The stage 1 translation assigns the Device-nGnRnE memory type.

Note

This means the access is Non-cacheable. Unexpected data cache hit behavior is IMPLEMENTATION DEFINED.

Instruction access

The stage 1 translation assigns Normal memory attribute, with the cacheability and shareability attributes determined by the value of:

- The Secure instance of SCTLR.I for the Secure PL1&0 translation regime.
- The Non-secure instance of SCTLR.I for the Non-secure PL1&0 translation regime.
- HSCTLR.I for the Non-secure PL2 translation regime.

In these cases, the meaning of the I bit is as follows:

When I is set to 0

The stage 1 translation assigns the attributes Outer Shareable, Non-cacheable.

When I is set to 1

The stage 1 translation assigns the attributes Inner Write-Through no Write-Allocate, Outer Write-Through no Write-Allocate Cacheable.

Note

On some implementations, if the SCTLR.TRE bit is set to 0 then this behavior can be changed by the remap settings in the memory remap registers. The details of TEX remap when SCTLR.TRE is set to 0 are IMPLEMENTATION DEFINED, see *SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers* on page G4-3679.

For this stage of translation, no memory access permission checks are performed, and therefore no MMU faults relating to this stage of translation can be generated.

Note

Alignment checking is performed, and therefore Alignment faults can occur.

For every access, when stage 1 translation is disabled, the output address of the stage 1 translation is equal to the input address. This is called a flat address mapping. If the implementation supports output addresses of more than 32 bits then the output address bits above bit[31] are zero. For example, for a VA to PA translation on an implementation that supports 40-bit PAs, PA[39:32] is `0x00`.

For a Non-secure PL1 or PL0 access, if the PL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

See also *Behavior of instruction fetches when all associated address translations are disabled* on page G4-3627.

Effect of the HCR.DC bit

The HCR.DC bit determines the default memory attributes assigned for the first stage of the Non-secure PL1&0 translation regime when that stage of translation is disabled.

When executing in a Non-secure PL1 or PL0 mode with HCR.DC set to 1:

- For all purposes other than reading the value of the SCTLR, the PE behaves as if the value of the SCTLR.M bit is 0. This means Non-secure PL1&0 stage 1 address translation is disabled.
- For all purposes other than reading the value of the HCR, the PE behaves as if the value of the HCR.VM bit is 1. This means Non-secure PL1&0 stage 2 address translation is enabled.

The effect of HCR.DC might be held in TLB entries associated with a particular VMID. Therefore, if software executing at EL2 changes the HCR.DC value without also changing the current VMID, it must also invalidate all TLB entries associated with the current VMID. Otherwise, the behavior of Non-secure software executing at EL1 or EL0 is UNPREDICTABLE.

Effect of disabling translation on maintenance and address translation instructions

Cache maintenance instructions act on the target cache whether address translation is enabled or not, and regardless of the values of the memory attributes. However, if a stage of translation is disabled, they use the flat address mapping for that stage, and all mappings are considered global.

TLB invalidate operations act on the target TLB whether address translation is enabled or not.

When the Non-secure PL1&0 stage 1 address translation is disabled, any ATS1C** or ATS12NSO** address translation instruction that accesses the Non-secure state translation reflects the effect of the HCR.DC bit. For more information about these operations see *Virtual Address to Physical Address translation instructions* on page G4-3737.

G4.3.2 VMSAv8-32 behavior when stage 2 address translation is disabled

When stage 2 address translation is disabled:

- The IPA output from the stage 1 translation maps flat to the PA
- The memory attributes and permissions from the stage 1 translation apply to the PA.

If the stage 1 address translation and the stage 2 address translation are both disabled, see *Behavior of instruction fetches when all associated address translations are disabled*.

G4.3.3 Behavior of instruction fetches when all associated address translations are disabled

The information in this section applies to memory accesses:

- From Secure PL1 and PL0 modes, when the Secure PL1&0 stage 1 address translation is disabled
- From Hyp mode, when the Non-secure PL2 stage 1 address translation is disabled
- From Non-secure PL1 and PL0 modes, when all of the following apply:
  - The Non-secure PL1&0 stage 1 address translation is disabled.
  - The Non-secure PL1&0 stage 2 address translation is disabled.
  - HCR.DC is set to 0.

In these cases, a memory location might be accessed as a result of an instruction fetch if one of the following conditions is met:

- The memory location is in the same 4KB block of memory (aligned to 4KB) as an instruction that a simple sequential execution of the program requires to be fetched, or is in the 4KB block of memory immediately following such a block.
- The memory location is in the same 4KB block of memory (aligned to 4KB) from which a simple sequential execution of the program with all associated stages of address translation disabled has previously required an instruction to be fetched, or is in the 4KB block immediately following such a block.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.

Note

To ensure architectural compliance, software must ensure that both of the following apply:

- Instructions that will be executed when address translation is disabled are located in 4KB blocks of the address space that contain only memory that is tolerant to speculative accesses.
- Each 4KB block of the address space that immediately follows a 4KB block that holds instructions that will be executed when address translation is disabled also contains only memory that is tolerant to speculative accesses.

G4.3.4 Enabling stages of address translation

On powerup or reset, only the SCTLR.M bit for the Exception level and Security state entered on reset is reset to 0, disabling address translation for the initial state of the PE. All other SCTLR.M and HSCTLR.M bits that are implemented are UNKNOWN after the reset.

This means, on powerup or reset:

- On an implementation that includes EL3, where EL3 is using AArch32:
  - The PL1&0 stage 1 address translation enable bit, SCTLR.M, is Banked, meaning there are separate enables for operation in Secure and Non-secure state.
  - If EL3 is using AArch32, only the Secure instance of the SCTLR.M bit resets to 0, disabling the Secure state PL1&0 stage 1 address translation. The reset value of the Non-secure instance of SCTLR.M is UNKNOWN.
- On an implementation that includes EL2, where EL2 is using AArch32, the HSCTLR.M bit, that controls the Non-secure PL2 stage 1 address translation:
  - If the implementation does not include EL3, resets to 0.
  - Otherwise, is UNKNOWN.
- On an implementation that does not include either EL2 or EL3, there is a single stage of translation. This is controlled by SCTLR.M, that resets to 0.

Note

If, for the software that enables or disables a stage of address translation, the input address of a stage 1 translation differs from the output address of that stage 1 translation, and the software is running in translation regime that is affected by that stage of translation, then the requirement to synchronize changes to the system registers means it is uncertain where in the instruction stream the change of the translation takes place. For this reason, ARM strongly recommends that the input address and the output address are identical in this situation.

G4.4 Translation tables

VMSAv8-32 defines two alternative translation table formats:

Short-descriptor format

It uses 32-bit descriptor entries in the translation tables, and provides:

- Up to two levels of address lookup.
- 32-bit input addresses.
- Output addresses of up to 40 bits.
- Support for PAs of more than 32 bits by use of supersections, with 16MB granularity.
- Support for No access, Client, and Manager domains.

Long-descriptor format

It uses 64-bit descriptor entries in the translation tables, and provides:

- Up to three levels of address lookup.
- Input addresses of up to 40 bits, when used for stage 2 translations.
- Output addresses of up to 40 bits.
- 4KB assignment granularity across the entire PA range.
- No support for domains, all memory regions are treated as in a Client domain.
- Fixed 4KB table size, unless truncated by the size of the input address space.

Note

— Translation with a 40-bit input address range requires two concatenated 4KB top level tables, aligned to 8KB.

— The VMASv8-64 Long-descriptor translation table format is generally similar to this format, but supports input and output addresses of up to 48 bits, and has an assignment granularity and table size defined by its *translation granule*. This can be 4KB, 16KB, or 64KB. See *The VMSAv8-64 translation table format* on page D4-1660.

In all implementations, of the possible address translations shown in Figure G4-2 on page G4-3622, for stages of address translation that are using AArch32:

- In a particular Security state, the translation tables for the PL1&0 stage 1 translations can use either translation table format, and the TTBCR.EAE bit indicates the current translation table format.
- The translation tables for the Non-secure PL2 stage 1 translations, and for the Non-secure PL1&0 stage 2 translations, must use the Long-descriptor translation table format.

Many aspects of performing a translation table walk depend on the current translation table format. Therefore, the following sections describe the two formats, including how the MMU performs a translation table walk for each format:

- *The VMSAv8-32 Short-descriptor translation table format* on page G4-3634.
- *The VMSAv8-32 Long-descriptor translation table format* on page G4-3647.

The following subsections describe aspects of the translation tables and translation table walks, for memory accesses from AArch32 state, that are independent of the translation table format:

- *Translation table walks for memory accesses using VMSAv8-32 translation regimes* on page G4-3630.
- *Information returned by a translation table lookup* on page G4-3630.
- *Determining the translation table base address in the VMSAv8-32 translation regimes* on page G4-3631.
- *Control of translation table walks on a TLB miss* on page G4-3632.
- *Access to the Secure or Non-secure physical address map* on page G4-3632.

See also *TLB maintenance requirements* on page G4-3689.

G4.4.1 Translation table walks for memory accesses using VMSAv8-32 translation regimes

A translation table walk occurs as the result of a TLB miss, and starts with a read of the appropriate starting level translation table. The result of that read determines whether additional translation table reads are required, for this stage of translation, as described in either:

- *Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format* on page G4-3640.
- *Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format* on page G4-3659.

Note

When using the Short-descriptor translation table format, the starting level for a translation table walk is always a level 1lookup. However, with the Long-descriptor translation table format, the starting level can be either a level 1 or a level 2 lookup.

For the PL1&0 stage 1 translations, SCTLR.EE determines the endianness of the translation table lookups. SCTLR is Banked, and therefore the endianness is determined independently for each Security state.

HSCTLR.EE defines the endianness for the Non-secure PL2 stage 1 and Non-secure PL1&0 stage 2 translations.

Note

Dynamically changing translation table endianness

Because any change to SCTLR.EE or HSCTLR.EE requires synchronization before it is visible to subsequent operations, ARM strongly recommends that:

- SCTLR.EE is changed only when either:
  - Executing in a mode that does not use the translation tables affected by SCTLR.EE.
  - Executing with SCTLR.M set to 0.
- HSCTLR.EE is changed only when either:
  - Executing in a mode that does not use the translation tables affected by HSCTLR.EE.
  - Executing with HSCTLR.M set to 0.

The physical address of the base of the starting level translation table is determined from the appropriate *Translation table base register* (TTBR), see *Determining the translation table base address in the VMSAv8-32 translation regimes* on page G4-3631.

For more information, see *TLB maintenance instructions and the memory order model* on page G4-3691.

Translation table walks must access data or unified caches, or data and unified caches, of other agents participating in the coherency protocol, according to the shareability attributes described in the TTBR. These shareability attributes must be consistent with the shareability attributes for the translation tables themselves.

G4.4.2 Information returned by a translation table lookup

When an associated stage of address translation is enabled, a memory access requires one or more translation table lookups. If the required translation table descriptor is not held in a TLB, a translation table walk is performed to obtain the descriptor. A lookup, whether from the TLB or as the result of a translation table walk, returns both:

- An output address that corresponds to the input address for the lookup.
- A set of properties that correspond to that output address.

The returned properties are classified as providing *address map control*, *access controls*, or *region attributes*. This classification determines how the descriptions of the properties are grouped. The classification is based on the following model:

Address map control

Memory accesses from Secure state can access either the Secure or the Non-secure address map, as summarized in *Access to the Secure or Non-secure physical address map* on page G4-3632.

Memory accesses from Non-secure state can only access the Non-secure address map.

Access controls

Determine whether the PE, in its current state, can access the output address that corresponds to the given input address. If not, a MMU fault is generated and there is no memory access.

Memory access control on page G4-3665 describes the properties in this group.

Attributes Are valid only for an output address that the PE, in its current state, can access. The attributes define aspects of the required behavior of accesses to the target memory region.

Memory region attributes on page G4-3674 describes the properties in this group.

G4.4.3 Determining the translation table base address in the VMSAv8-32 translation regimes

On a TLB miss, the VMSA must perform a translation table walk, and therefore must find the base address of the translation table to use for its lookup. A TTBR holds this address. As Figure G4-2 on page G4-3622 shows:

- For a Non-secure PL2 stage 1 translation, the HTTBR holds the required base address. The HTCR is the control register for these translations.
- For a Non-secure PL1&0 stage 2 translation, the VTTBR holds the required base address. The VTCR is the control register for these translations.
- For a PL1&0 stage 1 translation, either TTBR0 or TTBR1 holds the required base address. The TTBCR is the control register for these translations.

  The Non-secure copies of TTBR0, TTBR1, and TTBCR, relate to the Non-secure PL1&0 stage 1 translation. The Secure copies of TTBR0, TTBR1, and TTBCR, relate to the Secure PL1&0 stage 1 translation.

For the PL1&0 translation table walks:

- TTBR0 can be configured to describe the translation of VAs in the entire address map, or to describe only the translation of VAs in the lower part of the address map.
- If TTBR0 is configured to describe the translation of VAs in the lower part of the address map, TTBR1 is configured to describe the translation of VAs in the upper part of the address map.

The contents of the appropriate instance of the TTBCR determine whether the address map is separated into two parts, and where the separation occurs. The details of the separation depend on the current translation table format, see:

- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format* on page G4-3639.
- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format* on page G4-3654.

Example G4-1 shows a typical use of the two sets of translation tables:

Example G4-1 Example use of TTBR0 and TTBR1

An example of using the two TTBRs for PL1&0 stage 1 address translations is:

TTBR0 Used for process-specific addresses.

Each process maintains a separate level 1 translation table. On a context switch:

- TTBR0 is updated to point to the level 1 translation table for the new context.
- TTBCR is updated if this change changes the size of the translation table.
- The CONTEXTIDR is updated.

TTBCR can be programmed so that all translations use TTBR0 in a manner compatible with architecture versions before ARMv6.

TTBR1 Used for operating system and I/O addresses, that do not change on a context switch.

G4.4.4 Control of translation table walks on a TLB miss

Two bits in the TCR for the translation stage required by a memory access control whether a translation table walk is performed on a TLB miss. These two bits are the:

- PD0 and PD1 bits, on a PE using the Short-descriptor translation table format.
- EPD0 and EPD1 bits, on a PE using the Long-descriptor translation table format.

Note

For the VMSAv8-32 translation regimes, the different bit names are because the bits are in different positions in TTBCR, depending on the translation table format.

The effect of these bits is:

{E}PDx == 0 If a TLB miss occurs based on TTBRx, a translation table walk is performed. The current security state determines whether the memory access is Secure or Non-secure.

{E}PDx == 1 If a TLB miss occurs based on TTBRx, a First level Translation fault is returned, and no translation table walk is performed.

G4.4.5 Access to the Secure or Non-secure physical address map

As stated in *Address spaces in VMSAv8-32* on page G4-3620, a PE can access independent Secure and Non-secure address maps. When the PL1 Exception level is using AArch32, these are defined by the translation tables identified by the Secure TTBR0 and TTBR1. In both translation table formats in the Secure translation tables, the NS bit in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map:

NS == 0 Access the Secure physical address space.

NS == 1 Access the Non-secure physical address space.

Note

In the Non-secure translation tables, the corresponding bit is SBZ. Non-secure accesses always access the Non-secure physical address space, regardless of the value of this bit.

The Long-descriptor translation table format extends this control, adding an NSTable bit to the Secure translation tables, as described in *Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format* on page G4-3653. In the Non-secure translation tables, the corresponding bit is SBZ, and Non-secure accesses ignore the value of this bit.

The following sections describe the address map controls in the two implementations:

- *Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format* on page G4-3639.
- *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format* on page G4-3653.

The following subsection gives more information.

Secure and Non-secure address spaces

EL3 provides two physical address spaces, a Secure physical address space and a Non-secure physical address space.

As described in *Access to the Secure or Non-secure physical address map*, for the PL1&0 stage 1 translations when controlled from an Exception level using AArch32, the translation table base registers, TTBR0, TTBR1, and TTBCR are Banked between Secure and Non-secure versions, and the Security state of the PE when it performs a memory access selects the corresponding version of the registers. This means there are independent Secure and Non-secure versions of these translation tables, and translation table walks are made to the physical address space corresponding to the security state of the translation tables used.

For a translation table walk caused by a memory access from Non-secure state, all memory accesses are to the Non-secure address space.

For a translation table walk caused by a memory access from Secure state:

- When address translation is using the Long-descriptor translation table format:
  - The first lookup performed must access the Secure address space.
  - If a table descriptor read from the Secure address space has the NSTable bit set to 0, then the next level of lookup is from the Secure address space.
  - If a table descriptor read from the Secure address space has the NSTable bit set to 1, then the next level of lookup, and any subsequent level of lookup, is from the Non-secure address space.

  For more information, see *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format* on page G4-3653.
- Otherwise, all memory accesses are to the Secure address space.

Note

- When executing in Non-secure state, additional translations are supported. For memory accesses from AArch32 state these are:
  - Non-secure PL2 stage 1 translation.
  - Non-secure PL1&0 stage 2 translation.

  These translations can access only the Non-secure address space.
- A system implementation can alias parts of the Secure physical address space to the Non-secure physical address space in an implementation-specific way. As with any other aliasing of physical memory, the use of aliases in this way can require the use of cache maintenance instructions to ensure that changes to memory made using one alias of the physical memory are visible to accesses to the other alias of the physical memory.

G4.5 The VMSAv8-32 Short-descriptor translation table format

The Short-descriptor translation table format supports a memory map based on memory sections or pages:

Supersections Consist of 16MB blocks of memory. Support for Supersections is optional, except that an implementation that supports more than 32 bits of Physical Address must also support Supersections to provide access to the entire Physical Address space.

Sections Consist of 1MB blocks of memory.

Large pages Consist of 64KB blocks of memory.

Small pages Consist of 4KB blocks of memory.

Supersections, Sections and Large pages map large regions of memory using only a single TLB entry.

Note

Whether a VMSAv8-32 implementation of the Short-descriptor format translation tables supports supersections is IMPLEMENTATION DEFINED.

When using the Short-descriptor translation table format, two levels of translation tables are held in memory:

Level 1 table

Holds *level 1 descriptors* that contain the base address and

- Translation properties for a Section and Supersection.
- Translation properties and pointers to a level 2 table for a Large page or a Small page.

Level 2 tables

Hold *level 2 descriptors* that contain the base address and translation properties for a Small page or a Large page. With the Short-descriptor format, level 2 tables can be referred to as *Page tables*.

A level 2 table requires 1KB of memory.

In the translation tables, in general, a descriptor is one of level 2:

- An invalid or fault entry.
- A page table entry, that points to a next level translation table.
- A page or section entry, that defines the memory properties for the access.
- A reserved format.

Bits[1:0] of the descriptor give the primary indication of the descriptor type.

Figure G4-3 on page G4-3635 gives a general view of address translation when using the Short-descriptor translation table format.

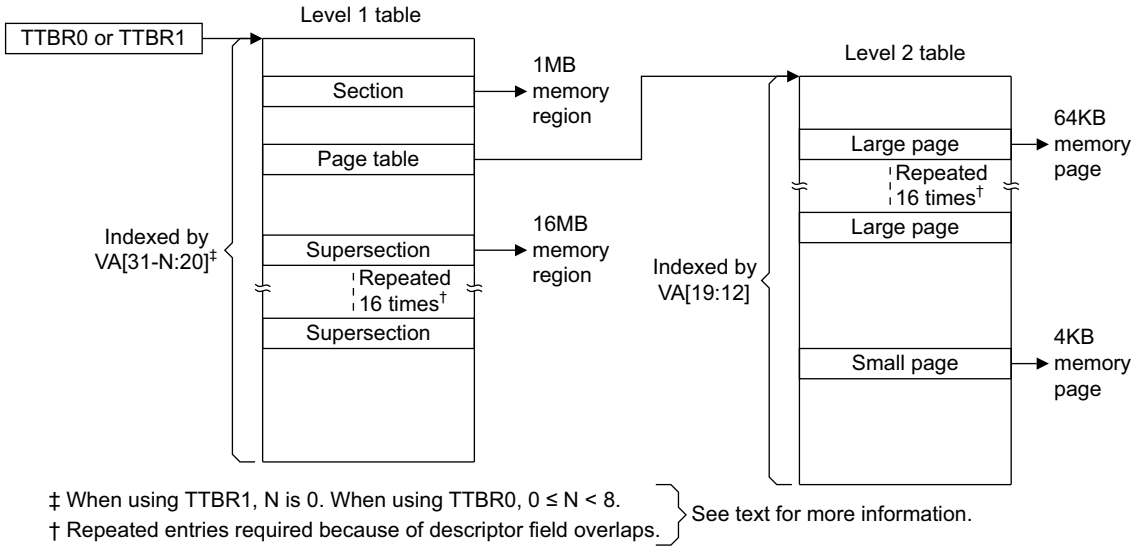

Figure G4-3 General view of address translation using Short-descriptor format translation tables

Additional requirements for Short-descriptor format translation tables on page G4-3638 describes why, when using the Short-descriptor format, Supersection and Large page entries must be repeated 16 times, as shown in Figure G4-3.

VMSAv8-32 Short-descriptor translation table format descriptors, *Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors* on page G4-3638, and *Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format* on page G4-3639 describe the format of the descriptors in the Short-descriptor format translation tables.

The following sections then describe the use of this translation table format:

- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format* on page G4-3639.
- *Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format* on page G4-3640.

G4.5.1 VMSAv8-32 Short-descriptor translation table format descriptors

The following sections describe the formats of the entries in the Short-descriptor translation tables:

- *Short-descriptor translation table level 1descriptor formats*.
- *Short-descriptor translation table level 2 descriptor formats* on page G4-3637.

For more information about level 2 translation tables see *Additional requirements for Short-descriptor format translation tables* on page G4-3638.

Note

Previous versions of the *ARM Architecture Reference Manual*, and some other documentation, describes the AP[2] bit in the translation table entries as the APX bit.

Information returned by a translation table lookup on page G4-3630 describes the classification of the non-address fields in the descriptors as address map control, access control, or attribute fields.

Short-descriptor translation table level 1descriptor formats

Each entry in the level 1 table describes the mapping of the associated 1MB VA range.

Figure G4-4 on page G4-3636 shows the possible level 1 descriptor formats.

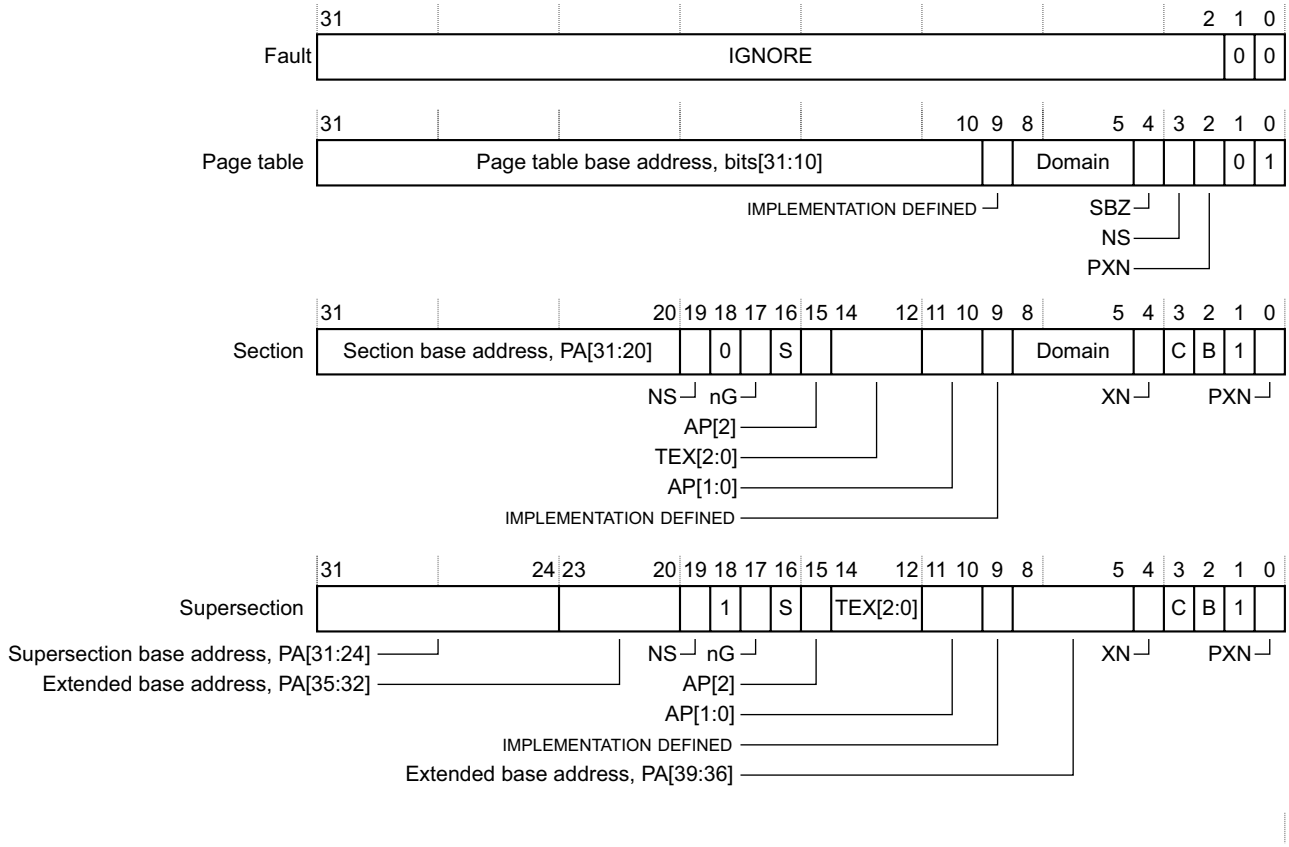

Figure G4-4 Short-descriptor level 1 descriptor formats

Descriptor bits[1:0] identify the descriptor type. The encoding of these bits is:

`0b00`, Invalid or fault entry

The associated VA is unmapped, and any attempt to access it generates a Translation fault.

Software can use bits[31:2] of the descriptor for its own purposes, because the hardware ignores these bits.

`0b01`, Page table

The descriptor gives the address of a level 2 translation table, that specifies the mapping of the associated 1MB VA range.

`0b10`, Section or Supersection

The descriptor gives the base address of the Section or Supersection. Bit[18] determines whether the entry describes a Section or a Supersection.

This encoding also defines the PXN bit as 0.

`0b11`, Section or Supersection, if the implementation supports the PXN attribute

This encoding is identical to `0b10`, except that it defines the PXN bit as 1.

Note

A VMSAv8-32 implementation can use the Short-descriptor translation table format for the PL1&0 stage 1 translations, by setting TTBCR.EAE to 0.

The address information in the level 1 descriptors is:

Page table Bits[31:10] of the descriptor are bits[31:10] of the address of a Page table.

Section Bits[31:20] of the descriptor are bits[31:20] of the address of the Section.

Supersection Bits[31:24] of the descriptor are bits[31:24] of the address of the Supersection.
Optionally, bits[8:5, 23:20] of the descriptor are bits[39:32] of the extended Supersection address.

For the Non-secure PL1&0 translation tables, the address in the descriptor is the IPA of the Page table, Section, or Supersection. Otherwise, the address is the PA of the Page table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see *Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors* on page G4-3638.

Short-descriptor translation table level 2 descriptor formats

Figure G4-5 shows the possible formats of a level 2 descriptor.

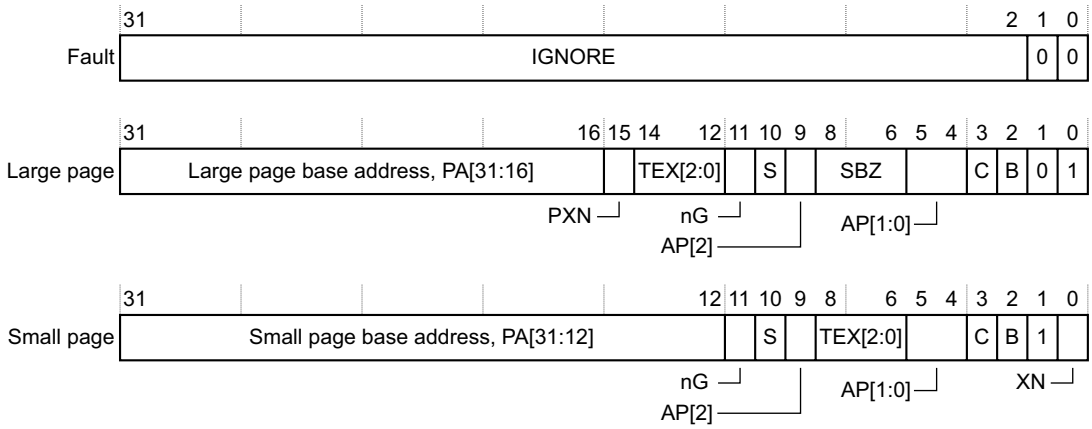

Figure G4-5 Short-descriptor level 2 descriptor formats

Descriptor bits[1:0] identify the descriptor type. The encoding of these bits is:

`0b00`, Invalid or fault entry

The associated VA is unmapped, and attempting to access it generates a Translation fault.

