walks that arise from the instruction are complete for that shareability domain.
- A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated are complete.

The completion of any cache or TLB maintenance instruction includes its completion on all PEs that are affected by both the instruction and the `DSB` operation that is required to guarantee visibility of the maintenance instruction.

Note

These completion rules mean that, for example, a cache maintenance instruction that operates by VA to the PoC completes only after memory at the PoC has been updated.

Additionally, for Device-nGnRnE memory, a read or write of a Location in a Memory-mapped peripheral that exhibits side-effects is complete only when the read or write both:

- Can begin to affect the state of the Memory-mapped peripheral.
- Can trigger all associated side-effects, whether they affect other peripheral devices, PEs, or memory.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This requirement for Device-nGnRnE memory is consistent with the memory access having reached the peripheral endpoint.

Peripherals

This section defines a Memory-mapped peripheral and the total order of reads and writes to a peripheral which is defined as the Peripheral coherence order:

Memory-mapped peripheral

A *Memory-mapped peripheral* occupies a memory region of IMPLEMENTATION DEFINED size and can be accessed using load and store instructions. Memory effects to a Memory-mapped peripheral can have side-effects, such as causing the peripheral to perform an action. Values that are read from addresses within a Memory-mapped peripheral might not correspond to the last data value written to those addresses. As such, Memory effects to a Memory-mapped peripheral might not appear in the Reads-from or Coherence order relations.

Peripheral coherence order

The *Peripheral coherence order* of a Memory-mapped peripheral is a total order on all reads and writes to that peripheral.

Note

The Peripheral coherence order for a Memory-mapped peripheral signifies the order in which accesses arrive at the endpoint.

For a read or a write RW_1 and a read or a write RW_2 to the same peripheral, then RW_1 will appear in the Peripheral coherence order for the peripheral before RW_2 if either of the following cases apply:

- RW_1 and RW_2 are accesses using Non-cacheable or Device attributes and RW_1 is Ordered-before RW_2.
- RW_1 and RW_2 are accesses using Device-nGnRE or Device-nGnRnE attributes and RW_1 appears in program order before RW_2.

Out-of-band-ordered-before

A read or a write RW_1 is *Out-of-band-ordered-before* a read or a write RW_2 if and only if either of the following cases apply:

- RW_1 appears in program order before a `DSB` instruction that begins an IMPLEMENTATION DEFINED instruction sequence indirectly leading to the generation of RW_2.
- RW_1 is Ordered-before a read or a write RW_3 and RW_3 is Out-of-band-ordered-before RW_2.

If a Memory effect M_1 is Out-of-band-ordered-before a read or a write M_2, then M_1 is seen to occur before M_2 by all Observers.

B2.3.5 Memory barriers

Memory barrier is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring Load/Store instructions. The memory barriers defined by the ARMv8 architecture provide a range of functionality, including:

- Ordering of Load/Store instructions.
- Completion of Load/Store instructions.
- Context synchronization.

The following subsections describe the ARMv8 memory barrier instructions:

- *Instruction Synchronization Barrier (ISB)* on page B2-99
- *Data Memory Barrier (DMB)* on page B2-99.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- *Data Synchronization Barrier (DSB)* on page B2-100.
- *Shareability and access limitations on the data barrier operations* on page B2-100.
- *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.
- *LoadLOAcquire, StoreLORelease* on page B2-102.

Note

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are only available when software execution is at EL1 or higher.

DMB and DSB instructions affect reads and writes to the memory system generated by Load/Store instructions and data or unified cache maintenance instructions being executed by the PE. Instruction fetches or accesses caused by a hardware translation table access are not explicit accesses.

Instruction Synchronization Barrier (ISB)

An ISB instruction ensures that all instructions that come after the ISB instruction in program order are fetched from the cache or memory after the ISB instruction has completed. Using an ISB ensures that the effects of context-changing operations executed before the ISB are visible to the instructions fetched after the ISB instruction. Examples of context-changing operations that require the insertion of an ISB instruction to ensure the effects of the operation are visible to instructions fetched after the ISB instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to System registers.

Any context-changing operations appearing in program order after the ISB instruction only take effect after the ISB has been executed.

The pseudocode function for the operation of an ISB is `InstructionSynchronizationBarrier()`.

See also *Memory barriers* on page D3-2079.

Data Memory Barrier (DMB)

The DMB instruction is a memory barrier instruction that ensures the relative order of memory accesses before the barrier with memory accesses after the barrier. The DMB instruction does not ensure the completion of any of the memory accesses for which it ensures relative order.

The full definition of the DMB is covered formally in the *Definition of the ARMv8 memory model* on page B2-92 and this introduction to the DMB instruction is not intended to contradict that section.

The basic principle of a DMB instruction is to introduce order between memory accesses that are specified to be affected by the DMB options supplied as arguments to the DMB instruction. The DMB instruction ensures that all affected memory accesses by the PE executing the DMB that appear in program order before the DMB and those which originate from a different PE, to the extent required by the DMB options, which have been Observed-by the PE before the DMB is executed, are Observed-by each PE, to the extent required by the DMB options, before any affected memory accesses that appear in program order after the DMB are Observed-by that PE.

The use of a DMB creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

DMB only affects memory accesses and the operation of data cache and unified cache maintenance instructions, see *A64 Cache maintenance instructions* on page D3-2062. It has no effect on the ordering of any other instructions executing on the PE. A DMB instruction intended to ensure the completion of cache maintenance instructions must have an access type of both loads and stores.

The pseudocode function for the operation of a DMB is `DataMemoryBarrier()`.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Data Synchronization Barrier (DSB)

A DSB is a memory barrier that ensures that memory accesses that occur before the DSB have completed before the completion of the DSB instruction. In doing this, it acts as a stronger barrier than a DMB and all ordering that is created by a DMB with specific options is also generated by a DSB with the same options.

Execution of a DSB:

- At EL2 ensures that any memory accesses caused by Speculative translation table walks from the Non-secure EL1&0 translation regime have been observed.
- At EL3 ensures that any memory accesses caused by speculative translation table walks from any of the following translation regimes have been observed:
  - The EL2 or EL2&0 translation regime.
  - The Secure EL1&0 translation regime.
  - The Non-secure EL1&0 translation regime.

For more information, see *Use of out-of-context translation regimes* on page D4-2103.

A DSB completes when all of the following apply:

- All explicit memory accesses that are observed by PEe before the DSB is executed and are of the required access types, and are from observers in the same required shareability domain as PEe, are complete for the set of observers in the required shareability domain.
- If the required access types of the DSB is reads and writes, then all cache maintenance instructions and all TLB maintenance instructions issued by PEe before the DSB are complete for the required shareability domain.

In addition, no instruction that appears in program order after the DSB instruction can alter any state of the system or perform any part of its functionality other than:

- Being fetched from memory and decoded.
- Reading the general-purpose, SIMD and floating-point, Special-purpose, or System registers that are directly or indirectly read without causing side-effects until the DSB completes.

The pseudocode function for the operation of a DSB is `DataSynchronizationBarrier()`.

See also *Memory barriers* on page D3-2079.

Shareability and access limitations on the data barrier operations

The DMB and DSB instructions take an argument that specifies:

- The shareability domain over which the instruction must operate. This is one of:
  - Full system.
  - Outer Shareable.
  - Inner Shareable.
  - Non-shareable.
- The accesses for which the instruction operates. This is one of:
  - Read and write accesses, both before and after the barrier instruction.
  - Write accesses only, before and after the barrier instruction.
  - Read accesses before the barrier instruction, and read and write accesses after the barrier instruction.

Note

This form of a DMB or DSB instruction can be described as a Load-Load/Store barrier.

For more information on whether an access is before or after a barrier instruction, see *Data Memory Barrier (DMB)* on page B2-99 or *Data Synchronization Barrier (DSB)*.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Table B2-1 shows how these options are encoded in the <option> field of the instruction:

Table B2-1 Encoding of the DMB and DSB <option> parameter

Accesses		Shareability domain			
Before the barrier	**After the barrier**	**Full system**	**Outer Shareable**	**Inner Shareable**	**Non-shareable**
Reads and writes	Reads and writes	SY	OSH	ISH	NSH
Writes	Writes	ST	OSHST	ISHST	NSHST
Reads	Reads and writes	LD	OSHLD	ISHLD	NSHLD

See the instruction descriptions for more information:

- *DMB* on page C6-628.
- *DSB* on page C6-631.

Note

ISB also supports an optional limitation argument that can only contain one value that corresponds to full system operation, see *ISB* on page C6-647.

Load-Acquire, Load-AcquirePC, and Store-Release

ARMv8 provides a set of instructions with Acquire semantics for loads, and Release semantics for stores. These instructions support the *Release Consistency sequentially consistent* (RCsc) model. In addition, ARMv8.3-RCPC provides Load-AcquirePC instructions. The combination of Load-AcquirePC and Store-Release can be use to support the weaker *Release Consistency processor consistent* (RCpc) model.

The full definitions of the Load-Acquire and Load-AcquirePC instructions are covered formally in the *Definition of the ARMv8 memory model* on page B2-92. This introduction to the Load-Acquire and Load-AcquirePC instructions is not intended to contradict that section.

The basic principle of both Load-Acquire and Load-AcquirePC instructions is to introduce order between the memory access generated by the Load-Acquire or Load-AcquirePC instruction and the memory accesses appearing in program order after the Load-Acquire or Load-AcquirePC instruction, such that the memory access generated by the Load-Acquire or Load-AcquirePC instruction is Observed-by each PE, to the extent that the PE is required to observe the access coherently, before any of the memory accesses appearing in program order after the Load-Acquire or Load-AcquirePC instruction are Observed-by that PE, to the extent that the PE is required to observe the accesses coherently.

The use of a Load-Acquire or Load-AcquirePC instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

The full definition of the Store-Release instruction is covered formally in the *Definition of the ARMv8 memory model* on page B2-92 and this introduction to the Store-Release instruction is not intended to contradict that section.

The basic principle of a Store-Release instruction is to introduce order between the memory accesses generated by the PE executing the Store-Release instruction, together with those which originate from a different PE, to the extent that the PE is required to observe them coherently, Observed-by the PE before executing the Store-release.

The use of a Store-Release instruction creates order between the Memory effects of instructions as described in the definition of Barrier-ordered-before.

Where a Load-Acquire appears in program order after a Store-Release, then the memory access generated by the Store-Release instruction is Observed-by each PE, to the extent that that PE is required to observe the access coherently, before the memory access generated by the Load-Acquire instruction are Observed-by that PE, to the extent that the PE is required to observe the access coherently. In addition, the use of a Load-Acquire,

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Load-AcquirePC or a Store-Release instruction on accesses to a Memory-mapped peripheral introduces order between the Memory effects of the instructions that access that peripheral, as described in the definition of Peripheral coherence order.

Load-Acquire, Load-AcquirePC and Store-Release, other than Load-Acquire Exclusive Pair and Store-Release-Exclusive Pair, access only a single data element. This access is single-copy atomic. The address of the data object must be aligned to the size of the data element being accessed, otherwise the access generates an Alignment fault.

Load-Acquire Exclusive Pair and Store-Release Exclusive Pair access two data elements. The address supplied to the instructions must be aligned to twice the size of the element being loaded, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction only has the release semantics if the store is successful.

Note

- Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties:
  - That apply to the Load-Exclusive instructions also apply to the Load-Acquire Exclusive instructions.
  - That apply to the Store-Exclusive instructions also apply to the Store-Release Exclusive instructions.
- The Load-Acquire, Load-AcquirePC, and Store-Release instructions can remove the requirement to use the explicit `DMB` instruction.

LoadLOAcquire, StoreLORelease

For each PE, the Non-secure physical memory map is divided into a set of LORegions using a table that is held within the PE. Any PA in the Non-secure memory map can be a member of one LORegion. If a PA is assigned to more than one LORegion, then an implementation might treat it as if it has been assigned to fewer LORegions than that have been specified. A PA in the Secure physical memory map cannot be a member of any LORegion. For more information, see *Limited ordering regions* on page B2-103.

ARMv8.1 provides a set of instructions with Acquire semantics for loads, and Release semantics for stores that apply in relation to the defined LORegions. The new variants of the Load-Acquire and Store-Release instructions are LoadLOAcquire and StoreLORelease. See *LoadLOAcquire/StoreLORelease* on page C3-175.

For all memory types, these instructions have the following ordering requirements:

- LoadLOAcquire has the same semantics as Load-Acquire except that the memory accesses affected lie within the same LORegion as the address of the memory access generated by the LoadLOAcquire instruction. See *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.
- StoreLORelease has the same semantics as Store-Release except that the memory accesses affected lie within the same LORegion as the address of the memory access generated by the StoreLORelease instruction. See *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

In addition, for accesses to Memory-mapped peripherals:

- LoadLOAcquire has the same semantics as Load-Acquire except that the affected Memory effects of instructions that access the peripheral lie within the same LORegion as the address of the memory access generated by the LoadLOAcquire instruction. See *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.
- StoreLORelease has the same semantics as Store-Release except that the affected Memory effects of instructions that access the peripheral lie within the same LORegion as the address of the memory access generated by the StoreLORelease instruction. See *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The LoadLOAcquire/StoreLORelease instructions can remove the requirement to use the explicit `DMB` instruction.

B2.3.6 Limited ordering regions

ARMv8.1 introduces *limited ordering regions* (LORegions), which allow large systems to perform special load-acquire and store-release instructions that provide order between the memory accesses to a region of the PA map as observed by a set of observers.

This feature is supported in AArch64 state only.

Specification of the LORegions

The LORegions are defined in the Non-secure physical memory map using a set of LORegion descriptors. The number of LORegion descriptors is IMPLEMENTATION DEFINED, and can be discovered by reading the LORID_EL1 register.

Each LORegion descriptor consists of:

- A tuple of the following values:
  - A Start Address.
  - An End Address.
  - An LORegion Number.
- Valid bit which indicates whether that LORegion descriptor is valid

A memory location lies within the LORegion identified by the LORegion Number if the PA lies between the Start Address and the End Address, inclusive. The Start Address must be defined to be aligned to 64KB and the End Address must be defined as the top byte of a 64KB block of memory.

The LORegion descriptors are programmed using the LORSA_EL1, LOREA_EL1, LORN_EL1, and LORC_EL1 registers in the System register space. These registers are only supported in the Non-secure memory map.

If a LoadLOAcquire or a StoreLORelease does not match with any LORegion, then:

- The LoadLOAcquire will behave as a Load-Acquire, and will be ordered in the same way with respect to all accesses, independent of their LORegions.
- The StoreLORelease will behave as a Store-Release, and will be ordered in the same way with respect to all accesses, independent of their LORegions.

Note

If no LORegions are implemented, then the LoadLOAcquire and StoreLORelease will therefore behave as a Load-Acquire and Store-Release.

A new access type `AccType_LIMITEDORDERED` has been added for these limited ordering instructions to be identified.

B2.4 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. ARMv8 defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- *Introduction to caches*.
- *Memory hierarchy* on page B2-105.
- *Application level access to functionality related to caches* on page B2-106
- *Implication of caches for the application programmer* on page B2-106.
- *Preloading caches* on page B2-108.

B2.4.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a *tag*.
- The associated data.

Caches increase the average speed of a memory access. Caching takes account of two principles of locality:

Spatial locality

An access to one Location is likely to be followed by accesses to adjacent Locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

Temporal locality

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a *cache line*. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a *cache hit*, and other accesses are called *cache misses*.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access is made to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. ARMv8 permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

B2.4.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, an ARMv8 memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. Figure B2-1 shows an example of such a system in an ARMv8-A system that supports virtual addressing.

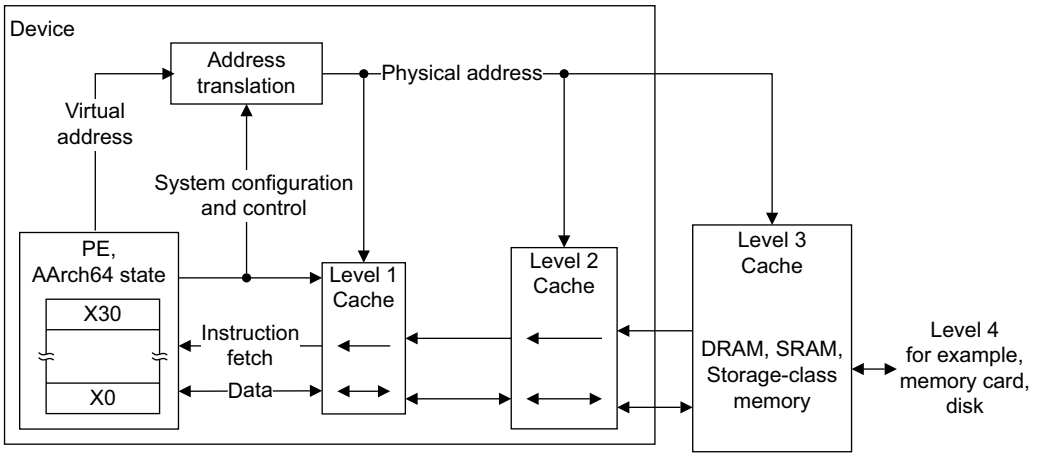

Figure B2-1 Multiple levels of cache in a memory hierarchy

Note

In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the processing element, as shown in Figure B2-1.

Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches that are located at the levels closest to the main memory. Memory coherency for cache topologies can be defined using the conceptual points Point of Unification (PoU), Point of Coherency (PoC), and Point of Persistence (PoP).

Note

ARMv8 ARMv8.2-DCPoP adds architectural support for Point of Persistence.

For more information, including the definitions of PoU, PoC, and PoP, see *About cache maintenance in AArch64 state* on page D3-2058.

The cacheability and shareability memory attributes

Cacheability and shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

Cacheability This attribute defines whether memory locations are allowed to be allocated into a cache or not. Cacheability is defined independently for Inner and Outer Cacheability locations.

Shareability This attribute defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability is defined independently for Inner and Outer Shareability domains.

For more information about Cacheability and Shareability, see *Memory types and attributes* on page B2-114.

Non-Confidential

B2.4.3 Application level access to functionality related to caches

As indicated in *About the Application level programmers' model* on page B1-76, the application level corresponds to execution at EL0. The architecture defines a set of cache maintenance instructions that software can use to manage cache coherency. Software executing at a higher Exception level can enable use of some of this functionality from EL0, as follows:

When the value of SCTLR_EL1.UCI is 1

Software executing at EL0 can access:

- The data cache maintenance instructions, `DC CVAU`, `DC CVAC`, `DC CVAP`, and `DC CIVAC`. See *The data cache maintenance instruction (DC)* on page D3-2063.
- The instruction cache maintenance instruction `IC IVAU`. See *The instruction cache maintenance instruction (IC)* on page D3-2063.

Attempted execution of these instructions might generate a Permission fault as described in *Permission fault* on page D4-2192.

When the value of SCTLR_EL1.UCT is 1

Software executing at EL0 can access the cache type register. See CTR_EL0.

When the value of SCTLR_EL1.DZE is 1

Software executing at EL0 can access the data cache zero instruction `DC ZVA`. See *Data cache zero instruction* on page D3-2071.

The SCTLR_EL1.{UCI, UCT, DZE} control fields are only accessible by software executing at EL1 or higher.

This functionality is UNDEFINED at EL0 when the value of the corresponding SCTLR_EL1 control field is 0, see:

- *Traps to EL1 of EL0 execution of cache maintenance instructions* on page D1-1913.
- *Traps to EL1 of EL0 accesses to the CTR_EL0* on page D1-1913.
- *Traps to EL1 of EL0 execution of DC ZVA instructions* on page D1-1914.

B2.4.4 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.

For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.
- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

Data coherency issues

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
  - Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
  - Not enabling caches in the system.
- By using cache maintenance instructions to manage the coherency issues in software. See *Application level access to functionality related to caches*.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see *Non-shareable Normal memory* on page B2-116 and *Shareable, Inner Shareable, and Outer Shareable Normal memory* on page B2-115.

  Note

  The performance of these hardware coherency mechanisms is highly implementation-specific. In some implementations, the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

Note

Not all these mechanisms are directly available to software operating at EL0 and might involve interaction with software operating at a higher Exception level.

Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last *Context synchronization event* on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being refetched from memory. In the absence of a *Context synchronization event*, there is no limit on the number of times such an instruction might be executed without being refetched from memory.

The ARM architecture does not require the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory.

If software requires coherency between instruction execution and memory, it must manage this coherency using *Context synchronization event*s and cache maintenance instructions. The following code sequence can be used to allow a PE to execute code that the same PE has written.

```
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Wt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Xn.
        STR Wt, [Xn]
        DC CVAU, Xn         ; Clean data cache by VA to point of unification (PoU)
        DSB ISH             ; Ensure visibility of the data cleaned from cache
        IC IVAU, Xn         ; Invalidate instruction cache by VA to PoU
        DSB ISH             ; Ensure completion of the invalidations
        ISB                 ; Synchronize the fetched instruction stream
```

Note

- For Non-cacheable or Write-Through accesses, the clean data cache by VA instruction is not required. However, the invalidate instruction cache instruction is required because the ARMv8-A AArch64 architecture allows Non-cacheable accesses to be held in an instruction cache. See *Non-cacheable accesses and instruction caches* on page D3-2057.
- This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The ARMv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See *Concurrent modification and execution of instructions* on page B2-90.
- The system software controls whether these cache maintenance instructions are available to the application level by setting SCTLR_EL1.UCI.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Note

If this sequence is not executed between writing data to a location and executing the instruction at that location, the lack of coherency between instruction caches and memory means that the instructions that are executed might be the old instruction or the updated instruction, and which is used can arbitrarily vary during execution. It must not be assumed by software, before the synchronization sequence is executed, that once the updated instruction has been seen, the old instruction will not be seen again.

B2.4.5 Preloading caches

The ARM architecture provides memory system hints `PRFM`, `LDNP`, and `STNP` that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring the data or instruction locations into caches.

The Preload instructions are hints, and so implementations can treat them as `NOP`s without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous External abort, which is taken using an SError interrupt exception. For more information, see *ISS encoding for an exception from a Data Abort* on page D10-2460.

`PrefetchHint{}` defines the prefetch hint types.

The `Hint_Prefetch()` function signals to the memory system that memory accesses of the type `hint` to or from the specified `address` are likely to occur in the near future. The memory system might take some action to speed up the memory accesses when they do occur, such as preloading the specified address into one or more caches as indicated by the innermost cache level `target` and non-temporal hint `stream`.

For more information on `PRFM` and Load/Store instructions that provide hints to the memory system, see *Prefetch memory* on page C3-180 and *Load/Store SIMD and Floating-point Non-temporal pair* on page C3-178.

B2.5 Alignment support

This section describes alignment support. It contains the following subsections:

- *Instruction alignment*.
- *Alignment of data accesses*.
- *Unaligned data access restrictions* on page B2-110.

B2.5.1 Instruction alignment

A64 instructions must be word-aligned.

Attempting to fetch an instruction from a misaligned location results in a PC alignment fault. See *PC alignment checking* on page D1-1868.

B2.5.2 Alignment of data accesses

An unaligned access to any type of Device memory causes an Alignment fault.

The alignment requirements for accesses to Normal memory are as follows:

- For all instructions that load or store a single or multiple registers, other than Load-Exclusive/Store-Exclusive and Load-Acquire/Store-Release, if the address that is accessed is not aligned to the size of the data element being accessed, then one of the following occurs:
  - An Alignment fault is generated.
  - An unaligned access is performed.

  When the value of SCTLR_ELx.A at the current Exception level is 1, alignment checking is enabled, and unaligned accesses generate Alignment faults.

  Note

  - The SCTLR_EL1.A bit applies to software running at EL0 and at EL1, although it can only be accessed from EL1 and higher.
  - Alignment checks are based on the size of the accessed elements, not the overall access size. This affects SIMD element and structure loads and stores, and also Load/Store pair instructions.
  - These alignment checking rules mean the ARMv8 architecture introduces requirements for 64-bit and 128-bit alignment checking.

- All Load-Exclusive/Store-Exclusive, Load-Acquire/Store-Release, and Compare and Swap memory accesses that access a single element or a pair of elements generate an Alignment fault if the address being accessed is not aligned to the size of the data structure being accessed.

A failed alignment check results in an Alignment fault, which is taken as a Data Abort exception, that is taken as follows:

- For an access from Non-secure EL0 or EL1, if the Alignment fault is generated only because the translation tables identify the address being accessed as Device memory then:
  - If the first stage of address translation marks the address as Device memory then the exception is taken to EL1.
  - If only the second stage of address translation marks the address as Device memory then the exception is taken to EL2.
- Otherwise, the exception is taken to the lowest Exception level that can handle the exception, consistent with the basic requirement that the Exception level never decreases on taking an exception. Therefore:
  - Alignment faults taken from EL0 or EL1 are taken to EL1 unless redirected by HCR_EL2.TGE
  - Alignment faults taken from EL2 are taken to EL2.
  - Alignment faults taken from EL3 are taken to EL3.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

B2.5.3 Unaligned data access restrictions

The following points apply to unaligned data accesses in ARMv8:

- Accesses are not guaranteed to be single-copy atomic except at the byte access level, see *Atomicity in the ARM architecture* on page B2-88.
- Unaligned accesses typically take a number of additional cycles to complete compared to a naturally-aligned access.
- An operation that performs an unaligned access can abort on any memory access that it makes, and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the boundary.

B2.6 Endian support

General description of endianness in the ARM architecture describes the relationship between endianness and memory addressing in the ARM architecture.

The following subsections then describe the endianness schemes supported by the architecture:

- *Instruction endianness* on page B2-112.
- *Data endianness* on page B2-112.
- *Endianness of memory-mapped peripherals* on page B2-113.

B2.6.1 General description of endianness in the ARM architecture

This section only describes memory addressing and the effects of endianness for data elements up to quadwords of 128 bits. However, this description can be extended to apply to larger data elements.

For an address A, Figure B2-2 shows, for big-endian and little-endian memory systems, the relationship between:

- The quadword at address A.
- The doubleword at address A and A+8.
- The words at addresses A, A+4, A+8, and A+12.
- The halfwords at addresses A, A+2, A+4, A+6, A+8, A+10, A+12, and A+14.
- The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, A+7, A+8, A+9, A+10, A+11, A+12, A+13, A+14, and A+15.

The terms in Figure B2-2 have the following definitions:

B_A Byte at address A.
HW_A Halfword at address A.
MSByte Most significant byte.
LSByte Least significant byte.

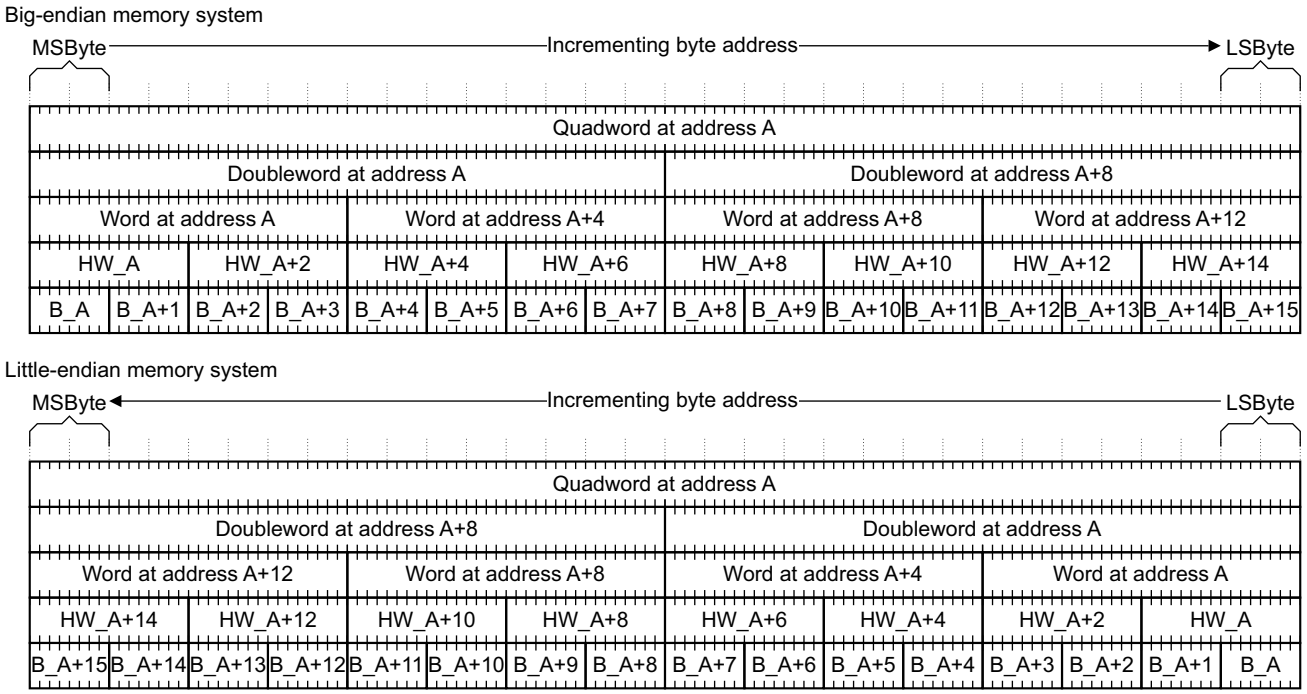

Figure B2-2 Endianness relationships

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

The big-endian and little-endian mapping schemes determine the order in which the bytes of a quadword, doubleword, word, or halfword are interpreted. For example, a load of a word from address `0x1000` always results in an access to the bytes at memory locations `0x1000`, `0x1001`, `0x1002`, and `0x1003`. The endianness mapping scheme determines the significance of these 4 bytes.

B2.6.2 Instruction endianness

In ARMv8-A, A64 instructions have a fixed length of 32 bits and are always little-endian.

B2.6.3 Data endianness

SCTLR_EL1.E0E, configurable at EL1 or higher, determines the data endianness for execution at EL0.

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for SIMD and floating-point register and general-purpose register loads and stores.
- Is the size of the data element that is loaded or stored for SIMD element and data structure loads and stores. For more information, see *Endianness in SIMD operations* on page B2-113.

Note

This means the ARMv8 architecture introduces a requirement for 128-bit endian conversions.

Instructions to reverse bytes in a general-purpose register or a SIMD and floating-point register

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

Table B2-2 shows the instructions that provide this functionality:

Table B2-2 Byte reversal instructions

Function	Instructions	Notes
Reverse bytes in 32-bit word or words[a]	REV32	For use with general-purpose registers
Reverse bytes in whole register	REV	For use with general-purpose registers
Reverse bytes in 16-bit halfwords	REV16	For use with general-purpose registers
Reverse elements in doublewords, vector	REV64	For use with SIMD and floating-point registers
Reverse elements in words, vector	REV32	For use with SIMD and floating-point registers
Reverse elements in halfwords, vector	REV16	For use with SIMD and floating-point registers

a. Can operate on multiple words.

Endianness in SIMD operations

SIMD element Load/Store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used to load and store data correctly in both big-endian and little-endian systems.

For example:

```
LD1 {V0.4H}, [X1]
```

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure B2-3. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

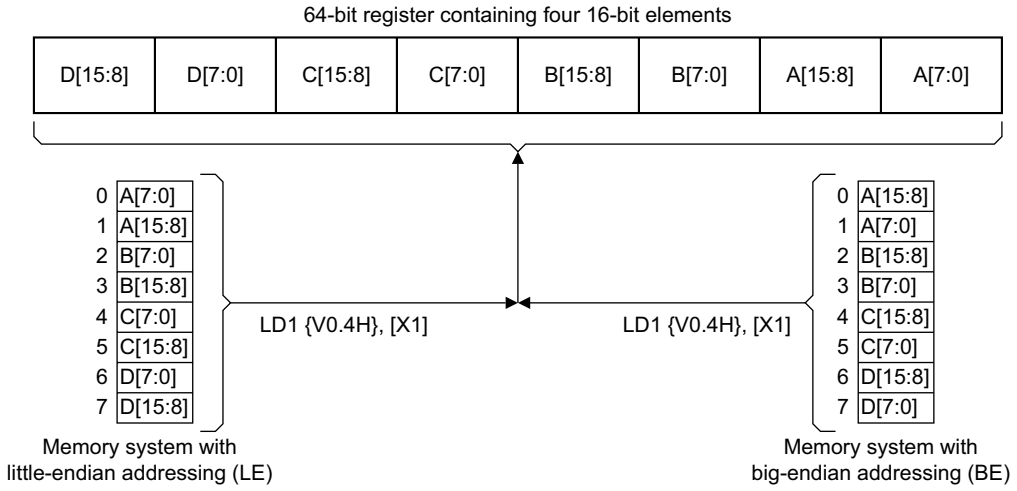

Figure B2-3 SIMD byte order example

The `BigEndian()` pseudocode function determines the current endianness of the data.

The `BigEndianReverse()` pseudocode function reverses the endianness of a bitstring.

The `BigEndian()` and `BigEndianReverse()` functions are defined in Chapter J1 *ARMv8 Pseudocode*.

B2.6.4 Endianness of memory-mapped peripherals

All memory-mapped peripherals defined in the ARM architecture must be little-endian.

Peripherals to which this requirement applies include:

- Memory-mapped register interfaces to a debugger, or to a cross-trigger interface, see Chapter H8 *About the External Debug Registers*.
- The memory-mapped register interface to the system level implementation of the Generic Timer, see Chapter I2 *System Level Implementation of the Generic Timer*.
- A memory-mapped register interface to the Performance Monitors, see Chapter I3 *Recommended External Interface to the Performance Monitors*.
- Memory-mapped register interfaces to an ARM Generic Interface Controller, see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0.*
- The memory-mapped register interface to an ARM trace component. See, for example, the *ARM® Embedded Trace Macrocell Architecture Specification, ETMv4.*

B2.7 Memory types and attributes

In ARMv8 the ordering of accesses for addresses in memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- *Normal memory*.
- *Device memory* on page B2-118.
- *Memory access restrictions* on page B2-124.

B2.7.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware is permitted by the architecture to perform *Speculative* data read accesses to these locations, regardless of the access permissions for these locations.

The Normal memory type has the following properties:

- A write to a memory location with the Normal attribute completes in finite time. This means that it is globally observed for the shareability domain of the memory location in finite time. For a Non-cacheable location, the location is observed by all observers in finite time.
- A completed write to a memory location with the Normal attribute is globally observed for the shareability domain of the memory location in finite time without the need for explicit cache maintenance instructions or barriers. For a Non-cacheable location, the completed write is globally observed for all observers in finite time without the need for explicit cache maintenance instructions or barriers.
- Writes to a memory location with the Normal memory attribute that are Non-cacheable must reach the endpoint for that location in the memory system in finite time.
- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.
- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See *Multi-register loads and stores that access Normal memory* on page B2-118.

Note

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
  - Read accesses can be repeated with no side-effects.
  - Repeated read accesses return the last value written to the resource being read.
  - Read accesses can fetch additional memory locations with no side-effects.
  - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
  - Unaligned accesses can be supported.
  - Accesses can be merged before accessing the target memory system.
- An instruction that generates a sequence of accesses as described in *Atomicity in the ARM architecture* on page B2-88 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore, one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

The following sections describe the other attributes for Normal memory:

- *Shareable Normal memory* on page B2-115.
- *Non-shareable Normal memory* on page B2-116.
- *Cacheability attributes for Normal memory* on page B2-116.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

See also:

- *Multi-register loads and stores that access Normal memory* on page B2-118.
- *Atomicity in the ARM architecture* on page B2-88.
- *Memory barriers* on page B2-98. For accesses to Normal memory, a `DMB` instruction is required to ensure the required ordering.
- *Concurrent modification and execution of instructions* on page B2-90.

Shareable Normal memory

A Normal memory location has a Shareability attribute that is one of:

- Inner Shareable, meaning it applies across the Inner Shareable shareability domain.
- Outer Shareable, meaning it applies across both the Inner Shareable and the Outer Shareable shareability domains.
- Non-shareable.

The shareability attributes define the data coherency requirements of the location, that hardware must enforce. They do not affect the coherency requirements of instruction fetches, see *Synchronization and coherency issues between data and instruction accesses* on page B2-107.

Note

- System designers can use the shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different processing elements.
- This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

Shareable, Inner Shareable, and Outer Shareable Normal memory

The ARM architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

- Each observer is only a member of a single Inner Shareability domain.
- Each observer is only a member of a single Outer Shareability domain.
- All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.
- The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.

The details of the use of the shareability attributes are system-specific. Example B2-1 shows how they might be used.

Example B2-1 Use of shareability attributes

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.
- However, between the two clusters, the caches:
  - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
  - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable shareability domain.

For shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

Non-shareable Normal memory

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

Cacheability attributes for Normal memory

In addition to being Outer Shareable, Inner Shareable or Non-shareable, each region of Normal memory is assigned a Cacheability attribute that is one of:

- Write-Through Cacheable.
- Write-Back Cacheable.
- Non-cacheable.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Also, for Write-Through Cacheable and Write-Back Cacheable Normal memory regions:

- A region might be assigned cache allocation hints for read and write accesses.
- It is IMPLEMENTATION DEFINED whether the cache allocation hints can have an additional attribute of Transient or Non-transient.

For more information see *Cacheability, cache allocation hints, and cache transient hints* on page D3-2054.

A memory location can be marked as having different cacheability attributes, for example when using aliases in a VA to PA mapping:

- If the attributes differ only in the cache allocation hint, this does not affect the behavior of accesses to that location.
- For other cases, see *Mismatched memory attributes* on page B2-125.

The cacheability attributes provide a mechanism of coherency control with observers that lie outside the shareability domain of a region of memory. In some cases, the use of Write-Through Cacheable or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. To this end, the architecture requires the following properties for Non-cacheable or Write-Through Cacheable memory:

- A completed write to a memory location that is Non-cacheable or Write-Through Cacheable for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.
- A completed write to a memory location that is Non-cacheable for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.
- For accesses to Normal memory that is Non-cacheable, a `DMB` instruction ensures that all members of Group A reach a single peripheral or block of memory, of IMPLEMENTATION DEFINED size, before any member of Group B, where:
  - The definition of the operation of a `DMB` instruction defines Group A and Group B, see *Data Memory Barrier (DMB)* on page B2-99.
  - The IMPLEMENTATION DEFINED size of the single peripheral or block of memory is defined by the peripheral or block of memory.

  This applies for all types of `DMB` instruction.

Note

Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

For Normal memory, the ARM architecture provides cacheability attributes that are defined independently for each of two conceptual levels of cache, the *inner* and the *outer* cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

- Inner refers to the innermost caches, meaning the caches that are closest to the PE, and always includes the lowest level of cache.
- No cache that is controlled by the Inner cacheability attributes can lie outside a cache that is controlled by the Outer cacheability attributes.
- An implementation might not have any outer cache.

Example B2-2 on page B2-118, Example B2-3 on page B2-118, and Example B2-4 on page B2-118 describe the possible ways of implementing a system with three levels of cache, *level 1* (L1) to *level 3* (L3).

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- L1 cache is the level closest to the PE, see *Memory hierarchy* on page B2-105.
- When managing coherency, system designs must consider both the inner and outer cacheability attributes, as well as the shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.

Example B2-2 Implementation with two inner and one outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 and L2 cache.
- The Outer cacheability attribute applied to L3 cache.

Example B2-3 Implementation with three inner and no outer cache levels

Implement the three levels of cache in the system, L1 to L3, with the Inner cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer cacheability attribute.

Example B2-4 Implementation with one inner and two outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 cache.
- The Outer cacheability attribute applied to L2 and L3 cache.

Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more SIMD&FP registers from an Exception level, there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.

B2.7.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for ARMv8 Device memory are:

Gathering Identified as G or nG, see *Gathering* on page B2-121.

Reordering Identified as R or nR, see *Reordering* on page B2-122.

Early Write Acknowledgement

Identified as E or nE, see *Early Write Acknowledgement* on page B2-123.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

The ARMv8 Device memory types are:

Device-nGnRnE Device non-Gathering, non-Reordering, No Early write acknowledgement.

Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.

Device-nGnRE Device non-Gathering, non-Reordering, Early Write Acknowledgement.

Equivalent to the Device memory type in earlier versions of the architecture.

Device-nGRE Device non-Gathering, Reordering, Early Write Acknowledgement.

ARMv8 adds this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory.

Device-GRE Device Gathering, Reordering, Early Write Acknowledgement.

ARMv8 adds this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that *Speculative* accesses to Device-GRE memory is forbidden.

Collectively these are referred to as *any Device memory type*. Going down the list, the memory types are described as getting *weaker*; conversely the going up the list the memory types are described as getting *stronger*.

Note

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.
- The architecture does not require an implementation to distinguish between each of these memory types and ARM recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.
- Earlier versions of the ARM architecture defined the following memory types:
  - Strongly-ordered memory. This is the equivalent of the Device-nGnRnE memory type.
  - Device memory. This is the equivalent of the Device-nGnRE memory type.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.

  The following exceptions to this apply:

  - Reads generated by the SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.
  - For Device memory with the Gathering attribute, reads generated by the `LDNP` instructions are permitted to access bytes that are not explicitly accessed by the instruction, provided that the bytes accessed are in a 128-byte window, aligned to 128-bytes, that contains at least one byte that is explicitly accessed by the instruction.
  - Where a load or store instruction performs a sequence of memory accesses, as opposed to one single-copy atomic access as defined in the rules for single-copy atomicity, these accesses might occur multiple times as a result of executing the load or store instruction. See *Properties of single-copy atomic accesses* on page B2-89.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Note

— An instruction that generates a sequence of accesses as described in *Atomicity in the ARM architecture* on page B2-88 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception, the instruction is restarted, and therefore, one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program only defines a single access. For this reason, ARM strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.

— Write speculation that is visible to other observers is prohibited for all memory types.

- A write to a memory location with any Device memory attribute completes in finite time. This means that it is globally observed for all observers in the system in finite time.
- If a location with any Device memory attribute changes without an explicit write by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.
- A completed write to a memory location with any Device memory attribute is globally observed for all observers in finite time without the need for explicit maintenance.
- Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.
- A memory location with any Device memory attribute cannot be allocated into a cache.
- Writes to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Typically, the endpoint is a peripheral or some physical memory.
- For accesses to any Device memory type, a `DMB` instruction ensures that all members of Group A reach a single peripheral or block of memory, of IMPLEMENTATION DEFINED size, before any member of Group B, where:

  — The definition of the operation of a `DMB` instruction defines Group A and Group B, see *Data Memory Barrier (DMB)* on page B2-99.

  — The IMPLEMENTATION DEFINED size of the single peripheral or block of memory is defined by the peripheral or block of memory.

  This applies for all types of `DMB` instruction.
- All accesses to memory with any Device memory attribute must be aligned. Any unaligned access generates an Alignment fault at the first stage of translation that defined the location as being Device.

  Note

  In the Non-secure EL1&0 translation regime in systems where HCR_EL2.TGE==1 and HCR_EL2.DC==0, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes ESR_EL2.ISS[24] to be 0.
- Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as Execute-never for all Exception levels.

  Note

  This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as Execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as Execute-never for all Exception levels is a programming error.

See also *Memory access restrictions* on page B2-124.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

The memory types for translation table walks cannot be defined as any Device memory type within the TCR_ELx. For the Non-secure EL1&0 translation regime, the memory accesses made during a stage 1 translation table walk are subject to a stage 2 translation, and as a result of this second stage of translation, the accesses from the first stage translation table walk might be made to memory locations with any Device memory type. These accesses might be made speculatively. When the value of the HCR_EL2.PTW bit is 1, a stage 2 permission fault is generated if a first stage translation table walk is made to any Device memory type.

Note

In general, making a translation table walk to any Device memory type is the result of a programming error.

For instruction fetches, if branches cause the program counter to point to an area of memory with the Device attribute which is not marked as Execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
- Take a Permission fault.

Gathering

In the Device memory attribute:

G Indicates that the location has the Gathering attribute.

nG Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

- Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
- Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

Note

This also applies to writebacks from the cache, whether caused by a *Natural eviction* or as a result of a cache maintenance instruction.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

- The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.
- All accesses occur at their programmed size, except that there is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See *Multi-register loads and stores that access Device memory* on page B2-124.

Gathering between memory accesses separated by a memory barrier that affects those memory accesses is not permitted. This applies if one memory access is in Group A and one memory access is in Group B. That is, gathering is not permitted between a memory access in Group A and a memory access in Group B if the two accesses are separated by a barrier that affects at least one of the accesses.

Gathering between two memory accesses generated by a Load-Acquire/Store-Release is not permitted.

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
  - The accesses are not separated by a DMB or DSB barrier that affects both of the accesses, for example if one access is in Group A and the other is in Group B.
  - The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
  - The accesses are not generated by a Store-Release instruction.
- The ARM architecture only defines programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the non-Gathering attribute.

An implementation is not permitted to perform an access with the non-Gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.

Reordering

In the Device memory attribute:

R Indicates that the location has the Reordering attribute. Accesses to the location can be reordered within the same rules that apply to accesses to Normal Non-cacheable memory. All memory types with the Reordering attribute have the same ordering rules as accesses to Normal Non-cacheable memory, see *Ordering relations* on page B2-95.

nR Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

Note

Some interconnect fabrics, such as PCIe, perform very limited re-ordering, which is not important for the software usage. It is outside the scope of the ARM architecture to prohibit the use of a non-Reordering memory type with these interconnects.

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program. That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

Note

- The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the DMB instruction.
- The ARM architecture only defines programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.

An implementation:

- Is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.
- Is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses with the non-Reordering attribute and accesses with the Reordering attribute.
- Accesses with the non-Reordering attribute and accesses to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

The non-Reordering attribute has no effect on the ordering of cache maintenance instructions, even if the memory location specified in the instruction has the non-Reordering attribute.

Early Write Acknowledgement

In the Device memory attribute:

E Indicates that the location has the Early Write Acknowledgement attribute.

nE Indicates that the location has the No Early Write Acknowledgement attribute.

For memory system endpoints where the system architecture in which the PE is operating requires that acknowledgement of a write comes from the endpoint, assigning the No Early Write Acknowledgement attribute to a Device memory location guarantees that:

- Only the endpoint of the write access returns a write acknowledgement of the access.
- No earlier point in the memory system returns a write acknowledgement.

This means that a `DSB` barrier instruction, executed by the PE that performed the write to the No Early Write Acknowledgement Location, completes only after the write has reached its endpoint in the memory system.

Peripherals are an example of system endpoints that require that the acknowledgement of a write comes from the endpoint.

Note

- The Early Write Acknowledgement attribute only affects where the endpoint acknowledgement is returned from, and does not affect the ordering of arrival at the endpoint between accesses, which is determined by either the Device Reordering attribute, or the use of barriers to create order.
- The areas of the physical memory map for which write acknowledgement from the endpoint is required is outside the scope of the ARM Architecture definition and must be defined as part of the system architecture in which the PE is operating. In particular, regions of memory handled as PCIe configuration writes are expected to support write acknowledgement from the endpoint.
- ARM recognizes that not all areas of a physical memory map will be capable of supporting write acknowledgement from the endpoint. In particular, ARM expects that regions of memory handled as posted writes under PCIe will not support write acknowledgement from the endpoint.
- For maximum software compatibility, ARM strongly recommends that all peripherals for which standard software drivers expect that the use of a `DSB` instruction will determine that a write has reached its endpoint are placed in areas of the physical memory map that support write acknowledgement from the endpoint.

Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture. This applies even to accesses to any type of Device memory.

For all instructions that load or store one or more floating-point and SIMD registers from an Exception level, there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions, even for access to any type of Device memory.

B2.7.3 Memory access restrictions

The following restrictions apply to memory accesses:

- For accesses to any two bytes, *p* and *q*, that are generated by the same instruction:
  - The bytes *p* and *q* must have the same memory type and shareability attributes, otherwise the results are CONSTRAINED UNPREDICTABLE. For example, an `LD1`, `ST1`, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRAINED UNPREDICTABLE.
  - Except for possible differences in the cache allocation hints, ARM deprecates having different cacheability attributes for bytes *p* and *q*.

  For the permitted CONSTRAINED UNPREDICTABLE behavior, see *Crossing a page boundary with different memory types or Shareability attributes* on page K1-6417.

- If the accesses of an instruction that causes multiple accesses to any type of Device memory cross an address boundary that corresponds to the smallest implemented translation granule, then behavior is CONSTRAINED UNPREDICTABLE, and *Crossing a peripheral boundary with a Device access* on page K1-6417 describes the permitted behaviors. For this reason, it is important that an access to a volatile memory device is not made using a single instruction that crosses an address boundary of the size of the smallest implemented translation granule.

  Note

  — The boundary referred to is between two Device memory regions that are both of the size of the smallest implemented translation granule and aligned to the size of the smallest implemented translation granule.

  — This restriction means it is important that an access to a volatile memory device is not made using a single instruction that crosses an address boundary of the size of the smallest implemented translation granule.

  — ARM expects this restriction to constrain the placing of volatile memory devices in the system memory map, rather than expecting a compiler to be aware of the alignment of memory accesses.

B2.8 Mismatched memory attributes

Memory attributes are controlled by privileged software. For more information, see Chapter D4 *The AArch64 Virtual Memory System Architecture*.

Physical memory locations are accessed with *mismatched attributes* if all accesses to the location do not use a common definition of all of the following attributes of that location:

- Memory type, Device or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.

Collectively these are referred to as memory attributes.

Note

In this document, the terms *location* and *memory location* refer to any byte within the current coherency granule and are used interchangeably.

When a memory Location is accessed with mismatched attributes, the only software visible effects are one or more of the following:

- Uniprocessor semantics for reads and writes to that memory Location might be lost. This means:
  - A read of the memory Location by one agent might not return the value most recently written to that memory Location by the same agent.
  - Multiple writes to the memory Location by one agent with different memory attributes might not be ordered in program order.
- There might be a loss of coherency when multiple agents attempt to access a memory Location.
- There might be a loss of properties derived from the memory type, as described in later bullets in this section.
- If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory Location do not use consistent memory attributes, the Exclusives monitor state becomes UNKNOWN.
- Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

- Prohibition of *Speculative* read accesses.
- Prohibition on Gathering.
- Prohibition on Re-ordering.

For the following situations, when a physical memory Location is accessed with mismatched attributes, a more restrictive set of behaviors applies. The description of each situation also describes the behaviors that apply:

1. If the only memory type mismatch associated with a memory Location across all users of the memory Location is between different types of Device memory, then all accesses might take the properties of the weakest Device memory type.
2. Any agent that reads that memory Location using the same common definition of the Shareability and Cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all the following conditions are met:
   - All writes are performed to an alias of the memory Location that uses the same definition of the Shareability and Cacheability attributes.
   - Either:
     - In the Non-secure EL1&0 translation regime, HCR_EL2.MIOCNCE has a value of 0.
     - All aliases with write permission have the Inner Cacheability attribute the same as the Outer Cacheability attribute.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- Either:
  - All writes are performed to an alias of the memory Location that has Inner Cacheability and Outer Cacheability attributes both as Non-cacheable.
  - All aliases to a memory Location use a definition of the Shareability attributes that encompasses all the agents with permission to access the Location.

3. The possible software-visible effects caused by mismatched attributes for a memory Location are defined more precisely if all of the mismatched attributes define the memory Location as one of:
   - Any Device memory type.
   - Normal Inner Non-cacheable, Outer Non-cacheable memory.

   In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:
   - Possible loss of properties derived from the memory type when multiple agents attempt to access the memory Location.
   - Possible reordering of memory transactions to the same memory Location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting `DMB` barrier instructions between accesses to the same memory Location that might use different attributes.

Where there is a loss of the uniprocessor semantics, ordering, or coherency, the following approaches can be used:

1. If the mismatched attributes for a memory location all assign the same shareability attribute to a Location that has a cacheable attribute, any loss of uniprocessor semantics, ordering, or coherency within a shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the ordering or coherency of cacheable Locations between agents in different shareability domains. This means:
   - Before writing to a cacheable Location not using the Write-Back attribute, software must invalidate, or clean, a Location from the caches if any agent might have written to the Location with the Write-Back attribute. This avoids the possibility of overwriting the Location with stale data.
   - After writing to a cacheable Location with the Write-Back attribute, software must clean the Location from the caches, to make the write visible to external memory.
   - Before reading the Location with a cacheable attribute, software must invalidate, or clean and invalidate, the Location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.
   - Executing a `DMB` barrier instruction, with scope that applies to the common shareability of the accesses, between any accesses to the same cacheable Location that use different attributes.

   In all cases:
   - Location refers to any byte within the current coherency granule.
   - A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
   - In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see *Ordering and completion of data and instruction cache instructions* on page D3-2069.

Note

With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same Location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

2. If the mismatched attributes for a Location mean that multiple cacheable accesses to the Location might be made with different shareability attributes, then uniprocessor semantics, ordering, and coherency are guaranteed only if:
   - Each PE that accesses the Location with a cacheable attribute performs a clean and invalidate of the Location before and after accessing that Location.
   - A `DMB` barrier with scope that covers the full shareability of the accesses is placed between any accesses to the same memory Location that use different attributes.

   Note

   The Note in rule 1 of this list, about possible race conditions, also applies to this rule.

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a Location, and the accesses from the different agents have different memory attributes associated with the Location, the Exclusives monitor state becomes UNKNOWN.

ARM strongly recommends that software does not use mismatched attributes for aliases of the same Location. An implementation might not optimize the performance of a system that uses mismatched aliases.

B2.9 Synchronization and semaphores

ARMv8 provides non-blocking synchronization of shared memory, using *synchronization primitives*. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal memory and to any type of Device memory.

Note

Use of the ARMv8 synchronization primitives scales for multiprocessing system designs.

Table B2-3 shows the synchronization primitives and the associated CLREX instruction.

Table B2-3 Synchronization primitives and associated instruction, A64 instruction set

Transaction size	Additional semantics	Load-Exclusive[a]	Store-Exclusive[a]	Other[a]
Byte	-	LDXRB	STXRB	-
	Load-Acquire/Store-Release	LDAXRB	STLXRB	-
Halfword	-	LDXRH	STXRH	-
	Load-Acquire/Store-Release	LDAXRH	STLXRH	-
Register[b]	-	LDXR	STXR	-
	Load-Acquire/Store-Release	LDAXR	STLXR	-
Pair[b]	-	LDXP	STXP	-
	Load-Acquire/Store-Release	LDAXP	STLXP	-
None	Clear-Exclusive	-	-	CLREX

a. Instruction in the A64 instruction set.
b. A register instruction operates on a doubleword if accessing an X register, or on a word if accessing a W register
A pair instruction operates on two doublewords if access X registers, or on two words if accessing W registers.

Except for the row showing the CLREX instruction, the two instructions in a single row are a Load-Exclusive/Store-Exclusive instruction pair. The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address *x* is:

- The Load-Exclusive instruction reads a value from memory address *x*.
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address *x* only if no other observer, process, or thread has performed a more recent store to address *x*. The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see *Marking and the size of the marked memory block* on page B2-134. A Store-Exclusive instruction to any address in the marked block clears the marking.

Note

In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

The following sections give more information:

- *Exclusive access instructions and Non-shareable memory locations* on page B2-129.
- *Exclusive access instructions and Shareable memory locations* on page B2-131.
- *Marking and the size of the marked memory block* on page B2-134.
- *Context switch support* on page B2-134.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- *Load-Exclusive and Store-Exclusive instruction usage restrictions* on page B2-135.
- *Use of WFE and SEV instructions by spin-locks* on page B2-138.

B2.9.1 Exclusive access instructions and Non-shareable memory locations

For memory locations for which the shareability attribute is Non-shareable, the exclusive access instructions rely on a *local Exclusives monitor*, or *local monitor*, that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

A Load-Exclusive instruction performs a load from memory, and:

- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state

- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
  - If the store took place, the status value is 0.
  - Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

When an Exclusives monitor is in the Exclusive Access state, the monitor is *set.*

If the local monitor is in the Open Access state

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

When an Exclusives monitor is in the Open Access state, the monitor is *clear*.

The Store-Exclusive instruction defines the register to which the status value is returned.

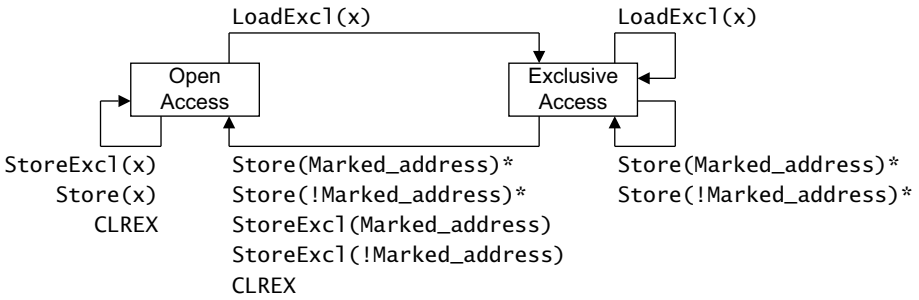
When a PE writes using any instruction other than a Store-Exclusive instruction:

- If the write is to a PA that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a PA that is marked as Exclusive Access by its local monitor, it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked PA causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the PA to be marked.

Figure B2-4 on page B2-130 shows the state machine for the local monitor and the effect of each of the operations shown in the figure.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential



Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: `LoadExcl` represents any Load-Exclusive instruction
`StoreExcl` represents any Store-Exclusive instruction
`Store` represents any other store instruction.

Any `LoadExcl` operation updates the marked address to the most significant bits of the address x used for the operation.

Figure B2-4 Local monitor state machine diagram

For more information about marking, see *Marking and the size of the marked memory block* on page B2-134.

Note

For the local monitor state machine, as shown in Figure B2-4:

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any PA, but instead treats any access as matching the address of the previous Load-Exclusive instruction.
- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.
- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.
- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the `Store` or `StoreExcl` is from another observer.

Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Figure B2-4.

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Figure B2-4.
- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Figure B2-4 must not indefinitely delay forward progress of execution.

B2.9.2 Exclusive access instructions and Shareable memory locations

In the context of this section, a shareable memory location is a memory location that has, or is treated as if it has, a Shareability attribute of Inner Shareable or Outer Shareable.

For shareable memory locations, exclusive access instructions rely on:

- A *local monitor* for each PE in the system, that marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in *Exclusive access instructions and Non-shareable memory locations* on page B2-129, except that for shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:
  - Updating memory.
  - Returning a status value of 0.

  The local monitor can ignore accesses from other PEs in the system.
- A *global monitor* that marks a PA as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
  - Can hold at least one marked block.
  - Maintains a state machine for each marked block it can hold.

  Note

  For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, see *Load-Exclusive and Store-Exclusive instruction usage restrictions* on page B2-135.

Note

The global monitor can either reside within the PE, or exist as a secondary monitor at the memory interfaces. The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

Note

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all ARM PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport's Bakery algorithm to achieve mutual exclusion.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global Exclusives monitor is implemented are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.
- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive or a Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an External abort.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Data Abort Fault status code of ESR_ELx.DFSC = `110101`.

  If the IMPLEMENTATION DEFINED MMU fault is generated for the Non-secure EL1&0 translation regime then:

  — If the fault is generated because of the memory type defined in the first stage of translation, or if the second stage of translation is disabled, then this is a first stage fault and the exception is taken to EL1.

  — Otherwise, the fault is a second stage fault and the exception is taken to EL2.

  The priority of this fault is IMPLEMENTATION DEFINED.
- The instruction is treated as a `NOP`.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN. In this case, if the store exclusive instruction is a store exclusive pair of 64-bit quantities, then the two quantities being stored might not be stored atomically.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by ARM PEs is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

Operation of the global Exclusives monitor

A Load-Exclusive instruction from shareable memory performs a load from memory, and causes the PA of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other PA that has been marked by the requesting PE.

Note

The global monitor only supports a single outstanding exclusive access to shareable memory per PE.

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the PA accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:

  — A status value of 0 is returned to a register to acknowledge the successful store.

  — The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.

  — If the address accessed is marked for exclusive access in the global monitor state machine for any other PE, then that state machine transitions to Open Access state.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  - A status value of 1 is returned to a register to indicate that the store failed.
  - The global monitor is not affected and remains in Open Access state for the requesting PE.
- If a different PA is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  - If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
  - If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to shareable memory by PE(n) can respond to all the shareable memory accesses visible to it. This means that it responds to:

- Accesses generated by PE(n).
- Accesses generated by the other observers in the shareability domain of the memory location. These accesses are identified as (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

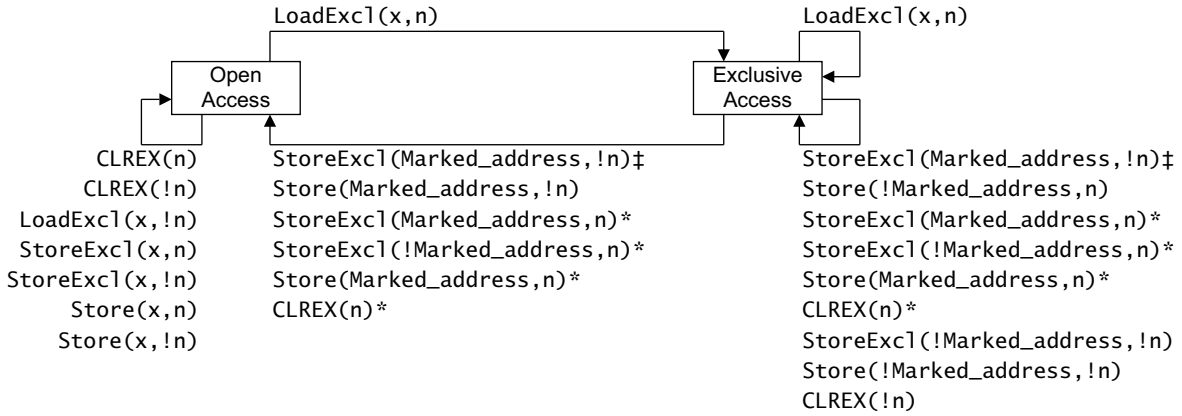
A global monitor:

- In the Exclusive Access state is *set*.
- In the Open Access state is *clear*.

Clear global monitor event

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see *Mechanisms for entering a low-power state* on page D1-1954.

Figure B2-5 shows the state machine for PE(n) in a global monitor.



‡StoreExcl(Marked_address,!n) clears the monitor only if the StoreExcl updates memory
Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: LoadExcl represents any Load-Exclusive instruction
StoreExcl represents any Store-Exclusive instruction
Store represents any other store instruction.

Any LoadExcl operation updates the marked address to the most significant bits of the address x used for the operation.

Figure B2-5 Global monitor state machine diagram for PE(n) in a multiprocessor system

For more information about marking, see *Marking and the size of the marked memory block* on page B2-134.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Note

For the global monitor state machine, as shown in Figure B2-5 on page B2-133:

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.
- Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, Figure B2-5 on page B2-133 only shows how the operations by (!n) cause state transitions of the state machine for PE(n).
- A Load-Exclusive instruction can only update the marked shareable memory address for the PE issuing the Load-Exclusive instruction.
- When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a `CLREX` instruction causes the global monitor to transition from Exclusive Access to Open Access state.
- It is IMPLEMENTATION DEFINED:
  - Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
  - Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

B2.9.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a Load-Exclusive instruction is executed, a marked block of size 2^a bytes is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. The size of the marked memory block is called the *Exclusives reservation granule*. The Exclusives reservation granule is IMPLEMENTATION DEFINED in the range 4-512 words.

Note

This definition means that the Exclusives reservation granule is:

- 4 words in an implementation where a is 4.
- 512 words in an implementation where a is 11.

For example, in an implementation where a is 4, a successful `LDXRB` of address `0x341B4` defines a marked block using bits[47:4] of the address. This means that the four words of memory from `0x341B0` to `0x341BF` are marked for exclusive access.

In some implementations the CTR identifies the Exclusives reservation granule, see CTR_EL0. Otherwise, software must assume that the maximum Exclusives reservation granule, 512 words, is implemented.

B2.9.4 Context switch support

An exception return clears the local monitor. As a result, performing a `CLREX` instruction as part of a context switch is not required in most situations.

Note

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

Non-Confidential

B2.9.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a LDXP/STXP pair or a LDXR/STXR pair. To support different implementations of these functions, software must follow the notes and restrictions given here.

The following notes describe the use of a LoadExcl/StoreExcl instruction pair, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in Table B2-3 on page B2-128. In this context, a LoadExcl/StoreExcl pair comprises two instructions in the same thread of execution:

- The exclusives support a single outstanding exclusive access for each PE thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the IsExclusiveLocal() function. If the target VA of a StoreExcl is different from the VA of the preceding LoadExcl instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The StoreExcl either passes or fails, the status value returned by the StoreExcl is UNKNOWN, and the states of the local and global monitors for that PE are UNKNOWN.

    Note

    This means the StoreExcl might pass for some instances of a LoadExcl/StoreExcl pair with mismatched addresses, and fail for other instances of a LoadExcl/StoreExcl pair with mismatched addresses.

  - The data at the address accessed by the LoadExcl, and at the address accessed by the StoreExcl, is UNKNOWN.

  This means software can rely on a LoadExcl/StoreExcl pair to eventually succeed only if the LoadExcl and the StoreExcl are executed with the same VA.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a StoreExcl instruction is the same as the transaction size of the preceding LoadExcl instruction executed in that thread. If the transaction size of a StoreExcl instruction is different from the preceding LoadExcl instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
  - The StoreExcl either passes or fails, and the status value returned by the StoreExcl is UNKNOWN.

    Note

    This means the StoreExcl might pass for some instances of a LoadExcl/StoreExcl pair with mismatched transaction sizes, and fail for other instances of a LoadExcl/StoreExcl pair with mismatched transaction sizes.

  - The block of data of the size of the larger of the transaction sizes used by the LoadExcl/StoreExcl pair at the address accessed by the LoadExcl/StoreExcl pair, is UNKNOWN.

  This means software can rely on a LoadExcl/StoreExcl pair to eventually succeed only if the LoadExcl and the StoreExcl have the same transaction size.

- An implementation of the LoadExcl and StoreExcl instructions can require that, in any thread of execution, the StoreExcl instruction accesses the same number of registers as the preceding LoadExcl instruction executed in that thread. If the StoreExcl instruction accesses a different number of registers than the preceding LoadExcl instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. As a result, software can rely on an LoadExcl/StoreExcl pair to eventually succeed only if they access the same number of registers. For more information, see *CONSTRAINED UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers* on page B2-137.

- LoadExcl/StoreExcl loops are guaranteed to make forward progress only if, for any LoadExcl/StoreExcl loop within a single thread of execution, the software meets all of the following conditions:

  1 Between the Load-Exclusive and the Store-Exclusive, there are no explicit memory accesses, preloads, direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

2 Between the Store-Exclusive returning a failing result and the retry of the corresponding Load-Exclusive:

- There are no stores or `PRFM` instructions to any address within the Exclusives reservation granule accessed by the Store-Exclusive.
- There are no loads or preloads to any address within the Exclusives reservation granule accessed by the Store-Exclusive that use a different VA alias to that address.
- There are no direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.
- All loads and stores are to a block of contiguous virtual memory of not more than 512 bytes in size.

The Exclusives monitor can be cleared at any time without an application-related cause, provided that such clearing is not systematically repeated so as to prevent the forward progress in finite time of at least one of the threads that is accessing the Exclusives monitor. However, it is permissible for the `LoadExcl`/`StoreExcl` loop not to make forward progress if a different thread is repeatedly doing any of the following in a tight loop:

— Performing stores to a PA covered by the Exclusives monitor.

— Prefetching with intent to write to a PA covered by the Exclusives monitor.

— Executing data cache clean, data cache invalidate, or data cache clean and invalidate instructions to a PA covered by the Exclusives monitor.

— Executing instruction cache invalidate all instructions.

— Executing instruction cache invalidate by VA instructions to a PA covered by the Exclusives monitor.

- Implementations can benefit from keeping the `LoadExcl` and `StoreExcl` operations close together in a single thread of execution. This minimizes the likelihood of the Exclusives monitor state being cleared between the `LoadExcl` instruction and the `StoreExcl` instruction. Therefore, for best performance, ARM strongly recommends a limit of 128 bytes between `LoadExcl` and `StoreExcl` instructions in a single thread of execution.
- The architecture sets an upper limit of 2048 bytes on the Exclusives reservation granule that can be marked as exclusive. For performance reasons, ARM recommends that objects that are accessed by exclusive accesses are separated by the size of the Exclusives reservation granule. This is a performance guideline rather than a functional requirement.
- After taking a Data Abort exception, the state of the Exclusives monitors is UNKNOWN.
- For the memory location accessed by a `LoadExcl`/`StoreExcl` pair, if the memory attributes for a `StoreExcl` instruction are different from the memory attributes for the preceding `LoadExcl` instruction in the same thread of execution, behavior is CONSTRAINED UNPREDICTABLE. Where this occurs because the translation of the accessed address changes between the `LoadExcl` instruction and the `StoreExcl` instruction, the CONSTRAINED UNPREDICTABLE behavior is as follows:

  — The `StoreExcl` either passes or fails, and the status value returned by the `StoreExcl` is UNKNOWN.

  Note

  This means the `StoreExcl` might pass for some instances of a `LoadExcl`/`StoreExcl` pair with changed memory attributes, and fail for other instances of a `LoadExcl`/`StoreExcl` pair with changed memory attributes.

  — The data at the address accessed by the `StoreExcl` is UNKNOWN.

Note

Another bullet point in this list covers the case where the memory attributes of a `LoadExcl`/`StoreExcl` pair differ as a result of using different VAs with different attributes that point to the same PA.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global Exclusives monitor that is in the Exclusive Access state is CONSTRAINED UNPREDICTABLE, and the instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same shareability domain as the PE executing the cache maintenance instruction, as determined by the shareability domain of the address being maintained.

  Note

  ARM strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

- If the mapping of the VA to PA is changed between the `LoadExcl` instruction and the `STREX` instruction, and the change is performed using a break-before-make sequence as described in *Using break-before-make when updating translation table entries* on page D4-2208, if the `StoreExcl` is performed after another write to the same PA as the `StoreExcl`, and that other write was performed after the old translation was properly invalidated and that invalidation was properly synchronized, then the `StoreExcl` will not pass its monitor check.

  Note

  ARM expects that, in many implementations, either:

  — The TLB invalidation will clear either the local or global monitor.

  — The PA will be checked between the `LoadExcl` and `StoreExcl`.

- The Exclusive Access state for an address accessed by a PE can be lost as a result of a `PFRM PST*` instruction to the same PA executed by another PE. This means that a very high rate of repeated `PFRM PST*` accesses to a memory location might impede the forward progress of another PE.

Note

In the event of repeatedly-contending `LoadExcl`/`StoreExcl` instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

CONSTRAINED UNPREDICTABLE behavior when Load-Exclusive/Store-Exclusive access a different number of registers

As stated in this section, an implementation can require that the instructions of a Load-Exclusive/Store-Exclusive pair access the same number of registers. In such an implementation, this means behavior is CONSTRAINED UNPREDICTABLE if, in a single thread of execution, either:

- An `LDXP` instruction of two 32-bit quantities is followed by an `STXR` instruction of one 64-bit quantity at the same address.
- An `LDXR` instruction of one 64-bit quantity is followed by an `STXP` instruction of two 32-bit quantities at the same address.

In these cases, the CONSTRAINED UNPREDICTABLE behavior must be one of:

- The `STXP` or `STXR` instruction generates an external Data Abort.
- The `STXP` or `STXR` instruction generates an IMPLEMENTATION DEFINED MMU fault reported using the Data Abort Fault status code of ESR_ELx.DFSC = `0b110101`.
- The `STXP` or `STXR` instruction always fails, returning a status of 1.
- The `STXP` or `STXR` instruction always passes, returning a status of 0.
- This `STXP` or `STXR` instruction has the same pass or fail behavior that it would have had if the instruction had used the same size and number of registers as the preceding `LDXR` or `LDXP` instruction.

B2.9.6 Use of WFE and SEV instructions by spin-locks

ARMv8 provides Wait For Event, Send Event, and Send Event Local instructions, `WFE`, `SEV`, and `SEVL`, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in *Wait for Event mechanism and Send event* on page D1-1954. However, in ARMv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

Note

This is equivalent to issuing an `SEVL` instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an `SEV` instruction after clearing a spinlock.

Part C
The AArch64 Instruction Set

Chapter C1
The A64 Instruction Set

This chapter describes the A64 instruction set. It contains the following sections:

- *About the A64 instruction set* on page C1-142.
- *Structure of the A64 assembler language* on page C1-143.
- *Address generation* on page C1-149.
- *Instruction aliases* on page C1-152.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C1.1 About the A64 instruction set

The A64 instruction set is the instruction set supported in the AArch64 Execution state.

All A64 instructions have a width of 32 bits. The A64 encoding structure breaks down into the following functional groups:

- A miscellaneous group of branch instructions, exception generating instructions, and system instructions.
- Data-processing instructions associated with general-purpose registers. These instructions are supported by two *functional groups*, depending on whether the operands:
  - Are all held in registers.
  - Include an operand with a constant immediate value.
- Load and store instructions associated with the general-purpose register file and the SIMD and floating-point register file.
- SIMD and scalar floating-point data-processing instructions that operate on the SIMD and floating-point registers.

The encoding hierarchy within a functional group breaks down as follows:

- A functional group consists of a set of related instruction classes. *A64 instruction set encoding* on page C4-224 provides an overview of the instruction encodings in the form of a list of instruction classes within their functional groups.
- An instruction class consists of a set of related instruction forms. Instruction forms are documented in one of two alphabetic lists:
  - The load, store, and data-processing instructions associated with the general-purpose registers, together with those in the other instruction classes. See Chapter C6 *A64 Base Instruction Descriptions*.
  - The load, store, and data-processing instructions associated with the SIMD and floating-point support. See Chapter C7 *A64 Advanced SIMD and Floating-point Instruction Descriptions*.
- An instruction form might support a single instruction syntax. Where an instruction supports more than one syntax, each syntax is an *instruction variant*. Instruction variants can occur because of differences in:
  - The size or format of the operands.
  - The register file used for the operands.
  - The addressing mode used for load/load/store memory operands.

  Instruction variants might also arise as the result of other factors.

  Instruction variants are described in the instruction description for the individual instructions.

A64 instructions have a regular bit encoding structure:

- 5-bit register operand fields at fixed positions within the instruction. For general-purpose register operands, the values 0-30 select one of 31 registers. The value 31 is used as a special case that can:
  - Indicate use of the current stack pointer, when identifying a load/store base register or in a limited set of data-processing instructions. See *The stack pointer registers* on page D1-1859.
  - Indicate the value zero when used as a source register operand.
  - Indicate discarding the result when used as a destination register operand.

  For SIMD and floating-point register access, the value used selects one of 32 registers.
- Immediate bits that provide constant data-processing values or address offsets are placed in contiguous bitfields. Some computed values in instruction variants use one or more immediate bitfields together with the secondary encoding bitfields.

All encodings that are not fully defined are described as unallocated. An attempt to execute an unallocated instruction is UNDEFINED, unless the behavior is otherwise defined in this Manual.

C1.2 Structure of the A64 assembler language

The following sections describe the A64 assembler syntax:

- *General requirements*.
- *Common syntax terms*.
- *Instruction Mnemonics* on page C1-144.
- *Condition code* on page C1-144.
- *Register names* on page C1-145.

C1.2.1 General requirements

The letter `W` denotes a general-purpose register holding a 32-bit word, and `X` denotes a general-purpose register holding a 64-bit doubleword.

An A64 assembler recognizes both uppercase and lowercase variants of the instruction mnemonics and register names, but not mixed case variants. An A64 disassembler can output either uppercase or lowercase mnemonics and register names. Program and data labels are case-sensitive.

The A64 assembly language does not require the # character to introduce constant immediate operands, but an assembler must allow immediate values introduced with or without the # character. ARM recommends that an A64 disassembler outputs a # before an immediate operand.

In Example C1-1 on page C1-144, the sequence // is used as a comment leader and A64 assemblers are encouraged to accept this syntax.

C1.2.2 Common syntax terms

The following syntax terms are used frequently throughout the A64 instruction set description.

`UPPER` Text in upper-case letters is fixed. Text in lower-case letters is variable. This means that register name `Xn` indicates that the `X` is required, followed by a variable register number, for example `X29`.

`< >` Any text enclosed by angle braces, < >, is a value that the user supplies. Subsequent text might supply additional information.

`{ }` Any item enclosed by curly brackets, { }, is optional. A description of the item and how its presence or absence affects the instruction is normally supplied by subsequent text. In some cases curly braces are actual symbols in the syntax, for example when they surround a register list. These cases are called out in the surrounding text.

`[ ]` Any items enclosed by square brackets, [ ], constitute a list of alternative characters. A single one of the characters can be used in that position and the subsequent text describes the meaning of the alternatives. In some case the square brackets are part of the syntax itself, such as addressing modes or vector elements. These cases are called out in the surrounding text.

`a|b` Alternative words are separated by a vertical bar, |, and can be surrounded by parentheses to delimit them. For example, `U(ADD|SUB)W` represents `UADDW` or `USUBW`.

`±` This indicates an optional + or - sign. If neither is used then + is assumed.

`uimm`*n* An *n*-bit unsigned, positive, immediate value.

`simm`*n* An *n*-bit two's complement, signed immediate value, where *n* includes the sign bit.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

`SP` See *Register names* on page C1-145.

`Wn` See *Register names* on page C1-145.

`WSP` See *Register names* on page C1-145.

`WZR` See *Register names* on page C1-145.

`Xn` See *Register names* on page C1-145.

`XZR` See *Register names* on page C1-145

C1.2.3 Instruction Mnemonics

The A64 assembly language overloads instruction mnemonics and distinguishes between the different forms of an instruction based on the operand types. For example, the following `ADD` instructions all have different opcodes. However, the programmer must only remember one mnemonic, as the assembler automatically chooses the correct opcode based on the operands. The disassembler follows the same procedure in reverse.

Example C1-1 ADD instructions with different opcodes

```
ADD W0, W1, W2              // add 32-bit register
ADD X0, X1, X2              // add 64-bit register
ADD X0, X1, W2, SXTW        // add 64-bit extended register
ADD X0, X1, #42             // add 64-bit immediate
```

C1.2.4 Condition code

The A64 ISA has some instructions that set Condition flags or test Condition codes or both. For information about instructions that set the Condition flags or use the condition mnemonics, see *Condition flags and related instructions* on page C6-525.

Table C1-1 shows the available Condition codes.

Table C1-1 Condition codes

cond	Mnemonic	Meaning (integer)	Meaning (floating-point)[a]	Condition flags
0000	EQ	Equal	Equal	Z == 1
0001	NE	Not equal	Not equal or unordered	Z == 0
0010	CS or HS	Carry set	Greater than, equal, or unordered	C == 1
0011	CC or LO	Carry clear	Less than	C == 0
0100	MI	Minus, negative	Less than	N == 1
0101	PL	Plus, positive or zero	Greater than, equal, or unordered	N == 0
0110	VS	Overflow	Unordered	V == 1
0111	VC	No overflow	Ordered	V == 0
1000	HI	Unsigned higher	Greater than, or unordered	C ==1 && Z == 0
1001	LS	Unsigned lower or same	Less than or equal	!(C ==1 && Z ==0)
1010	GE	Signed greater than or equal	Greater than or equal	N == V
1011	LT	Signed less than	Less than, or unordered	N! = V

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Table C1-1 Condition codes (continued)

cond	Mnemonic	Meaning (integer)	Meaning (floating-point)[a]	Condition flags
1100	GT	Signed greater than	Greater than	Z == 0 && N == V
1101	LE	Signed less than or equal	Less than, equal, or unordered	!(Z == 0 && N == V)
1110	AL	Always	Always	Any
1111	NV[b]	Always	Always	Any

a. Unordered means at least one NaN operand.

b. The Condition code NV exists only to provide a valid disassembly of the 0b1111 encoding, otherwise its behavior is identical to AL.

C1.2.5 Register names

This section describes the AArch64 registers. It contains the following subsections:

- *General-purpose register file and zero register and stack pointer*.
- *SIMD and floating-point register file* on page C1-146.
- *SIMD and floating-point scalar register names* on page C1-146.
- *SIMD vector register names* on page C1-147.
- *SIMD vector element names* on page C1-147.

General-purpose register file and zero register and stack pointer

The 31 general-purpose registers in the general-purpose register file are named R0-R30 and encoded in the instruction register fields with values 0-30. In a general-purpose register field the value 31 represents either the current stack pointer or the zero register, depending on the instruction and the operand position.

When the registers are used in a specific instruction variant, they must be qualified to indicate the operand data size, 32 bits or 64 bits, and the data size of the instruction.

When the data size is 32 bits, the lower 32 bits of the register are used and the upper 32 bits are ignored on a read and cleared to zero on a write.

Table C1-2 shows the qualified names for registers, where *n* is a register number 0-30.

Table C1-2 Naming of general-purpose registers, the zero register, and the stack pointer

Name	Size	Encoding	Description
Wn	32 bits	0-30	General-purpose register 0-30
Xn	64 bits	0-30	General-purpose register 0-30
WZR	32 bits	31	Zero register
XZR	64 bits	31	Zero register
WSP	32 bits	31	Current stack pointer
SP	64 bits	31	Current stack pointer

This list gives more information about the instruction arguments shown in Table C1-2:

- The names Xn and Wn both refer to the same general-purpose register, Rn.
- There is no register named W31 or X31.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- The name SP represents the stack pointer for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as a read or write of the current stack pointer. When instructions do not interpret this operand encoding as the stack pointer, use of the name SP is an error.
- The name WSP represents the current stack pointer in a 32-bit context.
- The name XZR represents the zero register for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as returning zero when read or discarding the result when written. When instructions do not interpret this operand encoding as the zero register, use of the name XZR is an error.
- The name WZR represents the zero register in a 32-bit context.
- The architecture does not define a specific name for general-purpose register R30 to reflect its role as the link register on procedure calls. However, an A64 assembler must always use W30 and X30 for this purpose, and additional software names might be defined as part of the Procedure Call Standard, see *Procedure Call Standard for the ARM 64-bit Architecture*.

SIMD and floating-point register file

The 32 registers in the SIMD and floating-point register file, V0-V31, hold floating-point operands for the scalar floating-point instructions, and both scalar and vector operands for the SIMD instructions. When they are used in a specific instruction form, the names must be further qualified to indicate the data shape, that is the data element size and the number of elements or lanes within the register. A similar requirement is placed on the general-purpose registers. See *General-purpose register file and zero register and stack pointer* on page C1-145.

Note

The data type is described by the instruction mnemonics that operate on the data. The data type is not described by the register name. The data type is the interpretation of bits within each register or vector element, whether these are integers, floating-point values, polynomials, or cryptographic hashes.

SIMD and floating-point scalar register names

SIMD and floating-point instructions that operate on scalar data only access the lower bits of a SIMD and floating-point register. The unused high bits are ignored on a read and cleared to 0 on a write.

Table C1-3 shows the qualified names for accessing scalar SIMD and floating-point registers. The letter *n* denotes a register number between 0 and 31.

Table C1-3 SIMD and floating-point scalar register names

Size	Name
8 bits	`Bn`
16 bits	`Hn`
32 bits	`Sn`
64 bits	`Dn`
128 bits	`Qn`

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

SIMD vector register names

If a register holds multiple data elements on which arithmetic is performed in a parallel, SIMD, manner, then a qualifier describes the vector shape. The vector shape is the element size and the number of elements or lanes. If the element size in bits multiplied by the number of lanes does not equal 128, then the upper 64 bits of the register are ignored on a read and cleared to zero on a write.

Table C1-4 shows the SIMD vector register names. The letter *n* denotes a register number between 0 and 31.

Table C1-4 SIMD vector register names

Shape	Name
8 bits × 8 lanes	`Vn.8B`
8 bits × 16 lanes	`Vn.16B`
16 bits × 4 lanes	`Vn.4H`
16 bits × 8 lanes	`Vn.8H`
32 bits × 2 lanes	`Vn.2S`
32 bits × 4 lanes	`Vn.4S`
64 bits × 1 lane	`Vn.1D`
64 bits × 2 lanes	`Vn.2D`

SIMD vector element names

Appending a constant, zero-based element index to the register name inside square brackets indicates that a single element from a SIMD and floating-point register is used as a scalar operand. The number of lanes is not represented, as it is not encoded in the instruction and can only be inferred from the index value.

Table C1-5 shows the vector register names and the element index. The letter *i* denotes the element index.

Table C1-5 Vector register names with element index

Size	Name
8 bits	`Vn.B[i]`
16 bits	`Vn.H[i]`
32 bits	`Vn.S[i]`
64 bits	`Vn.D[i]`

An assembler must accept a fully qualified SIMD register name if the number of lanes is greater than the index value. See *SIMD vector register names*. For example, an assembler must accept all of the following forms as the name for the 32-bit element in bits [63:32] of the SIMD and floating-point register V9:

```
V9.S[1]     //standard disassembly
V9.2S[1]    //optional number of lanes
V9.4S[1]    //optional number of lanes
```

Note

The SIMD and floating-point register element name `Vn.S[0]` is not equivalent to the scalar SIMD and floating-point register name `Sn`. Although they represent the same bits in the register, they select different instruction encoding forms, either the vector element or the scalar form.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

SIMD vector register list

Where an instruction operates on multiple SIMD and floating-point registers, for example vector Load/Store structure and table lookup operations, the registers are specified as a list enclosed by curly braces. This list consists of either a sequence of registers separated by commas, or a register range separated by a hyphen. The registers must be numbered in increasing order, modulo 32, in increments of one. The hyphenated form is preferred for disassembly if there are more than two registers in the list and the register number are increasing. The following examples are equivalent representations of a set of four registers `V4` to `V7`, each holding four lanes of 32-bit elements:

```
{ V4.4S - V7.4S }              //standard disassembly
{ V4.4S, V5.4S, V6.4S, V7.4S } //alternative representation
```

SIMD vector element list

Registers in a list can also have a vector element form. For example, the `LD4` instruction can load one element into each of four registers, and in this case the index is appended to the list as follows:

```
{ V4.S - V7.S }[3]                 //standard disassembly
{ V4.4S, V5.4S, V6.4S, V7.4S }[3]  //alternative with optional number of lanes
```

Non-Confidential

C1.3 Address generation

The A64 instruction set supports 64-bit virtual addresses (VAs). The valid VA range is determined by the following factors:

- The size of the implemented virtual address space.
- *Memory Management Unit* (MMU) configuration settings.

Limits on the VA size mean that the most significant bits of the virtual address do not hold valid address bits. These unused bits can hold:

- A tag, see *Address tagging in AArch64 state* on page D4-2084.
- If ARMv8.3-PAuth is implemented, a Pointer authentication code (PAC), see *Pointer authentication in AArch64 state* on page D4-2086.

For more information on memory management and address translation, see Chapter D4 *The AArch64 Virtual Memory System Architecture*.

C1.3.1 Register indexed addressing

The A64 instruction set allows a 64-bit index register to be added to the 64-bit base register, with optional scaling of the index by the access size. Additionally it allows for sign-extension or zero-extension of a 32-bit value within an index register, followed by optional scaling.

C1.3.2 PC-relative addressing

The A64 instruction set has support for position-independent code and data addressing:

- PC-relative literal loads have an offset range of ± 1MB.
- Process state flag and compare based conditional branches have a range of ± 1MB. Test bit conditional branches have a restricted range of ± 32KB.
- Unconditional branches, including branch and link, have a range of ± 128MB.

PC-relative Load/Store operations, and address generation with a range of ± 4GB can be performed using two instructions.

C1.3.3 Load/Store addressing modes

Load/Store addressing modes in the A64 instruction set require a 64-bit base address from a general-purpose register X0-X30 or the current stack pointer, `SP`, with an optional immediate or register offset. Table C1-6 shows the assembler syntax for the complete set of Load/Store addressing modes.

Table C1-6 A64 Load/Store addressing modes

Addressing Mode	Offset		
	Immediate	Register	Extended Register
Base register only (no offset)	`[base{, #0}]`	-	-
Base plus offset	`[base{, #imm}]`	`[base, Xm{, LSL #imm}]`	`[base, Wm, (S|U)XTW {#imm}]`
Pre-indexed	`[base, #imm]!`	-	-
Post-indexed	`[base], #imm`	`[base], Xm`[a]	-
Literal (PC-relative)	`label`	-	-

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

a. The post-indexed by register offset mode can be used with the SIMD Load/Store structure instructions described in *Load/Store Vector* on page C3-178. Otherwise the post-indexed by register offset mode is not available.

Some types of Load/Store instruction support only a subset of the Load/Store addressing modes listed in Table C1-6 on page C1-149. Details of the supported modes are as follows:

- Base plus offset addressing means that the address is the value in the 64-bit base register plus an offset.
- Pre-indexed addressing means that the address is the sum of the value in the 64-bit base register and an offset, and the address is then written back to the base register.
- Post-indexed addressing means that the address is the value in the 64-bit base register, and the sum of the address and the offset is then written back to the base register.
- Literal addressing means that the address is the value of the 64-bit program counter for this instruction plus a 19-bit signed word offset. This means that it is a 4 byte aligned address within ±1MB of the address of this instruction with no offset. Literal addressing can only be used for loads of at least 32 bits and for prefetch instructions. The PC cannot be referenced using any other addressing modes. The syntax for labels is specific to individual toolchains.
- An immediate offset can be unsigned or signed, and scaled or unscaled, depending on the type of Load/Store instruction. When the immediate offset is scaled it is encoded as a multiple of the transfer size, although the assembly language always uses a byte offset, and the assembler or disassembler performs the necessary conversion. The usable byte offsets therefore depend on the type of Load/Store instruction and the transfer size.

  Table C1-7 shows the offset and the type of Load/Store instruction.

Table C1-7 Immediate offsets and the type of Load/Store instruction

Offset bits	Sign	Scaling	Write-Back	Load/Store type
0	-	-	-	Exclusive/acquire/release
7	Signed	Scaled	Optional	Register pair
9	Signed	Unscaled	Optional	Single register
12	Unsigned	Scaled	No	Single register

- A register offset means that the offset is the 64 bits from a general-purpose register, Xm, optionally scaled by the transfer size, in bytes, if `LSL #imm` is present and where `imm` must be equal to $\log_2$(transfer_size).
- An extended register offset means that offset is the bottom 32 bits from a general-purpose register Wm, sign-extended or zero-extended to 64 bits, and then scaled by the transfer size if so indicated by `#imm`, where imm must be equal to $\log_2$(transfer_size). An assembler must accept Wm or Xm as an extended register offset, but Wm is preferred for disassembly.
- Generating an address lower than the value in the base register requires a negative signed immediate offset or a register offset holding a negative value.
- When stack alignment checking is enabled by system software and the base register is the SP, the current stack pointer must be initially quadword aligned, that is aligned to 16 bytes. Misalignment generates a Stack Alignment fault. The offset does not have to be a multiple of 16 bytes unless the specific Load/Store instruction requires this. SP cannot be used as a register offset.

Address calculation

General-purpose arithmetic instructions can calculate the result of most addressing modes and write the address to a general-purpose register or, in most cases, to the current stack pointer.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Table C1-8 shows the arithmetic instructions that can compute addressing modes.

Table C1-8 Arithmetic instructions to compute addressing modes

Addressing Form	Offset		
	Immediate	Register	Extended Register
Base register (no offset)	`MOV Xd|SP, base`	-	-

Base plus offset	`ADD Xd|SP, base, #imm`
	or
	`SUB Xd|SP, base, #imm`
		`ADD <Xd|SP>, base, Xm{,LSL#imm}`	`ADD <Xd|SP>, base, Wm,(S|U)XT(W|H|B|) {#imm}`

Pre-indexed	-	-	-
Post-indexed	-	-	-
Literal (PC-relative)	`ADR Xd, label`	-	-

Note

- To calculate a base plus immediate offset the `ADD` instructions defined in *Arithmetic (immediate)* on page C3-185 accept an unsigned 12-bit immediate offset, with an optional left shift by 12. This means that a single `ADD` instruction cannot support the full range of byte offsets available to a single register Load/Store with a scaled 12-bit immediate offset. For example, a quadword `LDR` effectively has a 16-bit byte offset. To calculate an address with a byte offset that requires more than 12 bits it is necessary to use two `ADD` instructions. The following example shows this:

  ```
  ADD  Xd, base, #(imm & 0xFFF)
  ADD  Xd, Xd, #(imm>>12), LSL #12
  ```

- To calculate a base plus extended register offset, the `ADD` instructions defined in *Arithmetic (extended register)* on page C3-191 provide a superset of the addressing mode that also supports sign-extension or zero-extension of a byte or halfword value with any shift amount between 0 and 4, for example:

  ```
  ADD   Xd, base, Wm, SXTW #3    // Xd = base + (SignExtend(Wm) LSL 3)
  ADD   Xd, base, Wm, UXTH #4    // Xd = base + (ZeroExtend(Wm<15:0>) LSL 4)
  ```

- If the same extended register offset is used by more than one Load/Store instruction, then, depending on the implementation, it might be more efficient to calculate the extended and scaled intermediate result just once, and then re-use it as a simple register offset. The extend and scale calculation can be performed using the `SBFIZ` and `UBFIZ` bitfield instructions defined in *Bitfield move* on page C3-188, for example:

  ```
  SBFIZ Xd, Xm, #3, #32    //Xd = “Wm, SXTW #3”
  UBFIZ Xd, Xm, #4, #16    //Xd = “Wm, UXTH #4”
  ```

C1.4 Instruction aliases

Some instructions have an associated *architecture alias* that is used for disassembly of the encoding when the associated conditions are met. Architecture alias instructions are included in the alphabetic lists of instruction types and clearly presented as an alias form in descriptions for the individual instructions.

Chapter C2
About the A64 Instruction Descriptions

This chapter describes the *instruction descriptions* contained in Chapter C6 *A64 Base Instruction Descriptions* and Chapter C7 *A64 Advanced SIMD and Floating-point Instruction Descriptions*.

It contains the following sections:

- *Understanding the A64 instruction descriptions* on page C2-154.
- *General information about the A64 instruction descriptions* on page C2-157.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C2.1 Understanding the A64 instruction descriptions

Each instruction description in Chapter C6 and Chapter C7 has the following content:

1. A title.
2. An introduction to the instruction.
3. The instruction encoding or encodings.
4. Any alias conditions.
5. A list of the assembler symbols for the instruction.
6. Pseudocode describing how the instruction operates.
7. Notes, if applicable.

The following sections describe each of these.

C2.1.1 The title

The title of an instruction description includes the base mnemonic for the instruction.

If different forms of an instruction use the same base mnemonic, each form has its own description. In this case, the title is the mnemonic followed by a short description of the instruction form in parentheses. This is most often used when an operand is an immediate value in one instruction form, but is a register in another form.

For example, in Chapter C6 there are the following titles for different forms of the `ADD` instruction:

- *ADD (extended register)* on page C6-529.
- *ADD (immediate)* on page C6-531.
- *ADD (shifted register)* on page C6-533.

C2.1.2 An introduction to the instruction

This briefly describes the function of the instruction. The introduction is not a complete description of the instruction, and it is not definitive. If there is any conflict between it and the more detailed information that follows it, the more detailed information takes priority.

C2.1.3 The instruction encoding or encodings

This shows the instruction encoding diagram, or if the instruction has more than one encoding, shows all of the encoding diagrams. Each diagram has a subheading.

For example, for load and store instructions, the subheadings might be:

- Post-index.
- Pre-index.
- Unsigned offset.

Each diagram numbers the bits from 31 to 0. The diagram for an instruction at address *A* shows, from left to right, the bytes at addresses *A*+3, *A*+2, *A*+1, and *A*.

There might be variants of an encoding, if the *assembler syntax prototype* differs depending on the value in one or more of the encoding fields. In this case, each variant has a subheading that describes the variant and shows the distinguishing field value or values in parentheses. For example, in Chapter C6 there are the following subheadings for variants of the `ADC` instruction encoding:

- 32-bit variant (sf = 0).
- 64-bit variant (sf = 1).

The assembler syntax prototype for an encoding or variant of an encoding shows how to form a complete assembler source code instruction that assembles to the encoding. Unless otherwise stated, the prototype is also the preferred syntax for a disassembler to disassemble the encoding to. Disassemblers are permitted to omit optional symbols that represent the default value of a field or set of fields, to produce more readable disassembled code, provided that the output re-assembles to the same encoding.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Each encoding diagram, and its associated assembler syntax prototypes, is followed by encoding-specific pseudocode that translates the fields of that encoding into inputs for the encoding-independent pseudocode that describes the operation of the instruction. See *Pseudocode describing how the instruction operates* on page C2-156.

C2.1.4 Any alias conditions, if applicable

This is an optional part of an instruction description. If included, it describes the set of conditions for which an alternative mnemonic and its associated assembler syntax prototypes are preferred for disassembly by a disassembler. It includes a link to the alias instruction description that defines the alternative syntax. The alias syntax and the original syntax can be used interchangeably in the assembler source code.

ARM recommends that if a disassembler outputs the alias syntax, it consistently outputs the alias syntax.

C2.1.5 A list of the assembler symbols for the instruction

The *Assembler symbols* subsection of the instruction description contains a list of the symbols that the assembler syntax prototype or prototypes use, if any.

In assembler syntax prototypes, the following conventions are used:

`< >` Angle brackets. Any symbol enclosed by these is a name or a value that the user supplies. For each symbol, there is a description of what the symbol represents. The description usually also specifies which encoding field or fields encodes the symbol.

`{ }` Brace brackets. Any symbols enclosed by these are optional. For each optional symbol, there is a description of what the symbol represents and how its presence or absence is encoded.

In some assembler syntax prototypes, some brace brackets are mandatory, for example if they surround a register list. When the use of brace brackets is mandatory, they are separated from other syntax items by one or more spaces.

`#` This usually precedes a numeric constant. All uses of # are optional in A64 assembler source code. ARM recommends that disassemblers output the # where the assembler syntax prototype includes it.

`+/-` This indicates an optional + or - sign. If neither is coded, + is assumed.

Single spaces are used for clarity, to separate syntax items. Where a space is mandatory, the assembler syntax prototype shows two or more consecutive spaces.

Any characters not shown in this conventions list must be coded exactly as shown in the assembler syntax prototype. Apart from brace brackets, the characters shown are used as part of a meta-language to define the architectural assembler syntax for an instruction encoding or alias, but have no architecturally defined significance in the input to an assembler or in the output from a disassembler.

The following symbol conventions are used:

`<Xn>` The 64-bit name of a general-purpose register (X0-X30) or the zero register (XZR).

`<Wn>` The 32-bit name of a general-purpose register (W0-W30) or the zero register (WZR).

`<Xn|SP>` The 64-bit name of a general-purpose register (X0-X30) or the current stack pointer (SP).

`<Wn|WSP>` The 32-bit name of a general-purpose register (W0-W30) or the current stack pointer (WSP).

`<Bn>, <Hn>, <Sn>, <Dn>, <Qn>`

The 8, 16, 32, 64 or 128-bit name of a SIMD and floating-point register in a scalar context as described in section *Register names* on page C1-145.

`<Vn>` The name of a SIMD and floating-point register name in a vector context as described in *Register names* on page C1-145.

If the description of a symbol specifies that the symbol is a register, the description might also specify that the range of permitted registers is extended or restricted. It also specifies any differences from the default rules for such fields.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Register names on page C1-145 provides the A64 register names.

C2.1.6 Pseudocode describing how the instruction operates

The *Operation* subsection of the instruction description contains this pseudocode.

It is encoding-independent pseudocode that provides a precise description of what the instruction does.

Note

For a description of ARM pseudocode, see Appendix K12 *ARM Pseudocode Definition*. This appendix also describes the execution model for an instruction.

C2.1.7 Notes, if applicable

If applicable, other notes about the instruction appear under additional subheadings.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

C2.2 General information about the A64 instruction descriptions

This section provides general information about the A64 instruction descriptions. Some of this information also applies to System register descriptions, for example the terms defined in *Fixed values in AArch64 instruction and System register descriptions* apply to the AArch64 descriptions throughout this manual. The following subsections provide this information:

- *Execution of instructions in debug state*.
- *Fixed values in AArch64 instruction and System register descriptions*.
- *Modified immediate constants in A64 instructions* on page C2-158.

C2.2.1 Execution of instructions in debug state

In general, except for the instructions described in *Debug state* on page C3-164, the A64 instruction descriptions do not indicate any differences in the behavior of the instruction if it is executed in Debug state. For this information, see *Executing instructions in Debug state* on page H2-5708.

Note

For many instructions, execution is unchanged in Debug state. *Executing instructions in Debug state* on page H2-5708 identifies these instructions,

C2.2.2 Fixed values in AArch64 instruction and System register descriptions

This section summarizes the terms used to describe fixed values in AArch64 register and instruction descriptions. The Glossary gives full descriptions of these terms, and each entry in this section includes a link to the corresponding Glossary entry.

Note

In register descriptions, the meaning of some bits depends on the PE state. This affects the definitions of RES0 and RES1, as shown in the Glossary.

The following terms are used to describe bits or fields with fixed values:

RAZ Read-As-Zero. See *Read-As-Zero (RAZ)*.

In diagrams, a RAZ bit can be shown as 0.

(0), RES0 Reserved, *Should-Be-Zero (SBZ)* or *RES0*.

In instruction encoding diagrams, and sometimes in other descriptions, `(0)` indicates an SBZ bit. If the bit is set to 1, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a `NOP`.
- The instruction executes as if the value of the bit was 0.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either `(0)(0)(0)` or as `(000)`.

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES0. See the Glossary definition of RES0 for more information.

Note

Some of the System instruction descriptions in this chapter are based on the *field description* of the input value for the instruction. These are register descriptions and therefore can include RES0 fields,

The `(0)` and RES0 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definitions cover these cases.

RAO Read-As-One. See *Read-As-One (RAO)*.

In diagrams, a RAO bit can be shown as 1.

(1), RES1 Reserved, *Should-Be-One (SBO)* or *RES1*.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

In instruction encoding diagrams, and sometimes in other descriptions, (1) indicates a SBO bit. If the bit is set to 0, behavior is CONSTRAINED UNPREDICTABLE, and must be one of the following:

- The instruction is UNDEFINED.
- The instruction is treated as a NOP.
- The instruction executes as if the value of the bit was 1.
- Any destination registers of the instruction become UNKNOWN.

This notation can be expanded for fields, so a three-bit field can be shown as either (1)(1)(1) or as (111).

In register diagrams, but not in the A64 encoding and instruction descriptions, bits or fields can be shown as RES1. See the Glossary definition of RES1 for more information.

Note

Some of the System instruction descriptions in this chapter are based on the *field description* of the input value for the instruction. These are register descriptions and therefore can include RES1 fields,

The (1) and RES1 descriptions can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definitions cover these cases.

C2.2.3 Modified immediate constants in A64 instructions

It contains the following subsections:

- *Modified immediate constants in A64 floating-point instructions*.

Modified immediate constants in A64 floating-point instructions

Table C2-1 shows the immediate constants available in FMOV (scalar, immediate) and FMOV (vector, immediate) floating-point instructions.

Table C2-1 A64 Floating-point modified immediate constants

Data type	immediate	Constant [a]
F16	abcdefgh	aBbbcdef gh000000
F32	abcdefgh	aBbbbbbc defgh000 00000000 00000000
F64	abcdefgh	aBbbbbbb bbcdefgh 00000000 00000000 00000000 00000000 00000000 00000000

a. In this column, B = NOT(b). The bit pattern represents the floating-point number $(-1)^S \times 2^{exp} \times$ mantissa, where S = UInt(a), exp = UInt(NOT(b):c:d)-3 and mantissa = (16+UInt(e:f:g:h))/16.

The immediate value shown in the table is either:

- The value of the imm8 field for an FMOV (scalar, immediate) instruction, see *FMOV (scalar, immediate)* on page C7-1276.
- The value obtained by concatenating the a:b:c:d:e:f:g:h fields field for an FMOV (vector, immediate) instruction, see *FMOV (vector, immediate)* on page C7-1269.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Table C2-2 shows the floating-point constant values encoded in the `b:c:d:e:f:g:h` fields of the `FMOV` (vector, immediate) instruction.

Table C2-2 Floating-point constant values

efgh \ bcd	000	001	010	011	100	101	110	111
0000	2.0	4.0	8.0	16.0	0.125	0.25	0.5	1.0

Chapter C3
A64 Instruction Set Overview

This chapter provides an overview of the A64 instruction set. It contains the following sections:

- *Branches, Exception generating, and System instructions* on page C3-162.
- *Loads and stores* on page C3-169.
- *Data processing - immediate* on page C3-185.
- *Data processing - register* on page C3-190.
- *Data processing - SIMD and floating-point* on page C3-198.

For a structured breakdown of instruction groups by encoding, see Chapter C4 *A64 Instruction Set Encoding*.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C3.1 Branches, Exception generating, and System instructions

This section describes the branch, exception generating, and system instructions. It contains the following subsections:

- *Conditional branch*.
- *Unconditional branch (immediate)* on page C3-163.
- *Unconditional branch (register)* on page C3-163.
- *Exception generation and return* on page C3-163.
- *System register instructions* on page C3-164.
- *System instructions* on page C3-164.
- *Hint instructions* on page C3-165.
- *Barriers and CLREX instructions* on page C3-165.
- *Pointer authentication instructions* on page C3-166.

For information about the encoding structure of the instructions in this instruction group, see *Branches, Exception Generating and System instructions* on page C4-228.

Note

Software must:

- Use only `BLR` or `BL` to perform a nested subroutine call when that subroutine is expected to return to the immediately following instruction, that is, the instruction with the address of the `BLR` or `BL` instruction incremented by four.
- Use only `RET` to perform a subroutine return, when that subroutine is expected to have been entered by a `BL` or `BLR` instruction.
- Use only `B`, `BR`, or the instructions listed in Table C3-1 to perform a control transfer that is not a subroutine call or subroutine return described in this *Note*.

C3.1.1 Conditional branch

Conditional branches change the flow of execution depending on the current state of the Condition flags or the value in a general-purpose register. See Table C1-1 on page C1-144 for a list of the Condition codes that can be used for `cond`.

Table C3-1 shows the Conditional branch instructions.

Table C3-1 Conditional branch instructions

Mnemonic	Instruction	Branch offset range from the PC	See
`B.cond`	Branch conditionally	±1MB	*B.cond* on page C6-561
`CBNZ`	Compare and branch if nonzero	±1MB	*CBNZ* on page C6-589
`CBZ`	Compare and branch if zero	±1MB	*CBZ* on page C6-590
`TBNZ`	Test bit and branch if nonzero	±32KB	*TBNZ* on page C6-981
`TBZ`	Test bit and branch if zero	±32KB	*TBZ* on page C6-982

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C3.1.2 Unconditional branch (immediate)

Unconditional branch (immediate) instructions change the flow of execution unconditionally by adding an immediate offset with a range of ±128MB to the value of the program counter that fetched the instruction. The BL instruction also writes the address of the sequentially following instruction to general-purpose register, X30.

Table C3-2 shows the Unconditional branch instructions with an immediate branch offset.

Table C3-2 Unconditional branch instructions (immediate)

Mnemonic	Instruction	Immediate branch offset range from the PC	See
B	Branch unconditionally	±128MB	*B* on page C6-562
BL	Branch with link	±128MB	*BL* on page C6-572

C3.1.3 Unconditional branch (register)

Unconditional branch (register) instructions change the flow of execution unconditionally by setting the program counter to the value in a general-purpose register. The BLR instruction also writes the address of the sequentially following instruction to general-purpose register X30. The RET instruction behaves identically to BR, but provides an additional hint to the PE that this is a return from a subroutine. Table C3-3 shows Unconditional branch instructions that jump directly to an address held in a general-purpose register.

Table C3-3 Unconditional branch instructions (register)

Mnemonic	Instruction	See
BLR	Branch with link to register	*BLR* on page C6-573
BR	Branch to register	*BR* on page C6-576
RET	Return from subroutine	*RET* on page C6-841

C3.1.4 Exception generation and return

This section describes the following exceptions:

- *Exception generating*.
- *Exception return* on page C3-164.
- *Debug state* on page C3-164.

Exception generating

Table C3-4 shows the Exception generating instructions.

Table C3-4 Exception generating instructions

For information about the allocated values for the data barriers, see:

- *DMB* on page C6-628.
- *DSB* on page C6-631.

C3.1.9 Pointer authentication instructions

ARMv8.3-PAuth adds support for pointer authentication, see *Pointer authentication in AArch64 state* on page D4-2086. This functionality includes the A64 instructions described in this section. These instructions fall into two groups, see:

- *Basic pointer authentication instructions*.
- *Combined instructions that include pointer authentication* on page C3-168.

Basic pointer authentication instructions

Each of these instructions only performs an operation that supports pointer authentication.

Table C3-11 shows the instructions that add a *Pointer Authentication Code* (PAC) to the address in a register:

Table C3-11 Instructions that add a PAC

Mnemonic	Instruction	See
PACIASP	Add PAC to instruction address using APIAKey_EL1 and SP	*PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA* on page C6-827
PACIAZ	Add PAC to instruction address using APIAKey_EL1 and zero	
PACIA1716	Add PAC to instruction address X17 using APIAKey_EL1 and X16	
PACIBSP	Add PAC to instruction address using APIBKey_EL1 and SP	*PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB* on page C6-829
PACIBZ	Add PAC to instruction address using APIBKey_EL1 and zero	
PACIB1716	Add PAC to instruction address X17 using APIBKey_EL1 and X16	
PACIA	Add PAC to instruction address using APIAKey_EL1, registers	*PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA* on page C6-827
PACDA	Add PAC to data address using APDAKey_EL1, registers	*PACDA, PACDZA* on page C6-824
PACIB	Add PAC to instruction address using APIBKey_EL1, registers	*PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB* on page C6-829
PACDB	Add PAC to data address using APDBKey_EL1, registers	*PACDB, PACDZB* on page C6-825
PACIZA	Add PAC to instruction address using APIAKey_EL1, register and zero	*PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA* on page C6-827
PACDZA	Add PAC to data address using APDAKey_EL1, register and zero	*PACDA, PACDZA* on page C6-824
PACIZB	Add PAC to instruction address using APIBKey_EL1, register and zero	*PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB* on page C6-829
PACDZB	Add PAC to data address using APDBKey_EL1, register and zero	*PACDB, PACDZB* on page C6-825
PACGA	Add generic PAC using APGAKey_EL1, registers	*PACGA* on page C6-826

Non-Confidential

Table C3-12 shows the instructions that authenticate a PAC in a register:

Table C3-12 Instructions that authenticate a PAC

Mnemonic	Instruction	See
AUTIASP	Authenticate PAC for instruction address using APIAKey_EL1 and SP	*AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA* on page C6-557
AUTIAZ	Authenticate PAC for instruction address using APIAKey_EL1 and zero	
AUTIA1716	Authenticate PAC for instruction address X17 using APIAKey_EL1 and X16	
AUTIBSP	Authenticate PAC for instruction address using APIBKey_EL1 and SP	*AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB* on page C6-559
AUTIBZ	Authenticate PAC for instruction address using APIBKey_EL1 and zero	
AUTIB1716	Authenticate PAC for instruction address X17 using APIBKey_EL1 and X16	
AUTIA	Authenticate PAC for instruction address using APIAKey_EL1, registers	*AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA* on page C6-557
AUTDA	Authenticate PAC for data address using APDAKey_EL1, registers	*AUTDA, AUTDZA* on page C6-555
AUTIB	Authenticate PAC for instruction address using APIBKey_EL1, registers	*AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB* on page C6-559
AUTDB	Authenticate PAC for data address using APDBKey_EL1, registers	*AUTDB, AUTDZB* on page C6-556
AUTIZA	Authenticate PAC for instruction address using APIAKey_EL1, register and zero	*AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA* on page C6-557
AUTDZA	Authenticate PAC for data address using APDAKey_EL1, register and zero	*AUTDA, AUTDZA* on page C6-555
AUTIZB	Authenticate PAC for instruction address using APIBKey_EL1, register and zero	*AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB* on page C6-559
AUTDZB	Authenticate PAC for data address using APDBKey_EL1, register and zero	*AUTDB, AUTDZB* on page C6-556

Table C3-13 shows the instructions that strip a PAC from a register, without performing any authentication:

Table C3-13 Instructions that strip a PAC

Mnemonic	Instruction	See
XPACLRI	Strip instruction address PAC from LR	*XPACD, XPACI, XPACLRI* on page C6-1002
XPACI	Strip instruction address PAC, register	
XPACD	Strip data address PAC, register

C3.2 Loads and stores

This section describes the Load/Store instructions. It contains the following subsections:

- *Load/Store register*.
- *Load/Store register (unscaled offset)* on page C3-170.
- *Load/Store Pair* on page C3-171.
- *Load/Store Non-temporal Pair* on page C3-172.
- *Load/Store unprivileged* on page C3-173.
- *Load-Exclusive/Store-Exclusive* on page C3-174.
- *Load-Acquire/Store-Release* on page C3-174.
- *LoadLOAcquire/StoreLORelease* on page C3-175.
- *Load/Store scalar SIMD and floating-point* on page C3-176.
- *Load/Store Vector* on page C3-178.
- *Prefetch memory* on page C3-180.
- *Compare and Swap* on page C3-181.
- *Atomic memory operations* on page C3-182.
- *Swap* on page C3-184.

Apart from Load-Exclusive, Store-Exclusive, Load-Acquire, and Store-Release, addresses can have any alignment unless strict alignment checking is enabled, that is if SCTLR_ELx.A == 1.

The additional control bits SCTLR_ELx.SA and SCTLR_EL1.SA0 control whether the stack pointer must be quadword aligned when used as a base register. See *SP alignment checking* on page D1-1868. Using a misaligned stack pointer generates an SP alignment fault exception.

For information about the encoding structure of the instructions in this instruction group, see *Loads and Stores* on page C4-234.

Note

In some cases, Load/Store instructions can lead to CONSTRAINED UNPREDICTABLE behavior. See *AArch64 CONSTRAINED UNPREDICTABLE behaviors* on page K1-6413.

C3.2.1 Load/Store register

The Load/Store register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset, optionally scaled.
- Base plus a 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
- PC-relative literal for loads of 32 bits or more.

See also *Load/Store addressing modes* on page C1-149.

If a Load instruction specifies writeback and the register being loaded is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs the load using the specified addressing mode and the base register becomes UNKNOWN. In addition, if an exception occurs during the execution of such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

If a Store instruction performs a writeback and the register that is stored is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs the store to the designated register using the specified addressing mode, but the value stored is UNKNOWN.

Table C3-15 shows the Load/Store Register instructions.

Table C3-15 Load/Store register instructions

Mnemonic	Instruction	See
LDR	Load register (register offset)	*LDR (register)* on page C6-698
	Load register (immediate offset)	*LDR (immediate)* on page C6-693
	Load register (PC-relative literal)	*LDR (literal)* on page C6-696
LDRB	Load byte (register offset)	*LDRB (register)* on page C6-704
	Load byte (immediate offset)	*LDRB (immediate)* on page C6-702
LDRSB	Load signed byte (register offset)	*LDRSB (register)* on page C6-713
	Load signed byte (immediate offset)	*LDRSB (immediate)* on page C6-710
LDRH	Load halfword (register offset)	*LDRH (register)* on page C6-708
	Load halfword (immediate offset)	*LDRH (immediate)* on page C6-706
LDRSH	Load signed halfword (register offset)	*LDRSH (register)* on page C6-718
	Load signed halfword (immediate offset)	*LDRSH (immediate)* on page C6-715
LDRSW	Load signed word (register offset)	*LDRSW (register)* on page C6-723
	Load signed word (immediate offset)	*LDRSW (immediate)* on page C6-720
	Load signed word (PC-relative literal)	*LDRSW (literal)* on page C6-722
STR	Store register (register offset)	*STR (register)* on page C6-904
	Store register (immediate offset)	*STR (immediate)* on page C6-901
STRB	Store byte (register offset)	*STRB (register)* on page C6-908
	Store byte (immediate offset)	*STRB (immediate)* on page C6-906
STRH	Store halfword (register offset)	*STRH (register)* on page C6-912
	Store halfword (immediate offset)	*STRH (immediate)* on page C6-910

C3.2.2 Load/Store register (unscaled offset)

The Load/Store register instructions with an unscaled offset support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See *Load/Store addressing modes* on page C1-149.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

The Load/Store register (unscaled offset) instructions are required to disambiguate this instruction class from the Load/Store register instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset, because that can represent some offset values in the same range.

The ambiguous immediate offsets are byte offsets that are both:

- In the range 0-255, inclusive.
- Naturally aligned to the access size.

Other byte offsets in the range -256 to 255 inclusive are unambiguous. An assembler program translating a Load/Store instruction, for example `LDR`, is required to encode an unambiguous offset using the unscaled 9-bit offset form, and to encode an ambiguous offset using the scaled 12-bit offset form. A programmer might force the generation of the unscaled 9-bit form by using one of the mnemonics in Table C3-16. ARM recommends that a disassembler outputs all unscaled 9-bit offset forms using one of these mnemonics, but unambiguous offsets can be output using a Load/Store single register mnemonic, for example, `LDR`.

Table C3-16 shows the Load/Store register instructions with an unscaled offset.

Table C3-16 Load/Store register (unscaled offset) instructions

Mnemonic	Instruction	See
`LDUR`	Load register (unscaled offset)	*LDUR* on page C6-769
`LDURB`	Load byte (unscaled offset)	*LDURB* on page C6-771
`LDURSB`	Load signed byte (unscaled offset)	*LDURSB* on page C6-773
`LDURH`	Load halfword (unscaled offset)	*LDURH* on page C6-772
`LDURSH`	Load signed halfword (unscaled offset)	*LDURSH* on page C6-775
`LDURSW`	Load signed word (unscaled offset)	*LDURSW* on page C6-777
`STUR`	Store register (unscaled offset)	*STUR* on page C6-946
`STURB`	Store byte (unscaled offset)	*STURB* on page C6-947
`STURH`	Store halfword (unscaled offset)	*STURH* on page C6-948

C3.2.3 Load/Store Pair

The Load/Store Pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also *Load/Store addressing modes* on page C1-149.

If a Load Pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

If a Load Pair instruction specifies writeback and one of the registers being loaded is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the base register becomes UNKNOWN. In addition, if an exception occurs during the instruction, the base address might be corrupted so that the instruction cannot be repeated.

If a Store Pair instruction performs a writeback and one of the registers being stored is also the base register, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the stores of the registers indicated by the specified addressing mode, but the value stored for the base register is UNKNOWN.

Table C3-17 shows the Load/Store Pair instructions.

Table C3-17 Load/Store Pair instructions

Mnemonic	Instruction	See
LDP	Load Pair	*LDP* on page C6-687
LDPSW	Load Pair signed words	*LDPSW* on page C6-690
STP	Store Pair	*STP* on page C6-898

C3.2.4 Load/Store Non-temporal Pair

The Load/Store Non-temporal Pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See *Load/Store addressing modes* on page C1-149.

The Load/Store Non-temporal Pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be preloaded and memory writes to be gathered to accelerate bulk memory transfers.

In addition, there is an exception to the usual memory ordering rules. If an address dependency exists between two memory reads, and a Load Non-temporal Pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, the memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a Load Non-Temporal Pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-18 shows the Load/Store Non-temporal Pair instructions.

Table C3-18 Load/Store Non-temporal Pair instructions

Mnemonic	Instruction	See
LDNP	Load Non-temporal Pair	*LDNP* on page C6-685
STNP	Store Non-temporal Pair	*STNP* on page C6-896

C3.2.5 Load/Store unprivileged

The Load/Store unprivileged instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See *Load/Store addressing modes* on page C1-149.

The accesses permissions that apply to accesses made at EL0 apply to the memory accesses made by a Load/Store unprivileged instruction that is executed either:

- At EL1 when the *Effective value* of PSTATE.UAO is 0.
- At EL2 when both the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1} and the *Effective value* of PSTATE.UAO is 0.

Otherwise, memory accesses made by a Load/Store unprivileged instruction are subject to the access permissions that apply to the Exception level at which the instruction is executed. These are the permissions that apply to the corresponding Load/Store register instruction, see *Load/Store register* on page C3-169.

Note

This means that when the value of PSTATE.UAO is 1 the access permissions for a Load/Store unprivileged instruction are always the same as those for the corresponding Load/Store register instruction.

Table C3-19 shows the Load/Store unprivileged instructions.

Table C3-19 Load-Store unprivileged instructions

Mnemonic	Instruction	See
LDTR	Load unprivileged register	*LDTR* on page C6-746
LDTRB	Load unprivileged byte	*LDTRB* on page C6-748
LDTRSB	Load unprivileged signed byte	*LDTRSB* on page C6-750
LDTRH	Load unprivileged halfword	*LDTRH* on page C6-749
LDTRSH	Load unprivileged signed halfword	*LDTRSH* on page C6-752
LDTRSW	Load unprivileged signed word	*LDTRSW* on page C6-754
STTR	Store unprivileged register	*STTR* on page C6-930
STTRB	Store unprivileged byte	*STTRB* on page C6-932
STTRH	Store unprivileged halfword	*STTRH* on page C6-933

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C3.2.6 Load-Exclusive/Store-Exclusive

The Load-Exclusive/Store-Exclusive instructions support only one addressing mode:

- Base register with no offset.

See *Load/Store addressing modes* on page C1-149.

The Load-Exclusive instructions mark the physical address being accessed as an exclusive access. This exclusive access mark is checked by the Store-Exclusive instruction, permitting the construction of atomic read-modify-write operations on shared memory variables, semaphores, mutexes, and spinlocks. See *Synchronization and semaphores* on page B2-128.

The Load-Exclusive/Store-Exclusive instructions other than Load-Exclusive pair and Store-Exclusive pair require natural alignment, and an unaligned address generates an Alignment fault. Memory accesses generated by Load-Exclusive pair or Store-Exclusive pair instructions must be aligned to the size of the pair, otherwise the access generates an Alignment fault. When a Store-Exclusive pair succeeds, it causes a single-copy atomic update of the entire memory location.

Table C3-20 shows the Load-Exclusive/Store-Exclusive instructions.

Table C3-20 Load-Exclusive/Store-Exclusive instructions

Mnemonic	Instruction	See
LDXR	Load Exclusive register	*LDXR* on page C6-780
LDXRB	Load Exclusive byte	*LDXRB* on page C6-781
LDXRH	Load Exclusive halfword	*LDXRH* on page C6-782
LDXP	Load Exclusive pair	*LDXP* on page C6-778
STXR	Store Exclusive register	*STXR* on page C6-951
STXRB	Store Exclusive byte	*STXRB* on page C6-953
STXRH	Store Exclusive halfword	*STXRH* on page C6-955
STXP	Store Exclusive pair	*STXP* on page C6-949

C3.2.7 Load-Acquire/Store-Release

The Load-Acquire, Load-AcquirePC, and Store-Release instructions support only one addressing mode:

- Base register with no offset.

See *Load/Store addressing modes* on page C1-149.

The Load-Acquire, Load-AcquirePC, and Store-Release instructions can remove the requirement to use the explicit DMB memory barrier instruction. For more information about the ordering of Load-Acquire, Load-AcquirePC, and Store-Release, see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

The Load-Acquire, Load-AcquirePC, and Store-Release instructions other than Load-Acquire pair and Store-Release pair require natural alignment, and an unaligned address generates an Alignment fault. Memory accesses generated by Load-Acquire pair or Store-Release pair instructions must be aligned to the size of the pair, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction only has the Release semantics if the store is successful.

ARMv8.1 adds more instructions with load-acquire and store-release mechanisms, see *LoadLOAcquire/StoreLORelease* on page C3-175.

STLXRH	Store-Release Exclusive halfword	*STLXRH* on page C6-894
STLXP	Store-Release Exclusive pair	*STLXP* on page C6-887

C3.2.8 LoadLOAcquire/StoreLORelease

The LoadLOAcquire/StoreLORelease instructions support only one addressing mode:

- Base register with no offset.

See *Load/Store addressing modes* on page C1-149.

The LoadLOAcquire/StoreLORelease instructions can remove the requirement to use the explicit DMB memory barrier instruction. For more information about the ordering of LoadLOAcquire/StoreLORelease, see *LoadLOAcquire, StoreLORelease* on page B2-102.

The LoadLOAcquire/StoreLORelease instructions require natural alignment, and an unaligned address generates an Alignment fault.

STLLR	StoreLORelease register	*STLLR* on page C6-883

C3.2.9 Load/Store scalar SIMD and floating-point

The Load/Store scalar SIMD and floating-point instructions operate on scalar values in the SIMD and floating-point register file as described in *SIMD and floating-point scalar register names* on page C1-146. The memory addressing modes available, described in *Load/Store addressing modes* on page C1-149, are identical to the general-purpose register Load/Store instructions, and like those instructions permit arbitrary address alignment unless strict alignment checking is enabled. However, unlike the Load/Store instructions that transfer general-purpose registers, Load/Store scalar SIMD and floating-point instructions make no guarantee of atomicity, even when the address is naturally aligned to the size of the data.

Load/Store scalar SIMD and floating-point register

The Load/Store scalar SIMD and floating-point register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus unscaled 9-bit signed immediate offset.
- Base plus 64-bit register offset, optionally scaled.
- Base plus 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
- PC-relative literal for loads of 32 bits or more.

For more information on the addressing modes, see *Load/Store addressing modes* on page C1-149.

Note

The unscaled 9-bit signed immediate offset address mode requires its own instruction form, see *Load/Store scalar SIMD and floating-point register (unscaled offset)* on page C3-177.

Table C3-24 shows the Load/Store instructions for a single SIMD and floating-point register.

Table C3-24 Load/Store single SIMD and floating-point register instructions

Mnemonic	Instruction	See

Load/Store scalar SIMD and floating-point register (unscaled offset)

The Load /Store scalar SIMD and floating-point register instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See also *Load/Store addressing modes* on page C1-149.

The Load/Store scalar SIMD and floating-point register (unscaled offset) instructions are required to disambiguate this instruction class from the Load/Store single SIMD and floating-point instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset. This is similar to the Load/Store register (unscaled offset) instructions, that disambiguate this instruction class from the Load/Store register instruction, see *Load/Store register (unscaled offset)* on page C3-170.

Table C3-25 shows the Load/Store SIMD and floating-point register instructions with an unscaled offset.

Table C3-25 Load/Store SIMD and floating-point register instructions

Mnemonic	Instruction	See
LDUR	Load scalar SIMD&FP register (unscaled offset)	*LDUR (SIMD&FP)* on page C7-1414
STUR	Store scalar SIMD&FP register (unscaled offset)	*STUR (SIMD&FP)* on page C7-1707

Load/Store SIMD and Floating-point register pair

The Load/Store SIMD and floating-point register pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also *Load/Store addressing modes* on page C1-149.

If a Load pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode and the register being loaded takes an UNKNOWN value.

Table C3-26 shows the Load/Store SIMD and floating-point register pair instructions.

Table C3-26 Load/Store SIMD and floating-point register pair instructions

Mnemonic	Instruction	See
LDP	Load pair of scalar SIMD&FP registers	*LDP (SIMD&FP)* on page C7-1402
STP	Store pair of scalar SIMD&FP registers	*STP (SIMD&FP)* on page C7-1697

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Load/Store SIMD and Floating-point Non-temporal pair

The Load/Store SIMD and Floating-point Non-temporal pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See also *Load/Store addressing modes* on page C1-149.

The Load/Store Non-temporal pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be preloaded and memory writes to be gathered to accelerate bulk memory transfers.

In addition, there is an exception to the usual memory ordering rules. If an address dependency exists between two memory reads, and a Load non-temporal pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, those memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a Load Non-temporal pair instruction specifies the same register for the two registers that are being loaded, then behavior is CONSTRAINED UNPREDICTABLE and one of the following behaviors must occur:

- The instruction is treated as UNDEFINED.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Table C3-27 shows the Load/Store SIMD and floating-point Non-temporal pair instructions.

Table C3-27 Load/Store SIMD and floating-point Non-temporal pair instructions

Mnemonic	Instruction	See
LDNP	Load pair of scalar SIMD&FP registers	*LDNP (SIMD&FP)* on page C7-1400
STNP	Store pair of scalar SIMD&FP registers	*STNP (SIMD&FP)* on page C7-1695

C3.2.10 Load/Store Vector

The Vector Load/Store structure instructions support the following addressing modes:

- Base register only.
- Post-indexed by a 64-bit register.
- Post-indexed by an immediate, equal to the number of bytes transferred.

Load/Store vector instructions, like other Load/Store instructions, allow any address alignment, unless strict alignment checking is enabled. If strict alignment checking is enabled, then alignment checking to the size of the element is performed. However, unlike the Load/Store instructions that transfer general-purpose registers, the Load/Store vector instructions do not guarantee atomicity, even when the address is naturally aligned to the size of the element.

Load/Store structures

Table C3-28 on page C3-179 shows the Load/Store structure instructions. A post-increment immediate offset, if present, must be 8, 16, 24, 32, 48, or 64, depending on the number of elements transferred.

Load single structure and replicate

Table C3-29 shows the Load single structure and replicate instructions. A post-increment immediate offset, if present, must be 1, 2, 3, 4, 6, 8, 12, 16, 24, or 32, depending on the number of elements transferred.

Table C3-29 Load single structure and replicate instructions

Mnemonic	Instruction	See
LD1R	Load single 1-element structure and replicate to all lanes of one register	*LD1R* on page C7-1367
LD2R	Load single 2-element structure and replicate to all lanes of two registers	*LD2R* on page C7-1377
LD3R	Load single 3-element structure and replicate to all lanes of three registers	*LD3R* on page C7-1387
LD4R	Load single 4-element structure and replicate to all lanes of four registers	*LD4R* on page C7-1397

C3.2.11 Prefetch memory

The Prefetch memory instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset. This can be optionally scaled by 8-bits, for example LSL#3.
- Base plus a 32-bit extended register offset. This can be optionally scaled by 8-bits.
- PC-relative literal.

The prefetch memory instructions signal to the memory system that memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory access when they do occur, such as preloading the specified address into one or more caches. Because these signals are only hints, it is valid for the PE to treat any or all prefetch instructions as a NOP.

Because they are hints to the memory system, the operation of a PRFM instruction cannot cause a synchronous exception. However, a memory operation performed as a result of one of these memory system hints might in exceptional cases trigger an asynchronous event, and thereby influence the execution of the PE. An example of an asynchronous event that might be triggered is an SError interrupt.

A PRFM instruction can only have an effect on software visible structures, such as caches and translation lookaside buffers associated with memory locations that can be accessed by reads, writes, or execution as defined in the translation regime of the current Exception level.

A PRFM instruction is guaranteed not to access Device memory.

A PRFM instruction using a PLI hint must not result in any access that could not be performed by the PE speculatively fetching an instruction. Therefore, if all associated MMUs are disabled, a PLI hint cannot access any memory location that cannot be accessed by instruction fetches.

The PRFM instructions require an additional <prfop> operand to be specified, which must be one of the following:

```
PLDL1KEEP, PLDL1STRM, PLDL2KEEP, PLDL2STRM, PLDL3KEEP, PLDL3STRM

PSTL1KEEP, PSTL1STRM, PSTL2KEEP, PSTL2STRM, PSTL3KEEP, PSTL3STRM

PLIL1KEEP, PLIL1STRM, PLIL2KEEP, PLIL2STRM, PLIL3KEEP, PLIL3STRM
```

<prfop> is defined as <type><target><policy>.

Here:

<type> Is one of:

PLD	Prefetch for load.
PST	Prefetch for store.
PLI	Preload instructions.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<target>	Is one of:	
	L1	Level 1 cache.
	L2	Level 2 cache.
	L3	Level 3 cache.
<policy>	Is one of:	
	KEEP	Retained or temporal prefetch, allocated in the cache normally.
	STRM	Streaming or non-temporal prefetch, for data that is used only once.

PRFUM explicitly uses the unscaled 9-bit signed immediate offset addressing mode, as described in *Load/Store register (unscaled offset)* on page C3-170.

Table C3-30 shows the Prefetch memory instructions.

Table C3-30 Prefetch memory instructions

Mnemonic	Instruction	See
PRFM	Prefetch memory (register offset)	*PRFM (register)* on page C6-835
	Prefetch memory (immediate offset)	*PRFM (immediate)* on page C6-831
	Prefetch memory (PC-relative offset)	*PRFM (literal)* on page C6-833
PRFUM	Prefetch memory (unscaled offset)	*PRFM (unscaled offset)* on page C6-837

C3.2.12 Compare and Swap

The Compare and Swap instructions support only one addressing mode:

- Base register only.

See also *Load/Store addressing modes* on page C1-149.

For the purpose of permission checking, and for watchpoints, all the new atomic instructions are treated as performing both a load and a store.

The CAS instructions require natural alignment.

The CASP instructions require alignment to the total size of the memory being accessed.

All Compare and Swap instructions generate an Alignment fault if the address being accessed is not aligned to the size of the data structure being accessed.

The instructions are provided with ordering options, which map to the acquire and release definitions used in the ARMv8-A architecture. If a compare and swap instruction does not perform a store, then the instruction does not have release semantics, regardless of the instruction ordering options.

The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

For the CAS and CASP instructions, the architecture permits that a data read clears any Exclusives monitors associated with that location, even if the compare subsequently fails. If these instructions generate a synchronous Data Abort, the registers which are compared and loaded are restored to the values held in the registers before the instruction was executed.

Table C3-31 Compare and swap instructions

Mnemonic	Instruction	See
CAS	Compare and swap	*CAS, CASA, CASAL, CASL* on page C6-587
CASB	Compare and swap byte	*CASB, CASAB, CASALB, CASLB* on page C6-580
CASH	Compare and swap halfword	*CASH, CASAH, CASALH, CASLH* on page C6-582
CASP	Compare and swap pair	*CASP, CASPA, CASPAL, CASPL* on page C6-584

C3.2.13 Atomic memory operations

The atomic memory operation instructions support only one addressing mode:

- Base register only.

See also *Load/Store addressing modes* on page C1-149.

For the purpose of permission checking, and for watchpoints, all the new atomic instructions are treated as performing both a load and a store.

The LD<OP> and ST<OP> instructions require natural alignment, and an unaligned address generates an Alignment fault.

The instructions are provided with ordering options, which map to the acquire and release definitions used in the ARMv8-A architecture. The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity. These operations map to the acquire and release definitions, and are counted as Load-Acquire and Store-Release operations respectively.

For the LD<OP> instructions, where the source and destination registers are the same, if the instruction generates a synchronous Data Abort, then the source register is restored to the value it held before the instruction was executed.

The ST<OP> instructions, and LD<OP> instructions where the destination register is WZR or XZR, are not regarded as doing a read for the purpose of a DMB LD barrier.

C3.2.14 Swap

The swap instructions support only one addressing mode:

- Base register only.

See also *Load/Store addressing modes* on page C1-149.

For the purpose of permission checking, and for watchpoints, all the new atomic instructions are treated as performing both a load and a store.

The SWP instructions require natural alignment, and an unaligned address generates an Alignment fault.

The instructions are provided with ordering options, which map to the acquire and release definitions used in the ARMv8-A architecture. The atomic instructions with release semantics have the same rules as Store-Release instructions regarding multi-copy atomicity.

For the SWP instructions, where the source and destination registers are the same, if the instruction generates a synchronous Data Abort, then the source register is restored to the value it held before the instruction was executed.

C3.3 Data processing - immediate

This section describes the instruction groups for data processing with immediate operands. It contains the following subsections:

- *Arithmetic (immediate)*.
- *Logical (immediate)* on page C3-186.
- *Move (wide immediate)* on page C3-186.
- *Move (immediate)* on page C3-187.
- *PC-relative address calculation* on page C3-187.
- *Bitfield move* on page C3-188.
- *Bitfield insert and extract* on page C3-188
- *Extract register* on page C3-188.
- *Shift (immediate)* on page C3-189.
- *Sign-extend and Zero-extend* on page C3-189.

For information about the encoding structure of the instructions in this instruction group, see *Data Processing -- Immediate* on page C4-224.

C3.3.1 Arithmetic (immediate)

The Arithmetic (immediate) instructions accept a 12-bit unsigned immediate value, optionally shifted left by 12 bits.

The Arithmetic (immediate) instructions that do not set Condition flags can read from and write to the current stack pointer. The flag setting instructions can read from the stack pointer, but they cannot write to it.

Table C3-34 shows the Arithmetic instructions with an immediate offset.

Table C3-34 Arithmetic instructions with an immediate

Mnemonic	Instruction	See
ADD	Add	*ADD (immediate)* on page C6-531
ADDS	Add and set flags	*ADDS (immediate)* on page C6-537
SUB	Subtract	*SUB (immediate)* on page C6-959
SUBS	Subtract and set flags	*SUBS (immediate)* on page C6-965
CMP	Compare	*CMP (immediate)* on page C6-607
CMN	Compare negative	*CMN (immediate)* on page C6-602

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C3.3.2 Logical (immediate)

The Logical (immediate) instructions accept a bitmask immediate value that is a 32-bit pattern or a 64-bit pattern viewed as a vector of identical elements of size e = 2, 4, 8, 16, 32 or, 64 bits. Each element contains the same sub-pattern, that is a single run of 1 to (e - 1) nonzero bits from bit 0 followed by zero bits, then rotated by 0 to (e - 1) bits. This mechanism can generate 5 334 unique 64-bit patterns as 2 667 pairs of pattern and their bitwise inverse.

Note

. Values that consist of only zeros or only ones cannot be described in this way.

The Logical (immediate) instructions that do not set the Condition flags can write to the current stack pointer, for example to align the stack pointer in a function prologue.

Note

Apart from `ANDS`, and its `TST` alias, Logical (immediate) instructions do not set the Condition flags. However, the final results of a bitwise operation can be tested by a `CBZ`, `CBNZ`, `TBZ`, or `TBNZ` conditional branch.

Table C3-35 shows the Logical immediate instructions.

Table C3-35 Logical immediate instructions

Mnemonic	Instruction	See
`AND`	Bitwise `AND`	*AND (immediate)* on page C6-543
`ANDS`	Bitwise `AND` and set flags	*ANDS (immediate)* on page C6-546
`EOR`	Bitwise exclusive `OR`	*EOR (immediate)* on page C6-635
`ORR`	Bitwise inclusive `OR`	*ORR (immediate)* on page C6-820
`TST`	Test bits	*TST (immediate)* on page C6-985

C3.3.3 Move (wide immediate)

The Move (wide immediate) instructions insert a 16-bit immediate, or inverted immediate, into a 16-bit aligned position in the destination register. The value of the other bits in the destination register depends on the variant used. The optional shift amount can be any multiple of 16 that is smaller than the register size.

Table C3-36 shows the Move (wide immediate) instructions.

Table C3-36 Move (wide immediate) instructions

Mnemonic	Instruction	See
`MOVZ`	Move wide with zero	*MOVZ* on page C6-800
`MOVN`	Move wide with NOT	*MOVN* on page C6-798
`MOVK`	Move wide with keep	*MOVK* on page C6-797

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C3.3.4 Move (immediate)

The Move (immediate) instructions are aliases for a single MOVZ, MOVN, or ORR (immediate with zero register), instruction to load an immediate value into the destination register. An assembler must permit a signed or unsigned immediate, as long as its binary representation can be generated using one of these instructions, and an assembler error results if the immediate cannot be generated in this way. On disassembly, it is unspecified whether the immediate is output as a signed or an unsigned value.

If there is a choice between the MOVZ, MOVN, and ORR instruction to encode the immediate, then an assembler must prefer MOVZ to MOVN, and MOVZ or MOVN to ORR, to ensure reversability. A disassembler must output ORR (immediate with zero register) MOVZ, and MOVN, as a MOV mnemonic except that the underlying instruction must be used when:

- ORR has an immediate that can be generated by a MOVZ or MOVN instruction.
- A MOVN instruction has an immediate that can be encoded by MOVZ.
- MOVZ #0 or MOVN #0 have a shift amount other than LSL #0.

Table C3-37 shows the Move (immediate) instructions.

Table C3-37 Move (immediate) instructions

Mnemonic	Instruction	See
MOV	Move (inverted wide immediate)	*MOV (inverted wide immediate)* on page C6-793
	Move (wide immediate)	*MOV (wide immediate)* on page C6-794
	Move (bitmask immediate)	*MOV (bitmask immediate)* on page C6-795

C3.3.5 PC-relative address calculation

The ADR instruction adds a signed, 21-bit immediate to the value of the program counter that fetched this instruction, and then writes the result to a general-purpose register. This permits the calculation of any byte address within ±1MB of the current PC.

The ADRP instruction shifts a signed, 21-bit immediate left by 12 bits, adds it to the value of the program counter with the bottom 12 bits cleared to zero, and then writes the result to a general-purpose register. This permits the calculation of the address at a 4KB aligned memory region. In conjunction with an ADD (immediate) instruction, or a Load/Store instruction with a 12-bit immediate offset, this allows for the calculation of, or access to, any address within ±4GB of the current PC.

Note

The term *page* used in the ADRP description is short-hand for the 4KB memory region, and is not related to the virtual memory translation granule size.

Table C3-38 shows the instructions used for PC-relative address calculations are as follows:

Table C3-38 PC-relative address calculation instructions

Mnemonic	Instruction	See
ADRP	Compute address of 4KB page at a PC-relative offset	*ADRP* on page C6-542
ADR	Compute address of label at a PC-relative offset.	*ADR* on page C6-541

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C3.3.6 Bitfield move

The Bitfield move instructions copy a field of constant width from bit 0 in the source register to a constant bit position in the destination register, or from a constant bit position in the source register to bit 0 in the destination register. The remaining bits in the destination register are set as follows:

- For `BFM`, the remaining bits are unchanged.
- For `UBFM` the lower bits, if any, and upper bits, if any, are set to zero.
- For `SBFM`, the lower bits, if any, are set to zero, and the upper bits, if any, are set to a copy of the most-significant bit in the copied field.

Table C3-39 shows the Bitfield move instructions.

Table C3-39 Bitfield move instructions

Mnemonic	Instruction	See
`BFM`	Bitfield move	*BFM* on page C6-565
`SBFM`	Signed bitfield move	*SBFM* on page C6-857
`UBFM`	Unsigned bitfield move (32-bit)	*UBFM* on page C6-989

C3.3.7 Bitfield insert and extract

The Bitfield insert and extract instructions are implemented as aliases of the Bitfield move instructions. Table C3-40 shows the Bitfield insert and extract aliases.

Table C3-40 Bitfield insert and extract instructions

Mnemonic	Instruction	See
`BFC`	Bitfield insert clear	*BFC* on page C6-563
`BFI`	Bitfield insert	*BFI* on page C6-564
`BFXIL`	Bitfield extract and insert low	*BFXIL* on page C6-567
`SBFIZ`	Signed bitfield insert in zero	*SBFIZ* on page C6-856
`SBFX`	Signed bitfield extract	*SBFX* on page C6-859
`UBFIZ`	Unsigned bitfield insert in zero	*UBFIZ* on page C6-988
`UBFX`	Unsigned bitfield extract	*UBFX* on page C6-991

C3.3.8 Extract register

Depending on the register width of the operands, the Extract register instruction copies a 32-bit or 64-bit field from a constant bit position within a double-width value formed by the concatenation of a pair of source registers to a destination register.

Table C3-41 shows the Extract (immediate) instructions.

Table C3-41 Extract register instructions

Mnemonic	Instruction	See
`EXTR`	Extract register from pair	*EXTR* on page C6-641

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C3.3.9 Shift (immediate)

Shifts and rotates by a constant amount are implemented as aliases of the Bitfield move or Extract register instructions. The shift or rotate amount must be in the range 0 to one less than the register width of the instruction, inclusive.

Table C3-42 shows the aliases that can be used as immediate shift and rotate instructions.

Table C3-42 Aliases for immediate shift and rotate instructions

Mnemonic	Instruction	See
ASR	Arithmetic shift right	*ASR (immediate)* on page C6-551
LSL	Logical shift left	*LSL (immediate)* on page C6-784
LSR	Logical shift right	*LSR (immediate)* on page C6-787
ROR	Rotate right	*ROR (immediate)* on page C6-849

C3.3.10 Sign-extend and Zero-extend

The Sign-extend and Zero-extend instructions are implemented as aliases of the Bitfield move instructions.

Table C3-43 shows the aliases that can be used as zero-extend and sign-extend instructions.

Table C3-43 Zero-extend and sign-extend instructions

Mnemonic	Instruction	See
SXTB	Sign-extend byte	*SXTB* on page C6-976
SXTH	Sign-extend halfword	*SXTH* on page C6-977
SXTW	Sign-extend word	*SXTW* on page C6-978

C3.4 Data processing - register

This section describes the instruction groups for data processing with all register operands. It contains the following subsections:

- *Arithmetic (shifted register)*.
- *Arithmetic (extended register)* on page C3-191.
- *Arithmetic with carry* on page C3-192.
- *Logical (shifted register)* on page C3-192.
- *Move (register)* on page C3-193.
- *Shift (register)* on page C3-193.
- *Multiply and divide* on page C3-194.
- *CRC32* on page C3-195.
- *Bit operation* on page C3-196.
- *Conditional select* on page C3-196.
- *Conditional comparison* on page C3-197.

For information about the encoding structure of the instructions in this instruction group, see *Data Processing -- Register* on page C4-266.

C3.4.1 Arithmetic (shifted register)

The Arithmetic (shifted register) instructions apply an optional shift operator to the second source register value before performing the arithmetic operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators `LSL`, `ASR`, and `LSR` accept an immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator implies `LSL #0`, which means that there is no shift. A disassembler must not output `LSL #0`. However, a disassembler must output all other shifts by zero.

The current stack pointer, SP or WSP, cannot be used with this class of instructions. See *Arithmetic (extended register)* on page C3-191 for arithmetic instructions that can operate on the current stack pointer.

Table C3-44 shows the Arithmetic (shifted register) instructions.

Table C3-44 Arithmetic (shifted register) instructions

Mnemonic	Instruction	See
`ADD`	Add	*ADD (shifted register)* on page C6-533
`ADDS`	Add and set flags	*ADDS (shifted register)* on page C6-539
`SUB`	Subtract	*SUB (shifted register)* on page C6-961
`SUBS`	Subtract and set flags	*SUBS (shifted register)* on page C6-967
`CMN`	Compare negative	*CMN (shifted register)* on page C6-603
`CMP`	Compare	*CMP (shifted register)* on page C6-608
`NEG`	Negate	*NEG (shifted register)* on page C6-811
`NEGS`	Negate and set flags	*NEGS* on page C6-813

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C3.4.2 Arithmetic (extended register)

The extended register instructions provide an optional sign-extension or zero-extension of a portion of the second source register value, followed by an optional left shift by a constant amount of 1-4, inclusive.

The extended shift is described by the mandatory extend operator `SXTB`, `SXTH`, `SXTW`, `UXTB`, `UXTH`, or `UXTW`. This is followed by an optional left shift amount. If the shift amount is not specified, the default shift amount is zero. A disassembler must not output a shift amount of zero.

For 64-bit instruction forms, the additional operators `UXTX` and `SXTX` use all 64 bits of the second source register with an optional shift. In that case, ARM recommends `UXTX` as the operator. If and only if at least one register is SP, ARM recommends use of the `LSL` operator name, rather than `UXTX`, and when the shift amount is also zero then both the operator and the shift amount can be omitted. `UXTW` and `SXTW` both use all 32 bits of the second source register with an optional shift. In that case ARM recommends `UXTW` as the operator. If and only if at least one register is WSP, ARM recommends use of the `LSL` operator name, rather than `UXTW`, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

For 32-bit instruction forms, the operators `UXTW` and `SXTW` both use all 32 bits of the second source register with an optional shift. In that case, ARM recommends `UXTW` as the operator. If and only if at least one register is WSP, ARM recommends use of the `LSL` operator name, rather than `UXTW`, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

The non-flag setting variants of the extended register instruction permit the use of the current stack pointer as either the destination register and the first source register. The flag setting variants only permit the stack pointer to be used as the first source register.

In the 64-bit form of these instructions, the final register operand is written as `Wm` for all except the `UXTX`/`LSL` and `SXTX` extend operators. For example:

```
CMP X4, W5, SXTW
ADD X1, X2, W3, UXTB #2
SUB SP, SP, X1              // SUB SP, SP, X1, UXTX #0
```

Table C3-45 shows the Arithmetic (extended register) instructions.

Table C3-45 Arithmetic (extended register) instructions

Mnemonic	Instruction	See
ADD	Add	*ADD (extended register)* on page C6-529
ADDS	Add and set flags	*ADDS (extended register)* on page C6-535
SUB	Subtract	*SUB (extended register)* on page C6-957
SUBS	Subtract and set flags	*SUBS (extended register)* on page C6-963
CMN	Compare negative	*CMN (extended register)* on page C6-600
CMP	Compare	*CMP (extended register)* on page C6-605

Non-Confidential

C3.4.3 Arithmetic with carry

The Arithmetic with carry instructions accept two source registers, with the carry flag as an additional input to the calculation. They do not support shifting of the second source register.

Table C3-46 shows the Arithmetic with carry instructions

Table C3-46 Arithmetic with carry instructions

Mnemonic	Instruction	See
ADC	Add with carry	*ADC* on page C6-527
ADCS	Add with carry and set flags	*ADCS* on page C6-528
SBC	Subtract with carry	*SBC* on page C6-852
SBCS	Subtract with carry and set flags	*SBCS* on page C6-854
NGC	Negate with carry	*NGC* on page C6-815
NGCS	Negate with carry and set flags	*NGCS* on page C6-816

C3.4.4 Logical (shifted register)

The Logical (shifted register) instructions apply an optional shift operator to the second source register value before performing the main operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators LSL, ASR, LSR, and ROR accept a constant immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator and amount implies LSL #0, which means that there is no shift. A disassembler must not output LSL #0. However, a disassembler must output all other shifts by zero.

Note

Apart from ANDS, TST, and BICS the logical instructions do not set the Condition flags, but the final result of a bit operation can usually directly control a CBZ, CBNZ, TBZ, or TBNZ conditional branch.

Table C3-47 shows the Logical (shifted register) instructions.

Table C3-47 Logical (shifted register) instructions

Mnemonic	Instruction	See
AND	Bitwise AND	*AND (shifted register)* on page C6-544
ANDS	Bitwise AND and set flags	*ANDS (shifted register)* on page C6-548
BIC	Bitwise bit clear	*BIC (shifted register)* on page C6-568
BICS	Bitwise bit clear and set flags	*BICS (shifted register)* on page C6-570
EON	Bitwise exclusive OR NOT	*EON (shifted register)* on page C6-633
EOR	Bitwise exclusive OR	*EOR (shifted register)* on page C6-636
ORR	Bitwise inclusive OR	*ORR (shifted register)* on page C6-822

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

Table C3-47 Logical (shifted register) instructions (continued)

Mnemonic	Instruction	See
MVN	Bitwise NOT	*MVN* on page C6-809
ORN	Bitwise inclusive OR NOT	*ORN (shifted register)* on page C6-818
TST	Test bits	*TST (shifted register)* on page C6-986

C3.4.5 Move (register)

The Move (register) instructions are aliases for other data processing instructions. They copy a value from a general-purpose register to another general-purpose register or the current stack pointer, or from the current stack pointer to a general-purpose register.

Table C3-48 MOV register instructions

Mnemonic	Instruction	See
MOV	Move register	*MOV (register)* on page C6-796
	Move register to SP or move SP to register	*MOV (to/from SP)* on page C6-792

C3.4.6 Shift (register)

In the Shift (register) instructions, the shift amount is the positive value in the second source register modulo the register size. The register width of the instruction controls whether the new bits are fed into the result on a right shift or rotate at bit[63] or bit[31].

Table C3-49 shows the Shift (register) instructions.

Table C3-49 Shift (register) instructions

Mnemonic	Instruction	See
ASRV	Arithmetic shift right variable	*ASRV* on page C6-552
LSLV	Logical shift left variable	*LSLV* on page C6-785
LSRV	Logical shift right variable	*LSRV* on page C6-788
RORV	Rotate right variable	*RORV* on page C6-851

However, the Shift (register) instructions have a preferred set of aliases that match the shift immediate aliases described in *Shift (immediate)* on page C3-189.

Table C3-50 shows the aliases for Shift (register) instructions.

Table C3-50 Aliases for Variable shift instructions

C3.4.7 Multiply and divide

This section describes the instructions used for integer multiplication and division. It contains the following subsections:

- *Multiply*.
- *Divide* on page C3-195.

Multiply

The Multiply instructions write to a single 32-bit or 64-bit destination register, and are built around the fundamental four operand multiply-add and multiply-subtract operation, together with 32-bit to 64-bit widening variants. A 64-bit to 128-bit widening multiple can be constructed with two instructions, using `SMULH` or `UMULH` to generate the upper 64 bits. Table C3-51 shows the Multiply instructions.

Table C3-51 Multiply integer instructions

Mnemonic	Instruction	See
`MADD`	Multiply-add	*MADD* on page C6-789
`MSUB`	Multiply-subtract	*MSUB* on page C6-806
`MNEG`	Multiply-negate	*MNEG* on page C6-791
`MUL`	Multiply	*MUL* on page C6-808
`SMADDL`	Signed multiply-add long	*SMADDL* on page C6-863
`SMSUBL`	Signed multiply-subtract long	*SMSUBL* on page C6-866
`SMNEGL`	Signed multiply-negate long	*SMNEGL* on page C6-865

Non-Confidential

Divide

The Divide instructions compute the quotient of a division, rounded towards zero. The remainder can then be computed as (numerator - (quotient × denominator)), using the MSUB instruction.

If a signed integer division (INT_MIN / -1) is performed where INT_MIN is the most negative integer value representable in the selected register size, then the result overflows the signed integer range. No indication of this overflow is produced and the result that is written to the destination register is INT_MIN.

A division by zero results in a zero being written to the destination register, without any indication that the division by zero occurred.

Table C3-52 shows the Divide instructions.

Table C3-52 Divide instructions

Mnemonic	Instruction	See
SDIV	Signed divide	*SDIV* on page C6-860
UDIV	Unsigned divide	*UDIV* on page C6-992

C3.4.8 CRC32

The CRC32 instructions operate on the general-purpose register file to update a 32-bit CRC value from an input value comprising 1, 2, 4, or 8 bytes. There are two different classes of CRC instructions, CRC32, and CRC32C, that support two commonly used 32-bit polynomials, known as CRC-32 and CRC-32C.

To fit with common usage, the bit order of the values is reversed as part of the operation.

When bits[19:16] of ID_AA64ISAR0_EL1 are set to 0b0001, the CRC instructions are implemented.

These instructions are optional in an ARMv8.0 implementation.

All implementations of ARMv8.1 architecture and later are required to implement the CRC32 instructions.

Table C3-53 shows the CRC instructions.

Table C3-53 CRC32 instructions

Mnemonic	Instruction	See
CRC32B	CRC-32 sum from byte	*CRC32B, CRC32H, CRC32W, CRC32X* on page C6-611
CRC32H	CRC-32 sum from halfword	*CRC32B, CRC32H, CRC32W, CRC32X* on page C6-611
CRC32W	CRC-32 sum from word	*CRC32B, CRC32H, CRC32W, CRC32X* on page C6-611
CRC32X	CRC-32 sum from doubleword	*CRC32B, CRC32H, CRC32W, CRC32X* on page C6-611
CRC32CB	CRC-32C sum from byte	*CRC32CB, CRC32CH, CRC32CW, CRC32CX* on page C6-613
CRC32CH	CRC-32C sum from halfword	*CRC32CB, CRC32CH, CRC32CW, CRC32CX* on page C6-613
CRC32CW	CRC-32C sum from word	*CRC32CB, CRC32CH, CRC32CW, CRC32CX* on page C6-613
CRC32CX	CRC-32C sum from doubleword	*CRC32CB, CRC32CH, CRC32CW, CRC32CX* on page C6-613

C3.4.9 Bit operation

Table C3-54 shows the Bit operation instructions.

Table C3-54 Bit operation instructions

Mnemonic	Instruction	See
CLS	Count leading sign bits	*CLS* on page C6-598
CLZ	Count leading zero bits	*CLZ* on page C6-599
RBIT	Reverse bit order	*RBIT* on page C6-840
REV	Reverse bytes in register	*REV* on page C6-843
REV16	Reverse bytes in halfwords	*REV16* on page C6-845
REV32	Reverses bytes in words	*REV32* on page C6-847
REV64	Reverse bytes in register	*REV64* on page C6-848

C3.4.10 Conditional select

The Conditional select instructions select between the first or second source register, depending on the current state of the Condition flags. When the named condition is true, the first source register is selected and its value is copied without modification to the destination register. When the condition is false the second source register is selected and its value might be optionally inverted, negated, or incremented by one, before writing to the destination register.

Other useful conditional set and conditional unary operations are implemented as aliases of the four Conditional select instructions.

Table C3-55 shows the Conditional select instructions.

Table C3-55 Conditional select instructions

Mnemonic	Instruction	See
CSEL	Conditional select	*CSEL* on page C6-615
CSINC	Conditional select increment	*CSINC* on page C6-618

CNEG	Conditional negate	*CNEG* on page C6-610

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C3.4.11 Conditional comparison

The Conditional comparison instructions provide a conditional select for the NZCV Condition flags, setting the flags to the result of an arithmetic comparison of its two source register values if the named input condition is true, or to an immediate value if the input condition is false. There are register and immediate forms. The immediate form compares the source register to a small 5-bit unsigned value.

Table C3-56 shows the Conditional comparison instructions.

Table C3-56 Conditional comparison instructions

C3.5 Data processing - SIMD and floating-point

This section describes the instruction groups for data processing with SIMD and floating-point register operands.

Common features of SIMD instructions gives general information about SIMD instructions.

The following subsections describe the scalar floating-point data processing instructions:

- *Floating-point move (register)* on page C3-199.
- *Floating-point move (immediate)* on page C3-199.
- *Floating-point conversion* on page C3-200.
- *Floating-point round to integer* on page C3-201.
- *Floating-point multiply-add* on page C3-202.
- *Floating-point arithmetic (one source)* on page C3-202.
- *Floating-point arithmetic (two sources)* on page C3-203.
- *Floating-point minimum and maximum* on page C3-203.
- *Floating-point comparison* on page C3-203.
- *Floating-point conditional select* on page C3-204.

The following subsections describe the SIMD data processing instructions:

- *SIMD move* on page C3-204
- *SIMD arithmetic* on page C3-205.
- *SIMD compare* on page C3-208.
- *SIMD widening and narrowing arithmetic* on page C3-209.
- *SIMD table lookup* on page C3-218.
- *SIMD by element arithmetic* on page C3-212.
- *SIMD permute* on page C3-213.
- *SIMD immediate* on page C3-213.
- *SIMD shift (immediate)* on page C3-213.
- *SIMD floating-point and integer conversion* on page C3-215.
- *SIMD reduce (across vector lanes)* on page C3-216.
- *SIMD pairwise arithmetic* on page C3-216.
- *SIMD dot product* on page C3-217.
- *SIMD table lookup* on page C3-218.
- *SIMD complex number arithmetic* on page C3-218.
- *The Cryptographic Extension* on page C3-218.

For information about the encoding structure of the instructions in this instruction group, see *Data Processing -- Scalar Floating-Point and Advanced SIMD* on page C4-275.

For information about the floating-point exceptions, see *Floating-point exceptions and exception traps* on page D1-1899.

C3.5.1 Common features of SIMD instructions

A number of SIMD instructions come in three forms:

Wide Indicated by the suffix *W*. The element width of the destination register and the first source operand is double that of the second source operand.

Long Indicated by the suffix *L*. The element width of the destination register is double that of both source operands.

Narrow Indicated by the suffix *N*. The element width of the destination register is half that of both source operands.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

In addition, each vector form of the instruction is part of a pair, with a second and upper half suffix of *2*, to identify the variant of the instruction:

- Where a SIMD operation widens or lengthens a 64-bit vector to a 128-bit vector, the instruction provides a second part operation that can extract the source from the upper 64 bits of the source registers.
- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the instruction provides a second-part operation that can pack the result of a second operation into the upper part of the same destination register.

Note

This is referred to as a *lane set specifier*.

C3.5.2 Floating-point move (register)

The Floating-point move (register) instructions copy a scalar floating-point value from one register to another register without performing any conversion.

Some of the Floating-point move (register) instructions overlap with the functionality provided by the Advanced SIMD instructions `DUP`, `INS`, and `UMOV`. However, ARM recommends using the `FMOV` instructions when operating on scalar floating-point data to avoid the creation of scalar floating-point code that depends on the availability of the Advanced SIMD instruction set.

Table C3-57 shows the Floating-point move (register) instructions.

Table C3-57 Floating-point move (register) instructions

Mnemonic	Instruction	See
`FMOV`	Floating-point move register without conversion	*FMOV (register)* on page C7-1271
	Floating-point move to or from general-purpose register without conversion	*FMOV (general)* on page C7-1273

C3.5.3 Floating-point move (immediate)

The Floating-point move (immediate) instructions convert a small constant immediate floating-point value into a half-precision, single-precision, or double-precision scalar floating-point value in a SIMD and floating-point register.

The floating-point constant can be specified either in decimal notation, such as 12.0 or -1.2e1, or as a string beginning with `0x` followed by a hexadecimal representation of the IEEE 754 half-precision, single-precision, or double-precision encoding. ARM recommends that a disassembler uses the decimal notation, provided that this displays the value precisely.

Note

When ARMv8.2-FP16 is not implemented, the only half-precision instructions that are supported are floating-point conversions between half-precision, single-precision, and double-precision.

The floating-point value must be expressible as $(\pm n/16 \times 2^r)$, where n is an integer in the range $16 \le n \le 31$ and r is an integer in the range of $-3 \le r \le 4$, that is a normalized binary floating-point encoding with one sign bit, four bits of fraction, and a 3-bit exponent.

Table C3-58 shows the Floating-point move (immediate) instruction:

Table C3-58 Floating-point move (immediate) instruction

Mnemonic	Instruction	See
`FMOV`	Floating-point move immediate	*FMOV (scalar, immediate)* on page C7-1276

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C3.5.4 Floating-point conversion

The following subsections describe the conversion of floating-point values:

- *Convert floating-point precision*.
- *Convert between floating-point and integer or fixed-point*.

Convert floating-point precision

These instructions convert a floating-point scalar with one precision to a floating-point scalar with a different precision, using the current rounding mode as specified by FPCR.RMode.

Table C3-59 shows the Floating-point precision conversion instruction.

Table C3-59 Floating-point precision conversion instruction

Mnemonic	Instruction	See
FCVT	Floating-point convert precision (scalar)	*FCVT* on page C7-1134

Convert between floating-point and integer or fixed-point

These instructions convert a floating-point scalar in a SIMD and floating-point register to or from a signed or unsigned integer or fixed-point value in a general-purpose register. For a fixed-point value, a final immediate operand indicates that the general-purpose register holds a fixed-point number and `fbits` indicates the number of bits after the binary point. `fbits` is in the range 1- 32 inclusive for a 32-bit general-purpose register name, and 1-64 inclusive for a 64-bit general-purpose register name.

These instructions can cause the following floating-point exceptions:

Invalid Operation

Occurs if the floating-point input is a NaN, infinity, or a numerical value that cannot be represented in the destination register. An out-of-range integer or fixed-point result is saturated to the size of the destination register.

Inexact Occurs if the numeric result that differs from the input value.

Input Denormal

As *Flush-to-zero* on page A1-53 describes, when Flush-to-zero mode is enabled, occurs when zero replaces a double-precision or single-precision denormal input.

Note

When ARMv8.2-FP16 is implemented, a half-precision denormal input that is flushed to zero does not generate an Input Denormal exception.

Table C3-60 shows the Floating-point and fixed-point conversion instructions.

Table C3-60 Floating-point and integer or fixed-point conversion instructions

Mnemonic	Instruction	See

	Unsigned fixed-point convert to floating-point, using the current rounding mode (scalar form)	*UCVTF (scalar, fixed-point)* on page C7-1749

C3.5.5 Floating-point round to integer

The Floating-point round to integer instructions round a floating-point value to an integer floating-point value of the same size.

For these instructions:

- A zero input gives a zero result with the same sign.
- An infinite input gives an infinite result with the same sign.
- A NaN is propagated as in normal floating-point arithmetic.

These instructions can cause the following floating-point exceptions:

Invalid Operation

Occurs in response to a floating-point input of a signaling NaN.

Inexact, FRINTX instruction only

Occurs if the result is numeric and does not have the same numerical value as the input.

Non-Confidential

Input Denormal

As *Flush-to-zero* on page A1-53 describes, when Flush-to-zero mode is enabled, occurs when zero replaces a double-precision or single-precision denormal input.

Note

When ARMv8.2-FP16 is implemented, a half-precision denormal input that is flushed to zero does not generate an Input Denormal exception.

Table C3-61 shows the Floating-point round to integer instructions.

Table C3-61 Floating-point round to integer instructions

Mnemonic	Instruction	See
FRINTA	Floating-point round to integer, to nearest with ties to away	*FRINTA (scalar)* on page C7-1315
FRINTI	Floating-point round to integer, using current rounding mode	*FRINTI (scalar)* on page C7-1319
FRINTM	Floating-point round to integer, toward minus infinity	*FRINTM (scalar)* on page C7-1323
FRINTN	Floating-point round to integer, to nearest with ties to even	*FRINTN (scalar)* on page C7-1327
FRINTP	Floating-point round to integer, toward positive infinity	*FRINTP (scalar)* on page C7-1331
FRINTX	Floating-point round to integer exact, using current rounding mode	*FRINTX (scalar)* on page C7-1335
FRINTZ	Floating-point round to integer, toward zero	*FRINTZ (scalar)* on page C7-1339

C3.5.6 Floating-point multiply-add

Table C3-62 shows the Floating-point multiply-add instructions that require three source register operands.

Table C3-62 Floating-point multiply-add instructions

C3.5.8 Floating-point arithmetic (two sources)

Table C3-64 shows the Floating-point arithmetic instructions that require two source register operands.

Table C3-64 Floating-point arithmetic instructions with two source registers

Mnemonic	Instruction	See
FADD	Floating-point scalar add	*FADD (scalar)* on page C7-1084
FDIV	Floating-point scalar divide	*FDIV (scalar)* on page C7-1204
FMUL	Floating-point scalar multiply	*FMUL (scalar)* on page C7-1286
FNMUL	Floating-point scalar multiply-negate	*FNMUL (scalar)* on page C7-1303
FSUB	Floating-point scalar subtract	*FSUB (scalar)* on page C7-1353

C3.5.9 Floating-point minimum and maximum

The `min(x,y)` and `max(x,y)` operations return a quiet NaN when either *x* or *y* is NaN.

As described in *Flush-to-zero* on page A1-53, in flush-to-zero mode, denormal operands are flushed to zero before comparison, and if the result of the comparison is the flushed value, then a zero value is returned. Where both *x* and *y* are zero, or denormal values flushed to zero, with different signs, then +0.0 is returned by `max()` and -0.0 by `min()`.

The `minNum(x,y)` and `maxNum(x,y)` operations follow the IEEE 754-2008 standard and return the numerical operand when one operand is numerical and the other a quiet NaN. Apart from this additional handling of a single quiet NaN the result is then identical to `min(x,y)` and `max(x,y)`.

Table C3-65 shows the Floating-point instructions that can perform floating-point minimum and maximum operations.

Table C3-65 Floating-point minimum and maximum instructions

Mnemonic	Instruction	See
FMAX	Floating-point scalar maximum	*FMAX (scalar)* on page C7-1211
FMAXNM	Floating-point scalar maximum number	*FMAXNM (scalar)* on page C7-1215
FMIN	Floating-point scalar minimum	*FMIN (scalar)* on page C7-1231
FMINNM	Floating-point scalar minimum number	*FMINNM (scalar)* on page C7-1235

C3.5.10 Floating-point comparison

These instructions set the NZCV Condition flags in PSTATE, based on the result of a comparison of two operands. If the floating-point comparisons are *unordered*, where one or both operands are a form of NaN, the C and V bits are set to 1 and the N and Z bits are cleared to 0.

Note

The NZCV flags in the FPSR are associated with AArch32 state. The A64 floating-point comparison instructions do not change the Condition flags in the FPSR.

For the conditional Floating-point comparison instructions, if the condition is TRUE, the flags are updated to the result of the comparison, otherwise the flags are updated to the immediate value that is defined in the instruction encoding.

Non-Confidential

The quiet compare instructions generate an Invalid Operation floating-point exception if either of the source operands is a signaling NaN. The signaling compare instructions generate an Invalid Operation floating-point exception if either of the source operands is any type of NaN.

Table C3-66 shows the Floating-point comparison instructions.

Table C3-66 Floating-point comparison instructions

Mnemonic	Instruction	See
FCMP	Floating-point quiet compare	*FCMP* on page C7-1128
FCMPE	Floating-point signaling compare	*FCMPE* on page C7-1130
FCCMP	Floating-point conditional quiet compare	*FCCMP* on page C7-1092
FCCMPE	Floating-point conditional signaling compare	*FCCMPE* on page C7-1094

C3.5.11 Floating-point conditional select

Table C3-67 shows the Floating-point conditional select instructions.

Table C3-67 Floating-point conditional select instructions

Mnemonic	Instruction	See
FCSEL	Floating-point scalar conditional select	*FCSEL* on page C7-1132

C3.5.12 SIMD move

The functionality of some data movement instructions overlaps with that provided by the scalar floating-point FMOV instructions described in *Floating-point move (register)* on page C3-199.

Table C3-68 shows the SIMD move instructions.

Table C3-68 SIMD move instructions

Mnemonic	Instruction	See
DUP	Duplicate vector element to vector or scalar	*DUP (element)* on page C7-1058
DUP	Duplicate general-purpose register to vector	*DUP (general)* on page C7-1061
INS[a]	Insert vector element from another vector element	*INS (element)* on page C7-1355
	Insert vector element from general-purpose register	*INS (general)* on page C7-1357

C3.5.14 SIMD compare

The SIMD compare instructions compare vector or scalar elements according to the specified condition and set the destination vector element to all ones if the condition holds, or to zero if the condition does not hold.

Note

Some of the comparisons, such as LS, LE, LO, and LT, can be made by reversing the operands and using the opposite comparison, HS, GE, HI, or GT.

Table C3-70 shows that SIMD compare instructions.

Table C3-70 SIMD compare instructions

Mnemonic	Instruction	See
CMEQ	Compare bitwise equal (vector and scalar form)	*CMEQ (register)* on page C7-1035

C3.5.21 SIMD floating-point and integer conversion

The SIMD floating-point and integer conversion instructions generate the Invalid Operation floating-point exception in response to a floating-point input of NaN, infinity, or a numerical value that cannot be represented within the destination register. An out-of-range integer or a fixed-point result is saturated to the size of the destination register. A numeric result that differs from the input raises the Inexact floating-point exception.

Table C3-77 shows the SIMD floating-point and integer conversion instructions.

Table C3-77 SIMD floating-point and integer conversion instructions

Mnemonic	Instruction	See
FCVTAS	Floating-point convert to signed integer, rounding to nearest with ties to away (vector and scalar form)	*FCVTAS (vector)* on page C7-1136

C3.5.22 SIMD reduce (across vector lanes)

The SIMD reduce (across vector lanes) instructions perform arithmetic operations horizontally, that is across all lanes of the input vector. They deliver a single scalar result.

Table C3-78 shows the SIMD reduce (across vector lanes) instructions.

Table C3-78 SIMD reduce (across vector lanes) instructions

Mnemonic	Instruction	See
ADDV	Add (across vector)	*ADDV* on page C7-1018

C3.5.24 SIMD dot product

ARMv8.2-DotProd provides SIMD instructions that perform the dot product of the four 8-bit subelements of the 32-bit elements of one vector with the four 8-bit subelements of a second vector. It provides two forms of the instructions, each with signed and unsigned versions:

Vector form The dot product is calculated for each element of the first vector with the corresponding element of the second element.

Indexed form The dot product is calculated for each element of the first vector with the element of the second vector that is indicated by the index argument to the instruction.

Note

That is, a single element from the second vector is used, and a the dot product is calculated between each element of the first vector and this single element from the second vector.

Table C3-80 SIMD dot product

Mnemonic	Instruction	See
SDOT	Signed dot product (vector form)	*SDOT (vector)* on page C7-1497
UDOT	Unsigned dot product (vector form)	*UDOT (vector)* on page C7-1755
SDOT	Signed dot product (indexed form)	*SDOT (by element)* on page C7-1495
UDOT	Unsigned dot product (indexed form)	*UDOT (by element)* on page C7-1753

C3.5.25 SIMD table lookup

Table C3-81 shows the SIMD table lookup instructions.

Table C3-81 SIMD table lookup instructions

Mnemonic	Instruction	See
TBL	Table vector lookup	*TBL* on page C7-1717
TBX	Table vector lookup extension	*TBX* on page C7-1719

C3.5.26 SIMD complex number arithmetic

ARMv8.3-CompNum provides SIMD instructions that perform arithmetic on complex numbers held in element pairs in vector registers, where the less significant element of the pair contains the real component and the more significant element contains the imaginary component.

These instructions provide double-precision and single-precision versions. If ARMv8.2-FP16 is implemented they also provide half-precision versions, otherwise the half-precision encodings are UNDEFINED.

Table C3-82 shows the ARMv8.3-CompNum SIMD instructions:

Table C3-82 SIMD complex number arithmetic

Mnemonic	Instruction	See
FCADD	Floating-point complex add	*FCADD* on page C7-1090
FCMLA	Floating-point complex multiply accumulate (vector form)	*FCMLA* on page C7-1120
FCMLA	Floating-point complex multiply accumulate (indexed form)	*FCMLA (by element)* on page C7-1117

A pair of FCMLA instructions can be used to perform a complex number multiplication. This is demonstrated in *Complex multiplication* on page K10-6514.

C3.5.27 The Cryptographic Extension

The instructions provided by the optional ARMv8.0 Cryptographic Extension use the SIMD and floating-point register file. For more information about the functions they provide see:

- *Announcing the Advanced Encryption Standard.*
- *The Galois/Counter Mode of Operation*.
- *Announcing the Secure Hash Standard.*

Table C3-83 shows the ARMv8.0 Cryptographic Extension instructions.

Non-Confidential

Table C3-83 Cryptographic Extension instructions (continued)

Mnemonic	Instruction	See
SHA1H	SHA1 fixed rotate	*SHA1H* on page C7-1500
SHA1M	SHA1 hash update (majority)	*SHA1M* on page C7-1501
SHA1P	SHA1 hash update (parity)	*SHA1P* on page C7-1502
SHA1SU0	SHA1 schedule update 0	*SHA1SU0* on page C7-1503
SHA1SU1	SHA1 schedule update 1	*SHA1SU1* on page C7-1504
SHA256H	SHA256 hash update, part 1	*SHA256H* on page C7-1506
SHA256H2	SHA256 hash update, part 2	*SHA256H2* on page C7-1505
SHA256SU0	SHA256 schedule update 0	*SHA256SU0* on page C7-1507
SHA256SU1	SHA256 schedule update 1	*SHA256SU1* on page C7-1508

a. The Cryptographic Extension adds the variant of the instruction that operates on two 64-bit polynomials.

See *The ARMv8 Cryptographic Extension* on page A1-58 for information about the permitted implementation options for the Cryptographic Extension.

ARMv8.2 extensions to the Cryptographic Extension

ARMv8.2 provides two optional extensions to the Cryptographic Extension, see:

- *ARMv8.2-SHA, SHA2-512 and SHA3*.
- *ARMv8.2-SM, SM3 and SM4* on page C3-220.

ARMv8.2-SHA, SHA2-512 and SHA3

ARMv8.2-SHA provides:

- Instructions to accelerate the SHA-2 hash algorithm using a digest that is larger than 256 bits. The relevant standards are SHA-384, SHA-512, SHA-512|224 and SHA-512|256. These are all based on the SHA-512 computation, and therefore this set of instructions is described as the *SHA512 instructions*.
- Instructions to accelerate the SHA-3 hash algorithm. This set of instructions is described as the *SHA3 instructions*.

Implementation of ARMv8.2-SHA requires the implementation of the SHA1 and SHA2-256 instructions from the ARMv8.0 Cryptographic Extension.

Note

Implementation of ARMv8.2-SHA does not require the implementation of the AES instructions, and the 64-bit polynomial variants of the PMULL instructions, from the ARMv8.0 Cryptographic Extension.

When ARMv8.2-SHA is implemented:

- The value of ID_AA64ISAR0_EL1.SHA2 is 0b0010, indicating support for the SHA512 instructions.
- The value of ID_AA64ISAR0_EL1.SHA3 is 0b0001, indicating support for the SHA3 instructions.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Table C3-84 shows the ARMv8.2-SHA SHA512 instructions:

Table C3-84 ARMv8.2-SHA SHA512 instructions

Mnemonic	Instruction	See
SHA512H	SHA512 Hash update part 1	*SHA512H* on page C7-1509
SHA512H2	SHA512 Hash update part 2	*SHA512H2* on page C7-1510
SHA512SU0	SHA512 Schedule Update 0	*SHA512SU0* on page C7-1511
SHA512SU1	SHA512 Schedule Update 1	*SHA512SU1* on page C7-1512

Use of the SHA512 instructions on page K10-6516 shows an example of the use of these instructions to calculate a SHA512 hash iteration. This example code is not part of the architectural definition of these instructions.

Table C3-85 shows the ARMv8.2-SHA SHA3 instructions. The SHA-3 hash algorithm is based on a running digest of 1600 bytes, arranged as a five by five array of 64-bit registers. The ARM acceleration of these instructions is based on mapping the 25 64-bit values into 25 vector registers, with each 64-bit value occupying the same 64-bit element in each vector. A series of transformations is performed on these registers as part of a round of the SHA-3 hash calculation.

The SIMD nature of the vector registers means the acceleration can compute two parallel SHA3 hash calculations, where one calculation is performed using the zeroth 64-bit element of each vector, and the other calculation is performed using the first 64-bit element of each vector.

Note

This is useful because the SHA-3 family of standards is being extended to introduce a fast parallel hash algorithm that benefits from being able to calculate SHA-3 hashes in parallel.

To provide acceleration where the SIMD calculation is not required, the instructions provide variants that operate only on the zeroth 64-bit elements. These are provided as a power optimization.

Table C3-85 ARMv8.2-SHA SHA3 instructions

Mnemonic	Instruction	See
EOR3	Three-way Exclusive OR	*EOR3* on page C7-1064
RAX1	Rotate and Exclusive OR	*RAX1* on page C7-1455
XAR	Exclusive OR and Rotate	*XAR* on page C7-1839
BCAX	Bit Clear and Exclusive OR	*BCAX* on page C7-1024

Use of the SHA3 instructions on page K10-6517 shows an example of the use of these instructions to calculate the combined theta, phi, rho and chi operations of a SHA3 iteration. This example code is not part of the architectural definition of these instructions.

ARMv8.2-SM, SM3 and SM4

ARMv8.2-SM provides:

- Instructions to accelerate the SM3 hash algorithm, the standard Chinese hash algorithm. These are described as the *SM3 instructions*.
- Instructions to accelerate the SM4 encryption algorithm, the standard Chinese encryption algorithm. This set of instructions is described as the *SM4 instructions*.

ARMv8.2-SM can be implemented independently of any part of the ARMv8.0 Cryptographic Extension, and independently of ARMv8.2-SHA.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Note

This means that ARMv8.2 permits an implementation of the Cryptographic Extension that provides only the ARMv8.2-SM functionality.

When ARMv8.2-SM is implemented:

- The value of ID_AA64ISAR0_EL1.SM3 is `0b0001`, indicating support for the SM3 instructions.
- The value of ID_AA64ISAR0_EL1.SM4 is `0b0001`, indicating support for the SM4 instructions.

Table C3-86 shows the ARMv8.2-SM SM3 instructions. The SM3 algorithm computes a digest of 256 bits, that can be held in two vector registers. The SM3 instructions include instructions to accelerate the computation of the hash and the schedule update.

Note

The SM3 instruction names refer to intermediate variables defined as part of the *SM3 Cryptographic Hash Algorithm* specification.

Table C3-86 ARMv8.2-SM SM3 instructions

Mnemonic	Instruction	See

SM3PARTW1	SM3 PARTW calculation, part 1	*SM3PARTW1* on page C7-1526
SM3PARTW2	SM3 PARTW calculation, part 1	*SM3PARTW2* on page C7-1527

Use of the SM3 instructions on page K10-6518 shows an example of the use of these instructions to generate an SM3 hash. This example code is not part of the architectural definition of these instructions.

Table C3-87 shows the ARMv8.2-SM SM4 instructions. The SM4 algorithm is 128-bit wide block cipher. The `SM4E` instruction accelerates a single round of encryption or decryption, and the `SM4EKEY` instruction accelerates a single round of key generation:

Table C3-87 ARMv8.2-SM SM4 instructions

Mnemonic	Instruction	See
SM4E	SM4 Encrypt	*SM4E* on page C7-1537
SM4EKEY	SM4 Key	*SM4EKEY* on page C7-1538

Use of the SM4 instructions on page K10-6520 shows an example of the use of these instructions to perform SM4 encryption and decryption. This example code is not part of the architectural definition of these instructions.

Chapter C4
A64 Instruction Set Encoding

This chapter describes the encoding of the A64 instruction set. It contains the following section:

- *A64 instruction set encoding* on page C4-224.

In this chapter:

- In the decode tables, an entry of - for a field value means the value of the field does not affect the decoding.
- In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.

Advanced SIMD load/store multiple structures (post-indexed)

This section describes the encoding of the Advanced SIMD load/store multiple structures (post-indexed) instruction class. The encodings in this section are decoded from *Loads and Stores* on page C4-234.

Atomic memory operations

This section describes the encoding of the Atomic memory operations instruction class. The encodings in this section are decoded from *Loads and Stores* on page C4-234.