Software can use bits[31:2] of the descriptor for its own purposes, because the hardware ignores these bits.

`0b01`, Large page

The descriptor gives the base address and properties of the Large page.

`0b1x`, Small page

The descriptor gives the base address and properties of the Small page.

In this descriptor format, bit[0] of the descriptor is the XN bit.

The address information in the level 2 descriptors is:

Large page Bits[31:16] of the descriptor are bits[31:16] of the address of the Large page.

Small page Bits[31:12] of the descriptor are bits[31:12] of the address of the Small page.

For the Non-secure PL1&0 translation tables, the address in the descriptor is the IPA of the Page table, Section, or Supersection. Otherwise, the address is the PA of the Page table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see *Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors* on page G4-3638.

Additional requirements for Short-descriptor format translation tables

When using Supersection or Large page descriptors in the Short-descriptor translation table format, the input address field that defines the Supersection or Large page descriptor address overlaps the table address field. In each case, the size of the overlap is 4 bits. The following diagrams show these overlaps:

- Figure G4-8 on page G4-3643 for the level 1 translation table Supersection entry.
- Figure G4-10 on page G4-3645 for the level 2 translation table Large page table entry.

Considering the case of using Large page table descriptors in a level 2 translation table, this overlap means that for any specific Large page, the bottom four bits of the level 2 translation table entry might take any value from `0b0000` to `0b1111`. Therefore, each of these sixteen index values must point to a separate copy of the same descriptor.

This means that each Large page or Supersection descriptor must:

- Occur first on a sixteen-word boundary.
- Be repeated in 16 consecutive memory locations.

G4.5.2 Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors

This section describes the descriptor fields other than the descriptor type field and the address field:

TEX[2:0], C, B

Memory region attribute bits, see *Memory region attributes* on page G4-3674.

These bits are not present in a Page table entry.

XN bit The Execute-never bit. Determines whether the PE can execute software from the addressed region, see *Execute-never restrictions on instruction fetching* on page G4-3668.

This bit is not present in a Page table entry.

PXN bit The Privileged execute-never bit. Determines whether the PE can execute software from the region when executing at PL1, see *Execute-never restrictions on instruction fetching* on page G4-3668.

Note

Memory accesses by software executing at EL2 always use the Long-descriptor translation table format.

When this bit is set to 1 in the Page table descriptor, it indicates that all memory pages described in the corresponding page table are Privileged execute-never.

NS bit Non-secure bit. Specifies whether the translated PA is in the Secure or Non-secure address map, see *Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format* on page G4-3639.

This bit is not present in level 2 descriptors. The value of the NS bit in the level 1 Page table descriptor applies to all entries in the corresponding level 2 translation table.

Domain Domain field, see *Domains, Short-descriptor format only* on page G4-3670.

This field is not present in a Supersection entry. Memory described by Supersections is in domain 0.

This bit is not present in level 2 descriptors. The value of the Domain field in the level 1Page table descriptor applies to all entries in the corresponding level 2translation table.

An IMPLEMENTATION DEFINED bit

This bit is not present in level 2 descriptors.

AP[2], AP[1:0]

Access Permissions bits, see *Memory access control* on page G4-3665.

AP[0] can be configured as the *Access flag*, see *The Access flag* on page G4-3671.

These bits are not present in a Page table entry.

S bit The Shareable bit. Determines whether the addressed region is Shareable memory, see *Memory region attributes* on page G4-3674.

This bit is not present in a Page table entry.

nG bit The not global bit. Determines how the translation is marked in the TLB, see *Global and process-specific translation table entries* on page G4-3686.

This bit is not present in a Page table entry.

Bit[18], when bits[1:0] indicate a *Section or Supersection* descriptor

0 Descriptor is for a Section.

1 Descriptor is for a Supersection.

G4.5.3 Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format

Access to the Secure or Non-secure physical address map on page G4-3632 describes how the NS bit in the translation table entries:

- For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
- Is ignored by accesses from Non-secure state.

In the Short-descriptor translation table format, the NS bit is defined only in the level 1 translation tables. This means that, in a level 1 Page table descriptor, the NS bit defines the physical address space, Secure or Non-secure, for all of the Large pages and Small pages of memory described by that table.

The NS bit of a level 1 Page table descriptor has no effect on the physical address space in which that translation table is held. As stated in *Secure and Non-secure address spaces* on page G4-3632, the physical address of that translation table is in:

- The Secure address space if the translation table walk is in Secure state.
- The Non-secure address space if the translation table walk is in Non-secure state.

This means the granularity of the Secure and Non-secure memory spaces is 1MB. However, in these memory spaces, table entries can define physical memory regions with a granularity of 4KB.

G4.5.4 Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format

As described in *Determining the translation table base address in the VMSAv8-32 translation regimes* on page G4-3631, two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and TTBR0 and TTBR1 hold the base addresses for the two sets of tables. When using the Short-descriptor translation table format, the value of TTBCR.N indicates the number of most significant bits of the input VA that determine whether TTBR0 or TTBR1 holds the required translation table base address, as follows:

- If N == 0 then use TTBR0. Setting TTBCR.N to zero disables use of a second set of translation tables.
- if N > 0 then:
  - If bits[31:32-N] of the input VA are all zero then use TTBR0.
  - Otherwise use TTBR1.

Table G4-4 shows how the value of N determines the lowest address translated using TTBR1, and the size of the level 1translation table addressed by TTBR0.

Table G4-4 Effect of TTBCR.N on address translation, Short-descriptor format

TTBCR.N	First address translated with TTBR1	TTBR0 table	
		Size	Index range
0b000	TTBR1 not used	16KB	VA[31:20]
0b001	0x80000000	8KB	VA[30:20]
0b010	0x40000000	4KB	VA[29:20]

Table G4-4 Effect of TTBCR.N on address translation, Short-descriptor format (continued)

TTBCR.N	First address translated with TTBR1	TTBR0 table	
		Size	Index range
0b011	0x20000000	2KB	VA[28:20]
0b100	0x10000000	1KB	VA[27:20]
0b101	0x08000000	512 bytes	VA[26:20]
0b110	0x04000000	256 bytes	VA[25:20]
0b111	0x02000000	128 bytes	VA[24:20]

Whenever TTBCR.N is nonzero, the size of the translation table addressed by TTBR1 is 16KB.

Figure G4-6 shows how the value of TTBCR.N controls the boundary between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.

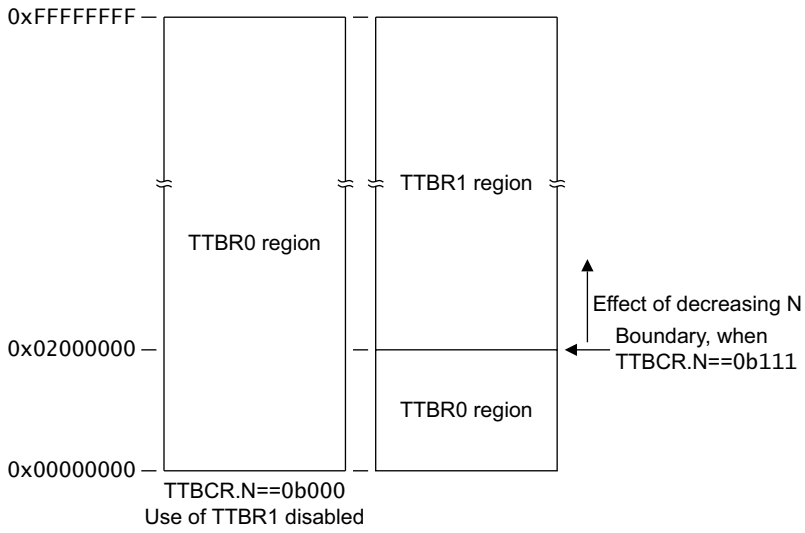

Figure G4-6 How TTBCR.N controls the boundary between the TTBRs, Short-descriptor format

In the selected TTBR, bits RGN, S and IRGN[1:0] define the memory region attributes for the translation table walk.

Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format describes the translation.

G4.5.5 Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format

When using the Short-descriptor translation table format, and a memory access requires a translation table walk:

- A section-mapped access only requires a read of the level 1 translation table.
- A page-mapped access also requires a read of the level 2 translation table.

Reading a level 1 translation table on page G4-3641 describes how either TTBR1 or TTBR0 is used, with the accessed VA, to determine the address of the level 1 descriptor.

Reading a level 1 translation table on page G4-3641 shows the output address as A[39:0]:

- For a Non-secure PL1&0 stage 1 translation, this is the IPA of the required descriptor. A Non-secure PL1&0 stage 2 translation of this address is performed to obtain the PA of the descriptor.
- Otherwise, this address is the PA of the required descriptor.

The full translation flow for Sections, Supersections, Small pages and Large pages then shows the complete translation flow for each valid memory access.

Reading a level 1 translation table

When performing a fetch based on TTBR0:

- The address bits taken from TTBR0 vary between bits[31:14] and bits[31:7].
- The address bits taken from the VA, that is the input address for the translation, vary between bits[31:20] and bits[24:20].

The width of the TTBR0 and VA fields depend on the value of TTBCR.N, as Figure G4-7 shows.

When performing a fetch based on TTBR1, Bits TTBR1[31:14] are concatenated with bits[31:20] of the VA. This makes the fetch equivalent to that shown in Figure G4-7, with N==0.

Note

See *The address and Properties fields shown in the translation flows* on page G4-3642 for more information about the *Properties* label used in this and other figures.

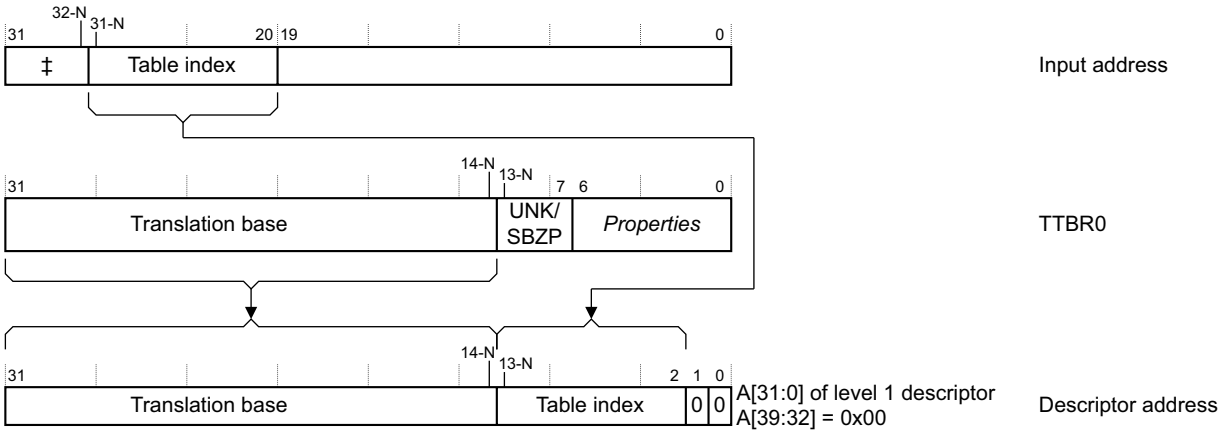

Figure G4-7 Accessing level 1 translation table based on TTBR0, Short-descriptor format

Regardless of which register is used as the base for the fetch, the resulting output address selects a four-byte translation table entry that is one of:

- A level 1 descriptor for a Section or Supersection.
- A *Page table* descriptor that points to a level 2 translation table. In this case:
  - A second fetch is performed to retrieve a level 2 descriptor.
  - The descriptor also contains some attributes for the access, see Figure G4-4 on page G4-3636.
- A faulting entry.

The full translation flow for Sections, Supersections, Small pages and Large pages

In a translation table walk, only the first lookup uses the translation table base address from the appropriate Translation table base register. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

This section summarizes how each of the memory section and page options is described in the translation tables, and has a subsection summarizing the full translation flow for each of the options.

As described in *VMSAv8-32 Short-descriptor translation table format descriptors* on page G4-3635, the four options are:

Supersection A 16MB memory region, see *Translation flow for a Supersection*.

Section A 1MB memory region, see *Translation flow for a Section* on page G4-3643.

Large page A 64KB memory region, described by the combination of:
- A level 1 translation table entry that indicates a level 2 Page table address.
- A level 2 descriptor that indicates a Large page.

See *Translation flow for a Large page* on page G4-3644.

Small page A 4KB memory region, described by the combination of:
- A level 1 translation table entry that indicates a level 2 Page table address.
- A level 2 descriptor that indicates a Small page.

See *Translation flow for a Small page* on page G4-3646.

The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation tables:
- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the Section, Supersection, Large page, or Small page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

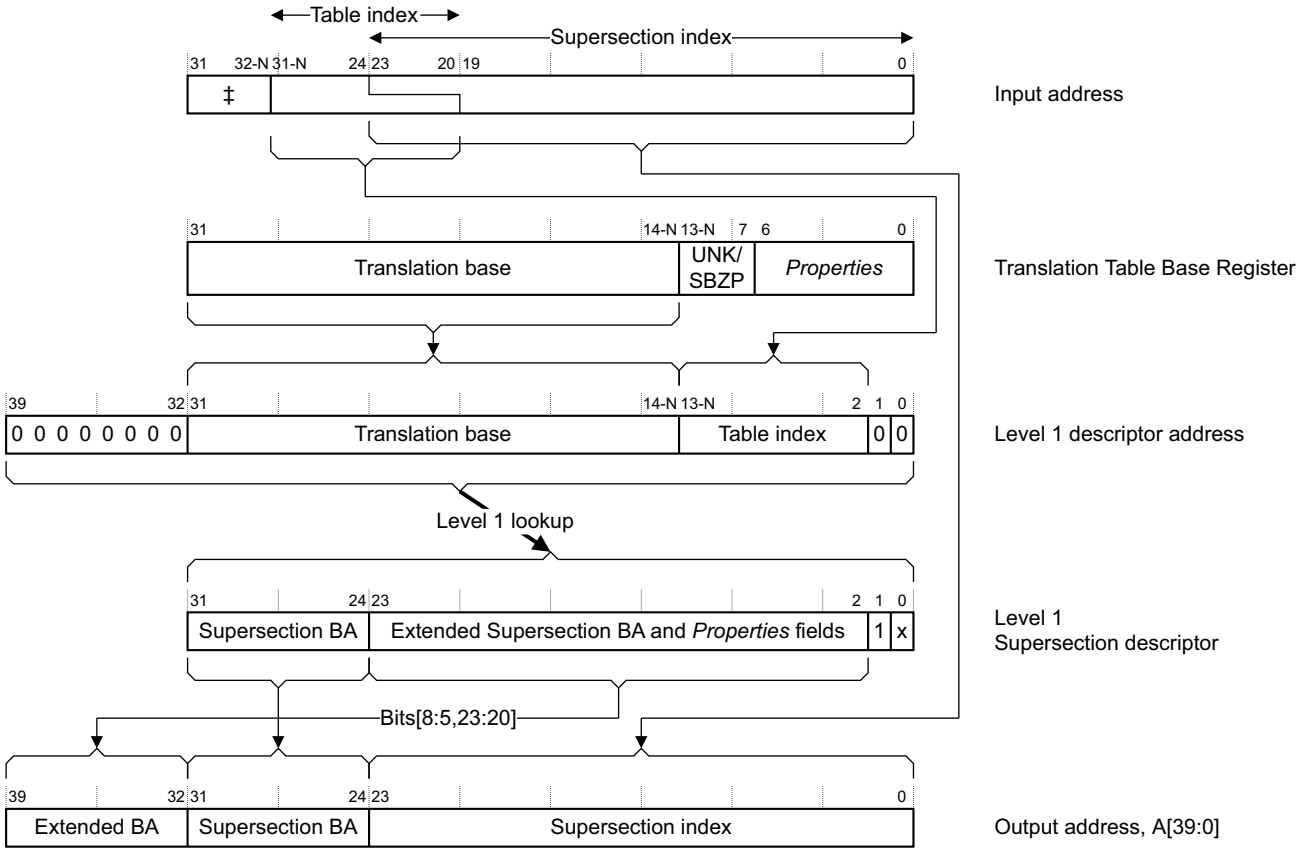
Otherwise, the address is the PA of the descriptor, Section, Supersection, Large page, or Small page.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see *Information returned by a translation table lookup* on page G4-3630, and the description of the register or translation table descriptor.

For translations using the Short-descriptor translation table format, *VMSAv8-32 Short-descriptor translation table format descriptors* on page G4-3635 describes the descriptors formats.

Translation flow for a Supersection

Figure G4-8 on page G4-3643 shows the complete translation flow for a Supersection. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows*.



‡ This field is absent if N is 0
BA = Base address
For a translation based on TTBR0, N is the value of TTBCR.N
For a translation based on TTBR1, N is 0
For details of *Properties* fields, see the register or descriptor description

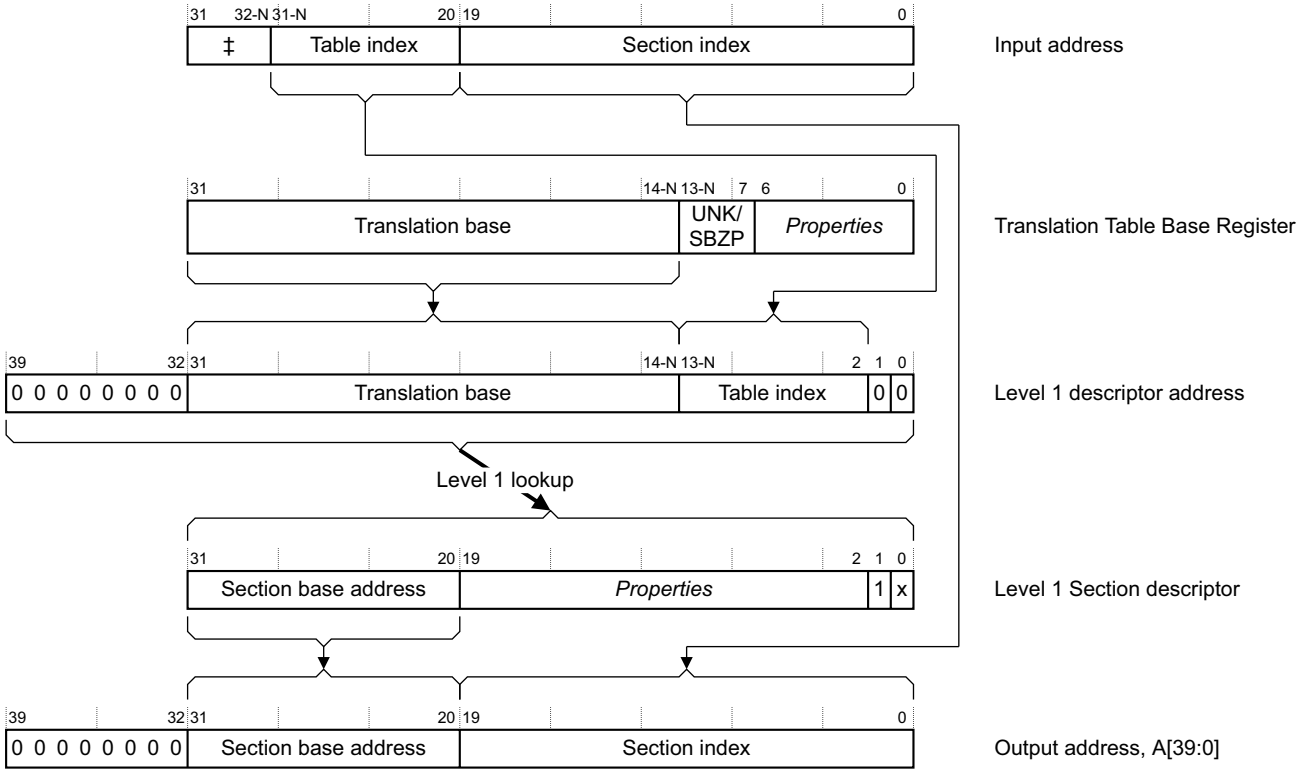
Figure G4-8 VMSAv8-32 Short-descriptor Supersection address translation

Note

Figure G4-8 shows how, when the input address, the VA, addresses a Supersection, the top four bits of the *Supersection index* bits of the address overlap the bottom four bits of the *Table index* bits. For more information, see *Additional requirements for Short-descriptor format translation tables* on page G4-3638.

Translation flow for a Section

Figure G4-9 on page G4-3644 shows the complete translation flow for a Section. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows* on page G4-3642.

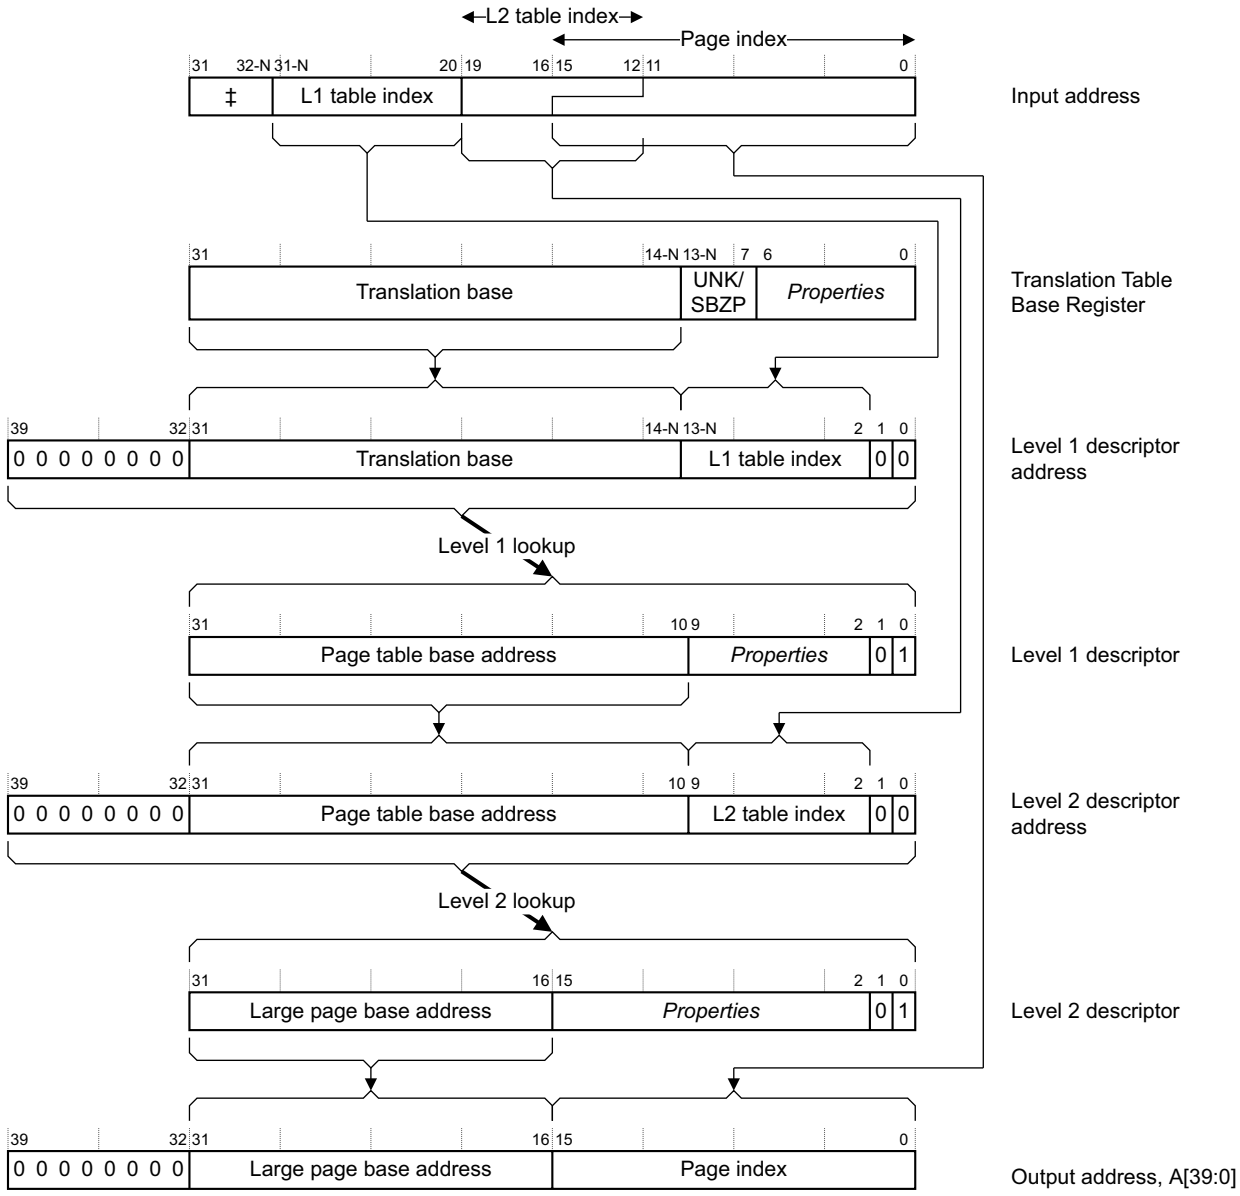


‡ This field is absent if N is 0
For a translation based on TTBR0, N is the value of TTBCR.N
For a translation based on TTBR1, N is 0
For details of *Properties* fields, see the register or descriptor description.

Figure G4-9 VMSAv8-32 Short-descriptor Section address translation

Translation flow for a Large page

Figure G4-10 on page G4-3645 shows the complete translation flow for a Large page. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows* on page G4-3642.



‡ This field is absent if N is 0
L1 = level 1, L2 = level 2
For a translation based on TTBR0, N is the value of TTBCR.N
For a translation based on TTBR1, N is 0
For details of *Properties* fields, see the register or descriptor description

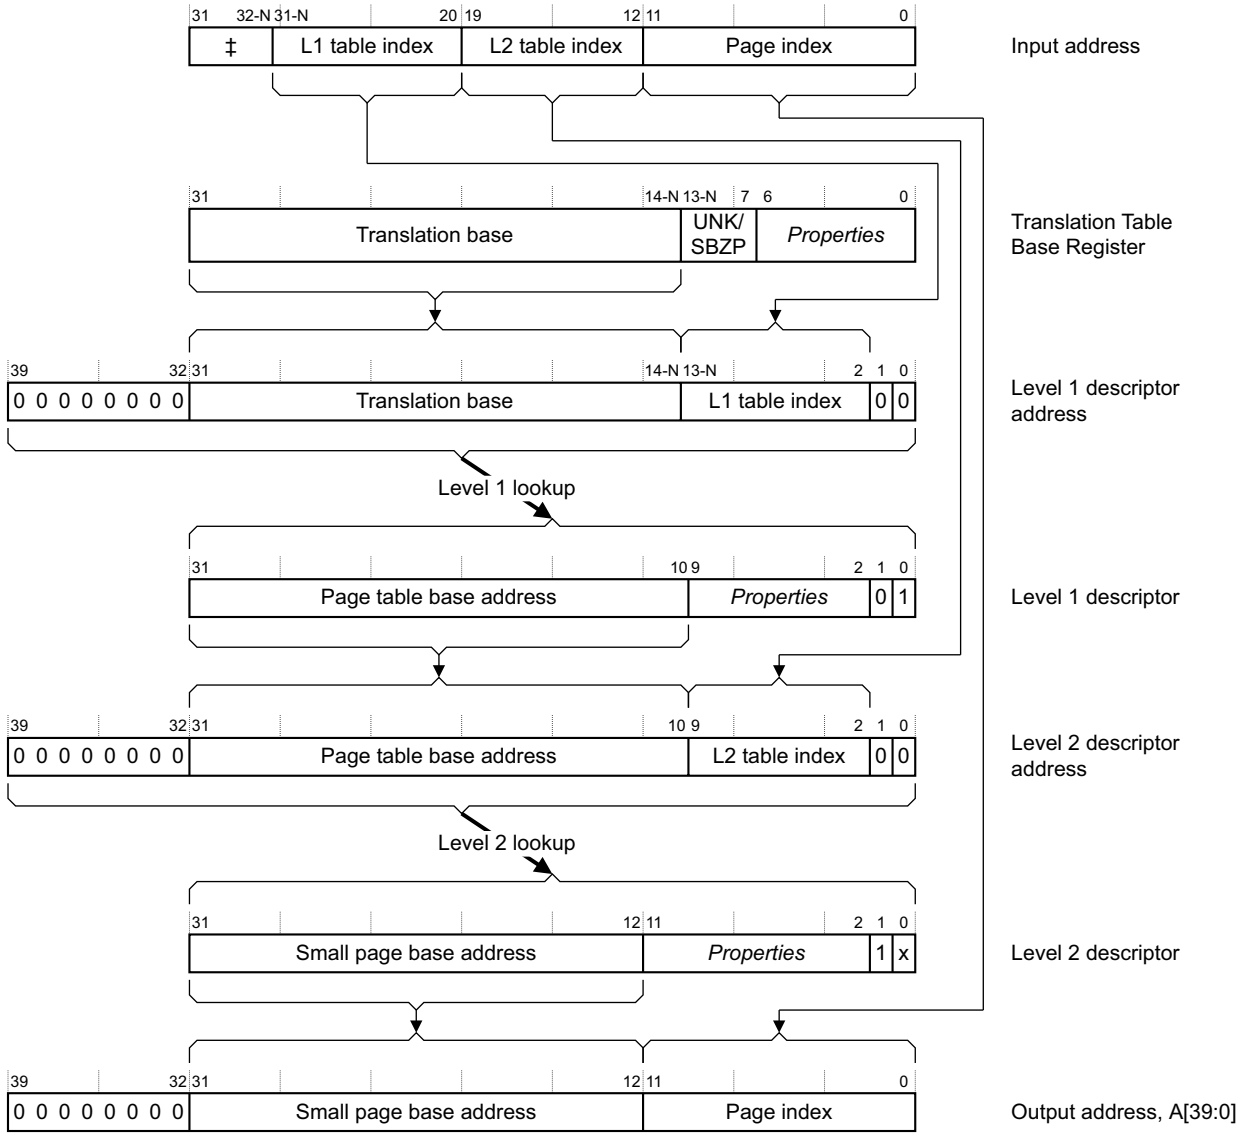
Figure G4-10 VMSAv8-32 Short-descriptor Large page address translation

Note

Figure G4-10 shows how, when the input address, the VA, addresses a Large page, the top four bits of the *page index* bits of the address overlap the bottom four bits of the *level 1 table index* bits. For more information, see *Additional requirements for Short-descriptor format translation tables* on page G4-3638.

Translation flow for a Small page

Figure G4-11 on page G4-3646 shows the complete translation flow for a Small page. For more information about the fields shown in this figure see *The address and Properties fields shown in the translation flows* on page G4-3642.



‡ This field is absent if N is 0
L1 = level 1, L2 = level 2
For a translation based on TTBR0, N is the value of TTBCR.N
For a translation based on TTBR1, N is 0
For details of *Properties* fields, see the register or descriptor description.

Figure G4-11 VMSAv8-32 Short-descriptor Small page address translation

G4.6 The VMSAv8-32 Long-descriptor translation table format

The VMSAv8-32 Long-descriptor translation table format supports the assignment of memory attributes to memory *Pages*, at a granularity of 4KB, across the complete input address range. It also supports the assignment of memory attributes to *blocks* of memory, where a block can be 2MB or 1GB.

Note

- Although the VMSAv8-32 Long-descriptor format is limited to three levels of address lookup, its design and naming conventions support extension to additional levels, to support a larger input address range.
- Similarly, while the VMSAv8-32 implementation limits the output address range to 40 bits, its design supports extension to a larger output address range.

Figure G4-2 on page G4-3622 shows the different address translation stages. The Long-descriptor translation table format:

- Is used for:
  - The Non-secure PL2 stage 1 translation.
  - The Non-secure PL1&0 stage 2 translation.
- Can be used for the Secure and Non-secure PL1&0 translations.

When used for a stage 1 translation, the translation tables support an input address of up to 32 bits, corresponding to the VA address range of the PE.

When used for a stage 2 translation, the translation tables support an input address range of up to 40 bits, to support the translation from IPA to PA. If the input address for the stage 2 translation is a 32-bit address then this address is zero-extended to 40 bits.

Note

When the Short-descriptor translation table format is used for the Non-secure stage 1 translations, this generates 32-bit IPAs. These are zero-extended to 40 bits to provide the input address for the stage 2 translation.

Overview of VMSAv8-32 address translation using Long-descriptor translation tables summarizes address translation from AArch32 state when using the Long-descriptor format translation tables.

VMSAv8-32 Long-descriptor translation table format descriptors on page G4-3648, *Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors* on page G4-3651, and *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format* on page G4-3653 describe the format of the descriptors in the Long-descriptor format translation tables.

The following sections then describe the use of this translation table format:

- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format* on page G4-3654.
- *VMSAv8-32 Long-descriptor translation table format address lookup levels* on page G4-3656.
- *Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format* on page G4-3659.

G4.6.1 Overview of VMSAv8-32 address translation using Long-descriptor translation tables

Figure G4-12 on page G4-3648 gives a general view of VMSAv8-32 stage 1 address translation when using the Long-descriptor translation table format.

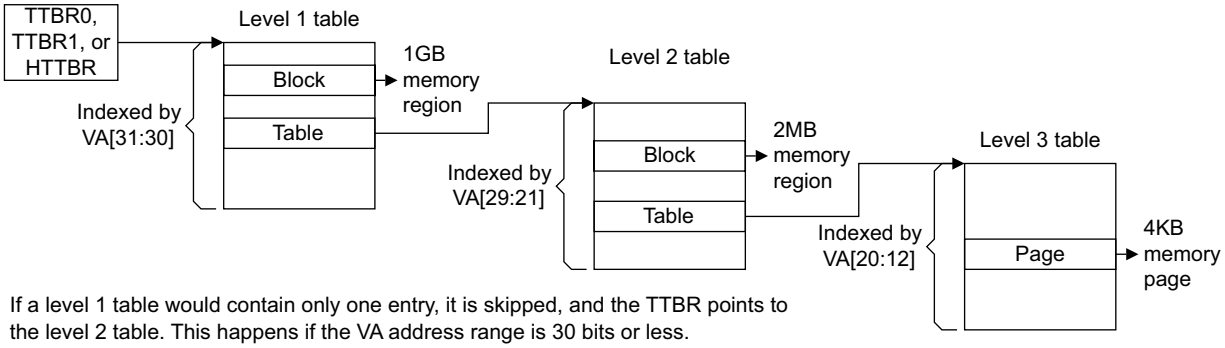


Figure G4-12 General view of VMSAv8-32 stage 1 address translation using Long-descriptor format

Figure G4-13 gives a general view of VMSAv8-32 stage 2 address translation. Stage 2 translation always uses the Long-descriptor translation table format.

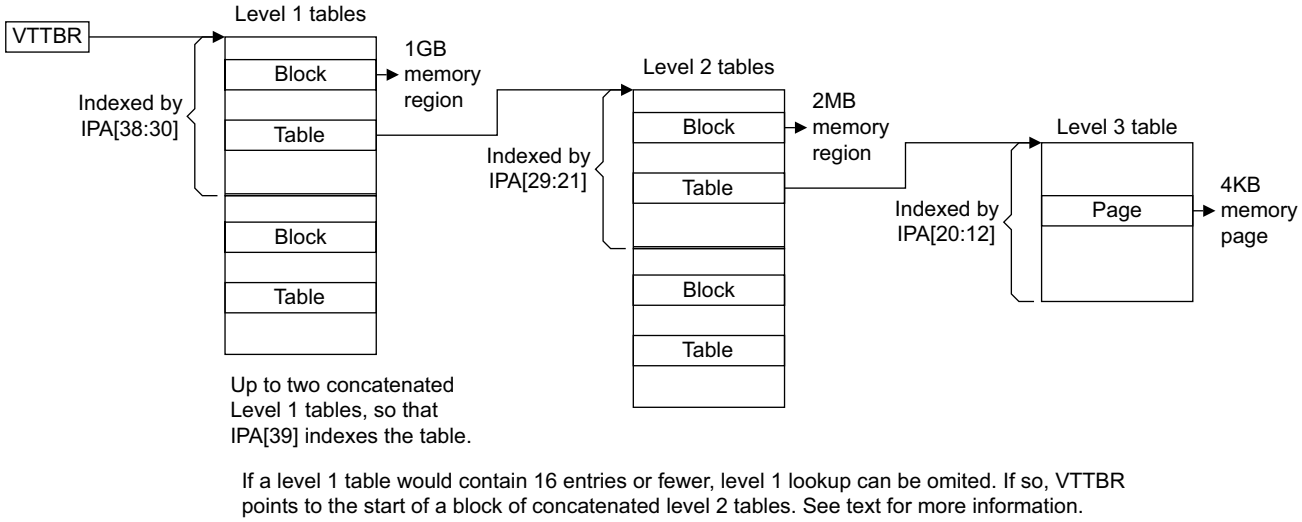

Figure G4-13 General view of VMSAv8-32 stage 2 address translation, Long-descriptor translation table format

Use of concatenated translation tables for stage 2 translations on page G4-3657 describes how using concatenated level 2 tables means lookup can start at the Second level, as referred to in Figure G4-13.

G4.6.2 VMSAv8-32 Long-descriptor translation table format descriptors

As described in *VMSAv8-32 Long-descriptor translation table format address lookup levels* on page G4-3656, the Long-descriptor translation table format provides up to three levels of address lookup. A translation table walk starts either at the first level or the second level of address lookup.

In general, a descriptor is one of:

- An invalid or fault entry.
- A table entry, that points to the next level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the Long-descriptor translation table descriptor formats:

- *VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats* on page G4-3649.
- *VMSAv8-32 Long-descriptor translation table level 3 descriptor formats* on page G4-3650.

Information returned by a translation table lookup on page G4-3630 describes the classification of the non-address fields in the descriptors between *address map control*, *access controls*, and *region attributes*.

VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats

In the Long-descriptor translation tables, the formats of the level 1 and level 2 descriptors differ only in the size of the block of memory addressed by the block descriptor. A block entry:

- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

Figure G4-14 shows the Long-descriptor level 1 and level 2 descriptor formats:

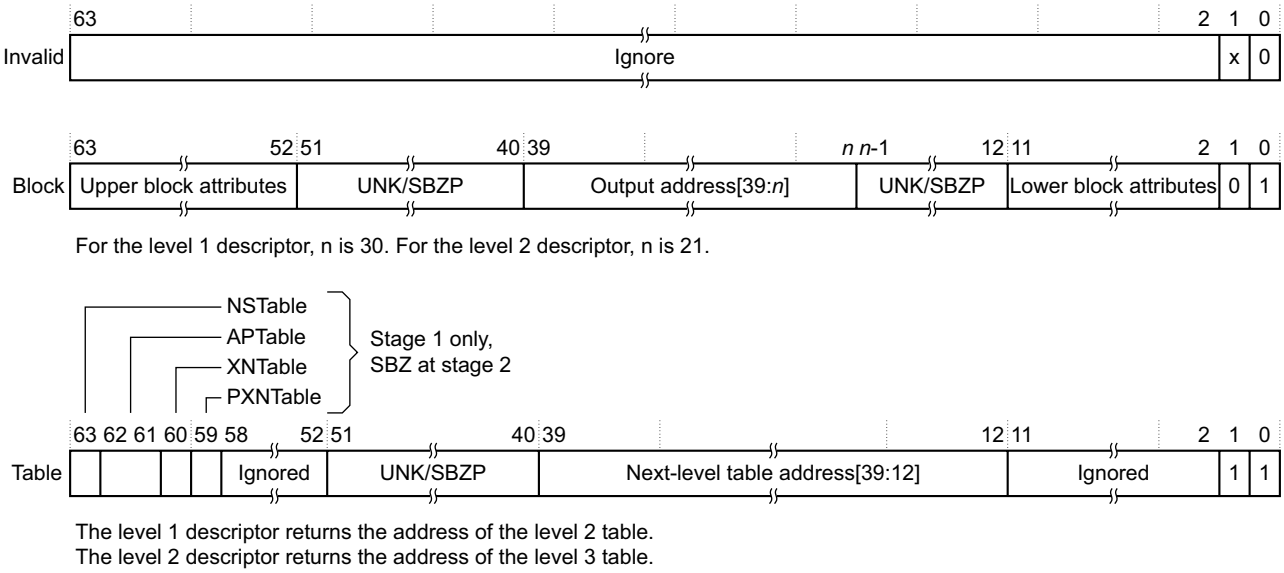

Figure G4-14 VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats

Descriptor encodings, Long-descriptor level 1 and level 2 formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

0, Block The descriptor gives the base address of a block of memory, and the attributes for that memory region.

1, Table The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

Block descriptor

Gives the base address and attributes of a block of memory:

- For a level 1 Block descriptor, bits[47:30] are bits[47:30] of the output address that specifies a 1GB block of memory.
- For a level 2 Block descriptor, bits[47:21] are bits[47:21] of the output address that specifies a 2MB block of memory.

Bits[63:52, 11:2] provide attributes for the target memory block, see *Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors* on page G4-3651. The position and contents of these bits are identical in the level 2 block descriptor and in the level 3 page descriptor.

Table descriptor

Bits[47:m] are bits[47:m] of the address of the required next level table. Bits[m-1:0] of the table address are zero:

- For a level 1 Table descriptor, this is the address of a level 2 table.
- For a level 2 Table descriptor, this is the address of a level 3 table.

For a stage 1 translation only, bits[63:59] provide attributes for the next level lookup, see *Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors* on page G4-3651.

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target block or table. Otherwise, it is the PA of the target block or table.

VMSAv8-32 Long-descriptor translation table level 3 descriptor formats

Each entry in a level 3 table describes the mapping of the associated 4KB input address range.

Figure G4-15 shows the Long-descriptor level 3 descriptor formats.

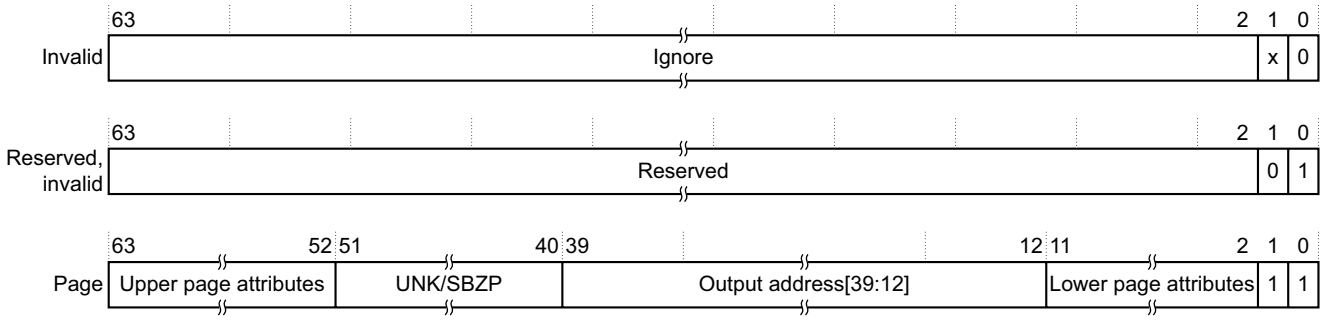

Figure G4-15 VMSAv8-32 Long-descriptor level 3 descriptor formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

0, Reserved, invalid

Behaves identically to encodings with bit[0] set to 0.

This encoding must not be used in level 3 translation tables.

1, Page Gives the address and attributes of a 4KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

Page descriptor

Bits[47:12] are bits[47:12] of the output address for a page of memory.

Bits[63:52, 11:2] provide attributes for the target memory page, see *Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors* on page G4-3651. The position and contents of these bits are identical in the level 1 block descriptor and in the level 2 block descriptor.

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target page. Otherwise, it is the PA of the target page.

G4.6.3 Memory attributes in the VMSAv8-32 Long-descriptor translation table format descriptors

The memory attributes in the VMSAv8-32 Long-descriptor translation tables are based on those in the Short-descriptor translation table format, with some extensions. *Memory region attributes* on page G4-3674 describes these attributes. In the Long-descriptor translation table format:

- Table entries for stage 1 translations define attributes for the next level of lookup, see *Next level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors*
- Block and Page entries define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:
  - *Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors*.
  - *Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors* on page G4-3652.

Next level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the following attributes for the next level translation table access:

NSTable, bit[63] For memory accesses from Secure state, specifies the security level for subsequent levels of lookup, see *Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format* on page G4-3653.

For memory accesses from Non-secure state, this bit is ignored.

APTable, bits[62:61] Access permissions limit for subsequent levels of lookup, see *Hierarchical control of access permissions, Long-descriptor format* on page G4-3666.

APTable[0] is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.

XNTable, bit[60] XN limit for subsequent levels of lookup, see *Hierarchical control of instruction fetching, Long-descriptor format* on page G4-3669.

PXNTable, bit[59] PXN limit for subsequent levels of lookup, see *Hierarchical control of instruction fetching, Long-descriptor format* on page G4-3669.

This bit is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.

Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors

Block and Page descriptors split the memory attributes into an upper block and a lower block. Figure G4-16 shows the memory attribute fields in these blocks, for a stage 1 translation:

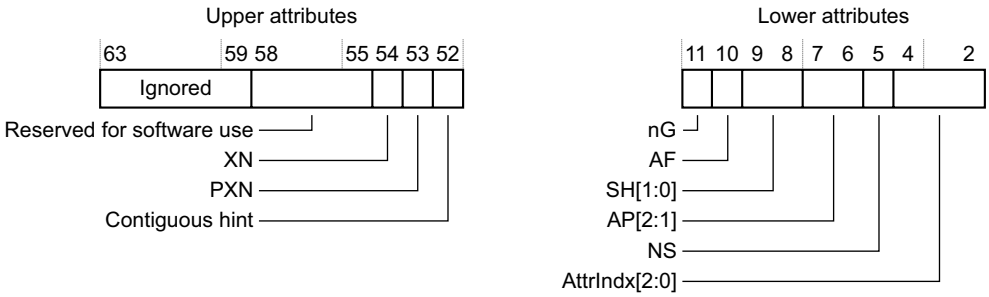

Figure G4-16 VMSAv8-32 memory attribute fields in Long-descriptor stage 1 Block and Page descriptors

For a stage 1 descriptor, the attributes are:

XN, bit[54] The Execute-never bit. Determines whether the region is executable, see *Execute-never restrictions on instruction fetching* on page G4-3668.

PXN, bit[53] The Privileged execute-never bit. Determines whether the region is executable at EL1, see *Execute-never restrictions on instruction fetching* on page G4-3668.

This bit is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.

Contiguous, bit[52]

Indicates that 16 adjacent translation table entries point to contiguous memory regions, see *Contiguous bit* on page G4-3681.

nG, bit[11] The not global bit. Determines how the translation is marked in the TLB, see *Global and process-specific translation table entries* on page G4-3686.

This bit is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.

AF, bit[10] The Access flag, see *The Access flag* on page G4-3671.

SH, bits[9:8] Shareability field, see *Memory region attributes* on page G4-3674.

AP[2:1], bits[7:6]

Access Permissions bits, see *Memory access control* on page G4-3665.

Note

For consistency with the Short-descriptor translation table formats, the Long-descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.

AP[1] is reserved, SBO, in the Non-secure PL2 stage 1 translation tables.

NS, bit[5] Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in Secure or Non-secure memory, see *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format* on page G4-3653.

For memory accesses from Non-secure state, this bit is ignored.

AttrIndx[2:0], bits[4:2]

Stage 1 memory attributes index field, for the indicated Memory Attribute Indirection Register, see *VMSAv8-32 Long-descriptor format memory region attributes* on page G4-3680.

In the upper attributes block, the architecture guarantees that hardware does not alter the fields marked as *Ignored* and *Reserved for software use*. For more information see *Other fields in the Long-descriptor translation table format descriptors* on page G4-3681.

Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors

Block and Page descriptors split the memory attributes into an upper block and a lower block. Figure G4-17 shows the memory attribute fields in these blocks, for a stage 2 translation:

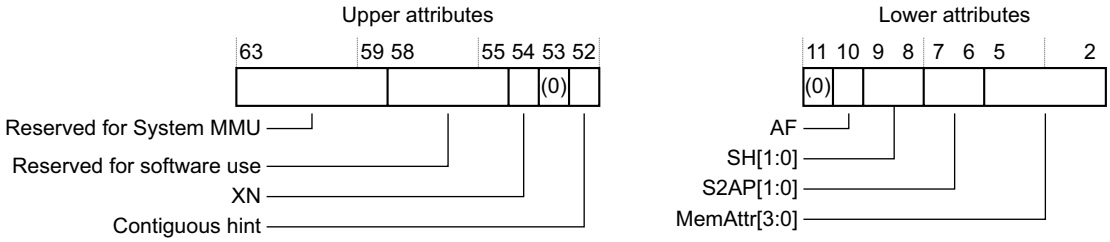

Figure G4-17 VMSAv8-32 memory attribute fields in Long-descriptor stage 2 Block and Page descriptors

For a stage 2 descriptor, the attributes are:

XN, bit[54] The Execute-never bit. Determines whether the region is executable, see *Execute-never restrictions on instruction fetching* on page G4-3668.

Contiguous, bit[52]

Indicates that 16 adjacent translation table entries point to contiguous memory regions, see *Contiguous bit* on page G4-3681.

AF, bit[10] The Access flag, see *The Access flag* on page G4-3671.

SH, bits[9:8] Shareability field, see *EL2 control of Non-secure memory region attributes* on page G4-3681.

S2AP, bits[7:6]

Stage 2 Access Permissions bits, see *Hyp mode control of Non-secure access permissions* on page G4-3672.

Note

In the original VMSAv7-32 Long-descriptor attribute definition, this field was called HAP[2:1], for consistency with the AP[2:1] field in the stage 1 descriptors and despite there being no HAP[0] bit. ARMv8 renames the field for greater clarity.

MemAttr, bits[5:2]

Stage 2 memory attributes, see *EL2 control of Non-secure memory region attributes* on page G4-3681.

In the upper attributes block:

- The field marked as *Reserved for System MMU use* is ignored by the PE. The architecture guarantees that the PE does not alter this field.
- The architecture guarantees that the PE does not alter the fields marked as *Ignored* and *Reserved for software use*.

For more information see *Other fields in the Long-descriptor translation table format descriptors* on page G4-3681.

G4.6.4 Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format

Access to the Secure or Non-secure physical address map on page G4-3632 describes how the NS bit in the translation table entries:

- For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
- Is ignored by accesses from Non-secure state.

In the Long-descriptor format:

- The NS bit relates only to the memory block or page at the output address defined by the descriptor.
- The descriptors also include an NSTable bit, see *Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format*.

The NS and NSTable bits are valid only for memory accesses from Secure state. Memory accesses from Non-secure state ignore the values of these bits.

Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format

For Long-descriptor format table descriptors for stage 1 translations, the descriptor includes an NSTable bit, that indicates whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state, the meaning of the NSTable bit is:

NSTable == 0 The defined table address is in the Secure physical address space. In the descriptors in that translation table, NS bits and NSTable bits have their defined meanings.

NSTable == 1 The defined table address is in the Non-secure physical address space. Because this table is fetched from the Non-secure address space, the NS and NSTable bits in the descriptors in this table must be ignored. This means that, for this table:

- The value of the NS bit in any block or page descriptor is ignored. The block or page address is refers to Non-secure memory.

- The value of the NSTable bit in any table descriptor is ignored, and the table address refers to Non-secure memory. When this table is accessed, the NS bit in any block or page descriptor is ignored, and all descriptors in the table refer to Non-secure memory.

In addition, an entry fetched in Secure state is treated as non-global if either:

- NSTable is set to 1.
- The fetch ignores the values of NS and NSTable, because of a higher-level fetch with NSTable set to 1.

That is, these entries must be treated as if nG==1, regardless of the value of the nG bit. For more information about the nG bit, see *Global and process-specific translation table entries* on page G4-3686.

Note

- When using the Long-descriptor format, table descriptors are defined only for the first level and second level of lookup.
- Stage 2 translations are performed only for operations in Non-secure state, that can access only the Non-secure address space. Therefore, the stage 2 descriptors do not include NS or NSTable bits.

G4.6.5 Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format

As described in *Determining the translation table base address in the VMSAv8-32 translation regimes* on page G4-3631, two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and TTBR0 and TTBR1 hold the base addresses for the two sets of tables. The Long-descriptor translation table format provides more flexibility in defining the boundary between using TTBR0 and using TTBR1. When a PL1&0 stage 1 address translation is enabled, TTBR0 is always used. If TTBR1 is also used then:

- TTBR1 is used for the top part of the input address range.
- TTBR0 is used for the bottom part of the input address range.

The TTBCR.T0SZ and TTBCR.T1SZ size fields control the use of TTBR0 and TTBR1, as Table G4-5 shows.

Table G4-5 Use of TTBR0 and TTBR1, Long-descriptor format

TTBCR		Input address range using:	
T0SZ	**T1SZ**	**TTBR0**	**TTBR1**
`0b000`	`0b000`	All addresses	Not used
M[a]	`0b000`	Zero to $(2^{(32-M)}-1)$	2^{32-M} to maximum input address
`0b000`	*N*[a]	Zero to $(2^{32}-2^{(32-N)}-1)$	$2^{32}-2^{(32-N)}$ to maximum input address
M[a]	*N*[a]	Zero to $(2^{(32-M)}-1)$	$2^{32}-2^{(32-N)}$ to maximum input address

a. *M*, *N* must be greater than 0.The maximum possible value for each of T0SZ and T1SZ is 7.

For stage 1 translations, the input address is always a VA, and the maximum possible VA is $(2^{32}-1)$.

When address translation is using the Long-descriptor translation table format:

- Figure G4-18 on page G4-3655 shows how, when TTBCR.T1SZ is zero, the value of TTBCR.T0SZ controls the boundary between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.

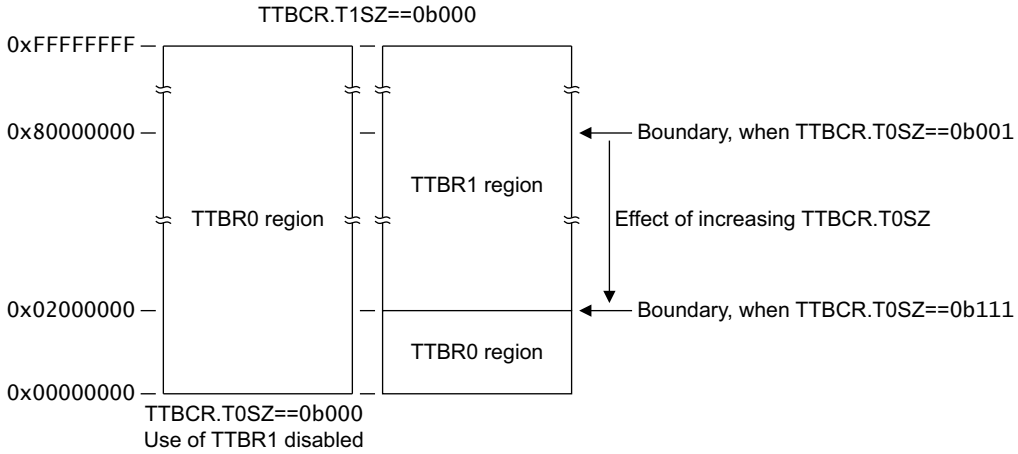

Figure G4-18 Control of TTBR boundary, when TTBCR.T1SZ is zero

- Figure G4-19 shows how, when TTBCR.T1SZ is nonzero, the values of TTBCR.T0SZ and TTBCR.T1SZ control the boundaries between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.

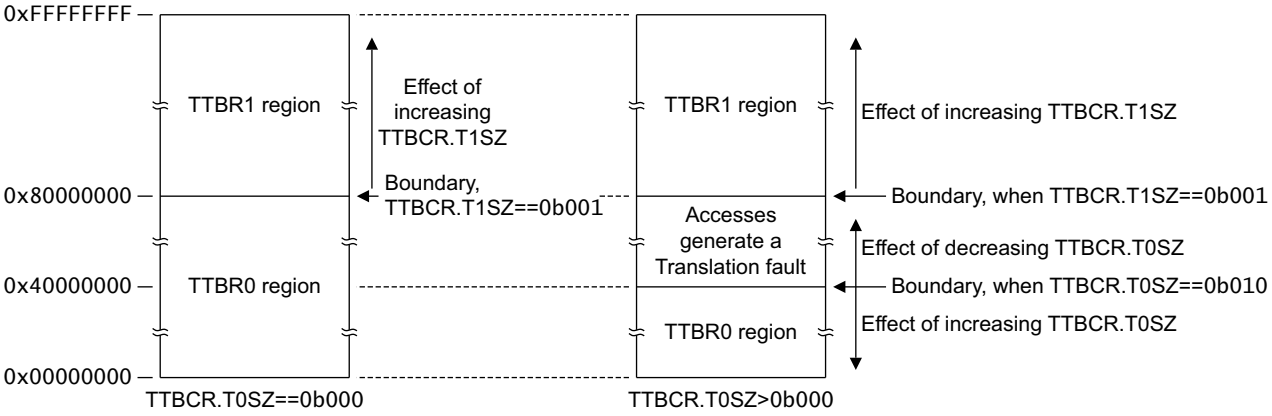

Figure G4-19 Control of TTBR boundaries, when TTBCR.T1SZ is nonzero

When T0SZ and T1SZ are both nonzero:

— If both fields are set to `0b001`, the boundary between the two regions is `0x80000000`. This is identical to having T0SZ set to `0b000` and T1SZ set to `0b001`.