Advanced SIMD across lanes

This section describes the encoding of the Advanced SIMD across lanes instruction class. The encodings in this section are decoded from *Data Processing -- Scalar Floating-Point and Advanced SIMD* on page C4-275.

Conversion between floating-point and integer

This section describes the encoding of the Conversion between floating-point and integer instruction class. The encodings in this section are decoded from *Data Processing -- Scalar Floating-Point and Advanced SIMD* on page C4-275.

Chapter C5
The A64 System Instruction Class

This chapter describes the A64 System instruction class, and the System instruction class encoding space, that is a subset of the System registers encoding space. It contains the following sections:

- *The System instruction class encoding space* on page C5-328.
- *Special-purpose registers* on page C5-339.
- *A64 System instructions for cache maintenance* on page C5-409.
- *A64 system instructions for address translation* on page C5-432.
- *A64 System instructions for TLB maintenance* on page C5-459.

See *General information about the A64 instruction descriptions* on page C2-157 for information about entries used in the instruction encoding descriptions.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.1 The System instruction class encoding space

Part of the A64 instruction encoding space is assigned to instructions that access the System register encoding space. These instructions provide:

- Access to *System registers*, including the debug registers, that provide system control, and system status information.
- Access to Special-purpose registers such as SPSR_ELx, ELR_ELx, and the equivalent fields of the Process State.
- The cache and TLB maintenance instructions and address translation instructions.
- Barriers and the `CLREX` instruction.
- Architectural hint instructions.

This section describes the general model for accessing this functionality.

Note

- See *Fixed values in AArch64 instruction and System register descriptions* on page C2-157 for information about abbreviations used in the System instruction descriptions.
- In AArch32 state much of this functionality is provided through the System register interface described in *The AArch32 System register interface* on page G1-4693. In AArch64 state, the parameters used to characterize the System register encoding space are {`op0`, `op1`, `CRn`, `CRm`, `op2`}. These are based on the parameters that characterize the AArch32 System register encoding space, which reflect the original implementation of these registers, as described in *Background to the System register interface* on page G1-4694. In ARMv8, there is no particular significance to the naming of these parameters, and no functional distinction between the `op`*n* parameters and the `CR`*x* parameters.

Principles of the System instruction class encoding describes some general properties of these encodings. *System instruction class encoding overview* on page C5-329 then describes the top-level encoding of these instructions, and the following sections then describe the next level of the encoding hierarchy of System instructions and Special-purpose registers:

- *op0==0b00, architectural hints, barriers and CLREX, and PSTATE access* on page C5-330.
- *op0==0b01, cache maintenance, TLB maintenance, and address translation instructions* on page C5-332.
- *op0==0b11, Moves to and from Special-purpose registers* on page C5-336.

For the description of the next level of encoding hierarchy of System registers, see:

- *op0==0b10, Moves to and from debug and trace System registers* on page D9-2333.
- *op0==0b11, Moves to and from non-debug System registers, Special-purpose registers* on page D9-2335.
- *Reserved encodings for IMPLEMENTATION DEFINED registers* on page D9-2345.

C5.1.1 Principles of the System instruction class encoding

In ARMv8, an encoding in the System instruction space is identified by a set of arguments, {`op0`, `op1`, `CRn`, `CRm`, `op2`}. These form an encoding hierarchy, where:

`op0` Defines the top-level division of the encoding space, see *System instruction class encoding overview* on page C5-329.

`op1` Identifies the lowest Exception level at which the encoding is accessible, as follows:

- **Accessible at EL0** `op1` has the value 3.
- **Accessible at EL1** `op1` has the value 0, 1, or 2. The value is the same as the `op1` value used to access the equivalent AArch32 register.
- **Accessible at EL2** `op1` has the value 4.
- **Accessible at EL3** `op1` has the value 6.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

ARM strongly recommends that implementers adopt this use of `op1` when using the IMPLEMENTATION DEFINED regions of the encoding space described in *Reserved encodings for IMPLEMENTATION DEFINED registers* on page D9-2345.

System register width

In AArch64 state, each encoding in the System instruction space can provide access to a 64-bit register. An AArch64 System register is described as either a *32-bit register* or a *64-bit register*. For a 32-bit registers, the upper bits, bits[63:32], are RES0.

C5.1.2 System instruction class encoding overview

The encoding of the System instruction class describes each instruction as being either:

- A transfer to a System register. This is a System instruction with the semantics of a write.
- A transfer from a System register. This is a System instruction with the semantics of a read.

A System instruction that initiates an operation operates as if it was making a transfer to a register.

In the AArch64 instruction set, the decode structure for the System instruction class is:

31 30 29 28	27 26 25 24	23 22	21	20 19 18 16	15 12	11 8	7 5	4 0
1 1 0 1	0 1 0 1	0 0	L	op0	op1	CRn	CRm	op2	Rt

The value of `L` indicates the transfer direction:

0 Transfer to System register.

1 Transfer from System register.

The `op0` field is the top level encoding of the System instruction type. Its possible values are:

`0b00` These encodings provide:

- Instructions with an immediate field for accessing PSTATE, the current PE state.
- The architectural hint instructions.
- Barriers and the `CLREX` instruction.

For more information about these encodings, see *op0==0b00, architectural hints, barriers and CLREX, and PSTATE access* on page C5-330.

`0b01` These encodings provide the cache maintenance, TLB maintenance, and address translation instructions.

Note

These are equivalent to operations in the AArch32 (`coproc==0b1111`) encoding space.

For more information, see *op0==0b01, cache maintenance, TLB maintenance, and address translation instructions* on page C5-332.

`0b10` These encodings provide moves to and from:

- Legacy AArch32 System registers for execution environments, to provide access to these registers from higher Exception levels that are using AArch64.
- Debug and trace registers.

Note

These are equivalent to the registers in the AArch32 (`coproc==0b1110`) encoding space.

For more information, see *op0==0b10, Moves to and from debug and trace System registers* on page D9-2333.

`0b11` These encodings provide:

- Moves to and from Non-debug System registers. The accessed registers provide system control, and system status information.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The accessed registers are equivalent to the registers in the AArch32 (`coproc==0b1111`) encoding space.

- Access to Special-purpose registers.

For more information, see *Instructions for accessing Special-purpose registers* on page C5-336 and *Instructions for accessing non-debug System registers* on page D9-2335.

UNDEFINED behaviors

In the System register instruction encoding space, the following principles apply:

- All unallocated encodings are treated as UNDEFINED.
- All encodings with `L==1` and `op0==0b0x` are UNDEFINED, except for encodings in the area reserved for IMPLEMENTATION DEFINED use, see *Reserved encodings for IMPLEMENTATION DEFINED registers* on page D9-2345.

For registers and operations that are accessible from a particular Exception level, any attempt to access those registers from a lower Exception level is UNDEFINED.

If a particular Exception level:

- Defines a register to be RO, then any attempt to write to that register, at that Exception level, is UNDEFINED. This means that any access to that register with `L==0` is UNDEFINED.
- Defines a register to be WO, then any attempt to read from that register, at that Exception level, is UNDEFINED. This means that any access to that register with `L==1` is UNDEFINED.

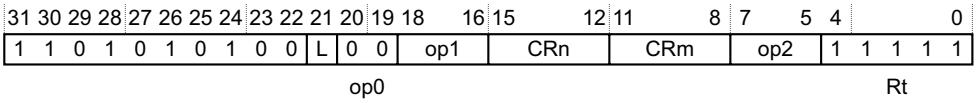
For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED, but see the recommendation in *Principles of the System instruction class encoding* on page C5-328.

C5.1.3 `op0==0b00`, architectural hints, barriers and `CLREX`, and PSTATE access

The different groups of System register instructions with `op0==0b00`:

- Are identified by the value of `CRn`.
- Are always encoded with a value of `0b11111` in the `Rt` field.

The encoding of these instructions is:



The encoding of the `CRn` field is as follows:

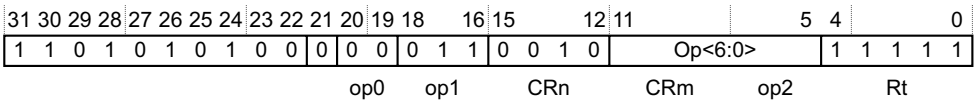
0b0010 See *Architectural hint instructions*.

0b0011 See *Barriers and CLREX* on page C5-331.

0b0100 See *Instructions for accessing the PSTATE fields* on page C5-332.

Architectural hint instructions

Within the `op0==0b00` encodings, the architectural hint instructions are identified by `CRn` having the value `0b0010`. The encoding of these instructions is:



The value of `op<6:0>`, formed by concatenating the `CRm` and `op2` fields, determines the hint instruction as follows:

`0b0000000` `NOP` instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

0b0000001 YIELD instruction.
0b0000010 WFE instruction.
0b0000011 WFI instruction.
0b0000100 SEV instruction.
0b0000101 SEVL instruction.
0b0000110-0b0001111
Unallocated values. These encodings behave as NOPs.
0b0010000 ESB instruction.
0b0010001 PSB CSYNC instruction.
0b0010010-0b1111111
Unallocated values. These encodings behave as NOPs.

These instructions are described in Chapter C6 *A64 Base Instruction Descriptions*.

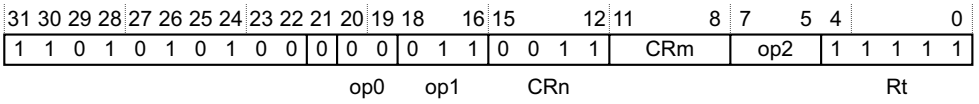
Note

- Instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.
- The operation of the A64 instructions for architectural hints are identical to the corresponding A32 and T32 instructions.

For more information about:
- The WFE, WFI, SEV, and SEVL instructions, see *Mechanisms for entering a low-power state* on page D1-1954.
- The YIELD instruction, see *Software control features and EL0* on page B1-82.

Barriers and CLREX

Within the op0==0b00 encodings, the barriers and CLREX instructions are identified by CRn having the value 0b0011. The encoding of these instructions is:



The value of op2 determines the instruction, as follows.
0b010 CLREX instruction.
0b100 DSB instruction.
0b101 DMB instruction.
0b110 ISB instruction.
0b000, 0b001, 0b011, 0b111
UNDEFINED.

These instructions are described in Chapter C6 *A64 Base Instruction Descriptions*.

Note

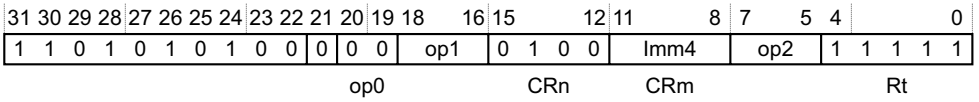
- Instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.
- The operation of the A64 instructions for barriers and CLREX are identical to the corresponding A32 and T32 instructions.

For more information about:
- The barrier instructions, see *Memory barriers* on page B2-98.
- The CLREX instruction, see *Synchronization and semaphores* on page B2-128.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Instructions for accessing the PSTATE fields

Within the op0==0b00 encodings, the instructions that can be used to modify PSTATE fields directly are identified by CRn having the value 0b0100. The encoding of these instructions is:



These instructions are:

```
MSR DAIFSet, #Imm4    ; Used to set any or all of DAIF to 1
MSR DAIFClr, #Imm4    ; Used to clear any or all of DAIF to 0
MSR SPSel, #Imm4      ; Used to select the Stack Pointer, between SP_EL0 and SP_ELx
MSR UAO, #Imm4        ; Used to set the value of PSTATE.UAO
MSR PAN, #Imm4        ; Used to set the value of PSTATE.PAN
```

The value of op2 selects the instruction form, which defines the constraints on the values of the op1 and Imm4 arguments, as follows:

op2==0b011 Selects the MSR UAO instruction.

op2==0b100 Selects the MSR PAN instruction.

op2==0b101 Selects the MSR SPSel instruction.

op2==0b110 Selects the MSR DAIFSet instruction, that sets the specified PSTATE.{D, A, I, F} bits to 1.

op2==0b111 Selects the MSR DAIFClr instruction, that clears the specified PSTATE.{D, A, I, F} bits to 0.

All other combinations of op1 and op2 are reserved, and the corresponding instructions are UNDEFINED.

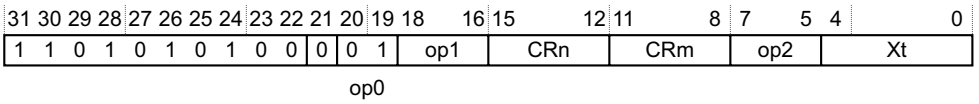
Note

For PSTATE updates, instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.

Writes to PSTATE.{PAN, D, A, I, F} occur in program order without the need for additional synchronization. Changing PSTATE.SPSel to use SP_EL0 synchronizes any updates to SP_EL0 that have been written by an MSR to SP_EL0, without the need for additional synchronization.

C5.1.4 op0==0b01, cache maintenance, TLB maintenance, and address translation instructions

The System instructions are encoded with op0==0b01. The different groups of System instructions are identified by the values of CRn and CRm, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:



The grouping of these instructions depending on the CRn and CRm fields is as follows:

CRn==7 The instruction group is determined by the value of CRm, as follows:

- CRm=={1, 5} Instruction cache maintenance instructions.
- CRm==4 Data cache zero operation.
- CRm=={6, 10, 11, 12, 14} Data cache maintenance instructions. See *Cache maintenance instructions, and data cache zero* on page C5-333.
- CRm==8 See *Address translation instructions* on page C5-334.

CRn==8 See *TLB maintenance instructions* on page C5-335.

CRn=={11, 15} See *Reserved encoding space for IMPLEMENTATION DEFINED instructions* on page C5-336.

Cache maintenance instructions, and data cache zero

Table C5-1 lists the Cache maintenance instructions and their encodings. Instructions that take an argument include `Xt` in the instruction syntax. For instructions that do not take an argument, the Xt field is encoded as `0b11111`.

Table C5-1 Cache maintenance instructions

Instruction	Access instruction encoding					Notes
	op0	op1	CRn	CRm	op2	
Instruction cache maintenance instructions						
IC IALLUIS	1	0	7	1	0	Accessible from EL1 or higher.
IC IALLU				5	0	
IC IVAU, `Xt`		3	7	5	1	When SCTLR_EL1.UCI == 1, accessible from EL0 or higher. Otherwise, accessible from EL1 or higher.
Data cache maintenance instructions						
DC IVAC, `Xt`	1	0	7	6	1	Accessible from EL1 or higher.
DC ISW, `Xt`					2	
DC CSW, `Xt`				10	2	
DC CISW, `Xt`				14	2	
DC CVAC, `Xt`		3	7	10	1	When SCTLR_EL1.UCI == 1, accessible from EL0 or higher. Otherwise, accessible from EL1 or higher.
DC CVAU, `Xt`				11	1	
DC CVAP, `Xt`				12	1	
DC CIVAC, `Xt`				14	1	
Data cache zero operation						
DC ZVA, `Xt`	1	3	7	4	1	When SCTLR_EL1.DZE == 1, accessible from EL0 or higher. Otherwise, accessible from EL1 or higher.

For more information about these instructions, see *About cache maintenance in AArch64 state* on page D3-2058 and *A64 Cache maintenance instructions* on page D3-2062.

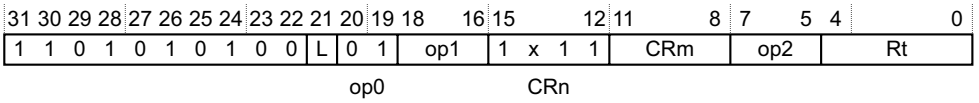
Table C5-3 TLB maintenance instructions (continued)

Instruction	Access instruction encoding					Notes
	op0	op1	CRn	CRm	op2	
TLBI ALLE3IS	1	6	8	3	0	Accessible only from EL3.
TLBI VAE3IS, Xt					1	
TLBI VALE3IS, Xt					5	
TLBI ALLE3				7	0	
TLBI VAE3, Xt					1	
TLBI VALE3, Xt					5	

For more information about these instructions, see *TLB maintenance instructions* on page D4-2209.

Reserved encoding space for IMPLEMENTATION DEFINED instructions

The A64 instruction set reserves the following encoding space for IMPLEMENTATION DEFINED instructions:



The value of L defines the use of Rt as follows:

0 Rt is an argument supplied to the instruction.

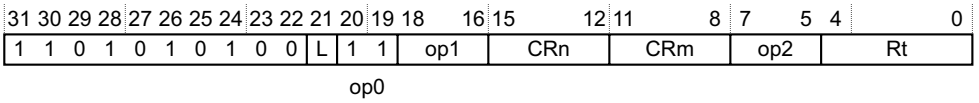
1 Rt is a result returned by the instruction.

IMPLEMENTATION DEFINED instructions in this encoding space are accessed using the SYS and SYSL instructions, see *SYS* on page C6-979 and *SYSL* on page C6-980.

See also *Reserved encodings for IMPLEMENTATION DEFINED registers* on page D9-2345.

C5.1.5 op0==0b11, Moves to and from Special-purpose registers

The instructions that move data to and from non-debug System registers are encoded with op0==0b11, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:



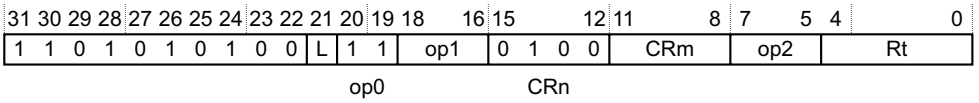
Instructions for accessing Special-purpose registers

The value of CRn provides the next level of decode of these instructions. For Special-purpose registers, the value of CRn is 4.

The A64 instructions for accessing Special-purpose registers are:

```
MSR <Special-purpose register>, Xt    ; Write to Special-purpose register
MRS Xt, <Special-purpose register>    ; Read from Special-purpose register
```

For these accesses, CRn has the value 4. The encoding for Special-purpose register accesses is:



Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

The Special-purpose registers are:

- CurrentEL, DAIF, and NZCV, that return PSTATE information.
- The ELRs, DLR_EL0 and ELR_ELx, that hold the return address for the return from Debug state, or for the exception return.
- FPCR and FPSR, that provide floating-point status and control.
- The stack pointers, SP_ELx, and stack pointer selector, SPSel.
- The SPSRs, DSPSR_EL0 and SPSR_ELx, that hold the PE state from immediately before entering Debug state or taking an exception. This means they hold the state required for the return from Debug state, or for the exception return.
- SPSR_abt, SPSR_fiq, SPSR_irq, and SPSR_und, that map to the corresponding AArch32 registers.

  Note

  The AArch32 SPSRs SPSR_hyp, SPSR_mon, and SPSR_svc are mapped to the AArch64 SPSR_ELx registers.

The characteristic of a Special-purpose register is that all direct and indirect reads and writes to the register appear to occur in program order relative to other instructions, without the need for any explicit synchronization.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Table C5-4 lists the encodings for `op1`, `CRm`, and `op2` fields for accesses to the Special-purpose registers in AArch64.

Table C5-4 Special-purpose register accesses

Register	Access instruction encoding					Notes
	op0	op1	CRn	CRm	op2	
SPSR_EL1	3	0	4	0	0	Accessible from EL1 or higher
ELR_EL1					1	
SP_EL0				1	0	Accessible from EL1 or higher. If SP_EL0 is the current stack pointer then the access is UNDEFINED.
SPSel				2	0	Accessible from EL1 or higher.
CurrentEL					2	RO. Accessible from EL1 or higher.
PAN					3	Accessible from EL1 or higher.
UAO					4	Accessible from EL1 or higher.
DAIF		3	4	2	1	Configurable whether accesses at EL0 are permitted.
NZCV					0	Accessible from EL0 or higher.
FPCR				4	0	Accessible from EL0 or higher.
FPSR					1	
DSPSR_EL0				5	0	Accessible only in Debug state, from EL0 or higher.
DLR_EL0					1	
SPSR_EL2		4	4	0	0	Accessible from EL2 or higher.
ELR_EL2					1	
SP_EL1				1	0	
SPSR_irq				3	0	
SPSR_abt					1	
SPSR_und					2	
SPSR_fiq					3	
*_EL12	3	5	4	{0-15}	{0-7}	Reserved for EL2 aliases of EL1 Special-purpose registers, see Table D4-47 on page D4-2187.
SPSR_EL3		6	4	0	0	Accessible from EL3 or higher.
ELR_EL3					1	
SP_EL2				1	0	

All direct and indirect reads and writes to Special-purpose registers appear to occur in program order relative to other instructions.

Non-Confidential

C5.2 Special-purpose registers

This section describes the following Special-purpose registers:

- CurrentEL, that holds PSTATE.EL, and that software can read to determine the current Exception level.
- DAIF, that holds the current PSTATE.{D, A, I, F} interrupt mask bits.
- ELR_EL1, that holds the address to return to for an exception return from EL1.
- ELR_EL2, that holds the address to return to for an exception return from EL2.
- ELR_EL3, that holds the address to return to for an exception return from EL3.
- FPCR, that provides control of floating-point operation.
- FPSR, that provides floating-point status information.
- NZCV, that holds the PSTATE.{N, Z, C, V} condition flags.
- PAN, that holds the PSTATE.PAN state bit.
- SP_EL0, that holds the stack pointer for EL0.
- SP_EL1, that holds the stack pointer for EL1.
- SP_EL2, that holds the stack pointer for EL2.
- SP_EL3, that holds the stack pointer for EL3.
- SPSel, that holds PSTATE.SP, that at EL1 or higher selects the current SP.
- SPSR_abt, that holds process state on taking an exception to AArch32 Abort mode.
- SPSR_EL1, that holds process state on taking an exception to AArch64 EL1.
- SPSR_EL2, that holds process state on taking an exception to AArch64 EL2.
- SPSR_EL3, that holds process state on taking an exception to AArch64 EL3.
- SPSR_fiq, that holds process state on taking an exception to AArch32 FIQ mode.
- SPSR_irq, that holds process state on taking an exception to AArch32 IRQ mode.
- SPSR_und, that holds process state on taking an exception to AArch32 Undefined mode.
- UAO, that holds the PSTATE.UAO bit.

The following registers are also Special-purpose registers:

- DLR_EL0, that holds the address to return to for a return from Debug state.
- DSPSR_EL0, that holds process state on entry to Debug state.

C5.2.1 CurrentEL, Current Exception Level

The CurrentEL characteristics are:

Purpose

Holds the current Exception level.

Configurations

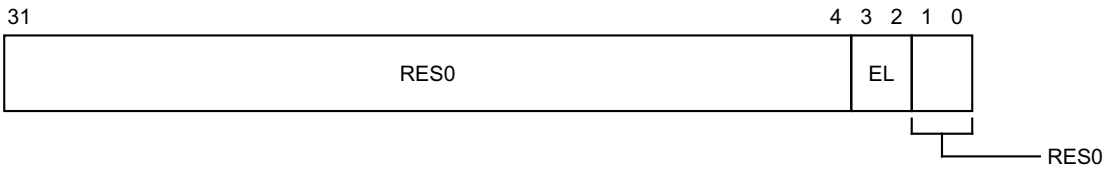
There are no configuration notes.

Attributes

CurrentEL is a 32-bit register.

Field descriptions

The CurrentEL bit assignments are:



Bits [31:4]

Reserved, RES0.

EL, bits [3:2]

Current Exception level. Possible values of this field are:

`00` EL0

`01` EL1

`10` EL2

`11` EL3

When the HCR_EL2.NV bit is 1, Non-secure EL1 read accesses to the CurrentEL register return the value of `0x2` in this field.

This field resets to a value that is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

Accessing the CurrentEL

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
CurrentEL	11	000	0100	0010	010

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	**TGE**	**NS**	**EL0**	**EL1**	**EL2**	**EL3**
x	x	0	-	RO	n/a	RO
x	0	1	-	RO	RO	RO
x	1	1	-	n/a	RO	RO

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.2 DAIF, Interrupt Mask Bits

The DAIF characteristics are:

Purpose

Allows access to the interrupt mask bits.

Configurations

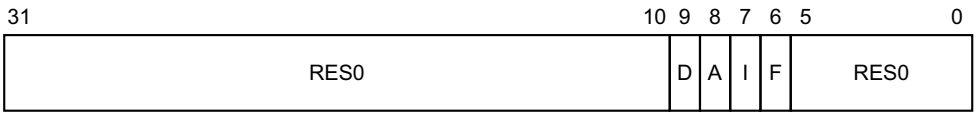
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DAIF is a 32-bit register.

Field descriptions

The DAIF bit assignments are:



Bits [31:10]

Reserved, RES0.

D, bit [9]

Process state D mask. The possible values of this bit are:

0 Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are not masked.

1 Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are masked.

When the target Exception level of the debug exception is higher than the current Exception level, the exception is not masked by this bit.

When this register has an architecturally-defined reset value, this field resets to 1.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

When this register has an architecturally-defined reset value, this field resets to 1.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

When this register has an architecturally-defined reset value, this field resets to 1.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

When this register has an architecturally-defined reset value, this field resets to 1.

Bits [5:0]

Reserved, RES0.

Accessing the DAIF

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
DAIF	11	011	0100	0010	001

This register can be modified using MSR (immediate) with the following syntax:

```
MSR <pstatefield>, <imm>
```

This syntax is encoded with the following settings in the instruction encoding:

<pstatefield>	op0	op1	CRn	op2
DAIFSet	00	011	0100	110
DAIFClr	00	011	0100	111

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
0	1	1	RW	n/a	RW	RW
1	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

When SCR_EL3.NS==0:

- If SCTLR_EL1.UMA==0, Secure accesses to this register from EL0 are trapped to EL1.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

When SCR_EL3.NS==1:

- If (HCR_EL2.E2H==1 and HCR_EL2.TGE==1), Non-secure accesses to this register from EL0 are trapped to EL2.
- If SCTLR_EL1.UMA==0, and !(HCR_EL2.E2H==1 && HCR_EL2.TGE==1), Non-secure accesses to this register from EL0 are trapped to EL1.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.3 DLR_EL0, Debug Link Register

This register is described in DLR_EL0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.4 DSPSR_EL0, Debug Saved Program Status Register

This register is described in DSPSR_EL0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.5 ELR_EL1, Exception Link Register (EL1)

The ELR_EL1 characteristics are:

Purpose

When taking an exception to EL1, holds the address to return to.

Configurations

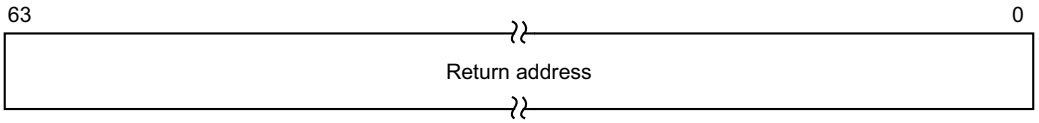
There are no configuration notes.

Attributes

ELR_EL1 is a 64-bit register.

Field descriptions

The ELR_EL1 bit assignments are:



Bits [63:0]

Return address.

An exception return from EL1 using AArch64 makes ELR_EL1 become UNKNOWN.

Accessing the ELR_EL1

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
ELR_EL1	11	000	0100	0000	001
ELR_EL12	11	101	0100	0000	001

Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
ELR_EL1	x	x	0	-	RW	n/a	RW
ELR_EL1	0	0	1	-	RW	RW	RW
ELR_EL1	0	1	1	-	n/a	RW	RW

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
ELR_EL1	1	0	1	-	RW	ELR_EL2	RW
ELR_EL1	1	1	1	-	n/a	ELR_EL2	RW
ELR_EL12	x	x	0	-	-	n/a	-
ELR_EL12	0	0	1	-	-	-	-
ELR_EL12	0	1	1	-	n/a	-	-
ELR_EL12	1	0	1	-	-	RW	RW
ELR_EL12	1	1	1	-	n/a	RW	RW

This table applies to all instructions that can access this register.

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic ELR_EL1 or ELR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 using accessor ELR_EL12 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If HCR_EL2.NV1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 using accessor ELR_EL12 are trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.6 ELR_EL2, Exception Link Register (EL2)

The ELR_EL2 characteristics are:

Purpose

When taking an exception to EL2, holds the address to return to.

Configurations

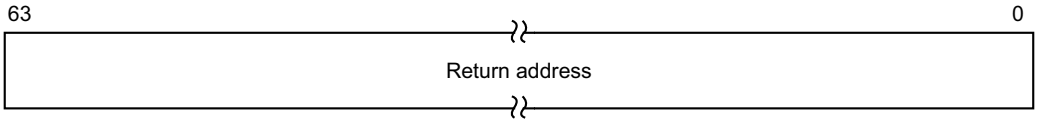
AArch64 System register ELR_EL2 is architecturally mapped to AArch32 System register ELR_hyp.

Attributes

ELR_EL2 is a 64-bit register.

Field descriptions

The ELR_EL2 bit assignments are:



Bits [63:0]

Return address.

An exception return from EL2 using AArch64 makes ELR_EL2 become UNKNOWN.

When EL2 is in AArch32 Execution state and an exception is taken from EL0, EL1, or EL2 to EL3 and AArch64 execution, the upper 32-bits of ELR_EL2 are either set to 0 or hold the same value that they did before AArch32 execution. Which option is adopted is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

Accessing the ELR_EL2

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
ELR_EL2	11	100	0100	0000	001
ELR_EL1	11	000	0100	0000	001

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
ELR_EL2	x	x	0	-	-	n/a	RW
ELR_EL2	0	0	1	-	-	RW	RW
ELR_EL2	0	1	1	-	n/a	RW	RW
ELR_EL2	1	0	1	-	-	RW	RW
ELR_EL2	1	1	1	-	n/a	RW	RW
ELR_EL1	x	x	0	-	ELR_EL1	n/a	ELR_EL1
ELR_EL1	0	0	1	-	ELR_EL1	ELR_EL1	ELR_EL1
ELR_EL1	0	1	1	-	n/a	ELR_EL1	ELR_EL1
ELR_EL1	1	0	1	-	ELR_EL1	RW	ELR_EL1
ELR_EL1	1	1	1	-	n/a	RW	ELR_EL1

This table applies to all instructions that can access this register.

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic ELR_EL2 or ELR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.7 ELR_EL3, Exception Link Register (EL3)

The ELR_EL3 characteristics are:

Purpose

When taking an exception to EL3, holds the address to return to.

Configurations

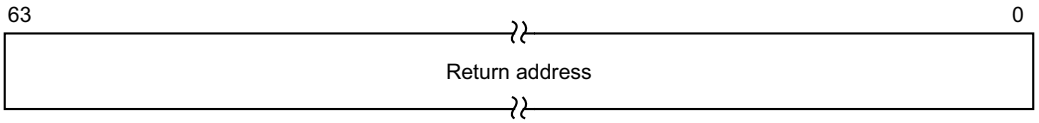
There are no configuration notes.

Attributes

ELR_EL3 is a 64-bit register.

Field descriptions

The ELR_EL3 bit assignments are:



Bits [63:0]

Return address.

An exception return from EL3 using AArch64 makes ELR_EL3 become UNKNOWN.

Accessing the ELR_EL3

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
ELR_EL3	11	110	0100	0000	001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	-	RW
x	1	1	-	n/a	-	RW

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.8 FPCR, Floating-point Control Register

The FPCR characteristics are:

Purpose

Controls floating-point behavior.

Configurations

The named fields in this register map to the equivalent fields in the AArch32 FPSCR.

It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.

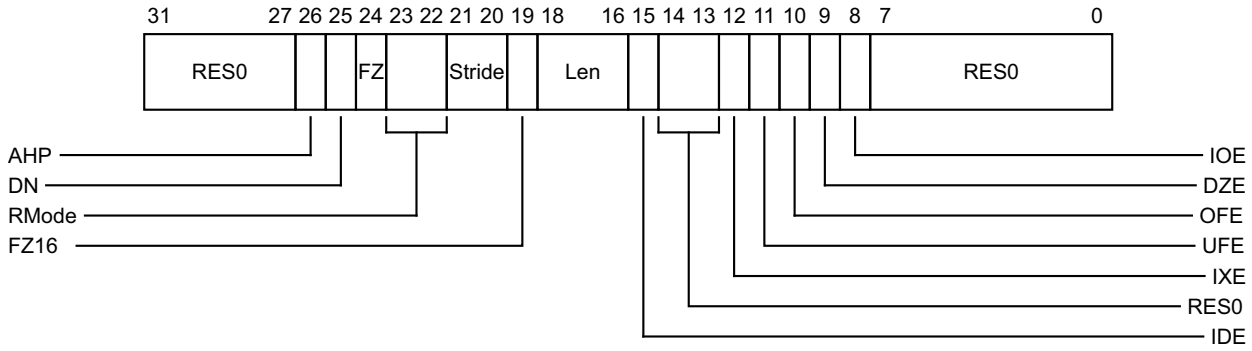
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

FPCR is a 32-bit register.

Field descriptions

The FPCR bit assignments are:



Bits [31:27]

Reserved, RES0.

AHP, bit [26]

Alternative half-precision control bit:

0 IEEE half-precision format selected.

1 Alternative half-precision format selected.

This bit is only used for conversions between half-precision floating-point and other floating-point formats.

The data-processing instructions added as part of the ARMv8.2-FP16 extension always use the IEEE half-precision format, and ignore the value of this bit.

DN, bit [25]

Default NaN mode control bit:

0 NaN operands propagate through to the output of a floating-point operation.

1 Any operation involving one or more NaNs returns the Default NaN.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

FZ, bit [24]

Flush-to-zero mode control bit:

`0` Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.

`1` Flush-to-zero mode enabled.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

This bit has no effect on half-precision calculations.

RMode, bits [23:22]

Rounding Mode control field. The encoding of this field is:

`00` Round to Nearest (RN) mode

`01` Round towards Plus Infinity (RP) mode

`10` Round towards Minus Infinity (RM) mode

`11` Round towards Zero (RZ) mode.

The specified rounding mode is used by both scalar and Advanced SIMD floating-point instructions.

Stride, bits [21:20]

This field has no function in AArch64 state, and non-zero values are ignored during execution in AArch64 state. It is included only for context saving and restoration of the AArch32 FPSCR.Stride field.

FZ16, bit [19]

In ARMv8.3 and ARMv8.2

When ARMv8.2-FP16 is implemented, flush-to-zero mode control bit on half-precision data-processing instructions:

`0` Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.

`1` Flush-to-zero mode enabled.

The value of this bit applies to both scalar and Advanced SIMD floating-point half-precision calculations. A half-precision floating-point number that is flushed to zero as a result of the value of the FZ16 bit does not generate an Input Denormal exception.

When ARMv8.2-FP16 is not implemented, this bit is RES0.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

Len, bits [18:16]

This field has no function in AArch64 state, and non-zero values are ignored during execution in AArch64 state. It is included only for context saving and restoration of the AArch32 FPSCR.Len field.

IDE, bit [15]

Input Denormal floating-point exception trap enable. Possible values are:

`0` Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.IDC bit is set to 1.

`1` Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IDC bit. The trap handling software can decide whether to set the FPSR.IDC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [14:13]

Reserved, RES0.

IXE, bit [12]

Inexact floating-point exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.IXC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IXC bit. The trap handling software can decide whether to set the FPSR.IXC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

UFE, bit [11]

Underflow floating-point exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.UFC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.UFC bit. The trap handling software can decide whether to set the FPSR.UFC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

OFE, bit [10]

Overflow floating-point exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.OFC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.OFC bit. The trap handling software can decide whether to set the FPSR.OFC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

DZE, bit [9]

Divide by Zero floating-point exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.DZC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.DZC bit. The trap handling software can decide whether to set the FPSR.DZC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RAZ/WI.

IOE, bit [8]

Invalid Operation floating-point exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.IOC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IOC bit. The trap handling software can decide whether to set the FPSR.IOC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

If the implementation does not support this exception, this bit is RAZ/WI.

Bits [7:0]

Reserved, RES0.

Accessing the FPCR

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
FPCR	11	011	0100	0100	000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CPACR_EL1.FPEN==00, accesses to this register from EL0 and EL1 are trapped to EL1.
  - If CPACR_EL1.FPEN==01, accesses to this register from EL0 are trapped to EL1.
  - If CPACR_EL1.FPEN==10, accesses to this register from EL0 and EL1 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If CPTR_EL2.TFP==1, Non-secure accesses to this register from EL0, EL1, and EL2 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CPACR_EL1.FPEN==00, Non-secure accesses to this register from EL0 and EL1 are trapped to EL1.
  - If CPACR_EL1.FPEN==01, Non-secure accesses to this register from EL0 are trapped to EL1.
  - If CPACR_EL1.FPEN==10, Non-secure accesses to this register from EL0 and EL1 are trapped to EL1.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

  - If CPTR_EL2.FPEN==00, Non-secure accesses to this register from EL0, EL1, and EL2 are trapped to EL2.
  - If CPTR_EL2.FPEN==10, Non-secure accesses to this register from EL0, EL1, and EL2 are trapped to EL2.

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CPTR_EL2.FPEN==00, Non-secure accesses to this register from EL0 and EL2 are trapped to EL2.
  - If CPTR_EL2.FPEN==01, Non-secure accesses to this register from EL0 are trapped to EL2.
  - If CPTR_EL2.FPEN==10, Non-secure accesses to this register from EL0 and EL2 are trapped to EL2.
- When EL3 is implemented and is using AArch64:
  - If CPTR_EL3.TFP==1, accesses to this register from EL0, EL1, EL2, and EL3 are trapped to EL3.

C5.2.9 FPSR, Floating-point Status Register

The FPSR characteristics are:

Purpose

Provides floating-point system status information.

Configurations

The named fields in this register map to the equivalent fields in the AArch32 FPSCR.

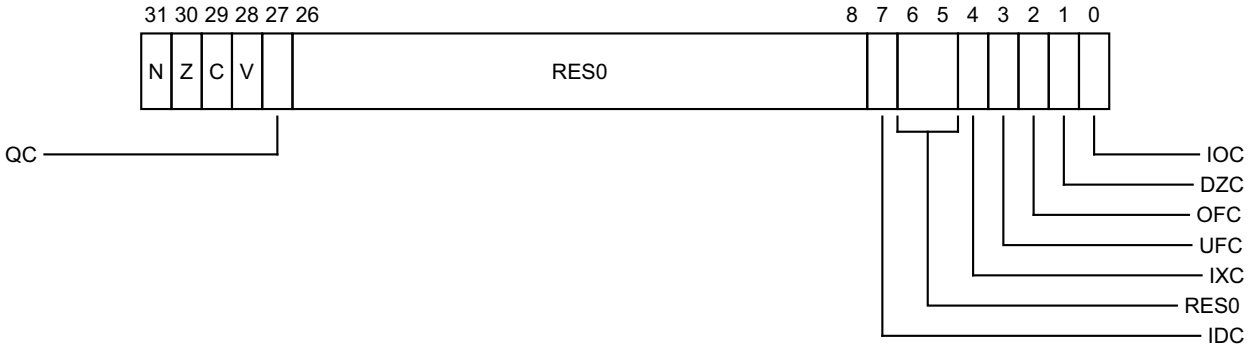
RW fields in this register reset to architecturally UNKNOWN values.

Attributes

FPSR is a 32-bit register.

Field descriptions

The FPSR bit assignments are:



N, bit [31]

Negative condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.N flag instead.

Z, bit [30]

Zero condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.Z flag instead.

C, bit [29]

Carry condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.C flag instead.

V, bit [28]

Overflow condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.V flag instead.

QC, bit [27]

Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.

Bits [26:8]

Reserved, RES0.

IDC, bit [7]

Input Denormal cumulative floating-point exception bit. This bit is set to 1 to indicate that the Input Denormal floating-point exception has occurred since 0 was last written to this bit.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IDE bit. This bit is only set to 1 to indicate a floating-point exception if FPCR.IDE is 0, or if trapping software sets it.

Bits [6:5]

Reserved, RES0.

IXC, bit [4]

Inexact cumulative floating-point exception bit. This bit is set to 1 to indicate that the Inexact exception floating-point has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IXE bit. This bit is only set to 1 to indicate a floating-point exception if FPCR.IXE is 0, or if trapping software sets it.

UFC, bit [3]

Underflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Underflow floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.UFE bit. This bit is only set to 1 to indicate a floating-point exception if FPCR.UFE is 0, or if trapping software sets it.

OFC, bit [2]

Overflow cumulative floating-point exception bit. This bit is set to 1 to indicate that the Overflow floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.OFE bit. This bit is only set to 1 to indicate a floating-point exception if FPCR.OFE is 0, or if trapping software sets it.

DZC, bit [1]

Divide by Zero cumulative floating-point exception bit. This bit is set to 1 to indicate that the Divide by Zero floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.DZE bit. This bit is only set to 1 to indicate a floating-point exception if FPCR.DZE is 0, or if trapping software sets it.

IOC, bit [0]

Invalid Operation cumulative floating-point exception bit. This bit is set to 1 to indicate that the Invalid Operation floating-point exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IOE bit. This bit is only set to 1 to indicate a floating-point exception if FPCR.IOE is 0, or if trapping software sets it.

Accessing the FPSR

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
FPSR	11	011	0100	0100	001

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When HCR_EL2.E2H == 0:
  - If CPACR_EL1.FPEN==00, accesses to this register from EL0 and EL1 are trapped to EL1.
  - If CPACR_EL1.FPEN==01, accesses to this register from EL0 are trapped to EL1.
  - If CPACR_EL1.FPEN==10, accesses to this register from EL0 and EL1 are trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If CPTR_EL2.TFP==1, Non-secure accesses to this register from EL0, EL1, and EL2 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If CPACR_EL1.FPEN==00, Non-secure accesses to this register from EL0 and EL1 are trapped to EL1.
  - If CPACR_EL1.FPEN==01, Non-secure accesses to this register from EL0 are trapped to EL1.
  - If CPACR_EL1.FPEN==10, Non-secure accesses to this register from EL0 and EL1 are trapped to EL1.
  - If CPTR_EL2.FPEN==00, Non-secure accesses to this register from EL0, EL1, and EL2 are trapped to EL2.
  - If CPTR_EL2.FPEN==10, Non-secure accesses to this register from EL0, EL1, and EL2 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If CPTR_EL2.FPEN==00, Non-secure accesses to this register from EL0 and EL2 are trapped to EL2.
  - If CPTR_EL2.FPEN==01, Non-secure accesses to this register from EL0 are trapped to EL2.
  - If CPTR_EL2.FPEN==10, Non-secure accesses to this register from EL0 and EL2 are trapped to EL2.
- When EL3 is implemented and is using AArch64:
  - If CPTR_EL3.TFP==1, accesses to this register from EL0, EL1, EL2, and EL3 are trapped to EL3.

C5.2.10 NZCV, Condition Flags

The NZCV characteristics are:

Purpose

Allows access to the condition flags.

Configurations

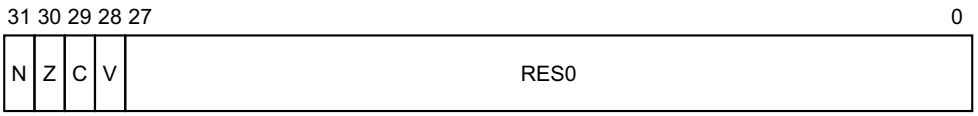
There are no configuration notes.

Attributes

NZCV is a 32-bit register.

Field descriptions

The NZCV bit assignments are:



N, bit [31]

Negative condition flag. Set to 1 if the result of the last flag-setting instruction was negative.

Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Bits [27:0]

Reserved, RES0.

Accessing the NZCV

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
NZCV	11	011	0100	0010	000

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	RW	RW	n/a	RW
x	0	1	RW	RW	RW	RW
x	1	1	RW	n/a	RW	RW

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.11 PAN, Privileged Access Never

The PAN characteristics are:

Purpose

When ARMv8.1-PAN is implemented, allows access to the Privileged Access Never bit.

When ARMv8.1-PAN is not implemented, this register is not implemented.

Configurations

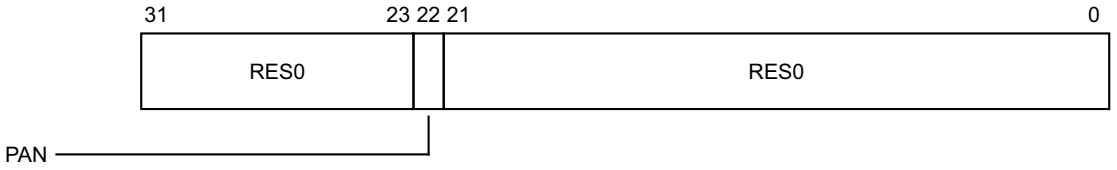
This register is introduced in ARMv8.1.

Attributes

PAN is a 32-bit register.

Field descriptions

The PAN bit assignments are:



Bits [31:23]

Reserved, RES0.

PAN, bit [22]

Privileged Access Never. Defined values are:

`0` The translation system is the same as ARMv8.0.

`1` Disables privileged read and write accesses to addresses accessible at EL0.

The value of this bit is usually preserved on taking an exception, except in the following situations:

- When the target of the exception is EL1, and the value of the SCTLR_EL1.SPAN bit is 0, this bit is set to 1.
- When the target of the exception is EL2, HCR_EL2.{E2H, TGE} is {1, 1}, and the value of the SCTLR_EL2.SPAN bit is 0, this bit is set to 1.

Bits [21:0]

Reserved, RES0.

Accessing the PAN

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
PAN	11	000	0100	0010	011

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This register can be modified using MSR (immediate) with the following syntax:

```
MSR <pstatefield>, <imm>
```

This syntax is encoded with the following settings in the instruction encoding:

<pstatefield>	op0	op1	CRn	op2
PAN	00	000	0100	100

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.12 SP_EL0, Stack Pointer (EL0)

The SP_EL0 characteristics are:

Purpose

Holds the stack pointer associated with EL0. At higher Exception levels, this is used as the current stack pointer when the value of SPSel.SP is 0.

Configurations

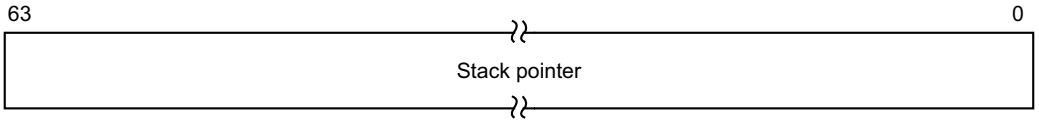
There are no configuration notes.

Attributes

SP_EL0 is a 64-bit register.

Field descriptions

The SP_EL0 bit assignments are:



Bits [63:0]

Stack pointer.

Accessing the SP_EL0

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
SP_EL0	11	000	0100	0001	000

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This accessibility information only applies when the value of SPSel.SP is 1, and only for accesses using the MRS or MSR instructions. In addition, this register is accessible at EL0 as the current stack pointer.

When the value of SPSel.SP is 0:

- Any access to SP_EL0 using the MRS or MSR instructions is UNDEFINED.
- This register is accessible at all Exception levels as the current stack pointer.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.13 SP_EL1, Stack Pointer (EL1)

The SP_EL1 characteristics are:

Purpose

Holds the stack pointer associated with EL1. When executing at EL1, the value of SPSel.SP determines the current stack pointer:

SPSel.SP	current stack pointer
0	SP_EL0
1	SP_EL1

Configurations

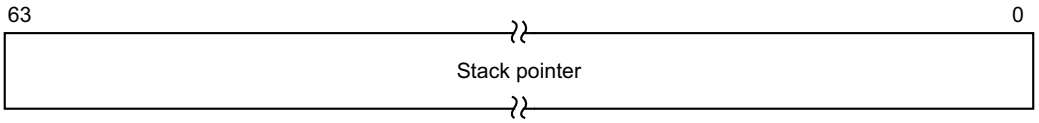
There are no configuration notes.

Attributes

SP_EL1 is a 64-bit register.

Field descriptions

The SP_EL1 bit assignments are:



Bits [63:0]

Stack pointer.

Accessing the SP_EL1

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
SP_EL1	11	100	0100	0001	000

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

This accessibility information only applies to accesses using the MRS or MSR instructions.

When the value of SPSel.SP is 1, this register is also accessible at EL1 as the current stack pointer.

Note

When the value of SPSel.SP is 0, SP_EL0 is used as the current stack pointer at all Exception levels.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.14 SP_EL2, Stack Pointer (EL2)

The SP_EL2 characteristics are:

Purpose

Holds the stack pointer associated with EL2. When executing at EL2, the value of SPSel.SP determines the current stack pointer:

SPSel.SP	current stack pointer
0	SP_EL0
1	SP_EL2

Configurations

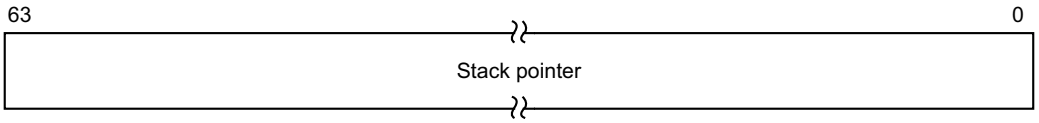
There are no configuration notes.

Attributes

SP_EL2 is a 64-bit register.

Field descriptions

The SP_EL2 bit assignments are:



Bits [63:0]

Stack pointer.

Accessing the SP_EL2

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
SP_EL2	11	110	0100	0001	000

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	-	RW
x	1	1	-	n/a	-	RW

This accessibility information only applies to accesses using the MRS or MSR instructions.

When the value of SPSel.SP is 1, this register is also accessible at EL2 as the current stack pointer.

Note

When the value of SPSel.SP is 0, SP_EL0 is used as the current stack pointer at all Exception levels.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.15 SP_EL3, Stack Pointer (EL3)

The SP_EL3 characteristics are:

Purpose

Holds the stack pointer associated with EL3. When executing at EL3, the value of SPSel.SP determines the current stack pointer:

SPSel.SP	current stack pointer
0	SP_EL0
1	SP_EL3

Configurations

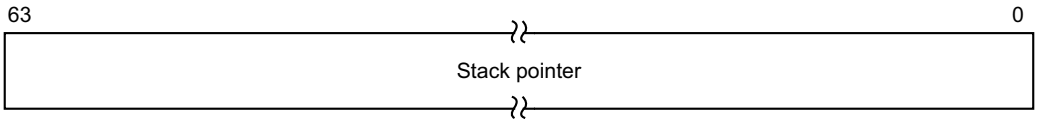
There are no configuration notes.

Attributes

SP_EL3 is a 64-bit register.

Field descriptions

The SP_EL3 bit assignments are:



Bits [63:0]

Stack pointer.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.16 SPSel, Stack Pointer Select

The SPSel characteristics are:

Purpose

Allows the Stack Pointer to be selected between SP_EL0 and SP_ELx.

Configurations

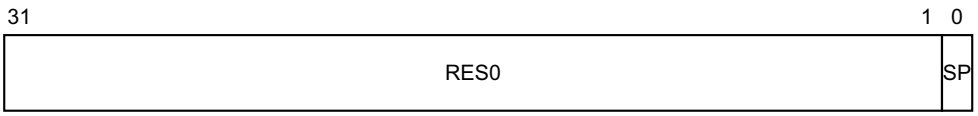
Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SPSel is a 32-bit register.

Field descriptions

The SPSel bit assignments are:



Bits [31:1]

Reserved, RES0.

SP, bit [0]

Stack pointer to use. Possible values of this bit are:

0 Use SP_EL0 at all Exception levels.

1 Use SP_ELx for Exception level ELx.

When this register has an architecturally-defined reset value, this field resets to 1.

Accessing the SPSel

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
SPSel	11	000	0100	0010	000

This register can be modified using MSR (immediate) with the following syntax:

```
MSR <pstatefield>, <imm>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax is encoded with the following settings in the instruction encoding:

<pstatefield>	op0	op1	CRn	op2
SPSel	00	000	0100	101

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.17 SPSR_abt, Saved Program Status Register (Abort mode)

The SPSR_abt characteristics are:

Purpose

Holds the saved process state when an exception is taken to Abort mode.

Configurations

AArch64 System register SPSR_abt is architecturally mapped to AArch32 System register SPSR_abt.

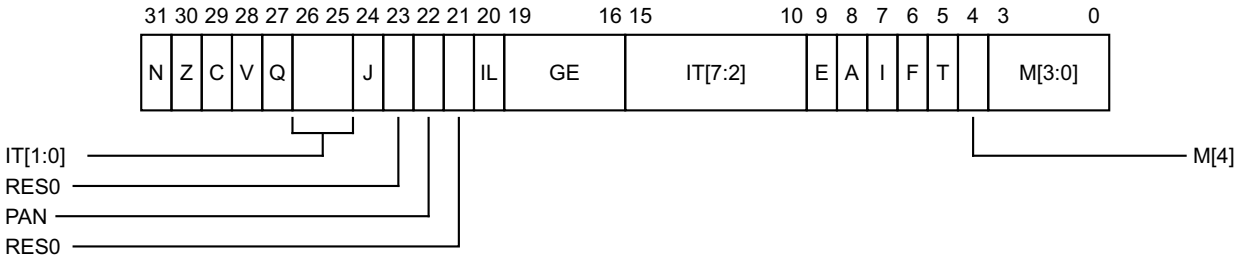
If EL1 does not support execution in AArch32 state, this register is RES0.

Attributes

SPSR_abt is a 32-bit register.

Field descriptions

The SPSR_abt bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Abort mode, and copied to CPSR.N on executing an exception return operation in Abort mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Abort mode, and copied to CPSR.Z on executing an exception return operation in Abort mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Abort mode, and copied to CPSR.C on executing an exception return operation in Abort mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Abort mode, and copied to CPSR.V on executing an exception return operation in Abort mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.3, ARMv8.2 and ARMv8.1

When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to Abort mode, and copied to CPSR.PAN on executing an exception return operation in Abort mode.

When ARMv8.1-PAN is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bit [21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

Accessing the SPSR_abt

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
SPSR_abt	11	100	0100	0011	001

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.18 SPSR_EL1, Saved Program Status Register (EL1)

The SPSR_EL1 characteristics are:

Purpose

Holds the saved process state when an exception is taken to EL1.

Configurations

AArch64 System register SPSR_EL1 is architecturally mapped to AArch32 System register SPSR_svc.

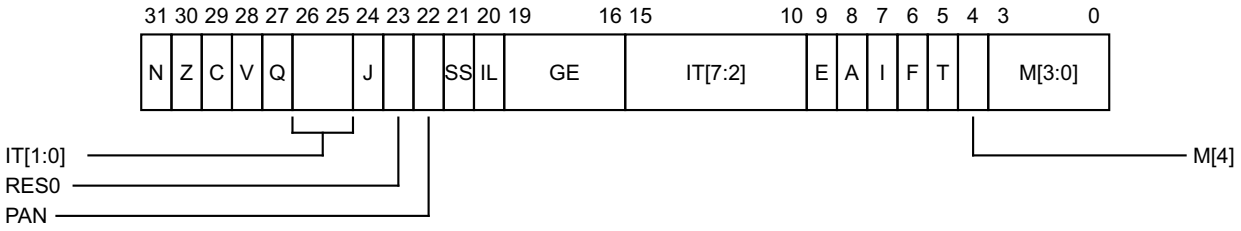
Attributes

SPSR_EL1 is a 32-bit register.

Field descriptions

The SPSR_EL1 bit assignments are:

When exception taken from AArch32:



An exception return from EL1 using AArch64 makes SPSR_EL1 become UNKNOWN.

N, bit [31]

Set to the value of CPSR.N on taking an exception to Supervisor mode, and copied to CPSR.N on executing an exception return operation in Supervisor mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Supervisor mode, and copied to CPSR.Z on executing an exception return operation in Supervisor mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Supervisor mode, and copied to CPSR.C on executing an exception return operation in Supervisor mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Supervisor mode, and copied to CPSR.V on executing an exception return operation in Supervisor mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.3, ARMv8.2 and ARMv8.1

When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to Supervisor mode, and copied to CPSR.PAN on executing an exception return operation in Supervisor mode.

When ARMv8.1-PAN is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

SS, bit [21]

Software step. Shows the value of PSTATE.SS immediately before the exception was taken.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

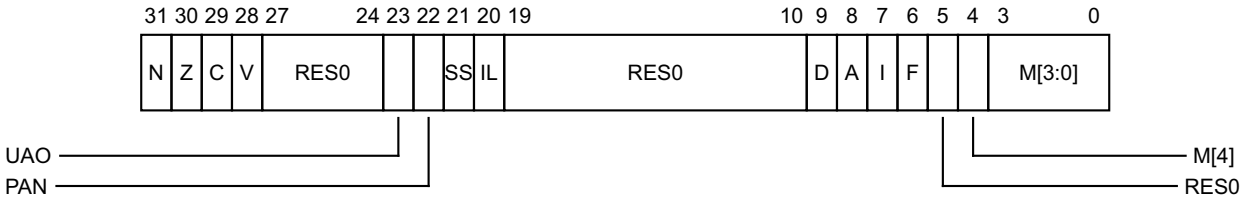
M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0111`	Abort
`0b1011`	Undefined
`0b1111`	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6427.

When exception taken from AArch64:



Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

An exception return from EL1 using AArch64 makes SPSR_EL1 become UNKNOWN.

N, bit [31]

Set to the value of the N condition flag on taking an exception to EL1, and copied to the N condition flag on executing an exception return operation in EL1.

Z, bit [30]

Set to the value of the Z condition flag on taking an exception to EL1, and copied to the Z condition flag on executing an exception return operation in EL1.

C, bit [29]

Set to the value of the C condition flag on taking an exception to EL1, and copied to the C condition flag on executing an exception return operation in EL1.

V, bit [28]

Set to the value of the V condition flag on taking an exception to EL1, and copied to the V condition flag on executing an exception return operation in EL1.

Bits [27:24]

Reserved, RES0.

UAO, bit [23]

In ARMv8.3 and ARMv8.2

When ARMv8.2-UAO is implemented, set to the value of PSTATE.UAO on taking an exception to EL1, and copied to PSTATE.UAO on executing an exception return operation in EL1.

When ARMv8.2-UAO is not implemented, this bit is RES0.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

PAN, bit [22]

In ARMv8.3, ARMv8.2 and ARMv8.1

When ARMv8.1-PAN is implemented, set to the value of PSTATE.PAN on taking an exception to EL1, and copied to PSTATE.PAN on executing an exception return operation in EL1.

When ARMv8.1-PAN is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

SS, bit [21]

Software step. Shows the value of PSTATE.SS immediately before the exception was taken.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

Bits [19:10]

Reserved, RES0.

D, bit [9]

Process state D mask. The possible values of this bit are:

`0` Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are not masked.

`1` Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are masked.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

When the target Exception level of the debug exception is higher than the current Exception level, the exception is not masked by this bit.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`0` Exception taken from AArch64.

M[3:0], bits [3:0]

AArch64 state (Exception level and selected SP) that an exception was taken from. The possible values are:

M[3:0]	State
`0b0000`	EL0t
`0b0100`	EL1t
`0b0101`	EL1h

Other values are reserved, and returning to an Exception level that is using AArch64 with a reserved value in this field is treated as an illegal exception return.

The bits in this field are interpreted as follows:

- M[3:2] holds the Exception Level.
- M[1] is unused and is RES0 for all non-reserved values.
- M[0] is used to select the SP:
  - 0 means the SP is always SP0.
  - 1 means the exception SP is determined by the EL.

Accessing the SPSR_EL1

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
SPSR_EL1	11	000	0100	0000	000
SPSR_EL12	11	101	0100	0000	000

Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
SPSR_EL1	x	x	0	-	RW	n/a	RW
SPSR_EL1	0	0	1	-	RW	RW	RW
SPSR_EL1	0	1	1	-	n/a	RW	RW
SPSR_EL1	1	0	1	-	RW	SPSR_EL2	RW
SPSR_EL1	1	1	1	-	n/a	SPSR_EL2	RW
SPSR_EL12	x	x	0	-	-	n/a	-
SPSR_EL12	0	0	1	-	-	-	-
SPSR_EL12	0	1	1	-	n/a	-	-
SPSR_EL12	1	0	1	-	-	RW	RW
SPSR_EL12	1	1	1	-	n/a	RW	RW

This table applies to all instructions that can access this register.

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL3 using the mnemonic SPSR_EL1 or SPSR_EL12 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 using accessor SPSR_EL12 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If HCR_EL2.NV1==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 using accessor SPSR_EL12 are trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.19 SPSR_EL2, Saved Program Status Register (EL2)

The SPSR_EL2 characteristics are:

Purpose

Holds the saved process state when an exception is taken to EL2.

Configurations

AArch64 System register SPSR_EL2 is architecturally mapped to AArch32 System register SPSR_hyp.

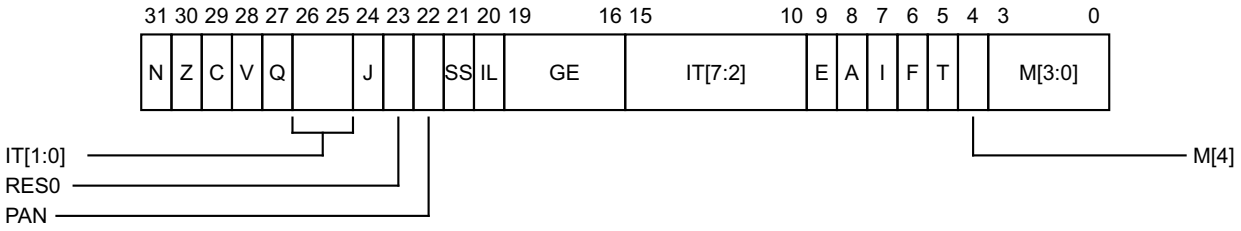
Attributes

SPSR_EL2 is a 32-bit register.

Field descriptions

The SPSR_EL2 bit assignments are:

When exception taken from AArch32:



An exception return from EL2 using AArch64 makes SPSR_EL2 become UNKNOWN.

N, bit [31]

Set to the value of CPSR.N on taking an exception to Hyp mode, and copied to CPSR.N on executing an exception return operation in Hyp mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Hyp mode, and copied to CPSR.Z on executing an exception return operation in Hyp mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Hyp mode, and copied to CPSR.C on executing an exception return operation in Hyp mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Hyp mode, and copied to CPSR.V on executing an exception return operation in Hyp mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.3, ARMv8.2 and ARMv8.1

When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to Hyp mode, and copied to CPSR.PAN on executing an exception return operation in Hyp mode.

When ARMv8.1-PAN is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

SS, bit [21]

Software step. Shows the value of PSTATE.SS immediately before the exception was taken.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

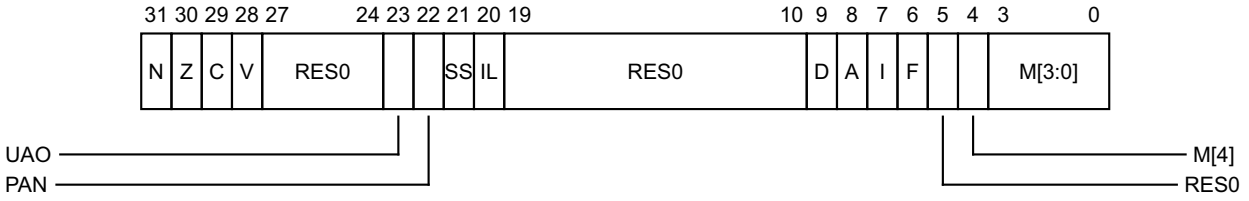
M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0111`	Abort
`0b1010`	Hyp
`0b1011`	Undefined
`0b1111`	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6427.

When exception taken from AArch64:



Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

An exception return from EL2 using AArch64 makes SPSR_EL2 become UNKNOWN.

N, bit [31]

Set to the value of the N condition flag on taking an exception to EL2, and copied to the N condition flag on executing an exception return operation in EL2.

Z, bit [30]

Set to the value of the Z condition flag on taking an exception to EL2, and copied to the Z condition flag on executing an exception return operation in EL2.

C, bit [29]

Set to the value of the C condition flag on taking an exception to EL2, and copied to the C condition flag on executing an exception return operation in EL2.

V, bit [28]

Set to the value of the V condition flag on taking an exception to EL2, and copied to the V condition flag on executing an exception return operation in EL2.

Bits [27:24]

Reserved, RES0.

UAO, bit [23]

In ARMv8.3 and ARMv8.2

When ARMv8.2-UAO is implemented, set to the value of PSTATE.UAO on taking an exception to EL2, and copied to PSTATE.UAO on executing an exception return operation in EL2.

When ARMv8.2-UAO is not implemented, this bit is RES0.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

PAN, bit [22]

In ARMv8.3, ARMv8.2 and ARMv8.1

When ARMv8.1-PAN is implemented, set to the value of PSTATE.PAN on taking an exception to EL2, and copied to PSTATE.PAN on executing an exception return operation in EL2.

When ARMv8.1-PAN is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

SS, bit [21]

Software step. Shows the value of PSTATE.SS immediately before the exception was taken.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

Bits [19:10]

Reserved, RES0.

D, bit [9]

Process state D mask. The possible values of this bit are:

`0` Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are not masked.

`1` Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are masked.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

When the target Exception level of the debug exception is higher than the current Exception level, the exception is not masked by this bit.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`0` Exception taken from AArch64.

M[3:0], bits [3:0]

AArch64 state (Exception level and selected SP) that an exception was taken from. The possible values are:

M[3:0]	State
`0b0000`	EL0t
`0b0100`	EL1t
`0b0101`	EL1h
`0b1000`	EL2t
`0b1001`	EL2h

Other values are reserved, and returning to an Exception level that is using AArch64 with a reserved value in this field is treated as an illegal exception return.

The bits in this field are interpreted as follows:

- M[3:2] holds the Exception Level.
- M[1] is unused and is RES0 for all non-reserved values.
- M[0] is used to select the SP:
  - 0 means the SP is always SP0.
  - 1 means the exception SP is determined by the EL.

Accessing the SPSR_EL2

This register can be read using MRS with the following syntax:

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
SPSR_EL2	11	100	0100	0000	000
SPSR_EL1	11	000	0100	0000	000

Accessibility

The register is accessible in software as follows:

<systemreg>	Control			Accessibility			
	E2H	TGE	NS	EL0	EL1	EL2	EL3
SPSR_EL2	x	x	0	-	-	n/a	RW
SPSR_EL2	0	0	1	-	-	RW	RW
SPSR_EL2	0	1	1	-	n/a	RW	RW
SPSR_EL2	1	0	1	-	-	RW	RW
SPSR_EL2	1	1	1	-	n/a	RW	RW
SPSR_EL1	x	x	0	-	SPSR_EL1	n/a	SPSR_EL1
SPSR_EL1	0	0	1	-	SPSR_EL1	SPSR_EL1	SPSR_EL1
SPSR_EL1	0	1	1	-	n/a	SPSR_EL1	SPSR_EL1
SPSR_EL1	1	0	1	-	SPSR_EL1	RW	SPSR_EL1
SPSR_EL1	1	1	1	-	n/a	RW	SPSR_EL1

This table applies to all instructions that can access this register.

When HCR_EL2.E2H is 1, without explicit synchronization, access from EL2 using the mnemonic SPSR_EL2 or SPSR_EL1 are not guaranteed to be ordered with respect to accesses using the other mnemonic.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.2.20 SPSR_EL3, Saved Program Status Register (EL3)

The SPSR_EL3 characteristics are:

Purpose

Holds the saved process state when an exception is taken to EL3.

Configurations

AArch64 System register SPSR_EL3 can be mapped to AArch32 System register SPSR_mon, but this is not architecturally mandated.

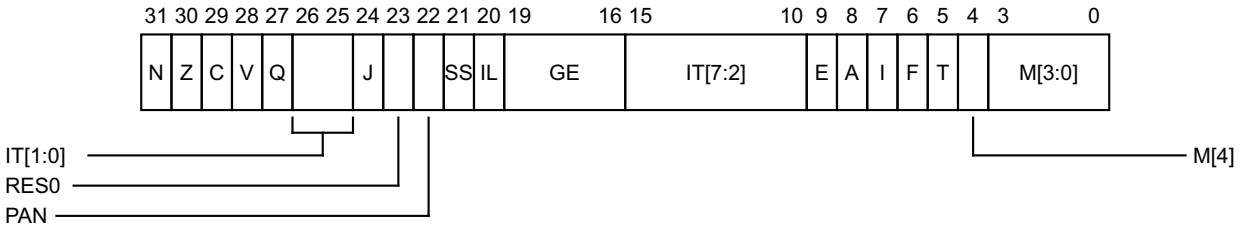
Attributes

SPSR_EL3 is a 32-bit register.

Field descriptions

The SPSR_EL3 bit assignments are:

When exception taken from AArch32:



An exception return from EL3 using AArch64 makes SPSR_EL3 become UNKNOWN.

N, bit [31]

Set to the value of CPSR.N on taking an exception to Monitor mode, and copied to CPSR.N on executing an exception return operation in Monitor mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Monitor mode, and copied to CPSR.Z on executing an exception return operation in Monitor mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Monitor mode, and copied to CPSR.C on executing an exception return operation in Monitor mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Monitor mode, and copied to CPSR.V on executing an exception return operation in Monitor mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.3, ARMv8.2 and ARMv8.1

When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to Monitor mode, and copied to CPSR.PAN on executing an exception return operation in Monitor mode.

When ARMv8.1-PAN is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

SS, bit [21]

Software step. Shows the value of PSTATE.SS immediately before the exception was taken.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

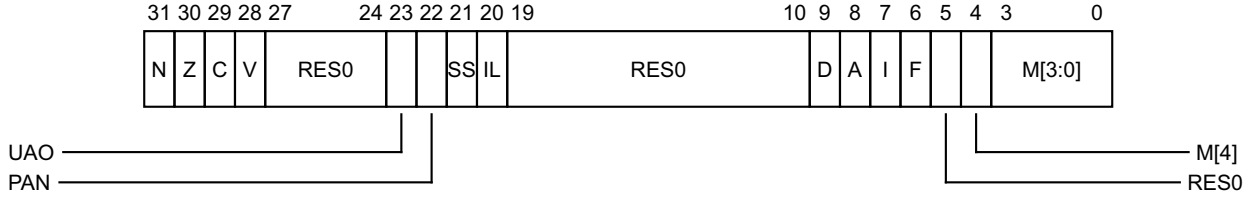
M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0110`	Monitor
`0b0111`	Abort
`0b1010`	Hyp
`0b1011`	Undefined
`0b1111`	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6427.

When exception taken from AArch64:



Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

An exception return from EL3 using AArch64 makes SPSR_EL3 become UNKNOWN.

N, bit [31]

Set to the value of the N condition flag on taking an exception to EL3, and copied to the N condition flag on executing an exception return operation in EL3.

Z, bit [30]

Set to the value of the Z condition flag on taking an exception to EL3, and copied to the Z condition flag on executing an exception return operation in EL3.

C, bit [29]

Set to the value of the C condition flag on taking an exception to EL3, and copied to the C condition flag on executing an exception return operation in EL3.

V, bit [28]

Set to the value of the V condition flag on taking an exception to EL3, and copied to the V condition flag on executing an exception return operation in EL3.

Bits [27:24]

Reserved, RES0.

UAO, bit [23]

In ARMv8.3 and ARMv8.2

When ARMv8.2-UAO is implemented, set to the value of PSTATE.UAO on taking an exception to EL3, and copied to PSTATE.UAO on executing an exception return operation in EL3.

When ARMv8.2-UAO is not implemented, this bit is RES0.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

PAN, bit [22]

In ARMv8.3, ARMv8.2 and ARMv8.1

When ARMv8.1-PAN is implemented, set to the value of PSTATE.PAN on taking an exception to EL3, and copied to PSTATE.PAN on executing an exception return operation in EL3.

When ARMv8.1-PAN is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

SS, bit [21]

Software step. Shows the value of PSTATE.SS immediately before the exception was taken.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

Bits [19:10]

Reserved, RES0.

D, bit [9]

Process state D mask. The possible values of this bit are:

`0` Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are not masked.

`1` Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are masked.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

When the target Exception level of the debug exception is higher than the current Exception level, the exception is not masked by this bit.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`0` Exception taken from AArch64.

M[3:0], bits [3:0]

AArch64 state (Exception level and selected SP) that an exception was taken from. The possible values are:

M[3:0]	State
`0b0000`	EL0t
`0b0100`	EL1t
`0b0101`	EL1h
`0b1000`	EL2t
`0b1001`	EL2h
`0b1100`	EL3t
`0b1101`	EL3h

Other values are reserved, and returning to an Exception level that is using AArch64 with a reserved value in this field is treated as an illegal exception return.

The bits in this field are interpreted as follows:

- M[3:2] holds the Exception Level.
- M[1] is unused and is RES0 for all non-reserved values.
- M[0] is used to select the SP:
  - 0 means the SP is always SP0.
  - 1 means the exception SP is determined by the EL.

C5.2.21 SPSR_fiq, Saved Program Status Register (FIQ mode)

The SPSR_fiq characteristics are:

Purpose

Holds the saved process state when an exception is taken to FIQ mode.

Configurations

AArch64 System register SPSR_fiq is architecturally mapped to AArch32 System register SPSR_fiq.

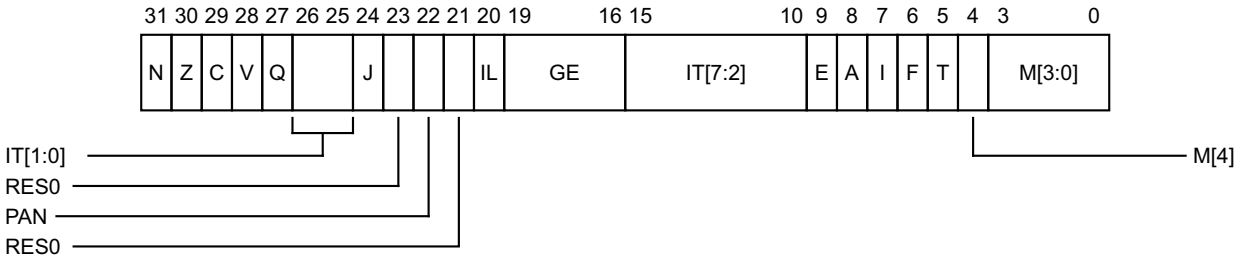
If EL1 does not support execution in AArch32 state, this register is RES0.

Attributes

SPSR_fiq is a 32-bit register.

Field descriptions

The SPSR_fiq bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to FIQ mode, and copied to CPSR.N on executing an exception return operation in FIQ mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to FIQ mode, and copied to CPSR.Z on executing an exception return operation in FIQ mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to FIQ mode, and copied to CPSR.C on executing an exception return operation in FIQ mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to FIQ mode, and copied to CPSR.V on executing an exception return operation in FIQ mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.3, ARMv8.2 and ARMv8.1

When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to FIQ mode, and copied to CPSR.PAN on executing an exception return operation in FIQ mode.

When ARMv8.1-PAN is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bit [21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0110`	Monitor
`0b0111`	Abort
`0b1010`	Hyp
`0b1011`	Undefined
`0b1111`	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6427.

Accessing the SPSR_fiq

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
SPSR_fiq	11	100	0100	0011	011

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 are trapped to EL2.

C5.2.22 SPSR_irq, Saved Program Status Register (IRQ mode)

The SPSR_irq characteristics are:

Purpose

Holds the saved process state when an exception is taken to IRQ mode.

Configurations

AArch64 System register SPSR_irq is architecturally mapped to AArch32 System register SPSR_irq.

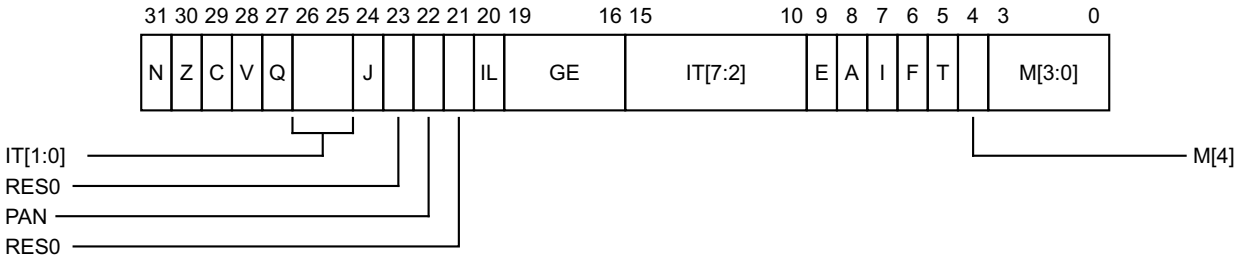
If EL1 does not support execution in AArch32 state, this register is RES0.

Attributes

SPSR_irq is a 32-bit register.

Field descriptions

The SPSR_irq bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to IRQ mode, and copied to CPSR.N on executing an exception return operation in IRQ mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to IRQ mode, and copied to CPSR.Z on executing an exception return operation in IRQ mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to IRQ mode, and copied to CPSR.C on executing an exception return operation in IRQ mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to IRQ mode, and copied to CPSR.V on executing an exception return operation in IRQ mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.3, ARMv8.2 and ARMv8.1

When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to IRQ mode, and copied to CPSR.PAN on executing an exception return operation in IRQ mode.

When ARMv8.1-PAN is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bit [21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0110`	Monitor
`0b0111`	Abort
`0b1010`	Hyp
`0b1011`	Undefined
`0b1111`	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6427.

Accessing the SPSR_irq

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

C5.2.23 SPSR_und, Saved Program Status Register (Undefined mode)

The SPSR_und characteristics are:

Purpose

Holds the saved process state when an exception is taken to Undefined mode.

Configurations

AArch64 System register SPSR_und is architecturally mapped to AArch32 System register SPSR_und.

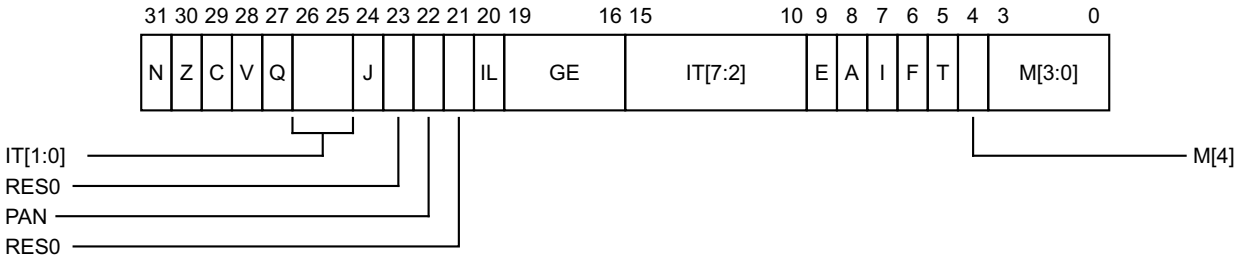
If EL1 does not support execution in AArch32 state, this register is RES0.

Attributes

SPSR_und is a 32-bit register.

Field descriptions

The SPSR_und bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Undefined mode, and copied to CPSR.N on executing an exception return operation in Undefined mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Undefined mode, and copied to CPSR.Z on executing an exception return operation in Undefined mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Undefined mode, and copied to CPSR.C on executing an exception return operation in Undefined mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Undefined mode, and copied to CPSR.V on executing an exception return operation in Undefined mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bit [23]

Reserved, RES0.

PAN, bit [22]

In ARMv8.3, ARMv8.2 and ARMv8.1

When ARMv8.1-PAN is implemented, set to the value of CPSR.PAN on taking an exception to Undefined mode, and copied to CPSR.PAN on executing an exception return operation in Undefined mode.

When ARMv8.1-PAN is not implemented, this bit is RES0.

In ARMv8.0.

Reserved, RES0.

Bit [21]

Reserved, RES0.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that an exception was taken from. The possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0110`	Monitor
`0b0111`	Abort
`0b1010`	Hyp
`0b1011`	Undefined
`0b1111`	System

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-6427.

Accessing the SPSR_und

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
SPSR_und	11	100	0100	0011	010

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	RW
x	0	1	-	-	RW	RW
x	1	1	-	n/a	RW	RW

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure accesses to this register from EL1 are trapped to EL2.

C5.2.24 UAO, User Access Override

The UAO characteristics are:

Purpose

When ARMv8.2-UAO is implemented, allows access to the User Access Override bit.

When ARMv8.2-UAO is not implemented, this register is not implemented.

Configurations

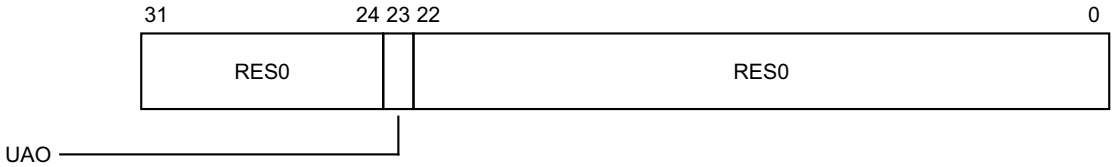
This register is introduced in ARMv8.2.

Attributes

UAO is a 32-bit register.

Field descriptions

The UAO bit assignments are:



Bits [31:24]

Reserved, RES0.

UAO, bit [23]

User Access Override. Defined values are:

`0` The behavior of `LDTR*` and `STTR*` instructions is as defined in the base ARMv8 architecture.

`1` When executed at EL1, or at EL2 with HCR_EL2.{E2H, TGE} == {1, 1}, `LDTR*` and `STTR*` instructions behave as the equivalent `LDR*` and `STR*` instructions.

When executed at EL3, or at EL2 with HCR_EL2.E2H == 0 or HCR_EL2.TGE == 0, the `LDTR*` and `STTR*` instructions behave as the equivalent `LDR*` and `STR*` instructions, regardless of the setting of the PSTATE.UAO bit.

Bits [22:0]

Reserved, RES0.

Accessing the UAO

This register can be read using MRS with the following syntax:

```
MRS <Xt>, <systemreg>
```

This register can be written using MSR (register) with the following syntax:

```
MSR <systemreg>, <Xt>
```

This syntax is encoded with the following settings in the instruction encoding:

<systemreg>	op0	op1	CRn	CRm	op2
UAO	11	000	0100	0010	100

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This register can be modified using MSR (immediate) with the following syntax:

```
MSR <pstatefield>, <imm>
```

This syntax is encoded with the following settings in the instruction encoding:

<pstatefield>	op0	op1	CRn	op2
UAO	00	000	0100	011

Accessibility

The register is accessible in software as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	RW	n/a	RW
x	0	1	-	RW	RW	RW
x	1	1	-	n/a	RW	RW

Non-Confidential

C5.3 A64 System instructions for cache maintenance

This section lists the A64 system instructions for cache maintenance.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.3.1 DC CISW, Data or unified Cache line Clean and Invalidate by Set/Way

The DC CISW characteristics are:

Purpose

Clean and Invalidate data cache by set/way.

Configurations

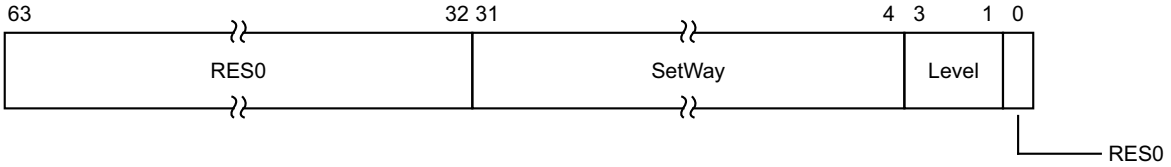
AArch64 System instruction DC CISW performs the same function as AArch32 System instruction DCCISW.

Attributes

DC CISW is a 64-bit System instruction.

Field descriptions

The DC CISW input value bit assignments are:



Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log_2(ASSOCIATIVITY), L = Log_2(LINELEN), B = (L + S), S = Log_2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing the DC CISW instruction

This instruction is executed using DC with the following syntax:

```
DC <dc_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<dc_op>	op0	op1	CRn	CRm	op2
CISW	01	000	0111	1110	010

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.3.2 DC CIVAC, Data or unified Cache line Clean and Invalidate by VA to PoC

The DC CIVAC characteristics are:

Purpose

Clean and Invalidate data cache by address to Point of Coherency.

Configurations

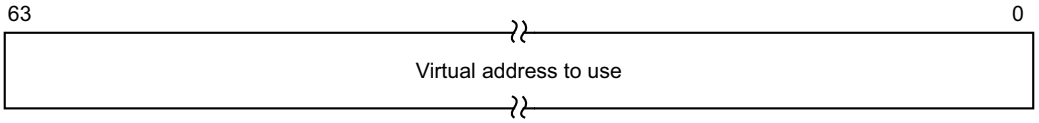
AArch64 System instruction DC CIVAC performs the same function as AArch32 System instruction DCCIMVAC.

Attributes

DC CIVAC is a 64-bit System instruction.

Field descriptions

The DC CIVAC input value bit assignments are:



Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing the DC CIVAC instruction

This instruction is executed using DC with the following syntax:

```
DC <dc_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<dc_op>	op0	op1	CRn	CRm	op2
CIVAC	01	011	0111	1110	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	WO	WO	n/a	WO
x	0	1	WO	WO	WO	WO
x	1	1	WO	n/a	WO	WO

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission Fault, subject to the constraints described in *Permission fault* on page D4-2192.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information see *The data cache maintenance instruction (DC)* on page D3-2063.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When SCTLR_EL1.UCI==0, execution of this instruction at EL0 is trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPC==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HCR_EL2.TPC==1, and SCTLR_EL1.UCI==1, Non-secure execution of this instruction at EL0 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TPC==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HCR_EL2.TPC==1 and SCTLR_EL1.UCI==1, Non-secure execution of this instruction at EL0 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If SCTLR_EL2.UCI==0, Non-secure execution of this instruction at EL0 is trapped to EL2.

Non-Confidential

C5.3.3 DC CSW, Data or unified Cache line Clean by Set/Way

The DC CSW characteristics are:

Purpose

Clean data cache by set/way.

Configurations

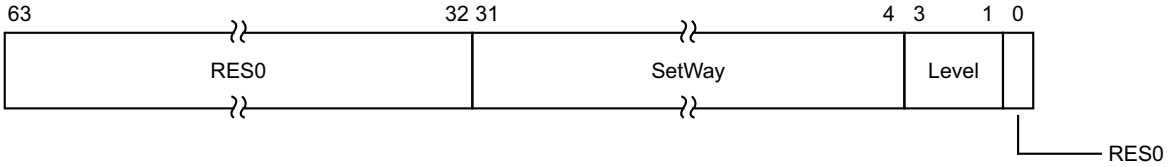
AArch64 System instruction DC CSW performs the same function as AArch32 System instruction DCCSW.

Attributes

DC CSW is a 64-bit System instruction.

Field descriptions

The DC CSW input value bit assignments are:



Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log_2(ASSOCIATIVITY), L = Log_2(LINELEN), B = (L + S), S = Log_2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing the DC CSW instruction

This instruction is executed using DC with the following syntax:

```
DC <dc_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<dc_op>	op0	op1	CRn	CRm	op2
CSW	01	000	0111	1010	010

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.3.4 DC CVAC, Data or unified Cache line Clean by VA to PoC

The DC CVAC characteristics are:

Purpose

Clean data cache by address to Point of Coherency.

Configurations

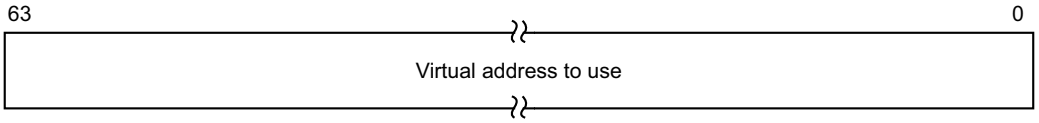
AArch64 System instruction DC CVAC performs the same function as AArch32 System instruction DCCMVAC.

Attributes

DC CVAC is a 64-bit System instruction.

Field descriptions

The DC CVAC input value bit assignments are:



Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing the DC CVAC instruction

This instruction is executed using DC with the following syntax:

```
DC <dc_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<dc_op>	op0	op1	CRn	CRm	op2
CVAC	01	011	0111	1010	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	WO	WO	n/a	WO
x	0	1	WO	WO	WO	WO
x	1	1	WO	n/a	WO	WO

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission Fault, subject to the constraints described in *Permission fault* on page D4-2192.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information see *The data cache maintenance instruction (DC)* on page D3-2063.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When SCTLR_EL1.UCI==0, execution of this instruction at EL0 is trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPC==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HCR_EL2.TPC==1, and SCTLR_EL1.UCI==1, Non-secure execution of this instruction at EL0 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TPC==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HCR_EL2.TPC==1 and SCTLR_EL1.UCI==1, Non-secure execution of this instruction at EL0 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If SCTLR_EL2.UCI==0, Non-secure execution of this instruction at EL0 is trapped to EL2.

Non-Confidential

C5.3.5 DC CVAP, Data or unified Cache line Clean by VA to PoP

The DC CVAP characteristics are:

Purpose

Clean data cache by address to Point of Persistence.

If the memory system does not identify a Point of Persistence, then this instruction behaves as a DC CVAC.

Configurations

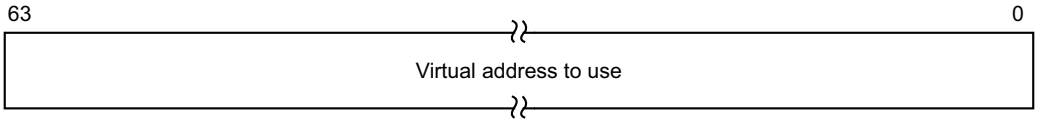
This instruction is introduced in ARMv8.2.

Attributes

DC CVAP is a 64-bit System instruction.

Field descriptions

The DC CVAP input value bit assignments are:



Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing the DC CVAP instruction

This instruction is executed using DC with the following syntax:

```
DC <dc_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<dc_op>	op0	op1	CRn	CRm	op2
CVAP	01	011	0111	1100	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	WO	WO	n/a	WO
x	0	1	WO	WO	WO	WO
x	1	1	WO	n/a	WO	WO

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission Fault, see *Permission fault* on page D4-2192.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information see *The data cache maintenance instruction (DC)* on page D3-2063.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When SCTLR_EL1.UCI==0, execution of this instruction at EL0 is trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPC==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HCR_EL2.TPC==1, and SCTLR_EL1.UCI==1, Non-secure execution of this instruction at EL0 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TPC==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HCR_EL2.TPC==1 and SCTLR_EL1.UCI==1, Non-secure execution of this instruction at EL0 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If SCTLR_EL2.UCI==0, Non-secure execution of this instruction at EL0 is trapped to EL2.

C5.3.6 DC CVAU, Data or unified Cache line Clean by VA to PoU

The DC CVAU characteristics are:

Purpose

Clean data cache by address to Point of Unification.

Configurations

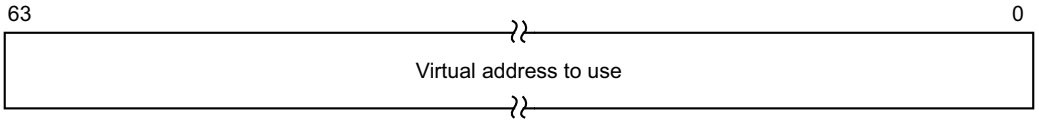
AArch64 System instruction DC CVAU performs the same function as AArch32 System instruction DCCMVAU.

Attributes

DC CVAU is a 64-bit System instruction.