— Otherwise, the TTBR0 and TTBR1 regions are non-contiguous. In this case, any attempt to access an address that is in that gap between the TTBR0 and TTBR1 regions generates a Translation fault.

When using the Long-descriptor translation table format:

- The TTBCR contains fields that define memory region attributes for the translation table walk, for each TTBR. These are the SH0, ORGN0, IRGN0, SH1, ORGN1, and IRGN1 bits.
- TTBR0 and TTBR1 each contain an ASID field, and the TTBCR.A1 field selects which ASID to use.

For this translation table format, *VMSAv8-32 Long-descriptor translation table format address lookup levels* on page G4-3656 summarizes the lookup levels, and *Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format* on page G4-3659 describes the possible translations.

Possible translation table registers programming errors

In all the descriptions in this subsection, the *size of the input address* supported for a PL1&0 stage 1 translation refers to the size specified by a TTBCR.TxSZ field.

Note

For a PL1&0 stage 1 translation, this section has described how the input address range can be split so that the lower addresses are translated by TTBR0 and the higher addresses are translated by TTBR1. In this case, each of input address sizes specified by TTBCR.{T0SZ, T1SZ} is smaller than the total address size supported by the stage of translation.

The following are possible errors in the programming of TTBR0, TTBR1, and TTBCR. For the translation of a particular address at a particular stage of translation, either:

- The block size being used to translate the address is larger than the size of the input address supported at a stage of translation used in performing the required translation. This can occur only for the PL1&0 stage 1 translations, and only when either TTBCR.T0SZ or TTBCR.T1SZ is zero, meaning there is no gap between the address range translated by TTBR0 and the range translated by TTBR1. In this case, this programming error occurs if a block translated from the region that has TxSZ set to zero straddles the boundary between the two address ranges. Example G4-2 shows an example of this mis-programming.
- The address range translated by a set of blocks marked as contiguous, by use of the contiguous bit, is larger than the size of the input address supported at a stage of translation used in performing the required translation.

Example G4-2 Translation table programming error

If TTBCR.T0SZ is programmed to 0 and TTBCR.T1SZ is programmed to 7, this means:

- TTBR0 translates addresses in the range `0x00000000-0xFDFFFFFF`.
- TTBR1 translates addresses in the range `0xFE000000-0xFFFFFFFF`.

The translation table indicated by TTBR0 might be programmed with a block entry for a 1GB region starting at `0xC0000000`. This covers the address range `0xC0000000-0xFFFFFFFF`, that overlaps the TTBR1 address range. This means this block size is larger than the input address size supported for translations using TTBR0, and therefore this is a programming error.

To understand why this must be a programming error, consider a memory access to address `0xFFFF0000`. According to the TTBCR.{T0SZ, T1SZ} values, this must be translated using TTBR1. However, the access matches a TLB entry for the translation, using TTBR0, of the block at `0xC0000000`. Hardware is not required to detect that the access to `0xFFFF0000` is being translated incorrectly.

In these cases, an implementation might use one of the following approaches:

- Treat such a block, that might be a block within a contiguous set of blocks, as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation.
- Treat such a block, that might be a block within a contiguous set of blocks, as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, provided that both of the following apply:
  - The block is valid.
  - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.

G4.6.6 VMSAv8-32 Long-descriptor translation table format address lookup levels

As stated at the start of this section, because the Long-descriptor translation table format is used for the Non-secure PL1&0 stage 2 translations, the format must support input addresses of up to 40 bits.

Table G4-6 summarizes the properties of the different levels of address lookup when using this format.

Table G4-6 Properties of the three levels of address lookup with VMSAv8-32 Long-descriptor translation tables

Level	Input address		Output address[a]		Number of entries
	Size	Address range[b]	Size	Address range	
First	Up to 512GB	Up to Address[38:0]	1GB	Address[39:30]	Up to 512
Second	Up to 1GB	Up to Address[29:0]	2MB	Address[39:21]	Up to 512
Third	2MB	Address[20:0]	4KB	Address[47:12]	512

a. Output address when an entry addresses a block of memory or a memory page. If an entry addresses the next level of address lookup it specifies Address[39:12] for the next level translation table.

b. Input address range for the translation table. See *Use of concatenated level 1 translation tables* on page G4-3658 for details of support for additional bits of address at a given level, including possible support of a 40-bit input address range at the first level.

For level 1 and level 2 tables, reducing the input address range reduces the number of addresses in the table and therefore reduces the table size.The appropriate Translation Table Control Register specifies the input address range.

Stage 1 translations require an input address range of up to 32 bits, corresponding to VA[31:0]. For these translations:

- For a memory access from a mode other than Hyp mode, the Secure or Non-secure TTBR0 or TTBR1 holds the translation table base address, and the Secure or Non-secure TTBCR is the control register.
- For a memory access from Hyp mode, HTTBR holds the translation table base address, and HTCR is the control register.

Note

For translations controlled by TTBR0 and TTBR1, if neither Translation Table Base Register has an input address range larger than 1GB, then translation starts at the second level. Together, TTBR0 and TTBR1 can still cover the 32-bit VA input address range.

Stage 2 translations require an input address range of up to 40 bits, corresponding to IPA[39:0], and the supported input address size is configurable in the range 25-40 bits. Table G4-6 indicates a requirement for the translation mechanism to support a 39-bit input address range, Address[38:0]. *Use of concatenated translation tables for stage 2 translations* describes how a 40-bit IPA address range is supported. For stage 2 translations:

- VTTBR holds the translation table base address, and VTCR is the control register.
- If a supplied input address is larger than the configured input address size, a Translation fault is generated.

Use of concatenated translation tables for stage 2 translations

If a stage 2 translation requires 16 entries or fewer in its top level translation table, it can instead:

- Require the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.
- Start the translation at that next translation level.

Note

Stage 2 translations always use the Long-descriptor translation table format.

Use of this translation scheme is:

- Required when the stage 2 translation supports a 40-bit input address range, see *Use of concatenated level 1 translation tables*.
- Supported for a stage 2 translation with an input address range of 31-34 bits, see *Use of concatenated level 2 translation tables*.

Note

This translation scheme:

- Avoids the overhead of an additional level of translation
- Requires the software that is defining the translation to:
  - Define the concatenated translation tables with the required overall alignment.
  - Program VTTBR to hold the address of the first of the concatenated translation tables.
  - Program VTCR to indicate the required input address range and first lookup level.

Use of concatenated level 1 translation tables

The Long-descriptor format translation tables provide 9 bits of address resolution at each level of lookup. However, a 40-bit input address range with a translation granularity of 4KB requires a total of 28 bits of address resolution. Therefore, a stage 2 translation that supports a 40-bit input address range requires two concatenated level 1 translation tables, together aligned to 8KB, where:

- The table at the address with PA[12:0]==`0b0_0000_0000_0000` defines the translations for input addresses with bit[39]==0.
- The table at the address with PA[12:0]==`0b1_0000_0000_0000` defines the translations for input addresses with bit[39]==1.
- The 8KB alignment requirement means that both table have the same value for PA[39:13].

Use of concatenated level 2 translation tables

A stage 2 translation with an input address range of 31-34 bits can start the translation either:

- With a level 1 lookup, accessing a level 1 translation table with 2-16 entries.
- With a level 2 lookup, accessing a set of concatenated level 2 translation tables.

Table G4-7 shows these options, for each of the input address ranges that can use this scheme.

Note

Because these are stage 2 translations, the input address range is an IPA range.

Table G4-7 Possible uses of concatenated translation tables for level 2 lookup

Input address range		Lookup starts at first level	Lookup starts at second level	
IPA range	Size	Required level 1 entries	Number of concatenated tables	Required alignment[a]
IPA[30:0]	2^{31} bytes	2	2	8KB
IPA[31:0]	2^{32} bytes	4	4	16KB
IPA[32:0]	2^{33} bytes	8	8	32KB
IPA[33:0]	2^{34} bytes	16	16	64KB

a. Required alignment of the set of concatenated level 2 tables.

See also *Determining the required first lookup level for stage 2 translations* on page G4-3661.

G4.6.7 Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format

Figure G4-2 on page G4-3622 shows the possible address translations. The following descriptions of the translations include the registers that control each translation if that translation is controlled from an Exception level that is using AArch32:

Stage 1 translations

For all stage 1 translations:

- The input address range is up to 32 bits, as determined by either:
  - TTBCR.T0SZ or TTBCR.T1SZ, for a PL1&0 stage 1 translation.
  - HTCR.T0SZ, for a PL2 stage 1 translation.
- The output address range is 40 bits.

The stage 1 translations are:

Non-secure PL1&0 stage 1 translation

The stage 1 translation for memory accesses from Non-secure modes other than Hyp mode. This translates a VA to an IPA. For this translation, when Non-secure EL1 is using AArch32:

- Non-secure TTBR0 or TTBR1 holds the translation table base address.
- Non-secure TTBCR determines which TTBR is used.

Non-secure PL2 stage 1 translation

The stage 1 translation for memory accesses from Hyp mode, translates a VA to a PA. For this translation, when EL2 is using AArch32, HTTBR holds the translation table base address.

Secure PL1&0 stage 1 translation

The stage 1 translation for memory accesses from Secure modes, translates a VA to a PA. For this translation, when the Secure PL1 modes are using AArch32:

- Secure TTBR0 or TTBR1 holds the translation table base address.
- Secure TTBCR determines which TTBR is used.

Stage 2 translation

Non-secure PL1&0 stage 2 translation

The stage 2 translation for memory accesses from Non-secure modes other than Hyp mode, and translates an IPA to a PA. For this translation, when EL2 is using AArch32:

- The input address range is 40 bits, as determined by VTCR.T0SZ.
- The output address range depends on the implemented memory system, and is up to 40 bits.
- VTTBR holds the translation table base address.
- VTCR specifies the required input address range, and whether the first lookup is at the first level or at the second level.

The descriptions of the VMSAv8-32 translation stages state that the maximum output address size is 40 bits. However, the register and Long-descriptor format descriptor fields that hold these addresses are 48 bits wide. If bits[47:40] of an output address are not all zero then the address generates an Address size fault.

The Long-descriptor translation table format provides up to three levels of address lookup, as described in *VMSAv8-32 Long-descriptor translation table format address lookup levels* on page G4-3656, and the first lookup, in which the MMU reads the translation table base address, is at either the first level or the second level. The following determines the level of the first lookup:

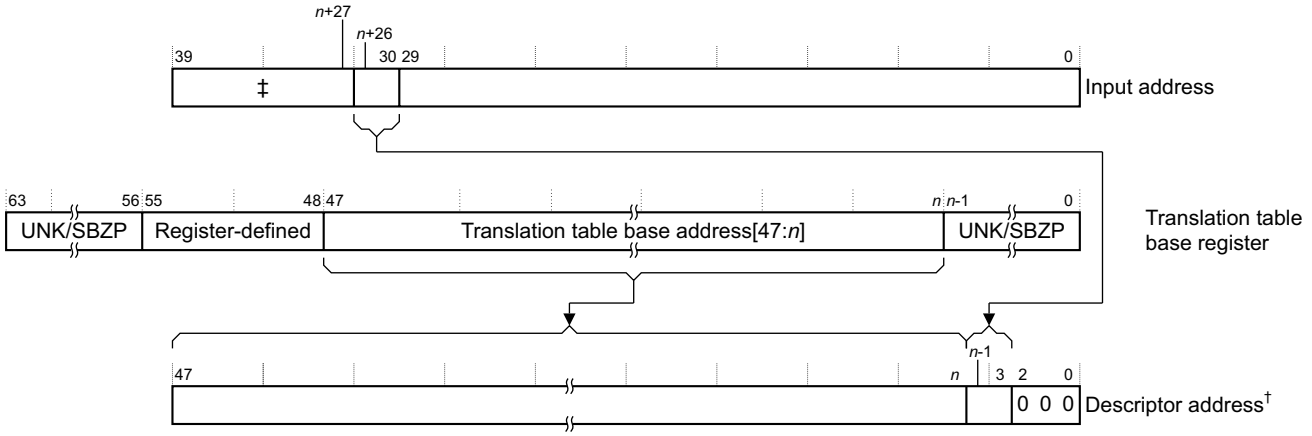
- For a stage 1 translation, the required input address range. For more information see *Determining the required first lookup level for stage 1 translations* on page G4-3661.

- For a stage 2 translation, the level specified by the VTCR.SL0 field. For more information see *Determining the required first lookup level for stage 2 translations* on page G4-3661.

Note

For a stage 2 translation, the size of the required input address range constrains the VTCR.SL0 value.

Figure G4-20 shows how the descriptor address for the first lookup for a translation using the Long-descriptor translation table format is determined from the input address and the translation table base register value. This figure shows the lookup for a translation that starts with a level 1 lookup, that translates bits[39:30] of the input address, zero extended if necessary.



See text for more information about the translation table base register used, and the value of *n*.
‡ This field is absent if *n* is 13.
† For a Non-secure PL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

Figure G4-20 Long-descriptor first lookup, starting at first level

For a translation that starts with a level 1 lookup, as shown in Figure G4-20:

For a stage 1 translation

n is in the range 4-5 and:

- For a memory access from Hyp mode:
  - HTTBR is the translation table base register.
  - *n*=5-(HTCR.T0SZ).
- For other accesses:
  - the Secure or Non-secure instance of TTBR0 or TTBR1 is the translation table base register.
  - *n*=(5-TTBCR.T*x*SZ), where *x* is 0 when using TTBR0, and 1 when using TTBR1.

For a stage 2 translation

n is in the range 4-13 and:

- VTTBR is the translation table base register.
- *n*=5-(VTCR.T0SZ).

For a translation that starts with a level 2 lookup, the descriptor address is obtained in the same way, except that bits[(*n*+17):21] of the input address provide bits[(*n*-1):3] of the descriptor address, where:

For a stage 1 translation

n is in the range 7-12. As *Determining the required first lookup level for stage 1 translations* on page G4-3661 shows, for a stage 1 translation to start with a level 2 lookup, the corresponding T0SZ or T1SZ field must be 2 or more. This means:

- For a memory access from Hyp mode, *n*=14-HTCR.T0SZ.

- For other memory accesses, *n*=14-(TTBCR.T*x*SZ), where *x* is 0 when using TTBR0, and 1 when using TTBR1.

For a stage 2 translation

n is in the range 7-16. For a stage 2 translation to start with a level 2 lookup, VTCR.SL0 is `0b00`, and *n*=14-(VTCR.T0SZ).

Determining the required first lookup level for stage 1 translations

For a stage 1 translation, the required input address range, indicated by a T0SZ or T1SZ field in a translation table control register, determines the first lookup level. The size of this input address region is $2^{(32-T_xSZ)}$ bytes, and if this size is:

- Less than or equal to 2^{30} bytes, the required start is at the second level, and translation requires two levels of table to map to 4KB pages. This corresponds to a T*x*SZ value of 2 or more.
- More than 2^{30} bytes, the required start is at the first level, and translation requires three levels of table to map to 4KB pages. This corresponds to a T*x*SZ value that is less than 2.

For the PL1&0 stage 1 translations, the TTBCR:

- Splits the 32-bit VA input address range between TTBR0 and TTBR1, see *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format* on page G4-3654.
- Holds the input address range sizes for TTBR0 and TTBR1, in the TTBCR.T0SZ and TTBCR.T1SZ fields.

For the PL2 stage 1 translations, HTCR.T0SZ indicates the size of the required input address range. For example, if this field is `0b000`, it indicates a 32-bit VA input address range, and translation lookup must start at the first level.

Determining the required first lookup level for stage 2 translations

For a PL1&0 stage 2 translation, the output address range from the PL1&0 stage 1 translations determines the required input address range for the stage 2 translation.

VTCR.SL0 indicates the starting level for the lookup. The permitted SL0 values are:

`0b00` Stage 2 translation lookup must start at the second level.

`0b01` Stage 2 translation lookup must start at the first level.

In addition, VTCR.T0SZ must indicate the required input address range. The size of the input address region is $2^{(32-T0SZ)}$ bytes.

Note

VTCR.T0SZ holds a four-bit signed integer value, meaning it supports values from -8 to 7. This is different from the other translation control registers, where T*n*SZ holds a three-bit unsigned integer, supporting values from 0 to 7.

The programming of VTCR must follow the constraints shown in Table G4-8, otherwise behavior is UNPREDICTABLE. The table also shows how the VTCR.SL0 and VTCR.T0SZ values determine the VTTBR.BADDR field width.

Table G4-8 Input address range constraints on programming VTCR

VTCR.SL0	VTCR.T0SZ	Input address range, R	First lookup level	BADDR[39:x] width[a]
`0b00`	2 to 7	$R \le 2^{30}$ bytes	Second	[39:12] to [39:7]
`0b00`	-2 to 1	$2^{30} < R \le 2^{34}$ bytes	Second	[39:16] to [39:13]
`0b01`	-2 to 1		First	[39:7] to [39:4]
`0b01`	-8 to -3	$2^{34} < R$	First	[39:13] to [39:8]

a. The first range corresponds to the first T0SZ value, the second range to the second T0SZ value.

Where necessary, the first lookup level provides multiple concatenated translation tables, as described in *Use of concatenated level 2 translation tables* on page G4-3658. This section also gives more information about the alternatives, shown in Table G4-8 on page G4-3661, when R is in the range 2^{31}-2^{34}.

Full translation flows for VMSAv8-32 Long-descriptor format translation tables

In a translation table walk, only the first lookup uses the translation table base address from the appropriate Translation table base register. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

The following sections describe full Long-descriptor format translation flows, down to an entry for a 4KB page:

- *The address and Properties fields shown in the translation flows* on page G4-3642.
- *Full translation flow, starting at level 1 lookup*.
- *Full translation flow, starting at level 2 lookup* on page G4-3664.

The address and Properties fields shown in the translation flows

For the Non-secure PL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

In these cases, a PL1&0 stage 2 translation is performed to translate the IPA to the required PA.

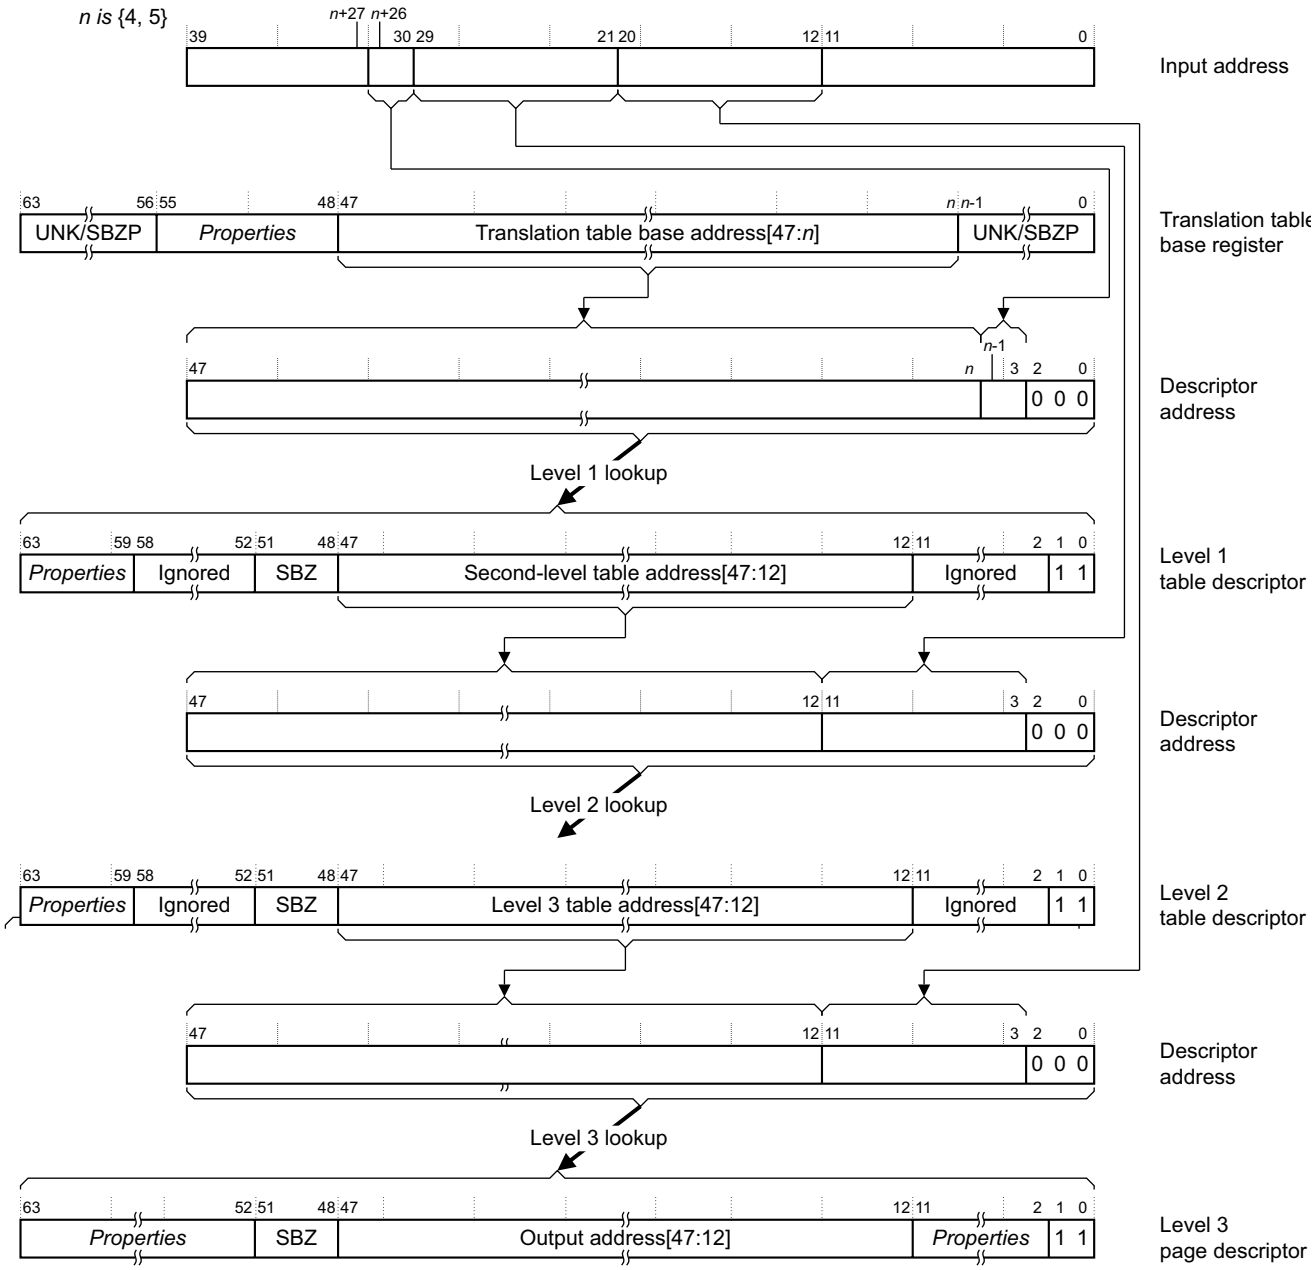
For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see *Information returned by a translation table lookup* on page G4-3630, and the description of the register or translation table descriptor.

For translations using the Long-descriptor translation table format, *VMSAv8-32 Long-descriptor translation table format descriptors* on page G4-3648 describes the descriptors formats.

Full translation flow, starting at level 1 lookup

Figure G4-21 on page G4-3663 shows the complete translation flow for a VMSAv8-32 Long-descriptor stage 1 translation table walk that starts with a level 1 lookup. For more information about the fields shown in the figure see *The address and Properties fields shown in the translation flows* on page G4-3642.



For details of *Properties* fields, see the register or descriptor description.

Figure G4-21 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at first level

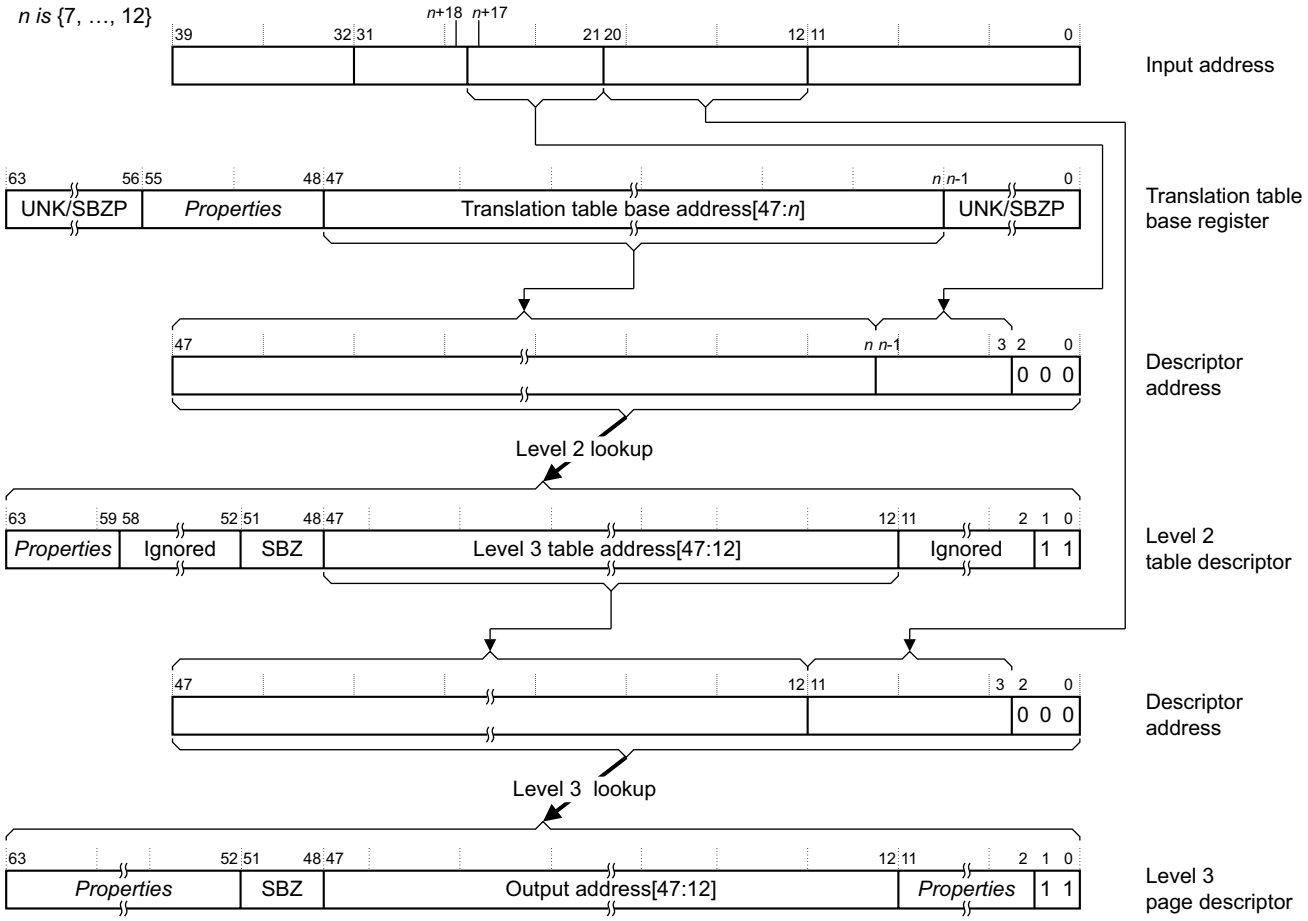
If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

A stage 2 translation that starts at a level 1 lookup differs from the translation shown in Figure G4-21 only as follows:

- The possible values of *n* are 4-13, to support an input address of between 31 and 40 bits.
- A descriptor and output addresses are always PAs.

Full translation flow, starting at level 2 lookup

Figure G4-22 shows the complete translation flow for a stage 1 VMSAv8-32 Long-descriptor translation table walk that starts at a level 2 lookup. For more information about the fields shown in the figure see *The address and Properties fields shown in the translation flows* on page G4-3642.



For details of *Properties* fields, see the register or descriptor description.

Figure G4-22 Complete VMSAv8-32 Long-descriptor format stage 1 translation, starting at second level

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

A stage 2 translation that starts at a level 2 lookup differs from the translation shown in Figure G4-22 only as follows:

- The possible values of *n* are 7-16, to support an input address of up to 34 bits.
- The descriptor and output addresses are always PAs.

G4.7 Memory access control

In addition to an output address, a translation table entry that refers to page or region of memory includes fields that define properties of the target memory region. *Information returned by a translation table lookup* on page G4-3630 describes the classification of those fields as address map control, access control, and memory attribute fields. The access control fields, described in this section, determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the translation table descriptor. If a translation stage does not permit the access then a MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

- *Access permissions*.
- *Execute-never restrictions on instruction fetching* on page G4-3668.
- *Domains, Short-descriptor format only* on page G4-3670.
- *The Access flag* on page G4-3671.
- *Hyp mode control of Non-secure access permissions* on page G4-3672.

G4.7.1 Access permissions

Note

This section gives a general description of memory access permissions. Software executing at PL1 in Non-secure state can see only the access permissions defined by the Non-secure PL1&0 stage 1 translations. However, software executing at PL2 can modify these permissions, as described in *Hyp mode control of Non-secure access permissions* on page G4-3672. This modification is invisible to Non-secure software executing at EL1 or EL0.

Access permission bits in a translation table descriptor control access to the corresponding memory region. The details of this control depend on the translation table format, as follows:

Short-descriptor format

This format supports two options for defining the access permissions:

- Three bits, AP[2:0], define the access permissions.
- Two bits, AP[2:1], define the access permissions, and AP[0] can be used as an Access flag.

SCTLR.AFE selects the access permissions option. Setting this bit to 1, to enable the Access flag, also selects use of AP[2:1] to define access permissions.

ARM deprecates any use of the AP[2:0] scheme for defining access permissions.

Long-descriptor format

AP[2:1] to control the access permissions, and the descriptors provide an AF bit for use as an Access flag. This means VMSAv8-32 behaves as if the value of SCTLR.AFE is 1, regardless of the value that software has written to this bit.

Note

When use of the Long-descriptor format is enabled, SCTLR.AFE is UNK/SBOP.

The Access flag on page G4-3671 describes the Access flag, for both translation table formats.

The XN and PXN bits provide additional access controls for instruction fetches, see *Execute-never restrictions on instruction fetching* on page G4-3668.

An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation. However, when using the Short-descriptor translation table format, it generates the fault only if the access is to memory in the Client domain, see *Domains, Short-descriptor format only* on page G4-3670.

Note

For the Non-secure PL1&0 translation regime, memory accesses are subject to two stages of translation. Each stage of translation has its own, independent, fault checking. Fault handling is different for the two stages, see *Exception reporting in a VMSAv8-32 implementation* on page G4-3715.

The following sections describe the two access permissions models:

- *AP[2:1] access permissions model*.
- *AP[2:0] access permissions control, Short-descriptor format only* on page G4-3667. This section includes some information on access permission control in earlier versions of the ARM VMSA.

AP[2:1] access permissions model

Note

ARM recommends that this model is always used, even where the AP[2:0] model is permitted. Some documentation describes the AP[2:1] model as the *simplified access permissions* model.

This access permissions model is used if the translation is either:

- Using the Long-descriptor translation table format.
- Using Short-descriptor translation table format, and the SCTLR.AFE bit is set to 1.

In this model:

- One bit, AP[2], selects between read-only and read/write access.
- A second bit, AP[1], selects between Application level (PL0) and System level (PL1) control.
  For the Non-secure PL2 stage 1 translations, AP[1] is SBO.

This provides four access combinations:

- Read-only at all privilege levels.
- Read/write at all privilege levels.
- Read-only at PL1, no access by software executing at PL0.
- Read/write at PL1, no access by software executing at PL0.

Table G4-9 shows this access control model.

Table G4-9 VMSAv8-32 AP[2:1] access permissions model

AP[2], disable write access	AP[1], enable unprivileged access	Access
0	0[a]	Read/write, only at PL1
0	1	Read/write, at any privilege level
1	0[a]	Read-only, only at PL1
1	1	Read-only, at any privilege level

a. Not valid for Non-secure PL2 stage 1 translation tables. AP[1] is SBO in these tables.

Hierarchical control of access permissions, Long-descriptor format

The Long-descriptor translation table format introduces a mechanism that entries at one level of translation table lookup can use to set limits on the permitted entries at subsequent levels of lookup. This applies to the access permissions, and also to the restrictions on instruction fetching described in *Hierarchical control of instruction fetching, Long-descriptor format* on page G4-3669.

The restrictions apply only to subsequent levels of lookup at the same stage of translation. The APTable[1:0] field restricts the access permissions, as Table G4-10 on page G4-3667 shows.

As stated in the table footnote, for the Non-secure PL2 stage 1 translation tables, APTable[0] is reserved, SBZ.

Table G4-10 Effect of APTable[1:0] on subsequent levels of lookup

APTable[1:0]	Effect
00	No effect on permissions in subsequent levels of lookup.
01[a]	Access at PL0 not permitted, regardless of permissions in subsequent levels of lookup.
10	Write access not permitted, at any exception level, regardless of permissions in subsequent levels of lookup.
11[a]	Regardless of permissions in subsequent levels of lookup: • Write access not permitted, at any exception level. • Read access not permitted at PL0.

a. Not valid for the Non-secure PL2 stage 1 translation tables. In those tables, APTable[0] is SBZ.

Note

The APTable[1:0] settings are combined with the translation table access permissions in the translation tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The Long-descriptor format provides APTable[1:0] control only for the stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

When APTable[1:0] is not set to `0b00`, its effects might be held in one or more TLB entries. Therefore, a change to APTable[1:0] might require coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

AP[2:0] access permissions control, Short-descriptor format only

This access permissions model applies when using the Short-descriptor translation tables format, and the SCTLR.AFE bit is set to 0. ARM deprecates any use of this access permissions model.

When SCTLR.AFE is set to 0, ensuring that the AP[0] bit is always set to 1 effectively changes the access model to the simpler model described in *AP[2:1] access permissions model* on page G4-3666.

Table G4-11 shows the full AP[2:0] access permissions model:

Table G4-11 VMSAv8-32 MMU access permissions

AP[2]	AP[1:0]	EL1 and EL2 access	Unprivileged access	Description
0	00	No access	No access	All accesses generate Permission faults
	01	Read/write	No access	Access only at PL1 or higher
	10	Read/write	Read-only	Writes at PL0 generate Permission faults
	11	Read/write	Read/write	Full access
1	00	-	-	Reserved
	01	Read-only	No access	Read-only, only at PL1 or higher
	10	Read-only	Read-only	Read-only at any exception level, deprecated[a]
	11	Read-only	Read-only	Read-only at any exception level[b]

a. From VMSAv7, ARM strongly recommends use of the `0b11` encoding for Read-only at any exception level.

b. This mapping was introduced in VMSAv7, and is reserved in earlier versions of the VMSA.

Note

- VMSAv8-32 supports the full set of access permissions shown in Table G4-11 on page G4-3667 only when SCTLR.AFE is set to 0. When SCTLR.AFE is set to 1, the only supported access permissions are those described in *AP[2:1] access permissions model* on page G4-3666.
- Some old documentation describes the AP[2] bit in the translation table entries as the APX bit.

G4.7.2 Execute-never restrictions on instruction fetching

Execute-never (XN) controls provide an additional level of control on memory accesses permitted by the access permissions settings. These controls are:

XN, Execute-never

When the XN bit is 1, a Permission fault is generated if the PE attempts to execute an instruction fetched from the corresponding memory region. However, when using the Short-descriptor translation table format, the fault is generated only if the access is to memory in the Client domain, see *Domains, Short-descriptor format only* on page G4-3670. A PE can execute instructions from a memory region only if the access permissions for its current state permit read access, and the XN bit is set to 0.

PXN, Privileged execute-never

When the PXN bit is 1, a Permission fault is generated if the PE is executing at PL1 and attempts to execute an instruction fetched from the corresponding memory region. As with the XN bit, when using the Short-descriptor translation table format, the fault is generated only if the access is to memory in the Client domain.

In both the Short-descriptor format and the Long-descriptor format translation tables, all descriptors for memory blocks and pages always include an XN bit.

Support for the PXN bit is as follows:

- The Long-descriptor translation table formats always include the PXN bit.
- All implementations must:
  - Support the use of the PXN bit.
  - Use the Short-descriptor translation table formats that include the PXN bit.

In the Non-secure PL2 stage 1 translation tables, the PXN bit is reserved, SBZ.

In addition, additional controls can enforce execute-never restrictions, regardless of the settings in the translation tables, see:

- *Restriction on Secure instruction fetch* on page G4-3669.
- *Preventing execution from writable locations* on page G4-3670.

The execute-never controls apply also to speculative instruction fetching. This means a speculative instruction fetch from a memory region that is execute-never at the current level of privilege is prohibited.

The XN control means that, when the stage of address translation is enabled, the PE can fetch, or speculatively fetch, an instruction from a memory location only if all of the following apply:

- If using the Short-descriptor translation table format, the translation table descriptor for the location does not indicate that it is in a No access domain.
- If using the Long-descriptor translation table format, or using the Short descriptor format and the descriptor indicates that the location is in a Client domain, in the descriptor for the location the following apply:
  - XN is set to 0.
  - The access permissions permit a read access from the current PE mode.
- No other Prefetch Abort condition exists.

Note

- The PXN control applies to the PE privilege when it attempts to execute the instruction. In an implementation that fetches instructions speculatively, this might not be the privilege when the instruction was prefetched. Therefore, the architecture does not require the PXN control to prevent instruction fetching.
- Although the XN control applies to speculative fetching, on a speculative instruction fetch from an XN location, no Permission fault is generated unless the PE attempts to execute the instruction fetched from that location. This means that, if a speculative fetch from an XN location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.
- The software that defines a translation table must mark any region of memory that is read-sensitive as XN, to avoid the possibility of a speculative fetch accessing the memory region. For example, it must mark any memory region that corresponds to a read-sensitive peripheral as XN.
- When using the Short-descriptor translation table format, the XN attribute is not checked for domains marked as Manager. Therefore, the system must not include read-sensitive memory in domains marked as Manager, because the XN bit does not prevent speculative fetches from a Manager domain.

When no stage of address translation for the translation regime is enabled, memory regions cannot have XN or PXN attributes assigned. *Behavior of instruction fetches when all associated address translations are disabled* on page G4-3627 describes how disabling all MMUs affects instruction fetching.

Hierarchical control of instruction fetching, Long-descriptor format

The Long-descriptor translation table format introduces a mechanism that means entries at one level of translation tables lookup can set limits on the permitted entries at subsequent levels of lookup. This applies to the restrictions on instruction fetching, and also to the access permissions described in *Hierarchical control of access permissions, Long-descriptor format* on page G4-3666.

The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

- XNTable restricts the XN control:
  - When XNTable is set to 1, the XN bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
  - When XNTable is set to 0 it has no effect.
- PXNTable restricts the PXN control:
  - When PXNTable is set to 1, the PXN bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
  - When PXNTable is set to 0 it has no effect.

Note

The XNTable and PXNTable settings are combined with the XN and PXN bits in the translation table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The XNTable and PXNTable controls are provided only in the Long-descriptor translation table format, and only for stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

When XNTable, or PXNTable, is set to 1, its effects might be held in one or more TLB entries. Therefore, a change to XNTable or PXNTable might require coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

Restriction on Secure instruction fetch

EL3 provides a Secure instruction fetch bit, SCR.SIF. When this bit is set to 1, any attempt in Secure state to execute an instruction fetched from Non-secure physical memory causes a Permission fault. As with all Permission fault checking, when using the Short-descriptor format translation tables the check applies only to Client domains, see *Access permissions* on page G4-3665.

ARM expects SCR.SIF to be static during normal operation. In particular, whether the TLB holds the effect of the SIF bit is IMPLEMENTATION DEFINED. The generic sequence to ensure visibility of a change to the SIF bit is:

```
Change the SCR.SIF bit
ISB                     ; This ensures synchronization of the change
Invalidate entire TLB
DSB                     ; This completes the TLB Invalidation
ISB                     ; This ensures instruction synchronization
```

Preventing execution from writable locations

The architecture includes control bits that, when the corresponding stage 1 address translation is enabled, force writable memory to be treated as XN, regardless of the setting of the XN bit. When the translation stages are controlled by an Exception level that is using AArch32:

- For PL1&0 stage 1 translations, when SCTLR.WXN is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN.
- For Non-secure PL2 stage 1 translations, when HSCTLR.WXN is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN.
- For PL1&0 stage 1 translations, when SCTLR.UWXN is set to 1, an instruction fetch is treated as accessing a PXN region if it accesses a region that software executing at PL0 can write to.

Note

Setting a WXN or UWXN bit to 1 changes the interpretation of the translation table entry, overriding a zero value of an XN or PXN field. It does not cause any change to the translation table entry.

For any given virtual machine, ARM expects WXN and UWXN to remain static in normal operation. In particular, it is IMPLEMENTATION DEFINED whether TLB entries associated with a particular VMID reflect the effect of the values of these bits. A generic sequence to ensure synchronization of a change to these bits, when that change is made without a corresponding change of VMID, is:

```
Change the WXN or UWXN bit
ISB                     ; This ensures synchronization of the change
Invalidate entire TLB of associated entries
DSB                     ; This completes the TLB Invalidation
ISB                     ; This ensures instruction synchronization
```

As with all Permission fault checking, if the stage 1 translation is using the Short-descriptor translation table format, the permission checks are performed only for Client domains. For more information see *Access permissions* on page G4-3665.

For more information about address translation see *About address translation for VMSAv8-32* on page G4-3621.

G4.7.3 Domains, Short-descriptor format only

A domain is a collection of memory regions. The Short-descriptor translation table format supports 16 domains, and requires the software that defines a translation table to assign each VMSAv8-32 memory region to a domain. When using the Short-descriptor format:

- Level 1 translation table entries for Page tables and Sections include a domain field.
- Translation table entries for Supersections do not include a domain field. The Short-descriptor format defines Supersections as being in domain 0.
- Level 2 translation table entries inherit a domain setting from the parent level 1 Page table entry.
- Each TLB entry includes a domain field.

The domain field specifies which of the 16 domains the entry is in, and a two-bit field in the DACR defines the permitted access for each domain. The possible settings for each domain are:

No access Any access using the translation table descriptor generates a Domain fault.

Clients On an access using the translation table descriptor, the access permission attributes are checked. Therefore, the access might generate a Permission fault.

Managers On an access using the translation table descriptor, the access permission attributes are not checked. Therefore, the access cannot generate a Permission fault.

See *The MMU fault-checking sequence* on page G4-3706 for more information about how, when using the Short-descriptor translation table format, the Domain attribute affects the checking of the other attributes in the translation table descriptor.

Note

A single program might:

- Be a Client of some domains.
- Be a Manager of some other domains.
- Have no access to the remaining domains.

The Long-descriptor translation table format does not support domains. When a stage of translation is using this format, all memory is treated as being in a Client domain, and the settings in the DACR are ignored.

G4.7.4 The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding translation table descriptor was set to 0:

- If address translation is using the Short-descriptor translation table format, it must set SCTLR.AFE to 1 to enable use of the Access flag. Setting this bit to 1 redefines the AP[0] bit in the translation table descriptors as an Access flag, and limits the access permissions information in the translation table descriptors to AP[2:1], as described in *AP[2:1] access permissions model* on page G4-3666.
- The Long-descriptor format always supports an Access flag bit in the translation table descriptors, and address translation using this format behaves as if SCTLR.AFE is set to 1, regardless of the value of that bit.

In ARMv8 the Access flag is managed by software as described in the following subsection.

Note

Previous version of the ARM architecture optionally supported hardware management of the Access flag. ARMv8 obsoletes this option.

Software management of the Access flag

An implementation that requires software to manage the Access flag generates an Access flag fault whenever a translation table entry with the Access flag set to 0 is read into the TLB

Note

When using the Short-descriptor translation table format, Access flag faults are generated only if SCTLR.AFE is set to 1, to enable use of a translation table descriptor bit as an Access flag.

The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.

G4.7.5 Hyp mode control of Non-secure access permissions

When EL2 is using AArch32, Non-secure software executing in Hyp mode controls two sets of translation tables, both of which use the Long-descriptor translation table format:

- The translation tables that control the Non-secure PL2 stage 1 translations. These map VAs to PAs, for memory accesses made when executing in Non-secure state in Hyp mode, and are indicated and controlled by the HTTBR and HTCR.

  These translations have similar access controls to other Non-secure stage 1 translations using the Long-descriptor translation table format, as described in:
  - *AP[2:1] access permissions model* on page G4-3666.
  - *Execute-never restrictions on instruction fetching* on page G4-3668.

  The differences from the Non-secure stage 1 translations are that:
  - The APTable[0], PXNTable, and PXN bits are reserved, SBZ.
  - AP[1] is reserved, SBO.

- The translation tables that control the Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, for memory accesses made when executing in Non-secure state at PL1 or PL0, and are indicated and controlled by the VTTBR and VTCR.

  The descriptors in the virtualization translation tables define a second level of access permissions, that are combined with the permissions defined in the stage 1 translation. This section describes this combining of access permissions.

Note

The level 2 access permissions mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:

- The Guest OS, in the stage 1 translation tables.
- The hypervisor, in the stage 2 translation tables.

The stage 2 access controls defined from Hyp mode:

- Affect only the Non-secure stage 1 access permissions settings.
- Take no account of whether the accesses are from a Non-secure PL1 mode or a Non-secure PL0 mode.
- Permit software executing in Hyp mode to assign a write-only attribute to a memory region.

The S2AP field in the stage 2 descriptors define the stage 2 access permissions, as Table G4-12 shows:

Table G4-12 Stage 2 control of access permissions

S2AP	Access permission
00	No access permitted
01	Read-only. Writes to the region are not permitted, regardless of the stage 1 permissions.
10	Write-only. Reads from the region are not permitted, regardless of the stage 1 permissions.
11	Read/write. The stage 1 permissions determine the access permissions for the region.

For more information about the S2AP field see *Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors* on page G4-3652.

If the stage 2 permissions cause a Permission fault, this is a stage 2 address translation fault. Stage 2 address translation faults are taken to Hyp mode, and reported in the HSR using an EC code of `0x20` or `0x24`. For more information, see *Use of the HSR* on page G4-3728.

Note

The combination of the EC code and the STATUS value in the HSR indicate that the fault is a stage 2 address translation fault.

The stage 2 permissions include an XN attribute. If this is set to 1, execution from the region is not permitted, regardless of the value of the XN attribute in the stage 1 translation. If a Permission fault is generated because the stage 2 XN bit is set to 1, this is reported as a stage 2 address translation fault.

Prioritization of aborts on page G4-3714 describes the abort prioritization if both stages of a translation generate a fault.

G4.8 Memory region attributes

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of that target memory region. *Information returned by a translation table lookup* on page G4-3630 describes the classification of those fields as address map control, access control, and memory attribute fields. The memory region attribute fields control the memory type, accesses to the caches, and whether the memory region is Shareable and therefore is coherent.

The following sections describe the assignment of memory region attributes for stage 1 translations:

- *Overview of memory region attributes for stage 1 translations*.
- *Short-descriptor format memory region attributes, without TEX remap* on page G4-3675.
- *Short-descriptor format memory region attributes, with TEX remap* on page G4-3676.
- *VMSAv8-32 Long-descriptor format memory region attributes* on page G4-3680.

For an implementation that is operating in Secure state, or in Hyp mode, these assignments define the memory attributes of the accessed region.

For an implementation that is operating in a Non-secure PL1 or PL0 mode, the Non-secure PL1&0 stage 2 translation can modify the memory attributes assigned by the stage 1 translation. *EL2 control of Non-secure memory region attributes* on page G4-3681 describes these stage 2 assignments.

G4.8.1 Overview of memory region attributes for stage 1 translations

The description of the memory region attributes in a translation descriptor divides into:

Memory type and attributes

These are described either:

- Directly, by bits in the translation table descriptor.
- Indirectly, by registers referenced by bits in the table descriptor. This is described as *remapping* the memory type and attribute description.

The Short-descriptor translation table format can use either of these approaches, selected by the SCTLR.TRE bit:

TRE == 0 Remap disabled. The TEX[2:0], C, and B bits in the translation table descriptor define the memory region attributes. *Short-descriptor format memory region attributes, without TEX remap* on page G4-3675 describes this encoding.

Note

With the Short-descriptor format, remapping is called *TEX remap*, and the SCTLR.TRE bit is the *TEX remap enabled* bit.

The description of the TRE == 0 encoding includes information about the encoding in previous versions of the architecture.

TRE == 1 Remap enabled. The TEX[0], C, and B bits in the translation table descriptor are index bits to the remap registers, that define the memory region attributes:

- The Primary Region Remap Register, PRRR.
- The Normal Memory Remap Register, NMRR.

Short-descriptor format memory region attributes, with TEX remap on page G4-3676 describes this encoding scheme.

This scheme reassigns translation table descriptor bits TEX[2:1] for use as bits managed by the operating system.

The Long-descriptor translation table format always uses remapping. This means VMSAv8-32 behaves as if the value of SCTLR.TRE is 1, regardless of the value that software has written to this bit.

Note

When use of the Long-descriptor format is enabled, SCTLR.TRE is UNK/SBOP.

VMSAv8-32 Long-descriptor format memory region attributes on page G4-3680 describes this encoding.

Shareability In the Short-descriptor translation table format, the S bit in the translation table descriptor encodes whether the region is shareable. Enabling TEX remap extends the shareability description. For more information see:

- *Shareability and the S bit, without TEX remap* on page G4-3676.
- *Shareability and the S bit, with TEX remap* on page G4-3678.

In the Long-descriptor translation table format, the SH[1:0] field in the translation table descriptor encodes shareability information. For more information see *Shareability, Long-descriptor format* on page G4-3680.

G4.8.2 Short-descriptor format memory region attributes, without TEX remap

When using the Short-descriptor translation table formats, TEX remap is disabled when SCTLR.TRE is set to 0.

Note

- The Short-descriptor format scheme without TEX remap is the scheme used in VMSAv6.
- The B (Bufferable), C (Cacheable), and TEX (Type extension) bit names are inherited from earlier versions of the architecture. These names no longer adequately describe the function of the B, C, and TEX bits.

Table G4-13 shows the C, B, and TEX[2:0] encodings when TEX remap is disabled:

Table G4-13 TEX, C, and B encodings when TRE == 0

TEX[2:0]	C	B	Description	Memory type	Page Shareable
000	0	0	Device-nGnRnE	Device-nGnRnE	Shareable
		1	Shareable Device-nGnRE[a]	Device-nGnRE	Shareable[a]
	1	0	Outer and Inner Write-Through, no Write-Allocate	Normal	S bit[b]
		1	Outer and Inner Write-Back, no Write-Allocate	Normal	S bit[b]
001	0	0	Outer and Inner Non-cacheable	Normal	S bit[b]
		1	Reserved	-	-
	1	0	IMPLEMENTATION DEFINED	IMPLEMENTATION DEFINED	IMPLEMENTATION DEFINED
		1	Outer and Inner Write-Back, Write-Allocate	Normal	S bit[b]
010	0	0	Non-shareable Device-nGnRE[a]	Device-nGnRE	Non-shareable[a]
		1	Reserved	-	-
	1	x	Reserved	-	-
011	x	x	Reserved	-	-
1BB	A	A	Cacheable memory: AA = Inner attribute[c] BB = Outer attribute	Normal	S bit[b]

a. Some implementations make no distinction between Shareable Device-nGnRE memory and Non-shareable Device-nGnRE memory, and refer to both memory types as Shareable Device-nGnRE memory.

b. For more information, see *Shareability and the S bit, without TEX remap* on page G4-3676.

c. For more information, see *Cacheable memory attributes, without TEX remap* on page G4-3676.

See *Memory types and attributes* on page E2-2273 for an explanation of Normal memory, and the types of Device memory, and of the shareability attribute.

Cacheable memory attributes, without TEX remap

When TEX[2] == 1, the memory described by the translation table entry is Cacheable, and the rest of the encoding defines the Inner and Outer cache attributes:

TEX[1:0] Define the Outer cache attribute.

C, B Define the Inner cache attribute.

The translation table entries use the same encoding for the Outer and Inner cache attributes, as Table G4-14 shows.

Table G4-14 Inner and Outer cache attribute encoding

Encoding	Cache attribute
00	Non-cacheable
01	Write-Back, Write-Allocate
10	Write-Through, no Write-Allocate
11	Write-Back, no Write-Allocate

Shareability and the S bit, without TEX remap

The translation table entries also include an S bit. This bit:

- Is ignored if the entry refers to any type of Device memory.
- For Normal memory, determines whether the memory region is Shareable or Non-shareable:

  S == 0 Normal memory region is Non-shareable.

  S == 1 Normal memory region is Shareable.

G4.8.3 Short-descriptor format memory region attributes, with TEX remap

When using the Short-descriptor translation table formats, TEX remap is enabled when SCTLR.TRE is set to 1. In this configuration:

- The software that defines the translation tables must program the PRRR and NMRR to define seven possible memory region attributes.
- The TEX[0], C, and B bits of the translation table descriptors define the memory region attributes, by indexing PRRR and NMRR.
- Hardware makes no use TEX[2:1], see *The OS managed translation table bits* on page G4-3679.

When TEX remap is enabled:

- For seven of the eight possible combinations of the TEX[0], C and B bits, fields in the PRRR and NMRR define the region attributes, as described in this section.
- The meaning of the eighth combination for the TEX[0], C and B bits is IMPLEMENTATION DEFINED.
- Four bits in the PRRR define whether the region is shareable, as described in *Shareability and the S bit, with TEX remap* on page G4-3678.

For each of the possible encodings of the TEX[0], C, and B bits in a translation table entry, Table G4-15 shows which fields of the PRRR and NMRR registers describe the memory region attributes.

Table G4-15 TEX, C, and B encodings when TRE == 1

Encoding			Memory type[a]	Cache attributes[a, b]:		Outer Shareable attribute[a, c]
TEX[0]	C	B		Inner cacheability	Outer cacheability	
0	0	0	PRRR[1:0]	NMRR[1:0]	NMRR[17:16]	NOT(PRRR[24])
		1	PRRR[3:2]	NMRR[3:2]	NMRR[19:18]	NOT(PRRR[25])
	1	0	PRRR[5:4]	NMRR[5:4]	NMRR[21:20]	NOT(PRRR[26])
		1	PRRR[7:6]	NMRR[7:6]	NMRR[23:22]	NOT(PRRR[27])
1	0	0	PRRR[9:8]	NMRR[9:8]	NMRR[25:24]	NOT(PRRR[28])
		1	PRRR[11:10]	NMRR[11:10]	NMRR[27:26]	NOT(PRRR[29])
	1	0	IMPLEMENTATION DEFINED			
		1	PRRR[15:14]	NMRR[15:14]	NMRR[31:30]	NOT(PRRR[31])

a. For details of the *Memory type* and *Outer Shareable* encodings see *PRRR, Primary Region Remap Register* on page G5-4052. For details of the *Cache attributes* encodings see Table G4-14 on page G4-3676.

b. Applies only if the memory type for the region is mapped as Normal memory.

c. Applies only if the memory type for the region is mapped as Normal or Device-nGnRE memory and the region is Shareable.

The TEX remap registers and the SCTLR.TRE bit are Banked between the Secure and Non-secure Security states. For more information, see *The effect of EL3 on TEX remap* on page G4-3680.

When TEX remap is enabled, the mappings specified by the PRRR and NMRR determine the mapping of the TEX[0], C and B bits in the translation tables to memory type and cacheability attributes:

1. The primary mapping, indicated by a field in the PRRR as shown in the *Memory type* column of Table G4-15, takes precedence.
2. For any region that the PRRR maps as Normal memory, the NMRR determines the Inner cacheability and Outer cacheability attributes.
3. If it is supported, the Outer Shareable mapping identifies Shareable memory as either Inner Shareable or Outer Shareable, see *Interpretation of the NOSn fields in the PRRR, with TEX remap* on page G4-3678.

The TEX remap registers must be static during normal operation. In particular, when the remap registers are changed:

- It is IMPLEMENTATION DEFINED when the changes take effect.
- It is UNPREDICTABLE whether the TLB caches the effect of the TEX remap on translation tables.

The software sequence to ensure the synchronization of changes to the TEX remap registers is:

1. Execute a `DSB` instruction. This ensures any memory accesses using the old mapping have completed.
2. Write the TEX remap registers or SCTLR.TRE bit.
3. Execute an `ISB` instruction. This ensures synchronization of the register updates.
4. Invalidate the entire TLB.
5. Execute a `DSB` instruction. This ensures completion of the entire TLB operation.
6. Clean and invalidate all caches. This removes any cached information associated with the old mapping.
7. Execute a `DSB` instruction. This ensures completion of the cache maintenance.
8. Execute an `ISB` instruction. This ensures instruction synchronization.

This extends the standard rules for the synchronization of changes to System registers described in *Synchronization of changes to System registers* on page G4-3757, and provides implementation freedom as to whether or not the effect of the TEX remap is cached.