Field descriptions

The DC CVAU input value bit assignments are:



Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing the DC CVAU instruction

This instruction is executed using DC with the following syntax:

```
DC <dc_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<dc_op>	op0	op1	CRn	CRm	op2
CVAU	01	011	0111	1011	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	WO	WO	n/a	WO
x	0	1	WO	WO	WO	WO
x	1	1	WO	n/a	WO	WO

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it generates a Permission Fault, subject to the constraints described in *Permission fault* on page D4-2192.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information see *The data cache maintenance instruction (DC)* on page D3-2063.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When SCTLR_EL1.UCI==0, execution of this instruction at EL0 is trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HCR_EL2.TPU==1, and SCTLR_EL1.UCI==1, Non-secure execution of this instruction at EL0 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HCR_EL2.TPU==1, and SCTLR_EL1.UCI==1, Non-secure execution of this instruction at EL0 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If SCTLR_EL2.UCI==0, Non-secure execution of this instruction at EL0 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

C5.3.7 DC ISW, Data or unified Cache line Invalidate by Set/Way

The DC ISW characteristics are:

Purpose

Invalidate data cache by set/way.

Configurations

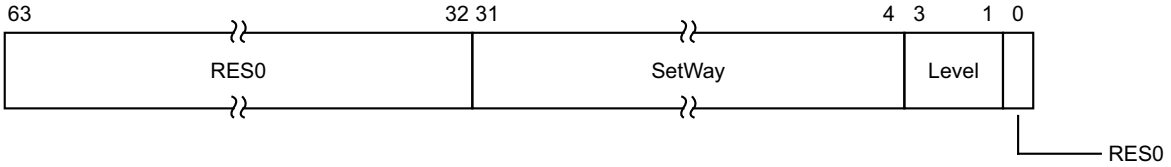
AArch64 System instruction DC ISW performs the same function as AArch32 System instruction DCISW.

Attributes

DC ISW is a 64-bit System instruction.

Field descriptions

The DC ISW input value bit assignments are:



Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log_2(ASSOCIATIVITY), L = Log_2(LINELEN), B = (L + S), S = Log_2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing the DC ISW instruction

This instruction is executed using DC with the following syntax:

```
DC <dc_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<dc_op>	op0	op1	CRn	CRm	op2
ISW	01	000	0111	0110	010

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

At EL1, this instruction performs a cache clean and invalidate, meaning it performs the same invalidation as a DC CISW instruction, if all of the following apply:

- EL2 is implemented.
- The value of HCR_EL2.SWIO is 1 or the value of HCR_EL2.VM is 1.
- The value of SCR_EL3.NS is 1 or EL3 is not implemented.

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONSTRAINED UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
  - No cache lines.
  - A single arbitrary cache line.
  - Multiple arbitrary cache lines.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.3.8 DC IVAC, Data or unified Cache line Invalidate by VA to PoC

The DC IVAC characteristics are:

Purpose

Invalidate data cache by address to Point of Coherency.

Configurations

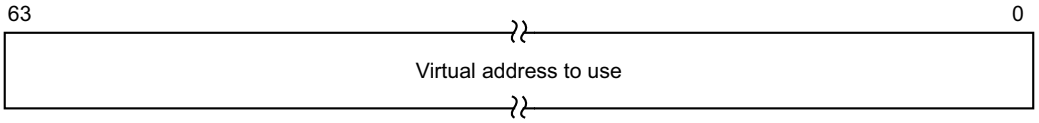
AArch64 System instruction DC IVAC performs the same function as AArch32 System instruction DCIMVAC.

Attributes

DC IVAC is a 64-bit System instruction.

Field descriptions

The DC IVAC input value bit assignments are:



Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing the DC IVAC instruction

This instruction is executed using DC with the following syntax:

```
DC <dc_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<dc_op>	op0	op1	CRn	CRm	op2
IVAC	01	000	0111	0110	001

When the instruction is executed, it can generate a watchpoint, which is prioritized in the same way as other watchpoints. If a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is set to 1.

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

This instruction requires write access permission to the VA, otherwise it generates a Permission Fault, subject to the constraints described in *Permission fault* on page D4-2192.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

At EL1, this instruction performs a cache clean and invalidate, meaning it performs the same invalidation as a DC CIVAC instruction, if all of the following apply:

- EL2 is implemented.
- HCR_EL2.VM is set to 1.
- SCR_EL3.NS is set to 1 or EL3 is not implemented.

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information see *The data cache maintenance instruction (DC)* on page D3-2063.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPC==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.3.9 DC ZVA, Data Cache Zero by VA

The DC ZVA characteristics are:

Purpose

Zero data cache by address. Zeroes a naturally aligned block of N bytes, where the size of N is identified in DCZID_EL0.

Configurations

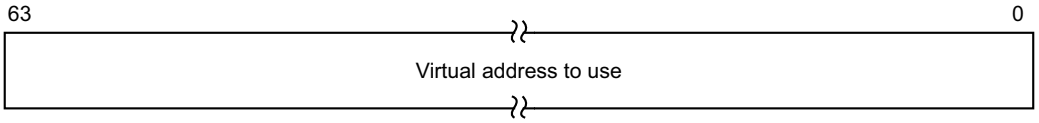
There are no configuration notes.

Attributes

DC ZVA is a 64-bit System instruction.

Field descriptions

The DC ZVA input value bit assignments are:



Bits [63:0]

Virtual address to use. There is no alignment restriction on the address within the block of N bytes that is used.

Executing the DC ZVA instruction

This instruction is executed using DC with the following syntax:

```
DC <dc_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<dc_op>	op0	op1	CRn	CRm	op2
ZVA	01	011	0111	0100	001

When this instruction is executed, it can generate memory faults or watchpoints which are prioritized in the same way as other memory-related faults or watchpoints. If a synchronous data abort fault or a watchpoint is generated, the CM bit in the ESR_ELx.ISS field is not set.

If the memory region being zeroed is any type of Device memory, this instruction can give an alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

This instruction applies to Normal memory regardless of cacheability attributes.

This instruction behaves as a set of Stores to each byte within the block being accessed, and so it:

- Generates a Permission Fault if the translation system does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instructions.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	WO	WO	n/a	WO
x	0	1	WO	WO	WO	WO
x	1	1	WO	n/a	WO	WO

When EL0 access is disabled (SCTLR_EL1.DZE is set to 0) and HCR_EL2.TDZ is set to 1, execution of this instruction at EL0 is UNDEFINED.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- In both security states, and not dependent on other bits:
  - If SCTLR_EL1.DZE==0, execution of this instruction at EL0 is trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TDZ==1, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TDZ==1, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.

C5.3.10 IC IALLU, Instruction Cache Invalidate All to PoU

The IC IALLU characteristics are:

Purpose

Invalidate all instruction caches to Point of Unification.

Configurations

AArch64 System instruction IC IALLU performs the same function as AArch32 System instruction ICIALLU.

Attributes

IC IALLU is a 64-bit System instruction.

Field descriptions

IC IALLU ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the IC IALLU instruction

This instruction is executed using IC with the following syntax:

```
IC <ic_op>
```

This syntax uses the following encoding in the System instruction encoding space:

<ic_op>	op0	op1	CRn	CRm	op2	Rt
IALLU	01	000	0111	0101	000	11111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

When HCR_EL2.FB is 1, at Non-secure EL1 this instruction executes as a IC IALLUIS.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.3.11 IC IALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable

The IC IALLUIS characteristics are:

Purpose

Invalidate all instruction caches in Inner Shareable domain to Point of Unification.

Configurations

AArch64 System instruction IC IALLUIS performs the same function as AArch32 System instruction ICIALLUIS.

Attributes

IC IALLUIS is a 64-bit System instruction.

Field descriptions

IC IALLUIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the IC IALLUIS instruction

This instruction is executed using IC with the following syntax:

```
IC <ic_op>
```

This syntax uses the following encoding in the System instruction encoding space:

<ic_op>	op0	op1	CRn	CRm	op2	Rt
IALLUIS	01	000	0111	0001	000	11111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
x	0	1	-	WO	WO	WO
x	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.3.12 IC IVAU, Instruction Cache line Invalidate by VA to PoU

The IC IVAU characteristics are:

Purpose

Invalidate instruction cache by address to Point of Unification.

Configurations

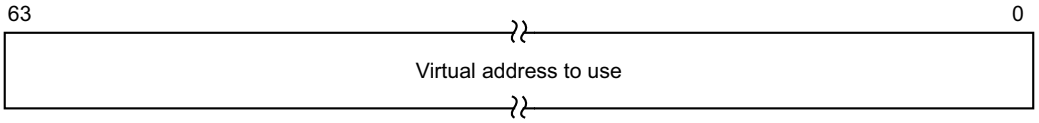
AArch64 System instruction IC IVAU performs the same function as AArch32 System instruction ICIMVAU.

Attributes

IC IVAU is a 64-bit System instruction.

Field descriptions

The IC IVAU input value bit assignments are:



Bits [63:0]

Virtual address to use. No alignment restrictions apply to this VA.

Executing the IC IVAU instruction

This instruction is executed using IC with the following syntax:

```
IC <ic_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<ic_op>	op0	op1	CRn	CRm	op2
IVAU	01	011	0111	0101	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	WO	WO	n/a	WO
x	0	1	WO	WO	WO	WO
x	1	1	WO	n/a	WO	WO

If EL0 access is enabled, when executed at EL0, this instruction requires read access permission to the VA, otherwise it is IMPLEMENTATION DEFINED whether it generates a Permission Fault, see *Permission fault* on page D4-2192.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Execution of this instruction might require an address translation from VA to PA, and that translation might fault. For more information, see *The instruction cache maintenance instruction (IC)* on page D3-2063.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When SCTLR_EL1.UCI==0, execution of this instruction at EL0 is trapped to EL1.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HCR_EL2.TPU==1, and SCTLR_EL1.UCI==1, Non-secure execution of this instruction at EL0 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TPU==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
  - If HCR_EL2.TPU==1, and SCTLR_EL1.UCI==1, Non-secure execution of this instruction at EL0 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 1):
  - If SCTLR_EL2.UCI==0, Non-secure execution of this instruction at EL0 is trapped to EL2.

C5.4 A64 system instructions for address translation

This section lists the A64 System instructions for address translation.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.4.1 AT S12E0R, Address Translate Stages 1 and 2 EL0 Read

The AT S12E0R characteristics are:

Purpose

Performs stage 1 and 2 address translations from EL0, with permissions as if reading from the given virtual address, using the following translation regime:

- In Secure state, and in Non-secure state when HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime.
- In Non-secure state when HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime.

Configurations

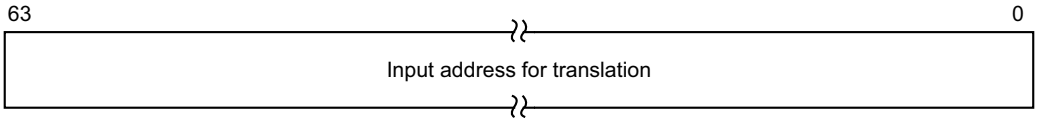
There are no configuration notes.

Attributes

AT S12E0R is a 64-bit System instruction.

Field descriptions

The AT S12E0R input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S12E0R instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S12E0R	01	100	0111	1000	110

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	WO	WO

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

If EL2 is not implemented, or stage 2 translation is disabled, or the instruction is executed at EL3 when the value of SCR_EL3.NS is 0, this instruction executes as AT S1E0R.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.4.2 AT S12E0W, Address Translate Stages 1 and 2 EL0 Write

The AT S12E0W characteristics are:

Purpose

Performs stage 1 and 2 address translations from EL0, with permissions as if writing to the given virtual address, using the following translation regime:

- In Secure state, and in Non-secure state when HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime.
- In Non-secure state when HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime.

Configurations

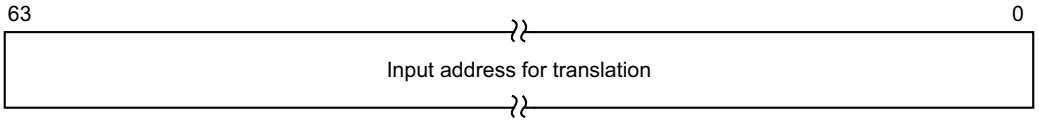
There are no configuration notes.

Attributes

AT S12E0W is a 64-bit System instruction.

Field descriptions

The AT S12E0W input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S12E0W instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S12E0W	01	100	0111	1000	111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	WO	WO

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

If EL2 is not implemented, or stage 2 translation is disabled, or the instruction is executed at EL3 when the value of SCR_EL3.NS is 0, this instruction executes as AT S1E0W.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.4.3 AT S12E1R, Address Translate Stages 1 and 2 EL1 Read

The AT S12E1R characteristics are:

Purpose

Performs stage 1 and 2 address translation, with permissions as if reading from the given virtual address, using the following translation regime and exception level:

- In Secure state, and in Non-secure state when HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime, accessed from EL1.
- In Non-secure state when HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime, accessed from EL2.

Configurations

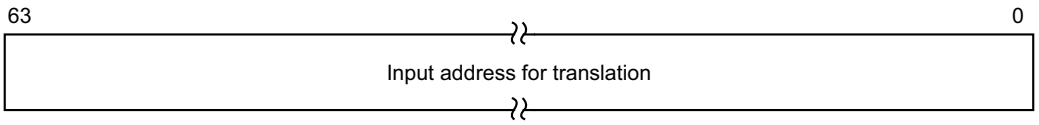
There are no configuration notes.

Attributes

AT S12E1R is a 64-bit System instruction.

Field descriptions

The AT S12E1R input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S12E1R instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S12E1R	01	100	0111	1000	100

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

If EL2 is not implemented, or stage 2 translation is disabled, or the instruction is executed at EL3 when the value of SCR_EL3.NS is 0, this instruction executes as AT S1E1R.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.4.4 AT S12E1W, Address Translate Stages 1 and 2 EL1 Write

The AT S12E1W characteristics are:

Purpose

Performs stage 1 and 2 address translation, with permissions as if writing to the given virtual address, using the following translation regime and exception level:

- In Secure state, and in Non-secure state when HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime, accessed from EL1.
- In Non-secure state when HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime, accessed from EL2.

Configurations

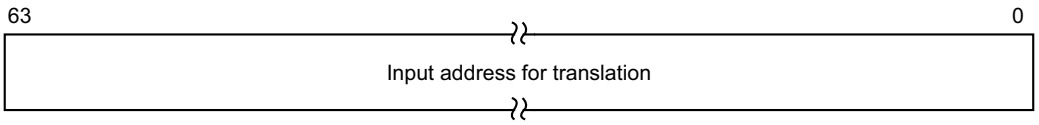
There are no configuration notes.

Attributes

AT S12E1W is a 64-bit System instruction.

Field descriptions

The AT S12E1W input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S12E1W instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S12E1W	01	100	0111	1000	101

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

If EL2 is not implemented, or stage 2 translation is disabled, or the instruction is executed at EL3 when the value of SCR_EL3.NS is 0, this instruction executes as AT S1E1W.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

C5.4.5 AT S1E0R, Address Translate Stage 1 EL0 Read

The AT S1E0R characteristics are:

Purpose

Performs stage 1 address translation from EL0, with permissions as if reading from the given virtual address, using the following translation regime:

- In Secure state, and in Non-secure state when HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime.
- In Non-secure state when HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime.

Configurations

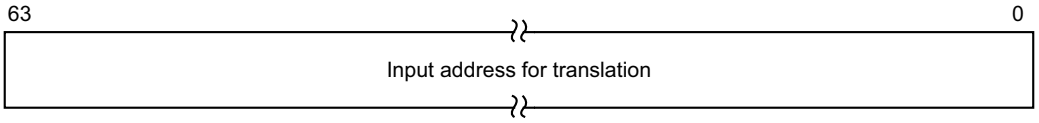
There are no configuration notes.

Attributes

AT S1E0R is a 64-bit System instruction.

Field descriptions

The AT S1E0R input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S1E0R instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S1E0R	01	000	0111	1000	010

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

C5.4.6 AT S1E0W, Address Translate Stage 1 EL0 Write

The AT S1E0W characteristics are:

Purpose

Performs stage 1 address translation from EL0, with permissions as if writing to the given virtual address, using the following translation regime:

- In Secure state, and in Non-secure state when HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime.
- In Non-secure state when HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime.

Configurations

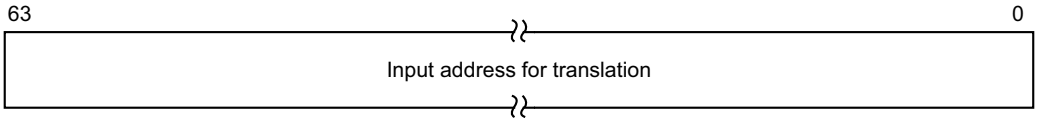
There are no configuration notes.

Attributes

AT S1E0W is a 64-bit System instruction.

Field descriptions

The AT S1E0W input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S1E0W instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S1E0W	01	000	0111	1000	011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO

C5.4.7 AT S1E1R, Address Translate Stage 1 EL1 Read

The AT S1E1R characteristics are:

Purpose

Performs stage 1 address translation, with permissions as if reading from the given virtual address, using the following translation regime and exception level:

- In Secure state, and in Non-secure state when HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime, accessed from EL1.
- In Non-secure state when HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime, accessed from EL2.

Configurations

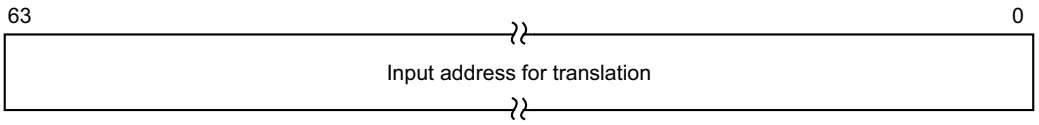
There are no configuration notes.

Attributes

AT S1E1R is a 64-bit System instruction.

Field descriptions

The AT S1E1R input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S1E1R instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S1E1R	01	000	0111	1000	000

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If HCR_EL2.AT==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.4.8 AT S1E1RP, Address Translate Stage 1 EL1 Read PAN

The AT S1E1RP characteristics are:

Purpose

When ARMv8.2-ATS1E1 is implemented, performs a stage 1 address translation, where the value of PSTATE.PAN determines if a read from a location will generate a permission fault for a privileged access, using the following translation regime and exception level:

- In Secure state, and in Non-secure state when HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime, accessed from EL1.
- In Non-secure state when HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime, accessed from EL2.

Configurations

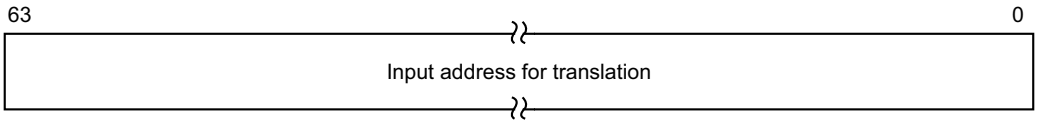
This instruction is introduced in ARMv8.2.

Attributes

AT S1E1RP is a 64-bit System instruction.

Field descriptions

The AT S1E1RP input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S1E1RP instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S1E1RP	01	000	0111	1001	000

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If HCR_EL2.AT==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.4.9 AT S1E1W, Address Translate Stage 1 EL1 Write

The AT S1E1W characteristics are:

Purpose

Performs stage 1 address translation, with permissions as if writing to the given virtual address, using the following translation regime and exception level:

- In Secure state, and in Non-secure state when HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime, accessed from EL1.
- In Non-secure state when HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime, accessed from EL2.

Configurations

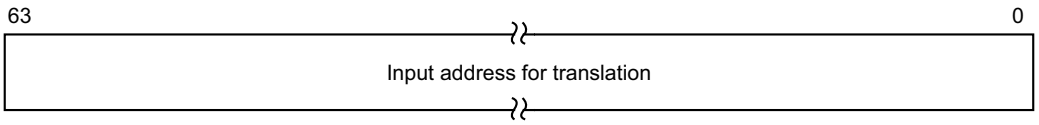
There are no configuration notes.

Attributes

AT S1E1W is a 64-bit System instruction.

Field descriptions

The AT S1E1W input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S1E1W instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S1E1W	01	000	0111	1000	001

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

C5.4.10 AT S1E1WP, Address Translate Stage 1 EL1 Write PAN

The AT S1E1WP characteristics are:

Purpose

When ARMv8.2-ATS1E1 is implemented, performs a stage 1 address translation, where the value of PSTATE.PAN determines if a write to a location will generate a permission fault for a privileged access, using the following translation regime and exception level:

- In Secure state, and in Non-secure state when HCR_EL2.{E2H, TGE} is not {1, 1}, the EL1&0 translation regime, accessed from EL1.
- In Non-secure state when HCR_EL2.{E2H, TGE} is {1, 1}, the EL2&0 translation regime, accessed from EL2.

Configurations

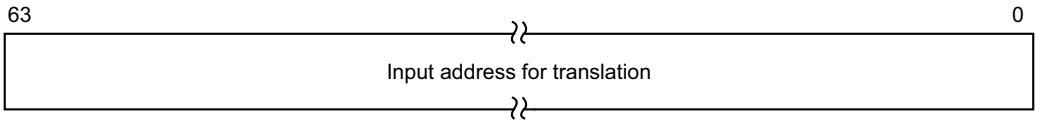
This instruction is introduced in ARMv8.2.

Attributes

AT S1E1WP is a 64-bit System instruction.

Field descriptions

The AT S1E1WP input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S1E1WP instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S1E1WP	01	000	0111	1001	001

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and SCR_EL3.NS == 1:
  - If HCR_EL2.AT==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.4.11 AT S1E2R, Address Translate Stage 1 EL2 Read

The AT S1E2R characteristics are:

Purpose

Performs stage 1 address translation as defined for EL2, with permissions as if reading from the given virtual address.

Configurations

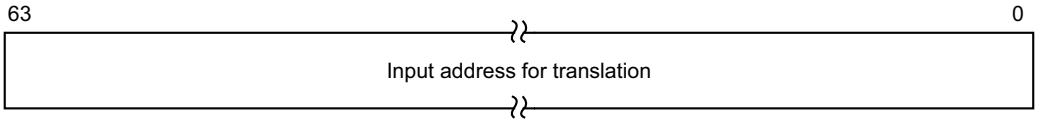
There are no configuration notes.

Attributes

AT S1E2R is a 64-bit System instruction.

Field descriptions

The AT S1E2R input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S1E2R instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S1E2R	01	100	0111	1000	000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

C5.4.12 AT S1E2W, Address Translate Stage 1 EL2 Write

The AT S1E2W characteristics are:

Purpose

Performs stage 1 address translation as defined for EL2, with permissions as if writing to the given virtual address.

Configurations

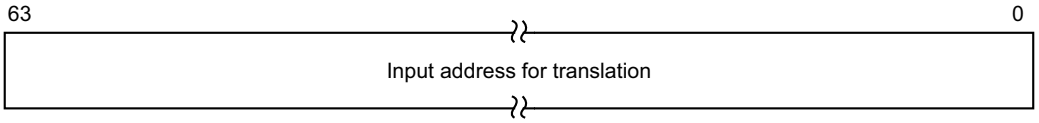
There are no configuration notes.

Attributes

AT S1E2W is a 64-bit System instruction.

Field descriptions

The AT S1E2W input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S1E2W instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S1E2W	01	100	0111	1000	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

C5.4.13 AT S1E3R, Address Translate Stage 1 EL3 Read

The AT S1E3R characteristics are:

Purpose

Performs stage 1 address translation as defined for EL3, with permissions as if reading from the given virtual address.

Configurations

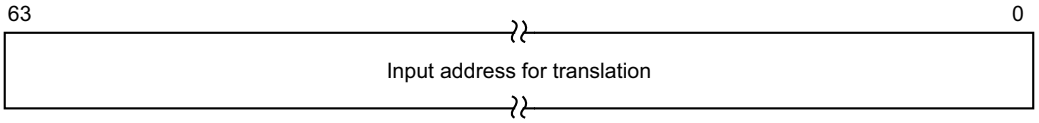
There are no configuration notes.

Attributes

AT S1E3R is a 64-bit System instruction.

Field descriptions

The AT S1E3R input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S1E3R instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S1E3R	01	110	0111	1000	000

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	-	WO
0	1	1	-	n/a	-	WO

C5.4.14 AT S1E3W, Address Translate Stage 1 EL3 Write

The AT S1E3W characteristics are:

Purpose

Performs stage 1 address translation as defined for EL3, with permissions as if writing to the given virtual address.

Configurations

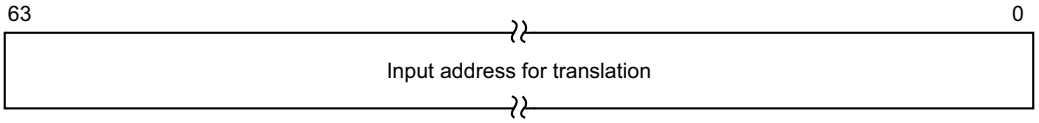
There are no configuration notes.

Attributes

AT S1E3W is a 64-bit System instruction.

Field descriptions

The AT S1E3W input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Executing the AT S1E3W instruction

This instruction is executed using AT with the following syntax:

```
AT <at_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<at_op>	op0	op1	CRn	CRm	op2
S1E3W	01	110	0111	1000	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	-	WO
0	1	1	-	n/a	-	WO

C5.5 A64 System instructions for TLB maintenance

This section lists the A64 System instructions for TLB maintenance.

For more information about these instructions see *TLB maintenance instructions* on page D4-2209. In particular, for the full description of the scope of each instruction see *Scope of the A64 TLB maintenance instructions* on page D4-2212.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.1 TLBI ALLE1, TLB Invalidate All, EL1

The TLBI ALLE1 characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- If SCR_EL3.NS is 0, the entry would be required to translate an address using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, the entry would be required to translate an address using the Non-secure EL1&0 translation regime.

The invalidation applies to entries with any VMID.

The invalidation only applies to the PE that executes this instruction.

Note

For the EL1&0 translation regime, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE1 is a 64-bit System instruction.

Field descriptions

TLBI ALLE1 ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBI ALLE1 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2	Rt
ALLE1	01	100	1000	0111	100	11111

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.2 TLBI ALLE1IS, TLB Invalidate All, EL1, Inner Shareable

The TLBI ALLE1IS characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- If SCR_EL3.NS is 0, the entry would be required to translate an address using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, the entry would be required to translate an address using the Non-secure EL1&0 translation regime.

The invalidation applies to entries with any VMID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Note

For the EL1&0 translation regime, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE1IS is a 64-bit System instruction.

Field descriptions

TLBI ALLE1IS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBI ALLE1IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2	Rt
ALLE1IS	01	100	1000	0011	100	11111

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.3 TLBI ALLE2, TLB Invalidate All, EL2

The TLBI ALLE2 characteristics are:

Purpose

If EL2 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- SCR_EL3.NS is 1.
- The entry would be required to translate an address using the EL2 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE2 is a 64-bit System instruction.

Field descriptions

TLBI ALLE2 ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBI ALLE2 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2	Rt
ALLE2	01	100	1000	0111	000	11111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

If EL2 is not implemented, this instruction is UNDEFINED.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.4 TLBI ALLE2IS, TLB Invalidate All, EL2, Inner Shareable

The TLBI ALLE2IS characteristics are:

Purpose

If EL2 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- SCR_EL3.NS is 1.
- The entry would be required to translate an address using the EL2 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE2IS is a 64-bit System instruction.

Field descriptions

TLBI ALLE2IS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBI ALLE2IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2	Rt
ALLE2IS	01	100	1000	0011	000	11111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

If EL2 is not implemented, this instruction is UNDEFINED.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.5 TLBI ALLE3, TLB Invalidate All, EL3

The TLBI ALLE3 characteristics are:

Purpose

If EL3 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be required to translate an address using the EL3 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE3 is a 64-bit System instruction.

Field descriptions

TLBI ALLE3 ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBI ALLE3 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2	Rt
ALLE3	01	110	1000	0111	000	11111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	-	WO
0	1	1	-	n/a	-	WO
1	0	1	-	-	-	WO
1	1	1	-	n/a	-	WO

C5.5.6 TLBI ALLE3IS, TLB Invalidate All, EL3, Inner Shareable

The TLBI ALLE3IS characteristics are:

Purpose

If EL3 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be required to translate an address using the EL3 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE3IS is a 64-bit System instruction.

Field descriptions

TLBI ALLE3IS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBI ALLE3IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2	Rt
ALLE3IS	01	110	1000	0011	000	11111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	-	WO
0	1	1	-	n/a	-	WO
1	0	1	-	-	-	WO
1	1	1	-	n/a	-	WO

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.7 TLBI ASIDE1, TLB Invalidate by ASID, EL1

The TLBI ASIDE1 characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- If SCR_EL3.NS is 0, the entry would be required to translate an address using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - If EL2 is not implemented, the entry would be required to translate an address using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate an address using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate an address using the EL2&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

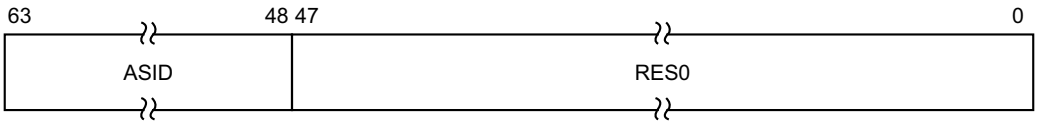
There are no configuration notes.

Attributes

TLBI ASIDE1 is a 64-bit System instruction.

Field descriptions

The TLBI ASIDE1 input value bit assignments are:



ASID, bits [63:48]

ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this operation.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

Bits [47:0]

Reserved, RES0.

Executing the TLBI ASIDE1 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
ASIDE1	01	000	1000	0111	010

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

When HCR_EL2.FB is 1, at Non-secure EL1 this instruction executes as a TLBI ASIDE1IS.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Non-Confidential

C5.5.8 TLBI ASIDE1IS, TLB Invalidate by ASID, EL1, Inner Shareable

The TLBI ASIDE1IS characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used for the specified ASID, and either:
  - Is from a level of lookup above the final level.
  - Is a non-global entry from the final level of lookup.
- If SCR_EL3.NS is 0, the entry would be required to translate an address using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - If EL2 is not implemented, the entry would be required to translate an address using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate an address using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate an address using the EL2&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

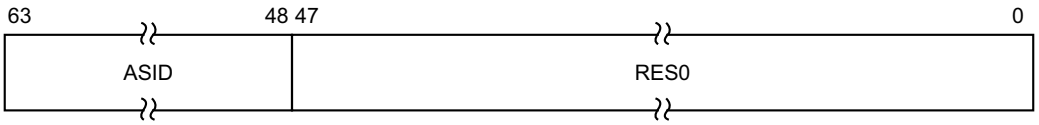
There are no configuration notes.

Attributes

TLBI ASIDE1IS is a 64-bit System instruction.

Field descriptions

The TLBI ASIDE1IS input value bit assignments are:



ASID, bits [63:48]

ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this operation.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

Bits [47:0]

Reserved, RES0.

Executing the TLBI ASIDE1IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
ASIDE1IS	01	000	1000	0011	010

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.9 TLBI IPAS2E1, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1

The TLBI IPAS2E1 characteristics are:

Purpose

If EL2 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- SCR_EL3.NS is 1.
- The entry would be used with the current VMID.
- The entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation only applies to the PE that executes this instruction.

For more information about the architectural requirements for this instruction see *Invalidation of TLB entries from stage 2 translations* on page D4-2216.

Configurations

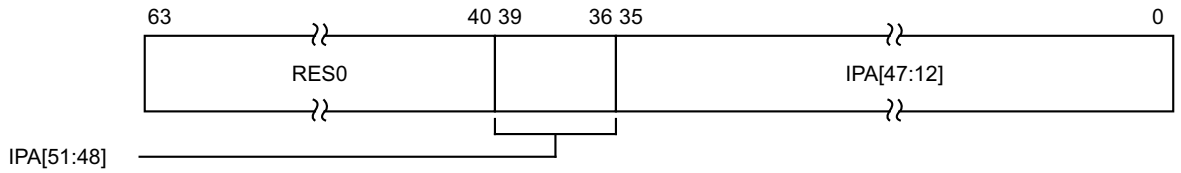
There are no configuration notes.

Attributes

TLBI IPAS2E1 is a 64-bit System instruction.

Field descriptions

The TLBI IPAS2E1 input value bit assignments are:



Bits [63:40]

Reserved, RES0.

IPA[51:48], bits [39:36]

In ARMv8.3 and ARMv8.2

Extension to IPA[47:12]. See IPA[47:12] for more details.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match.

When ARMv8.2-LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

Executing the TLBI IPAS2E1 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
IPAS2E1	01	100	1000	0100	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, or SCR_EL3.NS is 0, this instruction is a NOP.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.5.10 TLBI IPAS2E1IS, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable

The TLBI IPAS2E1IS characteristics are:

Purpose

If EL2 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from any level of the translation table walk.
- SCR_EL3.NS is 1.
- The entry would be used with the current VMID.
- The entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

For more information about the architectural requirements for this instruction see *Invalidation of TLB entries from stage 2 translations* on page D4-2216.

Configurations

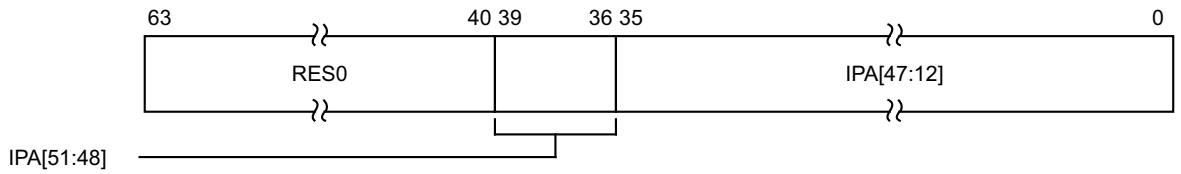
There are no configuration notes.

Attributes

TLBI IPAS2E1IS is a 64-bit System instruction.

Field descriptions

The TLBI IPAS2E1IS input value bit assignments are:



Bits [63:40]

Reserved, RES0.

IPA[51:48], bits [39:36]

In ARMv8.3 and ARMv8.2

Extension to IPA[47:12]. See IPA[47:12] for more details.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match.

When ARMv8.2-LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

Executing the TLBI IPAS2E1IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
IPAS2E1IS	01	100	1000	0000	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, or SCR_EL3.NS is 0, this instruction is a NOP.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

C5.5.11 TLBI IPAS2LE1, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1

The TLBI IPAS2LE1 characteristics are:

Purpose

If EL2 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- SCR_EL3.NS is 1.
- The entry would be used with the current VMID.
- The entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation only applies to the PE that executes this instruction.

For more information about the architectural requirements for this instruction see *Invalidation of TLB entries from stage 2 translations* on page D4-2216.

Configurations

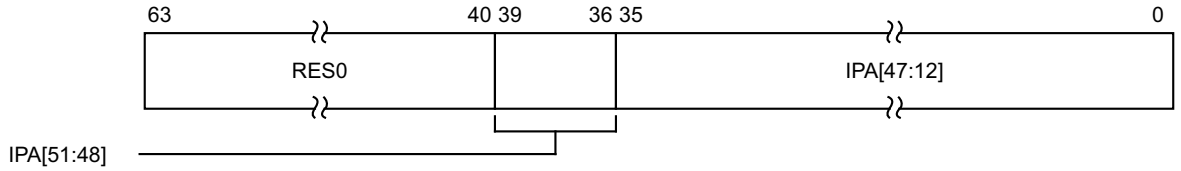
There are no configuration notes.

Attributes

TLBI IPAS2LE1 is a 64-bit System instruction.

Field descriptions

The TLBI IPAS2LE1 input value bit assignments are:



Bits [63:40]

Reserved, RES0.

IPA[51:48], bits [39:36]

In ARMv8.3 and ARMv8.2

Extension to IPA[47:12]. See IPA[47:12] for more details.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match.

When ARMv8.2-LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

Executing the TLBI IPAS2LE1 instruction

This instruction is executed using TLBI with the following syntax:

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
TLBI <tlbi_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
IPAS2LE1	01	100	1000	0100	101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, or SCR_EL3.NS is 0, this instruction is a NOP.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.12 TLBI IPAS2LE1IS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Inner Shareable

The TLBI IPAS2LE1IS characteristics are:

Purpose

If EL2 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 2 only translation table entry, from the final level of the translation table walk.
- SCR_EL3.NS is 1.
- The entry would be used with the current VMID.
- The entry would be required to translate the specified IPA using the Non-secure EL1&0 translation regime.

The invalidation is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

For more information about the architectural requirements for this instruction see *Invalidation of TLB entries from stage 2 translations* on page D4-2216.

Configurations

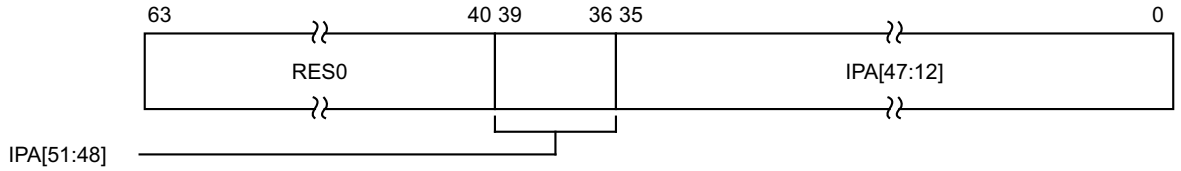
There are no configuration notes.

Attributes

TLBI IPAS2LE1IS is a 64-bit System instruction.

Field descriptions

The TLBI IPAS2LE1IS input value bit assignments are:



Bits [63:40]

Reserved, RES0.

IPA[51:48], bits [39:36]

In ARMv8.3 and ARMv8.2

Extension to IPA[47:12]. See IPA[47:12] for more details.

In ARMv8.1 and ARMv8.0.

Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match.

When ARMv8.2-LPA is implemented, and 52-bit addresses and a 64KB translation granule are in use, IPA[51:48] form the upper part of the address value. Otherwise, IPA[51:48] are RES0.

Non-Confidential

Executing the TLBI IPAS2LE1IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
IPAS2LE1IS	01	100	1000	0000	101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
x	0	1	-	-	WO	WO
x	1	1	-	n/a	WO	WO

If EL2 is not implemented, or SCR_EL3.NS is 0, this instruction is a NOP.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.13 TLBI VAAE1, TLB Invalidate by VA, All ASID, EL1

The TLBI VAAE1 characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified address.
- If SCR_EL3.NS is 0, the entry would be required to translate using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - If EL2 is not implemented, the entry would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate using the EL2&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

Note

For the EL1&0 translation regime, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

Configurations

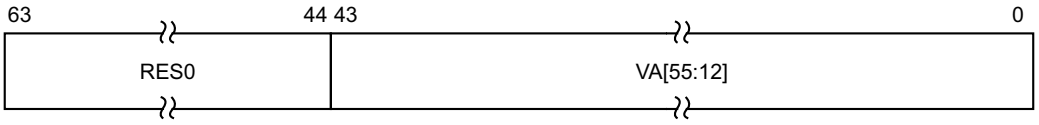
There are no configuration notes.

Attributes

TLBI VAAE1 is a 64-bit System instruction.

Field descriptions

The TLBI VAAE1 input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this operation, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VAAE1 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VAAE1	01	000	1000	0111	011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

When HCR_EL2.FB is 1, at Non-secure EL1 this instruction executes as a TLBI VAAE1IS.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.14 TLBI VAAE1IS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable

The TLBI VAAE1IS characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified address.
- If SCR_EL3.NS is 0, the entry would be required to translate using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - If EL2 is not implemented, the entry would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate using the EL2&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Note

For the EL1&0 translation regime, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

Configurations

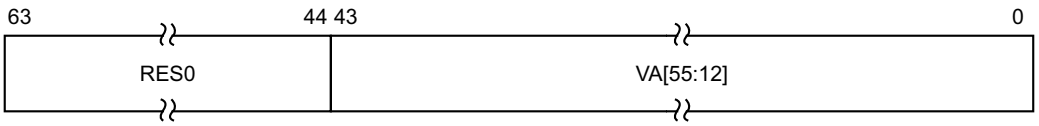
There are no configuration notes.

Attributes

TLBI VAAE1IS is a 64-bit System instruction.

Field descriptions

The TLBI VAAE1IS input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this operation, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VAAE1IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VAAE1IS	01	000	1000	0011	011

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Non-Confidential

C5.5.15 TLBI VAALE1, TLB Invalidate by VA, All ASID, Last level, EL1

The TLBI VAALE1 characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified address.
- If SCR_EL3.NS is 0, the entry would be required to translate using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - If EL2 is not implemented, the entry would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate using the EL2&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

Note

For the EL1&0 translation regime, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

Configurations

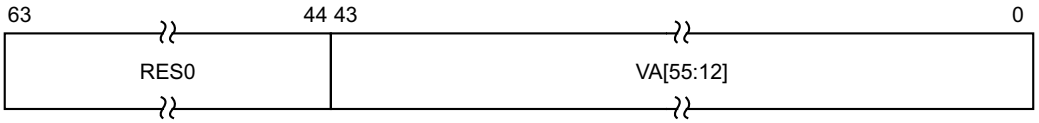
There are no configuration notes.

Attributes

TLBI VAALE1 is a 64-bit System instruction.

Field descriptions

The TLBI VAALE1 input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this operation, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VAALE1 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VAALE1	01	000	1000	0111	111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

When HCR_EL2.FB is 1, at Non-secure EL1 this instruction executes as a TLBI VAALE1IS.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.5.16 TLBI VAALE1IS, TLB Invalidate by VA, All ASID, Last Level, EL1, Inner Shareable

The TLBI VAALE1IS characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified address.
- If SCR_EL3.NS is 0, the entry would be required to translate using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - If EL2 is not implemented, the entry would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate using the EL2&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Note

For the EL1&0 translation regime, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

Configurations

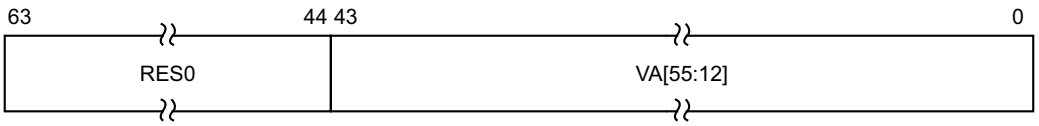
There are no configuration notes.

Attributes

TLBI VAALE1IS is a 64-bit System instruction.

Field descriptions

The TLBI VAALE1IS input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this operation, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VAALE1IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VAALE1IS	01	000	1000	0011	111

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.5.17 TLBI VAE1, TLB Invalidate by VA, EL1

The TLBI VAE1 characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If SCR_EL3.NS is 0, the entry would be required to translate using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - If EL2 is not implemented, the entry would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate using the EL2&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

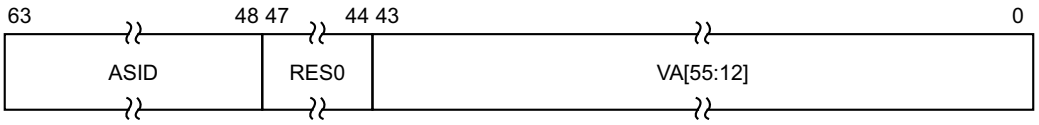
There are no configuration notes.

Attributes

TLBI VAE1 is a 64-bit System instruction.

Field descriptions

The TLBI VAE1 input value bit assignments are:



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

Bits [47:44]

Reserved, RES0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VAE1 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VAE1	01	000	1000	0111	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

When HCR_EL2.FB is 1, at Non-secure EL1 this instruction executes as a TLBI VAE1IS.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.5.18 TLBI VAE1IS, TLB Invalidate by VA, EL1, Inner Shareable

The TLBI VAE1IS characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is from a level of lookup above the final level and matches the specified ASID.
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If SCR_EL3.NS is 0, the entry would be required to translate using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - If EL2 is not implemented, the entry would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate using the EL2&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

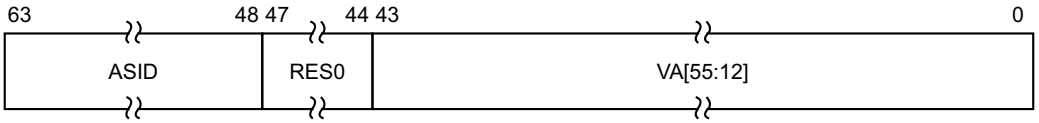
There are no configuration notes.

Attributes

TLBI VAE1IS is a 64-bit System instruction.

Field descriptions

The TLBI VAE1IS input value bit assignments are:



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

Bits [47:44]

Reserved, RES0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VAE1IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VAE1IS	01	000	1000	0011	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.19 TLBI VAE2, TLB Invalidate by VA, EL2

The TLBI VAE2 characteristics are:

Purpose

If EL2 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified address.
- SCR_EL3.NS is 1.
- The entry would be required to translate using the EL2 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

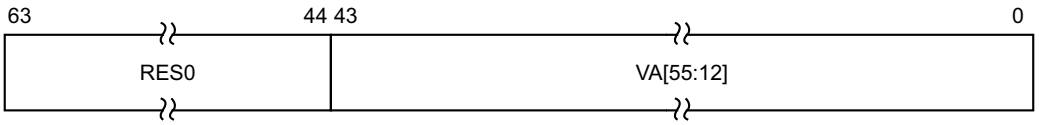
There are no configuration notes.

Attributes

TLBI VAE2 is a 64-bit System instruction.

Field descriptions

The TLBI VAE2 input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VAE2 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VAE2	01	100	1000	0111	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

If EL2 is not implemented, or SCR_EL3.NS is 0, this instruction is UNDEFINED.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Non-Confidential

C5.5.20 TLBI VAE2IS, TLB Invalidate by VA, EL2, Inner Shareable

The TLBI VAE2IS characteristics are:

Purpose

If EL2 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified address.
- SCR_EL3.NS is 1.
- The entry would be required to translate using the EL2 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

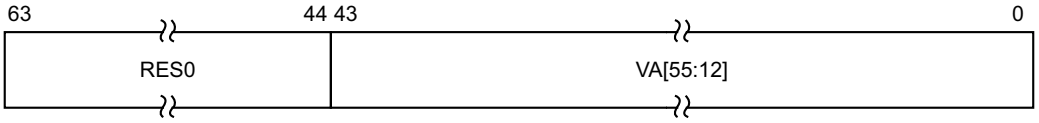
There are no configuration notes.

Attributes

TLBI VAE2IS is a 64-bit System instruction.

Field descriptions

The TLBI VAE2IS input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VAE2IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VAE2IS	01	100	1000	0011	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

If EL2 is not implemented, or SCR_EL3.NS is 0, this instruction is UNDEFINED.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.5.21 TLBI VAE3, TLB Invalidate by VA, EL3

The TLBI VAE3 characteristics are:

Purpose

If EL3 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified address.
- The entry would be required to translate using the EL3 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

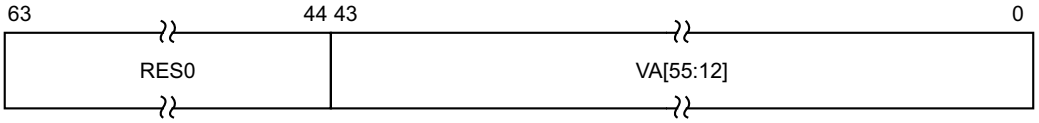
There are no configuration notes.

Attributes

TLBI VAE3 is a 64-bit System instruction.

Field descriptions

The TLBI VAE3 input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VAE3 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VAE3	01	110	1000	0111	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	-	WO
0	1	1	-	n/a	-	WO
1	0	1	-	-	-	WO
1	1	1	-	n/a	-	WO

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.22 TLBI VAE3IS, TLB Invalidate by VA, EL3, Inner Shareable

The TLBI VAE3IS characteristics are:

Purpose

If EL3 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- The entry would be used to translate the specified address.
- The entry would be required to translate using the EL3 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

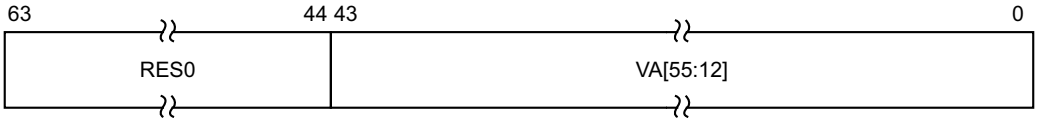
There are no configuration notes.

Attributes

TLBI VAE3IS is a 64-bit System instruction.

Field descriptions

The TLBI VAE3IS input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VAE3IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VAE3IS	01	110	1000	0011	001

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	-	WO
0	1	1	-	n/a	-	WO
1	0	1	-	-	-	WO
1	1	1	-	n/a	-	WO

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C5.5.23 TLBI VALE1, TLB Invalidate by VA, Last level, EL1

The TLBI VALE1 characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If SCR_EL3.NS is 0, the entry would be required to translate using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - If EL2 is not implemented, the entry would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate using the EL2&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

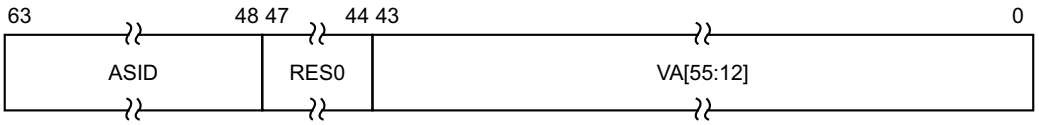
There are no configuration notes.

Attributes

TLBI VALE1 is a 64-bit System instruction.

Field descriptions

The TLBI VALE1 input value bit assignments are:



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

Bits [47:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VALE1 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VALE1	01	000	1000	0111	101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

When HCR_EL2.FB is 1, at Non-secure EL1 this instruction executes as a TLBI VALE1IS.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.5.24 TLBI VALE1IS, TLB Invalidate by VA, Last level, EL1, Inner Shareable

The TLBI VALE1IS characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry.
- The entry would be used to translate the specified address, and one of the following applies:
  - The entry is a global entry from the final level of lookup.
  - The entry is a non-global entry from the final level of lookup that matches the specified ASID.
- If SCR_EL3.NS is 0, the entry would be required to translate using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - If EL2 is not implemented, the entry would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate using the EL2&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

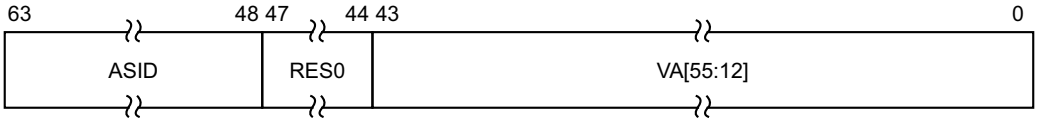
There are no configuration notes.

Attributes

TLBI VALE1IS is a 64-bit System instruction.

Field descriptions

The TLBI VALE1IS input value bit assignments are:



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are RES0.

Bits [47:44]

Reserved, RES0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VALE1IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VALE1IS	01	000	1000	0011	101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Non-Confidential

C5.5.25 TLBI VALE2, TLB Invalidate by VA, Last level, EL2

The TLBI VALE2 characteristics are:

Purpose

If EL2 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified address.
- SCR_EL3.NS is 1.
- The entry would be required to translate using the EL2 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

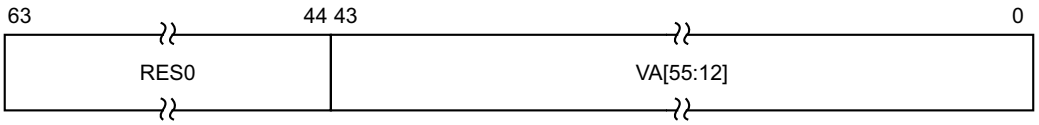
There are no configuration notes.

Attributes

TLBI VALE2 is a 64-bit System instruction.

Field descriptions

The TLBI VALE2 input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VALE2 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VALE2	01	100	1000	0111	101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

If EL2 is not implemented, or SCR_EL3.NS is 0, this instruction is UNDEFINED.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Non-Confidential

C5.5.26 TLBI VALE2IS, TLB Invalidate by VA, Last level, EL2, Inner Shareable

The TLBI VALE2IS characteristics are:

Purpose

If EL2 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified address.
- SCR_EL3.NS is 1.
- The entry would be required to translate using the EL2 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

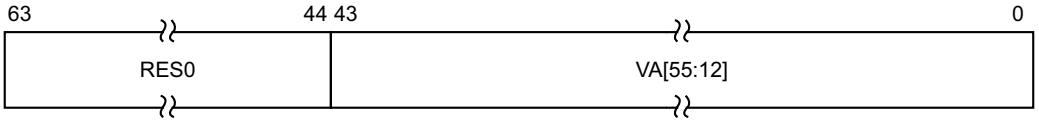
There are no configuration notes.

Attributes

TLBI VALE2IS is a 64-bit System instruction.

Field descriptions

The TLBI VALE2IS input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VALE2IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VALE2IS	01	100	1000	0011	101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	-
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

If EL2 is not implemented, or SCR_EL3.NS is 0, this instruction is UNDEFINED.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.5.27 TLBI VALE3, TLB Invalidate by VA, Last level, EL3

The TLBI VALE3 characteristics are:

Purpose

If EL3 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified address.
- The entry would be required to translate using the EL3 translation regime.

The invalidation only applies to the PE that executes this instruction.

Configurations

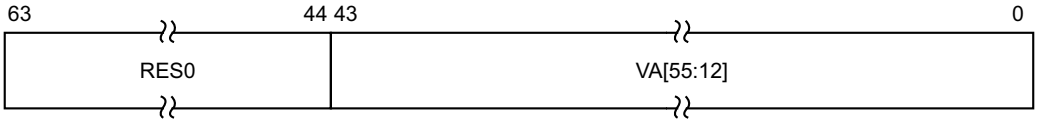
There are no configuration notes.

Attributes

TLBI VALE3 is a 64-bit System instruction.

Field descriptions

The TLBI VALE3 input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VALE3 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VALE3	01	110	1000	0111	101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	-	WO
0	1	1	-	n/a	-	WO
1	0	1	-	-	-	WO
1	1	1	-	n/a	-	WO

C5.5.28 TLBI VALE3IS, TLB Invalidate by VA, Last level, EL3, Inner Shareable

The TLBI VALE3IS characteristics are:

Purpose

If EL3 is implemented, invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from the final level of the translation table walk.
- The entry would be used to translate the specified address.
- The entry would be required to translate using the EL3 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Configurations

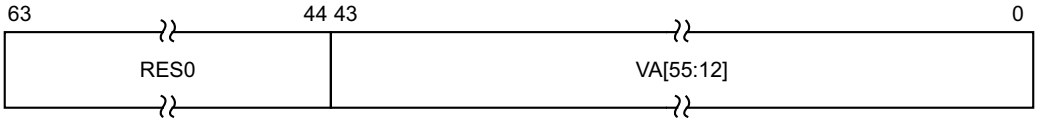
There are no configuration notes.

Attributes

TLBI VALE3IS is a 64-bit System instruction.

Field descriptions

The TLBI VALE3IS input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Executing the TLBI VALE3IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>, <Xt>
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2
VALE3IS	01	110	1000	0011	101

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	-	WO
0	1	1	-	n/a	-	WO
1	0	1	-	-	-	WO
1	1	1	-	n/a	-	WO

C5.5.29 TLBI VMALLE1, TLB Invalidate by VMID, All at stage 1, EL1

The TLBI VMALLE1 characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- If SCR_EL3.NS is 0, the entry would be required to translate an address using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - If EL2 is not implemented, the entry would be required to translate an address using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate an address using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate an address using the EL2&0 translation regime.

The invalidation only applies to the PE that executes this instruction.

Note

For the EL1&0 translation regime, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

Configurations

There are no configuration notes.

Attributes

TLBI VMALLE1 is a 64-bit System instruction.

Field descriptions

TLBI VMALLE1 ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBI VMALLE1 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2	Rt
VMALLE1	01	000	1000	0111	000	11111

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

When HCR_EL2.FB is 1, at Non-secure EL1 this instruction executes as a TLBI VMALLE1IS.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.5.30 TLBI VMALLE1IS, TLB Invalidate by VMID, All at stage 1, EL1, Inner Shareable

The TLBI VMALLE1IS characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 translation table entry, from any level of the translation table walk.
- If SCR_EL3.NS is 0, the entry would be required to translate an address using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - If EL2 is not implemented, the entry would be required to translate an address using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is not {1, 1}, the entry would be used with the current VMID, and would be required to translate an address using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented and HCR_EL2.{E2H, TGE} is {1, 1}, the entry would be required to translate an address using the EL2&0 translation regime.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Note

For the EL1&0 translation regime, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

Configurations

There are no configuration notes.

Attributes

TLBI VMALLE1IS is a 64-bit System instruction.

Field descriptions

TLBI VMALLE1IS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBI VMALLE1IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2	Rt
VMALLE1IS	01	000	1000	0011	000	11111

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	WO	n/a	WO
0	0	1	-	WO	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	WO	WO	WO
1	1	1	-	n/a	WO	WO

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.TTLB==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Non-Confidential

C5.5.31 TLBI VMALLS12E1, TLB Invalidate by VMID, All at Stage 1 and 2, EL1

The TLBI VMALLS12E1 characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- If SCR_EL3.NS is 0, the entry would be required to translate an address using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - The entry would be required to translate an address using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented, the entry would be used with the current VMID.

The invalidation only applies to the PE that executes this instruction.

Note

For the EL1&0 translation regime, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

Configurations

There are no configuration notes.

Attributes

TLBI VMALLS12E1 is a 64-bit System instruction.

Field descriptions

TLBI VMALLS12E1 ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBI VMALLS12E1 instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2	Rt
VMALLS12E1	01	100	1000	0111	110	11111

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

If SCR_EL3.NS==0, or EL2 is not implemented, this instruction executes as a TLBI VMALLE1.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

C5.5.32 TLBI VMALLS12E1IS, TLB Invalidate by VMID, All at Stage 1 and 2, EL1, Inner Shareable

The TLBI VMALLS12E1IS characteristics are:

Purpose

Invalidate cached copies of translation table entries from TLBs that meet all the following requirements:

- The entry is a stage 1 or stage 2 translation table entry, from any level of the translation table walk.
- If SCR_EL3.NS is 0, the entry would be required to translate an address using the Secure EL1&0 translation regime.
- If SCR_EL3.NS is 1, then:
  - The entry would be required to translate an address using the Non-secure EL1&0 translation regime.
  - If EL2 is implemented, the entry would be used with the current VMID.

The invalidation applies to all PEs in the same Inner Shareable shareability domain as the PE that executes this instructions.

Note

For the EL1&0 translation regime, the invalidation applies to both:

- Global entries.
- Non-global entries with any ASID.

Configurations

There are no configuration notes.

Attributes

TLBI VMALLS12E1IS is a 64-bit System instruction.

Field descriptions

TLBI VMALLS12E1IS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the TLBI VMALLS12E1IS instruction

This instruction is executed using TLBI with the following syntax:

```
TLBI <tlbi_op>
```

This syntax uses the following encoding in the System instruction encoding space:

<tlbi_op>	op0	op1	CRn	CRm	op2	Rt
VMALLS12E1IS	01	100	1000	0011	110	11111

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

Accessibility

The instruction is executable as follows:

Control			Accessibility			
E2H	TGE	NS	EL0	EL1	EL2	EL3
x	x	0	-	-	n/a	WO
0	0	1	-	-	WO	WO
0	1	1	-	n/a	WO	WO
1	0	1	-	-	WO	WO
1	1	1	-	n/a	WO	WO

If SCR_EL3.NS==0, or EL2 is not implemented, this instruction executes as a TLBI VMALLE1IS.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1895. Subject to the prioritization rules:

- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- When EL2 is implemented and is using AArch64 and (SCR_EL3.NS == 1) && (HCR_EL2.E2H == 1) && (HCR_EL2.TGE == 0):
  - If HCR_EL2.NV==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Chapter C6
A64 Base Instruction Descriptions

This chapter describes the A64 base instructions.

It contains the following sections:

- *About the A64 base instructions* on page C6-524.
- *Alphabetical list of A64 base instructions* on page C6-526.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.1 About the A64 base instructions

Alphabetical list of A64 base instructions on page C6-526 gives full descriptions of the A64 instructions that are in the following instruction groups:

- Branch, Exception generation, and system instructions.
- Loads and stores associated with the general-purpose registers.
- Data processing (immediate).
- Data processing (register).

A64 instruction set encoding on page C4-224 provides an overview of the instruction encodings as well as of the instruction classes within their functional groups.

The rest of this section is general description of the base instructions. It contains the following subsections:

- *Register size*.
- *Use of the PC*.
- *Use of the stack pointer* on page C6-525.
- *Condition flags and related instructions* on page C6-525.

C6.1.1 Register size

Most data processing, comparison, and conversion instructions that use the general-purpose registers as the source or destination operand have two instruction variants that operate on either a 32-bit or a 64-bit value.

Where a 32-bit instruction form is selected, the following holds:

- The upper 32 bits of the source registers are ignored.
- The upper 32 bits of the destination register are set to zero.
- Right shifts and right rotates inject at bit[31], not at bit[63].
- The Condition flags, where set by the instruction, are computed from the lower 32 bits.

This distinction applies even when the results of a 32-bit instruction form are indistinguishable from the lower 32 bits computed by the equivalent 64-bit instruction form. For example, a 32-bit bitwise `ORR` could be performed using a 64-bit `ORR` and simply ignoring the top 32 bits of the result. However, the A64 instruction set includes separate 32-bit and 64-bit forms of the `ORR` instruction.

As well as distinct sign-extend or zero-extend instructions, the A64 instruction set also provides the ability to extend and shift the final source register of an `ADD`, `SUB`, `ADDS`, `or SUBS` instruction and the index register of a Load/Store instruction. This enables array index calculations involving a 64-bit array pointer and a 32-bit array index to be implemented efficiently.

The assembly language notation enables the distinct identification of registers holding 32-bit values and registers holding 64-bit values. See *Register names* on page C1-145 and *Register indexed addressing* on page C1-149.

C6.1.2 Use of the PC

A64 instructions have limited access to the PC. The only instructions that can read the PC are those that generate a PC relative address:

- ADR and ADRP.
- The Load register (literal) instruction class.
- Direct branches that use an immediate offset.
- The unconditional branch with link instructions, BL and BLR, that use the PC to create the return link address.

Only explicit control flow instructions can modify the PC:

- Conditional and unconditional branch and return instructions.
- Exception generation and exception return instructions.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

For more details of instructions that can modify the PC, see *Branches, Exception generating, and System instructions* on page C3-162.

C6.1.3 Use of the stack pointer

A64 instructions can use the stack pointer only in a limited number of cases:

- Load/Store instructions use the current stack pointer as the base address:
  - When stack alignment checking is enabled by system software and the base register is SP, the current stack pointer must be initially quadword aligned, That is, it must be aligned to 16 bytes. Misalignment generates an SP alignment fault. See *SP alignment checking* on page D1-1868 for more information.
- Add and subtract data processing instructions in their immediate and extended register forms, use the current stack pointer as a source register or the destination register or both.
- Logical data processing instructions in their immediate form use the current stack pointer as the destination register.

C6.1.4 Condition flags and related instructions

The A64 base instructions that use the Condition flags as an input are:

- Conditional branch. The conditional branch instruction is `B.cond`.
- Add or subtract with carry. These instruction types include instructions to perform multi-precision arithmetic and calculate checksums. The add or subtract with carry instructions are `ADC`, `ADCS`, `SBC`, and `SBCS`, or an architectural alias for these instructions.
- Conditional select with increment, negate, or invert.This instruction type conditionally selects between one source register and a second, incremented, negated, inverted, or unmodified source register. The conditional select with increment, negate, or invert instructions are `CSINC`, `CSINV`, and `CSNEG`.

  These instructions also implement:
  - Conditional select or move. The Condition flags select one of two source registers as the destination register. Short conditional sequences can be replaced by unconditional instructions followed by a conditional select, `CSEL`.
  - Conditional set. Conditionally selects between 0 and 1, or 0 and -1. This can be used to convert the Condition flags to a Boolean value or mask in a general-purpose register, for example. These instructions include `CSET` and `CSETM`.
- Conditional compare. This instruction type sets the Condition flags to the result of a comparison if the original condition is true, otherwise it sets the Condition flags to an immediate value. It permits the flattening of nested conditional expressions without using conditional branches or performing Boolean arithmetic within the general-purpose registers.The conditional compare instructions are `CCMP` and `CCMN`.

The A64 base instructions that update the Condition flags as an output are:

- Flag-setting data processing instructions, such as `ADCS`, `ADDS`, `ANDS`, `BICS`, `SBCS`, and `SUBS`, and the aliases `CMN`, `CMP`, and `TST`.
- Conditional compare instructions such as `CCMN`, `CCMP`.

The flags can be directly accessed for a read/write using the *NZCV, Condition Flags* on page C5-360.

The A64 base instructions also include conditional branch instructions that do not use the Condition flags as an input:

- Compare and branch if a register is zero or nonzero, `CBZ` and `CBNZ`.
- Test a single bit in a register and branch if the bit is zero or nonzero, `TBZ` and `TBNZ`.

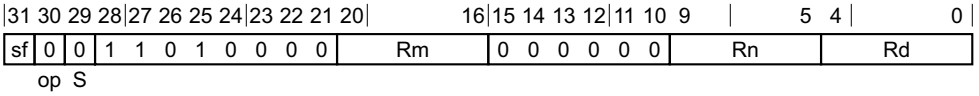
C6.2.1 ADC

Add with Carry adds two register values and the Carry flag value, and writes the result to the destination register.



32-bit variant

Applies when `sf == 0`.

```
ADC <Wd>, <Wn>, <Wm>
```

64-bit variant

Applies when `sf == 1`.

```
ADC <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

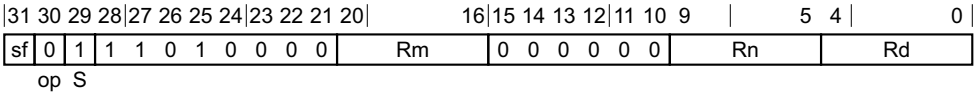
(result, -) = AddWithCarry(operand1, operand2, PSTATE.C);

X[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.2 ADCS

Add with Carry, setting flags, adds two register values and the Carry flag value, and writes the result to the destination register. It updates the condition flags based on the result.



32-bit variant

Applies when `sf == 0`.

```
ADCS <Wd>, <Wn>, <Wm>
```

64-bit variant

Applies when `sf == 1`.

```
ADCS <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);

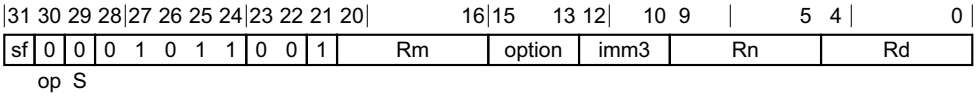
PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.3 ADD (extended register)

Add (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.



32-bit variant

Applies when sf == 0.

```
ADD <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

64-bit variant

Applies when sf == 1.

```
ADD <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then ReservedValue();
```

Assembler symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in the "option" field. It can have the following values:

W	when option = 00x
W	when option = 010
X	when option = x11
W	when option = 10x
W	when option = 110

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB when option = 000

UXTH when option = 001

LSL|UXTW when option = 010

UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB when option = 000

UXTH when option = 001

UXTW when option = 010

LSL|UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);

(result, -) = AddWithCarry(operand1, operand2, '0');

if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

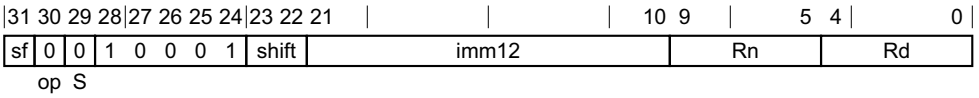
Non-Confidential

C6.2.4 ADD (immediate)

Add (immediate) adds a register value and an optionally-shifted immediate value, and writes the result to the destination register.

This instruction is used by the alias MOV (to/from SP). See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
ADD <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

64-bit variant

Applies when `sf == 1`.

```
ADD <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;

case shift of
    when '00' imm = ZeroExtend(imm12, datasize);
    when '01' imm = ZeroExtend(imm12:Zeros(12), datasize);
    when '1x' ReservedValue();
```

Alias conditions

Alias	is preferred when
MOV (to/from SP)	`shift == '00' && imm12 == '000000000000' && (Rd == '11111' || Rn == '11111')`

Assembler symbols

`<Wd|WSP>`	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
`<Wn|WSP>`	Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
`<Xd|SP>`	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
`<Xn|SP>`	Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
`<imm>`	Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "shift" field. It can have the following values:

LSL #0 when shift = 00

LSL #12 when shift = 01

The encoding shift = 1x is reserved.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];

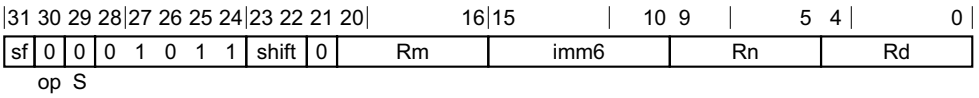
(result, -) = AddWithCarry(operand1, imm, '0');

if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.5 ADD (shifted register)

Add (shifted register) adds a register value and an optionally-shifted register value, and writes the result to the destination register.



32-bit variant

Applies when `sf == 0`.

```
ADD <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant

Applies when `sf == 1`.

```
ADD <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

if shift == '11' then ReservedValue();
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

`LSL` when `shift = 00`

`LSR` when `shift = 01`

`ASR` when `shift = 10`

The encoding `shift = 11` is reserved.

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Non-Confidential

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

(result, -) = AddWithCarry(operand1, operand2, '0');

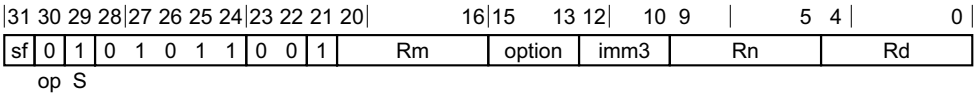
X[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.6 ADDS (extended register)

Add (extended register), setting flags, adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMN (extended register). See Alias conditions for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
ADDS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

64-bit variant

Applies when `sf == 1`.

```
ADDS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then ReservedValue();
```

Alias conditions

Alias	is preferred when
CMN (extended register)	`Rd == '11111'`

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in the "option" field. It can have the following values:

`W` when `option = 00x`

`W` when `option = 010`

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

X	when option = x11
W	when option = 10x
W	when option = 110

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB	when option = 000
UXTH	when option = 001
LSL|UXTW	when option = 010
UXTX	when option = 011
SXTB	when option = 100
SXTH	when option = 101
SXTW	when option = 110
SXTX	when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB	when option = 000
UXTH	when option = 001
UXTW	when option = 010
LSL|UXTX	when option = 011
SXTB	when option = 100
SXTH	when option = 101
SXTW	when option = 110
SXTX	when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '0');

PSTATE.<N,Z,C,V> = nzcv;

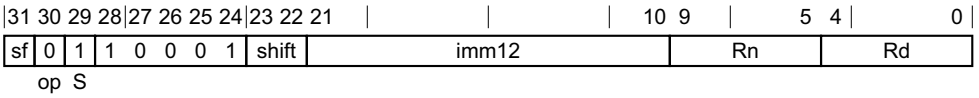
X[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.7 ADDS (immediate)

Add (immediate), setting flags, adds a register value and an optionally-shifted immediate value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMN (immediate). See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
ADDS <Wd>, <Wn|WSP>, #<imm>{, <shift>}
```

64-bit variant

Applies when `sf == 1`.

```
ADDS <Xd>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;

case shift of
    when '00' imm = ZeroExtend(imm12, datasize);
    when '01' imm = ZeroExtend(imm12:Zeros(12), datasize);
    when '1x' ReservedValue();
```

Alias conditions

Alias	is preferred when
CMN (immediate)	`Rd == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

`<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "shift" field. It can have the following values:

`LSL #0` when `shift = 00`

`LSL #12` when `shift = 01`

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

The encoding `shift = 1x` is reserved.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, imm, '0');

PSTATE.<N,Z,C,V> = nzcv;

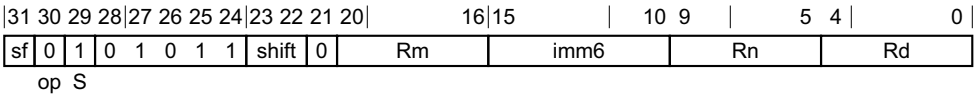
X[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.8 ADDS (shifted register)

Add (shifted register), setting flags, adds a register value and an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMN (shifted register). See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
ADDS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant

Applies when `sf == 1`.

```
ADDS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

if shift == '11' then ReservedValue();
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Alias conditions

Alias	is preferred when
CMN (shifted register)	`Rd == '11111'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

LSL when shift = 00

LSR when shift = 01

ASR when shift = 10

The encoding shift = 11 is reserved.

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '0');

PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

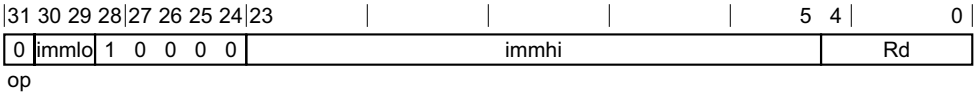
Non-Confidential

C6.2.9 ADR

Form PC-relative address adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.



Literal variant

```
ADR <Xd>, <label>
```

Decode for this encoding

```
integer d = UInt(Rd);
bits(64) imm;

imm = SignExtend(immhi:immlo, 64);
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<label> Is the program label whose address is to be calculated. Its offset from the address of this instruction, in the range +/-1MB, is encoded in "immhi:immlo".

Operation

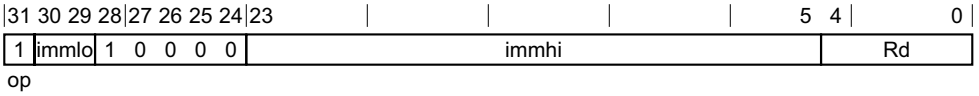
```
bits(64) base = PC[];

X[d] = base + imm;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.10 ADRP

Form PC-relative address to 4KB page adds an immediate value that is shifted left by 12 bits, to the PC value to form a PC-relative address, with the bottom 12 bits masked out, and writes the result to the destination register.



Literal variant

```
ADRP <Xd>, <label>
```

Decode for this encoding

```
integer d = UInt(Rd);
bits(64) imm;

imm = SignExtend(immhi:immlo:Zeros(12), 64);
```

Assembler symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<label>	Is the program label whose 4KB page address is to be calculated. Its offset from the page address of this instruction, in the range +/-4GB, is encoded as "immhi:immlo" times 4096.

Operation

```
bits(64) base = PC[];

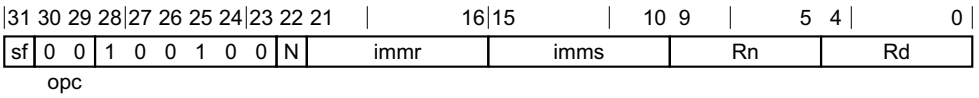
base<11:0> = Zeros(12);

X[d] = base + imm;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.11 AND (immediate)

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.



32-bit variant

Applies when `sf == 0 && N == 0`.

```
AND <Wd|WSP>, <Wn>, #<imm>
```

64-bit variant

Applies when `sf == 1`.

```
AND <Xd|SP>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;
if sf == '0' && N != '0' then ReservedValue();
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

Assembler symbols

`<Wd|WSP>`	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd|SP>`	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<imm>`	For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr". For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];

result = operand1 AND imm;
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

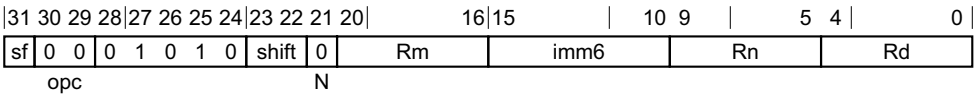
Non-Confidential

C6.2.12 AND (shifted register)

Bitwise AND (shifted register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.



32-bit variant

Applies when `sf == 0`.

```
AND <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant

Applies when `sf == 1`.

```
AND <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- `LSL` when `shift = 00`
- `LSR` when `shift = 01`
- `ASR` when `shift = 10`
- `ROR` when `shift = 11`

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

Non-Confidential

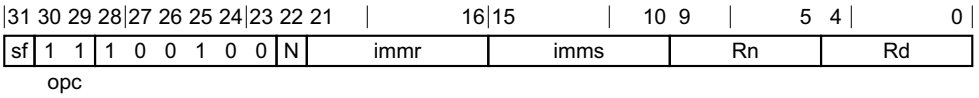
C6.2.13 ANDS (immediate)

Bitwise AND (immediate), setting flags, performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias TST (immediate). See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0 && N == 0`.

```
ANDS <Wd>, <Wn>, #<imm>
```

64-bit variant

Applies when `sf == 1`.

```
ANDS <Xd>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

bits(datasize) imm;
if sf == '0' && N != '0' then ReservedValue();
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

Alias conditions

Alias	is preferred when
TST (immediate)	`Rd == '11111'`

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
<imm>	For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr". For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
result = operand1 AND imm;
PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

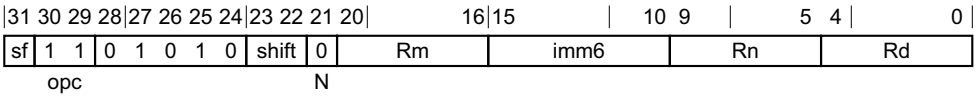
X[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.14 ANDS (shifted register)

Bitwise AND (shifted register), setting flags, performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias TST (shifted register). See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
ANDS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant

Applies when `sf == 1`.

```
ANDS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Alias conditions

Alias	is preferred when
TST (shifted register)	`Rd == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

`LSL` when `shift = 00`

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

LSR when shift = 01

ASR when shift = 10

ROR when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

result = operand1 AND operand2;
PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
```

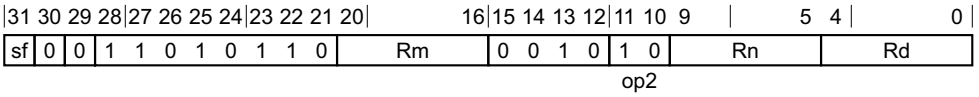
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.15 ASR (register)

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is an alias of the ASRV instruction. This means that:

- The encodings in this description are named to match the encodings of ASRV.
- The description of ASRV gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

`ASR <Wd>, <Wn>, <Wm>`

is equivalent to

`ASRV <Wd>, <Wn>, <Wm>`

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

`ASR <Xd>, <Xn>, <Xm>`

is equivalent to

`ASRV <Xd>, <Xn>, <Xm>`

and is always the preferred disassembly.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of ASRV gives the operational pseudocode for this instruction.

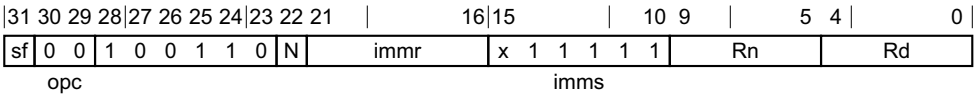
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.16 ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of the sign bit in the upper bits and zeros in the lower bits, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0 && imms == 011111`.

```
ASR <Wd>, <Wn>, #<shift>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #<shift>, #31
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1 && N == 1 && imms == 111111`.

```
ASR <Xd>, <Xn>, #<shift>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #<shift>, #63
```

and is always the preferred disassembly.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<shift>`	For the 32-bit variant: is the shift amount, in the range 0 to 31, encoded in the "immr" field. For the 64-bit variant: is the shift amount, in the range 0 to 63, encoded in the "immr" field.

Operation

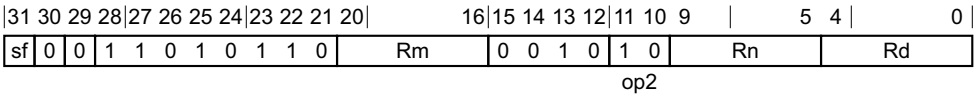
The description of SBFM gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.17 ASRV

Arithmetic Shift Right Variable shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ASR (register). The alias is always the preferred disassembly.



32-bit variant

Applies when `sf == 0`.

```
ASRV <Wd>, <Wn>, <Wm>
```

64-bit variant

Applies when `sf == 1`.

```
ASRV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

```
bits(datasize) result;
bits(datasize) operand2 = X[m];

result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
```

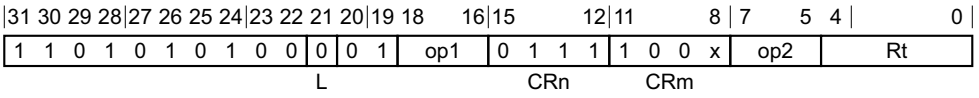
C6.2.18 AT

Address Translate. For more information, see *op0==0b01, cache maintenance, TLB maintenance, and address translation instructions* on page C5-332.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.



System variant

`AT <at_op>, <Xt>`

is equivalent to

`SYS #<op1>, C7, <Cm>, #<op2>, <Xt>`

and is the preferred disassembly when `SysOp(op1,'0111',CRm,op2) == Sys_AT`.

Assembler symbols

`<at_op>` Is an AT instruction name, as listed for the AT system instruction group, encoded in the "op1:CRm<0>:op2" field. It can have the following values:

`S1E1R`	when `op1 = 000`, `CRm<0> = 0`, `op2 = 000`
`S1E1W`	when `op1 = 000`, `CRm<0> = 0`, `op2 = 001`
`S1E0R`	when `op1 = 000`, `CRm<0> = 0`, `op2 = 010`
`S1E0W`	when `op1 = 000`, `CRm<0> = 0`, `op2 = 011`
`S1E2R`	when `op1 = 100`, `CRm<0> = 0`, `op2 = 000`
`S1E2W`	when `op1 = 100`, `CRm<0> = 0`, `op2 = 001`
`S12E1R`	when `op1 = 100`, `CRm<0> = 0`, `op2 = 100`
`S12E1W`	when `op1 = 100`, `CRm<0> = 0`, `op2 = 101`
`S12E0R`	when `op1 = 100`, `CRm<0> = 0`, `op2 = 110`
`S12E0W`	when `op1 = 100`, `CRm<0> = 0`, `op2 = 111`
`S1E3R`	when `op1 = 110`, `CRm<0> = 0`, `op2 = 000`
`S1E3W`	when `op1 = 110`, `CRm<0> = 0`, `op2 = 001`

When ARMv8.2-ATS1E1 is implemented, the following values are also valid:

`S1E1RP`	when `op1 = 000`, `CRm<0> = 1`, `op2 = 000`
`S1E1WP`	when `op1 = 000`, `CRm<0> = 1`, `op2 = 001`

`<op1>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

`<Cm>` Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

`<op2>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

`<Xt>` Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

C6.2.19 AUTDA, AUTDZA

Authenticate Data address, using key A. This instruction authenticates a data address, using a modifier and key A.

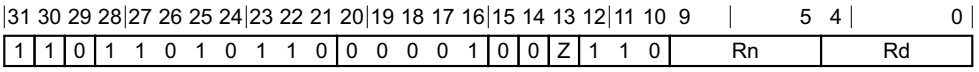
The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDA.
- The value zero, for AUTDZA.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

ARMv8.3



AUTDA variant

Applies when Z == 0.

```
AUTDA <Xd>, <Xn|SP>
```

AUTDZA variant

Applies when Z == 1 && Rn == 11111.

```
AUTDZA <Xd>
```

Decode for all variants of this encoding

```
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
    UnallocatedEncoding();

if Z == '0' then // AUTDA
    if n == 31 then source_is_sp = TRUE;
else // AUTDZA
    if n != 31 then UnallocatedEncoding();
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    X[d] = AuthDA(X[d], SP[]);
else
    X[d] = AuthDA(X[d], X[n]);
```

Non-Confidential

C6.2.20 AUTDB, AUTDZB

Authenticate Data address, using key B. This instruction authenticates a data address, using a modifier and key B.

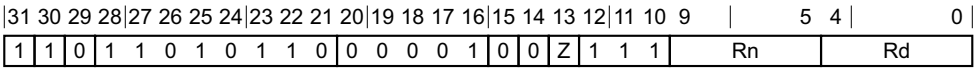
The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTDB.
- The value zero, for AUTDZB.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

ARMv8.3



AUTDB variant

Applies when Z == 0.

```
AUTDB <Xd>, <Xn|SP>
```

AUTDZB variant

Applies when Z == 1 && Rn == 11111.

```
AUTDZB <Xd>
```

Decode for all variants of this encoding

```
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
    UnallocatedEncoding();

if Z == '0' then // AUTDB
    if n == 31 then source_is_sp = TRUE;
else // AUTDZB
    if n != 31 then UnallocatedEncoding();
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    X[d] = AuthDB(X[d], SP[]);
else
    X[d] = AuthDB(X[d], X[n]);
```

C6.2.21 AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA

Authenticate Instruction address, using key A. This instruction authenticates an instruction address, using a modifier and key A.

The address is:

- In the general-purpose register that is specified by <Xd> for AUTIA and AUTIZA.
- In X17, for AUTIA1716.
- In X30, for AUTIASP and AUTIAZ.

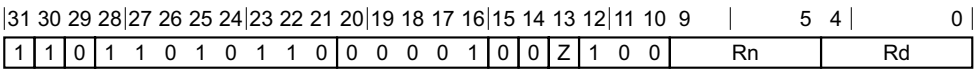
The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTIA.
- The value zero, for AUTIZA and AUTIAZ.
- In X16, for AUTIA1716.
- In SP, for AUTIASP.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

Integer

ARMv8.3



AUTIA variant

Applies when Z == 0.

```
AUTIA <Xd>, <Xn|SP>
```

AUTIZA variant

Applies when Z == 1 && Rn == 11111.

```
AUTIZA <Xd>
```

Decode for all variants of this encoding

```
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
    UnallocatedEncoding();

if Z == '0' then // AUTIA
    if n == 31 then source_is_sp = TRUE;
else // AUTIZA
    if n != 31 then UnallocatedEncoding();
```

AUTIA1716 variant

Applies when `CRm == 0001 && op2 == 100`.

```
AUTIA1716
```

AUTIASP variant

Applies when `CRm == 0011 && op2 == 101`.

```
AUTIASP
```

AUTIAZ variant

Applies when `CRm == 0011 && op2 == 100`.

```
AUTIAZ
```

Decode for all variants of this encoding

```
integer d;
integer n;
boolean source_is_sp = FALSE;

case CRm:op2 of
    when '0011 100'    // AUTIAZ
        d = 30;
        n = 31;
    when '0011 101'    // AUTIASP
        d = 30;
        source_is_sp = TRUE;
    when '0001 100'    // AUTIA1716
        d = 17;
        n = 16;
    when '0001 000' SEE "PACIA";
    when '0001 010' SEE "PACIB";
    when '0001 110' SEE "AUTIB";
    when '0011 00x' SEE "PACIA";
    when '0011 01x' SEE "PACIB";
    when '0011 11x' SEE "AUTIB";
    when '0000 111' SEE "XPACLRI";
    otherwise SEE "HINT";
```

Assembler symbols

`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation for all encodings

```
if HavePACExt() then
    if source_is_sp then
        X[d] = AuthIA(X[d], SP[]);
    else
        X[d] = AuthIA(X[d], X[n]);
```

C6.2.22 AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB

Authenticate Instruction address, using key B. This instruction authenticates an instruction address, using a modifier and key B.

The address is:

- In the general-purpose register that is specified by <Xd> for AUTIB and AUTIZB.
- In X17, for AUTIB1716.
- In X30, for AUTIBSP and AUTIBZ.

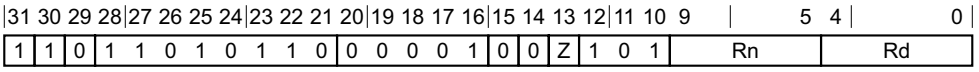
The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for AUTIB.
- The value zero, for AUTIZB and AUTIBZ.
- In X16, for AUTIB1716.
- In SP, for AUTIBSP.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. If the authentication fails, the upper bits are corrupted and any subsequent use of the address results in a Translation fault.

Integer

ARMv8.3



AUTIB variant

Applies when Z == 0.

```
AUTIB <Xd>, <Xn|SP>
```

AUTIZB variant

Applies when Z == 1 && Rn == 11111.

```
AUTIZB <Xd>
```

Decode for all variants of this encoding

```
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
    UnallocatedEncoding();

if Z == '0' then // AUTIB
    if n == 31 then source_is_sp = TRUE;
else // AUTIZB
    if n != 31 then UnallocatedEncoding();
```

AUTIB1716 variant

Applies when `CRm == 0001 && op2 == 110`.

```
AUTIB1716
```

AUTIBSP variant

Applies when `CRm == 0011 && op2 == 111`.

```
AUTIBSP
```

AUTIBZ variant

Applies when `CRm == 0011 && op2 == 110`.

```
AUTIBZ
```

Decode for all variants of this encoding

```
integer d;
integer n;
boolean source_is_sp = FALSE;

case CRm:op2 of
    when '0011 110'    // AUTIBZ
        d = 30;
        n = 31;
    when '0011 111'    // AUTIBSP
        d = 30;
        source_is_sp = TRUE;
    when '0001 110'    // AUTIB1716
        d = 17;
        n = 16;
    when '0001 000' SEE "PACIA";
    when '0001 010' SEE "PACIB";
    when '0001 100' SEE "AUTIA";
    when '0011 00x' SEE "PACIA";
    when '0011 01x' SEE "PACIB";
    when '0011 10x' SEE "AUTIA";
    when '0000 111' SEE "XPACLRI";
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation for all encodings

```
if HavePACExt() then
    if source_is_sp then
        X[d] = AuthIB(X[d], SP[]);
    else
        X[d] = AuthIB(X[d], X[n]);

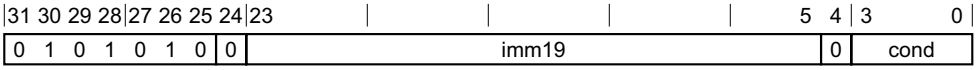
C6.2.23 B.cond

Branch conditionally to a label at a PC-relative offset, with a hint that this is not a subroutine call or return.