Shareability and the S bit, with TEX remap

The memory type of a region, as indicated in the Memory type column of Table G4-15 on page G4-3677, provides the first level of control of whether the region is shareable:

- If using the Long-descriptor translation table format, if the memory is any type of Device memory then the region is Shareable.
- If using the Short descriptor translation table format then:
  - If the memory is Device-nGnRnE memory then the region is Shareable.
  - Otherwise, the shareability is determined by using the value of the S bit in the translation table descriptor to index bits in the PRRR.

  Some implementations make no distinction between Shareable Device-nGnRE memory and Non-shareable Device-nGnRE memory, and refer to both memory types as Shareable Device memory.
- If the memory type is Normal then the shareability is determined by using the value of the S bit in the translation table descriptor to index bits in the PRRR.

Table G4-16 shows this determination:

Table G4-16 Determining shareability, with TEX remap

Memory type	Remapping when S == 0	Remapping when S == 1
Any type of Device	Shareable	Shareable
Normal	PRRR[18]	PRRR[19]

In the cases where the shareability is remapped, the appropriate bit of the PRRR indicates whether the region is Shareable or Non-shareable, as follows:

PRRR[n] == 0 Not shareable.

PRRR[n] == 1 Shareable.

Note

When TEX remap is enabled, a translation table entry with S == 0 can be mapped as Shareable memory.

Interpretation of the NOSn fields in the PRRR, with TEX remap

When all of the following apply, the NOSn fields in the PRRR distinguish between Inner Shareable and Outer Shareable memory regions:

- The SCTLR.TRE bit is set to 1.
- The region is mapped as Normal memory, or the Short-descriptor translation table format is used and the region is mapped as Device-nGnRE memory.
- The Normal memory remapping or Device-nGnRE memory remapping of the S bit value for the entry makes the region Shareable.
- The implementation supports the distinction between Inner Shareable and Outer Shareable.

If the SCTLR.TRE bit is set to 0, an implementation can provide an IMPLEMENTATION DEFINED mechanism to interpret the NOSn fields in the PRRR, see *SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers* on page G4-3679.

The values of the NOSn fields in the PRRR have no effect.

The NOSn fields in the PRRR are RAZ/WI if the implementation does not support the distinction between Inner Shareable and Outer Shareable memory regions.

Note

The meaning of shareability attributes for Device-nGnRE memory is IMPLEMENTATION DEFINED when the Short-descriptor translation table is used, and otherwise has no meaning.

SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers

When TEX remap is disabled, because the SCTLR.TRE bit is set to 0:

- The effect of the PRRR and NMRR registers can be IMPLEMENTATION DEFINED.
- The interpretation of the fields of the PRRR and NMRR registers can differ from the description given earlier in this section.

VMSAv8-32 requires that the effect of these registers is limited to remapping the attributes of memory locations. These registers must not change whether any cache hardware or stages of address translation are enabled. The mechanism by which the TEX remap registers have an effect when the SCTLR.TRE bit is set to 0 is IMPLEMENTATION DEFINED. The AArch32 architecture requires that from reset, if the IMPLEMENTATION DEFINED mechanism has not been invoked:

- If the PL1&0 stage 1 address translation is enabled and is using the Short-descriptor format translation tables, the architecturally-defined behavior of the TEX[2:0], C, and B bits must apply, without reference to the TEX remap functionality. In other words, memory attribute assignment must comply with the scheme described in *Short-descriptor format memory region attributes, without TEX remap* on page G4-3675.
- If the PL1&0 stage 1 address translation is disabled, then the architecturally-defined behavior of VMSAv8-32 with address translation disabled must apply, without reference to the TEX remap functionality. See *The effects of disabling address translation stages on VMSAv8-32 behavior* on page G4-3625.

Possible mechanisms for enabling the IMPLEMENTATION DEFINED effect of the TEX remap registers when SCTLR.TRE is set to 0 include:

- A control bit in the ACTLR, or in an IMPLEMENTATION DEFINED System register.
- Changing the behavior when the PRRR and NMRR registers are changed from their IMPLEMENTATION DEFINED reset values.

In addition, if the stage of address translation is disabled and the SCTLR.TRE bit is set to 1, the architecturally-defined behavior of the VMSAv8-32 with the stage of address translation disabled must apply without reference to the TEX remap functionality.

In an implementation that includes EL3, the IMPLEMENTATION DEFINED effect of these registers must only take effect in the Security state of the registers. See also *The effect of EL3 on TEX remap* on page G4-3680.

The OS managed translation table bits

When TEX remap is enabled, the TEX[2:1] bits in the translation table descriptors are available as two bits that can be managed by the operating system. In VMSAv8-32, as long as the SCTLR.TRE bit is set to 1, the values of the TEX[2:1] bits are ignored by the memory management hardware. Software can write any value to these bits in the translation tables.

The effect of EL3 on TEX remap

In an implementation that includes EL3, the TEX remap registers are Banked between the Secure and Non-secure Security states. The register instances for the current security state apply to all PL1&0 stage 1 translation table lookups in that state. The SCTLR.TRE bit is Banked in the Secure and Non-secure copies of the register, and the appropriate version of this bit determines whether TEX remap is applied to translation table lookups in the current security state.

Write accesses to the Secure copies of the TEX remap registers are disabled when the **CP15SDISABLE** input is asserted HIGH, meaning the MCR operations to access these registers are UNDEFINED. For more information, see *The CP15SDISABLE input* on page G4-3755.

G4.8.4 VMSAv8-32 Long-descriptor format memory region attributes

When a PE is using the VMSAv8-32 Long-descriptor translation table format, the AttrIndx[2:0] field in a block or page translation table descriptor for a stage 1 translation indicates the 8-bit field in the appropriate MAIR register, that specifies the attributes for the corresponding memory region, as follows:

- AttrIndx[2] indicates the MAIR register to be used:

  AttrIndx[2] == 0 Use MAIR0.

  AttrIndx[2] == 1 Use MAIR1.

- AttrIndx[2:0] indicates the required Attr field, Attr*n*, where *n* = AttrIndx[2:0].

Each AttrIndx field defines, for the corresponding memory region:

- The memory type, Normal or a type of Device memory.
- For Normal memory:
  - The inner and outer cacheability, Non-cacheable, Write-Through, or Write-Back.
  - For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is *Allocate* or *Do not allocate*.

For more information about the AttrIndx[2:0] descriptor field, see *Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors* on page G4-3651.

Shareability, Long-descriptor format

When a PE is using the Long-descriptor translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region, if the MAIR entry for that region identifies it as Normal memory. Table G4-17 shows the encoding of this field.

Table G4-17 SH[1:0] field encoding for Normal memory, Long-descriptor format

SH[1:0]	Normal memory
00	Non-shareable
01	UNPREDICTABLE
10	Outer Shareable
11	Inner Shareable

See *Combining the shareability attribute* on page G4-3685 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

For any type of Device memory, the value of the SH[1:0] field of the translation table descriptor is ignored.

Other fields in the Long-descriptor translation table format descriptors

The following subsections describe the other fields in the translation table block and page descriptors when a PE is using the Long-descriptor translation table format:

- *Contiguous bit*
- *Field reserved for software use*
- *Ignored fields*.

Contiguous bit

The Long-descriptor translation table format descriptors contain a Contiguous bit. Setting this bit to 1 indicates that 16 adjacent translation table entries point to a *contiguous output address range*. These 16 entries must be aligned in the translation table so that the top five bits of their input addresses, that index their position in the translation table, are the same. For example, referring to Figure G4-21 on page G4-3663, to use this hint for a block of 16 entries in the level 3 translation table, bits[20:16] of the input addresses for the 16 entries must be the same.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

Use of this bit means that the TLB can cache a single entry to cover the 16 translation table entries.

This bit acts as a hint. The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of this bit.

Note

The use of the contiguous bit is similar to the approach used, in the Short-descriptor translation table format, for optimized caching of Large Pages and Supersections in the TLB. However, an important difference in the contiguous bit capability is that TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues. That is, any use of the contiguous bit has no effect on the minimum size of entry that must be invalidated from the TLB.

Field reserved for software use

The architecture reserves a 4-bit field in the Block and Page table descriptors for software use. In considering migration from using the Short-descriptor format to the Long-descriptor format, this field is an extension of the Short-descriptor field described in *The OS managed translation table bits* on page G4-3679.

Ignored fields

For stage 1 translation descriptors, the architecture defines a 4-bit Ignored field in the Block and Page table descriptors, bit[63:59], and guarantees that the PE will not alter the value of this field. For stage 2 translation descriptors, the corresponding field is reserved for use by a System MMU. In a PE that is using the Long-descriptor translator table format, this field is an ignored field and the architecture guarantees that the PE does not update the field.

G4.8.5 EL2 control of Non-secure memory region attributes

Software executing at EL2 controls two sets of translation tables, both of which use the Long-descriptor translation table format. These are:

- The translation tables that control Non-secure PL2 stage 1 translations. These map VAs to PAs, and when EL2 is using AArch32 they are indicated and controlled by the HTTBR and HTCR.

  These translations have exactly the same memory region attribute controls as any other stage 1 translations, as described in *VMSAv8-32 Long-descriptor format memory region attributes* on page G4-3680.

- The translation tables that control Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, and are indicated and when EL2 is using AArch32 they are controlled by the VTTBR and VTCR.

The descriptors in the virtualization translation tables define a second level of memory region attributes, that are combined with the attributes defined in the stage 1 translation. This section describes this combining of attributes.

VMSAv8-32 Long-descriptor translation table format descriptors on page G4-3648 describes the format of the entries in these tables.

Note

In a virtualization implementation, a hypervisor might usefully:

- Reduce the permitted cacheability of a region.
- Increase the required shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

In the stage 2 translation table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- The definition of the stage 2 SH[1:0] field is identical to the same field for a stage 1 translation, see *Shareability, Long-descriptor format* on page G4-3680.
- MemAttr[3:2] give a top level definition of the memory type, and of the cacheability of a Normal memory region, as Table G4-18 shows:

Table G4-18 Long-descriptor MemAttr[3:2] encoding, stage 2 translation

MemAttr[3:2]	Memory type	Cacheability
00	Device, of type determined by MemAttr[1:0]	Not applicable
01	Normal	Outer Non-cacheable
10		Outer Write-Through Cacheable
11		Outer Write-Back Cacheable

The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

— When MemAttr[3:2]==`0b00`, indicating a type of Device memory, Table G4-19 shows the encoding of MemAttr[1:0]:

Table G4-19 MemAttr[1:0] encoding for the types of Device memory

MemAttr[1:0]	Meaning when MemAttr[3:2] == `0b00`
00	Region is Device-nGnRnE memory
01	Region is Device-nGnRE memory
10	Region is Device-nGRE memory
11	Region is Device-GRE memory

— When MemAttr[3:2]!=0b00, indicating Normal memory, Table G4-20 shows the encoding of MemAttr[1:0]:

Table G4-20 MemAttr[1:0] encoding for Normal memory

MemAttr[1:0]	Meaning when MemAttr[3:2] != 0b00
00	UNPREDICTABLE
01	Inner Non-cacheable
10	Inner Write-Through Cacheable
11	Inner Write-Back Cacheable

Note

The stage 2 translation does not assign any allocation hints.

The following sections describe how the memory type attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

- *Combining the memory type attribute*.
- *Combining the cacheability attribute* on page G4-3684.
- *Combining the shareability attribute* on page G4-3685.

Note

The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:

- MemAttr[3:2] == 0b11, Normal memory, Outer Write-Back Cacheable.
- MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.

Combining the memory type attribute

Table G4-21 shows how the stage 1 and stage 2 memory type assignments are combined:

Table G4-21 Combining the stage 1 and stage 2 memory type assignments

Assignment in stage 1	Assignment in stage 2	Resultant type
Device-nGnRnE	Any	Device-nGnRnE
Device-nGnRE	Device-nGnRnE	Device-nGnRnE
	Not Device-nGnRnE	Device-nGnRE
Device-nGRE	Device-nGnRnE	Device-nGnRnE
	Device-nGnRE	Device-nGnRE
	Not (Device-nGnRnE or Device-nGnRE)	Device-nGRE

Table G4-21 Combining the stage 1 and stage 2 memory type assignments (continued)

Assignment in stage 1	Assignment in stage 2	Resultant type
Device-GRE	Device-nGnRnE	Device-nGnRnE
	Device-nGnRE	Device-nGnRE
	Device-nGRE	Device-nGRE
	Device-GRE or Normal	Device-GRE
Normal	Any type of Device	Device type assigned at stage 2
	Normal	Normal

See *Combining the shareability attribute* on page G4-3685 for information about:

- The shareability of a region for which the resultant type is any Device type.
- The shareability requirements of a region with a resultant type of Normal for which the resultant cacheability, described in *Combining the cacheability attribute*, is Inner Non-cacheable, Outer Non-cacheable.

The combining of the memory type attribute means a translation table walk for a stage 1 translation can be made to type of Device memory. This is likely to indicate a Guest OS error, and setting the HCR.PTW bit to 1 causes such an access to generate a Translation fault, see *Stage 2 fault on a stage 1 translation table walk* on page G4-3710.

Combining the cacheability attribute

For a Normal memory region, Table G4-22 shows how the stage 1 and stage 2 cacheability assignments are combined. This combination applies, independently, for the Inner cacheability and Outer cacheability attributes:

Table G4-22 Combining the stage 1 and stage 2 cacheability assignments

Assignment in stage 1	Assignment in stage 2	Resultant cacheability
Non-cacheable	Any	Non-cacheable
Any	Non-cacheable	Non-cacheable
Write-Through Cacheable	Write-Through or Write-Back Cacheable	Write-Through Cacheable
Write-Through or Write-Back Cacheable	Write-Through Cacheable	Write-Through Cacheable
Write-Back Cacheable	Write-Back Cacheable	Write-Back Cacheable

Note

Only Normal memory has a cacheability attribute.

Combining the shareability attribute

A memory region for which the resultant memory type attribute, described in *Combining the memory type attribute on page G4-3683*, is any type of Device memory, is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation.

For a memory region with a resultant memory type attribute of Normal, Table G4-23 shows how the stage 1 and stage 2 shareability assignments are combined:

Table G4-23 Combining the stage 1 and stage 2 shareability assignments

Assignment in stage 1	Assignment in stage 2	Resultant shareability
Outer Shareable	Any	Outer Shareable
Inner Shareable	Outer Shareable	Outer Shareable
Inner Shareable	Inner Shareable	Inner Shareable
Inner Shareable	Non-shareable	Inner Shareable
Non-shareable	Outer Shareable	Outer Shareable
Non-shareable	Inner Shareable	Inner Shareable
Non-shareable	Non-shareable	Non-shareable

A memory region with a resultant memory type attribute of Normal, and a resultant cacheability attribute of Inner Non-cacheable, Outer Non-cacheable, must have a resultant shareability attribute of Outer Shareable, otherwise shareability is UNPREDICTABLE.

G4.9 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement to perform a translation table walk in memory for every memory access. The ARM architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.
- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.
- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.
- The architecture guarantees that a translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault is not held in the TLB. However a translation table entry that generates a Domain fault or a Permission fault might be held in the TLB.
- Any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault and is not out of context might be allocated to an enabled TLB at any time. The only translation table entries guaranteed not to be held in the TLB are those that generate a Translation fault, an Address size fault, or an Access flag fault.

  Note

  An enabled TLB can hold translation table entries that do not generate a Translation fault but point to subsequent tables in the translation table walk. This can be referred to as *intermediate caching* of TLB entries.

- Software can rely on the fact that between disabling and re-enabling a stage of address translation, entries in the TLB relating to that stage of translation have not have been corrupted to give incorrect translations.

The following sections give more information about TLB implementation:

- *Global and process-specific translation table entries*.
- *TLB matching* on page G4-3687.
- *TLB behavior at reset* on page G4-3687.
- *TLB lockdown* on page G4-3687.
- *TLB conflict aborts* on page D4-1733.

See also *TLB maintenance requirements* on page G4-3689.

G4.9.1 Global and process-specific translation table entries

For VMSAv8-32, system software can divide a virtual memory map used by memory accesses at PL1 and PL0 into global and non-global regions, indicated by the nG bit in the translation table descriptors:

nG == 0 The translation is global, meaning the region is available for all processes.

nG == 1 The translation is non-global, or process-specific, meaning it relates to the current ASID, as defined by the CONTEXTIDR.

Each non-global region has an associated *Address Space Identifier* (ASID). These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.

For a symmetric multiprocessor cluster where a single operating system is running on the set of PEs, the architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all PEs in the system.

The translation regime used for accesses made at PL2 does not support ASIDs, and all pages are treated as global.

When a PE is using the Long-descriptor translation table format, and is in Secure state, a translation must be treated as non-global, regardless of the value of the nG bit, if NSTable is set to 1 at any level of the translation table walk.

For more information see *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format* on page G4-3653.

G4.9.2 TLB matching

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance instructions described in *TLB maintenance requirements* on page G4-3689 can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular ASID and VMID are changed without suitable invalidation of the TLB. This is an issue regardless of whether or not the translation table entries are global. In some cases, the TLB can hold two mappings for the same address, and this might lead to UNPREDICTABLE behavior

G4.9.3 TLB behavior at reset

The architecture does not require a reset to invalidate the TLBs, and recognizes that an implementation might require caches, including TLBs, to maintain context over a system reset. Possible reasons for doing so include power management and debug requirements.

The architectural requirements for TLB behavior at reset are:

- All TLBs are disabled from reset. All stages of address translation that are used from the processor state entered on coming out of reset are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information see *Enabling stages of address translation* on page G4-3628.
- An implementation can require the use of a specific TLB *invalidation routine*, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device.

  ARM recommends that if an invalidation routine is required for this purpose, and the PE resets into AArch32 state, the routine is based on the AArch32 TLB maintenance instructions described in *The scope of TLB maintenance instructions* on page G4-3696.
- When TLBs that have not been invalidated by some mechanism since reset are enabled, the state of those TLBs is UNPREDICTABLE.

Similar rules apply:

- To cache behavior, see *Behavior of caches at reset* on page G3-3583.
- To branch predictor behavior, see *Behavior of the branch predictors at reset* on page G3-3591.

G4.9.4 TLB lockdown

The ARM architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

- The architecture does not require TLB lockdown support.
- If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.

This means that:

- The TLB Type Register, TLBTR, does not define the lockdown scheme in use.
- In AArch32 state, a region of the CP15 c10 encodings is reserved for IMPLEMENTATION DEFINED TLB functions, such as TLB lockdown functions. The reserved encodings are those with:
  - `<CRm>` == {c0, c1, c4, c8}.
  - All values of `<opc2>` and `<opc1>`.

  See also *VMSAv8-32 CP15 c10 register summary* on page G4-3771.

An implementation might use some of the CP15 c10 encodings that are reserved for IMPLEMENTATION DEFINED TLB functions to implement additional TLB control functions. These functions might include:

- Unlock all locked TLB entries.
- Preload into a specific level of TLB. This is beyond the scope of the `PLI` and `PLD` hint instructions.

The inclusion of EL2 in an implementation does not affect the TLB lockdown requirements. However, in an implementation that includes EL2, exceptions generated by problems related to TLB lockdown, in a Non-secure PL1 mode, can be routed to either:

- Non-secure Abort mode, using the Non-secure Data Abort exception vector.
- Hyp mode, using the Hyp Trap exception vector.

For more information, see *Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations* on page G1-3490.

G4.9.5 TLB conflict aborts

Fault status encodings for TLB conflict aborts are defined for both the Short-descriptor and Long-descriptor translation table formats, see:

- *PL1 fault reporting with the Short-descriptor translation table format* on page G4-3719
- *PL1 fault reporting with the Long-descriptor translation table format* on page G4-3721.

An implementation can generate a TLB conflict abort if it detects that the address being looked up in the TLB hits multiple entries. This can happen if the TLB has been invalidated inappropriately, for example if TLB invalidation required by this manual has not been performed. If it happens, the resulting behavior is UNPREDICTABLE, but must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Privilege level.

In some implementations, multiple hits in the TLB can generate a synchronous Data Abort or Prefetch Abort exception. In any case where this is possible it is IMPLEMENTATION DEFINED whether the abort is a stage 1 abort or a stage 2 abort.

Note

A stage 2 abort cannot be generated if the Non-secure PL1&0 stage 2 address translation is disabled.

The priority of the TLB conflict abort is IMPLEMENTATION DEFINED, because it depends on the form of any TLB that can generate the abort.

Note

The TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses.

On a TLB conflict abort, the fault address register returns the address that generated the fault. That is, it returns the address that was being looked up in the TLB.

G4.10 TLB maintenance requirements

Translation Lookaside Buffers (TLBs) on page G4-3686 describes the ARM architectural provision for TLBs. Although the ARM architecture does not specify the form of any TLB structures, it does define the mechanisms by which TLBs can be maintained.The following sections describe the VMSAv8-32 TLB maintenance instructions:

- *General TLB maintenance requirements*.
- *Maintenance requirements on changing System register values* on page G4-3692.
- *Atomicity of register changes on changing virtual machine* on page G4-3693.
- *Synchronization of changes of ASID and TTBR* on page G4-3694.
- *The scope of TLB maintenance instructions* on page G4-3696.

G4.10.1 General TLB maintenance requirements

TLB maintenance instructions provide a mechanism to invalidate entries from a TLB. As stated at the start of *Translation Lookaside Buffers (TLBs)* on page G4-3686, any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault might be allocated to an enabled TLB at any time. This means that software must perform TLB maintenance between updating translation table entries that apply in a particular context and accessing memory locations whose translation is determined by those entries in that context.

Note

This requirement applies to any translation table entry at any level of the translation tables, including an entry that points to further levels of the tables, provided that the entry in that level of the tables does not cause a Translation fault, an Address size fault, or an Access flag fault.

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory, software must ensure that any cached copies of affected locations are removed from the caches. For more information see *Cache maintenance requirement created by changing translation table attributes* on page G4-3702.

Because a TLB never holds any translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault, a change from a translation table entry that causes a Translation, Address size, or Access flag fault to one that does not fault, does not require any TLB or branch predictor invalidation.

In addition, software must perform TLB maintenance after updating the System registers if the update means that the TLB might hold information that applies to a current translation context, but is no longer valid for that context. *Maintenance requirements on changing System register values* on page G4-3692 gives more information about this maintenance requirement.

Each of the translation regimes defined in Figure G4-1 on page G4-3619 is a different context, and:

- For the Non-secure PL1&0 regime, a change in the VMID or ASID value changes the context.
- For the Secure PL1&0 regime, a change in the ASID value changes the context.

For operation in Non-secure PL1 or PL0 modes, a change of HCR.VM, unless made at the same time as a change of VMID, requires the invalidation of all TLB entries for the Non-secure PL1&0 translation regime that apply to the current VMID. Otherwise, there is no guarantee that the effect of the change of HCR.VM is visible to software executing in the Non-secure PL1 and PL0 modes.

Any TLB operation can affect any other TLB entries that are not locked down.

AArch32 state defines CP15 c8 functions for TLB maintenance instructions, and supports the following operations:

- Invalidate all unlocked entries in the TLB.
- Invalidate a single TLB entry, by VA, or VA and ASID for a non-global entry.
- Invalidate all TLB entries that match a specified ASID.
- Invalidate all TLB entries that match a specified VA, regardless of the ASID.
- Operations that apply across multiprocessors in the same Inner Shareable domain.

  Note

  An address-based TLB maintenance instruction that applies to the Inner Shareable domain does so regardless of the Shareability attributes of the address supplied as an argument to the operation.

A TLB maintenance instruction that specifies a virtual address that would generate any MMU fault, including a virtual address that is not in the range of virtual addresses that can be translated, does not generate an abort.

EL2 provides additional TLB maintenance instructions for use in AArch32 state at PL2, and has some implications for the effect of the other TLB maintenance instructions, see *The scope of TLB maintenance instructions* on page G4-3696.

In an implementation that includes EL3, the TLB operations take account of the current Security state, as part of the address translation required for the TLB operation.

Some TLB operations are defined as operating only on instruction TLBs, or only on data TLBs. ARMv8 AArch32 state includes these operations for backwards compatibility. However, more recent TLB operations do not support this distinction. From the introduction of ARMv7, ARM deprecates any use of Instruction TLB operations, or of Data TLB operations, and developers must not rely on this distinction being maintained in future revisions of the ARM architecture.

The ARM architecture does not dictate the form in which the TLB stores translation table entries. However, for TLB invalidate operations, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

The scope of TLB maintenance instructions on page G4-3696 describes the TLB operations.

The interaction of TLB lockdown with TLB maintenance instructions

The precise interaction of TLB lockdown with the TLB maintenance instructions is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance instructions must comply with these rules:

- The effect on locked entries of a TLB invalidate all unlocked entries operation or a TLB invalidate by VA all ASID operation is IMPLEMENTATION DEFINED. However, these operations must implement one of the following options:
  - Have no effect on entries that are locked down.
  - Generate an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down. For an invalidate operation performed in AArch32 state, the CP15 c5 fault status register definitions include a fault code for cache and TLB lockdown faults, see Table G4-26 on page G4-3720 for the codes used with the Short-descriptor translation table formats, or Table G4-27 on page G4-3721 for the codes used with the Long-descriptor translation table formats.

    In an implementation that includes EL2, if EL2 is using AArch32 and the value of HCR.TIDCP is 1, any such exceptions taken from a Non-secure PL1 mode are routed to Hyp mode, see *Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations* on page G1-3490.

  This permits a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.
- The effect on locked entries of a TLB invalidate by VA operation or a TLB invalidate by ASID match operation is IMPLEMENTATION DEFINED. However, these operations must implement one of the following options:
  - A locked entry is invalidated in the TLB.
  - The operation has no effect on a locked entry in the TLB. In the case of the Invalidate single entry by VA, this means the PE treats the operation as a NOP.
  - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down. For an invalidate operation performed in AArch32 state, the CP15 c5 fault status register definitions include a fault code for cache and TLB lockdown faults, see Table G4-26 on page G4-3720 and Table G4-27 on page G4-3721.

Note

Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other specified alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined operations. This minimizes the number of customized operations required.

In addition, an implementation that uses an abort mechanism for handling TLB maintenance instructions on entries that can be locked down but are not actually locked down must also must provide a mechanism that ensures that no TLB entries are locked.

Similar rules apply to cache lockdown, see *The interaction of cache lockdown with cache maintenance instructions on page G3-3598*.

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side-effect of a TLB maintenance instruction, any unlocked entry in the TLB might be invalidated.

TLB maintenance instructions and the memory order model

The following rules describe the relations between the memory order model and the TLB maintenance instructions:

- A TLB invalidate operation is complete when all memory accesses using the invalidated TLB entries have been observed by all observers, to the extent that those accesses must be observed. The shareability and cacheability of the accessed memory locations determine the extent to which the accesses must be observed.

  In addition, once the TLB invalidate operation is complete, no new memory accesses that can be observed by those observers will be performed using the invalidated TLB entries.

  For a TLB invalidate operation that affects other PEs, the set of memory accesses that have been observed when the TLB maintenance instruction is complete.must include the memory accesses from those processes that used the invalidated TLB entries.
- A TLB maintenance instruction is only guaranteed to be complete after the execution of a `DSB` instruction.
- An `ISB` instruction, or a return from an exception, causes the effect of all completed TLB maintenance instructions that appear in program order before the `ISB` or return from exception to be visible to all subsequent instructions, including the instruction fetches for those instructions.
- An exception causes all completed TLB maintenance instructions, that appear in the instruction stream before the point where the exception is taken, to be visible to all subsequent instructions, including the instruction fetches for those instructions.
- All TLB maintenance instructions are executed in program order relative to each other.
- The execution of a Data or Unified TLB maintenance instruction is only guaranteed to be visible to a subsequent explicit load or store operation after both:
  - The execution of a `DSB` instruction to ensure the completion of the TLB operation.
  - Execution of a subsequent *Context synchronization operation*.
- The execution of an Instruction or Unified TLB maintenance instruction is only guaranteed to be visible to a subsequent instruction fetch after both:
  - The execution of a `DSB` instruction to ensure the completion of the TLB operation.
  - Execution of a subsequent *Context synchronization operation*.

The following rules apply when writing translation table entries. They ensure that the updated entries are visible to subsequent accesses and cache maintenance instructions.

For TLB maintenance, the translation table walk is treated as a separate observer. This means:

- A write to the translation tables, after it has been cleaned from the cache if appropriate, is only guaranteed to be seen by a translation table walk caused by an explicit load or store after the execution of both a `DSB` and an `ISB`.

  However, the architecture guarantees that any writes to the translation tables are not seen by any explicit memory access that occurs in program order before the write to the translation tables.

- A write to the translation tables, after it has been cleaned from the cache if appropriate, is only guaranteed to be seen by a translation table walk caused by the instruction fetch of an instruction that follows the write to the translation tables after both a `DSB` and an `ISB`.