19-bit signed PC-relative branch offset variant

```
B.<cond> <label>
```

Decode for this encoding

```
bits(64) offset = SignExtend(imm19:'00', 64);
```

Assembler symbols

<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

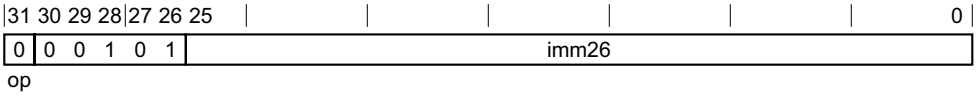
Operation

```
if ConditionHolds(cond) then
    BranchTo(PC[] + offset, BranchType_JMP);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.24 B

Branch causes an unconditional branch to a label at a PC-relative offset, with a hint that this is not a subroutine call or return.



26-bit signed PC-relative branch offset variant

```
B <label>
```

Decode for this encoding

```
bits(64) offset = SignExtend(imm26:'00', 64);
```

Assembler symbols

`<label>`	Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as "imm26" times 4.

Operation

```
BranchTo(PC[] + offset, BranchType_JMP);
```

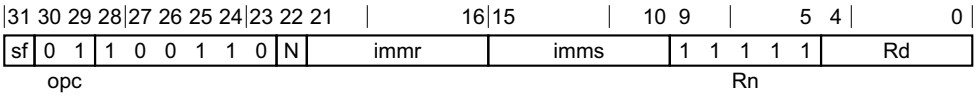
C6.2.25 BFC

Bitfield Clear, leaving other bits unchanged.

This instruction is an alias of the BFM instruction. This means that:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.

ARMv8.2



32-bit variant

Applies when `sf == 0 && N == 0`.

`BFC <Wd>, #<lsb>, #<width>`

is equivalent to

`BFM <Wd>, WZR, #(-<lsb> MOD 32), #(<width>-1)`

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

64-bit variant

Applies when `sf == 1 && N == 1`.

`BFC <Xd>, #<lsb>, #<width>`

is equivalent to

`BFM <Xd>, XZR, #(-<lsb> MOD 64), #(<width>-1)`

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<lsb>`	For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
`<width>`	For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of BFM gives the operational pseudocode for this instruction.

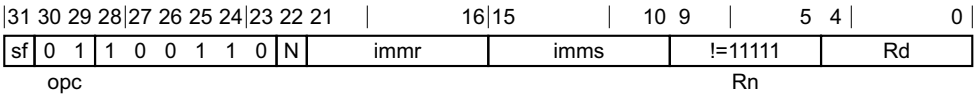
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.26 BFI

Bitfield Insert copies any number of low-order bits from a source register into the same number of adjacent bits at any position in the destination register, leaving other bits unchanged.

This instruction is an alias of the BFM instruction. This means that:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0`.

```
BFI <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
BFM  <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

64-bit variant

Applies when `sf == 1 && N == 1`.

```
BFI <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
BFM  <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<lsb>`	For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
`<width>`	For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

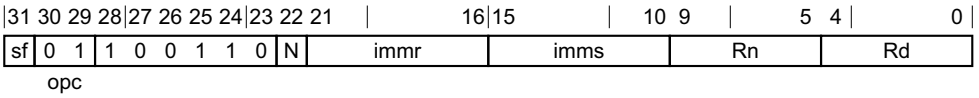
The description of BFM gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.27 BFM

Bitfield Move copies any number of low-order bits from a source register into the same number of adjacent bits at any position in the destination register, leaving other bits unchanged.

This instruction is used by the aliases BFC, BFI, and BFXIL. See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0 && N == 0`.

```
BFM <Wd>, <Wn>, #<immr>, #<imms>
```

64-bit variant

Applies when `sf == 1 && N == 1`.

```
BFM <Xd>, <Xn>, #<immr>, #<imms>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

integer R;
bits(datasize) wmask;
bits(datasize) tmask;

if sf == '1' && N != '1' then ReservedValue();
if sf == '0' && (N != '0' || immr<5> != '0' || imms<5> != '0') then ReservedValue();

R = UInt(immr);
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE);
```

Alias conditions

Alias	is preferred when
BFC	`Rn == '11111' && UInt(imms) < UInt(immr)`
BFI	`Rn != '11111' && UInt(imms) < UInt(immr)`
BFXIL	`UInt(imms) >= UInt(immr)`

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<immr> For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field.

For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.

<imms> For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field.

For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

Operation

```
bits(datasize) dst = X[d];
bits(datasize) src = X[n];

// perform bitfield move on low bits
bits(datasize) bot = (dst AND NOT(wmask)) OR (ROR(src, R) AND wmask);

// combine extension bits and result bits
X[d] = (dst AND NOT(tmask)) OR (bot AND tmask);
```

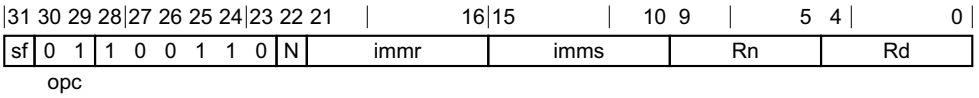
Non-Confidential

C6.2.28 BFXIL

Bitfield extract and insert at low end copies any number of low-order bits from a source register into the same number of adjacent bits at the low end in the destination register, leaving other bits unchanged.

This instruction is an alias of the BFM instruction. This means that:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0`.

`BFXIL <Wd>, <Wn>, #<lsb>, #<width>`

is equivalent to

`BFM  <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)`

and is the preferred disassembly when `UInt(imms) >= UInt(immr)`.

64-bit variant

Applies when `sf == 1 && N == 1`.

`BFXIL <Xd>, <Xn>, #<lsb>, #<width>`

is equivalent to

`BFM  <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)`

and is the preferred disassembly when `UInt(imms) >= UInt(immr)`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<lsb>`	For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
`<width>`	For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

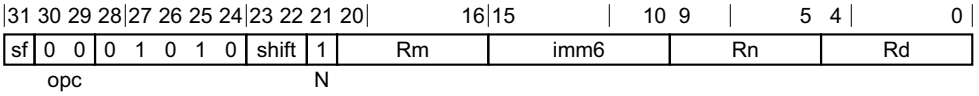
Operation

The description of BFM gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.29 BIC (shifted register)

Bitwise Bit Clear (shifted register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.



32-bit variant

Applies when `sf == 0`.

```
BIC <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant

Applies when `sf == 1`.

```
BIC <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- `LSL` when `shift = 00`
- `LSR` when `shift = 01`
- `ASR` when `shift = 10`
- `ROR` when `shift = 11`

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

operand2 = NOT(operand2);

result = operand1 AND operand2;
X[d] = result;
```

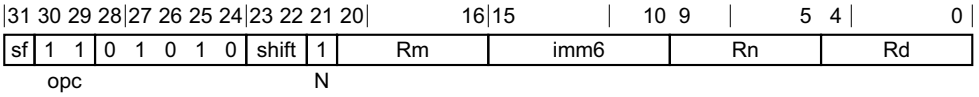
C6.2.30 BICS (shifted register)

Bitwise Bit Clear (shifted register), setting flags, performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.



32-bit variant

Applies when `sf == 0`.

```
BICS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant

Applies when `sf == 1`.

```
BICS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- `LSL` when `shift = 00`
- `LSR` when `shift = 01`
- `ASR` when `shift = 10`
- `ROR` when `shift = 11`

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

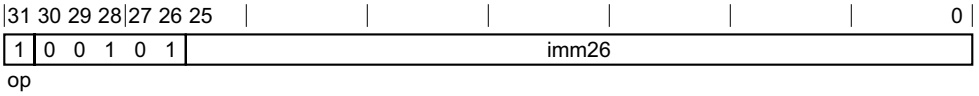
C6.2.31 BL

Branch with Link branches to a PC-relative offset, setting the register X30 to PC+4. It provides a hint that this is a subroutine call.



26-bit signed PC-relative branch offset variant

```
BL <label>
```

Decode for this encoding

```
bits(64) offset = SignExtend(imm26:'00', 64);
```

Assembler symbols

<label> Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as "imm26" times 4.

Operation

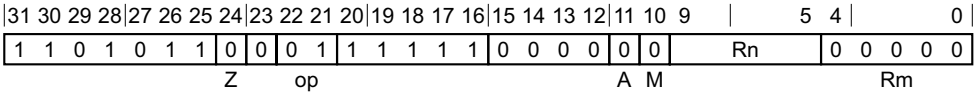
```
X[30] = PC[] + 4;

BranchTo(PC[] + offset, BranchType_CALL);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.32 BLR

Branch with Link to Register calls a subroutine at an address in a register, setting register X30 to PC+4.



Integer variant

```
BLR <Xn>
```

Decode for this encoding

```
integer n = UInt(Rn);
```

Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

Operation

```
bits(64) target = X[n];
X[30] = PC[] + 4;
BranchTo(target, BranchType_CALL);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.33 BLRAA, BLRAAZ, BLRAB, BLRABZ

Branch with Link to Register, with pointer authentication. This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and calls a subroutine at the authenticated address, setting register X30 to PC+4.

The modifier is:

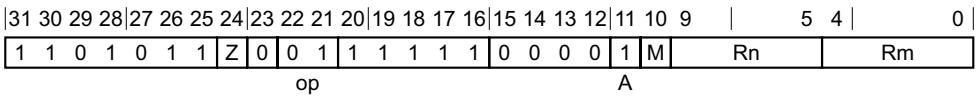
- In the general-purpose register or stack pointer that is specified by <Xm|SP> for BLRAA and BLRAB.
- The value zero, for BLRAAZ and BLRABZ.

Key A is used for BLRAA and BLRAAZ, and key B is used for BLRAB and BLRABZ.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the general-purpose register.

ARMv8.3



Key A, zero modifier variant

Applies when Z == 0 && M == 0 && Rm == 11111.

```
BLRAAZ <Xn>
```

Key A, register modifier variant

Applies when Z == 1 && M == 0.

```
BLRAA <Xn>, <Xm|SP>
```

Key B, zero modifier variant

Applies when Z == 0 && M == 1 && Rm == 11111.

```
BLRABZ <Xn>
```

Key B, register modifier variant

Applies when Z == 1 && M == 1.

```
BLRAB <Xn>, <Xm|SP>
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean use_key_a = (M == '0');
boolean source_is_sp = ((Z == '1') && (m == 31));

if !HavePACExt() then
    UnallocatedEncoding();

if Z == '0' && m != 31 then
    UnallocatedEncoding();
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

<Xm|SP> Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.

Operation

```
bits(64) target = X[n];
bits(64) modifier = if source_is_sp then SP[] else X[m];

if use_key_a then
    target = AuthIA(target, modifier);
else
    target = AuthIB(target, modifier);

X[30] = PC[] + 4;
BranchTo(target, BranchType_CALL);
```

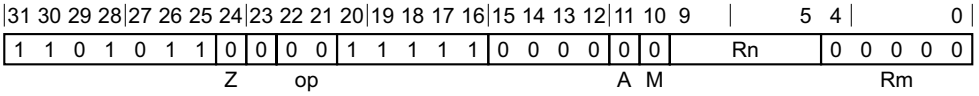
Non-Confidential

C6.2.34 BR

Branch to Register branches unconditionally to an address in a register, with a hint that this is not a subroutine return.



Integer variant

```
BR <Xn>
```

Decode for this encoding

```
integer n = UInt(Rn);
```

Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

Operation

```
bits(64) target = X[n];
BranchTo(target, BranchType_JMP);
```

Non-Confidential

C6.2.35 BRAA, BRAAZ, BRAB, BRABZ

Branch to Register, with pointer authentication. This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and branches to the authenticated address.

The modifier is:

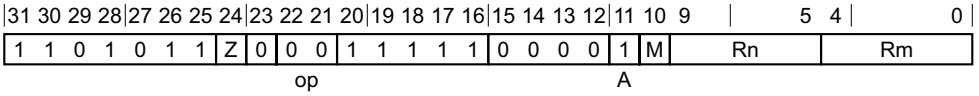
- In the general-purpose register or stack pointer that is specified by <Xm|SP> for BRAA and BRAB.
- The value zero, for BRAAZ and BRABZ.

Key A is used for BRAA and BRAAZ, and key B is used for BRAB and BRABZ.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the general-purpose register.

ARMv8.3



Key A, zero modifier variant

Applies when Z == 0 && M == 0 && Rm == 11111.

```
BRAAZ <Xn>
```

Key A, register modifier variant

Applies when Z == 1 && M == 0.

```
BRAA <Xn>, <Xm|SP>
```

Key B, zero modifier variant

Applies when Z == 0 && M == 1 && Rm == 11111.

```
BRABZ <Xn>
```

Key B, register modifier variant

Applies when Z == 1 && M == 1.

```
BRAB <Xn>, <Xm|SP>
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean use_key_a = (M == '0');
boolean source_is_sp = ((Z == '1') && (m == 31));

if !HavePACExt() then
    UnallocatedEncoding();

if Z == '0' && m != 31 then
    UnallocatedEncoding();
```

Non-Confidential

Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field.

<Xm|SP> Is the 64-bit name of the general-purpose source register or stack pointer holding the modifier, encoded in the "Rm" field.

Operation

```
bits(64) target = X[n];
bits(64) modifier = if source_is_sp then SP[] else X[m];

if use_key_a then
    target = AuthIA(target, modifier);
else
    target = AuthIB(target, modifier);

BranchTo(target, BranchType_JMP);
```

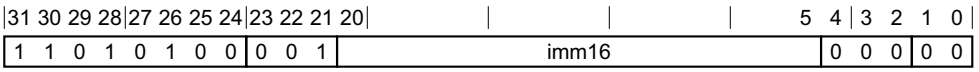
C6.2.36 BRK

Breakpoint instruction generates a Breakpoint Instruction exception. The PE records the exception in ESR_ELx, using the EC value 0x3c, and captures the value of the immediate argument in ESR_ELx.ISS.



System variant

```
BRK #<imm>
```

Decode for this encoding

```
// Empty.
```

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
AArch64.SoftwareBreakpoint(imm16);
```

C6.2.37 CASB, CASAB, CASALB, CASLB

Compare and Swap byte in memory reads an 8-bit byte from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- CASAB and CASALB load from memory with acquire semantics.
- CASLB and CASALB store to memory with release semantics.
- CASB has no memory ordering requirements.

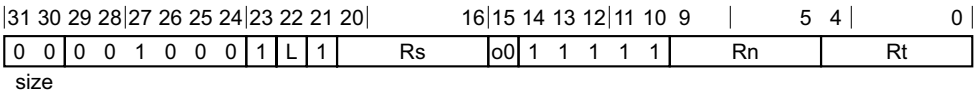
For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, is restored to the values held in the register before the instruction was executed.

ARMv8.1



CASAB variant

Applies when L == 1 && o0 == 0.

```
CASAB <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

CASALB variant

Applies when L == 1 && o0 == 1.

```
CASALB <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

CASB variant

Applies when L == 0 && o0 == 0.

```
CASB <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

CASLB variant

Applies when L == 0 && o0 == 1.

```
CASLB <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();

integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);
```

```
AccType ldacctype = if L == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if o0 == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Assembler symbols

<Ws>	Is the 32-bit name of the general-purpose register to be compared and loaded, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be conditionally stored, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) comparevalue;
bits(8) newvalue;
bits(8) data;

comparevalue = X[s];
newvalue = X[t];

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the
// following load and store atomically.
data = Mem[address, 1, ldacctype];
if data == comparevalue then
    Mem[address, 1, stacctype] = newvalue;

X[s] = ZeroExtend(data, 32);
```

C6.2.38 CASH, CASAH, CASALH, CASLH

Compare and Swap halfword in memory reads a 16-bit halfword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- CASAH and CASALH load from memory with acquire semantics.
- CASLH and CASALH store to memory with release semantics.
- CAS has no memory ordering requirements.

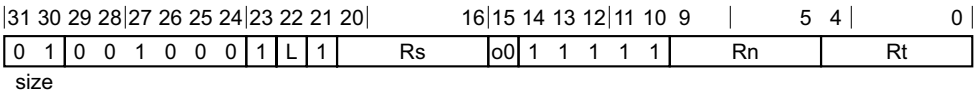
For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, is restored to the values held in the register before the instruction was executed.

ARMv8.1



CASAH variant

Applies when L == 1 && o0 == 0.

```
CASAH <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

CASALH variant

Applies when L == 1 && o0 == 1.

```
CASALH <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

CASH variant

Applies when L == 0 && o0 == 0.

```
CASH <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

CASLH variant

Applies when L == 0 && o0 == 1.

```
CASLH <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();

integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);

C6.2.39 CASP, CASPA, CASPAL, CASPL

Compare and Swap Pair of words or doublewords in memory reads a pair of 32-bit words or 64-bit doublewords from memory, and compares them against the values held in the first pair of registers. If the comparison is equal, the values in the second pair of registers are written to memory. If the writes are performed, the reads and writes occur atomically such that no other modification of the memory location can take place between the reads and writes.

- `CASPA` and `CASPAL` load from memory with acquire semantics.
- `CASPL` and `CASPAL` store to memory with release semantics.
- `CAS` has no memory ordering requirements.

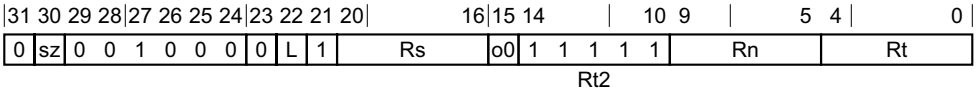
For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the registers which are compared and loaded, that is `<Ws>` and `<W(s+1)>`, or `<Xs>` and `<X(s+1)>`, are restored to the values held in the registers before the instruction was executed.

ARMv8.1



32-bit CASP variant

Applies when `sz == 0 && L == 0 && o0 == 0`.

```
CASP <Ws>, <W(s+1)>, <Wt>, <W(t+1)>, [<Xn|SP>{,#0}]
```

32-bit CASPA variant

Applies when `sz == 0 && L == 1 && o0 == 0`.

```
CASPA <Ws>, <W(s+1)>, <Wt>, <W(t+1)>, [<Xn|SP>{,#0}]
```

32-bit CASPAL variant

Applies when `sz == 0 && L == 1 && o0 == 1`.

```
CASPAL <Ws>, <W(s+1)>, <Wt>, <W(t+1)>, [<Xn|SP>{,#0}]
```

32-bit CASPL variant

Applies when `sz == 0 && L == 0 && o0 == 1`.

```
CASPL <Ws>, <W(s+1)>, <Wt>, <W(t+1)>, [<Xn|SP>{,#0}]
```

64-bit CASP variant

C6.2.40 CAS, CASA, CASAL, CASL

Compare and Swap word or doubleword in memory reads a 32-bit word or 64-bit doubleword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- CASA and CASAL load from memory with acquire semantics.
- CASL and CASAL store to memory with release semantics.
- CAS has no memory ordering requirements.

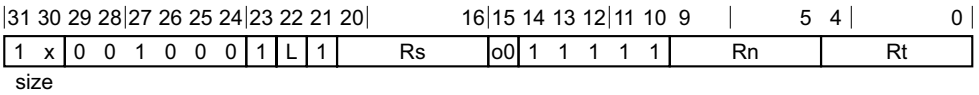
For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, or <Xs>, is restored to the value held in the register before the instruction was executed.

ARMv8.1



32-bit CAS variant

Applies when size == 10 && L == 0 && o0 == 0.

```
CAS <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

32-bit CASA variant

Applies when size == 10 && L == 1 && o0 == 0.

```
CASA <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

32-bit CASAL variant

Applies when size == 10 && L == 1 && o0 == 1.

```
CASAL <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

32-bit CASL variant

Applies when size == 10 && L == 0 && o0 == 1.

```
CASL <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

64-bit CAS variant

Applies when size == 11 && L == 0 && o0 == 0.

```
CAS <Xs>, <Xt>, [<Xn|SP>{,#0}]
```

64-bit CASA variant

Applies when size == 11 && L == 1 && o0 == 0.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
CASA <Xs>, <Xt>, [<Xn|SP>{,#0}]
```

Applies when size == 11 && L == 1 && o0 == 1.

```
CASAL <Xs>, <Xt>, [<Xn|SP>{,#0}]
```

64-bit CASL variant

Applies when size == 11 && L == 0 && o0 == 1.

```
CASL <Xs>, <Xt>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();

integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);

integer datasize = 8 << UInt(size);
integer regsize = if datasize == 64 then 64 else 32;
AccType ldacctype = if L == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if o0 == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Assembler symbols

<Ws>	Is the 32-bit name of the general-purpose register to be compared and loaded, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be conditionally stored, encoded in the "Rt" field.
<Xs>	Is the 64-bit name of the general-purpose register to be compared and loaded, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be conditionally stored, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(datasize) comparevalue;
bits(datasize) newvalue;
bits(datasize) data;

comparevalue = X[s];
newvalue = X[t];

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the
// following load and store atomically.
data = Mem[address, datasize DIV 8, ldacctype];
if data == comparevalue then
    Mem[address, datasize DIV 8, stacctype] = newvalue;

X[s] = ZeroExtend(data, regsize);
```

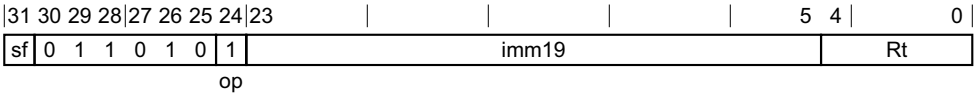
C6.2.41 CBNZ

Compare and Branch on Nonzero compares the value in a register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect the condition flags.



32-bit variant

Applies when `sf == 0`.

```
CBNZ <Wt>, <label>
```

64-bit variant

Applies when `sf == 1`.

```
CBNZ <Xt>, <label>
```

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer datasize = if sf == '1' then 64 else 32;
bits(64) offset = SignExtend(imm19:'00', 64);
```

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
`<Xt>`	Is the 64-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
`<label>`	Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

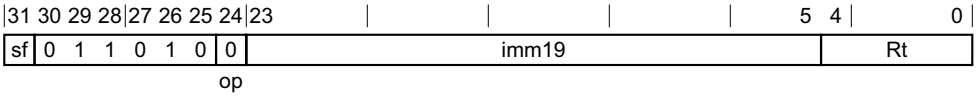
```
bits(datasize) operand1 = X[t];

if IsZero(operand1) == FALSE then
    BranchTo(PC[] + offset, BranchType_JMP);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.42 CBZ

Compare and Branch on Zero compares the value in a register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.



32-bit variant

Applies when `sf == 0`.

```
CBZ <Wt>, <label>
```

64-bit variant

Applies when `sf == 1`.

```
CBZ <Xt>, <label>
```

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer datasize = if sf == '1' then 64 else 32;
bits(64) offset = SignExtend(imm19:'00', 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
<Xt>	Is the 64-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
<label>	Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

```
bits(datasize) operand1 = X[t];

if IsZero(operand1) == TRUE then
    BranchTo(PC[] + offset, BranchType_JMP);
```

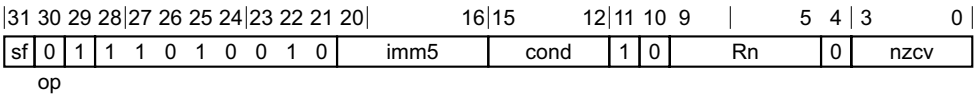
C6.2.43 CCMN (immediate)

Conditional Compare Negative (immediate) sets the value of the condition flags to the result of the comparison of a register value and a negated immediate value if the condition is TRUE, and an immediate value otherwise.



32-bit variant

Applies when `sf == 0`.

```
CCMN <Wn>, #<imm>, #<nzcv>, <cond>
```

64-bit variant

Applies when `sf == 1`.

```
CCMN <Xn>, #<imm>, #<nzcv>, <cond>
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(4) flags = nzcv;
bits(datasize) imm = ZeroExtend(imm5, datasize);
```

Assembler symbols

`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<imm>`	Is a five bit unsigned (positive) immediate encoded in the "imm5" field.
`<nzcv>`	Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.
`<cond>`	Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

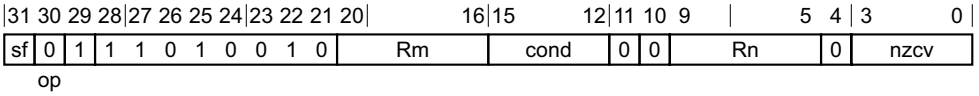
```
bits(datasize) operand1 = X[n];

if ConditionHolds(cond) then
    (-, flags) = AddWithCarry(operand1, imm, '0');
PSTATE.<N,Z,C,V> = flags;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.44 CCMN (register)

Conditional Compare Negative (register) sets the value of the condition flags to the result of the comparison of a register value and the inverse of another register value if the condition is TRUE, and an immediate value otherwise.



32-bit variant

Applies when `sf == 0`.

```
CCMN <Wn>, <Wm>, #<nzcv>, <cond>
```

64-bit variant

Applies when `sf == 1`.

```
CCMN <Xn>, <Xm>, #<nzcv>, <cond>
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
bits(4) flags = nzcv;
```

Assembler symbols

<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<nzcv>	Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.
<cond>	Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

if ConditionHolds(cond) then
    (-, flags) = AddWithCarry(operand1, operand2, '0');
PSTATE.<N,Z,C,V> = flags;
```

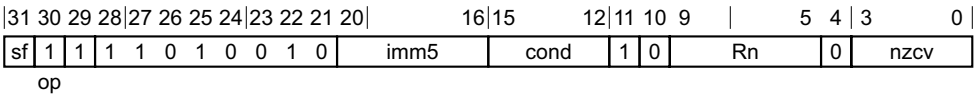
C6.2.45 CCMP (immediate)

Conditional Compare (immediate) sets the value of the condition flags to the result of the comparison of a register value and an immediate value if the condition is TRUE, and an immediate value otherwise.



32-bit variant

Applies when `sf == 0`.

```
CCMP <Wn>, #<imm>, #<nzcv>, <cond>
```

64-bit variant

Applies when `sf == 1`.

```
CCMP <Xn>, #<imm>, #<nzcv>, <cond>
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(4) flags = nzcv;
bits(datasize) imm = ZeroExtend(imm5, datasize);
```

Assembler symbols

<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<imm>	Is a five bit unsigned (positive) immediate encoded in the "imm5" field.
<nzcv>	Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.
<cond>	Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

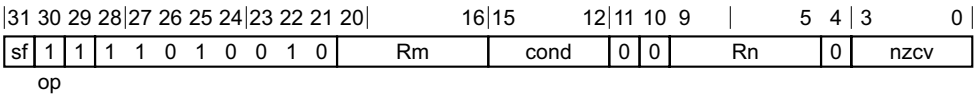
```
bits(datasize) operand1 = X[n];
bits(datasize) operand2;

if ConditionHolds(cond) then
    operand2 = NOT(imm);
    (-, flags) = AddWithCarry(operand1, operand2, '1');
PSTATE.<N,Z,C,V> = flags;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.46 CCMP (register)

Conditional Compare (register) sets the value of the condition flags to the result of the comparison of two registers if the condition is TRUE, and an immediate value otherwise.



32-bit variant

Applies when `sf == 0`.

```
CCMP <Wn>, <Wm>, #<nzcv>, <cond>
```

64-bit variant

Applies when `sf == 1`.

```
CCMP <Xn>, <Xm>, #<nzcv>, <cond>
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
bits(4) flags = nzcv;
```

Assembler symbols

<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<nzcv>	Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.
<cond>	Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

if ConditionHolds(cond) then
    operand2 = NOT(operand2);
    (-, flags) = AddWithCarry(operand1, operand2, '1');
PSTATE.<N,Z,C,V> = flags;
```

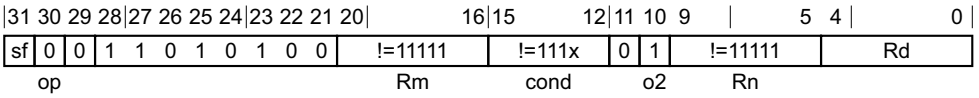
C6.2.47 CINC

Conditional Increment returns, in the destination register, the value of the source register incremented by 1 if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the CSINC instruction. This means that:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

`CINC <Wd>, <Wn>, <cond>`

is equivalent to

`CSINC <Wd>, <Wn>, <Wn>, invert(<cond>)`

and is the preferred disassembly when `Rn == Rm`.

64-bit variant

Applies when `sf == 1`.

`CINC <Xd>, <Xn>, <cond>`

is equivalent to

`CSINC <Xd>, <Xn>, <Xn>, invert(<cond>)`

and is the preferred disassembly when `Rn == Rm`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
`<cond>`	Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINC gives the operational pseudocode for this instruction.

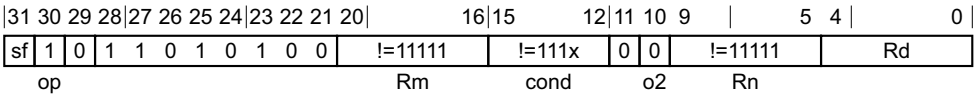
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.48 CINV

Conditional Invert returns, in the destination register, the bitwise inversion of the value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the CSINV instruction. This means that:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

`CINV <Wd>, <Wn>, <cond>`

is equivalent to

`CSINV <Wd>, <Wn>, <Wn>, invert(<cond>)`

and is the preferred disassembly when `Rn == Rm`.

64-bit variant

Applies when `sf == 1`.

`CINV <Xd>, <Xn>, <cond>`

is equivalent to

`CSINV <Xd>, <Xn>, <Xn>, invert(<cond>)`

and is the preferred disassembly when `Rn == Rm`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
`<cond>`	Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINV gives the operational pseudocode for this instruction.

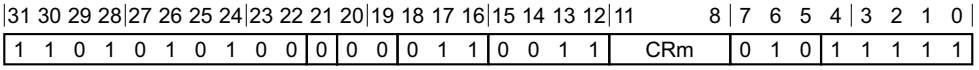
Non-Confidential

C6.2.49 CLREX

Clear Exclusive clears the local monitor of the executing PE.



System variant

```
CLREX {#<imm>}
```

Decode for this encoding

```
// CRm field is ignored
```

Assembler symbols

<imm> Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

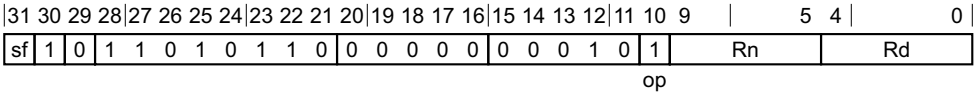
Operation

```
ClearExclusiveLocal(ProcessorID());
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.50 CLS

Count leading sign bits : `Rd = CLS(Rn)`.



32-bit variant

Applies when `sf == 0`.

```
CLS <Wd>, <Wn>
```

64-bit variant

Applies when `sf == 1`.

```
CLS <Xd>, <Xn>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
integer result;
bits(datasize) operand1 = X[n];

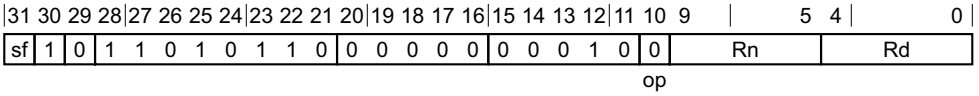
result = CountLeadingSignBits(operand1);

X[d] = result<datasize-1:0>;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.51 CLZ

Count leading zero bits : `Rd = CLZ(Rn)`.



32-bit variant

Applies when `sf == 0`.

```
CLZ <Wd>, <Wn>
```

64-bit variant

Applies when `sf == 1`.

```
CLZ <Xd>, <Xn>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
integer result;
bits(datasize) operand1 = X[n];

result = CountLeadingZeroBits(operand1);
X[d] = result<datasize-1:0>;
```

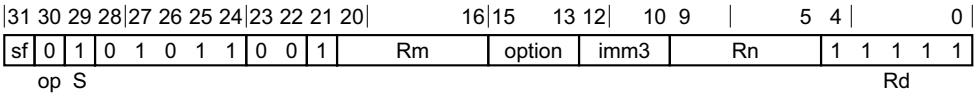
C6.2.52 CMN (extended register)

Compare Negative (extended register) adds a register value and a sign or zero-extended register value, followed by an optional left shift amount. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ADDS (extended register) instruction. This means that:

- The encodings in this description are named to match the encodings of ADDS (extended register).
- The description of ADDS (extended register) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
CMN <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

is equivalent to

```
ADDS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
CMN <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

is equivalent to

```
ADDS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

Assembler symbols

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in the "option" field. It can have the following values:

W	when `option = 00x`
W	when `option = 010`
X	when `option = x11`
W	when `option = 10x`
W	when `option = 110`

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB when option = 000

UXTH when option = 001

LSL|UXTW when option = 010

UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB when option = 000

UXTH when option = 001

UXTW when option = 010

LSL|UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

The description of ADDS (extended register) gives the operational pseudocode for this instruction.

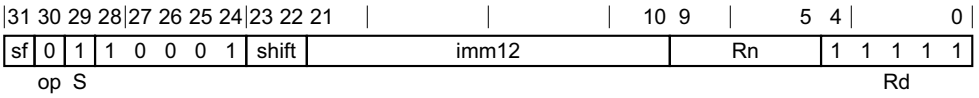
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.53 CMN (immediate)

Compare Negative (immediate) adds a register value and an optionally-shifted immediate value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ADDS (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ADDS (immediate).
- The description of ADDS (immediate) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
CMN <Wn|WSP>, #<imm>{, <shift>}
```

is equivalent to

```
ADDS WZR, <Wn|WSP>, #<imm> {, <shift>}
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
CMN <Xn|SP>, #<imm>{, <shift>}
```

is equivalent to

```
ADDS XZR, <Xn|SP>, #<imm> {, <shift>}
```

and is always the preferred disassembly.

Assembler symbols

`<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

`<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

`<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "shift" field. It can have the following values:

`LSL #0` when `shift = 00`

`LSL #12` when `shift = 01`

The encoding `shift = 1x` is reserved.

Operation

The description of ADDS (immediate) gives the operational pseudocode for this instruction.

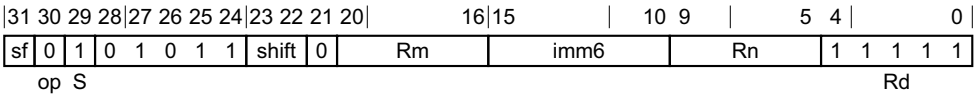
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.54 CMN (shifted register)

Compare Negative (shifted register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ADDS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ADDS (shifted register).
- The description of ADDS (shifted register) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
CMN <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ADDS WZR, <Wn>, <Wm> {, <shift> #<amount>}
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
CMN <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ADDS XZR, <Xn>, <Xm> {, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler symbols

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

`LSL` when `shift = 00`

`LSR` when `shift = 01`

`ASR` when `shift = 10`

The encoding `shift = 11` is reserved.

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

The description of ADDS (shifted register) gives the operational pseudocode for this instruction.

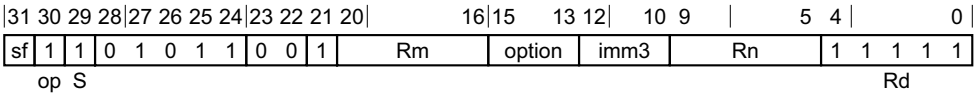
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.55 CMP (extended register)

Compare (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the SUBS (extended register) instruction. This means that:

- The encodings in this description are named to match the encodings of SUBS (extended register).
- The description of SUBS (extended register) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
CMP <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

is equivalent to

```
SUBS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
CMP <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

is equivalent to

```
SUBS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

Assembler symbols

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in the "option" field. It can have the following values:

W	when `option = 00x`
W	when `option = 010`
X	when `option = x11`
W	when `option = 10x`
W	when `option = 110`

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB when option = 000

UXTH when option = 001

LSL|UXTW when option = 010

UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB when option = 000

UXTH when option = 001

UXTW when option = 010

LSL|UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

The description of SUBS (extended register) gives the operational pseudocode for this instruction.

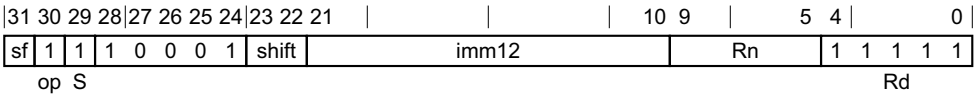
C6.2.56 CMP (immediate)

Compare (immediate) subtracts an optionally-shifted immediate value from a register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the SUBS (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of SUBS (immediate).
- The description of SUBS (immediate) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

`CMP <Wn|WSP>, #<imm>{, <shift>}`

is equivalent to

`SUBS WZR, <Wn|WSP>, #<imm> {, <shift>}`

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

`CMP <Xn|SP>, #<imm>{, <shift>}`

is equivalent to

`SUBS XZR, <Xn|SP>, #<imm> {, <shift>}`

and is always the preferred disassembly.

Assembler symbols

`<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

`<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

`<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "shift" field. It can have the following values:

`LSL #0` when `shift = 00`

`LSL #12` when `shift = 01`

The encoding `shift = 1x` is reserved.

Operation

The description of SUBS (immediate) gives the operational pseudocode for this instruction.

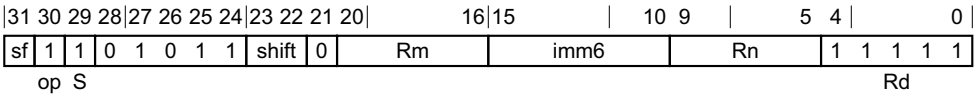
C6.2.57 CMP (shifted register)

Compare (shifted register) subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the SUBS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
CMP <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS WZR, <Wn>, <Wm> {, <shift> #<amount>}
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
CMP <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS XZR, <Xn>, <Xm> {, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler symbols

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- `LSL` when `shift = 00`
- `LSR` when `shift = 01`
- `ASR` when `shift = 10`

The encoding `shift = 11` is reserved.

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

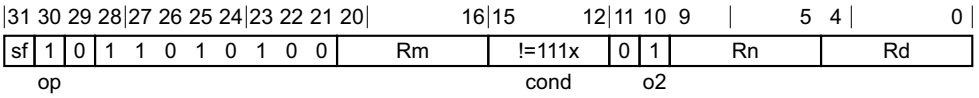
C6.2.58 CNEG

Conditional Negate returns, in the destination register, the negated value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This instruction is an alias of the CSNEG instruction. This means that:

- The encodings in this description are named to match the encodings of CSNEG.
- The description of CSNEG gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
CNEG <Wd>, <Wn>, <cond>
```

is equivalent to

```
CSNEG <Wd>, <Wn>, <Wn>, invert(<cond>)
```

and is the preferred disassembly when `Rn == Rm`.

64-bit variant

Applies when `sf == 1`.

```
CNEG <Xd>, <Xn>, <cond>
```

is equivalent to

```
CSNEG <Xd>, <Xn>, <Xn>, invert(<cond>)
```

and is the preferred disassembly when `Rn == Rm`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
`<cond>`	Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSNEG gives the operational pseudocode for this instruction.

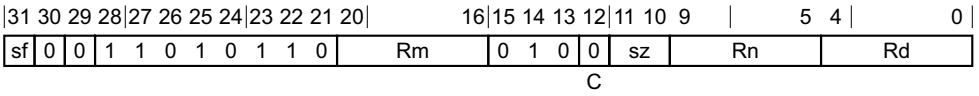
C6.2.59 CRC32B, CRC32H, CRC32W, CRC32X

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

In ARMv8-A, this is an OPTIONAL instruction, and in ARMv8.1 it is mandatory for all implementations to implement it.

Note

ID_AA64ISAR0_EL1.CRC32 indicates whether this instruction is supported.



CRC32B variant

Applies when sf == 0 && sz == 00.

```
CRC32B <Wd>, <Wn>, <Wm>
```

CRC32H variant

Applies when sf == 0 && sz == 01.

```
CRC32H <Wd>, <Wn>, <Wm>
```

CRC32W variant

Applies when sf == 0 && sz == 10.

```
CRC32W <Wd>, <Wn>, <Wm>
```

CRC32X variant

Applies when sf == 1 && sz == 11.

```
CRC32X <Wd>, <Wn>, <Xm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sf == '1' && sz != '11' then UnallocatedEncoding();
if sf == '0' && sz == '11' then UnallocatedEncoding();
integer size = 8 << UInt(sz);
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.
<Wm>	Is the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
if !HaveCRCExt() then
    UnallocatedEncoding();

bits(32) acc = X[n];    // accumulator
bits(size) val = X[m];    // input value
bits(32) poly = 0x04C11DB7<31:0>;

bits(32+size) tempacc = BitReverse(acc):Zeros(size);
bits(size+32) tempval = BitReverse(val):Zeros(32);

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

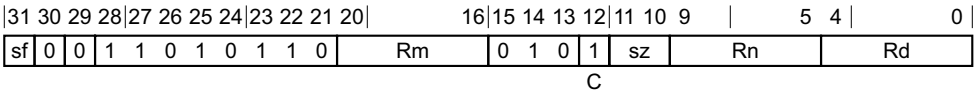
C6.2.60 CRC32CB, CRC32CH, CRC32CW, CRC32CX

CRC32 checksum performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x1EDC6F41 is used for the CRC calculation.

In ARMv8-A, this is an OPTIONAL instruction, and in ARMv8.1 it is mandatory for all implementations to implement it.

Note

ID_AA64ISAR0_EL1.CRC32 indicates whether this instruction is supported.



CRC32CB variant

Applies when sf == 0 && sz == 00.

```
CRC32CB <Wd>, <Wn>, <Wm>
```

CRC32CH variant

Applies when sf == 0 && sz == 01.

```
CRC32CH <Wd>, <Wn>, <Wm>
```

CRC32CW variant

Applies when sf == 0 && sz == 10.

```
CRC32CW <Wd>, <Wn>, <Wm>
```

CRC32CX variant

Applies when sf == 1 && sz == 11.

```
CRC32CX <Wd>, <Wn>, <Xm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sf == '1' && sz != '11' then UnallocatedEncoding();
if sf == '0' && sz == '11' then UnallocatedEncoding();
integer size = 8 << UInt(sz);
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose accumulator output register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose accumulator input register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the general-purpose data source register, encoded in the "Rm" field.
<Wm>	Is the 32-bit name of the general-purpose data source register, encoded in the "Rm" field.

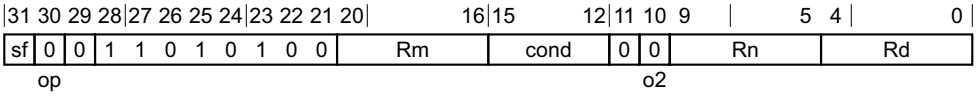
C6.2.61 CSEL

Conditional Select returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register.



32-bit variant

Applies when `sf == 0`.

```
CSEL <Wd>, <Wn>, <Wm>, <cond>
```

64-bit variant

Applies when `sf == 1`.

```
CSEL <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<cond>	Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

if ConditionHolds(cond) then
    result = operand1;
else
    result = operand2;

X[d] = result;
```

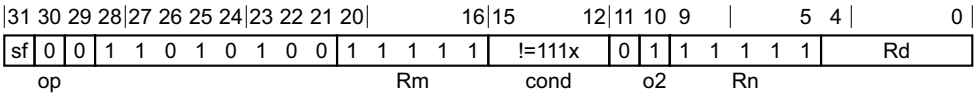
C6.2.62 CSET

Conditional Set sets the destination register to 1 if the condition is TRUE, and otherwise sets it to 0.

This instruction is an alias of the CSINC instruction. This means that:

- The encodings in this description are named to match the encodings of CSINC.
- The description of CSINC gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
CSET <Wd>, <cond>
```

is equivalent to

```
CSINC <Wd>, WZR, WZR, invert(<cond>)
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
CSET <Xd>, <cond>
```

is equivalent to

```
CSINC <Xd>, XZR, XZR, invert(<cond>)
```

and is always the preferred disassembly.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<cond>`	Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINC gives the operational pseudocode for this instruction.

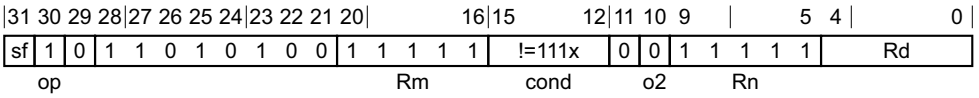
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.63 CSETM

Conditional Set Mask sets all bits of the destination register to 1 if the condition is TRUE, and otherwise sets all bits to 0.

This instruction is an alias of the CSINV instruction. This means that:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
CSETM <Wd>, <cond>
```

is equivalent to

```
CSINV <Wd>, WZR, WZR, invert(<cond>)
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
CSETM <Xd>, <cond>
```

is equivalent to

```
CSINV <Xd>, XZR, XZR, invert(<cond>)
```

and is always the preferred disassembly.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<cond>`	Is one of the standard conditions, excluding AL and NV, encoded in the "cond" field with its least significant bit inverted.

Operation

The description of CSINV gives the operational pseudocode for this instruction.

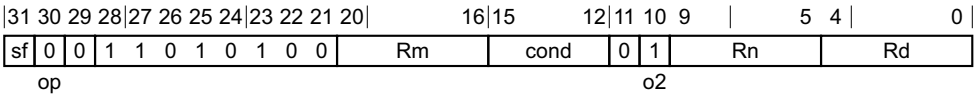
C6.2.64 CSINC

Conditional Select Increment returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the value of the second source register incremented by 1.

This instruction is used by the aliases CINC and CSET. See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
CSINC <Wd>, <Wn>, <Wm>, <cond>
```

64-bit variant

Applies when `sf == 1`.

```
CSINC <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Alias conditions

Alias	is preferred when
CINC	`Rm != '11111' && cond != '111x' && Rn != '11111' && Rn == Rm`
CSET	`Rm == '11111' && cond != '111x' && Rn == '11111'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
`<cond>`	Is one of the standard conditions, encoded in the "cond" field in the standard way.

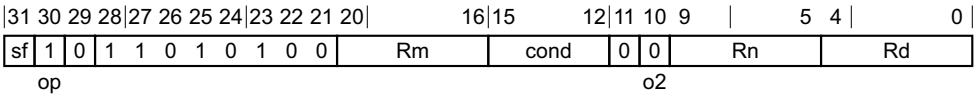
C6.2.65 CSINV

Conditional Select Invert returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the bitwise inversion value of the second source register.

This instruction is used by the aliases CINV and CSETM. See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
CSINV <Wd>, <Wn>, <Wm>, <cond>
```

64-bit variant

Applies when `sf == 1`.

```
CSINV <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Alias conditions

Alias	is preferred when
CINV	`Rm != '11111' && cond != '111x' && Rn != '11111' && Rn == Rm`
CSETM	`Rm == '11111' && cond != '111x' && Rn == '11111'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
`<cond>`	Is one of the standard conditions, encoded in the "cond" field in the standard way.

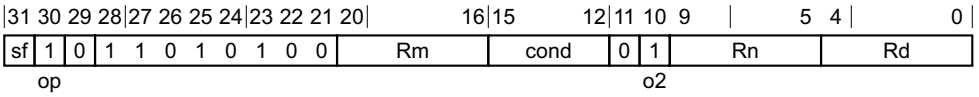
C6.2.66 CSNEG

Conditional Select Negation returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the negated value of the second source register.

This instruction is used by the alias CNEG. See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
CSNEG <Wd>, <Wn>, <Wm>, <cond>
```

64-bit variant

Applies when `sf == 1`.

```
CSNEG <Xd>, <Xn>, <Xm>, <cond>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Alias conditions

Alias	is preferred when
CNEG	`cond != '111x' && Rn == Rm`

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
<cond>	Is one of the standard conditions, encoded in the "cond" field in the standard way.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

if ConditionHolds(cond) then
```

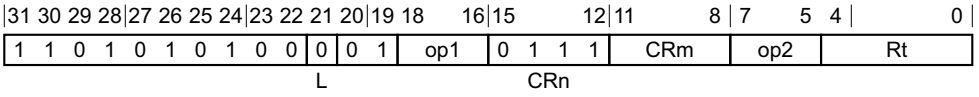
C6.2.67 DC

Data Cache operation. For more information, see *op0==0b01, cache maintenance, TLB maintenance, and address translation instructions* on page C5-332.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.



System variant

```
DC <dc_op>, <Xt>
```

is equivalent to

```
SYS #<op1>, C7, <Cm>, #<op2>, <Xt>
```

and is the preferred disassembly when `SysOp(op1,'0111',CRm,op2) == Sys_DC`.

Assembler symbols

`<dc_op>` Is a DC instruction name, as listed for the DC system instruction group, encoded in the "op1:CRm:op2" field. It can have the following values:

`IVAC`	when `op1 = 000`, `CRm = 0110`, `op2 = 001`
`ISW`	when `op1 = 000`, `CRm = 0110`, `op2 = 010`
`CSW`	when `op1 = 000`, `CRm = 1010`, `op2 = 010`
`CISW`	when `op1 = 000`, `CRm = 1110`, `op2 = 010`
`ZVA`	when `op1 = 011`, `CRm = 0100`, `op2 = 001`
`CVAC`	when `op1 = 011`, `CRm = 1010`, `op2 = 001`
`CVAU`	when `op1 = 011`, `CRm = 1011`, `op2 = 001`
`CIVAC`	when `op1 = 011`, `CRm = 1110`, `op2 = 001`

When ARMv8.2-DCPoP is implemented, the following value is also valid:

`CVAP`	when `op1 = 011`, `CRm = 1100`, `op2 = 001`

`<op1>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

`<Cm>` Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

`<op2>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

`<Xt>` Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

C6.2.68 DCPS1

Debug Change PE State to EL1, when executed in Debug state:

- If executed at EL0 changes the current Exception level and SP to EL1 using SP_EL1.
- Otherwise, if executed at ELx, selects SP_ELx.

The target exception level of a DCPS1 instruction is:

- EL1 if the instruction is executed at EL0.
- Otherwise, the Exception level at which the instruction is executed.

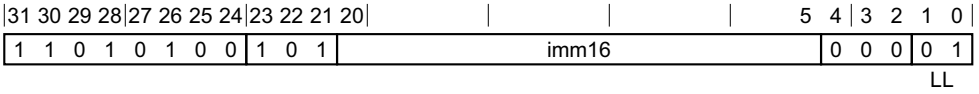
When the target Exception level of a DCPS1 instruction is ELx, on executing this instruction:

- ELR_ELx becomes UNKNOWN.
- SPSR_ELx becomes UNKNOWN.
- ESR_ELx becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_ELx.EE.

This instruction is UNDEFINED at EL0 in Non-secure state if EL2 is implemented and HCR_EL2.TGE == 1.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see *DCPS<n> on page H2-5724*.



System variant

```
DCPS1 {#<imm>}
```

Decode for this encoding

```
if !Halted() then AArch64.UndefinedFault();
```

Assembler symbols

<imm>	Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

```
DCPSInstruction(LL);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.69 DCPS2

Debug Change PE State to EL2, when executed in Debug state:

- If executed at EL0 or EL1 changes the current Exception level and SP to EL2 using SP_EL2.
- Otherwise, if executed at ELx, selects SP_ELx.

The target exception level of a DCPS2 instruction is:

- EL2 if the instruction is executed at an exception level that is not EL3.
- EL3 if the instruction is executed at EL3.

When the target Exception level of a DCPS2 instruction is ELx, on executing this instruction:

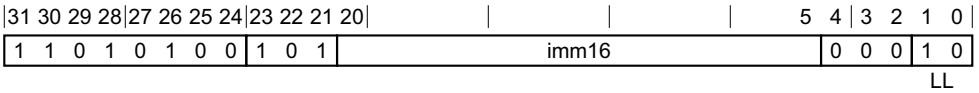
- ELR_ELx becomes UNKNOWN.
- SPSR_ELx becomes UNKNOWN.
- ESR_ELx becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_ELx.EE.

This instruction is UNDEFINED at the following exception levels:

- All exception levels if EL2 is not implemented.
- At EL0 and EL1 in Secure state if EL2 is implemented.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see *DCPS<n>* on page H2-5724.



System variant

```
DCPS2 {#<imm>}
```

Decode for this encoding

```
if !Halted() then AArch64.UndefinedFault();
```

Assembler symbols

<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

```
DCPSInstruction(LL);
```

C6.2.70 DCPS3

Debug Change PE State to EL3, when executed in Debug state:

- If executed at EL3 selects SP_EL3.
- Otherwise, changes the current Exception level and SP to EL3 using SP_EL3.

The target exception level of a DCPS3 instruction is EL3.

On executing a DCPS3 instruction:

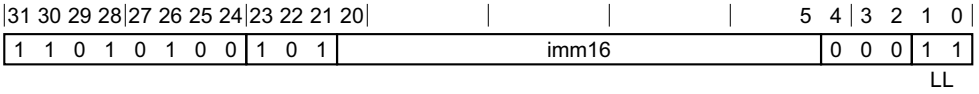
- ELR_EL3 becomes UNKNOWN.
- SPSR_EL3 becomes UNKNOWN.
- ESR_EL3 becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_EL3.EE.

This instruction is UNDEFINED at all exception levels if either:

- EDSCR.SDD == 1.
- EL3 is not implemented.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPSn instructions, see *DCPS<n> on page H2-5724*.



System variant

```
DCPS3 {#<imm>}
```

Decode for this encoding

```
if !Halted() then AArch64.UndefinedFault();
```

Assembler symbols

<imm>	Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

```
DCPSInstruction(LL);
```

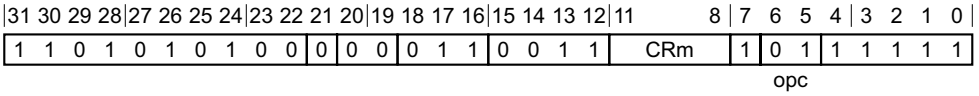
C6.2.71 DMB

Data Memory Barrier is a memory barrier that ensures the ordering of observations of memory accesses, see *Data Memory Barrier (DMB)* on page B2-99.



System variant

```
DMB <option>|#<imm>
```

Decode for this encoding

```
MBReqDomain domain;
MBReqTypes types;

case CRm<3:2> of
    when '00' domain = MBReqDomain_OuterShareable;
    when '01' domain = MBReqDomain_Nonshareable;
    when '10' domain = MBReqDomain_InnerShareable;
    when '11' domain = MBReqDomain_FullSystem;

case CRm<1:0> of
    when '01' types = MBReqTypes_Reads;
    when '10' types = MBReqTypes_Writes;
    when '11' types = MBReqTypes_All;
    otherwise
        types = MBReqTypes_All;
        domain = MBReqDomain_FullSystem;
```

Assembler symbols

`<option>` Specifies the limitation on the barrier operation. Values are:

`SY` Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = `0b1111`.

`ST` Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = `0b1110`.

`LD` Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = `0b1101`.

`ISH` Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = `0b1011`.

`ISHST` Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = `0b1010`.

`ISHLD` Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = `0b1001`.

`NSH` Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = `0b0111`.

`NSHST` Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = `0b0110`.

Non-Confidential

NSHLD Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0101.

OSH Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b0011.

OSHST Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0010.

OSHLD Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0001.

All other encodings of CRm that are not listed above are reserved, and can be encoded using the #<imm> syntax. It is IMPLEMENTATION DEFINED whether options other than SY are implemented. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see *Data Memory Barrier (DMB)* on page B2-99 or see *Data Synchronization Barrier (DSB)* on page B2-100.

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

Operation

```
DataMemoryBarrier(domain, types);
```

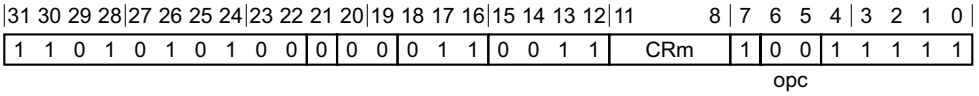
C6.2.73 DSB

Data Synchronization Barrier is a memory barrier that ensures the completion of memory accesses, see *Data Synchronization Barrier (DSB)* on page B2-100.



System variant

```
DSB <option>|#<imm>
```

Decode for this encoding

```
MBReqDomain domain;
MBReqTypes types;

case CRm<3:2> of
    when '00' domain = MBReqDomain_OuterShareable;
    when '01' domain = MBReqDomain_Nonshareable;
    when '10' domain = MBReqDomain_InnerShareable;
    when '11' domain = MBReqDomain_FullSystem;

case CRm<1:0> of
    when '01' types = MBReqTypes_Reads;
    when '10' types = MBReqTypes_Writes;
    when '11' types = MBReqTypes_All;
    otherwise
        types = MBReqTypes_All;
        domain = MBReqDomain_FullSystem;
```

Assembler symbols

`<option>` Specifies the limitation on the barrier operation. Values are:

- `SY` Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = `0b1111`.
- `ST` Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = `0b1110`.
- `LD` Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = `0b1101`.
- `ISH` Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = `0b1011`.
- `ISHST` Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = `0b1010`.
- `ISHLD` Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = `0b1001`.
- `NSH` Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = `0b0111`.
- `NSHST` Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = `0b0110`.

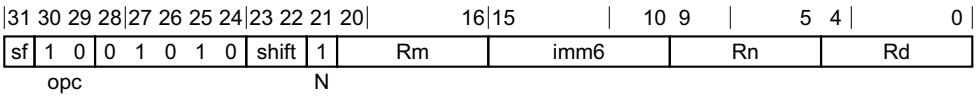
C6.2.74 EON (shifted register)

Bitwise Exclusive OR NOT (shifted register) performs a bitwise Exclusive OR NOT of a register value and an optionally-shifted register value, and writes the result to the destination register.



32-bit variant

Applies when `sf == 0`.

```
EON <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant

Applies when `sf == 1`.

```
EON <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- `LSL` when `shift = 00`
- `LSR` when `shift = 01`
- `ASR` when `shift = 10`
- `ROR` when `shift = 11`

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

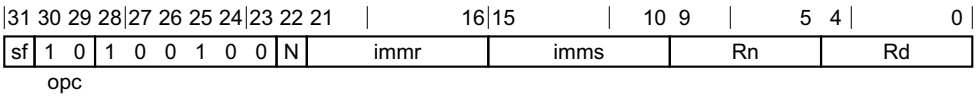
C6.2.75 EOR (immediate)

Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register.



32-bit variant

Applies when `sf == 0 && N == 0`.

```
EOR <Wd|WSP>, <Wn>, #<imm>
```

64-bit variant

Applies when `sf == 1`.

```
EOR <Xd|SP>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;
if sf == '0' && N != '0' then ReservedValue();
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

Assembler symbols

`<Wd|WSP>`	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd|SP>`	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<imm>`	For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr". For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];

result = operand1 EOR imm;

if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

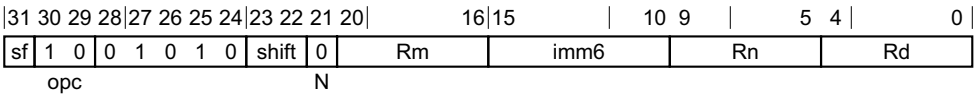
C6.2.76 EOR (shifted register)

Bitwise Exclusive OR (shifted register) performs a bitwise Exclusive OR of a register value and an optionally-shifted register value, and writes the result to the destination register.



32-bit variant

Applies when `sf == 0`.

```
EOR <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant

Applies when `sf == 1`.

```
EOR <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- `LSL` when `shift = 00`
- `LSR` when `shift = 01`
- `ASR` when `shift = 10`
- `ROR` when `shift = 11`

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

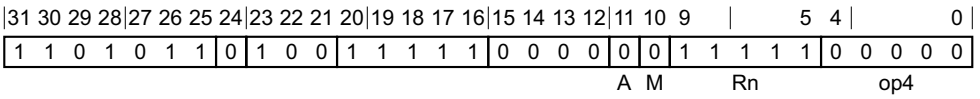
C6.2.77 ERET

Exception Return using the ELR and SPSR for the current Exception level. When executed, the PE restores PSTATE from the SPSR, and branches to the address held in the ELR.

The PE checks the SPSR for the current Exception level for an illegal return event. See *Illegal return events from AArch64 state* on page D1-1884.

ERET is UNDEFINED at EL0.



System variant

ERET

Decode for this encoding

```
if PSTATE.EL == EL0 then UnallocatedEncoding();
```

Operation

```
AArch64.CheckForERetTrap(FALSE, TRUE);
bits(64) target = ELR[];

AArch64.ExceptionReturn(target, SPSR[]);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.78 ERETAA, ERETAB

Exception Return, with pointer authentication. This instruction authenticates the address in ELR, using SP as the modifier and the specified key, the PE restores PSTATE from the SPSR for the current Exception level, and branches to the authenticated address.

Key A is used for `ERETAA`, and key B is used for `ERETAB`.

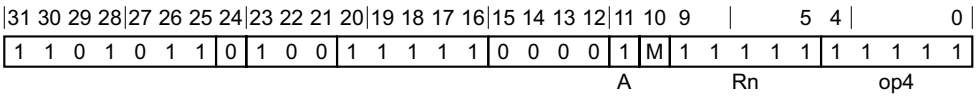
If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to ELR.

The PE checks the SPSR for the current Exception level for an illegal return event. See *Illegal return events from AArch64 state* on page D1-1884.

`ERETAA` and `ERETAB` are UNDEFINED at EL0.

ARMv8.3



ERETAA variant

Applies when `M == 0`.

`ERETAA`

ERETAB variant

Applies when `M == 1`.

`ERETAB`

Decode for all variants of this encoding

```
if PSTATE.EL == EL0 then UnallocatedEncoding();
boolean use_key_a = (M == '0');

if !HavePACExt() then
    UnallocatedEncoding();
```

Operation

```
AArch64.CheckForERetTrap(TRUE, use_key_a);
bits(64) target;

if use_key_a then
    target = AuthIA(ELR[], SP[]);
else
    target = AuthIB(ELR[], SP[]);

AArch64.ExceptionReturn(target, SPSR[]);
```

Non-Confidential

C6.2.79 ESB

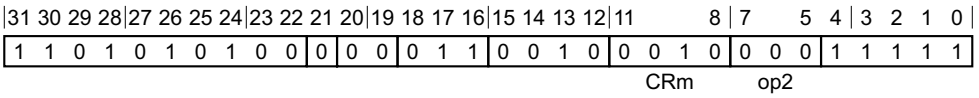
Error Synchronization Barrier is an error synchronization event that might also update DISR_EL1 and VDISR_EL2.

This instruction can be used at all Exception levels and in Debug state.

In Debug state, this instruction behaves as if SError interrupts are masked at all Exception levels. See Error Synchronization Barrier in the ARM(R) Reliability, Availability, and Serviceability (RAS) Specification, ARMv8, for ARMv8-A architecture profile.

If the RAS Extension is not implemented, this instruction executes as a `NOP`.

ARMv8.2



System variant

`ESB`

Decode for this encoding

```
if !HaveRASExt() then EndOfInstruction();
```

Operation

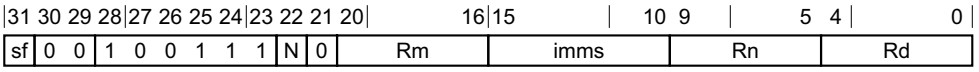
```
SynchronizeErrors();
AArch64.ESBOperation();
if HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0, EL1} then AArch64.vESBOperation();
TakeUnmaskedSErrorInterrupts();
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.80 EXTR

Extract register extracts a register from a pair of registers.

This instruction is used by the alias ROR (immediate). See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0 && N == 0 && imms == 0xxxxx`.

```
EXTR <Wd>, <Wn>, <Wm>, #<lsb>
```

64-bit variant

Applies when `sf == 1 && N == 1`.

```
EXTR <Xd>, <Xn>, <Xm>, #<lsb>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
integer lsb;

if N != sf then UnallocatedEncoding();
if sf == '0' && imms<5> == '1' then ReservedValue();
lsb = UInt(imms);
```

Alias conditions

Alias	is preferred when
ROR (immediate)	`Rn == Rm`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.
`<lsb>`	For the 32-bit variant: is the least significant bit position from which to extract, in the range 0 to 31, encoded in the "imms" field. For the 64-bit variant: is the least significant bit position from which to extract, in the range 0 to 63, encoded in the "imms" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(2*datasize) concat = operand1:operand2;

result = concat<lsb+datasize-1:lsb>;

X[d] = result;
```

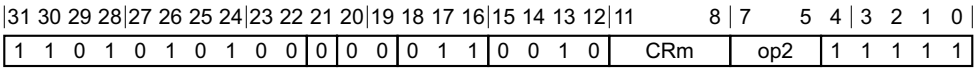
Non-Confidential

C6.2.81 HINT

Hint instruction is for the instruction set space that is reserved for architectural hint instructions.

Some encodings described here are not allocated in this revision of the architecture, and behave as NOPs. These encodings might be allocated to other hint functionality in future revisions of the architecture and therefore must not be used by software.



Hints 6 and 7 variant

Applies when `CRm == 0000 && op2 == 11x`.

```
HINT #<imm>
```

Hints 8 to 15, and 24 to 127 variant

Applies when `CRm != 00x0`.

```
HINT #<imm>
```

Hints 18 to 23 variant

Applies when `CRm == 0010 && op2 != 00x`.

```
HINT #<imm>
```

Assembler symbols

`<imm>` Is a 7-bit unsigned immediate, in the range 0 to 127, excluding the allocated encodings described below, encoded in "CRm:op2".

The following encodings of "CRm:op2" are allocated:

```
0000000    NOP
0000001    YIELD
0000010    WFE
0000011    WFI
0000100    SEV
0000101    SEVL
0010000    ESB
0010001    PSB CSYNC
```

Note

For allocated encodings of "CRm:op2":

- A disassembler will disassemble the allocated instruction, rather than the `HINT` instruction.
- An assembler may support assembly of allocated encodings using `HINT` with the corresponding `<imm>` value, but it is not required to do so.

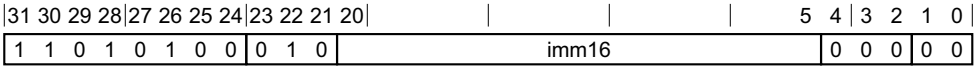
C6.2.82 HLT

Halt instruction generates a Halt Instruction debug event.



System variant

```
HLT #<imm>
```

Decode for this encoding

```
if EDSCR.HDE == '0' || !HaltingAllowed() then UndefinedFault();
```

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
Halt(DebugHalt_HaltInstruction);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

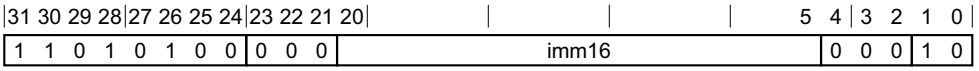
C6.2.83 HVC

Hypervisor Call causes an exception to EL2. Non-secure software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is UNDEFINED:

- At EL0, and Secure EL1.
- When SCR_EL3.HCE is set to 0.

On executing an HVC instruction, the PE records the exception as a Hypervisor Call exception in ESR_ELx, using the EC value 0x16, and the value of the immediate argument.



System variant

```
HVC #<imm>
```

Decode for this encoding

```
// Empty.
```

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
if !HaveEL(EL2) || PSTATE.EL == EL0 || (PSTATE.EL == EL1 && IsSecure()) then
    UnallocatedEncoding();

hvc_enable = if HaveEL(EL3) then SCR_EL3.HCE else NOT(HCR_EL2.HCD);
if hvc_enable == '0' then
    AArch64.UndefinedFault();
else
    AArch64.CallHypervisor(imm16);
```

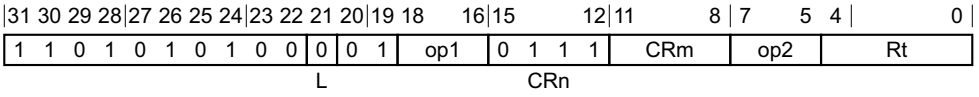
C6.2.84 IC

Instruction Cache operation. For more information, see *op0==0b01, cache maintenance, TLB maintenance, and address translation instructions* on page C5-332.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.



System variant

```
IC <ic_op>{, <Xt>}
```

is equivalent to

```
SYS #<op1>, C7, <Cm>, #<op2>{, <Xt>}
```

and is the preferred disassembly when `SysOp(op1,'0111',CRm,op2) == Sys_IC`.

Assembler symbols

`<ic_op>` Is an IC instruction name, as listed for the IC system instruction pages, encoded in the "op1:CRm:op2" field. It can have the following values:

`IALLUIS`	when `op1 = 000`, `CRm = 0001`, `op2 = 000`
`IALLU`	when `op1 = 000`, `CRm = 0101`, `op2 = 000`
`IVAU`	when `op1 = 011`, `CRm = 0101`, `op2 = 001`

`<op1>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

`<Cm>` Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

`<op2>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

`<Xt>` Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

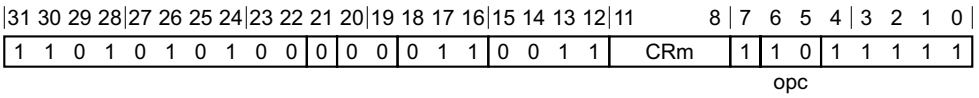
Operation

The description of SYS gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.85 ISB

Instruction Synchronization Barrier flushes the pipeline in the PE and is a context synchronization event. For more information, see *Instruction Synchronization Barrier (ISB)* on page B2-99.



System variant

```
ISB {<option>|#<imm>}
```

Decode for this encoding

```
// Empty.
```

Assembler symbols

`<option>` Specifies an optional limitation on the barrier operation. Values are:

`SY` Full system barrier operation, encoded as `CRm` = `0b1111`. Can be omitted.

All other encodings of `CRm` are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

`<imm>` Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the "CRm" field.

Operation

```
InstructionSynchronizationBarrier();
```

C6.2.86 LDADDB, LDADDAB, LDADDALB, LDADDLB

Atomic add on byte in memory atomically loads an 8-bit byte from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

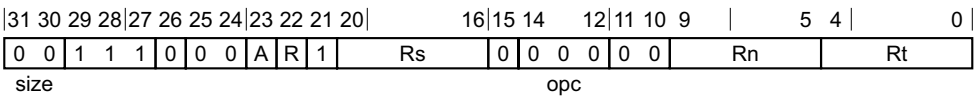
- If the destination register is not WZR, LDADDAB and LDADDALB load from memory with acquire semantics.
- LDADDLB and LDADDALB store to memory with release semantics.
- LDADDB has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STADDB, STADDLB. See *Alias conditions* on page C6-649 for details of when each alias is preferred.

ARMv8.1



LDADDAB variant

Applies when A == 1 && R == 0.

```
LDADDAB <Ws>, <Wt>, [<Xn|SP>]
```

LDADDALB variant

Applies when A == 1 && R == 1.

```
LDADDALB <Ws>, <Wt>, [<Xn|SP>]
```

LDADDB variant

Applies when A == 0 && R == 0.

```
LDADDB <Ws>, <Wt>, [<Xn|SP>]
```

LDADDLB variant

Applies when A == 0 && R == 1.

```
LDADDLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Non-Confidential

Alias conditions

Alias	is preferred when
STADDB, STADDLB	`A == '0' && Rt == '11111'`

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Wt>` Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) value;
bits(8) data;
bits(8) result;

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the
// following load and store atomically.
data = Mem[address, 1, ldacctype];

result = data + value;
Mem[address, 1, stacctype] = result;

if t != 31 then
    X[t] = ZeroExtend(data, 32);
```

C6.2.87 LDADDH, LDADDAH, LDADDALH, LDADDLH

Atomic add on halfword in memory atomically loads a 16-bit halfword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

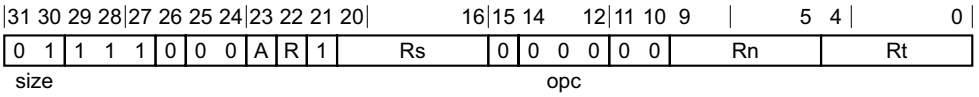
- If the destination register is not WZR, LDADDAH and LDADDALH load from memory with acquire semantics.
- LDADDLH and LDADDALH store to memory with release semantics.
- LDADDH has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STADDH, STADDLH. See *Alias conditions* on page C6-651 for details of when each alias is preferred.

ARMv8.1



LDADDAH variant

Applies when A == 1 && R == 0.

```
LDADDAH <Ws>, <Wt>, [<Xn|SP>]
```

LDADDALH variant

Applies when A == 1 && R == 1.

```
LDADDALH <Ws>, <Wt>, [<Xn|SP>]
```

LDADDH variant

Applies when A == 0 && R == 0.

```
LDADDH <Ws>, <Wt>, [<Xn|SP>]
```

LDADDLH variant

Applies when A == 0 && R == 1.

```
LDADDLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Alias conditions

Alias	is preferred when
STADDH, STADDLH	`A == '0' && Rt == '11111'`

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Wt>` Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) value;
bits(16) data;
bits(16) result;

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the
// following load and store atomically.
data = Mem[address, 2, ldacctype];

result = data + value;
Mem[address, 2, stacctype] = result;

if t != 31 then
    X[t] = ZeroExtend(data, 32);
```

C6.2.88 LDADD, LDADDA, LDADDAL, LDADDL

Atomic add on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

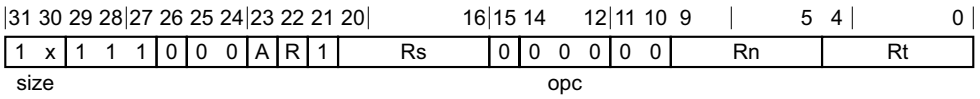
- If the destination register is not one of `WZR` or `XZR`, `LDADDA` and `LDADDAL` load from memory with acquire semantics.
- `LDADDL` and `LDADDAL` store to memory with release semantics.
- `LDADD` has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STADD, STADDL. See *Alias conditions* on page C6-653 for details of when each alias is preferred.

ARMv8.1



32-bit LDADD variant

Applies when `size == 10 && A == 0 && R == 0`.

```
LDADD <Ws>, <Wt>, [<Xn|SP>]
```

32-bit LDADDA variant

Applies when `size == 10 && A == 1 && R == 0`.

```
LDADDA <Ws>, <Wt>, [<Xn|SP>]
```

32-bit LDADDAL variant

Applies when `size == 10 && A == 1 && R == 1`.

```
LDADDAL <Ws>, <Wt>, [<Xn|SP>]
```

32-bit LDADDL variant

Applies when `size == 10 && A == 0 && R == 1`.

```
LDADDL <Ws>, <Wt>, [<Xn|SP>]
```

64-bit LDADD variant

Applies when `size == 11 && A == 0 && R == 0`.

```
LDADD <Xs>, <Xt>, [<Xn|SP>]
```

64-bit LDADDA variant

Applies when `size == 11 && A == 1 && R == 0`.

```
LDADDA <Xs>, <Xt>, [<Xn|SP>]
```

64-bit LDADDAL variant

Applies when size == 11 && A == 1 && R == 1.

```
LDADDAL <Xs>, <Xt>, [<Xn|SP>]
```

64-bit LDADDL variant

Applies when size == 11 && A == 0 && R == 1.

```
LDADDL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

integer datasize = 8 << UInt(size);
integer regsize = if datasize == 64 then 64 else 32;
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Alias conditions

Alias	is preferred when
STADD, STADDL	A == '0' && Rt == '11111'

Assembler symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xs>	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(datasize) value;
bits(datasize) data;
bits(datasize) result;

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the
// following load and store atomically.

C6.2.89 LDAPR

Load-Acquire RCpc Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from the derived address in memory, and writes it to a register.

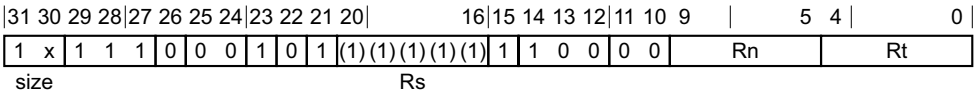
The instruction has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101, except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

ARMv8.3



32-bit variant

Applies when `size == 10`.

```
LDAPR <Wt>, [<Xn|SP> {,#0}]
```

64-bit variant

Applies when `size == 11`.

```
LDAPR <Xt>, [<Xn|SP> {,#0}]
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
```

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
`<Xt>`	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
```

C6.2.90 LDAPRB

Load-Acquire RCpc Register Byte derives an address from a base register value, loads a byte from the derived address in memory, zero-extends it and writes it to a register.

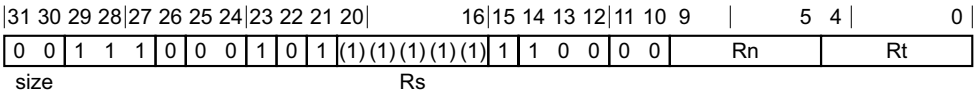
The instruction has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101, except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

ARMv8.3



Integer variant

```
LDAPRB <Wt>, [<Xn|SP> {,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 1, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);
```

C6.2.91 LDAPRH

Load-Acquire RCpc Register Halfword derives an address from a base register value, loads a halfword from the derived address in memory, zero-extends it and writes it to a register.

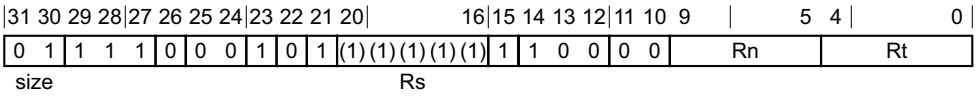
The instruction has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101, except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

ARMv8.3



Integer variant

```
LDAPRH <Wt>, [<Xn|SP> {,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 2, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);
```

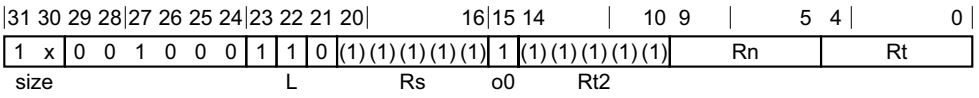
C6.2.92 LDAR

Load-Acquire Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Note

For this instruction, if the destination is WZR/ZXR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.



32-bit variant

Applies when `size == 10`.

```
LDAR <Wt>, [<Xn|SP>{,#0}]
```

64-bit variant

Applies when `size == 11`.

```
LDAR <Xt>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
```

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xt>`	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, dbytes, AccType_ORDERED];
X[t] = ZeroExtend(data, regsize);
```

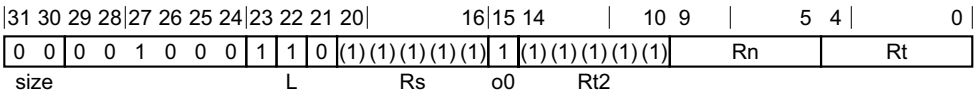
C6.2.93 LDARB

Load-Acquire Register Byte derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Note

For this instruction, if the destination is WZR/ZXR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.



No offset variant

```
LDARB <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 1, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);
```

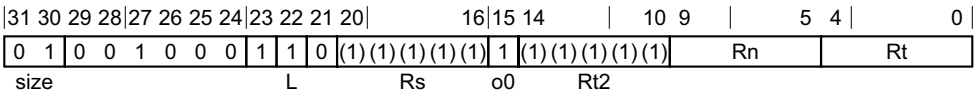
C6.2.94 LDARH

Load-Acquire Register Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it, and writes it to a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Note

For this instruction, if the destination is WZR/ZXR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.



No offset variant

```
LDARH <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 2, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);
```

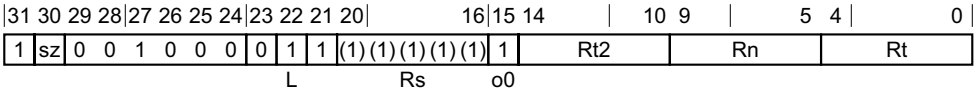
C6.2.95 LDAXP

Load-Acquire Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and is single-copy atomic for each doubleword at doubleword granularity. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores* on page B2-128. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101. For information about memory accesses see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when `sz == 0`.

```
LDAXP <Wt1>, <Wt2>, [<Xn|SP>{,#0}]
```

64-bit variant

Applies when `sz == 1`.

```
LDAXP <Xt1>, <Xt2>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDAXP* on page K1-6418.

Assembler symbols

`<Wt1>`	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
`<Wt2>`	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
`<Xt1>`	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
`<Xt2>`	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

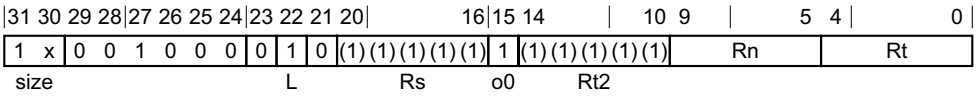
C6.2.96 LDAXR

Load-Acquire Exclusive Register derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores* on page B2-128. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101. For information about memory accesses see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when size == 10.

```
LDAXR <Wt>, [<Xn|SP>{,#0}]
```

64-bit variant

Applies when size == 11.

```
LDAXR <Xt>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, dbytes);

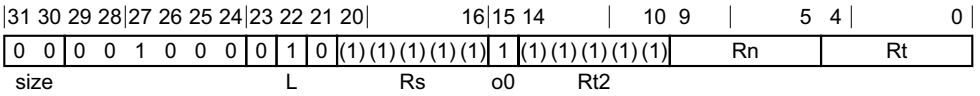
C6.2.97 LDAXRB

Load-Acquire Exclusive Register Byte derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores* on page B2-128. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101. For information about memory accesses see *Load/Store addressing modes* on page C1-149.



No offset variant

```
LDAXRB <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, 1);

data = Mem[address, 1, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);
```

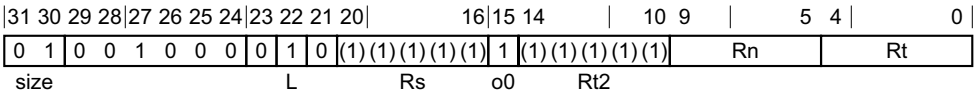
C6.2.98 LDAXRH

Load-Acquire Exclusive Register Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores* on page B2-128. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101. For information about memory accesses see *Load/Store addressing modes* on page C1-149.



No offset variant

```
LDAXRH <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, 2);

data = Mem[address, 2, AccType_ORDERED];
X[t] = ZeroExtend(data, 32);
```

C6.2.99 LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB

Atomic bit clear on byte in memory atomically loads an 8-bit byte from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

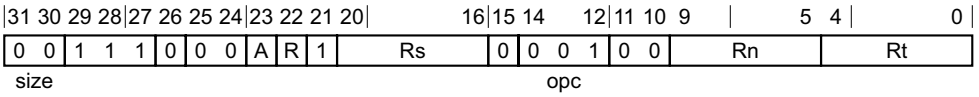
- If the destination register is not WZR, LDCLRAB and LDCLRALB load from memory with acquire semantics.
- LDCLRLB and LDCLRALB store to memory with release semantics.
- LDCLRB has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STCLRB, STCLRLB. See *Alias conditions* on page C6-669 for details of when each alias is preferred.

ARMv8.1



LDCLRAB variant

Applies when A == 1 && R == 0.

```
LDCLRAB <Ws>, <Wt>, [<Xn|SP>]
```

LDCLRALB variant

Applies when A == 1 && R == 1.

```
LDCLRALB <Ws>, <Wt>, [<Xn|SP>]
```

LDCLRB variant

Applies when A == 0 && R == 0.

```
LDCLRB <Ws>, <Wt>, [<Xn|SP>]
```

LDCLRLB variant

Applies when A == 0 && R == 1.

```
LDCLRLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Alias conditions

Alias	is preferred when
STCLRB, STCLRLB	A == '0' && Rt == '11111'

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) value;
bits(8) data;
bits(8) result;

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the
// following load and store atomically.
data = Mem[address, 1, ldacctype];

result = data AND NOT(value);
Mem[address, 1, stacctype] = result;

if t != 31 then
    X[t] = ZeroExtend(data, 32);
```

C6.2.100 LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH

Atomic bit clear on halfword in memory atomically loads a 16-bit halfword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

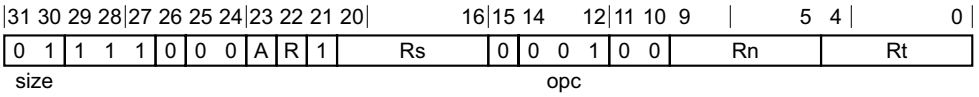
- If the destination register is not WZR, LDCLRAH and LDCLRALH load from memory with acquire semantics.
- LDCLRLH and LDCLRALH store to memory with release semantics.
- LDCLRH has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STCLRH, STCLRLH. See *Alias conditions* on page C6-671 for details of when each alias is preferred.

ARMv8.1



LDCLRAH variant

Applies when A == 1 && R == 0.

```
LDCLRAH <Ws>, <Wt>, [<Xn|SP>]
```

LDCLRALH variant

Applies when A == 1 && R == 1.

```
LDCLRALH <Ws>, <Wt>, [<Xn|SP>]
```

LDCLRH variant

Applies when A == 0 && R == 0.

```
LDCLRH <Ws>, <Wt>, [<Xn|SP>]
```

LDCLRLH variant

Applies when A == 0 && R == 1.

```
LDCLRLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

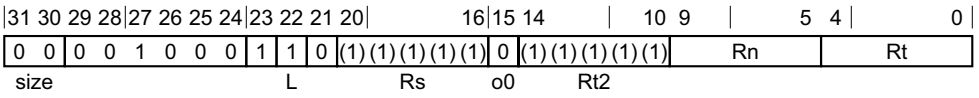
C6.2.105 LDLARB

Load LOAcquire Register Byte loads a byte from memory, zero-extends it and writes it to a register. The instruction also has memory ordering semantics as described in *LoadLOAcquire, StoreLORelease* on page B2-102. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Note

For this instruction, if the destination is WZR/ZXR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

ARMv8.1



No offset variant

```
LDLARB <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 1, AccType_LIMITEDORDERED];
X[t] = ZeroExtend(data, 32);

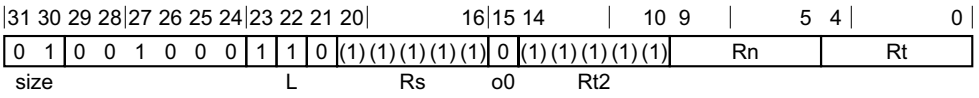
C6.2.106 LDLARH

Load LOAcquire Register Halfword loads a halfword from memory, zero-extends it, and writes it to a register. The instruction also has memory ordering semantics as described in *LoadLOAcquire, StoreLORelease* on page B2-102. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Note

For this instruction, if the destination is WZR/ZXR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

ARMv8.1



No offset variant

```
LDLARH <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, 2, AccType_LIMITEDORDERED];
X[t] = ZeroExtend(data, 32);
```

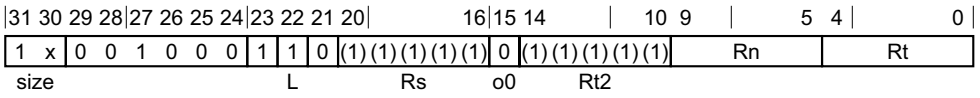
C6.2.107 LDLAR

Load LOAcquire Register loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The instruction also has memory ordering semantics as described in *LoadLOAcquire, StoreLORelease* on page B2-102. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Note

For this instruction, if the destination is WZR/ZXR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

ARMv8.1



32-bit variant

Applies when `size == 10`.

```
LDLAR <Wt>, [<Xn|SP>{,#0}]
```

64-bit variant

Applies when `size == 11`.

```
LDLAR <Xt>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
```

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xt>`	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = Mem[address, dbytes, AccType_LIMITEDORDERED];
X[t] = ZeroExtend(data, regsize);
```

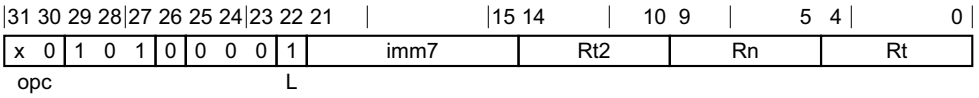
C6.2.108 LDNP

Load Pair of Registers, with non-temporal hint, calculates an address from a base register value and an immediate offset, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers.

For information about memory accesses, see *Load/Store addressing modes* on page C1-149. For information about Non-temporal pair instructions, see *Load/Store Non-temporal Pair* on page C3-172.



32-bit variant

Applies when `opc == 00`.

```
LDNP <Wt1>, <Wt2>, [<Xn|SP>{, #<imm>}]
```

64-bit variant

Applies when `opc == 10`.

```
LDNP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for all variants of this encoding

```
// Empty.
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDNP* on page K1-6419.

Assembler symbols

`<Wt1>`	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
`<Wt2>`	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
`<Xt1>`	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
`<Xt2>`	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
`<imm>`	For the 32-bit variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4. For the 64-bit variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

Shared decode for all encodings

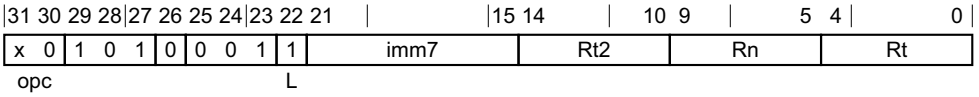
C6.2.109 LDP

Load Pair of Registers calculates an address from a base register value and an immediate offset, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Post-index



32-bit variant

Applies when `opc == 00`.

```
LDP <Wt1>, <Wt2>, [<Xn|SP>], #<imm>
```

64-bit variant

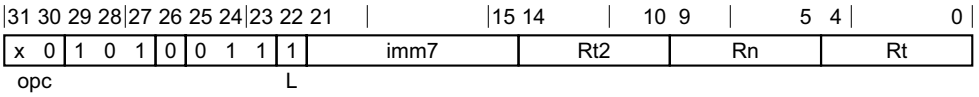
Applies when `opc == 10`.

```
LDP <Xt1>, <Xt2>, [<Xn|SP>], #<imm>
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = TRUE;
```

Pre-index



32-bit variant

Applies when `opc == 00`.

```
LDP <Wt1>, <Wt2>, [<Xn|SP>, #<imm>]!
```

64-bit variant

Applies when `opc == 10`.

```
LDP <Xt1>, <Xt2>, [<Xn|SP>, #<imm>]!
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = FALSE;
```

Signed offset

C6.2.111 LDR (immediate)

Load Register (immediate) loads a word or doubleword from memory and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see *Load/Store addressing modes* on page C1-149. The Unsigned offset variant scales the immediate offset value by the size of the value accessed before adding it to the base register value.

Post-index

32-bit variant

Applies when `size == 10`.

```
LDR <Wt>, [<Xn|SP>], #<simm>
```

64-bit variant

Applies when `size == 11`.

```
LDR <Xt>, [<Xn|SP>], #<simm>
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = TRUE;
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

32-bit variant

Applies when `size == 10`.

```
LDR <Wt>, [<Xn|SP>, #<simm>]!
```

64-bit variant

Applies when `size == 11`.

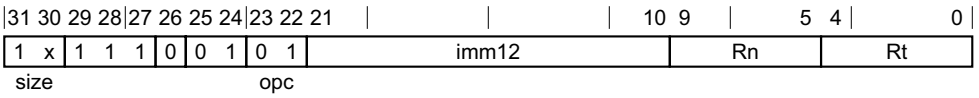
```
LDR <Xt>, [<Xn|SP>, #<simm>]!
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = FALSE;
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Unsigned offset



32-bit variant

Applies when `size == 10`.

```
LDR <Wt>, [<Xn|SP>{, #<pimm>}]
```

64-bit variant

Applies when `size == 11`.

```
LDR <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for all variants of this encoding

```
boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
bits(64) offset = LSL(ZeroExtend(imm12, 64), scale);
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDR (immediate)* on page K1-6420.

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xt>`	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
`<simm>`	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
`<pimm>`	For the 32-bit variant: is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4. For the 64-bit variant: is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer regsize;

regsize = if size == '11' then 64 else 32;
integer datasize = 8 << scale;
```

Operation for all encodings

```
bits(64) address;
bits(datasize) data;
boolean wb_unknown = FALSE;

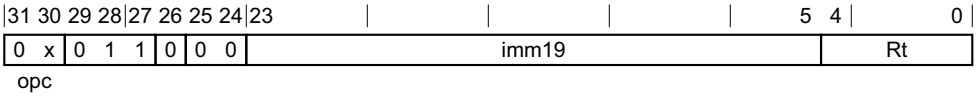
C6.2.112 LDR (literal)

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when `opc == 00`.

```
LDR <Wt>, <label>
```

64-bit variant

Applies when `opc == 01`.

```
LDR <Xt>, <label>
```

Decode for all variants of this encoding

```
integer t = UInt(Rt);
MemOp memop = MemOp_LOAD;
boolean signed = FALSE;
integer size;
bits(64) offset;

case opc of
    when '00'
        size = 4;
    when '01'
        size = 8;
    when '10'
        size = 4;
        signed = TRUE;
    when '11'
        memop = MemOp_PREFETCH;

offset = SignExtend(imm19:'00', 64);
```

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
`<Xt>`	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
`<label>`	Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

```
bits(64) address = PC[] + offset;
bits(size*8) data;

case memop of
    when MemOp_LOAD
        data = Mem[address, size, AccType_NORMAL];
        if signed then
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
            X[t] = SignExtend(data, 64);
        else
            X[t] = data;

    when MemOp_PREFETCH
        Prefetch(address, t<4:0>);
```

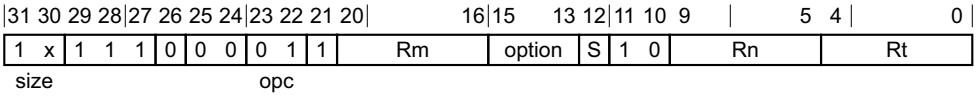
C6.2.113 LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted and extended. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when `size == 10`.

```
LDR <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

64-bit variant

Applies when `size == 11`.

```
LDR <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
integer scale = UInt(size);
if option<1> == '0' then UnallocatedEncoding();    // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;
```

Assembler symbols

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

`<Wm>` When `option<0>` is set to `0`, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

`<Xm>` When `option<0>` is set to `1`, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

`<extend>` Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

- `UXTW` when `option = 010`
- `LSL` when `option = 011`
- `SXTW` when `option = 110`
- `SXTX` when `option = 111`

`<amount>` For the 32-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- `#0` when `S = 0`
- `#2` when `S = 1`

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

For the 64-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

`#0` when `S = 0`

`#3` when `S = 1`

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
integer regsize;

regsize = if size == '11' then 64 else 32;
integer datasize = 8 << scale;
```

Operation

```
bits(64) offset = ExtendReg(m, extend_type, shift);
bits(64) address;
bits(datasize) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, datasize DIV 8, AccType_NORMAL];
X[t] = ZeroExtend(data, regsize);
```

C6.2.114 LDRAA, LDRAB

Load Register, with pointer authentication. This instruction authenticates an address from a base register using a modifier of zero and the specified key, adds an immediate offset to the authenticated address, and loads a 64-bit doubleword from memory at this resulting address into a register.

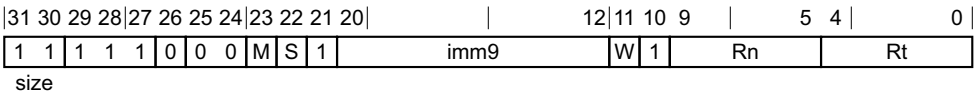
Key A is used for LDRAA, and key B is used for LDRAB.

If the authentication passes, the PE behaves the same as for an LDR instruction. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to the base register, unless the pre-indexed variant of the instruction is used. In this case, the address that is written back to the base register does not include the pointer authentication code.

For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

ARMv8.3



Key A, offset variant

Applies when M == 0 && W == 0.

```
LDRAA <Xt>, [<Xn|SP>{, #<simm>}]
```

Key A, pre-indexed variant

Applies when M == 0 && W == 1.

```
LDRAA <Xt>, [<Xn|SP>{, #<simm>}]!
```

Key B, offset variant

Applies when M == 1 && W == 0.

```
LDRAB <Xt>, [<Xn|SP>{, #<simm>}]
```

Key B, pre-indexed variant

Applies when M == 1 && W == 1.

```
LDRAB <Xt>, [<Xn|SP>{, #<simm>}]!
```

Decode for all variants of this encoding

```
if !HavePACExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
boolean wback = (W == '1');
boolean use_key_a = (M == '0');
bits(10) S10 = S:imm9;
bits(64) offset = LSL(SignExtend(S10, 64), 3);
```

Assembler symbols

<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<simm> Is the optional signed immediate byte offset, a multiple of 8 in the range -4096 to 4088, defaulting to 0 and encoded in the "S:imm9" field as <simm>/8.

Operation

```
bits(64) address;
bits(64) data;
boolean wb_unknown = FALSE;

if wback && n == t && n != 31 then
    c = ConstrainUnpredictable();
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE;    // writeback is suppressed
        when Constraint_UNKNOWN    wb_unknown = TRUE;    // writeback is UNKNOWN
        when Constraint_UNDEF      UnallocatedEncoding();
        when Constraint_NOP        EndOfInstruction();

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

if use_key_a then
    address = AuthDA(address, X[31]);
else
    address = AuthDB(address, X[31]);

address = address + offset;
data = Mem[address, 8, AccType_NORMAL];
X[t] = data;

if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    if n == 31 then
        SP[] = address;
    else
        X[n] = address;
```

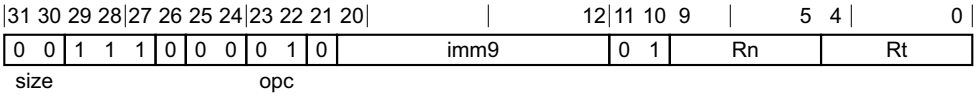
C6.2.115 LDRB (immediate)

Load Register Byte (immediate) loads a byte from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Post-index



Post-index variant

```
LDRB <Wt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

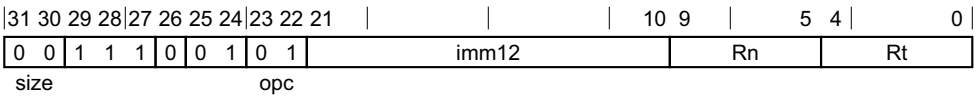
Pre-index variant

```
LDRB <Wt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset



Unsigned offset variant

```
LDRB <Wt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

```
boolean wback = FALSE;
boolean postindex = FALSE;
bits(64) offset = LSL(ZeroExtend(imm12, 64), 0);
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRB (immediate)* on page K1-6421.

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm>	Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Operation for all encodings

```
bits(64) address;
bits(8) data;
boolean wb_unknown = FALSE;

if wback && n == t && n != 31 then
    c = ConstrainUnpredictable();
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE;    // writeback is suppressed
        when Constraint_UNKNOWN    wb_unknown = TRUE;    // writeback is UNKNOWN
        when Constraint_UNDEF      UnallocatedEncoding();
        when Constraint_NOP        EndOfInstruction();

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

if !postindex then
    address = address + offset;

data = Mem[address, 1, AccType_NORMAL];
X[t] = ZeroExtend(data, 32);

if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    elsif postindex then
        address = address + offset;
    if n == 31 then
        SP[] = address;
    else
        X[n] = address;
```

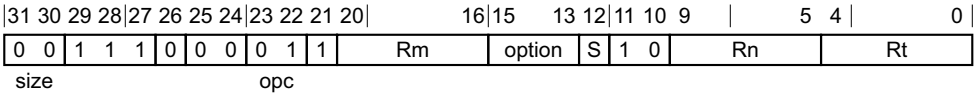
C6.2.116 LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



Extended register variant

Applies when `option != 011`.

```
LDRB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Shifted register variant

Applies when `option == 011`.

```
LDRB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Decode for all variants of this encoding

```
if option<1> == '0' then UnallocatedEncoding();    // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
```

Assembler symbols

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

`<Wm>` When `option<0>` is set to `0`, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

`<Xm>` When `option<0>` is set to `1`, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

`<extend>` Is the index extend specifier, encoded in the "option" field. It can have the following values:

- `UXTW` when `option = 010`
- `SXTW` when `option = 110`
- `SXTX` when `option = 111`

`<amount>` Is the index shift amount, it must be `#0`, encoded in "S" as `0` if omitted, or as `1` if present.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```

Operation

```
bits(64) offset = ExtendReg(m, extend_type, 0);
bits(64) address;
bits(8) data;
```

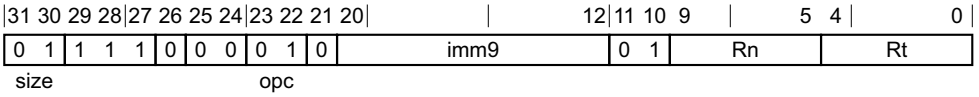
C6.2.117 LDRH (immediate)

Load Register Halfword (immediate) loads a halfword from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Post-index



Post-index variant

```
LDRH <Wt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

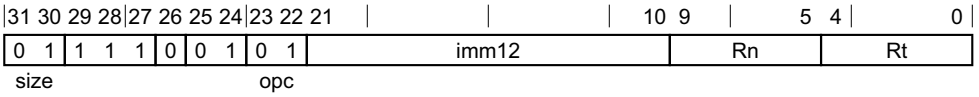
Pre-index variant

```
LDRH <Wt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset



Unsigned offset variant

```
LDRH <Wt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

```
boolean wback = FALSE;
boolean postindex = FALSE;
bits(64) offset = LSL(ZeroExtend(imm12, 64), 1);
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRH (immediate)* on page K1-6421.

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm>	Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Operation for all encodings

```
bits(64) address;
bits(16) data;
boolean wb_unknown = FALSE;

if wback && n == t && n != 31 then
    c = ConstrainUnpredictable();
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE;    // writeback is suppressed
        when Constraint_UNKNOWN    wb_unknown = TRUE;    // writeback is UNKNOWN
        when Constraint_UNDEF      UnallocatedEncoding();
        when Constraint_NOP        EndOfInstruction();

if n == 31 then

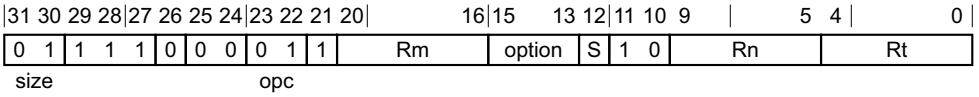
C6.2.118 LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



32-bit variant

```
LDRH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option<1> == '0' then UnallocatedEncoding();    // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then 1 else 0;
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler symbols

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

`<Wm>` When `option<0>` is set to `0`, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

`<Xm>` When `option<0>` is set to `1`, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

`<extend>` Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

- `UXTW` when `option = 010`
- `LSL` when `option = 011`
- `SXTW` when `option = 110`
- `SXTX` when `option = 111`

`<amount>` Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- `#0` when `S = 0`
- `#1` when `S = 1`

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```

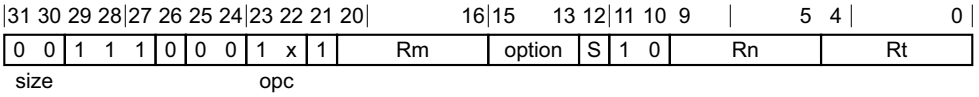
C6.2.120 LDRSB (register)

Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



32-bit with extended register offset variant

Applies when `opc == 11 && option != 011`.

```
LDRSB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

32-bit with shifted register offset variant

Applies when `opc == 11 && option == 011`.

```
LDRSB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

64-bit with extended register offset variant

Applies when `opc == 10 && option != 011`.

```
LDRSB <Xt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

64-bit with shifted register offset variant

Applies when `opc == 10 && option == 011`.

```
LDRSB <Xt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Decode for all variants of this encoding

```
if option<1> == '0' then UnallocatedEncoding();    // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
```

Assembler symbols

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

`<Wm>` When `option<0>` is set to `0`, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

`<Xm>` When `option<0>` is set to `1`, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

`<extend>` Is the index extend specifier, encoded in the "option" field. It can have the following values:

- `UXTW` when `option = 010`
- `SXTW` when `option = 110`
- `SXTX` when `option = 111`

`<amount>` Is the index shift amount, it must be `#0`, encoded in "S" as `0` if omitted, or as `1` if present.

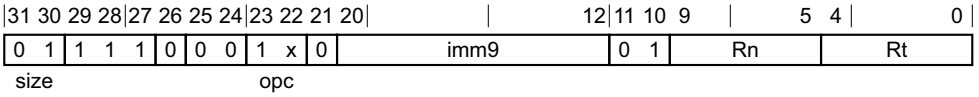
C6.2.121 LDRSH (immediate)

Load Register Signed Halfword (immediate) loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Post-index



32-bit variant

Applies when `opc == 11`.

```
LDRSH <Wt>, [<Xn|SP>], #<simm>
```

64-bit variant

Applies when `opc == 10`.

```
LDRSH <Xt>, [<Xn|SP>], #<simm>
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

32-bit variant

Applies when `opc == 11`.

```
LDRSH <Wt>, [<Xn|SP>, #<simm>]!
```

64-bit variant

Applies when `opc == 10`.

```
LDRSH <Xt>, [<Xn|SP>, #<simm>]!
```

Decode for all variants of this encoding

```
boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset

Non-Confidential

32-bit variant

Applies when opc == 11.

```
LDRSH <Wt>, [<Xn|SP>{, #<pimm>}]
```

64-bit variant

Applies when opc == 10.

```
LDRSH <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for all variants of this encoding

```
boolean wback = FALSE;
boolean postindex = FALSE;
bits(64) offset = LSL(ZeroExtend(imm12, 64), 1);
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRSH (immediate)* on page K1-6422.

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm>	Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
MemOp memop;
boolean signed;
integer regsize;

if opc<1> == '0' then
    // store or zero-extending load
    memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
    regsize = 32;
    signed = FALSE;
else
    // sign-extending load
    memop = MemOp_LOAD;
    regsize = if opc<0> == '1' then 32 else 64;
    signed = TRUE;
```

Operation for all encodings

```
bits(64) address;
bits(16) data;
boolean wb_unknown = FALSE;
boolean rt_unknown = FALSE;

if memop == MemOp_LOAD && wback && n == t && n != 31 then
    c = ConstrainUnpredictable();

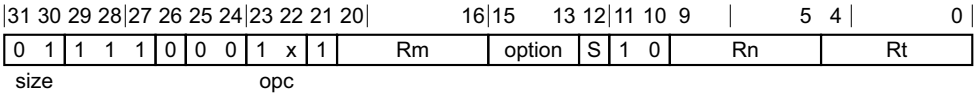
C6.2.122 LDRSH (register)

Load Register Signed Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it, and writes it to a register. For information about memory accesses see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when `opc == 11`.

```
LDRSH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

64-bit variant

Applies when `opc == 10`.

```
LDRSH <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
if option<1> == '0' then UnallocatedEncoding();    // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then 1 else 0;
```

Assembler symbols

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

`<Wm>` When `option<0>` is set to `0`, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

`<Xm>` When `option<0>` is set to `1`, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

`<extend>` Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

- `UXTW` when `option = 010`
- `LSL` when `option = 011`
- `SXTW` when `option = 110`
- `SXTX` when `option = 111`

`<amount>` Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- `#0` when `S = 0`
- `#1` when `S = 1`

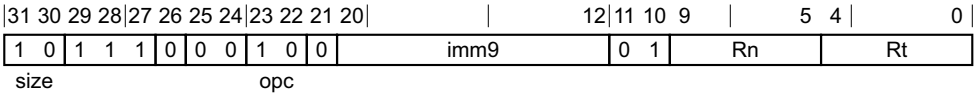
C6.2.123 LDRSW (immediate)

Load Register Signed Word (immediate) loads a word from memory, sign-extends it to 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Post-index



Post-index variant

```
LDRSW <Xt>, [<Xn|SP>], #<simm>
```

Decode for this encoding

```
boolean wback = TRUE;
boolean postindex = TRUE;
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

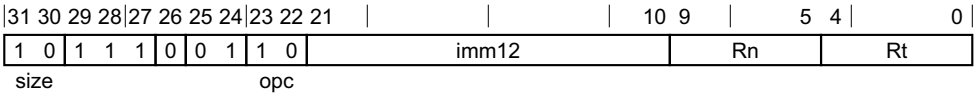
Pre-index variant

```
LDRSW <Xt>, [<Xn|SP>, #<simm>]!
```

Decode for this encoding

```
boolean wback = TRUE;
boolean postindex = FALSE;
bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset



Unsigned offset variant

```
LDRSW <Xt>, [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

```
boolean wback = FALSE;
boolean postindex = FALSE;
bits(64) offset = LSL(ZeroExtend(imm12, 64), 2);
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRSW (immediate)* on page K1-6422.

Assembler symbols

<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm>	Is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the "imm12" field as <pimm>/4.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Operation for all encodings

```
bits(64) address;
bits(32) data;
boolean wb_unknown = FALSE;

if wback && n == t && n != 31 then
    c = ConstrainUnpredictable();
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE;    // writeback is suppressed
        when Constraint_UNKNOWN    wb_unknown = TRUE;    // writeback is UNKNOWN
        when Constraint_UNDEF      UnallocatedEncoding();
        when Constraint_NOP        EndOfInstruction();

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

if !postindex then
    address = address + offset;

data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);
if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;

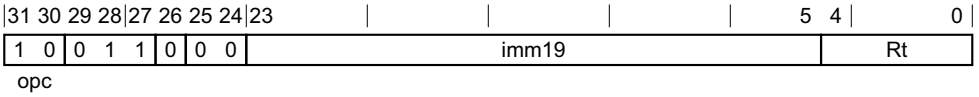
C6.2.124 LDRSW (literal)

Load Register Signed Word (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes on page C1-149*.



Literal variant

```
LDRSW <Xt>, <label>
```

Decode for this encoding

```
integer t = UInt(Rt);
bits(64) offset;

offset = SignExtend(imm19:'00', 64);
```

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<label> Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Operation

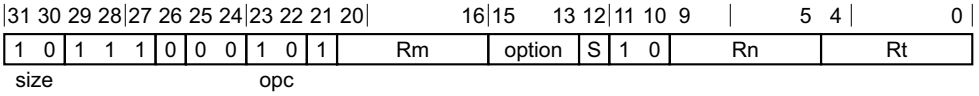
```
bits(64) address = PC[] + offset;
bits(32) data;

data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.125 LDRSW (register)

Load Register Signed Word (register) calculates an address from a base register value and an offset register value, loads a word from memory, sign-extends it to form a 64-bit value, and writes it to a register. The offset register value can be shifted left by 0 or 2 bits. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



64-bit variant

```
LDRSW <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option<1> == '0' then UnallocatedEncoding();    // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then 2 else 0;
```

Assembler symbols

`<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

`<Wm>` When `option<0>` is set to `0`, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

`<Xm>` When `option<0>` is set to `1`, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

`<extend>` Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

- `UXTW` when `option = 010`
- `LSL` when `option = 011`
- `SXTW` when `option = 110`
- `SXTX` when `option = 111`

`<amount>` Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- `#0` when `S = 0`
- `#2` when `S = 1`

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```

Operation

```
bits(64) offset = ExtendReg(m, extend_type, shift);
bits(64) address;
bits(32) data;
```

C6.2.126 LDSETB, LDSETAB, LDSETALB, LDSETLB

Atomic bit set on byte in memory atomically loads an 8-bit byte from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

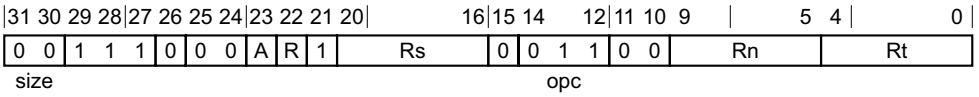
- If the destination register is not WZR, LDSETAB and LDSETALB load from memory with acquire semantics.
- LDSETLB and LDSETALB store to memory with release semantics.
- LDSETB has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STSETB, STSETLB. See *Alias conditions* on page C6-726 for details of when each alias is preferred.

ARMv8.1



LDSETAB variant

Applies when A == 1 && R == 0.

```
LDSETAB <Ws>, <Wt>, [<Xn|SP>]
```

LDSETALB variant

Applies when A == 1 && R == 1.

```
LDSETALB <Ws>, <Wt>, [<Xn|SP>]
```

LDSETB variant

Applies when A == 0 && R == 0.

```
LDSETB <Ws>, <Wt>, [<Xn|SP>]
```

LDSETLB variant

Applies when A == 0 && R == 1.

```
LDSETLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Alias conditions

Alias	is preferred when
STSETB, STSETLB	A == '0' && Rt == '11111'

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) value;
bits(8) data;
bits(8) result;

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the
// following load and store atomically.
data = Mem[address, 1, ldacctype];

result = data OR value;
Mem[address, 1, stacctype] = result;

if t != 31 then
    X[t] = ZeroExtend(data, 32);
```

C6.2.127 LDSETH, LDSETAH, LDSETALH, LDSETLH

Atomic bit set on halfword in memory atomically loads a 16-bit halfword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

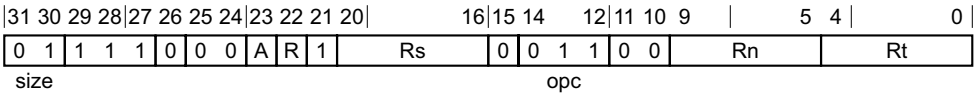
- If the destination register is not `WZR`, `LDSETAH` and `LDSETALH` load from memory with acquire semantics.
- `LDSETLH` and `LDSETALH` store to memory with release semantics.
- `LDSETH` has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STSETH, STSETLH. See *Alias conditions* on page C6-728 for details of when each alias is preferred.

ARMv8.1



LDSETAH variant

Applies when `A == 1 && R == 0`.

```
LDSETAH <Ws>, <Wt>, [<Xn|SP>]
```

LDSETALH variant

Applies when `A == 1 && R == 1`.

```
LDSETALH <Ws>, <Wt>, [<Xn|SP>]
```

LDSETH variant

Applies when `A == 0 && R == 0`.

```
LDSETH <Ws>, <Wt>, [<Xn|SP>]
```

LDSETLH variant

Applies when `A == 0 && R == 1`.

```
LDSETLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Alias conditions

Alias	is preferred when
STSETH, STSETLH	A == '0' && Rt == '11111'

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) value;
bits(16) data;
bits(16) result;

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the
// following load and store atomically.
data = Mem[address, 2, ldacctype];

result = data OR value;
Mem[address, 2, stacctype] = result;

if t != 31 then
    X[t] = ZeroExtend(data, 32);
```

C6.2.128 LDSET, LDSETA, LDSETAL, LDSETL

Atomic bit set on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

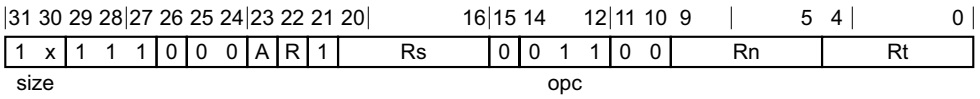
- If the destination register is not one of `WZR` or `XZR`, `LDSETA` and `LDSETAL` load from memory with acquire semantics.
- `LDSETL` and `LDSETAL` store to memory with release semantics.
- `LDSET` has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STSET, STSETL. See *Alias conditions* on page C6-730 for details of when each alias is preferred.

ARMv8.1



32-bit LDSET variant

Applies when `size == 10 && A == 0 && R == 0`.

```
LDSET <Ws>, <Wt>, [<Xn|SP>]
```

32-bit LDSETA variant

Applies when `size == 10 && A == 1 && R == 0`.

```
LDSETA <Ws>, <Wt>, [<Xn|SP>]
```

32-bit LDSETAL variant

Applies when `size == 10 && A == 1 && R == 1`.

```
LDSETAL <Ws>, <Wt>, [<Xn|SP>]
```

32-bit LDSETL variant

Applies when `size == 10 && A == 0 && R == 1`.

```
LDSETL <Ws>, <Wt>, [<Xn|SP>]
```

64-bit LDSET variant

Applies when `size == 11 && A == 0 && R == 0`.

```
LDSET <Xs>, <Xt>, [<Xn|SP>]
```

64-bit LDSETA variant

Applies when `size == 11 && A == 1 && R == 0`.

```
LDSETA <Xs>, <Xt>, [<Xn|SP>]
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

64-bit LDSETAL variant

Applies when size == 11 && A == 1 && R == 1.

```
LDSETAL <Xs>, <Xt>, [<Xn|SP>]
```

64-bit LDSETL variant

Applies when size == 11 && A == 0 && R == 1.

```
LDSETL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

integer datasize = 8 << UInt(size);
integer regsize = if datasize == 64 then 64 else 32;
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Alias conditions

Alias	is preferred when
STSET, STSETL	A == '0' && Rt == '11111'

Assembler symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xs>	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(datasize) value;
bits(datasize) data;
bits(datasize) result;

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the
// following load and store atomically.
data = Mem[address, datasize DIV 8, ldacctype];

result = data OR value;
Mem[address, datasize DIV 8, stacctype] = result;

C6.2.129 LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB

Atomic signed maximum on byte in memory atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers. The value initially loaded from memory is returned in the destination register.

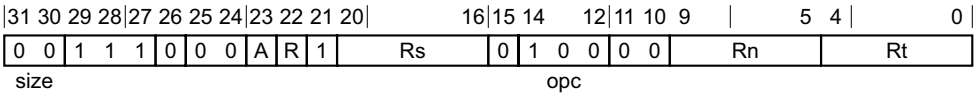
- If the destination register is not `WZR`, `LDSMAXAB` and `LDSMAXALB` load from memory with acquire semantics.
- `LDSMAXLB` and `LDSMAXALB` store to memory with release semantics.
- `LDSMAXB` has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STSMAXB, STSMAXLB. See *Alias conditions* on page C6-733 for details of when each alias is preferred.

ARMv8.1



LDSMAXAB variant

Applies when `A == 1 && R == 0`.

```
LDSMAXAB <Ws>, <Wt>, [<Xn|SP>]
```

LDSMAXALB variant

Applies when `A == 1 && R == 1`.

```
LDSMAXALB <Ws>, <Wt>, [<Xn|SP>]
```

LDSMAXB variant

Applies when `A == 0 && R == 0`.

```
LDSMAXB <Ws>, <Wt>, [<Xn|SP>]
```

LDSMAXLB variant

Applies when `A == 0 && R == 1`.

```
LDSMAXLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Alias conditions

Alias	is preferred when
STSMAXB, STSMAXLB	A == '0' && Rt == '11111'

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) value;
bits(8) data;
bits(8) result;

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the
// following load and store atomically.
data = Mem[address, 1, ldacctype];

result = if SInt(data) > SInt(value) then data else value;
Mem[address, 1, stacctype] = result;

if t != 31 then
    X[t] = ZeroExtend(data, 32);
```

C6.2.130 LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH

Atomic signed maximum on halfword in memory atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers. The value initially loaded from memory is returned in the destination register.

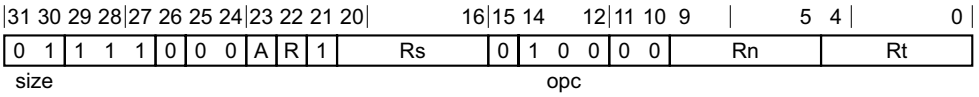
- If the destination register is not WZR, LDSMAXAH and LDSMAXALH load from memory with acquire semantics.
- LDSMAXLH and LDSMAXALH store to memory with release semantics.
- LDSMAXH has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STSMAXH, STSMAXLH. See *Alias conditions* on page C6-735 for details of when each alias is preferred.

ARMv8.1



LDSMAXAH variant

Applies when A == 1 && R == 0.

```
LDSMAXAH <Ws>, <Wt>, [<Xn|SP>]
```

LDSMAXALH variant

Applies when A == 1 && R == 1.

```
LDSMAXALH <Ws>, <Wt>, [<Xn|SP>]
```

LDSMAXH variant

Applies when A == 0 && R == 0.

```
LDSMAXH <Ws>, <Wt>, [<Xn|SP>]
```

LDSMAXLH variant

Applies when A == 0 && R == 1.

```
LDSMAXLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

C6.2.135 LDTR

Load Register (unprivileged) loads a word or doubleword from memory, and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

32-bit variant

Applies when size == 10.

```
LDTR <Wt>, [<Xn|SP>{, #<simm>}]
```

64-bit variant

Applies when size == 11.

```
LDTR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype = AccType_UNPRIV;
if (HaveNVExt() && HaveEL(EL2) && HCR_EL2.NV == 1 && HCR_EL2.NV1 == 1) then
    acctype = AccType_NORMAL;
integer regsize;

regsize = if size == '11' then 64 else 32;
integer datasize = 8 << scale;
```

Non-Confidential

C6.2.136 LDTRB

Load Register Byte (unprivileged) loads a byte from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Unscaled offset variant

```
LDTRB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype = AccType_UNPRIV;
if (HaveNVExt() && HaveEL(EL2) && HCR_EL2.NV == 1 && HCR_EL2.NV1 == 1) then
    acctype = AccType_NORMAL;
```

Operation

```
bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 1, acctype];

C6.2.137 LDTRH

Load Register Halfword (unprivileged) loads a halfword from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Unscaled offset variant

```
LDTRH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype = AccType_UNPRIV;
if (HaveNVExt() && HaveEL(EL2) && HCR_EL2.NV == 1 && HCR_EL2.NV1 == 1) then
    acctype = AccType_NORMAL;
```

Operation

```
bits(64) address;
bits(16) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 2, acctype];
X[t] = ZeroExtend(data, 32);
```

C6.2.138 LDTRSB

Load Register Signed Byte (unprivileged) loads a byte from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

32-bit variant

Applies when opc == 11.

```
LDTRSB <Wt>, [<Xn|SP>{, #<simm>}]
```

64-bit variant

Applies when opc == 10.

```
LDTRSB <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype = AccType_UNPRIV;

C6.2.141 LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB

Atomic unsigned maximum on byte in memory atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

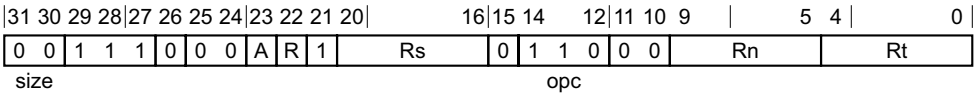
- If the destination register is not WZR, LDUMAXAB and LDUMAXALB load from memory with acquire semantics.
- LDUMAXLB and LDUMAXALB store to memory with release semantics.
- LDUMAXB has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STUMAXB, STUMAXLB. See *Alias conditions* on page C6-756 for details of when each alias is preferred.

ARMv8.1



LDUMAXAB variant

Applies when A == 1 && R == 0.

```
LDUMAXAB <Ws>, <Wt>, [<Xn|SP>]
```

LDUMAXALB variant

Applies when A == 1 && R == 1.

```
LDUMAXALB <Ws>, <Wt>, [<Xn|SP>]
```

LDUMAXB variant

Applies when A == 0 && R == 0.

```
LDUMAXB <Ws>, <Wt>, [<Xn|SP>]
```

LDUMAXLB variant

Applies when A == 0 && R == 1.

```
LDUMAXLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Alias conditions

Alias	is preferred when
STUMAXB, STUMAXLB	`A == '0' && Rt == '11111'`

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Wt>` Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) value;
bits(8) data;
bits(8) result;

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the
// following load and store atomically.
data = Mem[address, 1, ldacctype];

result = if UInt(data) > UInt(value) then data else value;
Mem[address, 1, stacctype] = result;

if t != 31 then
    X[t] = ZeroExtend(data, 32);
```

C6.2.142 LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH

Atomic unsigned maximum on halfword in memory atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

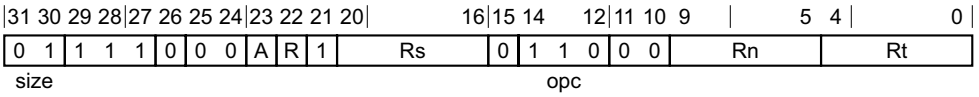
- If the destination register is not WZR, LDUMAXAH and LDUMAXALH load from memory with acquire semantics.
- LDUMAXLH and LDUMAXALH store to memory with release semantics.
- LDUMAXH has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STUMAXH, STUMAXLH. See *Alias conditions* on page C6-758 for details of when each alias is preferred.

ARMv8.1



LDUMAXAH variant

Applies when A == 1 && R == 0.

```
LDUMAXAH <Ws>, <Wt>, [<Xn|SP>]
```

LDUMAXALH variant

Applies when A == 1 && R == 1.

```
LDUMAXALH <Ws>, <Wt>, [<Xn|SP>]
```

LDUMAXH variant

Applies when A == 0 && R == 0.

```
LDUMAXH <Ws>, <Wt>, [<Xn|SP>]
```

LDUMAXLH variant

Applies when A == 0 && R == 1.

```
LDUMAXLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

C6.2.143 LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL

Atomic unsigned maximum on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

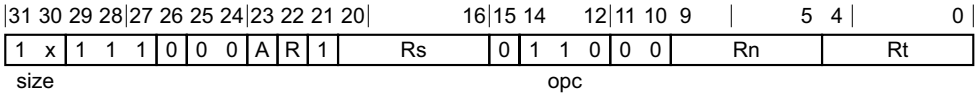
- If the destination register is not one of `WZR` or `XZR`, `LDUMAXA` and `LDUMAXAL` load from memory with acquire semantics.
- `LDUMAXL` and `LDUMAXAL` store to memory with release semantics.
- `LDUMAX` has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STUMAX, STUMAXL. See *Alias conditions* on page C6-760 for details of when each alias is preferred.

ARMv8.1



32-bit LDUMAX variant

Applies when `size == 10 && A == 0 && R == 0`.

```
LDUMAX <Ws>, <Wt>, [<Xn|SP>]
```

32-bit LDUMAXA variant

Applies when `size == 10 && A == 1 && R == 0`.

```
LDUMAXA <Ws>, <Wt>, [<Xn|SP>]
```

32-bit LDUMAXAL variant

Applies when `size == 10 && A == 1 && R == 1`.

```
LDUMAXAL <Ws>, <Wt>, [<Xn|SP>]
```

32-bit LDUMAXL variant

Applies when `size == 10 && A == 0 && R == 1`.

```
LDUMAXL <Ws>, <Wt>, [<Xn|SP>]
```

64-bit LDUMAX variant

Applies when `size == 11 && A == 0 && R == 0`.

```
LDUMAX <Xs>, <Xt>, [<Xn|SP>]
```

64-bit LDUMAXA variant

Applies when `size == 11 && A == 1 && R == 0`.

```

C6.2.144 LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB

Atomic unsigned minimum on byte in memory atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

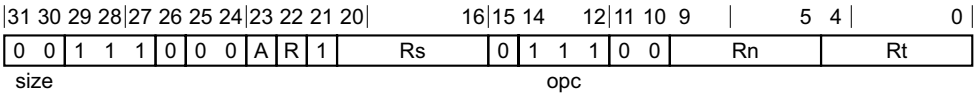
- If the destination register is not WZR, LDUMINAB and LDUMINALB load from memory with acquire semantics.
- LDUMINLB and LDUMINALB store to memory with release semantics.
- LDUMINB has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STUMINB, STUMINLB. See *Alias conditions* on page C6-763 for details of when each alias is preferred.

ARMv8.1



LDUMINAB variant

Applies when A == 1 && R == 0.

```
LDUMINAB <Ws>, <Wt>, [<Xn|SP>]
```

LDUMINALB variant

Applies when A == 1 && R == 1.

```
LDUMINALB <Ws>, <Wt>, [<Xn|SP>]
```

LDUMINB variant

Applies when A == 0 && R == 0.

```
LDUMINB <Ws>, <Wt>, [<Xn|SP>]
```

LDUMINLB variant

Applies when A == 0 && R == 1.

```
LDUMINLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

LDUMINAH variant

Applies when A == 1 && R == 0.

```
LDUMINAH <Ws>, <Wt>, [<Xn|SP>]
```

LDUMINALH variant

Applies when A == 1 && R == 1.

```
LDUMINALH <Ws>, <Wt>, [<Xn|SP>]
```

LDUMINH variant

Applies when A == 0 && R == 0.

```
LDUMINH <Ws>, <Wt>, [<Xn|SP>]
```

LDUMINLH variant

Applies when A == 0 && R == 1.

```
LDUMINLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Alias conditions

Alias	is preferred when
STUMINH, STUMINLH	`A == '0' && Rt == '11111'`

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Wt>` Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) value;
bits(16) data;
bits(16) result;

value = X[s];
if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the
// following load and store atomically.
data = Mem[address, 2, ldacctype];

result = if UInt(data) > UInt(value) then value else data;

Mem[address, 2, stacctype] = result;

if t != 31 then
    X[t] = ZeroExtend(data, 32);
```

C6.2.146 LDUMIN, LDUMINA, LDUMINAL, LDUMINL

Atomic unsigned minimum on word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

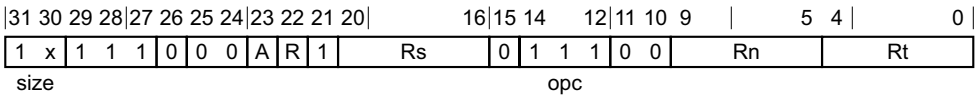
- If the destination register is not one of `WZR` or `XZR`, `LDUMINA` and `LDUMINAL` load from memory with acquire semantics.
- `LDUMINL` and `LDUMINAL` store to memory with release semantics.
- `LDUMIN` has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is used by the alias STUMIN, STUMINL. See *Alias conditions* on page C6-767 for details of when each alias is preferred.

ARMv8.1



32-bit LDUMIN variant

Applies when `size == 10 && A == 0 && R == 0`.

```
LDUMIN <Ws>, <Wt>, [<Xn|SP>]
```

32-bit LDUMINA variant

Applies when `size == 10 && A == 1 && R == 0`.

```
LDUMINA <Ws>, <Wt>, [<Xn|SP>]
```

32-bit LDUMINAL variant

Applies when `size == 10 && A == 1 && R == 1`.

```
LDUMINAL <Ws>, <Wt>, [<Xn|SP>]
```

32-bit LDUMINL variant

Applies when `size == 10 && A == 0 && R == 1`.

```
LDUMINL <Ws>, <Wt>, [<Xn|SP>]
```

64-bit LDUMIN variant

Applies when `size == 11 && A == 0 && R == 0`.

```
LDUMIN <Xs>, <Xt>, [<Xn|SP>]
```

64-bit LDUMINA variant

Applies when `size == 11 && A == 1 && R == 0`.

```
LDUMINA <Xs>, <Xt>, [<Xn|SP>]
```

64-bit LDUMINAL variant

Applies when size == 11 && A == 1 && R == 1.

```
LDUMINAL <Xs>, <Xt>, [<Xn|SP>]
```

64-bit LDUMINL variant

Applies when size == 11 && A == 0 && R == 1.

```
LDUMINL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();
integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

integer datasize = 8 << UInt(size);
integer regsize = if datasize == 64 then 64 else 32;
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Alias conditions

Alias	is preferred when
STUMIN, STUMINL	A == '0' && Rt == '11111'

Assembler symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xs>	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

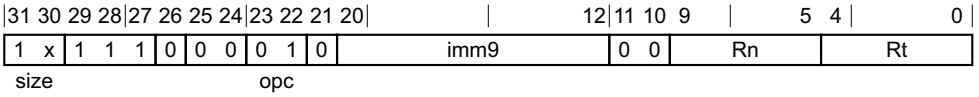
C6.2.147 LDUR

Load Register (unscaled) calculates an address from a base register and an immediate offset, loads a 32-bit word or 64-bit doubleword from memory, zero-extends it, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when `size == 10`.

```
LDUR <Wt>, [<Xn|SP>{, #<simm>}]
```

64-bit variant

Applies when `size == 11`.

```
LDUR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xt>`	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
`<simm>`	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer regsize;

regsize = if size == '11' then 64 else 32;
integer datasize = 8 << scale;
```

Operation

```
bits(64) address;
bits(datasize) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;
```

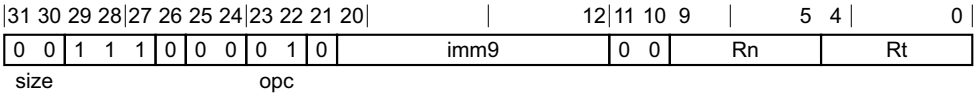
C6.2.148 LDURB

Load Register Byte (unscaled) calculates an address from a base register and an immediate offset, loads a byte from memory, zero-extends it, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



Unscaled offset variant

```
LDURB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Operation

```
bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 1, AccType_NORMAL];
X[t] = ZeroExtend(data, 32);
```

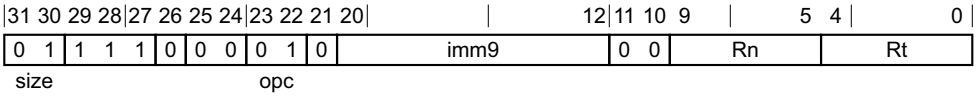
C6.2.149 LDURH

Load Register Halfword (unscaled) calculates an address from a base register and an immediate offset, loads a halfword from memory, zero-extends it, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



Unscaled offset variant

```
LDURH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Operation

```
bits(64) address;
bits(16) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 2, AccType_NORMAL];
X[t] = ZeroExtend(data, 32);
```

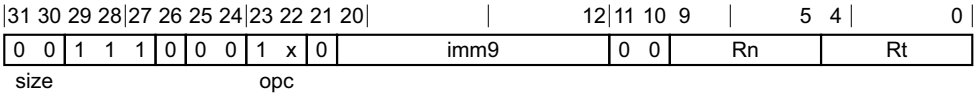
C6.2.150 LDURSB

Load Register Signed Byte (unscaled) calculates an address from a base register and an immediate offset, loads a signed byte from memory, sign-extends it, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when `opc == 11`.

```
LDURSB <Wt>, [<Xn|SP>{, #<simm>}]
```

64-bit variant

Applies when `opc == 10`.

```
LDURSB <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xt>`	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
`<simm>`	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
MemOp memop;
boolean signed;
integer regsize;

if opc<1> == '0' then
    // store or zero-extending load
    memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
    regsize = 32;
    signed = FALSE;
else
    // sign-extending load
    memop = MemOp_LOAD;

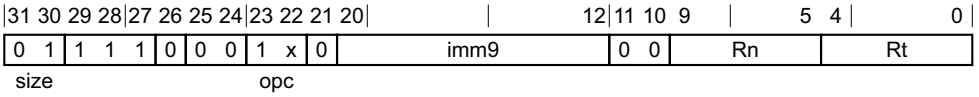
C6.2.151 LDURSH

Load Register Signed Halfword (unscaled) calculates an address from a base register and an immediate offset, loads a signed halfword from memory, sign-extends it, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when opc == 11.

```
LDURSH <Wt>, [<Xn|SP>{, #<simm>}]
```

64-bit variant

Applies when opc == 10.

```
LDURSH <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
MemOp memop;
boolean signed;
integer regsize;

if opc<1> == '0' then
    // store or zero-extending load
    memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
    regsize = 32;
    signed = FALSE;
else
    // sign-extending load
    memop = MemOp_LOAD;
    regsize = if opc<0> == '1' then 32 else 64;
    signed = TRUE;
```

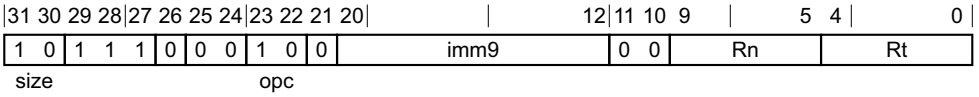
C6.2.152 LDURSW

Load Register Signed Word (unscaled) calculates an address from a base register and an immediate offset, loads a signed word from memory, sign-extends it, and writes it to a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



Unscaled offset variant

```
LDURSW <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Operation

```
bits(64) address;
bits(32) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = Mem[address, 4, AccType_NORMAL];
X[t] = SignExtend(data, 64);
```

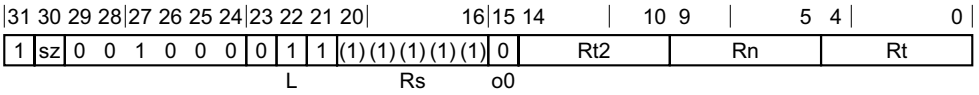
C6.2.153 LDXP

Load Exclusive Pair of Registers derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and is single-copy atomic for each doubleword at doubleword granularity. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores* on page B2-128. For information about memory accesses see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when `sz == 0`.

```
LDXP <Wt1>, <Wt2>, [<Xn|SP>{,#0}]
```

64-bit variant

Applies when `sz == 1`.

```
LDXP <Xt1>, <Xt2>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDXP* on page K1-6422.

Assembler symbols

`<Wt1>`	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
`<Wt2>`	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
`<Xt1>`	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
`<Xt2>`	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

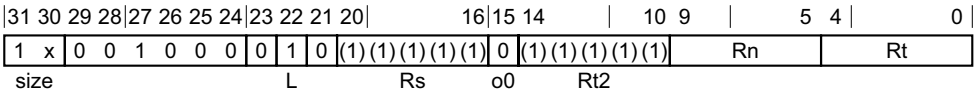
C6.2.154 LDXR

Load Exclusive Register derives an address from a base register value, loads a 32-bit word or a 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores* on page B2-128. For information about memory accesses see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when size == 10.

```
LDXR <Wt>, [<Xn|SP>{,#0}]
```

64-bit variant

Applies when size == 11.

```
LDXR <Xt>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, dbytes);

data = Mem[address, dbytes, AccType_ATOMIC];
X[t] = ZeroExtend(data, regsize);
```

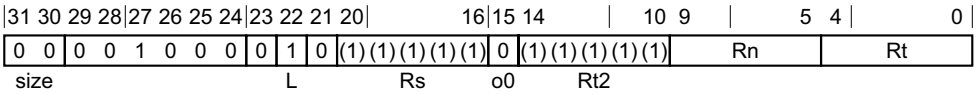
C6.2.155 LDXRB

Load Exclusive Register Byte derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores* on page B2-128. For information about memory accesses see *Load/Store addressing modes* on page C1-149.



No offset variant

```
LDXRB <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, 1);

data = Mem[address, 1, AccType_ATOMIC];
X[t] = ZeroExtend(data, 32);
```

LDXRH <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// Tell the Exclusives monitors to record a sequence of one or more atomic
// memory reads from virtual address range [address, address+dbytes-1].
// The Exclusives monitor will only be set if all the reads are from the
// same dbytes-aligned physical address, to allow for the possibility of
// an atomicity break if the translation is changed between reads.
AArch64.SetExclusiveMonitors(address, 2);

data = Mem[address, 2, AccType_ATOMIC];
X[t] = ZeroExtend(data, 32);
```

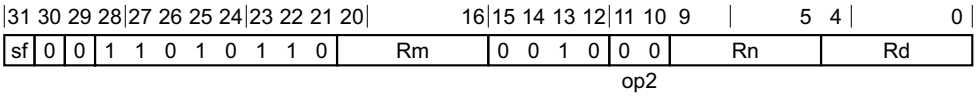
C6.2.157 LSL (register)

Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is left-shifted.

This instruction is an alias of the LSLV instruction. This means that:

- The encodings in this description are named to match the encodings of LSLV.
- The description of LSLV gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

`LSL <Wd>, <Wn>, <Wm>`

is equivalent to

`LSLV <Wd>, <Wn>, <Wm>`

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

`LSL <Xd>, <Xn>, <Xm>`

is equivalent to

`LSLV <Xd>, <Xn>, <Xm>`

and is always the preferred disassembly.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of LSLV gives the operational pseudocode for this instruction.

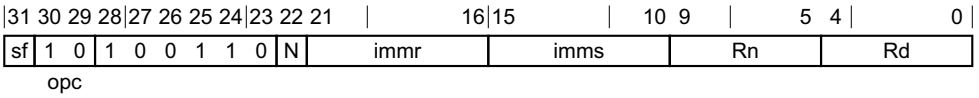
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.158 LSL (immediate)

Logical Shift Left (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0 && imms != 011111`.

`LSL <Wd>, <Wn>, #<shift>`

is equivalent to

`UBFM <Wd>, <Wn>, #(-<shift> MOD 32), #(31-<shift>)`

and is the preferred disassembly when `imms + 1 == immr`.

64-bit variant

Applies when `sf == 1 && N == 1 && imms != 111111`.

`LSL <Xd>, <Xn>, #<shift>`

is equivalent to

`UBFM <Xd>, <Xn>, #(-<shift> MOD 64), #(63-<shift>)`

and is the preferred disassembly when `imms + 1 == immr`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<shift>`	For the 32-bit variant: is the shift amount, in the range 0 to 31. For the 64-bit variant: is the shift amount, in the range 0 to 63.

Operation

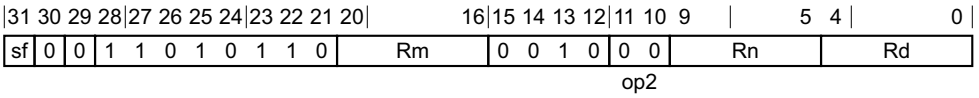
The description of UBFM gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.159 LSLV

Logical Shift Left Variable shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is left-shifted.

This instruction is used by the alias LSL (register). The alias is always the preferred disassembly.



32-bit variant

Applies when `sf == 0`.

```
LSLV <Wd>, <Wn>, <Wm>
```

64-bit variant

Applies when `sf == 1`.

```
LSLV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

```
bits(datasize) result;
bits(datasize) operand2 = X[m];

result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
```

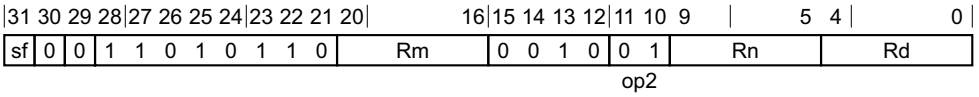
C6.2.160 LSR (register)

Logical Shift Right (register) shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is an alias of the LSRV instruction. This means that:

- The encodings in this description are named to match the encodings of LSRV.
- The description of LSRV gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

`LSR <Wd>, <Wn>, <Wm>`

is equivalent to

`LSRV <Wd>, <Wn>, <Wm>`

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

`LSR <Xd>, <Xn>, <Xm>`

is equivalent to

`LSRV <Xd>, <Xn>, <Xm>`

and is always the preferred disassembly.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of LSRV gives the operational pseudocode for this instruction.

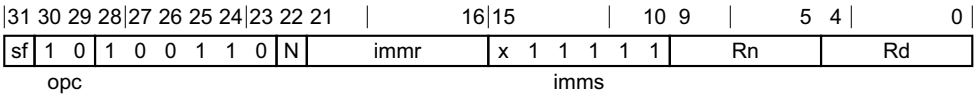
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.161 LSR (immediate)

Logical Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0 && imms == 011111`.

```
LSR <Wd>, <Wn>, #<shift>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #<shift>, #31
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1 && N == 1 && imms == 111111`.

```
LSR <Xd>, <Xn>, #<shift>
```

is equivalent to

```
UBFM <Xd>, <Xn>, #<shift>, #63
```

and is always the preferred disassembly.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<shift>`	For the 32-bit variant: is the shift amount, in the range 0 to 31, encoded in the "immr" field. For the 64-bit variant: is the shift amount, in the range 0 to 63, encoded in the "immr" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

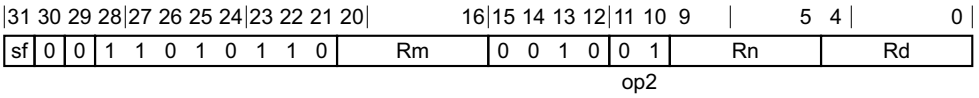
Non-Confidential

C6.2.162 LSRV

Logical Shift Right Variable shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias LSR (register). The alias is always the preferred disassembly.



32-bit variant

Applies when `sf == 0`.

```
LSRV <Wd>, <Wn>, <Wm>
```

64-bit variant

Applies when `sf == 1`.

```
LSRV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

```
bits(datasize) result;
bits(datasize) operand2 = X[m];

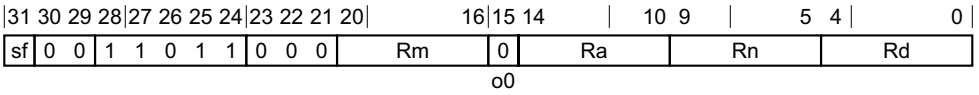
result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.163 MADD

Multiply-Add multiplies two register values, adds a third register value, and writes the result to the destination register.

This instruction is used by the alias MUL. See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
MADD <Wd>, <Wn>, <Wm>, <Wa>
```

64-bit variant

Applies when `sf == 1`.

```
MADD <Xd>, <Xn>, <Xm>, <Xa>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = if sf == '1' then 64 else 32;
```

Alias conditions

Alias	is preferred when
MUL	`Ra == '11111'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
`<Wa>`	Is the 32-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<Xa> Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation

```
bits(destsize) operand1 = X[n];
bits(destsize) operand2 = X[m];
bits(destsize) operand3 = X[a];

integer result;

result = UInt(operand3) + (UInt(operand1) * UInt(operand2));

X[d] = result<destsize-1:0>;
```

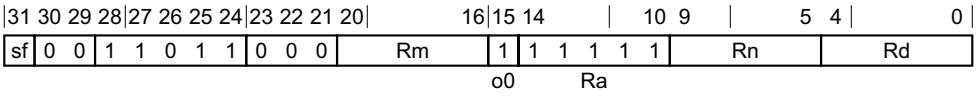
C6.2.164 MNEG

Multiply-Negate multiplies two register values, negates the product, and writes the result to the destination register.

This instruction is an alias of the MSUB instruction. This means that:

- The encodings in this description are named to match the encodings of MSUB.
- The description of MSUB gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
MNEG <Wd>, <Wn>, <Wm>
```

is equivalent to

```
MSUB <Wd>, <Wn>, <Wm>, WZR
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
MNEG <Xd>, <Xn>, <Xm>
```

is equivalent to

```
MSUB <Xd>, <Xn>, <Xm>, XZR
```

and is always the preferred disassembly.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of MSUB gives the operational pseudocode for this instruction.

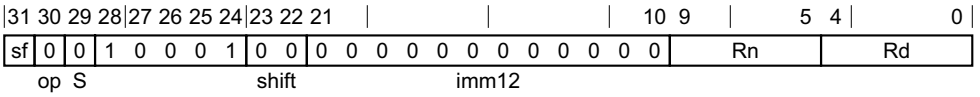
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.165 MOV (to/from SP)

Move between register and stack pointer : `Rd = Rn`.

This instruction is an alias of the ADD (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ADD (immediate).
- The description of ADD (immediate) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
MOV <Wd|WSP>, <Wn|WSP>
```

is equivalent to

```
ADD <Wd|WSP>, <Wn|WSP>, #0
```

and is the preferred disassembly when `(Rd == '11111' || Rn == '11111')`.

64-bit variant

Applies when `sf == 1`.

```
MOV <Xd|SP>, <Xn|SP>
```

is equivalent to

```
ADD <Xd|SP>, <Xn|SP>, #0
```

and is the preferred disassembly when `(Rd == '11111' || Rn == '11111')`.

Assembler symbols

`<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

`<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

`<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

`<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Operation

The description of ADD (immediate) gives the operational pseudocode for this instruction.

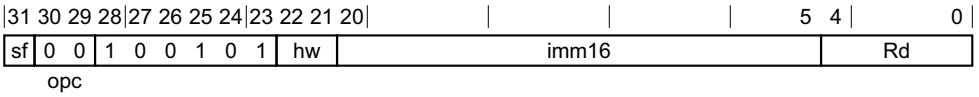
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.166 MOV (inverted wide immediate)

Move (inverted wide immediate) moves an inverted 16-bit immediate value to a register.

This instruction is an alias of the MOVN instruction. This means that:

- The encodings in this description are named to match the encodings of MOVN.
- The description of MOVN gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
MOV <Wd>, #<imm>
```

is equivalent to

```
MOVN <Wd>, #<imm16>, LSL #<shift>
```

and is the preferred disassembly when `! (IsZero(imm16) && hw != '00') && ! IsOnes(imm16)`.

64-bit variant

Applies when `sf == 1`.

```
MOV <Xd>, #<imm>
```

is equivalent to

```
MOVN <Xd>, #<imm16>, LSL #<shift>
```

and is the preferred disassembly when `! (IsZero(imm16) && hw != '00')`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<imm>`	For the 32-bit variant: is a 32-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw", but excluding 0xffff0000 and 0x0000ffff For the 64-bit variant: is a 64-bit immediate, the bitwise inverse of which can be encoded in "imm16:hw".
`<shift>`	For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16. For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

The description of MOVN gives the operational pseudocode for this instruction.

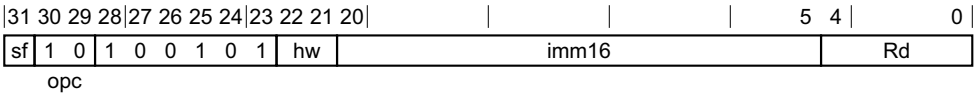
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.167 MOV (wide immediate)

Move (wide immediate) moves a 16-bit immediate value to a register.

This instruction is an alias of the MOVZ instruction. This means that:

- The encodings in this description are named to match the encodings of MOVZ.
- The description of MOVZ gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
MOV <Wd>, #<imm>
```

is equivalent to

```
MOVZ <Wd>, #<imm16>, LSL #<shift>
```

and is the preferred disassembly when `! (IsZero(imm16) && hw != '00')`.

64-bit variant

Applies when `sf == 1`.

```
MOV <Xd>, #<imm>
```

is equivalent to

```
MOVZ <Xd>, #<imm16>, LSL #<shift>
```

and is the preferred disassembly when `! (IsZero(imm16) && hw != '00')`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<imm>`	For the 32-bit variant: is a 32-bit immediate which can be encoded in "imm16:hw". For the 64-bit variant: is a 64-bit immediate which can be encoded in "imm16:hw".
`<shift>`	For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16. For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

The description of MOVZ gives the operational pseudocode for this instruction.

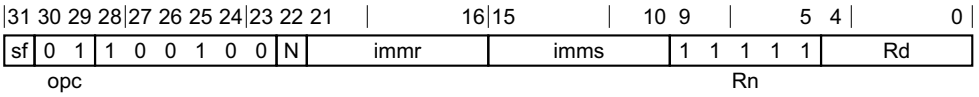
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.168 MOV (bitmask immediate)

Move (bitmask immediate) writes a bitmask immediate value to a register.

This instruction is an alias of the ORR (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (immediate).
- The description of ORR (immediate) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0`.

```
MOV <Wd|WSP>, #<imm>
```

is equivalent to

```
ORR <Wd|WSP>, WZR, #<imm>
```

and is the preferred disassembly when `! MoveWidePreferred(sf, N, imms, immr)`.

64-bit variant

Applies when `sf == 1`.

```
MOV <Xd|SP>, #<imm>
```

is equivalent to

```
ORR <Xd|SP>, XZR, #<imm>
```

and is the preferred disassembly when `! MoveWidePreferred(sf, N, imms, immr)`.

Assembler symbols

`<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

`<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

`<imm>` For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr", but excluding values which could be encoded by MOVZ or MOVN.

For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr", but excluding values which could be encoded by MOVZ or MOVN.

Operation

The description of ORR (immediate) gives the operational pseudocode for this instruction.

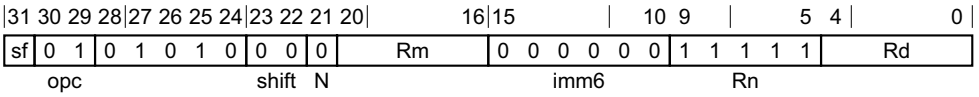
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.169 MOV (register)

Move (register) copies the value in a source register to the destination register.

This instruction is an alias of the ORR (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ORR (shifted register).
- The description of ORR (shifted register) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
MOV <Wd>, <Wm>
```

is equivalent to

```
ORR <Wd>, WZR, <Wm>
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
MOV <Xd>, <Xm>
```

is equivalent to

```
ORR <Xd>, XZR, <Xm>
```

and is always the preferred disassembly.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wm>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xm>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

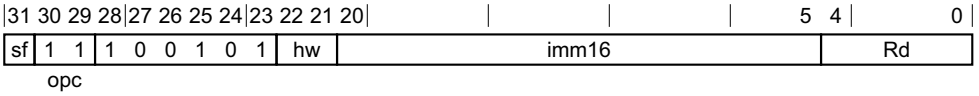
Operation

The description of ORR (shifted register) gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.170 MOVK

Move wide with keep moves an optionally-shifted 16-bit immediate value into a register, keeping other bits unchanged.



32-bit variant

Applies when `sf == 0`.

```
MOVK <Wd>, #<imm>{, LSL #<shift>}
```

64-bit variant

Applies when `sf == 1`.

```
MOVK <Xd>, #<imm>{, LSL #<shift>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
integer pos;

if sf == '0' && hw<1> == '1' then UnallocatedEncoding();
pos = UInt(hw:'0000');
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<imm>`	Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
`<shift>`	For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16. For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

```
bits(datasize) result;

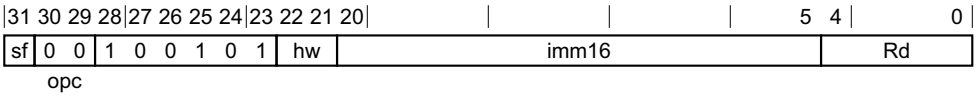
result = X[d];
result<pos+15:pos> = imm16;
X[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.171 MOVN

Move wide with NOT moves the inverse of an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (inverted wide immediate). See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
MOVN <Wd>, #<imm>{, LSL #<shift>}
```

64-bit variant

Applies when `sf == 1`.

```
MOVN <Xd>, #<imm>{, LSL #<shift>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
integer pos;

if sf == '0' && hw<1> == '1' then UnallocatedEncoding();
pos = UInt(hw:'0000');
```

Alias conditions

Alias	of variant	is preferred when
MOV (inverted wide immediate)	64-bit	`! (IsZero(imm16) && hw != '00')`
MOV (inverted wide immediate)	32-bit	`! (IsZero(imm16) && hw != '00') && ! IsOnes(imm16)`

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<imm>	Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
<shift>	For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16. For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

```
bits(datasize) result;

result = Zeros();
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
result<pos+15:pos> = imm16;
result = NOT(result);
X[d] = result;
```

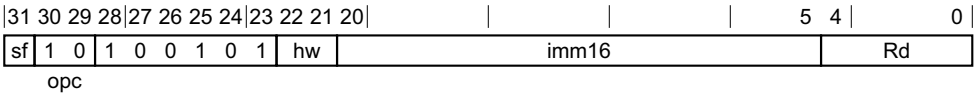
C6.2.172 MOVZ

Move wide with zero moves an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (wide immediate). See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when sf == 0.

```
MOVZ <Wd>, #<imm>{, LSL #<shift>}
```

64-bit variant

Applies when sf == 1.

```
MOVZ <Xd>, #<imm>{, LSL #<shift>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
integer pos;

if sf == '0' && hw<1> == '1' then UnallocatedEncoding();
pos = UInt(hw:'0000');
```

Alias conditions

Alias	is preferred when
MOV (wide immediate)	! (IsZero(imm16) && hw != '00')

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<imm>	Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
<shift>	For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16. For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.

Operation

```
bits(datasize) result;

result = Zeros();
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
result<pos+15:pos> = imm16;
X[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

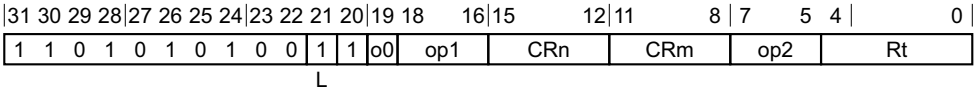
C6.2.173 MRS

Move System Register allows the PE to read an AArch64 System register into a general-purpose register.



System variant

```
MRS <Xt>, (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>)
```

Decode for this encoding

```
AArch64.CheckSystemAccess('1':o0, op1, CRn, CRm, op2, Rt, L);

integer t = UInt(Rt);

integer sys_op0 = 2 + UInt(o0);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);
```

Assembler symbols

<Xt>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.
<systemreg>	Is a System register name, encoded in the "o0:op1:CRn:CRm:op2". The System register names are defined in Chapter D10 *AArch64 System Register Descriptions*.
<op0>	Is an unsigned immediate, encoded in the "o0" field. It can have the following values: 2 when o0 = 0 3 when o0 = 1
<op1>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cn>	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

Operation

```
X[t] = AArch64.SysRegRead(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

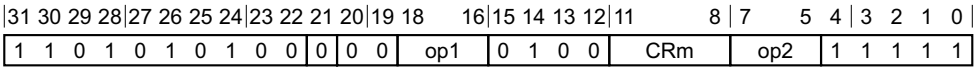
C6.2.174 MSR (immediate)

Move immediate value to Special Register moves an immediate value to selected bits of the PSTATE. For more information, see PSTATE.

The bits that can be written are D, A, I, F, and SP. This set of bits is expanded in extensions to the architecture as follows:

- ARMv8.1-PAN adds the PAN bit.
- ARMv8.2-UAO adds the UAO bit.



System variant

```
MSR <pstatefield>, #<imm>
```

Decode for this encoding

```
AArch64.CheckSystemAccess('00', op1, '0100', CRm, op2, '11111', '0');

PSTATEField field;
case op1:op2 of
    when '000 011'
        if !HaveUAOExt() then
            UnallocatedEncoding();
        field = PSTATEField_UAO;
    when '000 100'
        if !HavePANExt() then
            UnallocatedEncoding();
        field = PSTATEField_PAN;
    when '000 101' field = PSTATEField_SP;
    when '011 110' field = PSTATEField_DAIFSet;
    when '011 111' field = PSTATEField_DAIFClr;
    otherwise UnallocatedEncoding();

// Check that an AArch64 MSR/MRS access to the DAIF flags is permitted
if op1 == '011' && PSTATE.EL == EL0 && (IsInHost() || SCTLR_EL1.UMA == '0') then
    AArch64.SystemRegisterTrap(EL1, '00', op2, op1, '0100', '11111', CRm, '0');
```

Assembler symbols

<pstatefield> Is a PSTATE field name, encoded in the "op1:op2" field. It can have the following values:

SPSel when op1 = 000, op2 = 101

DAIFSet when op1 = 011, op2 = 110

DAIFClr when op1 = 011, op2 = 111

When ARMv8.2-UAO is implemented, the following value is also valid:

UAO when op1 = 000, op2 = 011

When ARMv8.1-PAN is implemented, the following value is also valid:

PAN when op1 = 000, op2 = 100

The following encodings are reserved:

- op1 = 000, op2 = 00x.
- op1 = 000, op2 = 010.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

- op1 = 000, op2 = 11x.
- op1 = 001, op2 = xxx.
- op1 = 010, op2 = xxx.
- op1 = 011, op2 = 0xx.
- op1 = 011, op2 = 10x.
- op1 = 1xx, op2 = xxx.

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

Operation

```
case field of
    when PSTATEField_SP
        PSTATE.SP = CRm<0>;
    when PSTATEField_DAIFSet
        PSTATE.D = PSTATE.D OR CRm<3>;
        PSTATE.A = PSTATE.A OR CRm<2>;
        PSTATE.I = PSTATE.I OR CRm<1>;
        PSTATE.F = PSTATE.F OR CRm<0>;
    when PSTATEField_DAIFClr
        PSTATE.D = PSTATE.D AND NOT(CRm<3>);
        PSTATE.A = PSTATE.A AND NOT(CRm<2>);
        PSTATE.I = PSTATE.I AND NOT(CRm<1>);
        PSTATE.F = PSTATE.F AND NOT(CRm<0>);
    when PSTATEField_PAN
        PSTATE.PAN = CRm<0>;
    when PSTATEField_UAO
        PSTATE.UAO = CRm<0>;
```

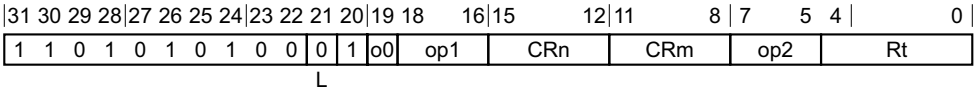
C6.2.175 MSR (register)

Move general-purpose register to System Register allows the PE to write an AArch64 System register from a general-purpose register.



System variant

```
MSR (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>), <Xt>
```

Decode for this encoding

```
AArch64.CheckSystemAccess('1':o0, op1, CRn, CRm, op2, Rt, L);

integer t = UInt(Rt);

integer sys_op0 = 2 + UInt(o0);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);
```

Assembler symbols

<systemreg>	Is a System register name, encoded in the "o0:op1:CRn:CRm:op2". The System register names are defined in Chapter D10 *AArch64 System Register Descriptions*.
<op0>	Is an unsigned immediate, encoded in the "o0" field. It can have the following values: 2 when o0 = 0 3 when o0 = 1
<op1>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cn>	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

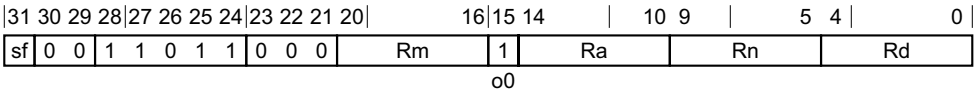
```
AArch64.SysRegWrite(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, X[t]);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.176 MSUB

Multiply-Subtract multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register.

This instruction is used by the alias MNEG. See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
MSUB <Wd>, <Wn>, <Wm>, <Wa>
```

64-bit variant

Applies when `sf == 1`.

```
MSUB <Xd>, <Xn>, <Xm>, <Xa>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = if sf == '1' then 64 else 32;
```

Alias conditions

Alias	is preferred when
MNEG	`Ra == '11111'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
`<Wa>`	Is the 32-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<Xa> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Operation

```
bits(destsize) operand1 = X[n];
bits(destsize) operand2 = X[m];
bits(destsize) operand3 = X[a];

integer result;

result = UInt(operand3) - (UInt(operand1) * UInt(operand2));
X[d] = result<destsize-1:0>;
```

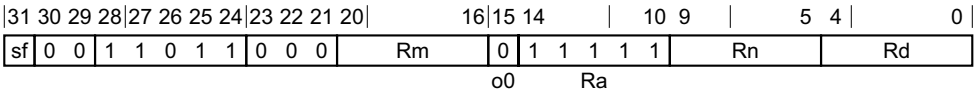
C6.2.177 MUL

Multiply : `Rd = Rn * Rm`.

This instruction is an alias of the MADD instruction. This means that:

- The encodings in this description are named to match the encodings of MADD.
- The description of MADD gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

`MUL <Wd>, <Wn>, <Wm>`

is equivalent to

`MADD <Wd>, <Wn>, <Wm>, WZR`

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

`MUL <Xd>, <Xn>, <Xm>`

is equivalent to

`MADD <Xd>, <Xn>, <Xm>, XZR`

and is always the preferred disassembly.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of MADD gives the operational pseudocode for this instruction.

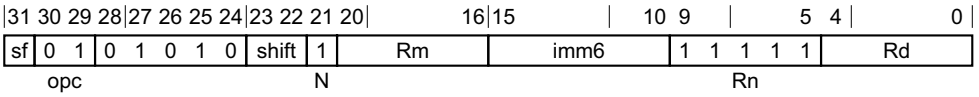
C6.2.178 MVN

Bitwise NOT writes the bitwise inverse of a register value to the destination register.

This instruction is an alias of the ORN (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ORN (shifted register).
- The description of ORN (shifted register) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
MVN <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ORN <Wd>, WZR, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
MVN <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ORN <Xd>, XZR, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wm>` Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xm>` Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- `LSL` when `shift = 00`
- `LSR` when `shift = 01`
- `ASR` when `shift = 10`
- `ROR` when `shift = 11`

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

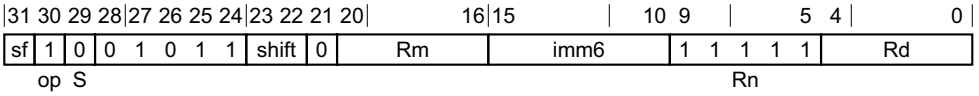
C6.2.179 NEG (shifted register)

Negate (shifted register) negates an optionally-shifted register value, and writes the result to the destination register.

This instruction is an alias of the SUB (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of SUB (shifted register).
- The description of SUB (shifted register) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
NEG <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUB  <Wd>, WZR, <Wm> {, <shift> #<amount>}
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
NEG <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUB  <Xd>, XZR, <Xm> {, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wm>` Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xm>` Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- `LSL` when `shift = 00`
- `LSR` when `shift = 01`
- `ASR` when `shift = 10`

The encoding `shift = 11` is reserved.

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

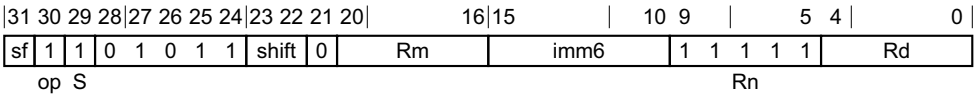
C6.2.180 NEGS

Negate, setting flags, negates an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is an alias of the SUBS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
NEGS <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS <Wd>, WZR, <Wm> {, <shift> #<amount>}
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
NEGS <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS <Xd>, XZR, <Xm> {, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wm>` Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xm>` Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- `LSL` when `shift = 00`
- `LSR` when `shift = 01`
- `ASR` when `shift = 10`

The encoding `shift = 11` is reserved.

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

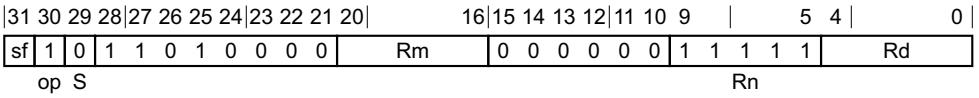
C6.2.181 NGC

Negate with Carry negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register.

This instruction is an alias of the SBC instruction. This means that:

- The encodings in this description are named to match the encodings of SBC.
- The description of SBC gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
NGC <Wd>, <Wm>
```

is equivalent to

```
SBC <Wd>, WZR, <Wm>
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
NGC <Xd>, <Xm>
```

is equivalent to

```
SBC <Xd>, XZR, <Xm>
```

and is always the preferred disassembly.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wm>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xm>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SBC gives the operational pseudocode for this instruction.

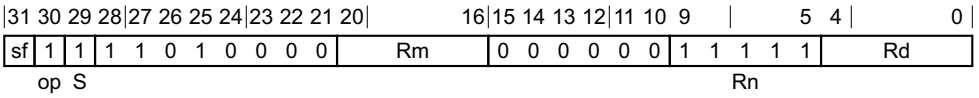
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.182 NGCS

Negate with Carry, setting flags, negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is an alias of the SBCS instruction. This means that:

- The encodings in this description are named to match the encodings of SBCS.
- The description of SBCS gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

`NGCS <Wd>, <Wm>`

is equivalent to

`SBCS <Wd>, WZR, <Wm>`

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

`NGCS <Xd>, <Xm>`

is equivalent to

`SBCS <Xd>, XZR, <Xm>`

and is always the preferred disassembly.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wm>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xm>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SBCS gives the operational pseudocode for this instruction.

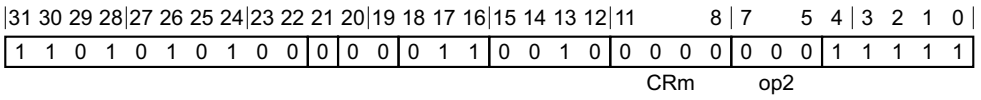
Non-Confidential

C6.2.183 NOP

No Operation does nothing, other than advance the value of the program counter by 4. This instruction can be used for instruction alignment purposes.

Note

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.



System variant

NOP

Decode for this encoding

```
// Empty.
```

Operation

```
// do nothing
```

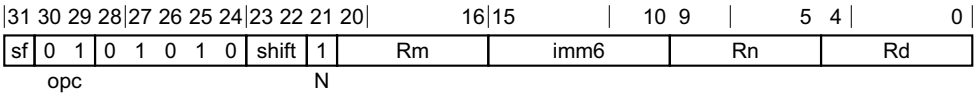
C6.2.184 ORN (shifted register)

Bitwise OR NOT (shifted register) performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias MVN. See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
ORN <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant

Applies when `sf == 1`.

```
ORN <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Alias conditions

Alias	is preferred when
MVN	`Rn == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- `LSL` when `shift = 00`
- `LSR` when `shift = 01`

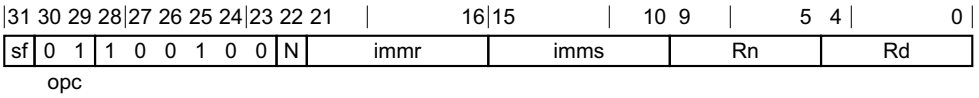
C6.2.185 ORR (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate register value, and writes the result to the destination register.

This instruction is used by the alias MOV (bitmask immediate). See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0 && N == 0`.

```
ORR <Wd|WSP>, <Wn>, #<imm>
```

64-bit variant

Applies when `sf == 1`.

```
ORR <Xd|SP>, <Xn>, #<imm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;
if sf == '0' && N != '0' then ReservedValue();
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

Alias conditions

Alias	is preferred when
MOV (bitmask immediate)	`Rn == '11111' && ! MoveWidePreferred(sf, N, imms, immr)`

Assembler symbols

`<Wd|WSP>`	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd|SP>`	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<imm>`	For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr". For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

Non-Confidential

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];

result = operand1 OR imm;
if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

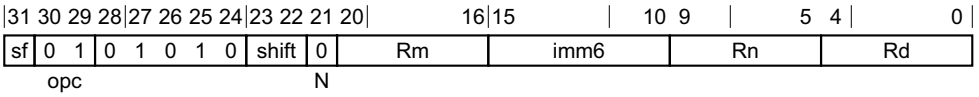
Non-Confidential

C6.2.186 ORR (shifted register)

Bitwise OR (shifted register) performs a bitwise (inclusive) OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

This instruction is used by the alias MOV (register). See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
ORR <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant

Applies when `sf == 1`.

```
ORR <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Alias conditions

Alias	is preferred when
MOV (register)	`shift == '00' && imm6 == '000000' && Rn == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- `LSL` when `shift = 00`
- `LSR` when `shift = 01`

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

ASR when shift = 10

ROR when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

result = operand1 OR operand2;
X[d] = result;
```

C6.2.187 PACDA, PACDZA

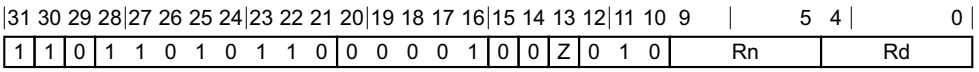
Pointer Authentication Code for Data address, using key A. This instruction computes and inserts a pointer authentication code for a data address, using a modifier and key A.

The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACDA.
- The value zero, for PACDZA.

ARMv8.3



PACDA variant

Applies when Z == 0.

```
PACDA <Xd>, <Xn|SP>
```

PACDZA variant

Applies when Z == 1 && Rn == 11111.

```
PACDZA <Xd>
```

Decode for all variants of this encoding

```
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
    UnallocatedEncoding();

if Z == '0' then // PACDA
    if n == 31 then source_is_sp = TRUE;
else // PACDZA
    if n != 31 then UnallocatedEncoding();
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    X[d] = AddPACDA(X[d], SP[]);
else
    X[d] = AddPACDA(X[d], X[n]);
```

C6.2.188 PACDB, PACDZB

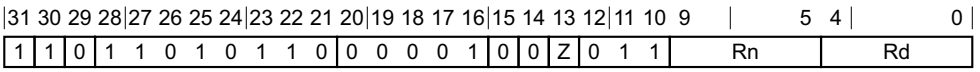
Pointer Authentication Code for Data address, using key B. This instruction computes and inserts a pointer authentication code for a data address, using a modifier and key B.

The address is in the general-purpose register that is specified by <Xd>.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACDB.
- The value zero, for PACDZB.

ARMv8.3



PACDB variant

Applies when Z == 0.

```
PACDB <Xd>, <Xn|SP>
```

PACDZB variant

Applies when Z == 1 && Rn == 11111.

```
PACDZB <Xd>
```

Decode for all variants of this encoding

```
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
    UnallocatedEncoding();

if Z == '0' then // PACDB
    if n == 31 then source_is_sp = TRUE;
else // PACDZB
    if n != 31 then UnallocatedEncoding();
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation

```
if source_is_sp then
    X[d] = AddPACDB(X[d], SP[]);
else
    X[d] = AddPACDB(X[d], X[n]);
```

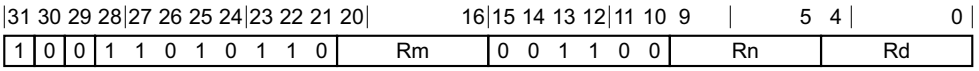
C6.2.189 PACGA

Pointer Authentication Code, using Generic key. This instruction computes the pointer authentication code for an address in the first source register, using a modifier in the second source register, and the Generic key. The computed pointer authentication code is returned in the upper 32 bits of the destination register.

ARMv8.3



Integer variant

```
PACGA <Xd>, <Xn>, <Xm|SP>
```

Decode for this encoding

```
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if !HavePACExt() then
    UnallocatedEncoding();

if m == 31 then source_is_sp = TRUE;
```

Assembler symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm|SP>	Is the 64-bit name of the second general-purpose source register or stack pointer, encoded in the "Rm" field.

Operation

```
if source_is_sp then
    X[d] = AddPACGA(X[n], SP[]);
else
    X[d] = AddPACGA(X[n], X[m]);
```

C6.2.190 PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA

Pointer Authentication Code for Instruction address, using key A. This instruction computes and inserts a pointer authentication code for an instruction address, using a modifier and key A.

The address is:

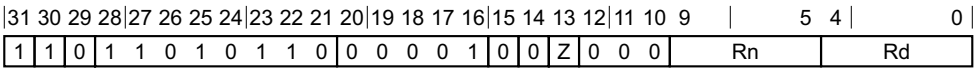
- In the general-purpose register that is specified by <Xd> for PACIA and PACIZA.
- In X17, for PACIA1716.
- In X30, for PACIASP and PACIAZ.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACIA.
- The value zero, for PACIZA and PACIAZ.
- In X16, for PACIA1716.
- In SP, for PACIASP.

Integer

ARMv8.3



PACIA variant

Applies when Z == 0.

```
PACIA <Xd>, <Xn|SP>
```

PACIZA variant

Applies when Z == 1 && Rn == 11111.

```
PACIZA <Xd>
```

Decode for all variants of this encoding

```
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
    UnallocatedEncoding();

if Z == '0' then // PACIA
    if n == 31 then source_is_sp = TRUE;
else // PACIZA
    if n != 31 then UnallocatedEncoding();
```

PACIA1716 variant

Applies when `CRm == 0001 && op2 == 000`.

```
PACIA1716
```

PACIASP variant

Applies when `CRm == 0011 && op2 == 001`.

```
PACIASP
```

PACIAZ variant

Applies when `CRm == 0011 && op2 == 000`.

```
PACIAZ
```

Decode for all variants of this encoding

```
integer d;
integer n;
boolean source_is_sp = FALSE;

case CRm:op2 of
    when '0011 000'    // PACIAZ
        d = 30;
        n = 31;
    when '0011 001'    // PACIASP
        d = 30;
        source_is_sp = TRUE;
    when '0001 000'    // PACIA1716
        d = 17;
        n = 16;
    when '0001 010' SEE "PACIB";
    when '0001 100' SEE "AUTIA";
    when '0001 110' SEE "AUTIB";
    when '0011 01x' SEE "PACIB";
    when '0011 10x' SEE "AUTIA";
    when '0011 11x' SEE "AUTIB";
    when '0000 111' SEE "XPACLRI";
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation for all encodings

```
if HavePACExt() then
    if source_is_sp then
        X[d] = AddPACIA(X[d], SP[]);
    else
        X[d] = AddPACIA(X[d], X[n]);
```

C6.2.191 PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB

Pointer Authentication Code for Instruction address, using key B. This instruction computes and inserts a pointer authentication code for an instruction address, using a modifier and key B.

The address is:

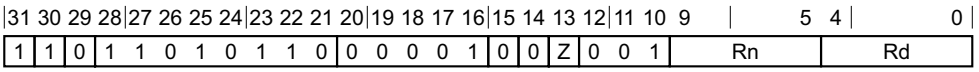
- In the general-purpose register that is specified by <Xd> for PACIB and PACIZB.
- In X17, for PACIB1716.
- In X30, for PACIBSP and PACIBZ.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for PACIB.
- The value zero, for PACIZB and PACIBZ.
- In X16, for PACIB1716.
- In SP, for PACIBSP.

Integer

ARMv8.3



PACIB variant

Applies when Z == 0.

```
PACIB <Xd>, <Xn|SP>
```

PACIZB variant

Applies when Z == 1 && Rn == 11111.

```
PACIZB <Xd>
```

Decode for all variants of this encoding

```
boolean source_is_sp = FALSE;
integer d = UInt(Rd);
integer n = UInt(Rn);

if !HavePACExt() then
    UnallocatedEncoding();

if Z == '0' then // PACIB
    if n == 31 then source_is_sp = TRUE;
else // PACIZB
    if n != 31 then UnallocatedEncoding();
```

PACIB1716 variant

Applies when `CRm == 0001 && op2 == 010`.

```
PACIB1716
```

PACIBSP variant

Applies when `CRm == 0011 && op2 == 011`.

```
PACIBSP
```

PACIBZ variant

Applies when `CRm == 0011 && op2 == 010`.

```
PACIBZ
```

Decode for all variants of this encoding

```
integer d;
integer n;
boolean source_is_sp = FALSE;

case CRm:op2 of
    when '0011 010'    // PACIBZ
        d = 30;
        n = 31;
    when '0011 011'    // PACIBSP
        d = 30;
        source_is_sp = TRUE;
    when '0001 010'    // PACIB1716
        d = 17;
        n = 16;
    when '0001 000' SEE "PACIA";
    when '0001 100' SEE "AUTIA";
    when '0001 110' SEE "AUTIB";
    when '0011 00x' SEE "PACIA";
    when '0011 10x' SEE "AUTIA";
    when '0011 11x' SEE "AUTIB";
    when '0000 111' SEE "XPACLRI";
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the general-purpose source register or stack pointer, encoded in the "Rn" field.

Operation for all encodings

```
if HavePACExt() then
    if source_is_sp then
        X[d] = AddPACIB(X[d], SP[]);
    else
        X[d] = AddPACIB(X[d], X[n]);

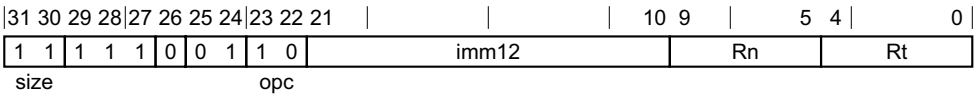
C6.2.192 PRFM (immediate)

Prefetch Memory (immediate) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see *Prefetch memory* on page C3-180.

For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



Unsigned offset variant

```
PRFM (<prfop>|#<imm5>), [<Xn|SP>{, #<pimm>}]
```

Decode for this encoding

```
bits(64) offset = LSL(ZeroExtend(imm12, 64), 3);
```

Assembler symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.

<type> is one of:

PLD Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.

PLI Preload instructions, encoded in the "Rt<4:3>" field as 0b01.

PST Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.

<target> is one of:

L1 Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.

L2 Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.

L3 Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

<policy> is one of:

KEEP Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.

STRM Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see *Prefetch memory* on page C3-180.

For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field.

This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<pimm> Is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the "imm12" field as <pimm>/8.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Operation

```
bits(64) address;

if n == 31 then
    address = SP[];
else
    address = X[n];

address = address + offset;

Prefetch(address, t<4:0>);
```

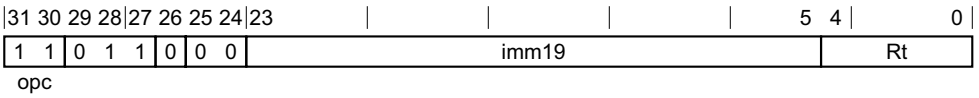
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.193 PRFM (literal)

Prefetch Memory (literal) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see *Prefetch memory* on page C3-180.

For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



Literal variant

```
PRFM (<prfop>|#<imm5>), <label>
```

Decode for this encoding

```
integer t = UInt(Rt);
bits(64) offset;

offset = SignExtend(imm19:'00', 64);
```

Assembler symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.

<type> is one of:

PLD Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.

PLI Preload instructions, encoded in the "Rt<4:3>" field as 0b01.

PST Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.

<target> is one of:

L1 Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.

L2 Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.

L3 Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

<policy> is one of:

KEEP Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.

STRM Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see *Prefetch memory* on page C3-180.

For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field.

This syntax is only for encodings that are not accessible using <prfop>.

<label> Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as "imm19" times 4.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
bits(64) address = PC[] + offset;

Prefetch(address, t<4:0>);
```

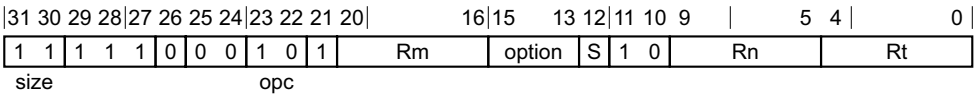
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.194 PRFM (register)

Prefetch Memory (register) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFM instruction is IMPLEMENTATION DEFINED. For more information, see *Prefetch memory* on page C3-180.

For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



Integer variant

```
PRFM (<prfop>|#<imm5>), [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option<1> == '0' then UnallocatedEncoding();    // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then 3 else 0;
```

Assembler symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.

<type> is one of:

PLD Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.

PLI Preload instructions, encoded in the "Rt<4:3>" field as 0b01.

PST Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.

<target> is one of:

L1 Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.

L2 Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.

L3 Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

<policy> is one of:

KEEP Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.

STRM Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see *Prefetch memory* on page C3-180.

For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field.

This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Wm> When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<Xm> When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

- UXTW when option = 010
- LSL when option = 011
- SXTW when option = 110
- SXTX when option = 111

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- #0 when S = 0
- #3 when S = 1

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```

Operation

```
bits(64) offset = ExtendReg(m, extend_type, shift);
bits(64) address;

if n == 31 then
    address = SP[];
else
    address = X[n];

address = address + offset;

Prefetch(address, t<4:0>);
```

C6.2.195 PRFM (unscaled offset)

Prefetch Memory (unscaled offset) signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of an PRFUM instruction is IMPLEMENTATION DEFINED. For more information, see *Prefetch memory* on page C3-180.

For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Unscaled offset variant

```
PRFUM (<prfop>|#<imm5>), [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.

<type> is one of:

PLD Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.

PLI Preload instructions, encoded in the "Rt<4:3>" field as 0b01.

PST Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.

<target> is one of:

L1 Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.

L2 Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.

L3 Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

<policy> is one of:

KEEP Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.

STRM Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see *Prefetch memory* on page C3-180.

For other encodings of the "Rt" field, use <imm5>.

<imm5> Is the prefetch operation encoding as an immediate, in the range 0 to 31, encoded in the "Rt" field.

This syntax is only for encodings that are not accessible using <prfop>.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<simm> Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Non-Confidential

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Operation

```
bits(64) address;

if n == 31 then
    address = SP[];
else
    address = X[n];

address = address + offset;

Prefetch(address, t<4:0>);
```

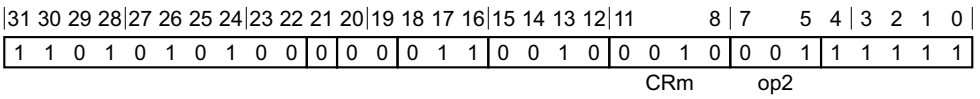
C6.2.196 PSB CSYNC

Profiling Synchronization Barrier. This instruction is a barrier that ensures that all existing profiling data for the current PE has been formatted, and profiling buffer addresses have been translated such that all writes to the profiling buffer have been initiated. A following DSB instruction completes when the writes to the profiling buffer have completed.

If the Statistical Profiling Extension is not implemented, this instruction executes as a NOP.

ARMv8.2



System variant

```
PSB CSYNC
```

Decode for this encoding

```
if !HaveStatisticalProfiling() then EndOfInstruction();
```

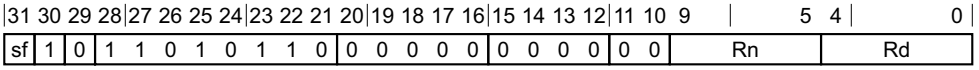
Operation

```
ProfilingSynchronizationBarrier();
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.197 RBIT

Reverse Bits reverses the bit order in a register.