Therefore, in a uniprocessor system, an example instruction sequence for writing a translation table entry, covering changes to the instruction or data mappings is:

```
STR rx, [Translation table entry]          ; write new entry to the translation table
DSB            ; ensures visibility of the data cleaned from the D Cache
Invalidate TLB entry by VA (and ASID if non-global) [page address]
Invalidate BTC
DSB            ; ensure completion of the Invalidate TLB operation
ISB            ; ensure table changes visible to instruction fetch
```

G4.10.2 Maintenance requirements on changing System register values

The TLB contents can be influenced by control bits in a number of System registers. This means the TLB must be invalidated after any changes to these bits, unless the changes are accompanied by a change to the VMID or ASID that defines the context to which the bits apply. The general form of the required invalidation sequence is as follows:

```
; Change control bits in System registers
ISB        ; Synchronize changes to the control bits
; Perform TLB invalidation of all entries that might be affected by the changed control bits
```

The System register changes that this applies to are:

- Any change to the NMRR, PRRR, MAIR0,MAIR1, HMAIR0 or HMAIR1 registers.
- Any change to the SCTLR.AFE bit, see *Changing the Access flag enable* on page G4-3693.
- Any change to any of the SCTLR.{TRE, WXN, UWXN} bits.
- Any change to the Translation table base 0 address in TTBR0.
- Any change to the Translation table base 1 address in TTBR1.
- Any change to HTTBR.BADDR.
- Any change to VTTBR.BADDR.
- Changing TTBCR.EAE, see *Changing the current Translation table format* on page G4-3693.
- In an implementation that includes EL3, any change to the SCR.SIF bit.
- In an implementation that includes EL2:
  - Any change to the HCR.VM bit.
  - Any change to HCR.PTW bit, see *Changing HCR.PTW* on page G4-3693.
- When using the Short-descriptor translation table format:
  - Any change to the RGN, IRGN, S, or NOS fields in TTBR0 or TTBR1.
  - Any change to the PD0 or PD1 fields in TTBCR
- When using the Long-descriptor translation table format:
  - Any change to the T*n*SZ, ORGN*n*, IRGN*n*, SH*n*, or EPD*n* fields in the TTBCR, where *n* is 0 or 1.
  - Any change to the T0SZ, ORGN0, IRGN0, or SH0 fields in the HTCR.
  - Any change to the T0SZ, ORGN0, IRGN0, or SH0 fields in the VTCR.

Changing the Access flag enable

In a PE that is using the Short-descriptor translation table format, it is UNPREDICTABLE whether the TLB caches the effect of the SCTLR.AFE bit on translation tables. This means that, after changing the SCTLR.AFE bit software must invalidate the TLB before it relies on the effect of the new value of the SCTLR.AFE bit.

Note

There is no enable bit for use of the Access flag when using the Long-descriptor translation table format.

Changing HCR.PTW

When EL2 is using AArch32 and the value of the Protected table walk bit, HCR.PTW, is 1, a stage 1 translation table access in the Non-secure PL1&0 translation regime, to an address that is mapped to any type of Device memory by its stage 2 translation, generates a stage 2 Permission fault. A TLB associated with a particular VMID might hold entries that depend on the effect of HCR.PTW. Therefore, if the value of HCR.PTW is changed without a change to the VMID value, all TLB entries associated with the current VMID must be invalidated before executing software in a Non-secure PL1 or PL0 mode. If this is not done, behavior is UNPREDICTABLE.

Changing the current Translation table format

The effect of changing TTBCR.EAE when executing in the translation regime affected by TTBCR.EAE with any stage of address translation for that translation regime enabled is UNPREDICTABLE. When TTBCR.EAE is changed for a given context, the TLB must be invalidated before resuming execution in that context, otherwise the effect is UNPREDICTABLE.

G4.10.3 Atomicity of register changes on changing virtual machine

From the viewpoint of software executing in a Non-secure PL1 or PL0 mode, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for:

- Non-secure PL1&0 stage 1 address translations. This means that all of the following registers must change atomically:
  - PRRR and NMRR, if using the Short-descriptor translation table format.
  - MAIR0 and MAIR1, if using the Long-descriptor translation table format.
  - TTBR0, TTBR1, TTBCR, DACR, and CONTEXTIDR.
  - The SCTLR.
- Non-secure PL1&0 stage 2 address translations. When EL2 is using AArch32, this means that all of the following registers and register fields must change atomically:
  - VTTBR and VTCR.
  - HMAIR0 and HMAIR1.
  - The HSCTLR.

Note

Only some bits of SCTLR affect the stage 1 translation, and only some bits of HSCTLR affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution in Non-secure PL1&0 modes. However, when updated as part of a switch of virtual machines they are updated by software executing in Hyp mode. This means the registers are *out of context* when they are updated, and no synchronization precautions are required.

Note

By contrast, a translation table change associated with a change of ASID, made by software executing at PL1, can require changes to registers that are *in context*. *Synchronization of changes of ASID and TTBR* describes appropriate precautions for such a change.

Software executing in Hyp mode, or in Secure state, must not use the registers associated with the Non-secure PL1&0 translation regime for speculative memory accesses.

G4.10.4 Synchronization of changes of ASID and TTBR

A common virtual memory management requirement is to change the ASID and Translation Table Base Registers together to associate the new ASID with different translation tables, without any change to the current translation regime. When using the Short-descriptor translation table format, different registers hold the ASID and the translation table base address, meaning these two values cannot be updated atomically. Since a PE can perform a speculative memory access at any time, this lack of atomicity is a problem that software must address. Such a change is complicated by:

- The depth of speculative fetch being IMPLEMENTATION DEFINED.
- The use of branch prediction.

When using the Short-descriptor translation table format, the virtual memory management operations must ensure the synchronization of changes of the ContextID and the translation table registers. For example, some or all of the TLBs, branch predictors, and other caching of ASID and translation information might become corrupt with invalid translations. Synchronization is required to avoid either:

- The old ASID being associated with translation table walks from the new translation tables.
- The new ASID being associated with translation table walks from the old translation tables.

There are a number of possible solutions to this problem, and the most appropriate approach depends on the system. Example G4-3, Example G4-4 on page G4-3695, and Example G4-5 on page G4-3695 describe three possible approaches.

Note

Another instance of the synchronization problem occurs if a branch is encountered between changing the ASID and performing the synchronization. In this case the value in the branch predictor might be associated with the incorrect ASID. Software can address this possibility using any of these approaches, but instead software might be written in a way that avoids such branches.

Example G4-3 Using a reserved ASID to synchronize ASID and TTBR changes

In this approach, a particular ASID value is reserved for use by the operating system, and is used only for the synchronization of the ASID and Translation Table Base Register. This example uses the value of 0 for this purpose, but any value could be used.

This approach can be used only when the size of the mapping for any given virtual address is the same in the old and new translation tables.

The maintenance software uses the following sequence, that must be executed from memory marked as global:

```
Change ASID to 0
ISB
Change Translation Table Base Register
ISB
Change ASID to new value
```

This approach ensures that any non-global pages fetched at a time when it is uncertain whether the old or new translation tables are being accessed are associated with the unused ASID value of 0. Since the ASID value of 0 is not used for any normal operations these entries cannot cause corruption of execution.

Example G4-4 Using translation tables containing only global mappings when changing the ASID

A second approach involves switching the translation tables to a set of translation tables that only contain global mappings while switching the ASID.

The maintenance software uses the following sequence, that must be executed from memory marked as global:

```
Change Translation Table Base Register to the global-only mappings
ISB
Change ASID to new value
ISB
Change Translation Table Base Register to new value
```

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.

This approach works without the need for TLB invalidations in systems that have caching of intermediate levels of translation tables, as described in *General TLB maintenance requirements* on page G4-3689, provided that the translation tables containing only global mappings have only level 1 translation table entries of the following kinds:

- Entries that are global.
- Pointers to level 2 tables that hold only global entries, and that are the same level 2 tables that are used for accessing global entries by both:
  - The set of translation tables that were used under the old ASID value.
  - The set of translation tables that will be used with the new ASID value.
- Invalid level 1 entries.

In addition, all sets of translation tables in this example should have the same shareability and cacheability attributes, as held in the TTBR0.{ORGN, IRGN} or TTBR1.{ORGN, IRGN} fields.

If these rules are not followed, then the implementation might cache level 1 translation table entries that require explicit invalidation.

Example G4-5 Disabling non-global mappings when changing the ASID

In systems where only the translation tables indexed by TTBR0 hold non-global mappings, maintenance software can use the TTBCR.PD0 field to disable use of TTBR0 during the change of ASID. This means the system does not require a set of global-only mappings.

The maintenance software uses the following sequence, that must be executed from a memory region with a translation that is accessed using the base address in the TTBR1 register, and is marked as global:

```
Set TTBCR.PD0 = 1
ISB
Change ASID to new value
Change Translation Table Base Register to new value
ISB
Set TTBCR.PD0 = 0
```

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.

When using the Long-descriptor translation table format, TTBCR.A1 holds the number, 0 or 1, of the TTBR that holds the current ASID. This means the current Translation Table Base Register can also hold the current ASID, and the current translation table base address and ASID can be updated atomically when:

- TTBR0 is the only Translation Table Base Register being used. TTBCR.A1 must be set to 0.
- TTBR0 points to the only translation tables that hold non-global entries, and TTBCR.A1 is set to 0.
- TTBR1 points to the only translation tables that hold non-global entries, and TTBCR.A1 is set to 1.

In these cases, software can update the current translation table base address and ASID atomically, by updating the appropriate TTBR, and does not require a specific routine to ensure synchronization of the change of ASID and base address.

However, in all other cases using the Long-descriptor format, the synchronization requirements are identical to those when using the Short-descriptor formats, and the examples in this section indicate how synchronization might be achieved.

Note

When using the Long-descriptor translation table format, CONTEXTIDR.ASID has no significance for address translation, and is only an extension of the Context ID value.

G4.10.5 The scope of TLB maintenance instructions

TLB maintenance instructions provide a mechanism for invalidating entries from TLB caching structures, to ensure that changes to the translation tables are reflected correctly in the TLB caching structures. To support TLB maintenance in multiprocessor systems, there are maintenance operations that apply to the TLBs of all PEs in the same Inner Shareable domain.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault and that does not, itself, cause a Translation Fault, an Address size fault, or an Access Flag fault. This means the TLB:

- Cannot hold an entry that, when used for a translation table lookup, causes a Translation fault, an Address size fault, or an Access Flag fault.
- Can hold an entry for a translation table lookup for a translation that causes a Translation Fault, an Address size fault, or an Access Flag fault at a subsequent level of translation table lookup. For example, it can hold an entry for the first level lookup of a translation that causes a a Translation fault, an Address size fault, or an Access Flag fault at the second or third level of lookup.

This means that entries cached in the TLB can include:

- Translation table entries that point to a subsequent table to be used in the current stage of translation.
- In an implementation that includes EL2:
  - Stage 2 translation table entries that are used as part of a stage 1 translation table walk.
  - Stage 2 translation table entries for translating the output address of a stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are distinct from the data caches, in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction on the form of these intermediate TLB caching structures.

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries. In particular for translation regimes that involve two stages of translation, it recognizes that such caching structures might contain:

- At any level of the translation table walk, entries containing information from stage 1 translation table entries.
- In an implementation that includes EL2:
  - At any level of the translation table walk, entries containing information from stage 2 translation table entries.
  - At any level of the translation table walk, entries combining information from both stage 1 and stage 2 translation table entries.

Where a TLB maintenance instruction is:

- Required to apply to stage 1 entries, then it must apply to any cached entry in the caching structures that includes any stage 1 information that would be used to translate the address being invalidated, including any entry that combines information from both stage 1 and stage 2 translation table entries.
- Required to apply to stage 2 entries only, then:
  - It is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
  - It must apply to caching structures that contain information only from stage 2 translation table entries.
- Required to apply to both stage 1 and stage 2 entries, then it must apply to any entry in the caching structures that includes information from either a stage 1 translation table entry or a stage 2 translation table entry, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Table G4-24 on page G4-3698 summarizes the required effect of the preferred TLB operations, for execution in AArch32 state, that operate only on TLBs on the PE that executes the instruction. Additional TLB operations:

- Apply across all PEs in the same Inner Shareable domain. Each operation shown in the table has an Inner Shareable equivalent, identified by an IS suffix. For example, the Inner Shareable equivalent of TLBIALL is TLBIALLIS. See also *EL2 upgrading of TLB maintenance instructions* on page G4-3699.
- Can apply to separate Instruction or Data TLBs, as indicated by a footnote to the table. ARM deprecates any use of these operations.

Note

- The architecture permits a TLB invalidation operation to affect any unlocked entry in the TLB. Table G4-24 on page G4-3698 defines only the entries that each operation must invalidate.
- All TLB operations, including those that operate on an VA match, operate regardless of the value of SCTLR.M.

When interpreting the table:

Related operations Each operation description applies also to any equivalent operation that either:
- Applies to all PEs in the same Inner Shareable domain.
- Applies only to a data TLB, or only to an instruction TLB.

So, for example, the TLBIALL description applies also to TLBIALLIS, ITLBIALL, and DTLBIALL.

TLB maintenance instructions, functional group on page G4-3795 lists all of the TLB maintenance instructions.

Matches the VA Means the VA argument for the operation must match the VA value in the TLB entry.

Matches the ASID Means the ASID argument for the operation must match the ASID in use when the TLB entry was assigned.

Matches the current VMID

Means the current VMID must match the VMID in use when the TLB entry was assigned.

The dependency on the VMID applies even when the value of HCR.VM is 0, including situations where there is no use of virtualization. However, VTTBR.VMID resets to zero, meaning there is a valid VMID from reset.

Execution at PL2 Descriptions of operations at PL2 apply only to implementations that include EL2.

For the definitions of the translation regimes referred to in the table see *About VMSAv8-32* on page G4-3618.

Table G4-24 Effect of the TLB maintenance instructions

Operation	Executed from		Effect, must invalidate any entry that matches all stated conditions
	State	Mode	
TLBIALL[a]	Secure	PL1	All entries for the Secure PL1&0 translation regime. That is, all entries that were allocated in Secure state.
	Non-secure	PL1	All entries for stage 1 of the Non-secure PL1&0 translation regime that match the current VMID.
		Hyp	All entries for stage 1 or stage 2 of the Non-secure PL1&0 translation regime that match the current VMID.
TLBIMVA[a]	Secure	PL1	Any entry for the Secure PL1&0 translation regime that both: • Matches the VA argument. • Matches the ASID argument, or is global.
	Non-secure	PL1 or Hyp	Any entry for stage 1 of the Non-secure PL1&0 translation regime for which all of the following apply. The entry: • Matches the VA argument. • Matches the ASID argument, or is global. • Matches the current VMID.
TLBIASID[a]	Secure	PL1	Any entry for the Secure PL1&0 translation regime that matches the ASID argument.
	Non-secure	PL1 or Hyp	Any entry for stage 1 of the Non-secure PL1&0 translation regime that both: • Is not global and matches the ASID argument. • Matches the current VMID.
TLBIMVAA	Secure	PL1	Any entry for the Secure PL1&0 translation regime that matches the VA argument.
	Non-secure	PL1 or Hyp	Any entry for stage 1 of the Non-secure PL1&0 translation regime that both: • Matches the VA argument. • Matches the current VMID.
TLBIALLNSNH[b]	Secure	Monitor	All entries for stage 1 or stage 2 of the Non-secure PL1&0 translation regime, regardless of the associated VMID.
	Non-secure	Hyp	
TLBIALLH[b]	Secure	Monitor	All entries for the Non-secure PL2 translation regime. That is, any entry that was allocated in Non-secure state from Hyp mode.
	Non-secure	Hyp	
TLBIMVAL	Secure	PL1	Any entry for stage 1 of the Secure PL1&0 translation regime that is the last level of the translation table walk and matches: • The VA argument. • The ASID argument.
	Non-secure	PL1 or Hyp	Any entry for stage 1 of the Non-secure PL1&0 translation regime that is the last level of the translation table walk and matches: • The VA argument. • The ASID argument. • The current VMID.

Table G4-24 Effect of the TLB maintenance instructions (continued)

Operation	Executed from		Effect, must invalidate any entry that matches all stated conditions
	State	Mode	
TLBIMVAAL	Secure	PL1	Any entry for stage 1 of the Secure PL1&0 translation regime that is the last level of the translation table walk and matches the VA argument.
	Non-secure	PL1 or Hyp	Any entry for stage 1 of the Non-secure PL1&0 translation regime that is the last level of the translation table walk and matches: • The VA argument. • The current VMID.
TLBIMVAH[b]	Secure	Monitor	Any entry for the Non-secure PL2 translation regime that matches the VA argument.
	Non-secure	Hyp	
TLBIMVALH[b]	Secure	Monitor	Any entry for stage 1 of the translation regime that is the last level of the translation table walk and matches the given VA.
	Non-secure	Hyp	
TLBIIPAS2[b]	Secure	Monitor	Any entry for an PL1&0 stage 2 of the translation regime holding the IPA to PA translations and the current VMID[c].
	Non-secure	Hyp	Any entry for an PL1&0 stage 2 of the translation regime holding the IPA to PA translations and the current VMID[d].
TLBIIPAS2L[b]	Secure	Monitor	Any entry for an PL1&0 stage 2 of the translation regime for the last level of translation holding the IPA to PA translations and the current VMID[c].
	Non-secure	Hyp	Any entry for an PL1&0 stage 2 of the translation regime for the last level of translation holding the IPA to PA translations and the current VMID[d].

a. The architecture defines variants of these operations that apply only to instruction TLBs, and only to data TLBs. ARM deprecates any use of these variants. For more information, see the referenced description of the operation.

b. Available only in an implementation that includes EL2. See also *EL2 upgrading of TLB maintenance instructions*.

c. This operation execute as NOPs when SCR.NS == 0.

d. This operation is CONSTRAINED UNPREDICTABLE from any AArch32 Secure privileged mode.

EL2 upgrading of TLB maintenance instructions

In an implementation that includes EL2, when the value of HCR.FB is 1, the TLB maintenance instructions that are not broadcast across the Inner Shareable domain are upgraded to operate across the Inner Shareable domain when performed in a Non-secure PL1 mode. For example, when the value of HCR.FB is 1, a TLBIMVA operation performed in a Non-secure PL1 mode operates as a TLBIMVAIS operation.

TLB maintenance with different translation granule sizes

If a TLB maintenance instruction specifying a virtual address affecting the PL2 translation regime is broadcast from a PE using AArch32 to a PE using AArch64 using a translation granule size that is different from the AArch32 translation granule size for that same translation regime, the TLB maintenance instruction is not required to perform any invalidation on the recipient PE.

If a TLB maintenance instruction specifying a virtual address affecting the PL1 translation regime is broadcast from a PE using AArch32 using one translation granule size for that translation regime for a particular ASID, VMID (if applicable), and Security state, to a PE using AArch64 where EL1 for the same ASID, VMID (if applicable), and Security state, is using a translation granule size that is different from the AArch32 translation granule size, the TLB maintenance instruction is not required to perform any invalidation on the recipient PE.

G4.11 Caches in VMSAv8-32

The ARM architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

Maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

- Summarizes the architectural requirements for the interaction between caches and memory translation.
- Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

- *Data and unified caches*.
- *Instruction caches*.

In addition *Cache maintenance requirement created by changing translation table attributes* on page G4-3702 describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance see:

- *Cache support* on page G3-3580. This section describes the ARM cache maintenance instructions.
- *Cache maintenance instructions, functional group* on page G4-3794. This section summarizes the System register encodings used for these operations when executing in AArch32 state.

G4.11.1 Data and unified caches

For data and unified caches, the use of memory address translation is entirely transparent to any data access that is not UNPREDICTABLE.

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

- Two writes to the same PA occur in program order.
- A read of a PA returns the value of the last successful write to that PA.
- A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance instructions.

In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses as *Physically-indexed, physically-tagged* (PIPT) caches.

G4.11.2 Instruction caches

In the ARM architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The ARM architecture supports three different behaviors for instruction caches. For ease of reference and description these are identified by descriptions of the associated expected implementation, as follows:

- PIPT instruction caches.
- *Virtually-indexed, physically-tagged* (VIPT) instruction caches.
- ASID and VMID tagged *Virtually-indexed, virtually-tagged* (VIVT) instruction caches.

In AArch32 state, the CTR identifies the form of the instruction caches, see *CTR, Cache Type Register* on page G5-3866.

The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of memory address translation transparent to the instruction cache:

- *PIPT instruction caches*.
- *VIPT instruction caches*.
- *ASID and VMID tagged VIVT instruction caches*.

Note

For software to be portable between implementations that might use any of PIPT instruction caches, VIPT instruction caches, or ASID and VMID tagged VIVT instruction caches, the software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

PIPT instruction caches

For PIPT instruction caches, the use of memory address translation is entirely transparent to all instruction fetches that are not UNPREDICTABLE.

If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IVIPT Extension, see *IVIPT architecture Extension* on page G4-3702.

VIPT instruction caches

For VIPT instruction caches, the use of memory address translation is transparent to all instruction fetches that are not UNPREDICTABLE, except for the effect of memory address translation on instruction cache invalidate by address operations.

Note

Cache invalidation is the only cache maintenance instruction that can be performed on an instruction cache.

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the virtual address supplied with the operation. The effect of the invalidation might not be visible to any other virtual address aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a physical address from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IVIPT Extension, see *IVIPT architecture Extension* on page G4-3702.

ASID and VMID tagged VIVT instruction caches

For ASID and VMID tagged VIVT instruction caches, if the instructions at any virtual address change, for a given translation regime and a given ASID and VMID, as appropriate, then instruction cache maintenance is required to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

- Enabling or disabling the stage of address translation.
- Writing new mappings to the translation tables.

- In AArch32 state, any change to the TTBR0, TTBR1, or TTBCR registers, unless accompanied by a change to the ContextID, or a change to the VMID.
- In AArch32 state, changes to the VTTBR or VTCR registers, unless accompanied by a change to the VMID.

Note

For ASID and VMID tagged VIVT instruction caches only, invalidation is not required if the changes to the translations are such that the instructions associated with the non-faulting translations of a virtual address, for a given translation regime and a given ASID and VMID, as appropriate, remain unchanged, through the sequence of changes to the translations. Examples of translation changes to which this applies are:

- Changing a valid translation to a translation that generates an MMU fault.
- Changing a translation that generates a MMU fault to a valid translation.

This does not apply for VIPT or PIPT instruction caches.

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the virtual address supplied with the operation. The effect of the invalidation might not be visible to any other virtual address aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a physical address from an ASID and VMID tagged VIVT instruction cache is to invalidate the entire instruction cache.

IVIPT architecture Extension

An implementation in which the instruction cache exhibits the behaviors described in *PIPT instruction caches* on page G4-3701, or those described in *VIPT instruction caches* on page G4-3701, is said to implement the *IVIPT Extension* to the ARM architecture.

The formal definition of the IVIPT Extension to the ARM architecture is that it reduces the instruction cache maintenance requirement to the following condition:

- Instruction cache maintenance is required only after writing new data to a physical address that holds an instruction.

G4.11.3 Cache maintenance requirement created by changing translation table attributes

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in *General TLB maintenance requirements* on page G4-3689. If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:

- Write-Back to Write-Through.
- Write-Back to Non-cacheable.
- Write-Through to Non-cacheable.
- Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.

Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from them cache.
3. Change the shareability attributes to the required new values.

G4.12 VMSAv8-32 memory aborts

In a VMSAv8-32 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

Debug exception An exception caused by the debug configuration, see Chapter G2 *AArch32 Self-hosted Debug* and *Exception Catch debug event* on page H3-4449.

Alignment fault An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information see *Unaligned data access* on page E2-2256 and *Alignment faults* on page G4-3710.

MMU fault A MMU fault is a fault generated by the fault checking sequence for the current translation regime.

External abort Any memory system fault other than a Debug exception, an Alignment fault, or a MMU fault.

Collectively, these mechanisms are called *aborts*. Chapter G2 *AArch32 Self-hosted Debug* and Chapter H3 *Halting Debug Events* describe Debug exceptions, and the remainder of this section describes Alignment faults, MMU faults, and External aborts.

The exception generated on a synchronous memory abort:

- On an instruction fetch is called the Prefetch Abort exception.
- On a data access is called the Data Abort exception.

Note

The Prefetch Abort exception applies to any synchronous memory abort on an instruction fetch. It is not restricted to speculative instruction fetches.

In AArch32 state, asynchronous memory aborts are a type of External abort, and are treated as a special type of Data Abort exception.

The following sections describe the abort mechanisms:

- *Routing of aborts taken to AArch32 state*.
- *VMSAv8-32 MMU fault terminology* on page G4-3706.
- *The MMU fault-checking sequence* on page G4-3706.
- *Alignment faults* on page G4-3710.
- *MMU faults in AArch32 state* on page G4-3711.
- *External abort on a translation table walk* on page G4-3713.
- *Prioritization of aborts* on page G4-3714.

An access that causes an abort is said to be aborted, and uses the *Fault Address Registers* (FARs) and *Fault Status Registers* (FSRs) to record context information. For more information about the FARs and FSRs, see *Exception reporting in a VMSAv8-32 implementation* on page G4-3715.

G4.12.1 Routing of aborts taken to AArch32 state

A memory abort is either a Data Abort exception or a Prefetch Abort exception. When executing in AArch32 state, depending on the cause of the abort, and possibly on configuration settings, an abort is taken either:

- To the Exception level of the PE mode from which the abort is taken. In this case the abort is taken to AArch32 state.
- To a higher Exception level. In this case the Exception level to which the abort is taken is either:
  - Using AArch32. In this case, this chapter describes how the abort is handled.
  - Using AArch64. In this case, Chapter D4 *The AArch64 Virtual Memory System Architecture*describes how the abort is handled.

For an abort taken to an Exception level that is using AArch32, the mode to which a memory abort is taken depends on the reason for the exception, the mode the PE is in when it takes the exception, and configuration settings, as follows:

Memory aborts taken to Monitor mode

If an implementation includes EL3, when the value of SCR.EA is 1, all External aborts are taken to EL3, and if EL3 is using AArch32 they are taken to Monitor mode. This applies to aborts taken from Secure modes and from Non-secure modes. For more information see *Asynchronous exception routing controls* on page G1-3420.

Note

- Although the referenced section mostly describes the routing of asynchronous exceptions, it includes the SCR.EA control that applies to both synchronous and asynchronous external aborts.
- The SCR is implemented only as part of EL3.

Memory aborts taken to Secure Abort mode

If an implementation includes EL3, when the PE is executing in Secure state, all memory aborts that are not routed to EL3 are taken to Secure Abort mode.

Note

The only memory aborts that can be routed to Monitor mode are External aborts.

Memory aborts taken to Hyp mode

If an implementation includes EL2, when the PE is executing in Non-secure state, the following aborts are taken to EL2. If EL2 is using AArch32 this means they are taken to Hyp mode:

- Alignment faults taken:
  - When the PE is in Hyp mode.
  - When the PE is in a Non-secure PL1 or EPL0 mode and the exception is generated because the Non-secure PL1&0 stage 2 translation identifies the target of an unaligned access as any type of Device memory.
  - When the PE is in Non-secure User mode and HCR.TGE is set to 1. For more information see *Abort exceptions, when HCR.TGE is set to 1* on page G1-3411.
- When the PE is using the Non-secure PL1&0 translation regime:
  - MMU faults from stage 2 translations, for which the stage 1 translation did not cause an MMU fault.
  - Any abort taken during the stage 2 translation of an address accessed in a stage 1 translation table walk that is not routed to Secure Monitor mode, see *Stage 2 fault on a stage 1 translation table walk* on page G4-3710.
- When the PE is using the Non-secure PL2 translation regime, MMU faults from stage 1 translations.

  Note

  The Non-secure PL2 translation regime has only one stage of translation.
- External aborts, if SCR.EA is set to 0 and any of the following applies:
  - The PE was executing in Hyp mode when it took the exception.
  - The PE was executing in a Non-secure PL0 or PL1 mode when it took the exception, the abort is asynchronous, and HCR.AMO is set to 1. For more information see *Asynchronous exception routing controls* on page G1-3420.
  - The PE was executing in the Non-secure User mode when it took the exception, the abort is synchronous, and HCR.TGE is set to 1. For more information see *Abort exceptions, when HCR.TGE is set to 1* on page G1-3411.

  - The abort occurred on a stage 2 translation table walk.
- Debug exceptions, if HDCR.TDE is set to 1. For more information, see *Routing debug exceptions to EL2* on page G1-3411.

Memory aborts taken to Non-secure Abort mode

In an implementation that does not include EL3, all memory aborts that are taken to an Exception level that is using AArch32 are taken to Abort mode.