32-bit variant

Applies when `sf == 0`.

```
RBIT <Wd>, <Wn>
```

64-bit variant

Applies when `sf == 1`.

```
RBIT <Xd>, <Xn>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
bits(datasize) operand = X[n];
bits(datasize) result;

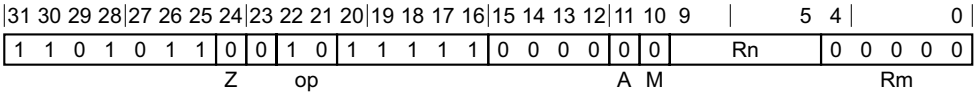
for i = 0 to datasize-1
    result<datasize-1-i> = operand<i>;

X[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.198 RET

Return from subroutine branches unconditionally to an address in a register, with a hint that this is a subroutine return.



Integer variant

```
RET {<Xn>}
```

Decode for this encoding

```
integer n = UInt(Rn);
```

Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the "Rn" field. Defaults to X30 if absent.

Operation

```
bits(64) target = X[n];
BranchTo(target, BranchType_RET);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.199 RETAA, RETAB

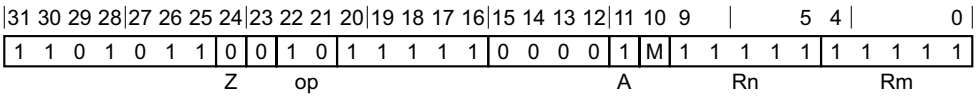
Return from subroutine, with pointer authentication. This instruction authenticates the address that is held in LR, using SP as the modifier and the specified key, branches to the authenticated address, with a hint that this instruction is a subroutine return.

Key A is used for `RETAA`, and key B is used for `RETAB`.

If the authentication passes, the PE continues execution at the target of the branch. If the authentication fails, a Translation fault is generated.

The authenticated address is not written back to LR.

ARMv8.3



RETAA variant

Applies when `M == 0`.

`RETAA`

RETAB variant

Applies when `M == 1`.

`RETAB`

Decode for all variants of this encoding

```
boolean use_key_a = (M == '0');

if !HavePACExt() then
    UnallocatedEncoding();
```

Operation

```
bits(64) target = X[30];
bits(64) modifier = SP[];

if use_key_a then
    target = AuthIA(target, modifier);
else
    target = AuthIB(target, modifier);

BranchTo(target, BranchType_RET);
```

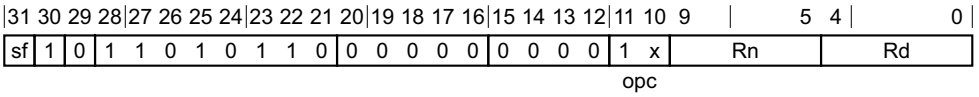
Non-Confidential

C6.2.200 REV

Reverse Bytes reverses the byte order in a register.

This instruction is used by the pseudo-instruction REV64. The pseudo-instruction is never the preferred disassembly.



32-bit variant

Applies when `sf == 0 && opc == 10`.

```
REV <Wd>, <Wn>
```

64-bit variant

Applies when `sf == 1 && opc == 11`.

```
REV <Xd>, <Xn>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer datasize = if sf == '1' then 64 else 32;

integer container_size;
case opc of
    when '00'
        Unreachable();
    when '01'
        container_size = 16;
    when '10'
        container_size = 32;
    when '11'
        if sf == '0' then UnallocatedEncoding();
        container_size = 64;
```

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
bits(datasize) operand = X[n];
bits(datasize) result;

integer containers = datasize DIV container_size;
integer elements_per_container = container_size DIV 8;
integer index = 0;
integer rev_index;
```

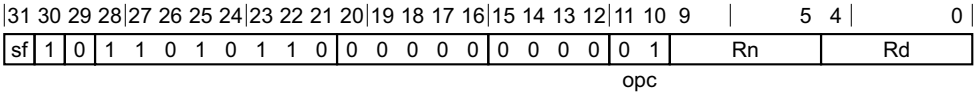
C6.2.201 REV16

Reverse bytes in 16-bit halfwords reverses the byte order in each 16-bit halfword of a register.



32-bit variant

Applies when `sf == 0`.

```
REV16 <Wd>, <Wn>
```

64-bit variant

Applies when `sf == 1`.

```
REV16 <Xd>, <Xn>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer datasize = if sf == '1' then 64 else 32;

integer container_size;
case opc of
    when '00'
        Unreachable();
    when '01'
        container_size = 16;
    when '10'
        container_size = 32;
    when '11'
        if sf == '0' then UnallocatedEncoding();
        container_size = 64;
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
bits(datasize) operand = X[n];
bits(datasize) result;

integer containers = datasize DIV container_size;
integer elements_per_container = container_size DIV 8;
integer index = 0;
integer rev_index;

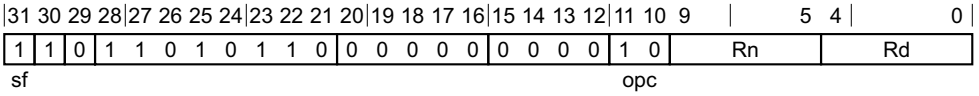
C6.2.202 REV32

Reverse bytes in 32-bit words reverses the byte order in each 32-bit word of a register.



64-bit variant

```
REV32 <Xd>, <Xn>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer datasize = if sf == '1' then 64 else 32;

integer container_size;
case opc of
    when '00'
        Unreachable();
    when '01'
        container_size = 16;
    when '10'
        container_size = 32;
    when '11'
        if sf == '0' then UnallocatedEncoding();
        container_size = 64;
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
bits(datasize) operand = X[n];
bits(datasize) result;

integer containers = datasize DIV container_size;
integer elements_per_container = container_size DIV 8;
integer index = 0;
integer rev_index;
for c = 0 to containers-1
    rev_index = index + ((elements_per_container - 1) * 8);
    for e = 0 to elements_per_container-1
        result<rev_index+7:rev_index> = operand<index+7:index>;
        index = index + 8;
        rev_index = rev_index - 8;

X[d] = result;
```

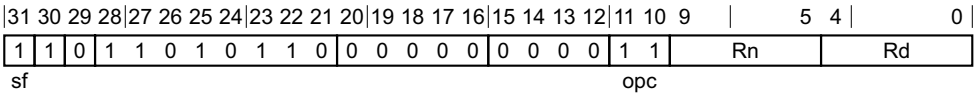
C6.2.203 REV64

Reverse Bytes reverses the byte order in a 64-bit general-purpose register.

When assembling for ARMv8.2, an assembler must support this pseudo-instruction. It is OPTIONAL whether an assembler supports this pseudo-instruction when assembling for an architecture earlier than ARMv8.2.

This instruction is a pseudo-instruction of the REV instruction. This means that:

- The encodings in this description are named to match the encodings of REV.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of REV gives the operational pseudocode for this instruction.



64-bit variant

`REV64 <Xd>, <Xn>`

is equivalent to

`REV  <Xd>, <Xn>`

and is never the preferred disassembly.

Assembler symbols

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of REV gives the operational pseudocode for this instruction.

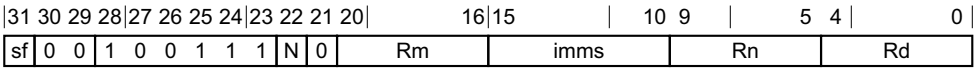
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.204 ROR (immediate)

Rotate right (immediate) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This instruction is an alias of the EXTR instruction. This means that:

- The encodings in this description are named to match the encodings of EXTR.
- The description of EXTR gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0 && imms == 0xxxxx`.

`ROR <Wd>, <Ws>, #<shift>`

is equivalent to

`EXTR <Wd>, <Ws>, <Ws>, #<shift>`

and is the preferred disassembly when `Rn == Rm`.

64-bit variant

Applies when `sf == 1 && N == 1`.

`ROR <Xd>, <Xs>, #<shift>`

is equivalent to

`EXTR <Xd>, <Xs>, <Xs>, #<shift>`

and is the preferred disassembly when `Rn == Rm`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Ws>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xs>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
`<shift>`	For the 32-bit variant: is the amount by which to rotate, in the range 0 to 31, encoded in the "imms" field. For the 64-bit variant: is the amount by which to rotate, in the range 0 to 63, encoded in the "imms" field.

Operation

The description of EXTR gives the operational pseudocode for this instruction.

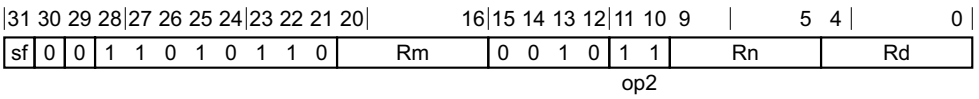
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.205 ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is an alias of the RORV instruction. This means that:

- The encodings in this description are named to match the encodings of RORV.
- The description of RORV gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

`ROR <Wd>, <Wn>, <Wm>`

is equivalent to

`RORV <Wd>, <Wn>, <Wm>`

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

`ROR <Xd>, <Xn>, <Xm>`

is equivalent to

`RORV <Xd>, <Xn>, <Xm>`

and is always the preferred disassembly.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

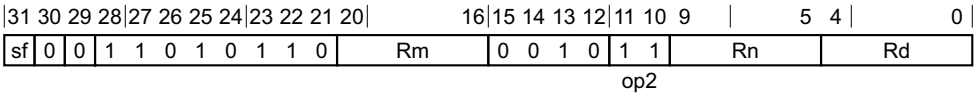
The description of RORV gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.206 RORV

Rotate Right Variable provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The remainder obtained by dividing the second source register by the data size defines the number of bits by which the first source register is right-shifted.

This instruction is used by the alias ROR (register). The alias is always the preferred disassembly.



32-bit variant

Applies when `sf == 0`.

```
RORV <Wd>, <Wn>, <Wm>
```

64-bit variant

Applies when `sf == 1`.

```
RORV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

```
bits(datasize) result;
bits(datasize) operand2 = X[m];

result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

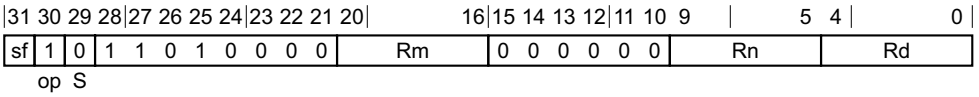
C6.2.207 SBC

Subtract with Carry subtracts a register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

This instruction is used by the alias NGC. See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
SBC <Wd>, <Wn>, <Wm>
```

64-bit variant

Applies when `sf == 1`.

```
SBC <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Alias conditions

Alias	is preferred when
NGC	`Rn == '11111'`

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

operand2 = NOT(operand2);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

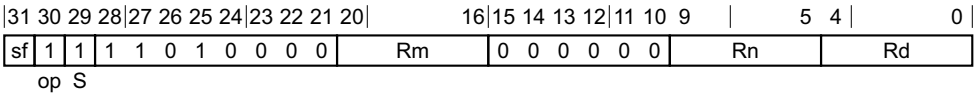
C6.2.208 SBCS

Subtract with Carry, setting flags, subtracts a register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias NGCS. See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
SBCS <Wd>, <Wn>, <Wm>
```

64-bit variant

Applies when `sf == 1`.

```
SBCS <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Alias conditions

Alias	is preferred when
NGCS	`Rn == '11111'`

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(4) nzcv;

operand2 = NOT(operand2);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);

PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

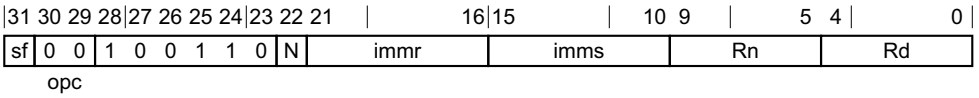
C6.2.209 SBFIZ

Signed Bitfield Insert in Zero zeroes the destination register and copies any number of contiguous bits from a source register into any position in the destination register, sign-extending the most significant bit of the transferred value.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0`.

```
SBFIZ <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

64-bit variant

Applies when `sf == 1 && N == 1`.

```
SBFIZ <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<lsb>`	For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
`<width>`	For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

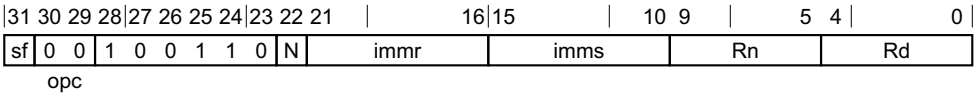
The description of SBFM gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.210 SBFM

Signed Bitfield Move copies any number of low-order bits from a source register into the same number of adjacent bits at any position in the destination register, shifting in copies of the sign bit in the upper bits and zeros in the lower bits.

This instruction is used by the aliases ASR (immediate), SBFIZ, SBFX, SXTB, SXTH, and SXTW. See *Alias conditions* on page C6-858 for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0 && N == 0`.

```
SBFM <Wd>, <Wn>, #<immr>, #<imms>
```

64-bit variant

Applies when `sf == 1 && N == 1`.

```
SBFM <Xd>, <Xn>, #<immr>, #<imms>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

integer R;
integer S;
bits(datasize) wmask;
bits(datasize) tmask;

if sf == '1' && N != '1' then ReservedValue();
if sf == '0' && (N != '0' || immr<5> != '0' || imms<5> != '0') then ReservedValue();

R = UInt(immr);
S = UInt(imms);
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Alias conditions

Alias	of variant	is preferred when
ASR (immediate)	32-bit	`imms == '011111'`
ASR (immediate)	64-bit	`imms == '111111'`
SBFIZ	-	`UInt(imms) < UInt(immr)`
SBFX	-	`BFXPreferred(sf, opc<1>, imms, immr)`
SXTB	-	`immr == '000000' && imms == '000111'`
SXTH	-	`immr == '000000' && imms == '001111'`
SXTW	-	`immr == '000000' && imms == '011111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

`<immr>` For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field.

For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.

`<imms>` For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field.

For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

Operation

```
bits(datasize) src = X[n];

// perform bitfield move on low bits
bits(datasize) bot = ROR(src, R) AND wmask;

// determine extension bits (sign, zero or dest register)
bits(datasize) top = Replicate(src<S>);

// combine extension bits and result bits
X[d] = (top AND NOT(tmask)) OR (bot AND tmask);
```

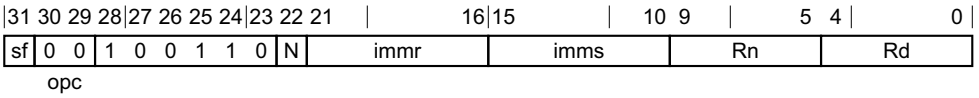
Non-Confidential

C6.2.211 SBFX

Signed Bitfield Extract extracts any number of adjacent bits at any position from a register, sign-extends them to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0`.

`SBFX <Wd>, <Wn>, #<lsb>, #<width>`

is equivalent to

`SBFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)`

and is the preferred disassembly when `BFXPreferred(sf, opc<1>, imms, immr)`.

64-bit variant

Applies when `sf == 1 && N == 1`.

`SBFX <Xd>, <Xn>, #<lsb>, #<width>`

is equivalent to

`SBFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)`

and is the preferred disassembly when `BFXPreferred(sf, opc<1>, imms, immr)`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<lsb>`	For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
`<width>`	For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

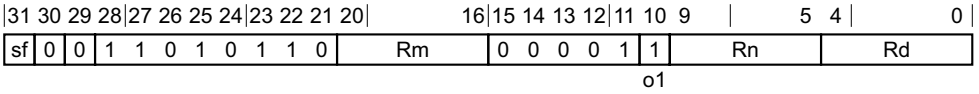
Non-Confidential

C6.2.212 SDIV

Signed Divide divides a signed integer register value by another signed integer register value, and writes the result to the destination register. The condition flags are not affected.



32-bit variant

Applies when `sf == 0`.

```
SDIV <Wd>, <Wn>, <Wm>
```

64-bit variant

Applies when `sf == 1`.

```
SDIV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
integer result;

if IsZero(operand2) then
    result = 0;
else
    result = RoundTowardsZero(Real(Int(operand1, FALSE)) / Real(Int(operand2, FALSE)));

X[d] = result<datasize-1:0>;
```

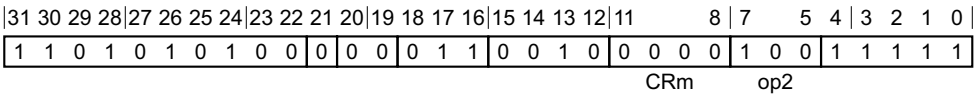
C6.2.213 SEV

Send Event is a hint instruction. It causes an event to be signaled to all PEs in the multiprocessor system. For more information, see *Wait for Event mechanism and Send event* on page D1-1954.



System variant

SEV

Decode for this encoding

```
// Empty.
```

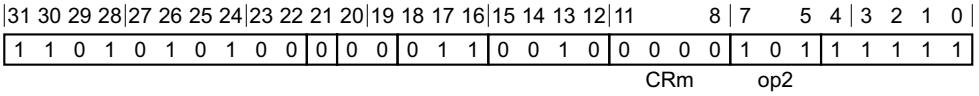
Operation

```
SendEvent();
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.214 SEVL

Send Event Local is a hint instruction that causes an event to be signaled locally without requiring the event to be signaled to other PEs in the multiprocessor system. It can prime a wait-loop which starts with a `WFE` instruction.



System variant

`SEVL`

Decode for this encoding

```
// Empty.
```

Operation

```
SendEventLocal();
```

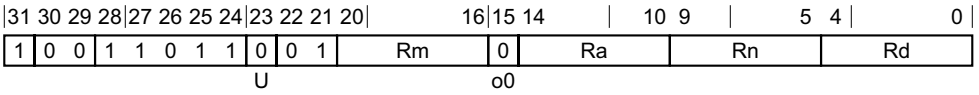
Non-Confidential

C6.2.215 SMADDL

Signed Multiply-Add Long multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMULL. See *Alias conditions* for details of when each alias is preferred.



64-bit variant

```
SMADDL <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
```

Alias conditions

Alias	is preferred when
SMULL	`Ra == '11111'`

Assembler symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation

```
bits(32) operand1 = X[n];
bits(32) operand2 = X[m];
bits(64) operand3 = X[a];

integer result;

result = Int(operand3, FALSE) + (Int(operand1, FALSE) * Int(operand2, FALSE));

X[d] = result<63:0>;
```

C6.2.216 SMC

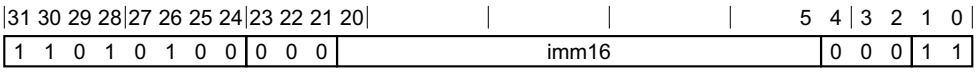
Secure Monitor Call causes an exception to EL3.

`SMC` is available only for software executing at EL1 or higher. It is UNDEFINED in EL0.

If the values of HCR_EL2.TSC and SCR_EL3.SMD are both 0, execution of an `SMC` instruction at EL1 or higher generates a Secure Monitor Call exception, recording it in ESR_ELx, using the EC value `0x17`, that is taken to EL3.

If the value of HCR_EL2.TSC is 1, execution of an `SMC` instruction in a Non-secure EL1 state generates an exception that is taken to EL2, regardless of the value of SCR_EL3.SMD. For more information, see *Traps to EL2 of Non-secure EL1 execution of SMC instructions* on page D1-1927.

If the value of HCR_EL2.TSC is 0 and the value of SCR_EL3.SMD is 1, the SMC instruction is UNDEFINED.



System variant

```
SMC #<imm>
```

Decode for this encoding

```
// Empty.
```

Assembler symbols

`<imm>` Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
AArch64.CheckForSMCUndefOrTrap(imm16);

if SCR_EL3.SMD == '1' then
    // SMC disabled
    AArch64.UndefinedFault();
else
    AArch64.CallSecureMonitor(imm16);
```

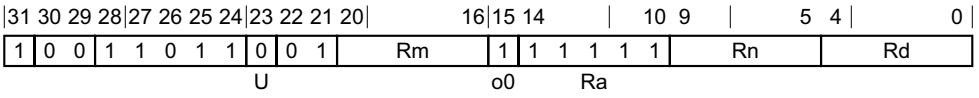
C6.2.217 SMNEGL

Signed Multiply-Negate Long multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This instruction is an alias of the SMSUBL instruction. This means that:

- The encodings in this description are named to match the encodings of SMSUBL.
- The description of SMSUBL gives the operational pseudocode for this instruction.



64-bit variant

```
SMNEGL <Xd>, <Wn>, <Wm>
```

is equivalent to

```
SMSUBL <Xd>, <Wn>, <Wm>, XZR
```

and is always the preferred disassembly.

Assembler symbols

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

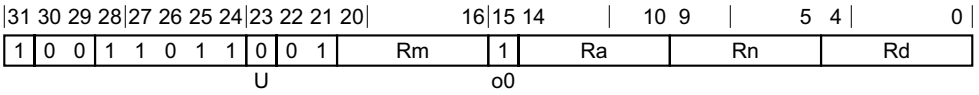
The description of SMSUBL gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.218 SMSUBL

Signed Multiply-Subtract Long multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias SMNEGL. See *Alias conditions* for details of when each alias is preferred.



64-bit variant

```
SMSUBL <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
```

Alias conditions

Alias	is preferred when
SMNEGL	`Ra == '11111'`

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xa> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Operation

```
bits(32) operand1 = X[n];
bits(32) operand2 = X[m];
bits(64) operand3 = X[a];

integer result;

result = Int(operand3, FALSE) - (Int(operand1, FALSE) * Int(operand2, FALSE));
X[d] = result<63:0>;
```

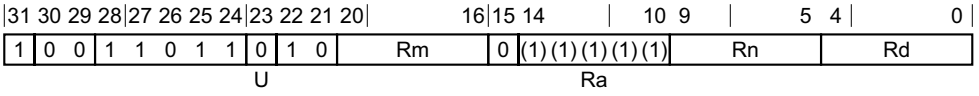
C6.2.219 SMULH

Signed Multiply High multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.



64-bit variant

```
SMULH <Xd>, <Xn>, <Xm>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

```
bits(64) operand1 = X[n];
bits(64) operand2 = X[m];

integer result;

result = Int(operand1, FALSE) * Int(operand2, FALSE);

X[d] = result<127:64>;
```

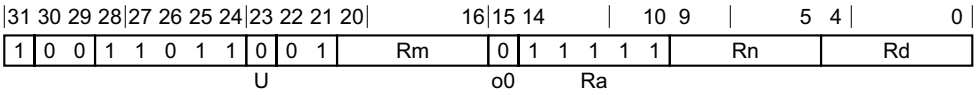
Non-Confidential

C6.2.220 SMULL

Signed Multiply Long multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This instruction is an alias of the SMADDL instruction. This means that:

- The encodings in this description are named to match the encodings of SMADDL.
- The description of SMADDL gives the operational pseudocode for this instruction.



64-bit variant

```
SMULL <Xd>, <Wn>, <Wm>
```

is equivalent to

```
SMADDL <Xd>, <Wn>, <Wm>, XZR
```

and is always the preferred disassembly.

Assembler symbols

`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of SMADDL gives the operational pseudocode for this instruction.

Non-Confidential

C6.2.221 STADDB, STADDLB

Atomic add on byte in memory, without return, atomically loads an 8-bit byte from memory, adds the value held in a register to it, and stores the result back to memory.

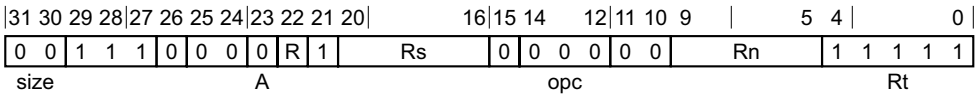
- `STADDB` has no memory ordering semantics.
- `STADDLB` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDADDB, LDADDAB, LDADDALB, LDADDLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDADDB, LDADDAB, LDADDALB, LDADDLB.
- The description of LDADDB, LDADDAB, LDADDALB, LDADDLB gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

```
STADDB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDADDB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

```
STADDLB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDADDLB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>`	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDADDB, LDADDAB, LDADDALB, LDADDLB gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.222 STADDH, STADDLH

Atomic add on halfword in memory, without return, atomically loads a 16-bit halfword from memory, adds the value held in a register to it, and stores the result back to memory.

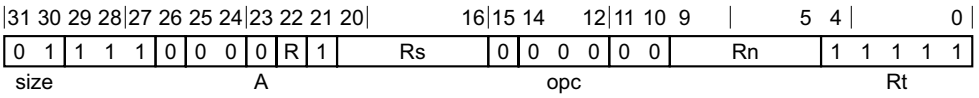
- `STADDH` has no memory ordering semantics.
- `STADDLH` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDADDH, LDADDAH, LDADDALH, LDADDLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDADDH, LDADDAH, LDADDALH, LDADDLH.
- The description of LDADDH, LDADDAH, LDADDALH, LDADDLH gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

`STADDH <Ws>, [<Xn|SP>]`

is equivalent to

`LDADDH <Ws>, WZR, [<Xn|SP>]`

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

`STADDLH <Ws>, [<Xn|SP>]`

is equivalent to

`LDADDLH <Ws>, WZR, [<Xn|SP>]`

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDADDH, LDADDAH, LDADDALH, LDADDLH gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.223 STADD, STADDL

Atomic add on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory.

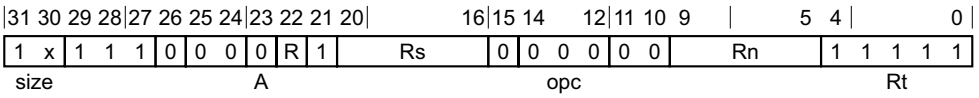
- `STADD` has no memory ordering semantics.
- `STADDL` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDADD, LDADDA, LDADDAL, LDADDL instruction. This means that:

- The encodings in this description are named to match the encodings of LDADD, LDADDA, LDADDAL, LDADDL.
- The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational pseudocode for this instruction.

ARMv8.1



32-bit LDADD alias variant

Applies when `size == 10 && R == 0`.

```
STADD <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDADD <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

32-bit LDADDL alias variant

Applies when `size == 10 && R == 1`.

```
STADDL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDADDL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

64-bit LDADD alias variant

Applies when `size == 11 && R == 0`.

```
STADD <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDADD <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

64-bit LDADDL alias variant

Applies when `size == 11 && R == 1`.

```
STADDL <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDADDL <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>`	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
`<Xs>`	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.224 STCLRB, STCLRLB

Atomic bit clear on byte in memory, without return, atomically loads an 8-bit byte from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

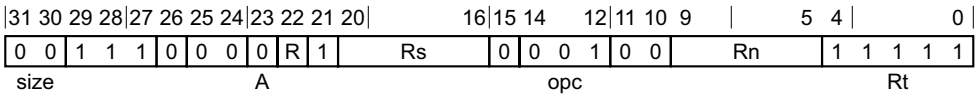
- `STCLRB` has no memory ordering semantics.
- `STCLRLB` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB.
- The description of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

```
STCLRB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDCLRB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

```
STCLRLB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDCLRLB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.225 STCLRH, STCLRLH

Atomic bit clear on halfword in memory, without return, atomically loads a 16-bit halfword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

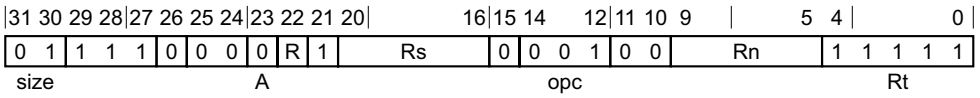
- `STCLRH` has no memory ordering semantics.
- `STCLRLH` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH.
- The description of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

`STCLRH <Ws>, [<Xn|SP>]`

is equivalent to

`LDCLRH <Ws>, WZR, [<Xn|SP>]`

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

`STCLRLH <Ws>, [<Xn|SP>]`

is equivalent to

`LDCLRLH <Ws>, WZR, [<Xn|SP>]`

and is always the preferred disassembly.

Assembler symbols

`<Ws>`	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.226 STCLR, STCLRL

Atomic bit clear on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory.

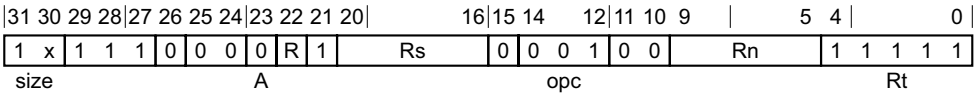
- STCLR has no memory ordering semantics.
- STCLRL stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDCLR, LDCLRA, LDCLRAL, LDCLRL instruction. This means that:

- The encodings in this description are named to match the encodings of LDCLR, LDCLRA, LDCLRAL, LDCLRL.
- The description of LDCLR, LDCLRA, LDCLRAL, LDCLRL gives the operational pseudocode for this instruction.

ARMv8.1



32-bit LDCLR alias variant

Applies when `size == 10 && R == 0`.

```
STCLR <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDCLR <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

32-bit LDCLRL alias variant

Applies when `size == 10 && R == 1`.

```
STCLRL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDCLRL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

64-bit LDCLR alias variant

Applies when `size == 11 && R == 0`.

```
STCLR <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDCLR <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

64-bit LDCLRL alias variant

Applies when `size == 11 && R == 1`.

```
STCLRL <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDCLRL <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>`	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
`<Xs>`	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDCLR, LDCLRA, LDCLRAL, LDCLRL gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.227 STEORB, STEORLB

Atomic exclusive OR on byte in memory, without return, atomically loads an 8-bit byte from memory, performs an exclusive OR with the value held in a register on it, and stores the result back to memory.

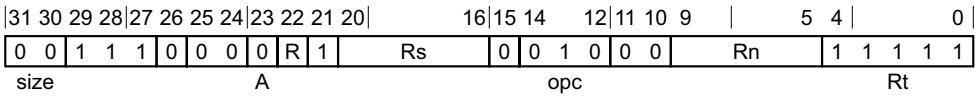
- `STEORB` has no memory ordering semantics.
- `STEORLB` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDEORB, LDEORAB, LDEORALB, LDEORLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDEORB, LDEORAB, LDEORALB, LDEORLB.
- The description of LDEORB, LDEORAB, LDEORALB, LDEORLB gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

```
STEORB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDEORB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

```
STEORLB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDEORLB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDEORB, LDEORAB, LDEORALB, LDEORLB gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.228 STEORH, STEORLH

Atomic exclusive OR on halfword in memory, without return, atomically loads a 16-bit halfword from memory, performs an exclusive OR with the value held in a register on it, and stores the result back to memory.

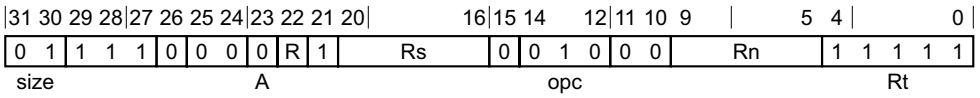
- `STEORH` has no memory ordering semantics.
- `STEORLH` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDEORH, LDEORAH, LDEORALH, LDEORLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDEORH, LDEORAH, LDEORALH, LDEORLH.
- The description of LDEORH, LDEORAH, LDEORALH, LDEORLH gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

`STEORH <Ws>, [<Xn|SP>]`

is equivalent to

`LDEORH <Ws>, WZR, [<Xn|SP>]`

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

`STEORLH <Ws>, [<Xn|SP>]`

is equivalent to

`LDEORLH <Ws>, WZR, [<Xn|SP>]`

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDEORH, LDEORAH, LDEORALH, LDEORLH gives the operational pseudocode for this instruction.

Non-Confidential

C6.2.229 STEOR, STEORL

Atomic exclusive OR on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, performs an exclusive OR with the value held in a register on it, and stores the result back to memory.

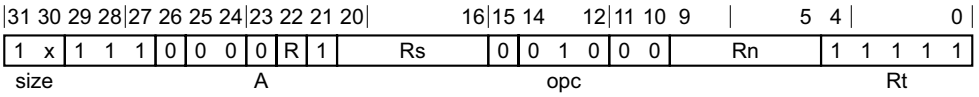
- `STEOR` has no memory ordering semantics.
- `STEORL` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDEOR, LDEORA, LDEORAL, LDEORL instruction. This means that:

- The encodings in this description are named to match the encodings of LDEOR, LDEORA, LDEORAL, LDEORL.
- The description of LDEOR, LDEORA, LDEORAL, LDEORL gives the operational pseudocode for this instruction.

ARMv8.1



32-bit LDEOR alias variant

Applies when `size == 10 && R == 0`.

```
STEOR <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDEOR <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

32-bit LDEORL alias variant

Applies when `size == 10 && R == 1`.

```
STEORL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDEORL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

64-bit LDEOR alias variant

Applies when `size == 11 && R == 0`.

```
STEOR <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDEOR <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

64-bit LDEORL alias variant

Applies when `size == 11 && R == 1`.

`STEORL <Xs>, [<Xn|SP>]`

is equivalent to

`LDEORL <Xs>, XZR, [<Xn|SP>]`

and is always the preferred disassembly.

Assembler symbols

`<Ws>`	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
`<Xs>`	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDEOR, LDEORA, LDEORAL, LDEORL gives the operational pseudocode for this instruction.

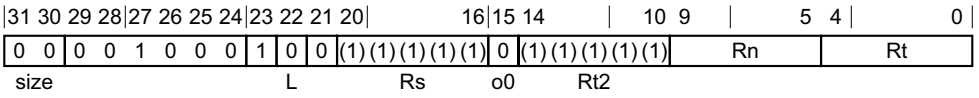
C6.2.230 STLLRB

Store LORelease Register Byte stores a byte from a 32-bit register to a memory location. The instruction also has memory ordering semantics as described in *LoadLOAcquire, StoreLORelease* on page B2-102. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

ARMv8.1



No offset variant

```
STLLRB <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = X[t];
Mem[address, 1, AccType_LIMITEDORDERED] = data;
```

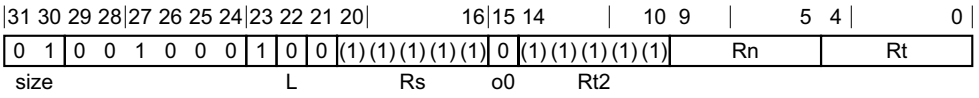
C6.2.231 STLLRH

Store LORelease Register Halfword stores a halfword from a 32-bit register to a memory location. The instruction also has memory ordering semantics as described in *LoadLOAcquire, StoreLORelease* on page B2-102. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

ARMv8.1



No offset variant

```
STLLRH <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = X[t];
Mem[address, 2, AccType_LIMITEDORDERED] = data;
```

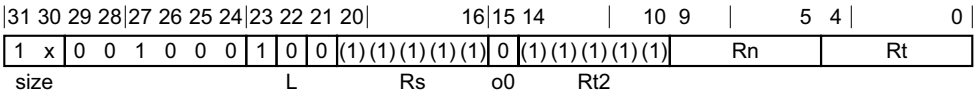
C6.2.232 STLLR

Store LORelease Register stores a 32-bit word or a 64-bit doubleword to a memory location, from a register. The instruction also has memory ordering semantics as described in *LoadLOAcquire, StoreLORelease* on page B2-102. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

ARMv8.1



32-bit variant

Applies when `size == 10`.

```
STLLR <Wt>, [<Xn|SP>{,#0}]
```

64-bit variant

Applies when `size == 11`.

```
STLLR <Xt>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
```

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xt>`	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = X[t];
Mem[address, dbytes, AccType_LIMITEDORDERED] = data;
```

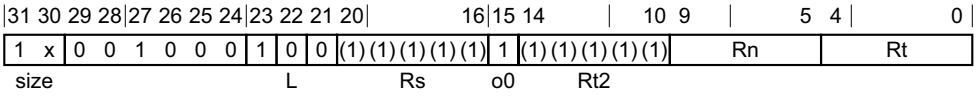
C6.2.233 STLR

Store-Release Register stores a 32-bit word or a 64-bit doubleword to a memory location, from a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when `size == 10`.

```
STLR <Wt>, [<Xn|SP>{,#0}]
```

64-bit variant

Applies when `size == 11`.

```
STLR <Xt>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);

integer elsize = 8 << UInt(size);
```

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xt>`	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(elsize) data;
constant integer dbytes = elsize DIV 8;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = X[t];
Mem[address, dbytes, AccType_ORDERED] = data;
```

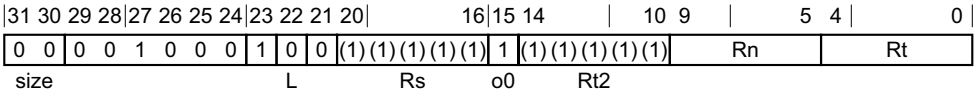
C6.2.234 STLRB

Store-Release Register Byte stores a byte from a 32-bit register to a memory location. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



No offset variant

```
STLRB <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = X[t];
Mem[address, 1, AccType_ORDERED] = data;
```

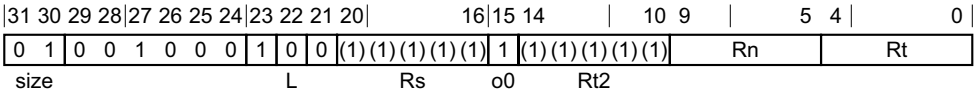
C6.2.235 STLRH

Store-Release Register Halfword stores a halfword from a 32-bit register to a memory location. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



No offset variant

```
STLRH <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(16) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

data = X[t];
Mem[address, 2, AccType_ORDERED] = data;
```

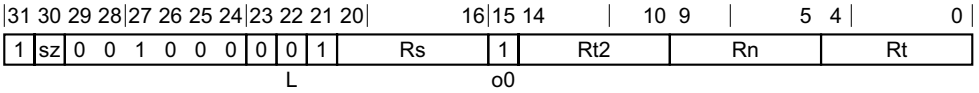
C6.2.236 STLXP

Store-Release Exclusive Pair of registers stores two 32-bit words or two 64-bit doublewords to a memory location if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores* on page B2-128. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and, if the Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101. For information about memory accesses see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when `sz == 0`.

```
STLXP <Ws>, <Wt1>, <Wt2>, [<Xn|SP>{,#0}]
```

64-bit variant

Applies when `sz == 1`.

```
STLXP <Ws>, <Xt1>, <Xt2>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);    // ignored by load/store single register
integer s = UInt(Rs);    // ignored by all loads and store-release

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STLXP* on page K1-6423.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Xt1>` Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

`<Xt2>` Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

`<Wt1>` Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

`<Wt2>` Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;

if s == t || (s == t2) then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_NONE    rt_unknown = FALSE;    // store original value
        when Constraint_UNDEF   UnallocatedEncoding();
        when Constraint_NOP     EndOfInstruction();
if s == n && n != 31 then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_NONE    rn_unknown = FALSE;    // address is original base
        when Constraint_UNDEF   UnallocatedEncoding();
        when Constraint_NOP     EndOfInstruction();

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];

if rt_unknown then
    data = bits(datasize) UNKNOWN;
else
    bits(datasize DIV 2) el1 = X[t];
    bits(datasize DIV 2) el2 = X[t2];
    data = if BigEndian() then el1:el2 else el2:el1;
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, dbytes) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
```

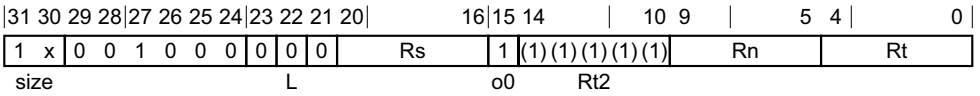
C6.2.237 STLXR

Store-Release Exclusive Register stores a 32-bit word or a 64-bit doubleword to memory if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores* on page B2-128. The memory access is atomic. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101. For information about memory accesses see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when `size == 10`.

```
STLXR <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

64-bit variant

Applies when `size == 11`.

```
STLXR <Ws>, <Xt>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);    // ignored by all loads and store-release

integer elsize = 8 << UInt(size);
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STLXR* on page K1-6423.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

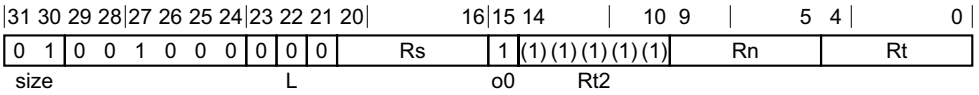
C6.2.239 STLXRH

Store-Release Exclusive Register Halfword stores a halfword from a 32-bit register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores* on page B2-128. The memory access is atomic. The instruction also has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101. For information about memory accesses see *Load/Store addressing modes* on page C1-149.



No offset variant

```
STLXRH <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);    // ignored by all loads and store-release
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STLXRH* on page K1-6424.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch64.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch64.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

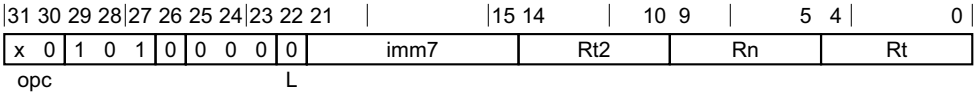
C6.2.240 STNP

Store Pair of Registers, with non-temporal hint, calculates an address from a base register value and an immediate offset, and stores two 32-bit words or two 64-bit doublewords to the calculated address, from two registers. For information about memory accesses, see *Load/Store addressing modes* on page C1-149. For information about Non-temporal pair instructions, see *Load/Store Non-temporal Pair* on page C3-172.



32-bit variant

Applies when `opc == 00`.

```
STNP <Wt1>, <Wt2>, [<Xn|SP>{, #<imm>}]
```

64-bit variant

Applies when `opc == 10`.

```
STNP <Xt1>, <Xt2>, [<Xn|SP>{, #<imm>}]
```

Decode for all variants of this encoding

```
// Empty.
```

Assembler symbols

`<Wt1>` Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

`<Wt2>` Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

`<Xt1>` Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

`<Xt2>` Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

`<imm>` For the 32-bit variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4.

For the 64-bit variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);
if opc<0> == '1' then UnallocatedEncoding();
integer scale = 2 + UInt(opc<1>);
integer datasize = 8 << scale;
bits(64) offset = LSL(SignExtend(imm7, 64), scale);

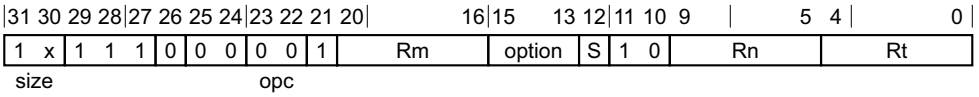
C6.2.243 STR (register)

Store Register (register) calculates an address from a base register value and an offset register value, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.



32-bit variant

Applies when `size == 10`.

```
STR <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

64-bit variant

Applies when `size == 11`.

```
STR <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for all variants of this encoding

```
integer scale = UInt(size);
if option<1> == '0' then UnallocatedEncoding();    // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;
```

Assembler symbols

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

`<Wm>` When `option<0>` is set to `0`, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

`<Xm>` When `option<0>` is set to `1`, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

`<extend>` Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

- `UXTW` when `option = 010`
- `LSL` when `option = 011`
- `SXTW` when `option = 110`
- `SXTX` when `option = 111`

`<amount>` For the 32-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- `#0` when `S = 0`
- `#2` when `S = 1`

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

For the 64-bit variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

`#0` when `S = 0`

`#3` when `S = 1`

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);

integer datasize = 8 << scale;
```

Operation

```
bits(64) offset = ExtendReg(m, extend_type, shift);
bits(64) address;
bits(datasize) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];

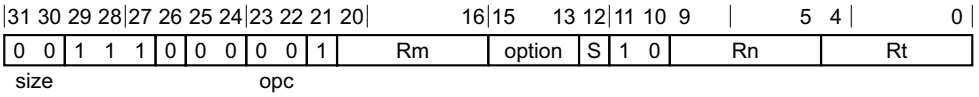
C6.2.245 STRB (register)

Store Register Byte (register) calculates an address from a base register value and an offset register value, and stores a byte from a 32-bit register to the calculated address. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.



Extended register variant

Applies when `option != 011`.

```
STRB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Shifted register variant

Applies when `option == 011`.

```
STRB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

Decode for all variants of this encoding

```
if option<1> == '0' then UnallocatedEncoding();    // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
```

Assembler symbols

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

`<Wm>` When `option<0>` is set to `0`, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

`<Xm>` When `option<0>` is set to `1`, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

`<extend>` Is the index extend specifier, encoded in the "option" field. It can have the following values:

- `UXTW` when `option = 010`
- `SXTW` when `option = 110`
- `SXTX` when `option = 111`

`<amount>` Is the index shift amount, it must be `#0`, encoded in "S" as `0` if omitted, or as `1` if present.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```

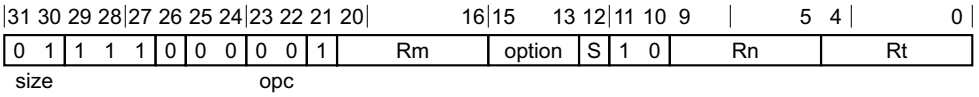
C6.2.247 STRH (register)

Store Register Halfword (register) calculates an address from a base register value and an offset register value, and stores a halfword from a 32-bit register to the calculated address. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.



32-bit variant

```
STRH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

Decode for this encoding

```
if option<1> == '0' then UnallocatedEncoding();    // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then 1 else 0;
```

Assembler symbols

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

`<Wm>` When `option<0>` is set to `0`, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.

`<Xm>` When `option<0>` is set to `1`, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

`<extend>` Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in the "option" field. It can have the following values:

- `UXTW` when `option = 010`
- `LSL` when `option = 011`
- `SXTW` when `option = 110`
- `SXTX` when `option = 111`

`<amount>` Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in the "S" field. It can have the following values:

- `#0` when `S = 0`
- `#1` when `S = 1`

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
bits(64) offset = ExtendReg(m, extend_type, shift);
bits(64) address;
bits(16) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, 2, AccType_NORMAL] = data;
```

C6.2.248 STSETB, STSETLB

Atomic bit set on byte in memory, without return, atomically loads an 8-bit byte from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

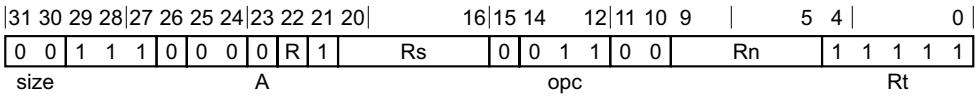
- `STSETB` has no memory ordering semantics.
- `STSETLB` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDSETB, LDSETAB, LDSETALB, LDSETLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDSETB, LDSETAB, LDSETALB, LDSETLB.
- The description of LDSETB, LDSETAB, LDSETALB, LDSETLB gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

```
STSETB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSETB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

```
STSETLB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSETLB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSETB, LDSETAB, LDSETALB, LDSETLB gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.249 STSETH, STSETLH

Atomic bit set on halfword in memory, without return, atomically loads a 16-bit halfword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

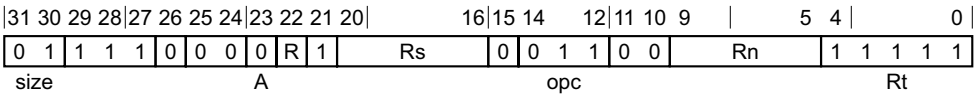
- `STSETH` has no memory ordering semantics.
- `STSETLH` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDSETH, LDSETAH, LDSETALH, LDSETLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDSETH, LDSETAH, LDSETALH, LDSETLH.
- The description of LDSETH, LDSETAH, LDSETALH, LDSETLH gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

```
STSETH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSETH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

```
STSETLH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSETLH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSETH, LDSETAH, LDSETALH, LDSETLH gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.250 STSET, STSETL

Atomic bit set on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

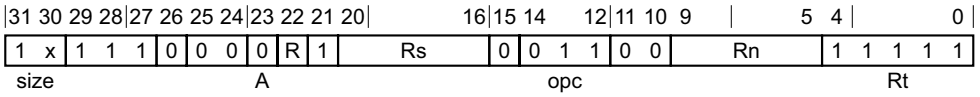
- `STSET` has no memory ordering semantics.
- `STSETL` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDSET, LDSETA, LDSETAL, LDSETL instruction. This means that:

- The encodings in this description are named to match the encodings of LDSET, LDSETA, LDSETAL, LDSETL.
- The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational pseudocode for this instruction.

ARMv8.1



32-bit LDSET alias variant

Applies when `size == 10 && R == 0`.

```
STSET <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSET <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

32-bit LDSETL alias variant

Applies when `size == 10 && R == 1`.

```
STSETL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSETL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

64-bit LDSET alias variant

Applies when `size == 11 && R == 0`.

```
STSET <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDSET <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

64-bit LDSETL alias variant

Applies when `size == 11 && R == 1`.

`STSETL <Xs>, [<Xn|SP>]`

is equivalent to

`LDSETL <Xs>, XZR, [<Xn|SP>]`

and is always the preferred disassembly.

Assembler symbols

`<Ws>`	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
`<Xs>`	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.251 STSMAXB, STSMAXLB

Atomic signed maximum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

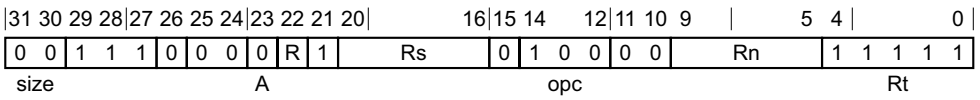
- `STSMAXB` has no memory ordering semantics.
- `STSMAXLB` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB.
- The description of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

```
STSMAXB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMAXB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

```
STSMAXLB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMAXLB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

C6.2.252 STSMAXH, STSMAXLH

Atomic signed maximum on halfword in memory, without return, atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

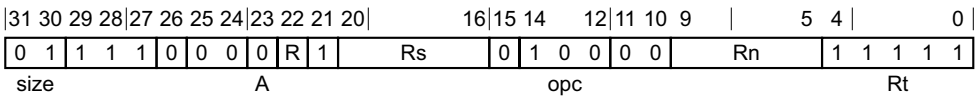
- `STSMAXH` has no memory ordering semantics.
- `STSMAXLH` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH.
- The description of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

```
STSMAXH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMAXH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

```
STSMAXLH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMAXLH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

C6.2.253 STSMAX, STSMAXL

Atomic signed maximum on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as signed numbers.

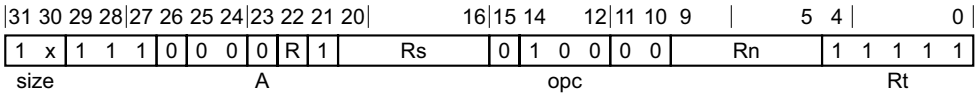
- `STSMAX` has no memory ordering semantics.
- `STSMAXL` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL.
- The description of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL gives the operational pseudocode for this instruction.

ARMv8.1



32-bit LDSMAX alias variant

Applies when `size == 10 && R == 0`.

```
STSMAX <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMAX <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

32-bit LDSMAXL alias variant

Applies when `size == 10 && R == 1`.

```
STSMAXL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMAXL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

64-bit LDSMAX alias variant

Applies when `size == 11 && R == 0`.

```
STSMAX <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDSMAX <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

C6.2.254 STSMINB, STSMINLB

Atomic signed minimum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers.

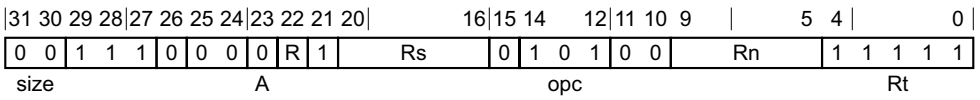
- `STSMINB` has no memory ordering semantics.
- `STSMINLB` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB.
- The description of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

```
STSMINB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMINB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

```
STSMINLB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMINLB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

C6.2.255 STSMINH, STSMINLH

Atomic signed minimum on halfword in memory, without return, atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers.

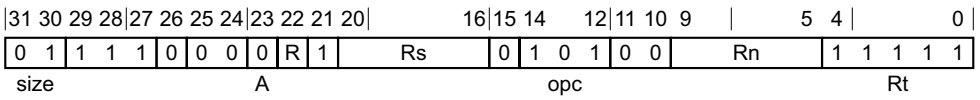
- `STSMINH` has no memory ordering semantics.
- `STSMINLH` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH.
- The description of LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

```
STSMINH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMINH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

```
STSMINLH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMINLH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

C6.2.256 STSMIN, STSMINL

Atomic signed minimum on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers.

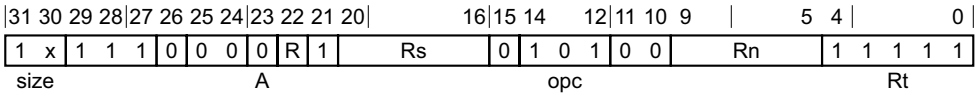
- `STSMIN` has no memory ordering semantics.
- `STSMINL` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDSMIN, LDSMINA, LDSMINAL, LDSMINL instruction. This means that:

- The encodings in this description are named to match the encodings of LDSMIN, LDSMINA, LDSMINAL, LDSMINL.
- The description of LDSMIN, LDSMINA, LDSMINAL, LDSMINL gives the operational pseudocode for this instruction.

ARMv8.1



32-bit LDSMIN alias variant

Applies when `size == 10 && R == 0`.

```
STSMIN <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMIN <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

32-bit LDSMINL alias variant

Applies when `size == 10 && R == 1`.

```
STSMINL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDSMINL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

64-bit LDSMIN alias variant

Applies when `size == 11 && R == 0`.

```
STSMIN <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDSMIN <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

C6.2.257 STTR

Store Register (unprivileged) stores a word or doubleword from a register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

32-bit variant

Applies when `size == 10`.

```
STTR <Wt>, [<Xn|SP>{, #<simm>}]
```

64-bit variant

Applies when `size == 11`.

```
STTR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xt>`	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
`<simm>`	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype = AccType_UNPRIV;
if (HaveNVExt() && HaveEL(EL2) && HCR_EL2.NV == 1 && HCR_EL2.NV1 == 1) then
    acctype = AccType_NORMAL;

integer datasize = 8 << scale;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
bits(64) address;
bits(datasize) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, datasize DIV 8, acctype] = data;
```

C6.2.258 STTRB

Store Register Byte (unprivileged) stores a byte from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Unscaled offset variant

```
STTRB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype = AccType_UNPRIV;
if (HaveNVExt() && HaveEL(EL2) && HCR_EL2.NV == 1 && HCR_EL2.NV1 == 1) then
    acctype = AccType_NORMAL;
```

Operation

```
bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, 1, acctype] = data;
```

C6.2.259 STTRH

Store Register Halfword (unprivileged) stores a halfword from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Memory accesses made by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the memory access operates with the restrictions determined by the Exception level at which the instruction is executed. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.

Unscaled offset variant

```
STTRH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype = AccType_UNPRIV;
if (HaveNVExt() && HaveEL(EL2) && HCR_EL2.NV == 1 && HCR_EL2.NV1 == 1) then
    acctype = AccType_NORMAL;
```

Operation

```
bits(64) address;
bits(16) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, 2, acctype] = data;
```

C6.2.260 STUMAXB, STUMAXLB

Atomic unsigned maximum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

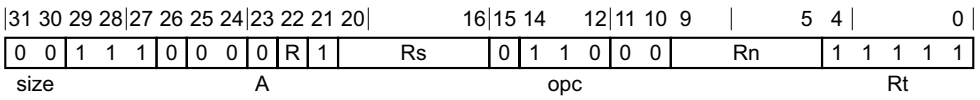
- `STUMAXB` has no memory ordering semantics.
- `STUMAXLB` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB.
- The description of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

```
STUMAXB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMAXB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

```
STUMAXLB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMAXLB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

C6.2.261 STUMAXH, STUMAXLH

Atomic unsigned maximum on halfword in memory, without return, atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

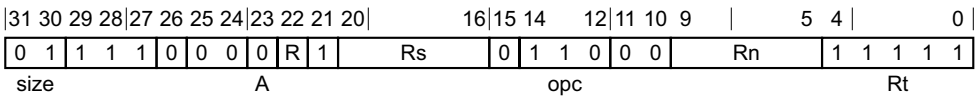
- `STUMAXH` has no memory ordering semantics.
- `STUMAXLH` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH.
- The description of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

```
STUMAXH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMAXH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

```
STUMAXLH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMAXLH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

C6.2.262 STUMAX, STUMAXL

Atomic unsigned maximum on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers.

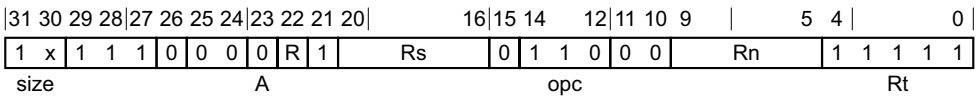
- `STUMAX` has no memory ordering semantics.
- `STUMAXL` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL.
- The description of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL gives the operational pseudocode for this instruction.

ARMv8.1



32-bit LDUMAX alias variant

Applies when `size == 10 && R == 0`.

```
STUMAX <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMAX <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

32-bit LDUMAXL alias variant

Applies when `size == 10 && R == 1`.

```
STUMAXL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMAXL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

64-bit LDUMAX alias variant

Applies when `size == 11 && R == 0`.

```
STUMAX <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDUMAX <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

64-bit LDUMAXL alias variant

Applies when `size == 11 && R == 1`.

```
STUMAXL <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDUMAXL <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>`	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
`<Xs>`	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL gives the operational pseudocode for this instruction.

C6.2.263 STUMINB, STUMINLB

Atomic unsigned minimum on byte in memory, without return, atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers.

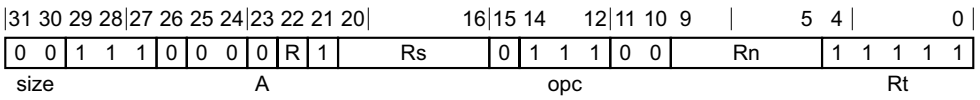
- `STUMINB` has no memory ordering semantics.
- `STUMINLB` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB.
- The description of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

```
STUMINB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMINB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

```
STUMINLB <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMINLB <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

C6.2.264 STUMINH, STUMINLH

Atomic unsigned minimum on halfword in memory, without return, atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers.

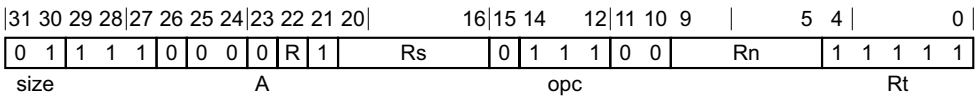
- `STUMINH` has no memory ordering semantics.
- `STUMINLH` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH.
- The description of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH gives the operational pseudocode for this instruction.

ARMv8.1



No memory ordering variant

Applies when `R == 0`.

```
STUMINH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMINH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release variant

Applies when `R == 1`.

```
STUMINLH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMINLH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

C6.2.265 STUMIN, STUMINL

Atomic unsigned minimum on word or doubleword in memory, without return, atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as unsigned numbers.

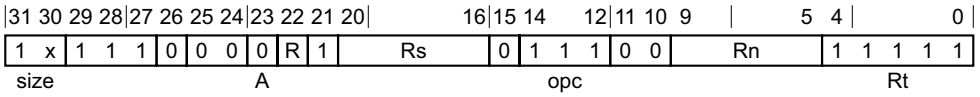
- `STUMIN` has no memory ordering semantics.
- `STUMINL` stores to memory with release semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

This instruction is an alias of the LDUMIN, LDUMINA, LDUMINAL, LDUMINL instruction. This means that:

- The encodings in this description are named to match the encodings of LDUMIN, LDUMINA, LDUMINAL, LDUMINL.
- The description of LDUMIN, LDUMINA, LDUMINAL, LDUMINL gives the operational pseudocode for this instruction.

ARMv8.1



32-bit LDUMIN alias variant

Applies when `size == 10 && R == 0`.

```
STUMIN <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMIN <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

32-bit LDUMINL alias variant

Applies when `size == 10 && R == 1`.

```
STUMINL <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMINL <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

64-bit LDUMIN alias variant

Applies when `size == 11 && R == 0`.

```
STUMIN <Xs>, [<Xn|SP>]
```

is equivalent to

```
LDUMIN <Xs>, XZR, [<Xn|SP>]
```

and is always the preferred disassembly.

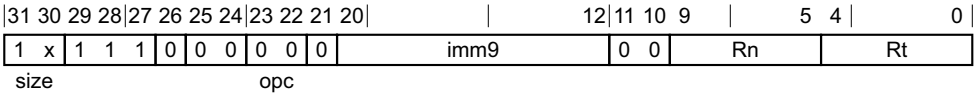
C6.2.266 STUR

Store Register (unscaled) calculates an address from a base register value and an immediate offset, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when `size == 10`.

```
STUR <Wt>, [<Xn|SP>{, #<simm>}]
```

64-bit variant

Applies when `size == 11`.

```
STUR <Xt>, [<Xn|SP>{, #<simm>}]
```

Decode for all variants of this encoding

```
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

`<Wt>`	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xt>`	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
`<Xn|SP>`	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
`<simm>`	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);

integer datasize = 8 << scale;
```

Operation

```
bits(64) address;
bits(datasize) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, datasize DIV 8, AccType_NORMAL] = data;
```

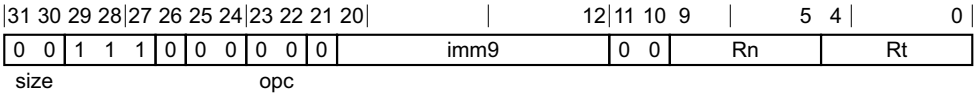
Non-Confidential

C6.2.267 STURB

Store Register Byte (unscaled) calculates an address from a base register value and an immediate offset, and stores a byte to the calculated address, from a 32-bit register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



Unscaled offset variant

```
STURB <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Operation

```
bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, 1, AccType_NORMAL] = data;
```

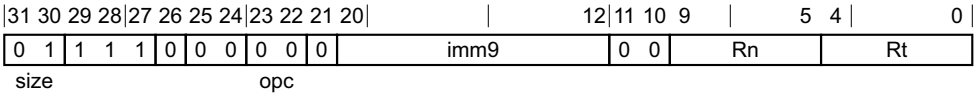
C6.2.268 STURH

Store Register Halfword (unscaled) calculates an address from a base register value and an immediate offset, and stores a halfword to the calculated address, from a 32-bit register. For information about memory accesses, see *Load/Store addressing modes* on page C1-149.



Unscaled offset variant

```
STURH <Wt>, [<Xn|SP>{, #<simm>}]
```

Decode for this encoding

```
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared decode for all encodings

```
integer n = UInt(Rn);
integer t = UInt(Rt);
```

Operation

```
bits(64) address;
bits(16) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

address = address + offset;

data = X[t];
Mem[address, 2, AccType_NORMAL] = data;
```

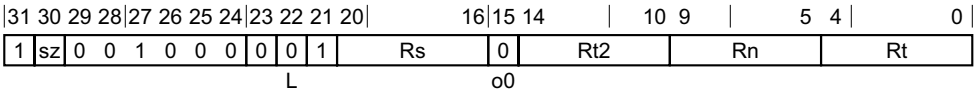
C6.2.269 STXP

Store Exclusive Pair of registers stores two 32-bit words or two 64-bit doublewords from two registers to a memory location if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores* on page B2-128. A 32-bit pair requires the address to be doubleword aligned and is single-copy atomic at doubleword granularity. A 64-bit pair requires the address to be quadword aligned and, if the Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. For information about memory accesses see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when `sz == 0`.

```
STXP <Ws>, <Wt1>, <Wt2>, [<Xn|SP>{,#0}]
```

64-bit variant

Applies when `sz == 1`.

```
STXP <Ws>, <Xt1>, <Xt2>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2);    // ignored by load/store single register
integer s = UInt(Rs);    // ignored by all loads and store-release

integer elsize = 32 << UInt(sz);
integer datasize = elsize * 2;
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STXP* on page K1-6425.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Xt1>` Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

`<Xt2>` Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

`<Wt1>` Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

`<Wt2>` Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(datasize) data;
constant integer dbytes = datasize DIV 8;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;

if s == t || (s == t2) then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_NONE    rt_unknown = FALSE;    // store original value
        when Constraint_UNDEF   UnallocatedEncoding();
        when Constraint_NOP     EndOfInstruction();
if s == n && n != 31 then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_NONE    rn_unknown = FALSE;    // address is original base
        when Constraint_UNDEF   UnallocatedEncoding();
        when Constraint_NOP     EndOfInstruction();

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];

if rt_unknown then
    data = bits(datasize) UNKNOWN;
else
    bits(datasize DIV 2) el1 = X[t];
    bits(datasize DIV 2) el2 = X[t2];
    data = if BigEndian() then el1:el2 else el2:el1;
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, dbytes) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, dbytes, AccType_ATOMIC] = data;
    status = ExclusiveMonitorsStatus();
X[s] = ZeroExtend(status, 32);
```

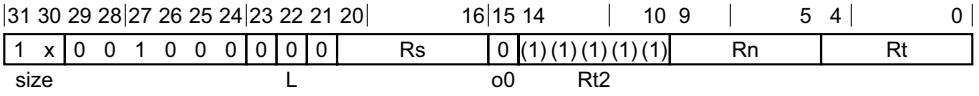
C6.2.270 STXR

Store Exclusive Register stores a 32-bit word or a 64-bit doubleword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores* on page B2-128. For information about memory accesses see *Load/Store addressing modes* on page C1-149.



32-bit variant

Applies when `size == 10`.

```
STXR <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

64-bit variant

Applies when `size == 11`.

```
STXR <Ws>, <Xt>, [<Xn|SP>{,#0}]
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);    // ignored by all loads and store-release

integer elsize = 8 << UInt(size);
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STXR* on page K1-6426.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

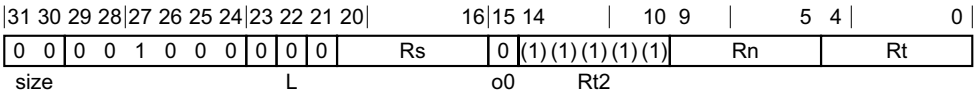
C6.2.271 STXRB

Store Exclusive Register Byte stores a byte from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores* on page B2-128. The memory access is atomic.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.



No offset variant

```
STXRB <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);    // ignored by all loads and store-release
```

Notes for all encodings

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix K1 *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STXRB* on page K1-6426.

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

If `AArch64.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(8) data;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;

if s == t then
    Constraint c = ConstrainUnpredictable();
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_NONE    rt_unknown = FALSE;    // store original value
        when Constraint_UNDEF   UnallocatedEncoding();
        when Constraint_NOP     EndOfInstruction();
if s == n && n != 31 then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_NONE    rn_unknown = FALSE;    // address is original base
        when Constraint_UNDEF   UnallocatedEncoding();
        when Constraint_NOP     EndOfInstruction();

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];

if rt_unknown then
    data = bits(8) UNKNOWN;
else
    data = X[t];

bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, 1) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 1, AccType_ATOMIC] = data;
    status = ExclusiveMonitorsStatus();
X[s] = ZeroExtend(status, 32);
```

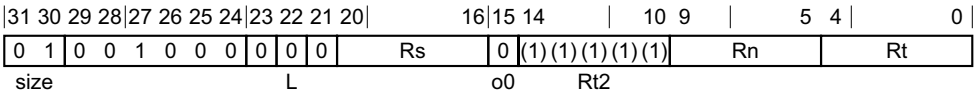
C6.2.272 STXRH

Store Exclusive Register Halfword stores a halfword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores* on page B2-128. The memory access is atomic.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.



No offset variant

```
STXRH <Ws>, <Wt>, [<Xn|SP>{,#0}]
```

Decode for this encoding

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer s = UInt(Rs);    // ignored by all loads and store-release
```

Assembler symbols

`<Ws>` Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Ws>` is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch64.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch64.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(16) data;
boolean rt_unknown = FALSE;
boolean rn_unknown = FALSE;

if s == t then
```

    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rt_unknown = TRUE;    // store UNKNOWN value
        when Constraint_NONE    rt_unknown = FALSE;    // store original value
        when Constraint_UNDEF   UnallocatedEncoding();
        when Constraint_NOP     EndOfInstruction();
if s == n && n != 31 then
    Constraint c = ConstrainUnpredictable();
    assert c IN {Constraint_UNKNOWN, Constraint_NONE, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_UNKNOWN rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_NONE    rn_unknown = FALSE;    // address is original base
        when Constraint_UNDEF   UnallocatedEncoding();
        when Constraint_NOP     EndOfInstruction();

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n];

if rt_unknown then
    data = bits(16) UNKNOWN;
else
    data = X[t];

bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
if AArch64.ExclusiveMonitorsPass(address, 2) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 2, AccType_ATOMIC] = data;
    status = ExclusiveMonitorsStatus();
X[s] = ZeroExtend(status, 32);
```

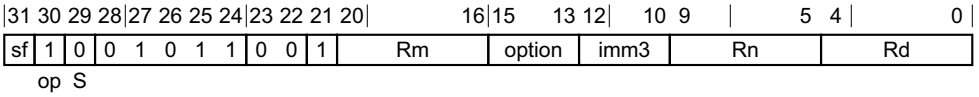
C6.2.273 SUB (extended register)

Subtract (extended register) subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.



32-bit variant

Applies when sf == 0.

```
SUB <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

64-bit variant

Applies when sf == 1.

```
SUB <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then ReservedValue();
```

Assembler symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in the "option" field. It can have the following values:

W	when option = 00x
W	when option = 010
X	when option = x11
W	when option = 10x
W	when option = 110

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB when option = 000

UXTH when option = 001

LSL|UXTW when option = 010

UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB when option = 000

UXTH when option = 001

UXTW when option = 010

LSL|UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);

operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, '1');

if d == 31 then
    SP[] = result;
else
    X[d] = result;
```

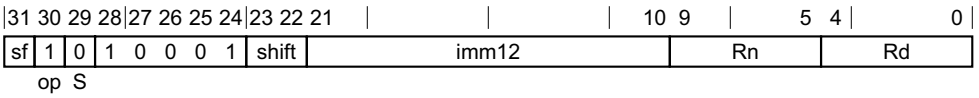
Non-Confidential

C6.2.274 SUB (immediate)

Subtract (immediate) subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register.



32-bit variant

Applies when `sf == 0`.

```
SUB <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

64-bit variant

Applies when `sf == 1`.

```
SUB <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;

case shift of
    when '00' imm = ZeroExtend(imm12, datasize);
    when '01' imm = ZeroExtend(imm12:Zeros(12), datasize);
    when '1x' ReservedValue();
```

Assembler symbols

`<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

`<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

`<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

`<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

`<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "shift" field. It can have the following values:

`LSL #0` when `shift = 00`

`LSL #12` when `shift = 01`

The encoding `shift = 1x` is reserved.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

Non-Confidential

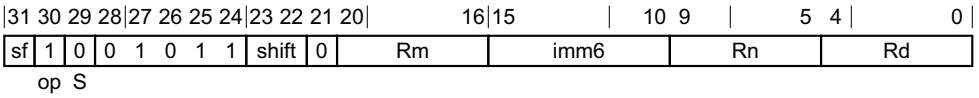
C6.2.275 SUB (shifted register)

Subtract (shifted register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.

This instruction is used by the alias NEG (shifted register). See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
SUB <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant

Applies when `sf == 1`.

```
SUB <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

if shift == '11' then ReservedValue();
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Alias conditions

Alias	is preferred when
NEG (shifted register)	`Rn == '11111'`

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

LSL when shift = 00

LSR when shift = 01

ASR when shift = 10

The encoding shift = 11 is reserved.

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

operand2 = NOT(operand2);
(result, -) = AddWithCarry(operand1, operand2, '1');

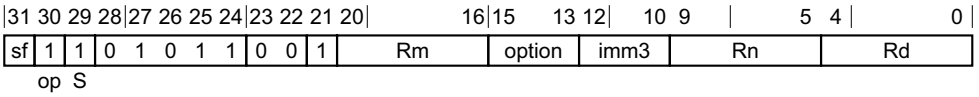
X[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.276 SUBS (extended register)

Subtract (extended register), setting flags, subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMP (extended register). See Alias conditions for details of when each alias is preferred.



32-bit variant

Applies when sf == 0.

```
SUBS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

64-bit variant

Applies when sf == 1.

```
SUBS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then ReservedValue();
```

Alias conditions

Alias	is preferred when
CMP (extended register)	Rd == '11111'

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in the "option" field. It can have the following values:

W when option = 00x

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

W	when option = 010
X	when option = x11
W	when option = 10x
W	when option = 110

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB	when option = 000
UXTH	when option = 001
LSL|UXTW	when option = 010
UXTX	when option = 011
SXTB	when option = 100
SXTH	when option = 101
SXTW	when option = 110
SXTX	when option = 111

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the "option" field. It can have the following values:

UXTB	when option = 000
UXTH	when option = 001
UXTW	when option = 010
LSL|UXTX	when option = 011
SXTB	when option = 100
SXTH	when option = 101
SXTW	when option = 110
SXTX	when option = 111

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;

operand2 = NOT(operand2);
(result, nzcv) = AddWithCarry(operand1, operand2, '1');

PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

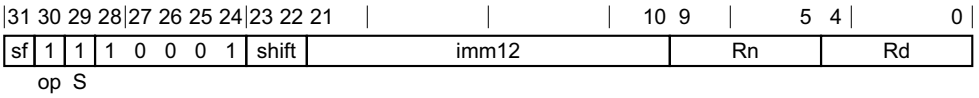
C6.2.277 SUBS (immediate)

Subtract (immediate), setting flags, subtracts an optionally-shifted immediate value from a register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias CMP (immediate). See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
SUBS <Wd>, <Wn|WSP>, #<imm>{, <shift>}
```

64-bit variant

Applies when `sf == 1`.

```
SUBS <Xd>, <Xn|SP>, #<imm>{, <shift>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
bits(datasize) imm;

case shift of
    when '00' imm = ZeroExtend(imm12, datasize);
    when '01' imm = ZeroExtend(imm12:Zeros(12), datasize);
    when '1x' ReservedValue();
```

Alias conditions

Alias	is preferred when
CMP (immediate)	`Rd == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

`<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the "shift" field. It can have the following values:

`LSL #0` when `shift = 00`

`LSL #12` when `shift = 01`

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

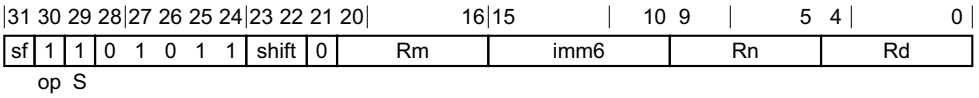
C6.2.278 SUBS (shifted register)

Subtract (shifted register), setting flags, subtracts an optionally-shifted register value from a register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the aliases CMP (shifted register) and NEGS. See *Alias conditions* for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0`.

```
SUBS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant

Applies when `sf == 1`.

```
SUBS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;

if shift == '11' then ReservedValue();
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Alias conditions

Alias	is preferred when
CMP (shifted register)	`Rd == '11111'`
NEGS	`Rn == '11111'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<shift> Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the "shift" field. It can have the following values:

LSL when shift = 00

LSR when shift = 01

ASR when shift = 10

The encoding shift = 11 is reserved.

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(4) nzcv;

operand2 = NOT(operand2);
(result, nzcv) = AddWithCarry(operand1, operand2, '1');

PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

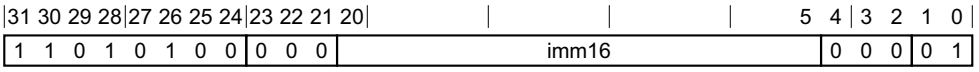
C6.2.279 SVC

Supervisor Call causes an exception to be taken to EL1.

On executing an SVC instruction, the PE records the exception as a Supervisor Call exception in ESR_ELx, using the EC value 0x15, and the value of the immediate argument.



System variant

```
SVC #<imm>
```

Decode for this encoding

```
// Empty.
```

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
AArch64.CallSupervisor(imm16);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.280 SWPB, SWPAB, SWPALB, SWPLB

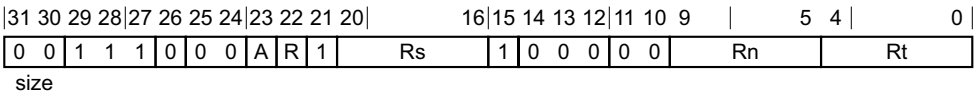
Swap byte in memory atomically loads an 8-bit byte from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, SWPAB and SWPALB load from memory with acquire semantics.
- SWPLB and SWPALB store to memory with release semantics.
- SWPB has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

ARMv8.1



SWPAB variant

Applies when A == 1 && R == 0.

```
SWPAB <Ws>, <Wt>, [<Xn|SP>]
```

SWPALB variant

Applies when A == 1 && R == 1.

```
SWPALB <Ws>, <Wt>, [<Xn|SP>]
```

SWPB variant

Applies when A == 0 && R == 0.

```
SWPB <Ws>, <Wt>, [<Xn|SP>]
```

SWPLB variant

Applies when A == 0 && R == 1.

```
SWPLB <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();

integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register to be stored, encoded in the "Rs" field.

<Wt> Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(8) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the
// following load and store atomically.
data = Mem[address, 1, ldacctype];
Mem[address, 1, stacctype] = X[s];

X[t] = ZeroExtend(data, 32);
```

C6.2.281 SWPH, SWPAH, SWPALH, SWPLH

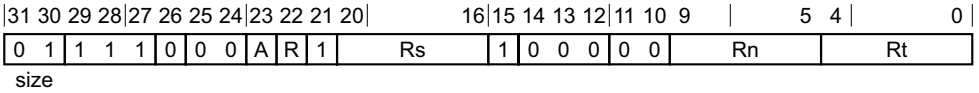
Swap halfword in memory atomically loads a 16-bit halfword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, SWPAH and SWPALH load from memory with acquire semantics.
- SWPLH and SWPALH store to memory with release semantics.
- SWPH has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

ARMv8.1



SWPAH variant

Applies when A == 1 && R == 0.

```
SWPAH <Ws>, <Wt>, [<Xn|SP>]
```

SWPALH variant

Applies when A == 1 && R == 1.

```
SWPALH <Ws>, <Wt>, [<Xn|SP>]
```

SWPH variant

Applies when A == 0 && R == 0.

```
SWPH <Ws>, <Wt>, [<Xn|SP>]
```

SWPLH variant

Applies when A == 0 && R == 1.

```
SWPLH <Ws>, <Wt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();

integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Assembler symbols

<Ws> Is the 32-bit name of the general-purpose register to be stored, encoded in the "Rs" field.

C6.2.282 SWP, SWPA, SWPAL, SWPL

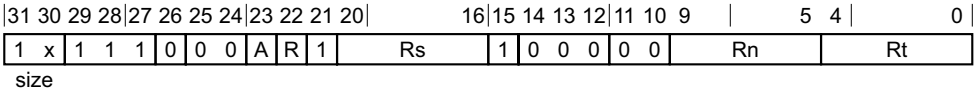
Swap word or doubleword in memory atomically loads a 32-bit word or 64-bit doubleword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of `WZR` or `XZR`, `SWPA` and `SWPAL` load from memory with acquire semantics.
- `SWPL` and `SWPAL` store to memory with release semantics.
- `SWP` has no memory ordering requirements.

For more information about memory ordering semantics see *Load-Acquire, Load-AcquirePC, and Store-Release* on page B2-101.

For information about memory accesses see *Load/Store addressing modes* on page C1-149.

ARMv8.1



32-bit SWP variant

Applies when `size == 10 && A == 0 && R == 0`.

```
SWP <Ws>, <Wt>, [<Xn|SP>]
```

32-bit SWPA variant

Applies when `size == 10 && A == 1 && R == 0`.

```
SWPA <Ws>, <Wt>, [<Xn|SP>]
```

32-bit SWPAL variant

Applies when `size == 10 && A == 1 && R == 1`.

```
SWPAL <Ws>, <Wt>, [<Xn|SP>]
```

32-bit SWPL variant

Applies when `size == 10 && A == 0 && R == 1`.

```
SWPL <Ws>, <Wt>, [<Xn|SP>]
```

64-bit SWP variant

Applies when `size == 11 && A == 0 && R == 0`.

```
SWP <Xs>, <Xt>, [<Xn|SP>]
```

64-bit SWPA variant

Applies when `size == 11 && A == 1 && R == 0`.

```
SWPA <Xs>, <Xt>, [<Xn|SP>]
```

64-bit SWPAL variant

Applies when `size == 11 && A == 1 && R == 1`.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
SWPAL <Xs>, <Xt>, [<Xn|SP>]
```

64-bit SWPL variant

Applies when size == 11 && A == 0 && R == 1.

```
SWPL <Xs>, <Xt>, [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !HaveAtomicExt() then UnallocatedEncoding();

integer t = UInt(Rt);
integer n = UInt(Rn);
integer s = UInt(Rs);

integer datasize = 8 << UInt(size);
integer regsize = if datasize == 64 then 64 else 32;
AccType ldacctype = if A == '1' && Rt != '11111' then AccType_ORDEREDRW else AccType_ATOMICRW;
AccType stacctype = if R == '1' then AccType_ORDEREDRW else AccType_ATOMICRW;
```

Assembler symbols

<Ws>	Is the 32-bit name of the general-purpose register to be stored, encoded in the "Rs" field.
<Wt>	Is the 32-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xs>	Is the 64-bit name of the general-purpose register to be stored, encoded in the "Rs" field.
<Xt>	Is the 64-bit name of the general-purpose register to be loaded, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;
bits(datasize) data;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

// All observers in the shareability domain observe the

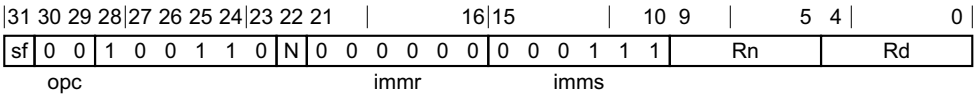
C6.2.283 SXTB

Signed Extend Byte extracts an 8-bit value from a register, sign-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0`.

`SXTB <Wd>, <Wn>`

is equivalent to

`SBFM <Wd>, <Wn>, #0, #7`

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1 && N == 1`.

`SXTB <Xd>, <Wn>`

is equivalent to

`SBFM <Xd>, <Xn>, #0, #7`

and is always the preferred disassembly.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

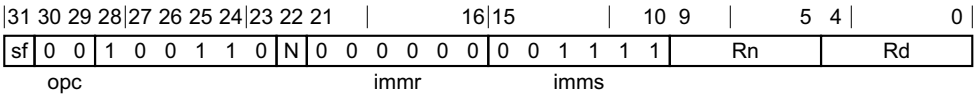
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.284 SXTH

Sign Extend Halfword extracts a 16-bit value, sign-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0`.

`SXTH <Wd>, <Wn>`

is equivalent to

`SBFM <Wd>, <Wn>, #0, #15`

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1 && N == 1`.

`SXTH <Xd>, <Wn>`

is equivalent to

`SBFM <Xd>, <Xn>, #0, #15`

and is always the preferred disassembly.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

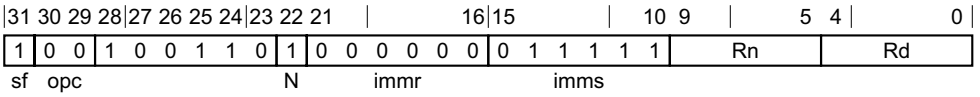
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.285 SXTW

Sign Extend Word sign-extends a word to the size of the register, and writes the result to the destination register.

This instruction is an alias of the SBFM instruction. This means that:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode for this instruction.



64-bit variant

```
SXTW <Xd>, <Wn>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #0, #31
```

and is always the preferred disassembly.

Assembler symbols

`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

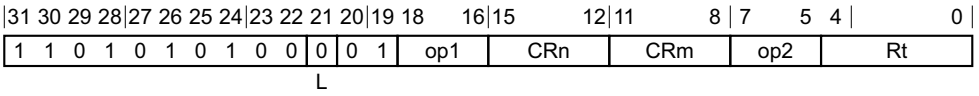
C6.2.286 SYS

System instruction. For more information, see *op0==0b01, cache maintenance, TLB maintenance, and address translation instructions* on page C5-332 for the encodings of System instructions.

This instruction is used by the aliases AT, DC, IC, and TLBI. See *Alias conditions* for details of when each alias is preferred.



System variant

```
SYS #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}
```

Decode for this encoding

```
AArch64.CheckSystemAccess('01', op1, CRn, CRm, op2, Rt, L);

integer t = UInt(Rt);

integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);
```

Alias conditions

Alias	is preferred when
AT	`CRn == '0111' && CRm == '100x' && SysOp(op1,'0111',CRm,op2) == Sys_AT`
DC	`CRn == '0111' && SysOp(op1,'0111',CRm,op2) == Sys_DC`
IC	`CRn == '0111' && SysOp(op1,'0111',CRm,op2) == Sys_IC`
TLBI	`CRn == '1000' && SysOp(op1,'1000',CRm,op2) == Sys_TLBI`

Assembler symbols

<op1>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cn>	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
<Xt>	Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

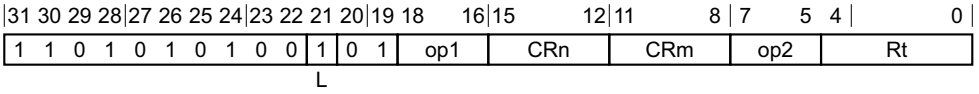
Operation

```
AArch64.SysInstr(1, sys_op1, sys_crn, sys_crm, sys_op2, X[t]);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.287 SYSL

System instruction with result. For more information, see *op0==0b01, cache maintenance, TLB maintenance, and address translation instructions* on page C5-332 for the encodings of System instructions.



System variant

```
SYSL <Xt>, #<op1>, <Cn>, <Cm>, #<op2>
```

Decode for this encoding

```
AArch64.CheckSystemAccess('01', op1, CRn, CRm, op2, Rt, L);

integer t = UInt(Rt);

integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);
```

Assembler symbols

<Xt>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.
<op1>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cn>	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

Operation

```
X[t] = AArch64.SysInstrWithResult(1, sys_op1, sys_crn, sys_crm, sys_op2);
```

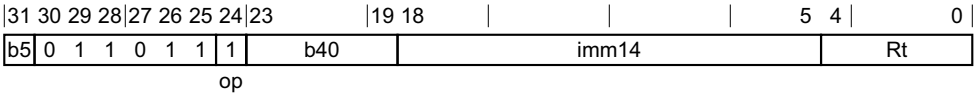
C6.2.288 TBNZ

Test bit and Branch if Nonzero compares the value of a bit in a general-purpose register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.



14-bit signed PC-relative branch offset variant

```
TBNZ <R><t>, #<imm>, <label>
```

Decode for this encoding

```
integer t = UInt(Rt);

integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bits(64) offset = SignExtend(imm14:'00', 64);
```

Assembler symbols

<R> Is a width specifier, encoded in the "b5" field. It can have the following values:

W when b5 = 0

X when b5 = 1

In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.

<t> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.

<imm> Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

Operation

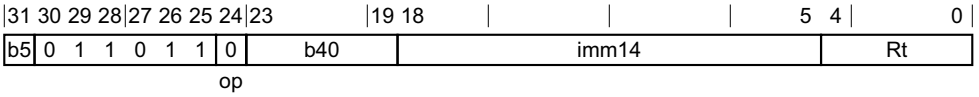
```
bits(datasize) operand = X[t];

if operand<bit_pos> == op then
    BranchTo(PC[] + offset, BranchType_JMP);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.289 TBZ

Test bit and Branch if Zero compares the value of a test bit with zero, and conditionally branches to a label at a PC-relative offset if the comparison is equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.



14-bit signed PC-relative branch offset variant

```
TBZ <R><t>, #<imm>, <label>
```

Decode for this encoding

```
integer t = UInt(Rt);

integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bits(64) offset = SignExtend(imm14:'00', 64);
```

Assembler symbols

<R> Is a width specifier, encoded in the "b5" field. It can have the following values:

W when b5 = 0

X when b5 = 1

In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.

<t> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.

<imm> Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

Operation

```
bits(datasize) operand = X[t];

if operand<bit_pos> == op then
    BranchTo(PC[] + offset, BranchType_JMP);
```

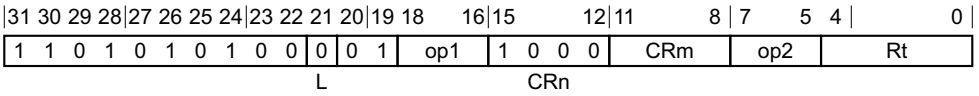
C6.2.290 TLBI

TLB Invalidate operation. For more information, see *op0==0b01, cache maintenance, TLB maintenance, and address translation instructions* on page C5-332.

This instruction is an alias of the SYS instruction. This means that:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode for this instruction.



System variant

```
TLBI <tlbi_op>{, <Xt>}
```

is equivalent to

```
SYS #<op1>, C8, <Cm>, #<op2>{, <Xt>}
```

and is the preferred disassembly when `SysOp(op1,'1000',CRm,op2) == Sys_TLBI`.

Assembler symbols

`<op1>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.

`<Cm>` Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.

`<op2>` Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

`<tlbi_op>` Is a TLBI instruction name, as listed for the TLBI system instruction group, encoded in the "op1:CRm:op2" field. It can have the following values:

`VMALLE1IS`	when `op1 = 000, CRm = 0011, op2 = 000`
`VAE1IS`	when `op1 = 000, CRm = 0011, op2 = 001`
`ASIDE1IS`	when `op1 = 000, CRm = 0011, op2 = 010`
`VAAE1IS`	when `op1 = 000, CRm = 0011, op2 = 011`
`VALE1IS`	when `op1 = 000, CRm = 0011, op2 = 101`
`VAALE1IS`	when `op1 = 000, CRm = 0011, op2 = 111`
`VMALLE1`	when `op1 = 000, CRm = 0111, op2 = 000`
`VAE1`	when `op1 = 000, CRm = 0111, op2 = 001`
`ASIDE1`	when `op1 = 000, CRm = 0111, op2 = 010`
`VAAE1`	when `op1 = 000, CRm = 0111, op2 = 011`
`VALE1`	when `op1 = 000, CRm = 0111, op2 = 101`
`VAALE1`	when `op1 = 000, CRm = 0111, op2 = 111`
`IPAS2E1IS`	when `op1 = 100, CRm = 0000, op2 = 001`
`IPAS2LE1IS`	when `op1 = 100, CRm = 0000, op2 = 101`
`ALLE2IS`	when `op1 = 100, CRm = 0011, op2 = 000`
`VAE2IS`	when `op1 = 100, CRm = 0011, op2 = 001`
`ALLE1IS`	when `op1 = 100, CRm = 0011, op2 = 100`

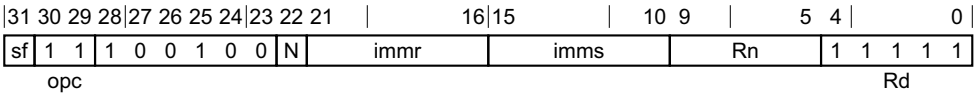
C6.2.291 TST (immediate)

Test bits (immediate) , setting the condition flags and discarding the result : `Rn AND imm`.

This instruction is an alias of the ANDS (immediate) instruction. This means that:

- The encodings in this description are named to match the encodings of ANDS (immediate).
- The description of ANDS (immediate) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0`.

```
TST <Wn>, #<imm>
```

is equivalent to

```
ANDS WZR, <Wn>, #<imm>
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
TST <Xn>, #<imm>
```

is equivalent to

```
ANDS XZR, <Xn>, #<imm>
```

and is always the preferred disassembly.

Assembler symbols

`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<imm>`	For the 32-bit variant: is the bitmask immediate, encoded in "imms:immr". For the 64-bit variant: is the bitmask immediate, encoded in "N:imms:immr".

Operation

The description of ANDS (immediate) gives the operational pseudocode for this instruction.

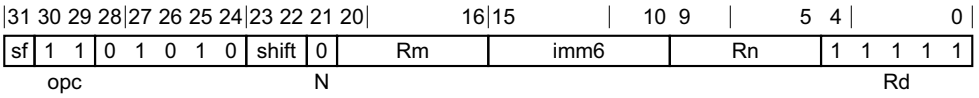
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.292 TST (shifted register)

Test (shifted register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This instruction is an alias of the ANDS (shifted register) instruction. This means that:

- The encodings in this description are named to match the encodings of ANDS (shifted register).
- The description of ANDS (shifted register) gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0`.

```
TST <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ANDS WZR, <Wn>, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

64-bit variant

Applies when `sf == 1`.

```
TST <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ANDS XZR, <Xn>, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler symbols

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the "shift" field. It can have the following values:

- `LSL` when `shift = 00`
- `LSR` when `shift = 01`
- `ASR` when `shift = 10`
- `ROR` when `shift = 11`

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

Operation

The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

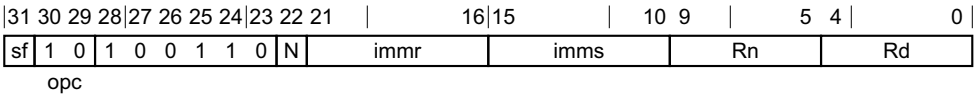
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.293 UBFIZ

Unsigned Bitfield Insert in Zero zeroes the destination register and copies any number of contiguous bits from a source register into any position in the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0`.

`UBFIZ <Wd>, <Wn>, #<lsb>, #<width>`

is equivalent to

`UBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)`

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

64-bit variant

Applies when `sf == 1 && N == 1`.

`UBFIZ <Xd>, <Xn>, #<lsb>, #<width>`

is equivalent to

`UBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)`

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<lsb>`	For the 32-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
`<width>`	For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

Operation

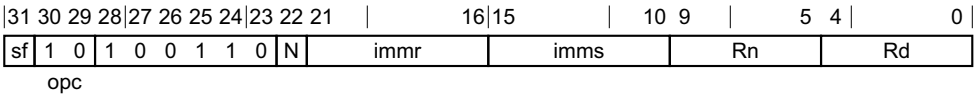
The description of UBFM gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.294 UBFM

Unsigned Bitfield Move copies any number of low-order bits from a source register into the same number of adjacent bits at any position in the destination register, with zeros in the upper and lower bits.

This instruction is used by the aliases LSL (immediate), LSR (immediate), UBFIZ, UBFX, UXTB, and UXTH. See *Alias conditions* on page C6-990 for details of when each alias is preferred.



32-bit variant

Applies when `sf == 0 && N == 0`.

```
UBFM <Wd>, <Wn>, #<immr>, #<imms>
```

64-bit variant

Applies when `sf == 1 && N == 1`.

```
UBFM <Xd>, <Xn>, #<immr>, #<imms>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

integer R;
bits(datasize) wmask;
bits(datasize) tmask;

if sf == '1' && N != '1' then ReservedValue();
if sf == '0' && (N != '0' || immr<5> != '0' || imms<5> != '0') then ReservedValue();

R = UInt(immr);
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Alias conditions

Alias	of variant	is preferred when
LSL (immediate)	32-bit	`imms != '011111' && imms + 1 == immr`
LSL (immediate)	64-bit	`imms != '111111' && imms + 1 == immr`
LSR (immediate)	32-bit	`imms == '011111'`
LSR (immediate)	64-bit	`imms == '111111'`
UBFIZ	-	`UInt(imms) < UInt(immr)`
UBFX	-	`BFXPreferred(sf, opc<1>, imms, immr)`
UXTB	-	`immr == '000000' && imms == '000111'`
UXTH	-	`immr == '000000' && imms == '001111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

`<immr>` For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field.

For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.

`<imms>` For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field.

For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.

Operation

```
bits(datasize) src = X[n];

// perform bitfield move on low bits
bits(datasize) bot = ROR(src, R) AND wmask;

// combine extension bits and result bits
X[d] = bot AND tmask;
```

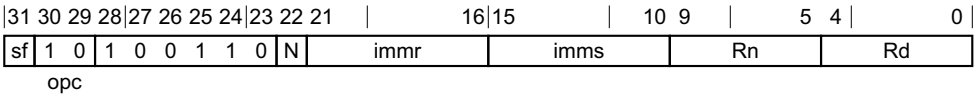
Non-Confidential

C6.2.295 UBFX

Unsigned Bitfield Extract extracts any number of adjacent bits at any position from a register, zero-extends them to the size of the register, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.



32-bit variant

Applies when `sf == 0 && N == 0`.

`UBFX <Wd>, <Wn>, #<lsb>, #<width>`

is equivalent to

`UBFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)`

and is the preferred disassembly when `BFXPreferred(sf, opc<1>, imms, immr)`.

64-bit variant

Applies when `sf == 1 && N == 1`.

`UBFX <Xd>, <Xn>, #<lsb>, #<width>`

is equivalent to

`UBFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)`

and is the preferred disassembly when `BFXPreferred(sf, opc<1>, imms, immr)`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
`<lsb>`	For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31. For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
`<width>`	For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

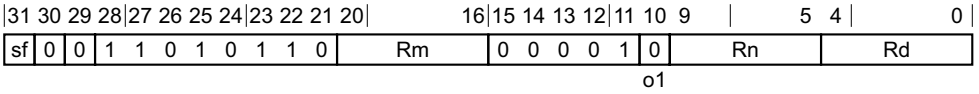
Operation

The description of UBFM gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.296 UDIV

Unsigned Divide divides an unsigned integer register value by another unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.



32-bit variant

Applies when `sf == 0`.

```
UDIV <Wd>, <Wn>, <Wm>
```

64-bit variant

Applies when `sf == 1`.

```
UDIV <Xd>, <Xn>, <Xm>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
integer result;

if IsZero(operand2) then
    result = 0;
else
    result = RoundTowardsZero(Real(Int(operand1, TRUE)) / Real(Int(operand2, TRUE)));

X[d] = result<datasize-1:0>;
```

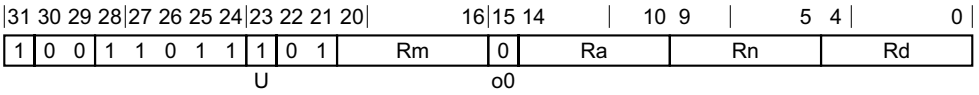
C6.2.297 UMADDL

Unsigned Multiply-Add Long multiplies two 32-bit register values, adds a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMULL. See *Alias conditions* for details of when each alias is preferred.



64-bit variant

```
UMADDL <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
```

Alias conditions

Alias	is preferred when
UMULL	`Ra == '11111'`

Assembler symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation

```
bits(32) operand1 = X[n];
bits(32) operand2 = X[m];
bits(64) operand3 = X[a];

integer result;

result = Int(operand3, TRUE) + (Int(operand1, TRUE) * Int(operand2, TRUE));

X[d] = result<63:0>;
```

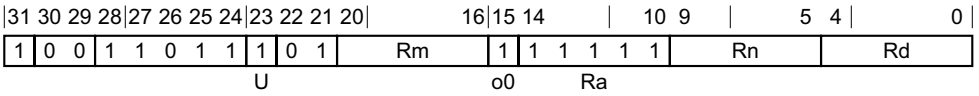
Non-Confidential

C6.2.298 UMNEGL

Unsigned Multiply-Negate Long multiplies two 32-bit register values, negates the product, and writes the result to the 64-bit destination register.

This instruction is an alias of the UMSUBL instruction. This means that:

- The encodings in this description are named to match the encodings of UMSUBL.
- The description of UMSUBL gives the operational pseudocode for this instruction.



64-bit variant

```
UMNEGL <Xd>, <Wn>, <Wm>
```

is equivalent to

```
UMSUBL <Xd>, <Wn>, <Wm>, XZR
```

and is always the preferred disassembly.

Assembler symbols

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

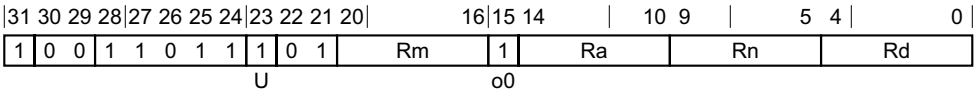
The description of UMSUBL gives the operational pseudocode for this instruction.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.299 UMSUBL

Unsigned Multiply-Subtract Long multiplies two 32-bit register values, subtracts the product from a 64-bit register value, and writes the result to the 64-bit destination register.

This instruction is used by the alias UMNEGL. See *Alias conditions* for details of when each alias is preferred.



64-bit variant

```
UMSUBL <Xd>, <Wn>, <Wm>, <Xa>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
```

Alias conditions

Alias	is preferred when
UMNEGL	`Ra == '11111'`

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Xa> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Operation

```
bits(32) operand1 = X[n];
bits(32) operand2 = X[m];
bits(64) operand3 = X[a];

integer result;

result = Int(operand3, TRUE) - (Int(operand1, TRUE) * Int(operand2, TRUE));
X[d] = result<63:0>;
```

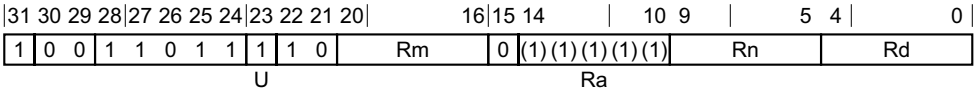
Non-Confidential

C6.2.300 UMULH

Unsigned Multiply High multiplies two 64-bit register values, and writes bits[127:64] of the 128-bit result to the 64-bit destination register.



64-bit variant

```
UMULH <Xd>, <Xn>, <Xm>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xn> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

```
bits(64) operand1 = X[n];
bits(64) operand2 = X[m];

integer result;

result = Int(operand1, TRUE) * Int(operand2, TRUE);

X[d] = result<127:64>;
```

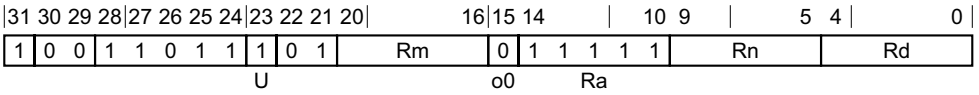
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.301 UMULL

Unsigned Multiply Long multiplies two 32-bit register values, and writes the result to the 64-bit destination register.

This instruction is an alias of the UMADDL instruction. This means that:

- The encodings in this description are named to match the encodings of UMADDL.
- The description of UMADDL gives the operational pseudocode for this instruction.



64-bit variant

```
UMULL <Xd>, <Wn>, <Wm>
```

is equivalent to

```
UMADDL <Xd>, <Wn>, <Wm>, XZR
```

and is always the preferred disassembly.

Assembler symbols

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of UMADDL gives the operational pseudocode for this instruction.

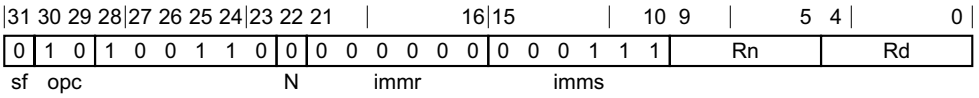
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.302 UXTB

Unsigned Extend Byte extracts an 8-bit value from a register, zero-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.



32-bit variant

```
UXTB <Wd>, <Wn>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #0, #7
```

and is always the preferred disassembly.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

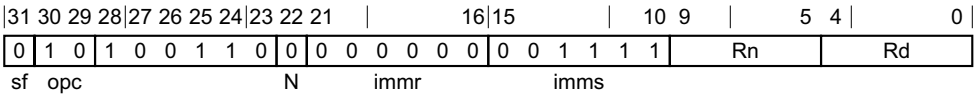
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.303 UXTH

Unsigned Extend Halfword extracts a 16-bit value from a register, zero-extends it to the size of the register, and writes the result to the destination register.

This instruction is an alias of the UBFM instruction. This means that:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode for this instruction.



32-bit variant

```
UXTH <Wd>, <Wn>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #0, #15
```

and is always the preferred disassembly.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

`<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

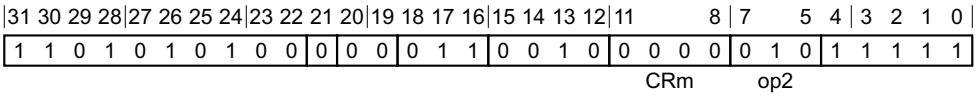
C6.2.304 WFE

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any PE in the multiprocessor system. For more information, see *Wait for Event mechanism and Send event* on page D1-1954.

As described in *Wait for Event mechanism and Send event* on page D1-1954, the execution of a WFE instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level. See:

- *Traps to EL1 of EL0 execution of WFE and WFI instructions* on page D1-1913.
- *Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions* on page D1-1931.
- *Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions* on page D1-1944.



System variant

```
WFE
```

Decode for this encoding

```
// Empty.
```

Operation

```
if IsEventRegisterSet() then
    ClearEventRegister();
else
    if PSTATE.EL == EL0 then
        // Check for traps described by the OS which may be EL1 or EL2.
        AArch64.CheckForWFxTrap(EL1, TRUE);
    if HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0, EL1} && !IsInHost() then
        // Check for traps described by the Hypervisor.
        AArch64.CheckForWFxTrap(EL2, TRUE);
    if HaveEL(EL3) && PSTATE.EL != EL3 then
        // Check for traps described by the Secure Monitor.
        AArch64.CheckForWFxTrap(EL3, TRUE);
    WaitForEvent();
```

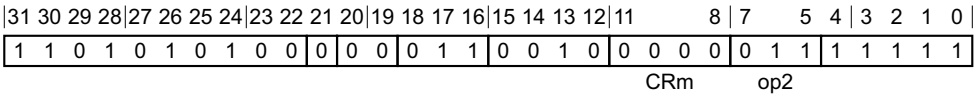
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C6.2.305 WFI

Wait For Interrupt is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. For more information, see *Wait For Interrupt* on page D1-1957.

As described in *Wait For Interrupt* on page D1-1957, the execution of a `WFI` instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level. See:

- *Traps to EL1 of EL0 execution of WFE and WFI instructions* on page D1-1913.
- *Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions* on page D1-1931.
- *Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions* on page D1-1944.



System variant

```
WFI
```

Decode for this encoding

```
// Empty.
```

Operation

```
if !InterruptPending() then
    if PSTATE.EL == EL0 then
        // Check for traps described by the OS which may be EL1 or EL2.
        AArch64.CheckForWFxTrap(EL1, FALSE);
    if HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0, EL1} && !IsInHost() then
        // Check for traps described by the Hypervisor.
        AArch64.CheckForWFxTrap(EL2, FALSE);
    if HaveEL(EL3) && PSTATE.EL != EL3 then
        // Check for traps described by the Secure Monitor.
        AArch64.CheckForWFxTrap(EL3, FALSE);
    WaitForInterrupt();
```

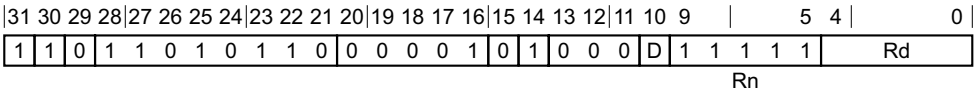
C6.2.306 XPACD, XPACI, XPACLRI

Strip Pointer Authentication Code. This instruction removes the pointer authentication code from an address. The address is in the specified general-purpose register for XPACI and XPACD, and is in LR for XPACLRI.

The XPACD instruction is used for data addresses, and XPACI and XPACLRI are used for instruction addresses.

Integer

ARMv8.3



XPACD variant

Applies when D == 1.

```
XPACD <Xd>
```

XPACI variant

Applies when D == 0.

```
XPACI <Xd>
```

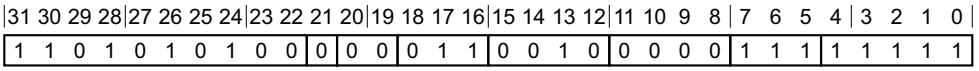
Decode for all variants of this encoding

```
boolean data = (D == '1');
integer d = UInt(Rd);

if !HavePACExt() then
    UnallocatedEncoding();
```

System

ARMv8.3



System variant

```
XPACLRI
```

Decode for this encoding

```
integer d = 30;
boolean data = FALSE;
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation for all encodings

```
if HavePACExt() then
    X[d] = Strip(X[d], data);
```

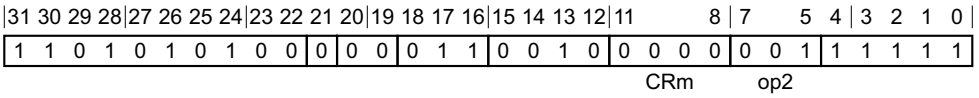
Non-Confidential

C6.2.307 YIELD

YIELD is a hint instruction. Software with a multithreading capability can use a `YIELD` instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction, see *The YIELD instruction* on page B1-82.



System variant

`YIELD`

Decode for this encoding

```
// Empty.
```

Operation

```
Hint_Yield();
```

Chapter C7
A64 Advanced SIMD and Floating-point Instruction Descriptions

This chapter describes the A64 Advanced SIMD and floating-point instructions.

It contains the following sections:

- *About the A64 SIMD and floating-point instructions* on page C7-1006.
- *Alphabetical list of A64 Advanced SIMD and floating-point instructions* on page C7-1008.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C7.1 About the A64 SIMD and floating-point instructions

Alphabetical list of A64 Advanced SIMD and floating-point instructions on page C7-1008 gives full descriptions of the A64 instructions that are in the following instruction groups:

- Loads and store instructions associated with the SIMD and floating-point registers.
- Data processing instructions with SIMD and floating-point registers.

A64 instruction set encoding on page C4-224 in the A64 Instruction Encodings chapter provides an overview of the instruction encodings as part of an instruction class within a functional group.

The rest of this section is a general description of the SIMD and floating-point instructions. It contains the following subsections:

- *Register size*.
- *Data types*.
- *Condition flags and related instructions* on page C7-1007.
- *General capabilities* on page C7-1007.

C7.1.1 Register size

A64 provides a comprehensive set of packed Single Instruction Multiple Data (SIMD) and scalar operations using data held in the 32 entry 128-bit wide SIMD and floating-point register file.

Each SIMD and floating-point register can be used to hold:

- A single scalar value of the floating-point or integer type.
- A 64-bit wide vector containing one or more elements.
- A 128-bit wide vector containing two or more elements.

Where the entire 128-bit wide register is not fully utilized, the vector or scalar quantity is held in the least significant bits of the register, with the most significant bits being cleared to zero on a write, see *Vector formats* on page A1-41.

The following instructions can insert data into individual elements within a SIMD and floating-pointer register without clearing the remaining bits to zero:

- Insert vector element from another vector element or general-purpose register, `INS`.
- Load structure into a single lane, for example `LD3`.
- All second-part narrowing operations, for example `SHRN2`.

C7.1.2 Data types

The A64 instruction set provides support for arithmetic, conversion, and bitwise operations on:

- Half-precision, single-precision, and double-precision floating-points.
- Signed and unsigned integers.
- Polynomials over {0, 1}.
- When ARMv8.3-CompNum is implemented, complex numbers.

For all AArch64 floating-point operations, including SIMD operations, the rounding mode and exception trap handling are controlled by the FPCR.

Note

- AArch32 Advanced SIMD operations always use ARM standard floating-point arithmetic, regardless of the rounding mode specified by the AArch64 FPCR or the AArch32 FPSCR.
- In AArch64 state, floating-point multiply-add operations are always performed as fused operations, but AArch32 state provides both fused and chained multiply-add instructions.

Non-Confidential

In addition to operations that consume and produce values of the same width and type, the A64 instruction set supports SIMD and scalar operations that produce a wider or narrower vector result:

- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the A64 instruction set provides a second-part operation, for example `SHRN2`, that can pack the result of a second operation into the upper part of the same destination register.
- Where a SIMD operation widens a 64-bit vector to a 128-bit vector, the A64 instruction set provides a second-part operation, for example `SMLAL2`, that can extract the source from the upper 64 bits of the source registers.

All SIMD operations that could produce side-effects that are not limited to the destination SIMD and floating-point register, for example a potential update of FPSR.Q or FPSR.IDC, have a dedicated scalar variant to support the use of SIMD with loops requiring specialised head or tail handling, or both.

C7.1.3 Condition flags and related instructions

The A64 instruction set provides support for flag setting and conditional operations on the SIMD and floating-point register file:

- Floating-point `FCSEL` and `FCCMP` instructions are equivalent to the integer `CSEL` and `CCMP` instructions.
- Floating-point `FCMP`, `FCMPE`, `FCCMP`, and `FCCMP` instructions set the PSTATE.{N, Z, C, V} flags based on the result of the floating-point comparison.
- Floating-point `FJCVTZS` instruction sets the PSTATE.Z flag if the result of the conversion, when converted back to a double-precision floating-point number, gives precisely the same value as the original. Other PSTATE flags are cleared by this instruction.
- Floating-point and integer instructions provide a means of producing either a scalar or a vector mask based on a comparison in a SIMD and floating-point register, for example `FCMEQ`.

Note

`FCMP` and `FCMPE` differ from the A32/T32 `VCMP` and `VCMPE` instructions, which use the dedicated FPSCR.NZCV field for the result. A64 instructions store the result of an `FCMP` or `FCMPE` operation in the PSTATE.{N, Z, C, V} field.

C7.1.4 General capabilities

A64 SIMD and floating-point instructions provide the following capabilities:

- General arithmetic on vector and scalar floating-point and integer values.
- Dedicated polynomial multiply over {0, 1}.
- Vector and scalar fused multiply-addition of single-precision and double-precision floating-points, and for half-precision floating-points when ARMv8.2-FP16 is implemented.
- Load and store of single and pairs of SIMD and floating-point registers.
- Load and store of structures and individual lanes of between one and four SIMD and floating-point registers.
- Direct conversion between 64-bit integers and floating-point values, with explicit rounding.
- When ARMv8.3-JSConv is implemented, conversion from double precision floating-point values to 32-bit integers, with rounding to zero.
- Double-rounding free conversion between double-precision and half-precision floating-point values.
- Comprehensive SIMD with widening and narrowing support.
- Vector to scalar reduction returning the minimum or maximum value, or the sum.
- Floating-point to nearest integer in floating-point format.
- When ARMv8.3-CompNum is implemented, complex number arithmetic.

Non-Confidential

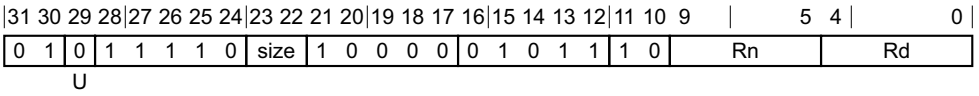
C7.2.1 ABS

Absolute value (vector). This instruction calculates the absolute value of each vector element in the source SIMD&FP register, puts the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar



Scalar variant

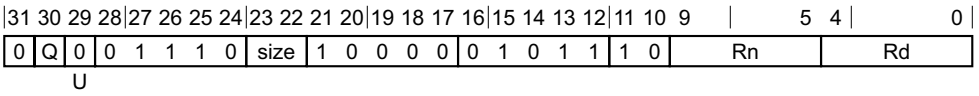
```
ABS <V><d>, <V><n>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean neg = (U == '1');
```

Vector



Vector variant

```
ABS <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean neg = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

D when `size = 11`

The following encodings are reserved:

- `size = 0x`.
- `size = 10`.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;

for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;
```

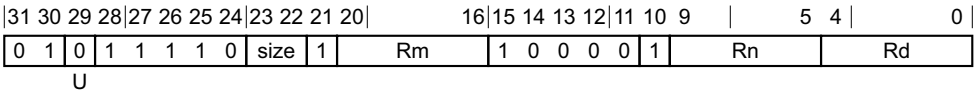
Non-Confidential

C7.2.2 ADD (vector)

Add (vector). This instruction adds corresponding elements in the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar



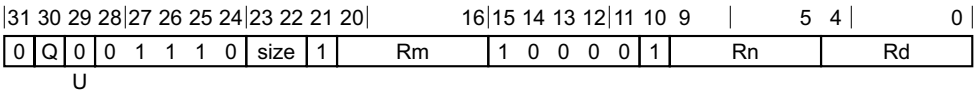
Scalar variant

```
ADD <V><d>, <V><n>, <V><m>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size != '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean sub_op = (U == '1');
```

Vector



Vector variant

```
ADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean sub_op = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

`D` when `size = 11`

The following encodings are reserved:

- `size = 0x`.
- `size = 10`.

Non-Confidential

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if sub_op then
        Elem[result, e, esize] = element1 - element2;
    else
        Elem[result, e, esize] = element1 + element2;

V[d] = result;
```

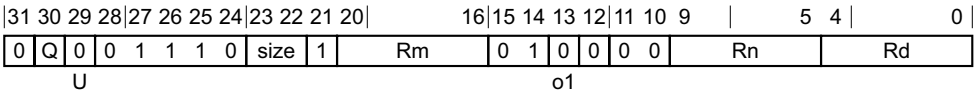
C7.2.3 ADDHN, ADDHN2

Add returning High Narrow. This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are truncated. For rounded results, see RADDHN, RADDHN2.

The ADDHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the ADDHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Three registers, not all the same type variant

```
ADDHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');
```

Assembler symbols

2 — Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd> — Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> — Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H when size = 00

4S when size = 01

2D when size = 10

The encoding size = 11 is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;

for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;
```

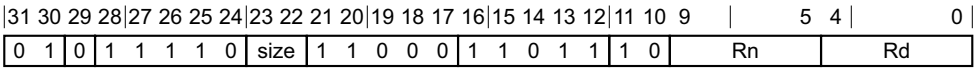
Non-Confidential

C7.2.4 ADDP (scalar)

Add Pair of elements (scalar). This instruction adds two vector elements in the source SIMD&FP register and writes the scalar result into the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Advanced SIMD variant

```
ADDP <V><d>, <Vn>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '11' then ReservedValue();

integer esize = 8 << UInt(size);
integer datasize = esize * 2;
```

Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:

D when size = 11

The following encodings are reserved:

- size = 0x.
- size = 10.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is the source arrangement specifier, encoded in the "size" field. It can have the following values:

2D when size = 11

The following encodings are reserved:

- size = 0x.
- size = 10.

Operation

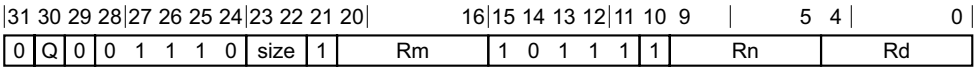
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_ADD, operand, esize);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.5 ADDP (vector)

Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Three registers of the same type variant

```
ADDP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1
2D	when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
bits(esize) element1;
bits(esize) element2;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
for e = 0 to elements-1
    element1 = Elem[concat, 2*e, esize];
    element2 = Elem[concat, (2*e)+1, esize];
    Elem[result, e, esize] = element1 + element2;

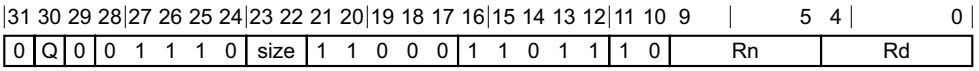
V[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.6 ADDV

Add across Vector. This instruction adds every vector element in the source SIMD&FP register together, and writes the scalar result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Advanced SIMD variant

```
ADDV <V><d>, <Vn>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();

integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
```

Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:

- B when size = 00
- H when size = 01
- S when size = 10

The encoding size = 11 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 4S when size = 10, Q = 1

The following encodings are reserved:

- size = 10, Q = 0.
- size = 11, Q = x.

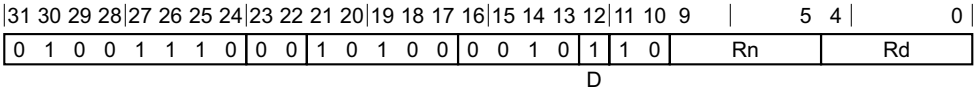
Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(ReduceOp_ADD, operand, esize);
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.7 AESD

AES single round decryption



Advanced SIMD variant

```
AESD <Vd>.16B, <Vn>.16B
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HaveCryptoExt() then UnallocatedEncoding();
```

Assembler symbols

<Vd> Is the name of the SIMD&FP source and destination register, encoded in the "Rd" field.

<Vn> Is the name of the second SIMD&FP source register, encoded in the "Rn" field.

Operation

```
CheckCryptoEnabled64();

bits(128) operand1 = V[d];
bits(128) operand2 = V[n];
bits(128) result;
result = operand1 EOR operand2;
result = AESInvSubBytes(AESInvShiftRows(result));
V[d] = result;
```

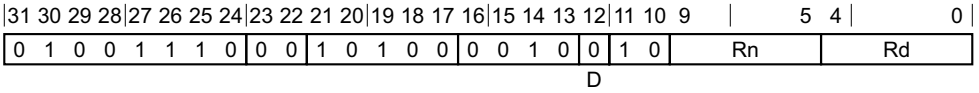
Non-Confidential

C7.2.8 AESE

AES single round encryption



Advanced SIMD variant

```
AESE <Vd>.16B, <Vn>.16B
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HaveCryptoExt() then UnallocatedEncoding();
```

Assembler symbols

<Vd> Is the name of the SIMD&FP source and destination register, encoded in the "Rd" field.

<Vn> Is the name of the second SIMD&FP source register, encoded in the "Rn" field.

Operation

```
CheckCryptoEnabled64();

bits(128) operand1 = V[d];
bits(128) operand2 = V[n];
bits(128) result;
result = operand1 EOR operand2;
result = AESSubBytes(AESShiftRows(result));

V[d] = result;
```

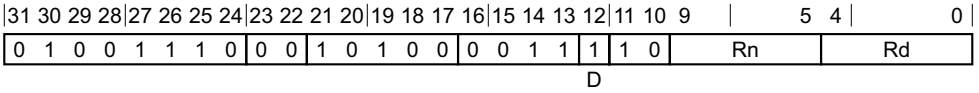
Non-Confidential

C7.2.9 AESIMC

AES inverse mix columns



Advanced SIMD variant

```
AESIMC <Vd>.16B, <Vn>.16B
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HaveCryptoExt() then UnallocatedEncoding();
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

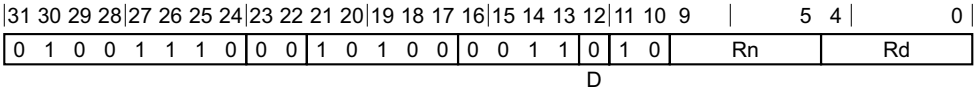
```
CheckCryptoEnabled64();

bits(128) operand = V[n];
bits(128) result;
result = AESInvMixColumns(operand);
V[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.10 AESMC

AES mix columns



Advanced SIMD variant

```
AESMC <Vd>.16B, <Vn>.16B
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
if !HaveCryptoExt() then UnallocatedEncoding();
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
CheckCryptoEnabled64();

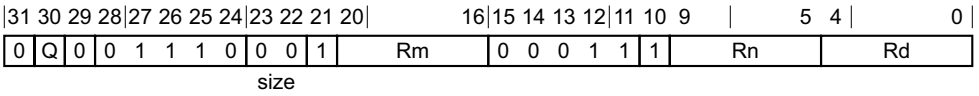
bits(128) operand = V[n];
bits(128) result;
result = AESMixColumns(operand);
V[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.11 AND (vector)

Bitwise AND (vector). This instruction performs a bitwise AND between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Three registers of the same type variant

```
AND <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 8B when Q = 0
- 16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

result = operand1 AND operand2;
V[d] = result;
```

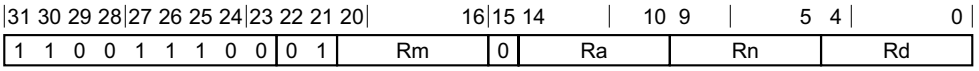
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.12 BCAX

Bit Clear and Exclusive OR performs a bitwise AND of the 128-bit vector in a source SIMD&FP register and the complement of the vector in another source SIMD&FP register, then performs a bitwise exclusive OR of the resulting vector and the vector in a third source SIMD&FP register, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when ARMv8.2-SHA is implemented.

ARMv8.2



Advanced SIMD variant

```
BCAX <Vd>.16B, <Vn>.16B, <Vm>.16B, <Va>.16B
```

Decode for this encoding

```
if !HaveCryptoExt2() then UnallocatedEncoding();
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer a = UInt(Ra);
```

Assembler symbols

<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<Va>	Is the name of the third SIMD&FP source register, encoded in the "Ra" field.

Operation

```
bits(128) Vm = V[m];
bits(128) Vn = V[n];
bits(128) Va = V[a];
V[d] = Vn EOR (Vm AND NOT(Va));
```

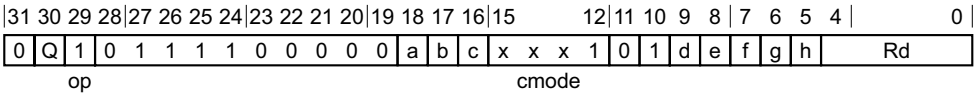
C7.2.13 BIC (vector, immediate)

Bitwise bit Clear (vector, immediate). This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise AND between each result and the complement of an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



16-bit variant

Applies when cmode == 10x1.

```
BIC <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

32-bit variant

Applies when cmode == 0xx1.

```
BIC <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

Decode for all variants of this encoding

```
integer rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
case cmode:op of
    when '0xx01' operation = ImmediateOp_MVNI;
    when '0xx11' operation = ImmediateOp_BIC;
    when '10x01' operation = ImmediateOp_MVNI;
    when '10x11' operation = ImmediateOp_BIC;
    when '110x1' operation = ImmediateOp_MVNI;
    when '1110x' operation = ImmediateOp_MOVI;
    when '11111'
        // FMOV Dn,#imm is in main FP instruction set
        if Q == '0' then UnallocatedEncoding();
        operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```

Assembler symbols

<Vd> Is the name of the SIMD&FP register, encoded in the "Rd" field.

<T> For the 16-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0

8H when Q = 1

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

For the 32-bit variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

2S when Q = 0

4S when Q = 1

<imm8> Is an 8-bit immediate encoded in "a:b:c:d:e:f:g:h".

<amount> For the 16-bit variant: is the shift amount encoded in the "cmode<1>" field. It can have the following values:

0 when cmode<1> = 0

8 when cmode<1> = 1

defaulting to 0 if LSL is omitted.

For the 32-bit variant: is the shift amount encoded in the "cmode<2:1>" field. It can have the following values:

0 when cmode<2:1> = 00

8 when cmode<2:1> = 01

16 when cmode<2:1> = 10

24 when cmode<2:1> = 11

defaulting to 0 if LSL is omitted.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
    when ImmediateOp_MOVI
        result = imm;
    when ImmediateOp_MVNI
        result = NOT(imm);
    when ImmediateOp_ORR
        operand = V[rd];
        result = operand OR imm;
    when ImmediateOp_BIC
        operand = V[rd];
        result = operand AND NOT(imm);

V[rd] = result;
```

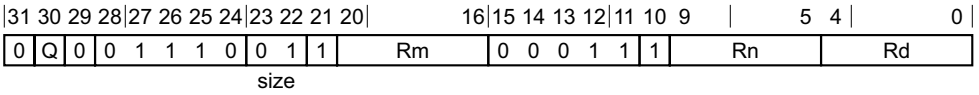
C7.2.14 BIC (vector, register)

Bitwise bit Clear (vector, register). This instruction performs a bitwise AND between the first source SIMD&FP register and the complement of the second source SIMD&FP register, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Three registers of the same type variant

```
BIC <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 8B when Q = 0
- 16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

operand2 = NOT(operand2);

result = operand1 AND operand2;
V[d] = result;
```

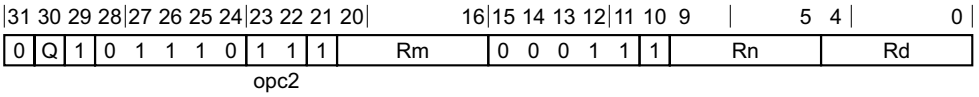
C7.2.15 BIF

Bitwise Insert if False. This instruction inserts each bit from the first source SIMD&FP register into the destination SIMD&FP register if the corresponding bit of the second source SIMD&FP register is 0, otherwise leaves the bit in the destination register unchanged.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Three registers of the same type variant

```
BIF <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 8B when Q = 0
- 16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;
bits(datasize) operand3;
bits(datasize) operand4 = V[n];

operand1 = V[d];
operand3 = NOT(V[m]);

V[d] = operand1 EOR ((operand1 EOR operand4) AND operand3);
```

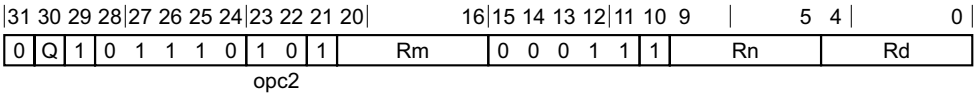
C7.2.16 BIT

Bitwise Insert if True. This instruction inserts each bit from the first source SIMD&FP register into the SIMD&FP destination register if the corresponding bit of the second source SIMD&FP register is 1, otherwise leaves the bit in the destination register unchanged.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Three registers of the same type variant

```
BIT <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 8B when Q = 0
- 16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;
bits(datasize) operand3;
bits(datasize) operand4 = V[n];

operand1 = V[d];
operand3 = V[m];
V[d] = operand1 EOR ((operand1 EOR operand4) AND operand3);
```

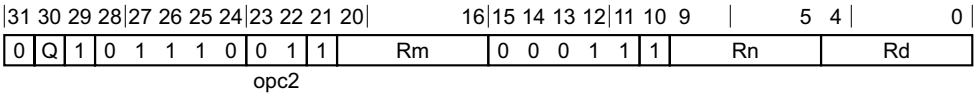
C7.2.17 BSL

Bitwise Select. This instruction sets each bit in the destination SIMD&FP register to the corresponding bit from the first source SIMD&FP register when the original destination bit was 1, otherwise from the second source SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Three registers of the same type variant

```
BSL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 8B when Q = 0
- 16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;
bits(datasize) operand3;
bits(datasize) operand4 = V[n];

operand1 = V[m];
operand3 = V[d];
V[d] = operand1 EOR ((operand1 EOR operand4) AND operand3);
```

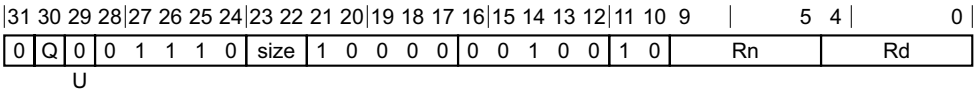
C7.2.18 CLS (vector)

Count Leading Sign bits (vector). This instruction counts the number of consecutive bits following the most significant bit that are the same as the most significant bit in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The count does not include the most significant bit itself.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Vector variant

```
CLS <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

CountOp countop = if U == '1' then CountOp_CLZ else CountOp_CLS;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B	when size = 00, Q = 0
16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

integer count;
for e = 0 to elements-1
    if countop == CountOp_CLS then
        count = CountLeadingSignBits(Elem[operand, e, esize]);
    else
```

Non-Confidential

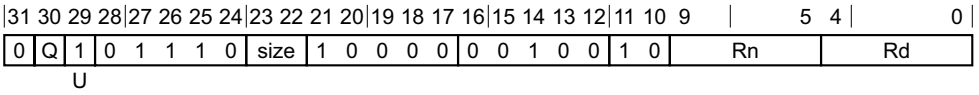
C7.2.19 CLZ (vector)

Count Leading Zero bits (vector). This instruction counts the number of consecutive zeros, starting from the most significant bit, in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Vector variant

```
CLZ <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

CountOp countop = if U == '1' then CountOp_CLZ else CountOp_CLS;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

integer count;
for e = 0 to elements-1
    if countop == CountOp_CLS then
        count = CountLeadingSignBits(Elem[operand, e, esize]);
    else
```

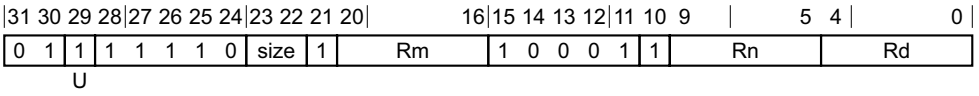
C7.2.20 CMEQ (register)

Compare bitwise Equal (vector). This instruction compares each vector element from the first source SIMD&FP register with the corresponding vector element from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar



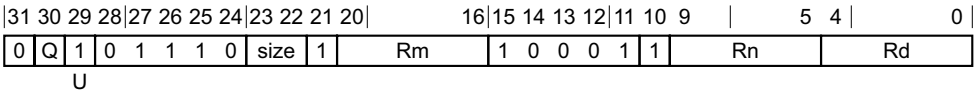
Scalar variant

```
CMEQ <V><d>, <V><n>, <V><m>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size != '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean and_test = (U == '0');
```

Vector



Vector variant

```
CMEQ <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean and_test = (U == '0');
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

`D` when `size = 11`

The following encodings are reserved:

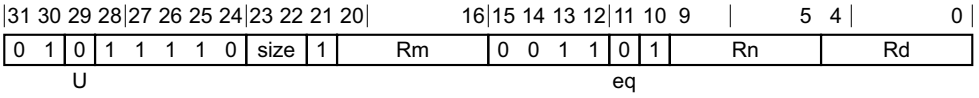
C7.2.24 CMGT (register)

Compare signed Greater than (vector). This instruction compares each vector element in the first source SIMD&FP register with the corresponding vector element in the second source SIMD&FP register and if the first signed integer value is greater than the second signed integer value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar



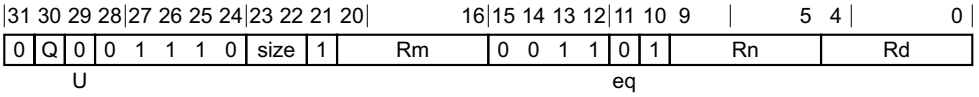
Scalar variant

```
CMGT <V><d>, <V><n>, <V><m>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size != '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
boolean cmp_eq = (eq == '1');
```

Vector



Vector variant

```

- `size = 10`.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when `size = 00`, `Q = 0`

16B when `size = 00`, `Q = 1`

4H when `size = 01`, `Q = 0`

8H when `size = 01`, `Q = 1`

2S when `size = 10`, `Q = 0`

4S when `size = 10`, `Q = 1`

2D when `size = 11`, `Q = 1`

The encoding `size = 11`, `Q = 0` is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
boolean test_passed;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if and_test then
        test_passed = !IsZero(element1 AND element2);
    else
        test_passed = (element1 == element2);
    Elem[result, e, esize] = if test_passed then Ones() else Zeros();

V[d] = result;
```

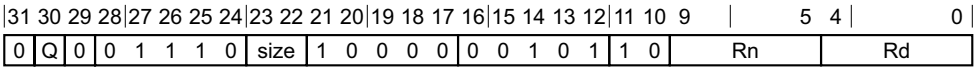
C7.2.31 CNT

Population Count per byte. This instruction counts the number of bits that have a value of one in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Vector variant

```
CNT <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '00' then ReservedValue();
integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

The following encodings are reserved:

- size = 01, Q = x.
- size = 1x, Q = x.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

integer count;
for e = 0 to elements-1
    count = BitCount(Elem[operand, e, esize]);
    Elem[result, e, esize] = count<esize-1:0>;
V[d] = result;
```

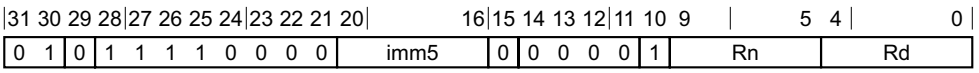
C7.2.32 DUP (element)

Duplicate vector element to vector or scalar. This instruction duplicates the vector element at the specified element index in the source SIMD&FP register into a scalar or each element in a vector, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (scalar). The alias is always the preferred disassembly.

Scalar



Scalar variant

```
DUP <V><d>, <Vn>.<T>[<index>]
```

Decode for this encoding

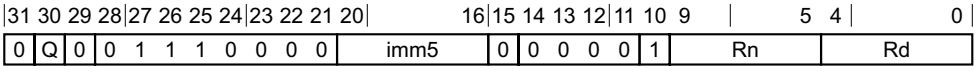
```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();

integer index = UInt(imm5<4:size+1>);
integer idxdsize = if imm5<4> == '1' then 128 else 64;

integer esize = 8 << size;
integer datasize = esize;
integer elements = 1;
```

Vector



Vector variant

```
DUP <Vd>.<T>, <Vn>.<Ts>[<index>]
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();

integer index = UInt(imm5<4:size+1>);
integer idxdsize = if imm5<4> == '1' then 128 else 64;

if size == 3 && Q == '0' then ReservedValue();
integer esize = 8 << size;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

<T> For the scalar variant: is the element width specifier, encoded in the "imm5" field. It can have the following values:

B when imm5 = xxxx1

H when imm5 = xxx10

S when imm5 = xx100

D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

For the vector variant: is an arrangement specifier, encoded in the "imm5:Q" field. It can have the following values:

8B when imm5 = xxxx1, Q = 0

16B when imm5 = xxxx1, Q = 1

4H when imm5 = xxx10, Q = 0

8H when imm5 = xxx10, Q = 1

2S when imm5 = xx100, Q = 0

4S when imm5 = xx100, Q = 1

2D when imm5 = x1000, Q = 1

The following encodings are reserved:

- imm5 = x0000, Q = x.
- imm5 = x1000, Q = 0.

<Ts> Is an element size specifier, encoded in the "imm5" field. It can have the following values:

B when imm5 = xxxx1

H when imm5 = xxx10

S when imm5 = xx100

D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<V> Is the destination width specifier, encoded in the "imm5" field. It can have the following values:

B when imm5 = xxxx1

H when imm5 = xxx10

S when imm5 = xx100

D when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<index> Is the element index encoded in the "imm5" field. It can have the following values:

imm5<4:1> when imm5 = xxxx1

imm5<4:2> when imm5 = xxx10

imm5<4:3> when imm5 = xx100

imm5<4> when imm5 = x1000

The encoding imm5 = x0000 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

Non-Confidential

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(idxdsize) operand = V[n];
bits(datasize) result;
bits(esize) element;

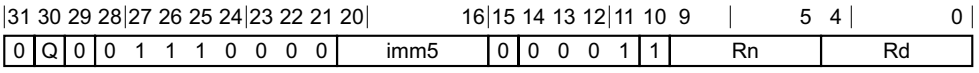
element = Elem[operand, index, esize];
for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.33 DUP (general)

Duplicate general-purpose register to vector. This instruction duplicates the contents of the source general-purpose register into a scalar or each element in a vector, and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Advanced SIMD variant

```
DUP <Vd>.<T>, <R><n>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();

// imm5<4:size+1> is IGNORED

if size == 3 && Q == '0' then ReservedValue();
integer esize = 8 << size;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "imm5:Q" field. It can have the following values:

8B when imm5 = xxxx1, Q = 0

16B when imm5 = xxxx1, Q = 1

4H when imm5 = xxx10, Q = 0

8H when imm5 = xxx10, Q = 1

2S when imm5 = xx100, Q = 0

4S when imm5 = xx100, Q = 1

2D when imm5 = x1000, Q = 1

The following encodings are reserved:

- imm5 = x0000, Q = x.
- imm5 = x1000, Q = 0.

<R> Is the width specifier for the general-purpose source register, encoded in the "imm5" field. It can have the following values:

W when imm5 = xxxx1

W when imm5 = xxx10

W when imm5 = xx100

X when imm5 = x1000

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

The encoding `imm5 = x0000` is reserved.

Unspecified bits in "imm5" are ignored but should be set to zero by an assembler.

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the "Rn" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(esize) element = X[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d] = result;
```

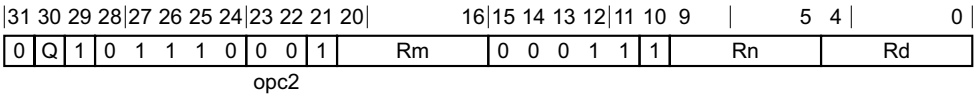
Non-Confidential

C7.2.34 EOR (vector)

Bitwise Exclusive OR (vector). This instruction performs a bitwise Exclusive OR operation between the two source SIMD&FP registers, and places the result in the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Three registers of the same type variant

```
EOR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if Q == '1' then 128 else 64;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 8B when Q = 0
- 16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;
bits(datasize) operand2;
bits(datasize) operand3;
bits(datasize) operand4 = V[n];

operand1 = V[m];
operand2 = Zeros();
operand3 = Ones();
V[d] = operand1 EOR ((operand2 EOR operand4) AND operand3);
```

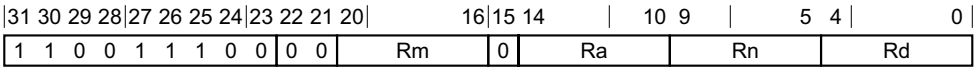
Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.35 EOR3

Three-way Exclusive OR performs a three-way exclusive OR of the values in the three source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

This instruction is implemented only when ARMv8.2-SHA is implemented.

ARMv8.2



Advanced SIMD variant

```
EOR3 <Vd>.16B, <Vn>.16B, <Vm>.16B, <Va>.16B
```

Decode for this encoding

```
if !HaveCryptoExt2() then UnallocatedEncoding();
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer a = UInt(Ra);
```

Assembler symbols

<Vd>	Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
<Vn>	Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
<Vm>	Is the name of the second SIMD&FP source register, encoded in the "Rm" field.
<Va>	Is the name of the third SIMD&FP source register, encoded in the "Ra" field.

Operation

```
bits(128) Vm = V[m];
bits(128) Vn = V[n];
bits(128) Va = V[a];
V[d] = Vn EOR Vm EOR Va;
```

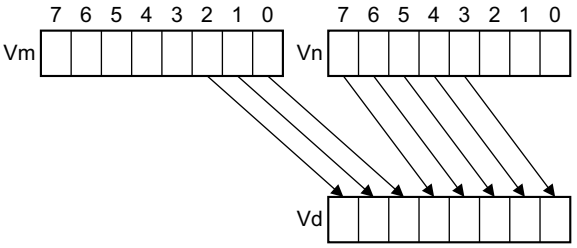
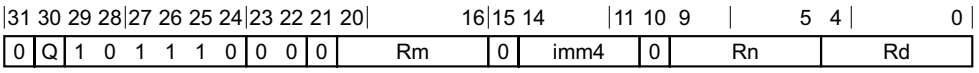
C7.2.36 EXT

Extract vector from pair of vectors. This instruction extracts the lowest vector elements from the second source SIMD&FP register and the highest vector elements from the first source SIMD&FP register, concatenates the results into a vector, and writes the vector to the destination SIMD&FP register vector. The index value specifies the lowest vector element to extract from the first source register, and consecutive elements are extracted from the first, then second, source registers until the destination vector is filled.

The following figure shows the operation of EXT doubleword operation for Q = 0 and imm4<2:0> = 3.



Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Advanced SIMD variant

```
EXT <Vd>.<T>, <Vn>.<T>, <Vm>.<T>, #<index>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if Q == '0' && imm4<3> == '1' then UnallocatedEncoding();

integer datasize = if Q == '1' then 128 else 64;
integer position = UInt(imm4) << 3;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:

- 8B when Q = 0
- 16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<index> Is the lowest numbered byte element to be extracted, encoded in the "Q:imm4" field. It can have the following values:

- imm4<2:0> when Q = 0, imm4<3> = 0
- imm4 when Q = 1, imm4<3> = x

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

The encoding `Q = 0`, `imm4<3> = 1` is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) hi = V[m];
bits(datasize) lo = V[n];
bits(datasize*2) concat = hi:lo;

V[d] = concat<position+datasize-1:position>;
```

Non-Confidential

C7.2.37 FABD

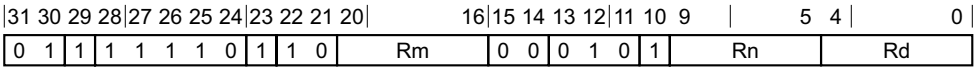
Floating-point Absolute Difference (vector). This instruction subtracts the floating-point values in the elements of the second source SIMD&FP register, from the corresponding floating-point values in the elements of the first source SIMD&FP register, places the absolute value of each result in a vector, and writes the vector to the destination SIMD&FP register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar half precision

ARMv8.2



Scalar half precision variant

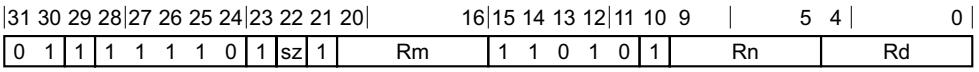
```
FABD <Hd>, <Hn>, <Hm>
```

Decode for this encoding

```
if !HaveFP16Ext() then UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 16;
integer datasize = esize;
integer elements = 1;
boolean abs = TRUE;
```

Scalar single-precision and double-precision



Scalar single-precision and double-precision variant

```
FABD <V><d>, <V><n>, <V><m>
```

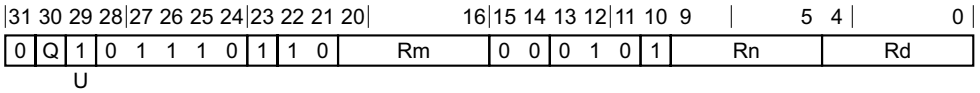
Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;
boolean abs = TRUE;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

Vector half precision

ARMv8.2



Vector half precision variant

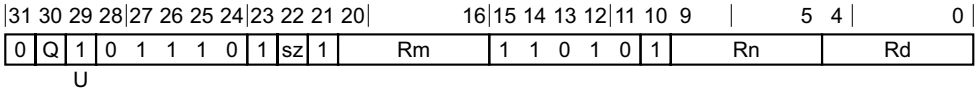
```
FABD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
if !HaveFP16Ext() then UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 16;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean abs = (U == '1');
```

Vector single-precision and double-precision



Vector single-precision and double-precision variant

```
FABD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean abs = (U == '1');
```

Assembler symbols

<Hd>	Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Hn>	Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<Hm>	Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<V>	Is a width specifier, encoded in the "sz" field. It can have the following values: S when sz = 0 D when sz = 1
<d>	Is the number of the SIMD&FP destination register, in the "Rd" field.
<n>	Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0

8H when Q = 1

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) diff;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    diff = FPSub(element1, element2, FPCR);
    Elem[result, e, esize] = if abs then FPAbs(diff) else diff;

V[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

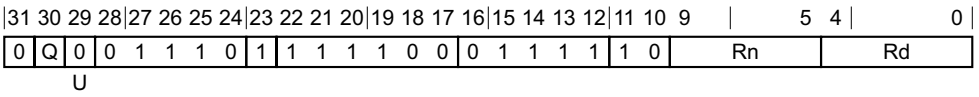
C7.2.38 FABS (vector)

Floating-point Absolute value (vector). This instruction calculates the absolute value of each vector element in the source SIMD&FP register, writes the result to a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Half-precision

ARMv8.2



Half-precision variant

```
FABS <Vd>.<T>, <Vn>.<T>
```

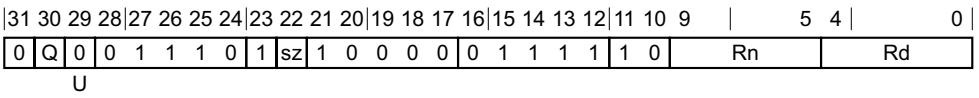
Decode for this encoding

```
if !HaveFP16Ext() then UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 16;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean neg = (U == '1');
```

Single-precision and double-precision



Single-precision and double-precision variant

```
FABS <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean neg = (U == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the half-precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

8H when Q = 1

For the single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    if neg then
        element = FPNeg(element);
    else
        element = FPAbs(element);
    Elem[result, e, esize] = element;

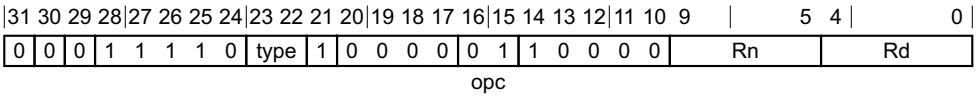
V[d] = result;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.39 FABS (scalar)

Floating-point Absolute value (scalar). This instruction calculates the absolute value in the SIMD&FP source register and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Half-precision variant

Applies when `type == 11`.

```
FABS <Hd>, <Hn>
```

Single-precision variant

Applies when `type == 00`.

```
FABS <Sd>, <Sn>
```

Double-precision variant

Applies when `type == 01`.

```
FABS <Dd>, <Dn>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '10' UnallocatedEncoding();
    when '11'
        if HaveFP16Ext() then
            datasize = 16;
        else
            UnallocatedEncoding();
```

Assembler symbols

<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Dn>	Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Hd>	Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Hn>	Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
<Sn>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

C7.2.40 FACGE

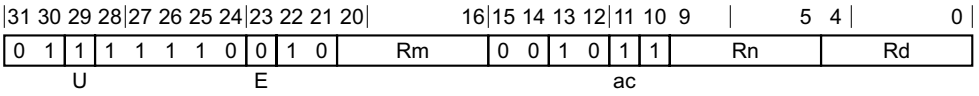
Floating-point Absolute Compare Greater than or Equal (vector). This instruction compares the absolute value of each floating-point value in the first source SIMD&FP register with the absolute value of the corresponding floating-point value in the second source SIMD&FP register and if the first value is greater than or equal to the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar half precision

ARMv8.2



Scalar half precision variant

```
FACGE <Hd>, <Hn>, <Hm>
```

Decode for this encoding

```
if !HaveFP16Ext() then UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 16;
integer datasize = esize;
integer elements = 1;
CompareOp cmp;
boolean abs;

case E:U:ac of
    when '000' cmp = CompareOp_EQ; abs = FALSE;
    when '010' cmp = CompareOp_GE; abs = FALSE;

C7.2.41 FACGT

Floating-point Absolute Compare Greater than (vector). This instruction compares the absolute value of each vector element in the first source SIMD&FP register with the absolute value of the corresponding vector element in the second source SIMD&FP register and if the first value is greater than the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.45 FADDP (vector)

Floating-point Add Pairwise (vector). This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are floating-point values.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.46 FCADD

Floating-point Complex Add.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 90 or 270 degrees.
- The rotated complex number is added to the complex number from the first source register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

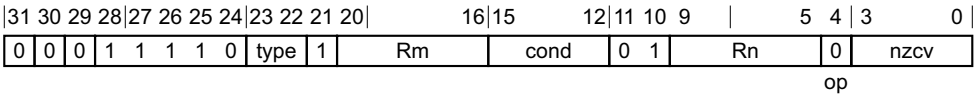
C7.2.47 FCCMP

Floating-point Conditional quiet Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE.{N, Z, C, V} flags. If the condition does not pass then the PSTATE.{N, Z, C, V} flags are set to the flag bit specifier.

It raises an Invalid Operation exception only if either operand is a signaling NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Half-precision variant

Applies when type == 11.

```
FCCMP <Hn>, <Hm>, #<nzcv>, <cond>
```

Single-precision variant

Applies when type == 00.

```
FCCMP <Sn>, <Sm>, #<nzcv>, <cond>
```

Double-precision variant

Applies when type == 01.

```
FCCMP <Dn>, <Dm>, #<nzcv>, <cond>
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '10' UnallocatedEncoding();
    when '11'
        if HaveFP16Ext() then
            datasize = 16;
        else
            UnallocatedEncoding();

bits(4) flags = nzcv;
```

Assembler symbols

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Hn> Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<Hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.

<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This case results in the FPSCR flags being set to N=0, Z=0, C=1, and V=1.

Operation

```
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;

operand2 = V[m];

if ConditionHolds(cond) then
    flags = FPCompare(operand1, operand2, FALSE, FPCR);
PSTATE.<N,Z,C,V> = flags;
```

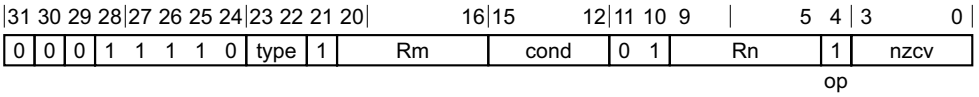
C7.2.48 FCCMPE

Floating-point Conditional signaling Compare (scalar). This instruction compares the two SIMD&FP source register values and writes the result to the PSTATE.{N, Z, C, V} flags. If the condition does not pass then the PSTATE.{N, Z, C, V} flags are set to the flag bit specifier.

If either operand is any type of NaN, or if either operand is a signaling NaN, the instruction raises an Invalid Operation exception.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Half-precision variant

Applies when type == 11.

```
FCCMPE <Hn>, <Hm>, #<nzcv>, <cond>
```

Single-precision variant

Applies when type == 00.

```
FCCMPE <Sn>, <Sm>, #<nzcv>, <cond>
```

Double-precision variant

Applies when type == 01.

```
FCCMPE <Dn>, <Dm>, #<nzcv>, <cond>
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '10' UnallocatedEncoding();
    when '11'
        if HaveFP16Ext() then
            datasize = 16;
        else
            UnallocatedEncoding();

bits(4) flags = nzcv;
```

Assembler symbols

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<Hn> Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<Hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<nzcv> Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the "nzcv" field.

<cond> Is one of the standard conditions, encoded in the "cond" field in the standard way.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This case results in the FPSCR flags being set to N=0, Z=0, C=1, and V=1.

FCCMPE raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

Operation

```
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;

operand2 = V[m];

if ConditionHolds(cond) then
    flags = FPCompare(operand1, operand2, TRUE, FPCR);
PSTATE.<N,Z,C,V> = flags;
```

C7.2.49 FCMEQ (register)

Floating-point Compare Equal (vector). This instruction compares each floating-point value from the first source SIMD&FP register, with the corresponding floating-point value from the second source SIMD&FP register, and if the comparison is equal sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.52 FCMGE (zero)

Floating-point Compare Greater than or Equal to zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is greater than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.55 FCMLA (by element)

Floating-point Complex Multiply Accumulate (by element).

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on complex numbers from the first source register and the destination register with the specified complex number from the second source register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.56 FCMLA

Floating-point Complex Multiply Accumulate.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers and the destination register:

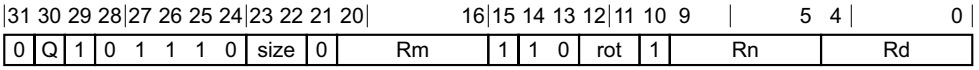
- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

ARMv8.3



Three registers of the same type variant

```
FCMLA <Vd>.<T>, <Vn>.<T>, <Vm>.<T>, #<rotate>
```

Decode for this encoding

```
if !HaveFCADDExt() then UnallocatedEncoding();
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '00' then ReservedValue();
if Q == '0' && size == '11' then ReservedValue();

C7.2.57 FCMLE (zero)

Floating-point Compare Less than or Equal to zero (vector). This instruction reads each floating-point value in the source SIMD&FP register and if the value is less than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

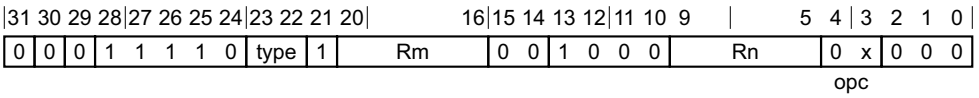
C7.2.59 FCMP

Floating-point quiet Compare (scalar). This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the PSTATE.{N, Z, C, V} flags.

It raises an Invalid Operation exception only if either operand is a signaling NaN.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Half-precision variant

Applies when `type == 11 && opc == 00`.

```
FCMP <Hn>, <Hm>
```

Half-precision, zero variant

Applies when `type == 11 && Rm == (00000) && opc == 01`.

```
FCMP <Hn>, #0.0
```

Single-precision variant

Applies when `type == 00 && opc == 00`.

```
FCMP <Sn>, <Sm>
```

Single-precision, zero variant

Applies when `type == 00 && Rm == (00000) && opc == 01`.

```
FCMP <Sn>, #0.0
```

Double-precision variant

Applies when `type == 01 && opc == 00`.

```
FCMP <Dn>, <Dm>
```

Double-precision, zero variant

Applies when `type == 01 && Rm == (00000) && opc == 01`.

```
FCMP <Dn>, #0.0
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer m = UInt(Rm);    // ignored when opc<0> == '1'

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
    when '10' UnallocatedEncoding();
    when '11'
        if HaveFP16Ext() then
            datasize = 16;
        else
            UnallocatedEncoding();

boolean signal_all_nans = (opc<1> == '1');
boolean cmp_with_zero = (opc<0> == '1');
```

Assembler symbols

<Dn> For the double-precision variant: is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

For the double-precision, zero variant: is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Hn> For the half-precision variant: is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

For the half-precision, zero variant: is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Sn> For the single-precision variant: is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

For the single-precision, zero variant: is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This case results in the FPSCR flags being set to N=0, Z=0, C=1, and V=1.

Operation

```
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;

operand2 = if cmp_with_zero then FPZero('0') else V[m];

PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR);
```

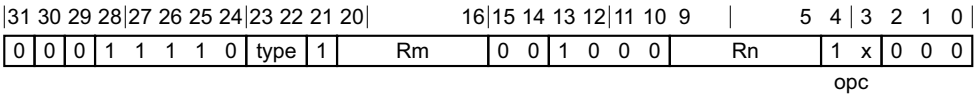
C7.2.60 FCMPE

Floating-point signaling Compare (scalar). This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the PSTATE.{N, Z, C, V} flags.

If either operand is any type of NaN, or if either operand is a signaling NaN, the instruction raises an Invalid Operation exception.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Half-precision variant

Applies when `type == 11 && opc == 10`.

```
FCMPE <Hn>, <Hm>
```

Half-precision, zero variant

Applies when `type == 11 && Rm == (00000) && opc == 11`.

```
FCMPE <Hn>, #0.0
```

Single-precision variant

Applies when `type == 00 && opc == 10`.

```
FCMPE <Sn>, <Sm>
```

Single-precision, zero variant

Applies when `type == 00 && Rm == (00000) && opc == 11`.

```
FCMPE <Sn>, #0.0
```

Double-precision variant

Applies when `type == 01 && opc == 10`.

```
FCMPE <Dn>, <Dm>
```

Double-precision, zero variant

Applies when `type == 01 && Rm == (00000) && opc == 11`.

```
FCMPE <Dn>, #0.0
```

Decode for all variants of this encoding

```
integer n = UInt(Rn);
integer m = UInt(Rm);    // ignored when opc<0> == '1'

integer datasize;
case type of
    when '00' datasize = 32;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
    when '01' datasize = 64;
    when '10' UnallocatedEncoding();
    when '11'
        if HaveFP16Ext() then
            datasize = 16;
        else
            UnallocatedEncoding();

boolean signal_all_nans = (opc<1> == '1');
boolean cmp_with_zero = (opc<0> == '1');
```

Assembler symbols

<Dn> For the double-precision variant: is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

For the double-precision, zero variant: is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Hn> For the half-precision variant: is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

For the half-precision, zero variant: is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Sn> For the single-precision variant: is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

For the single-precision, zero variant: is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This case results in the FPSCR flags being set to N=0, Z=0, C=1, and V=1.

FCMPE raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

Operation

```
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;

operand2 = if cmp_with_zero then FPZero('0') else V[m];

PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR);
```

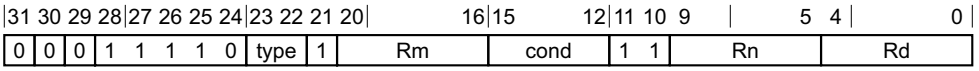
C7.2.61 FCSEL

Floating-point Conditional Select (scalar). This instruction allows the SIMD&FP destination register to take the value from either one or the other of two SIMD&FP source registers. If the condition passes, the first SIMD&FP source register value is taken, otherwise the second SIMD&FP source register value is taken.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Half-precision variant

Applies when `type == 11`.

```
FCSEL <Hd>, <Hn>, <Hm>, <cond>
```

Single-precision variant

Applies when `type == 00`.

```
FCSEL <Sd>, <Sn>, <Sm>, <cond>
```

Double-precision variant

Applies when `type == 01`.

```
FCSEL <Dd>, <Dn>, <Dm>, <cond>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '10' UnallocatedEncoding();
    when '11'
        if HaveFP16Ext() then
            datasize = 16;
        else
            UnallocatedEncoding();
```

Assembler symbols

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field.

<Hm> Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

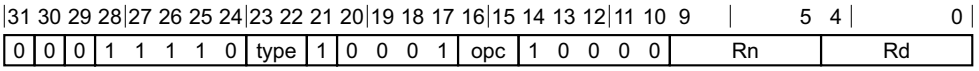
C7.2.62 FCVT

Floating-point Convert precision (scalar). This instruction converts the floating-point value in the SIMD&FP source register to the precision for the destination register data type using the rounding mode that is determined by the FPCR and writes the result to the SIMD&FP destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Half-precision to single-precision variant

Applies when `type == 11 && opc == 00`.

```
FCVT <Sd>, <Hn>
```

Half-precision to double-precision variant

Applies when `type == 11 && opc == 01`.

```
FCVT <Dd>, <Hn>
```

Single-precision to half-precision variant

Applies when `type == 00 && opc == 11`.

```
FCVT <Hd>, <Sn>
```

Single-precision to double-precision variant

Applies when `type == 00 && opc == 01`.

```
FCVT <Dd>, <Sn>
```

Double-precision to half-precision variant

Applies when `type == 01 && opc == 11`.

```
FCVT <Hd>, <Dn>
```

Double-precision to single-precision variant

Applies when `type == 01 && opc == 00`.

```
FCVT <Sd>, <Dn>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if type == opc then UnallocatedEncoding();

integer srcsize;
case type of
    when '00' srcsize = 32;
    when '01' srcsize = 64;
    when '10' UnallocatedEncoding();
    when '11' srcsize = 16;
integer dstsize;
```

C7.2.63 FCVTAS (vector)

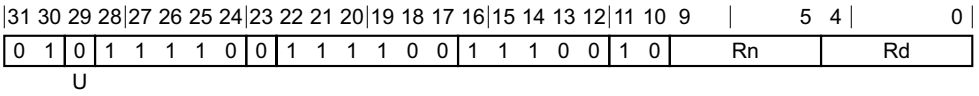
Floating-point Convert to Signed integer, rounding to nearest with ties to Away (vector). This instruction converts each element in a vector from a floating-point value to a signed integer value using the Round to Nearest with Ties to Away rounding mode and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar half precision

ARMv8.2



Scalar half precision variant

```
FCVTAS <Hd>, <Hn>
```

Decode for this encoding

```
if !HaveFP16Ext() then UnallocatedEncoding();

integer d = UInt(Rd);

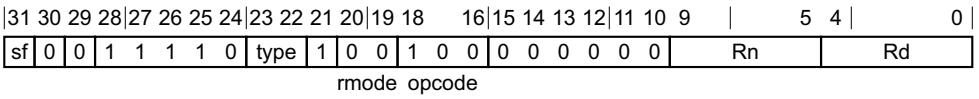
C7.2.64 FCVTAS (scalar)

Floating-point Convert to Signed integer, rounding to nearest with ties to Away (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round to Nearest with Ties to Away rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Half-precision to 32-bit variant

Applies when `sf == 0 && type == 11`.

```
FCVTAS <Wd>, <Hn>
```

Half-precision to 64-bit variant

Applies when `sf == 1 && type == 11`.

```
FCVTAS <Xd>, <Hn>
```

Single-precision to 32-bit variant

Applies when `sf == 0 && type == 00`.

```
FCVTAS <Wd>, <Sn>
```

Single-precision to 64-bit variant

Applies when `sf == 1 && type == 00`.

```
FCVTAS <Xd>, <Sn>
```

Double-precision to 32-bit variant

Applies when `sf == 0 && type == 01`.

```
FCVTAS <Wd>, <Dn>
```

Double-precision to 64-bit variant

Applies when `sf == 1 && type == 01`.

```
FCVTAS <Xd>, <Dn>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;

case type of

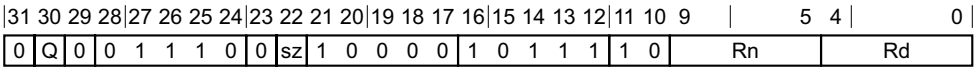
C7.2.67 FCVTL, FCVTL2

Floating-point Convert to higher precision Long (vector). This instruction reads each element in a vector in the SIMD&FP source register, converts each value to double the precision of the source element using the rounding mode that is determined by the FPCR, and writes each result to the equivalent element of the vector in the SIMD&FP destination register.

Where the operation lengthens a 64-bit vector to a 128-bit vector, the FCVTL2 variant operates on the elements in the top 64 bits of the source register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Vector single-precision and double-precision variant

```
FCVTL{2} <Vd>.<Ta>, <Vn>.<Tb>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 16 << UInt(sz);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
```

Assembler symbols

2 — Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd> — Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> — Is an arrangement specifier, encoded in the "sz" field. It can have the following values:

- 4S when sz = 0
- 2D when sz = 1

<Vn> — Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> — Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- 4H when sz = 0, Q = 0
- 8H when sz = 0, Q = 1
- 2S when sz = 1, Q = 0
- 4S when sz = 1, Q = 1

C7.2.68 FCVTMS (vector)

Floating-point Convert to Signed integer, rounding toward Minus infinity (vector). This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round towards Minus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0

8H when Q = 1

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, 0, unsigned, FPCR, rounding);

V[d] = result;
```

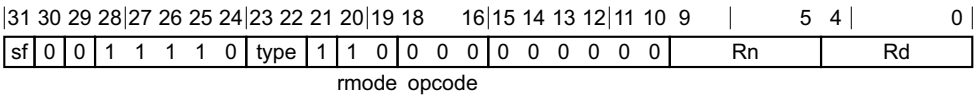
C7.2.69 FCVTMS (scalar)

Floating-point Convert to Signed integer, rounding toward Minus infinity (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round towards Minus Infinity rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Half-precision to 32-bit variant

Applies when `sf == 0 && type == 11`.

```
FCVTMS <Wd>, <Hn>
```

Half-precision to 64-bit variant

Applies when `sf == 1 && type == 11`.

```
FCVTMS <Xd>, <Hn>
```

Single-precision to 32-bit variant

Applies when `sf == 0 && type == 00`.

```
FCVTMS <Wd>, <Sn>
```

Single-precision to 64-bit variant

Applies when `sf == 1 && type == 00`.

```
FCVTMS <Xd>, <Sn>
```

Double-precision to 32-bit variant

Applies when `sf == 0 && type == 01`.

```
FCVTMS <Wd>, <Dn>
```

Double-precision to 64-bit variant

Applies when `sf == 1 && type == 01`.

```
FCVTMS <Xd>, <Dn>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;
FPRounding rounding;
```

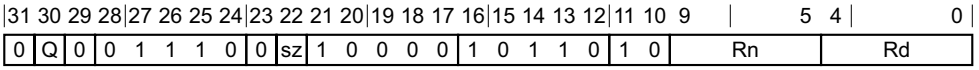
C7.2.72 FCVTN, FCVTN2

Floating-point Convert to lower precision Narrow (vector). This instruction reads each vector element in the SIMD&FP source register, converts each result to half the precision of the source element, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The rounding mode is determined by the FPCR.

The FCVTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the FCVTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.



Vector single-precision and double-precision variant

```
FCVTN{2} <Vd>.<Tb>, <Vn>.<Ta>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 16 << UInt(sz);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
```

Assembler symbols

2 — Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd> — Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> — Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

- 4H when sz = 0, Q = 0
- 8H when sz = 0, Q = 1
- 2S when sz = 1, Q = 0
- 4S when sz = 1, Q = 1

<Vn> — Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> — Is an arrangement specifier, encoded in the "sz" field. It can have the following values:

- 4S when sz = 0

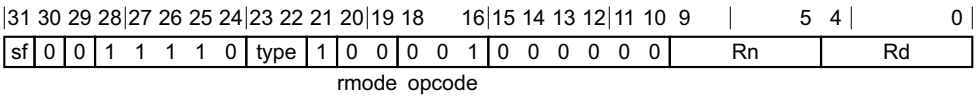
C7.2.76 FCVTNU (scalar)

Floating-point Convert to Unsigned integer, rounding to nearest with ties to even (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit unsigned integer using the Round to Nearest rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Half-precision to 32-bit variant

Applies when `sf == 0 && type == 11`.

```
FCVTNU <Wd>, <Hn>
```

Half-precision to 64-bit variant

Applies when `sf == 1 && type == 11`.

```
FCVTNU <Xd>, <Hn>
```

Single-precision to 32-bit variant

Applies when `sf == 0 && type == 00`.

```
FCVTNU <Wd>, <Sn>
```

Single-precision to 64-bit variant

Applies when `sf == 1 && type == 00`.

```
FCVTNU <Xd>, <Sn>
```

Double-precision to 32-bit variant

Applies when `sf == 0 && type == 01`.

```
FCVTNU <Wd>, <Dn>
```

Double-precision to 64-bit variant

Applies when `sf == 1 && type == 01`.

```
FCVTNU <Xd>, <Dn>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;
FPRounding rounding;
```

C7.2.77 FCVTPS (vector)

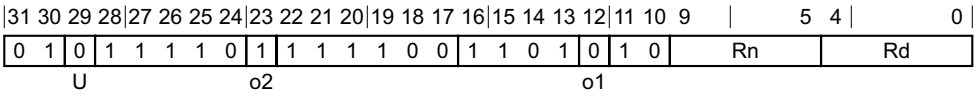
Floating-point Convert to Signed integer, rounding toward Plus infinity (vector). This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round towards Plus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Scalar half precision

ARMv8.2



Scalar half precision variant

C7.2.81 FCVTXN, FCVTXN2

Floating-point Convert to lower precision Narrow, rounding to odd (vector). This instruction reads each vector element in the source SIMD&FP register, narrows each value to half the precision of the source element using the Round to Odd rounding mode, writes the result to a vector, and writes the vector to the destination SIMD&FP register.

Note

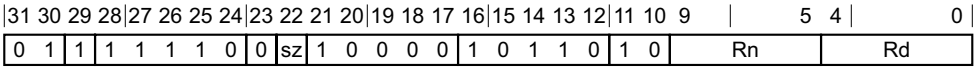
This instruction uses the Round to Odd rounding mode which is not defined by the IEEE 754-2008 standard. This rounding mode ensures that if the result of the conversion is inexact the least significant bit of the mantissa is forced to 1. This rounding mode enables a floating-point value to be converted to a lower precision format via an intermediate precision format while avoiding double rounding errors. For example, a 64-bit floating-point value can be converted to a correctly rounded 16-bit floating-point value by first using this instruction to produce a 32-bit value and then using another instruction with the wanted rounding mode to convert the 32-bit value to the final 16-bit floating-point value.

The FCVTXN instruction writes the vector to the lower half of the destination register and clears the upper half, while the FCVTXN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar



Scalar variant

```
FCVTXN <Vb><d>, <Va><n>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if sz == '0' then ReservedValue();
integer esize = 32;
integer datasize = esize;
integer elements = 1;
integer part = 0;

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz == '0' then ReservedValue();
integer esize = 32;
integer datasize = 64;
integer elements = 2;
integer part = UInt(Q);
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S when sz = 1, Q = 0

4S when sz = 1, Q = 1

The encoding sz = 0, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "sz" field. It can have the following values:

2D when sz = 1

The encoding sz = 0 is reserved.

<Vb> Is the destination width specifier, encoded in the "sz" field. It can have the following values:

S when sz = 1

The encoding sz = 0 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Va> Is the source width specifier, encoded in the "sz" field. It can have the following values:

D when sz = 1

The encoding sz = 0 is reserved.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = FPConvert(Elem[operand, e, 2*esize], FPCR, FPRounding_ODD);

Vpart[d, part] = result;
```

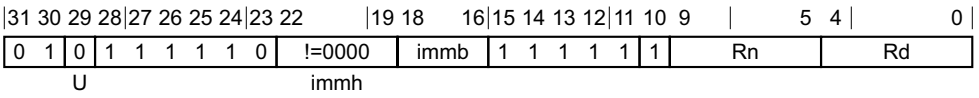
C7.2.82 FCVTZS (vector, fixed-point)

Floating-point Convert to Signed fixed-point, rounding toward Zero (vector). This instruction converts a scalar or each element in a vector from floating-point to fixed-point signed integer using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Scalar



Scalar variant

```
FCVTZS <V><d>, <V><n>, #<fbits>
```

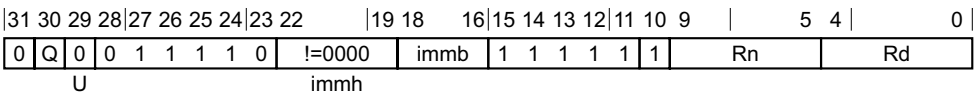
Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '000x' || (immh == '001x' && !HaveFP16Ext()) then ReservedValue();
integer esize = if immh == '1xxx' then 64 else if immh == '01xx' then 32 else 16;
integer datasize = esize;
integer elements = 1;

integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRounding_ZERO;
```

Vector



Vector variant

```
FCVTZS <Vd>.<T>, <Vn>.<T>, #<fbits>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh == '000x' || (immh == '001x' && !HaveFP16Ext()) then ReservedValue();
if immh<3>:Q == '10' then ReservedValue();
integer esize = if immh == '1xxx' then 64 else if immh == '01xx' then 32 else 16;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRounding_ZERO;
```

Assembler symbols

<V> Is a width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 001x

S when immh = 01xx

D when immh = 1xxx

The encoding immh = 000x is reserved.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

2D when immh = 1xxx, Q = 1

See *Advanced SIMD modified immediate* on page C4-306 when immh = 0000, Q = x.

The following encodings are reserved:

- immh = 0001, Q = x.
- immh = 1xxx, Q = 0.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:

(32-Uint(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

(128-UInt(immh:immb)) when immh = 1xxx

The encoding immh = 000x is reserved.

For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:

(32-Uint(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

(128-UInt(immh:immb)) when immh = 1xxx

See *Advanced SIMD modified immediate* on page C4-306 when immh = 0000.

The encoding immh = 0001 is reserved.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
        element = Elem[operand, e, esize];
        Elem[result, e, esize] = FPToFixed(element, fracbits, unsigned, FPCR, rounding);

    V[d] = result;
```

C7.2.83 FCVTZS (vector, integer)

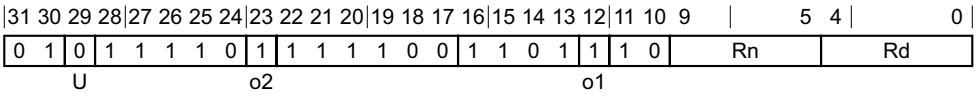
Floating-point Convert to Signed integer, rounding toward Zero (vector). This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Scalar half precision

ARMv8.2



Scalar half precision variant

```
FCVTZS <Hd>, <Hn>
```

Decode for this encoding

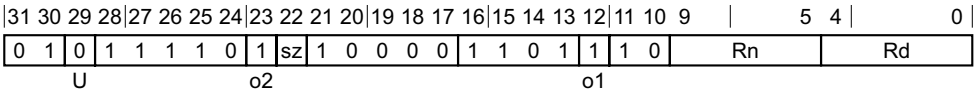
```
if !HaveFP16Ext() then UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 16;
integer datasize = esize;
integer elements = 1;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Scalar single-precision and double-precision



Scalar single-precision and double-precision variant

```
FCVTZS <V><d>, <V><n>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

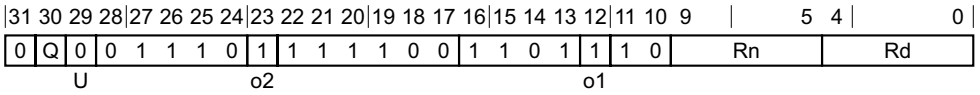
Non-Confidential

Vector half precision

ARMv8.2



Vector half precision variant

```
FCVTZS <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

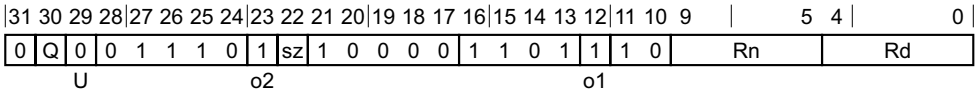
```
if !HaveFP16Ext() then UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 16;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Vector single-precision and double-precision



Vector single-precision and double-precision variant

```
FCVTZS <Vd>.<T>, <Vn>.<T>
```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Assembler symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<V> Is a width specifier, encoded in the "sz" field. It can have the following values:

- S when sz = 0
- D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the vector half precision variant: is an arrangement specifier, encoded in the "Q" field. It can have the following values:

4H when Q = 0

8H when Q = 1

For the vector single-precision and double-precision variant: is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

2D when sz = 1, Q = 1

The encoding sz = 1, Q = 0 is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, 0, unsigned, FPCR, rounding);

V[d] = result;
```

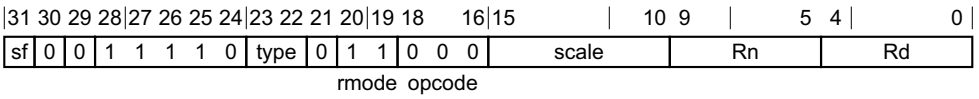
C7.2.84 FCVTZS (scalar, fixed-point)

Floating-point Convert to Signed fixed-point, rounding toward Zero (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit fixed-point signed integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.



Half-precision to 32-bit variant

Applies when sf == 0 && type == 11.

```
FCVTZS <Wd>, <Hn>, #<fbits>
```

Half-precision to 64-bit variant

Applies when sf == 1 && type == 11.

```
FCVTZS <Xd>, <Hn>, #<fbits>
```

Single-precision to 32-bit variant

Applies when sf == 0 && type == 00.

```
FCVTZS <Wd>, <Sn>, #<fbits>
```

Single-precision to 64-bit variant

Applies when sf == 1 && type == 00.

```
FCVTZS <Xd>, <Sn>, #<fbits>
```

Double-precision to 32-bit variant

Applies when sf == 0 && type == 01.

```
FCVTZS <Wd>, <Dn>, #<fbits>
```

Double-precision to 64-bit variant

Applies when sf == 1 && type == 01.

```
FCVTZS <Xd>, <Dn>, #<fbits>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;

case type of
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.
Non-Confidential

```
    when '00' fltsize = 32;
    when '01' fltsize = 64;
    when '10' UnallocatedEncoding();
    when '11'
        if HaveFP16Ext() then
            fltsize = 16;
        else
            UnallocatedEncoding();

if sf == '0' && scale<5> == '0' then UnallocatedEncoding();
integer fracbits = 64 - UInt(scale);
```

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Sn> Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Dn> Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<fbits> For the double-precision to 32-bit, half-precision to 32-bit and single-precision to 32-bit variant: is the number of bits after the binary point in the fixed-point destination, in the range 1 to 32, encoded as 64 minus "scale".

For the double-precision to 64-bit, half-precision to 64-bit and single-precision to 64-bit variant: is the number of bits after the binary point in the fixed-point destination, in the range 1 to 64, encoded as 64 minus "scale".

Operation

```
CheckFPAdvSIMDEnabled64();

bits(fltsize) fltval;
bits(intsize) intval;

fltval = V[n];
intval = FPToFixed(fltval, fracbits, FALSE, FPCR, FPRounding_ZERO);
X[d] = intval;
```

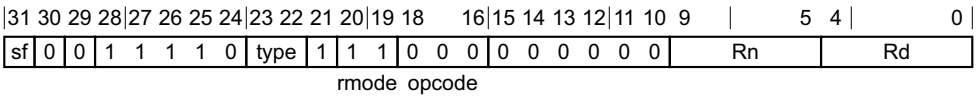
C7.2.85 FCVTZS (scalar, integer)

Floating-point Convert to Signed integer, rounding toward Zero (scalar). This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.



Half-precision to 32-bit variant

Applies when `sf == 0 && type == 11`.

```
FCVTZS <Wd>, <Hn>
```

Half-precision to 64-bit variant

Applies when `sf == 1 && type == 11`.

```
FCVTZS <Xd>, <Hn>
```

Single-precision to 32-bit variant

Applies when `sf == 0 && type == 00`.

```
FCVTZS <Wd>, <Sn>
```

Single-precision to 64-bit variant

Applies when `sf == 1 && type == 00`.

```
FCVTZS <Xd>, <Sn>
```

Double-precision to 32-bit variant

Applies when `sf == 0 && type == 01`.

```
FCVTZS <Wd>, <Dn>
```

Double-precision to 64-bit variant

Applies when `sf == 1 && type == 01`.

```
FCVTZS <Xd>, <Dn>
```

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;
FPRounding rounding;
```

Copyright © 2013-2017 ARM Limited or its affiliates. All rights reserved.

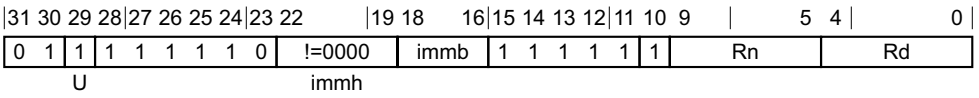
C7.2.86 FCVTZU (vector, fixed-point)

Floating-point Convert to Unsigned fixed-point, rounding toward Zero (vector). This instruction converts a scalar or each element in a vector from floating-point to fixed-point unsigned integer using the Round towards Zero rounding mode, and writes the result to the general-purpose destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR, or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps* on page D1-1899.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Scalar



Scalar variant

```
FCVTZU <V><d>, <V><n>, #<fbits>
```

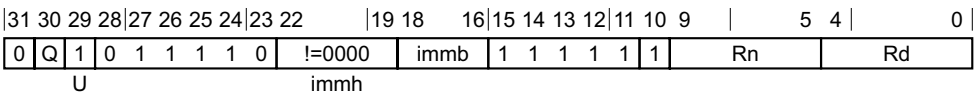
Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '000x' || (immh == '001x' && !HaveFP16Ext()) then ReservedValue();
integer esize = if immh == '1xxx' then 64 else if immh == '01xx' then 32 else 16;
integer datasize = esize;
integer elements = 1;

integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRounding_ZERO;
```

Vector



Vector variant

```
FCVTZU <Vd>.<T>, <Vn>.<T>, #<fbits>
```

Decode for this encoding

```
integer d = UInt(Rd);