Otherwise, when the PE is executing in Non-secure state, the following aborts are taken to Non-secure Abort mode:

- When the PE is in a Non-secure PL1 or PL0 mode, Alignment faults taken for any of the following reasons:
  - SCTLR.A is set to 1.
  - An instruction that does not support unaligned accesses is committed for execution, and the instruction accesses an unaligned address.
  - The PL1&0 stage 1 translation identifies the target of an unaligned access as any type of Device memory.

    Note

    In an implementation that does not include EL2, this case results in an UNPREDICTABLE memory access, see *Cases where unaligned accesses are UNPREDICTABLE* on page E2-2256.

  If an implementation includes EL2 and the PE is in Non-secure User mode, these exceptions are taken to Abort mode only if the value of HCR.TGE is 0.
- When the PE is using the Non-secure PL1&0 translation regime, a stage of address translation faults from stage 1 translations.
- External aborts, if all of the following apply:
  - The abort is not on a stage 2 translation table walk.
  - The PE is not in Hyp mode.
  - The value of SCR.EA is 0.
  - The abort is asynchronous, and HCR.AMO is set to 0.
  - The abort is synchronous, and HCR.TGE is set to 0.
- Virtual Aborts, see *Virtual exceptions when an implementation includes EL2* on page G1-3418.
- When the value of HDCR.TDE is 0, Debug exceptions. For more information, see *Routing debug exceptions to EL2* on page G1-3411.

Note

If EL0 is using AArch32 and EL1 is using AArch64 then any of these memory aborts taken from User mode are taken to EL1 as described in Chapter D4 *The AArch64 Virtual Memory System Architecture*.

Memory aborts with IMPLEMENTATION DEFINED behavior

In addition, a PE can generate an abort for an IMPLEMENTATION DEFINED reason associated with lockdown. In an implementation that includes EL2, whether such an abort is taken to Non-secure Abort mode or is taken to EL2 is IMPLEMENTATION DEFINED, and an implementation might include a mechanism to select whether the abort is routed to Non-secure Abort mode or to EL2.

When the PE is in a Non-secure mode other than Hyp mode, if multiple factors cause an Alignment fault, the abort is taken to Non-secure Abort mode if any of the factors require the abort to be taken to Abort mode. For example, if the SCTLR.A bit is set to 1, and the access is an unaligned access to an address that the stage 2 translation tables mark as Device-nGnRnE, then the abort is taken to Non-secure Abort mode.

For more information see *Handling exceptions that are taken to an Exception level using AArch32* on page G1-3396.

G4.12.2 VMSAv8-32 MMU fault terminology

The ARMv7 Large Physical Address Extension introduced new terminology for faults on a stage of address translation, to provide consistent terminology across all implementations. Table G4-25 shows the terminology used in this manual for a MMU faults, compared with older ARM documentation. The current terms are the same for faults that occur with the Short-descriptor translation table format and with the Long-descriptor format, and also apply to faults in a level 3 lookup when using the Long-descriptor translation table format.

Table G4-25 Address translation fault terminology

Current term	Old term	Note
First level Translation fault	Section Translation fault	-
Second level Translation fault	Page Translation fault	-
Third level Translation fault	-	Long-descriptor translation table format only.
First level Access flag fault	Section Access flag fault	-
Second level Access flag fault	Page Access flag fault	-
Third level Access flag fault	-	Long-descriptor translation table format only.
First level Domain fault	Section Domain fault	Short-descriptor translation table format only, except for reporting faults on address translation instructions in the 64-bit PAR, see *Determining the PAR format* on page G4-3740. Cannot occur at third level.
Second level Domain fault	Page Domain fault	
First level Permission fault	Section Permission fault	-
Second level Permission fault	Page Permission fault	-
Third level Permission fault	-	Long-descriptor translation table format only.

In an implementation that includes EL2, MMU faults are also classified by the translation stage at which the fault is generated. This means that a memory access from a Non-secure PL1 or PL0 mode can generate:

- A stage 1 address translation fault, for example, a stage 1 Translation fault.
- A stage 2 address translation fault, for example, a stage 2 Translation fault.

G4.12.3 The MMU fault-checking sequence

This section describes the MMU checks made for the memory accesses required for instruction fetches and for explicit memory accesses:

- If an instruction fetch faults it generates a Prefetch Abort exception.
- If an data memory access faults it generates a Data Abort exception.

For more information about Prefetch Abort exceptions and Data Abort exceptions see *Handling exceptions that are taken to an Exception level using AArch32* on page G1-3396.

In VMSAv8-32, all memory accesses require VA to PA translation. Therefore, when a corresponding stage of address translation is enabled, each access requires a lookup of the translation table descriptor for the accessed VA. For more information, see *Translation tables* on page G4-3629 and subsequent sections of this chapter. MMU fault checking is performed for each level of translation table lookup. If an implementation includes EL2 and is operating in Non-secure state, MMU fault checking is performed for each stage of address translation.

Note

In an implementation that includes EL2, if a PE is executing in Non-secure state, the operating system or similar Non-secure system software defines the stage 1 translation tables in the IPA address space, and typically is unaware of the stage 2 translation from IPA to PA. However, each Non-secure stage 1 translation table access is subject to stage 2 address translation, and might be faulted at that stage.

The MMU fault checking sequence is largely independent of the translation table format, as the figures in this section show. The differences are:

When using the Short-descriptor format

- There are one or two levels of lookup.
- Lookup always starts at the first level.
- The final level of lookup checks the Domain field of the descriptor and:
  - Faults if there is no access to the Domain.
  - Checks the access permissions only for Client domains.

When using the Long-descriptor format

- There are one, two, or three levels of lookup.
- Lookup starts at either the first level or the second level.
- Domains are not supported. All accesses are treated as Client domain accesses.

The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see *About address translation for VMSAv8-32* on page G4-3621.

Note

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in *TLB conflict aborts* on page G4-3688.

MMU faults in AArch32 state on page G4-3711 describes the faults that a MMU fault-checking sequence can report.

Figure G4-23 on page G4-3708 shows the process of fetching a descriptor from the translation table. For the top level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, in an implementation that includes EL2, if the translation is stage 1 of the Non-secure PL1&0 translation regime, then the descriptor address is in the IPA address space, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.

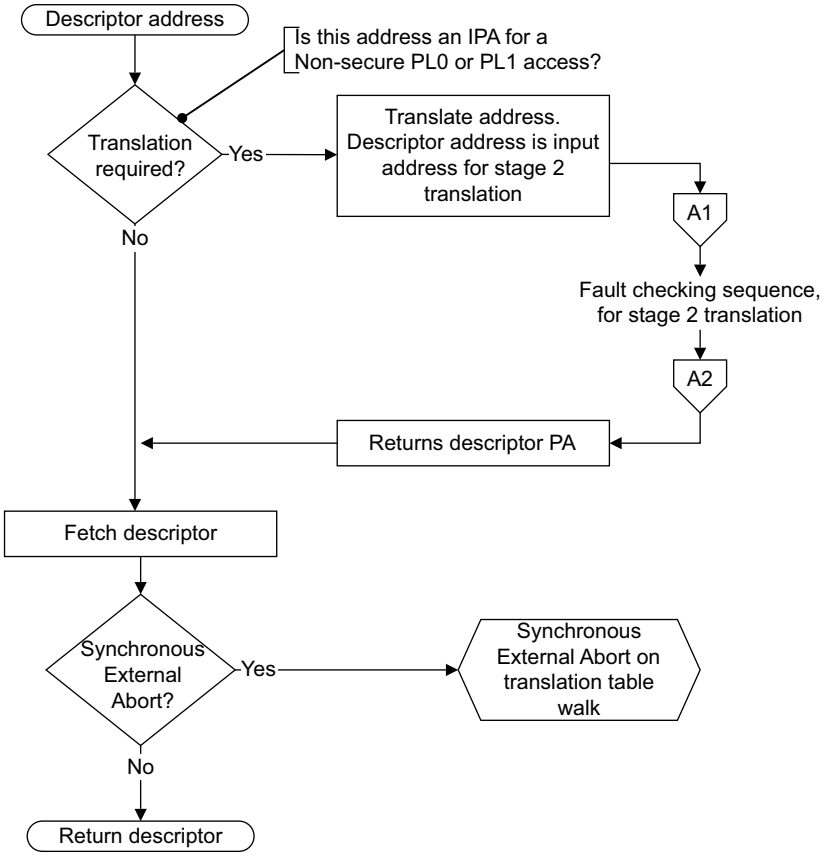


Figure G4-23 Fetching the descriptor in a VMSAv8-32 translation table walk

Figure G4-24 shows the full VMSAv8-32 fault checking sequence, including the alignment check on the initial access.

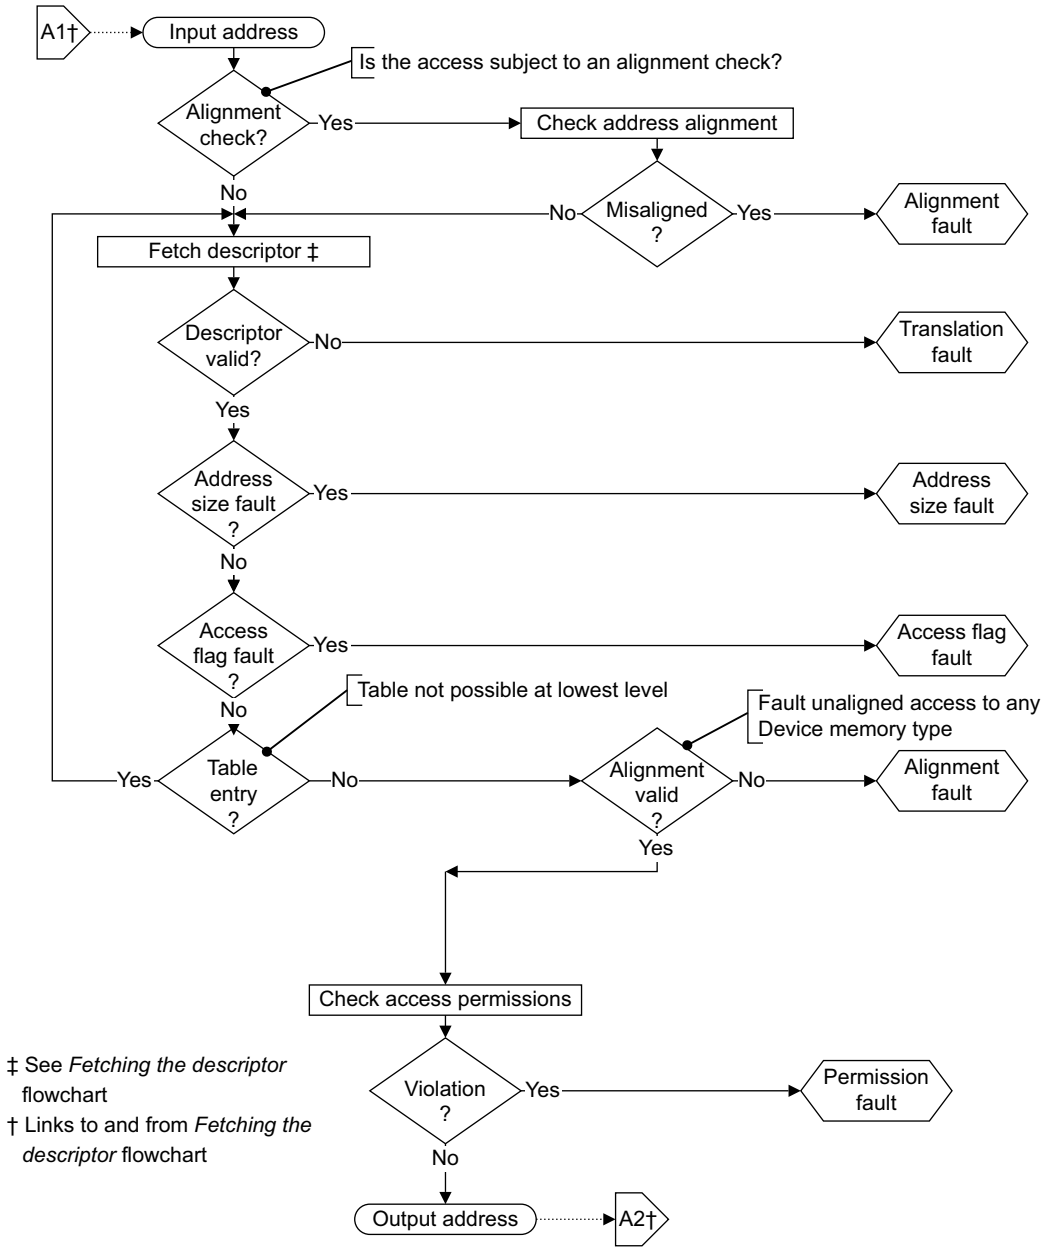

Figure G4-24 VMSAv8-32 fault checking sequence

Stage 2 fault on a stage 1 translation table walk

When an implementation that includes EL2 is operating in a Non-secure PL1 or PL0 mode, any memory access goes through two stages of translation:

- Stage 1, from VA to IPA.
- Stage 2, from IPA to PA.

Note

In a virtualized system that is using AArch32, typically, a Guest OS operating in a Non-secure PL1 mode defines the translation tables and translation table register entries controlling the Non-secure PL1&0 stage 1 translations. A Guest OS has no awareness of the stage 2 address translation, and therefore believes it is specifying translation table addresses in the physical address space. However, it actually specifies these addresses in its IPA space. Therefore, to support virtualization, translation table addresses for the Non-secure PL1&0 stage 1 translations are always defined in the IPA address space.

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

- A Translation fault, Access flag fault, or Permission fault.
- A synchronous external abort on the memory access.

If SCR.EA is set to 1, a synchronous external abort is taken to EL3, and if EL3 is using AArch32 it is taken to Secure Monitor mode. Otherwise, these faults are reported as stage 2 memory aborts. When EL2 is using AArch32, HSR.ISS[7] is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information see *Use of the HSR* on page G4-3728.

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the any type of Device memory attribute assigned on the stage 2 translation of the address accessed. When the value of the HCR.PTW bit is 1, such an access generates a stage 2 Permission fault.

Note

- On most systems, such a mapping to a Device memory type on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.

A TLB might hold entries that depend on the effect of HCR.PTW. Therefore, if HCR.PTW is changed without changing the current VMID, the TLBs must be invalidated before executing in a Non-secure PL1 or PL0 mode. For more information see *Changing HCR.PTW* on page G4-3693.

A cache maintenance instruction performed from a Non-secure PL1 mode can cause a stage 1 translation table walk that might generate a stage 2 Permission fault, as described in this section. This is an exception to the general rule that a cache maintenance instruction cannot generate a Permission fault.

G4.12.4 Alignment faults

The ARM memory architecture requires support for strict alignment checking. This checking is controlled by SCTLR.A. In addition, some instructions do not support unaligned accesses, regardless of the value of SCTLR.A. *Unaligned data access* on page E2-2256 defines when Alignment faults are generated, for both values of SCTLR.A.

An Alignment fault can occur on an access for which the stage of address translation is disabled.

Any unaligned access to memory region with any Device memory type attribute generates an Alignment fault.

Routing of aborts taken to AArch32 state on page G4-3703 defines the mode to which an Alignment fault is taken.

The prioritization of Alignment faults depends on whether the fault was generated because of an access to a Device memory type, or for another reason. For more information see *Prioritization of aborts* on page G4-3714.

G4.12.5 MMU faults in AArch32 state

This section describes the faults that might be detected during one of the fault-checking sequences described in *The MMU fault-checking sequence* on page G4-3706. Unless indicated otherwise, information in this section applies to the fault checking sequences for both the Short-descriptor translation table format and the Long-descriptor translation table format.

MMU faults are always synchronous.

When a MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as any type of Device memory.

The following subsections describe the MMU faults that might be detected during a fault checking sequence:

- *Translation fault*.
- *Address size fault*.
- *Access flag fault* on page G4-3712.
- *Domain fault, Short-descriptor format translation tables only* on page G4-3712.
- *Permission fault* on page G4-3713.

See also *External abort on a translation table walk* on page G4-3713.

Translation fault

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a translation table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information see:

- *VMSAv8-32 Short-descriptor translation table format descriptors* on page G4-3635.
- *VMSAv8-32 Long-descriptor translation table format descriptors* on page G4-3648.

In addition, a Translation fault is generated if the input address for a translation either does not map on to an address range of a Translation Table Base Register, or the Translation Table Base Register range that it maps on to is disabled. In these cases the fault is reported as a first level Translation fault on the translation stage at which the mapping to a region described by a Translation Table Base Register failed.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

A data or unified cache maintenance instruction by VA can generate a Translation fault. Whether an instruction cache invalidate by VA operation can generate a Translation fault is IMPLEMENTATION DEFINED, because it is IMPLEMENTATION DEFINED whether the operation requires an address translation. If the instruction cache invalidate by VA operation requires an address translation then the operation can generate a Translation fault, otherwise it cannot generate a Translation fault.

Whether branch predictor maintenance operations can generate Translation faults is IMPLEMENTATION DEFINED, because it is IMPLEMENTATION DEFINED whether the operation requires an address translation. If the branch predictor maintenance operation requires an address translation then the operation can generate a Translation fault, otherwise it cannot generate a Translation fault.

Address size fault

An Address size fault can be generated at any level of lookup, and the reported fault code identifies the lookup level.

An Address size fault is generated if one of the following applies:

- The translation table entries or the TTBR for the stage of translation have address bits above the most significant bit of the specified PA size as non zero.

  Since VMSAv8-32 supports a maximum PA and IPA size of 40 bits, this includes any case where a translation table entry or the TTBR holds an address for which A[47:40] is nonzero.

- The specified output address size is larger than the implemented PA.

The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

Access flag fault

An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if all of the following apply:

- The translation tables support an Access flag bit:
  - The Short-descriptor format supports an Access flag only when SCTLR.AFE is set to 1.
  - The Long-descriptor format always supports an Access flag.
- A translation table descriptor with the Access flag bit set to 0 is loaded.

For more information about the Access flag bit see:

- *VMSAv8-32 Short-descriptor translation table format descriptors* on page G4-3635
- *VMSAv8-32 Long-descriptor translation table format descriptors* on page G4-3648.

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

Whether any cache maintenance instruction by VA can generate Access flag faults is IMPLEMENTATION DEFINED.

Whether branch predictor invalidate by VA operations can generate Access flag faults is IMPLEMENTATION DEFINED.

For more information, see *The Access flag* on page G4-3671.

Domain fault, Short-descriptor format translation tables only

When using the Short-descriptor translation table format, a Domain fault can be generated at the first level or second level of lookup. The reported fault code identifies the lookup level. The conditions for generating a Domain fault are:

First level When a level 1 descriptor fetch returns a valid Section level 1 descriptor, the domain field of that descriptor is checked against the DACR. A level 1 Domain fault is generated if this check fails.

Second level When a level 2 descriptor fetch returns a valid level 2 descriptor, the domain field of the level 1 descriptor that required the level 2 fetch is checked against the DACR, and a level 2 Domain fault is generated if this check fails.

For more information, see *Domains, Short-descriptor format only* on page G4-3670.

Domain faults cannot occur on cache or branch predictor maintenance operations.

A TLB might hold a translation table entry that cause a Domain fault. Therefore, if the handling of a Domain fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in *TLB maintenance instructions and the memory order model* on page G4-3691.

Any change to the DACR must be synchronized by a context synchronization operation. For more information see *Synchronization of changes to System registers* on page G4-3757.

Permission fault

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See *Access permissions* on page G4-3665 for information about conditions that cause a Permission fault.

Note

When using the Short-descriptor translation table format, the translation table descriptors are checked for Permission faults only for accesses to memory regions in Client domains.

A TLB might hold a translation table entry that cause a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in *TLB maintenance instructions and the memory order model* on page G4-3691.

Note

In an implementation that includes EL2, this maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.

Cache or branch predictor maintenance operations cannot cause a Permission fault, except that:

- A stage 1 translation table walk performed as part of a cache or branch predictor maintenance operation can generate a stage 2 Permission fault as described in *Stage 2 fault on a stage 1 translation table walk* on page G4-3710.
- A DCIMVAC issued in Non-secure state that attempts to update a location for which it does not have stage 2 write access can generate a stage 2 Permission fault, as described in *Data cache maintenance instructions (DC*)* on page G3-3590.

G4.12.6 External abort on a translation table walk

An external abort on a translation table walk can be either synchronous or asynchronous. For more information on external aborts, see *External aborts* on page G3-3602.

An external abort on a translation table walk is reported:

- If the external abort is synchronous, using:
  - A synchronous Prefetch Abort exception if the translation table walk is for an instruction fetch.
  - A synchronous Data Abort exception if the translation table walk is for a data access.
- If the external abort is asynchronous, using an asynchronous Data Abort exception.

If an implementation reports the error in the translation table walk asynchronously from executing the instruction whose instruction fetch or memory access caused the translation table walk, these aborts behave essentially as interrupts. The aborts are masked when CPSR.A is set to 1, otherwise they are reported using the Data Abort exception.

Behavior of external aborts on a translation table walk caused by address translation instructions

The address translation instructions summarized in *Address translation instructions, functional group* on page G4-3796 require translation table walks. An external abort can occur in the translation table walk. The abort generates a Data Abort exception, and can be synchronous or asynchronous. For more information, see *Handling of faults and aborts during an address translation instruction* on page G4-3740.

G4.12.7 Prioritization of aborts

This section describes the abort prioritization that applies to a single memory access from AArch32 state that might generate multiple aborts:

On a single memory access from AArch32 state, the following rules apply:

- If a memory access generates an Alignment fault because SCTLR.A is set to 1, or because it is an unaligned access by an instruction that does not support unaligned accesses, then that access cannot generate any of:
  - A MMU fault, on either the stage 1 translation or the stage 2 translation.
  - An external abort.
  - A Breakpoint or Vector Catch exception, if it is an instruction fetch, or a Watchpoint exception if it is a data access.

  An Alignment fault generated by an unaligned access to any type of Device memory is prioritized as an MMU fault. For more information see *Alignment faults caused by accessing Device memory types*.
- If a memory access generates an MMU fault on its stage 1 translation, and also generates an abort on its stage 2 translation, the fault from the stage 1 translation has priority:
  - If a memory access made as part of a stage 1 translation table walk generates an MMU fault on its stage 2 translation, as described in *Stage 2 fault on a stage 1 translation table walk* on page G4-3710, the stage 1 translation table walk does not generate an MMU fault on the stage 1 translation.
  - A fault on a particular stage of translation might be a synchronous external abort on a translation table walk made at that stage of translation.
- If a memory access generates an MMU fault on either its stage 1 translation or on its stage 2 translation, then the PE cannot generate a Breakpoint, Vector Catch, or Watchpoint exception.
- If a memory access generates an MMU fault on either its stage 1 translation or on its stage 2 translation, or generates a Breakpoint, Vector Catch, or Watchpoint exception, then the memory access cannot generate an external abort.
- Except as defined in this list, the architecture does not define any prioritization of asynchronous external aborts relative to any other asynchronous aborts.

If a single instruction generates aborts on more than one memory access, the architecture does not define any prioritization between those aborts.

In general, the ARM architecture does not define when asynchronous events are taken, and therefore the prioritization of asynchronous events is IMPLEMENTATION DEFINED.

Alignment faults caused by accessing Device memory types

Any unaligned access to any type of Device memory generates an Alignment fault. When applying the prioritization rules, this fault is prioritized at any MMU fault. The priority of this Alignment fault relative to possible MMU faults is as follows:

- The Alignment fault has lower priority than an Access flag fault.
- If the translation stage that generates the Access flag fault:
  - Can generate Domain faults, the Alignment fault has higher priority than a Domain fault.
  - Cannot generate Domain faults, the Alignment fault has higher priority than a Permission fault.

The MMU fault checking sequence in Figure G4-24 on page G4-3709 shows this prioritization.

G4.13 Exception reporting in a VMSAv8-32 implementation

This section describes exception reporting, in AArch32 state, in a VMSAv8-32 implementation. That is, it describes only the reporting of exceptions that are taken to an Exception level that is using AArch32. EL2 provides an enhanced reporting mechanism for exceptions taken to the Non-secure EL2 mode, Hyp mode. This means that, for VMSAv8-32, the exception reporting depends on the mode to which the exception is taken.

Note

The enhanced reporting mechanism for exceptions that are taken to Hyp mode is generally similar to the reporting of exceptions that are taken to an Exception level that is using AArch64.

About exception reporting introduces the general approach to exception reporting, and the following sections then describe exception reporting at different privilege levels:

- *Reporting exceptions taken to PL1 modes* on page G4-3716.
- *Fault reporting in PL1 modes* on page G4-3719.
- *Summary of register updates on faults taken to PL1 modes* on page G4-3722.
- *Reporting exceptions taken to Hyp mode* on page G4-3724.
- *Use of the HSR* on page G4-3728.
- *Summary of register updates on exceptions taken to Hyp mode* on page G4-3734.

Note

The registers used for exception reporting also report information about debug exceptions. For more information see:

- *Data Abort exceptions, taken to a PL1 mode* on page G4-3717.
- *Prefetch Abort exceptions, taken to a PL1 mode* on page G4-3718.
- *Reporting exceptions taken to Hyp mode* on page G4-3724.

G4.13.1 About exception reporting

In an implementation that includes EL2 and EL3, exceptions can be taken to:

- Monitor mode, if EL3 is using AArch32.
- Hyp mode, if EL2 is using AArch32.
- A Secure or Non-secure PL1 mode.

Monitor mode is a PL1 mode, but:

- It is accessible only when EL3 is using AArch32.
- It is present only in Secure state.
- When EL3 is using AArch32, System register controls route some exceptions from Non-secure state to Monitor mode. These are the only cases where taking an exception to an Exception level that is using AArch32 changes the Security state of the PE.

Exception reporting in Hyp mode differs significantly from that in the other modes, but in general, exception reporting returns:

- Information about the exception:
  - On taking an exception to Hyp mode, the *Hyp Syndrome Register*, HSR, returns syndrome information.
  - On taking an exception to any other mode, a *Fault Status Register* (FSR) returns status information.
- For synchronous exceptions, one or more addresses associated with the exceptions, returned in *Fault Address Registers* (FARs).

In all modes, additional IMPLEMENTATION DEFINED registers can provide additional information about exceptions.

Note

- *PE mode for taking exceptions* on page G1-3404 describes how the mode to which an exception is taken is determined.
- EL2 provides:
  - Specific exception types, that can only be taken from Non-secure PL1 and PL0 modes, and are always taken to Hyp mode.
  - Routing controls that can route some exceptions from Non-secure PL1 and PL0 modes to Hyp mode.

  These exceptions are reported using the same mechanism as the Hyp mode reporting of VMSAv8-32 memory aborts, as described in this section.

Memory system faults generate either a Data Abort exception or a Prefetch Abort exception, as summarized in:

- *Reporting exceptions taken to PL1 modes*.
- *Memory fault reporting in Hyp mode* on page G4-3726.

On an access that might have multiple aborts, the MMU fault checking sequence and the prioritization of aborts determine which abort occurs. For more information, see *The MMU fault-checking sequence* on page G4-3706 and *Prioritization of aborts* on page G4-3714.

G4.13.2 Reporting exceptions taken to PL1 modes

The following sections give general information about the reporting of exceptions when they are taken to a Secure or Non-secure PL1 mode:

- *Registers used for reporting exceptions taken to PL1 modes*.
- *Data Abort exceptions, taken to a PL1 mode* on page G4-3717.
- *Prefetch Abort exceptions, taken to a PL1 mode* on page G4-3718.

Fault reporting in PL1 modes on page G4-3719 then describes the fault reporting in these modes, including the encodings used for reporting the faults.

Note

Execution privilege, Exception levels, and AArch32 Privilege levels on page G4-3616 describes how the Secure and Non-secure PL1 modes map onto the Exception levels.

Registers used for reporting exceptions taken to PL1 modes

AArch32 state defines the following registers, and register encodings, for exceptions taken to PL1 modes:

- The DFSR holds information about a Data Abort exception.
- The DFAR holds the faulting address for some synchronous Data Abort exceptions.
- The IFSR holds information about a Prefetch Abort exception.
- The IFAR holds the faulting address of a Prefetch Abort exception.

In addition, if implemented, the optional ADFSR and AIFSR can provide additional fault information, see *Auxiliary Fault Status Registers*.

Auxiliary Fault Status Registers

AArch32 state defines the following Auxiliary Fault Status Registers:

- The Auxiliary Data Fault Status Register, ADFSR.
- The Auxiliary Instruction Fault Status Register, AIFSR.

The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED. An implementation can use these registers to return additional fault status information. An example use of these registers is to return more information for diagnosing parity errors.

An implementation that does not need to report additional fault information must implement these registers as UNK/SBZP. This ensures that an attempt to access these registers from software executing at PL1 does not cause an Undefined Instruction exception.

Data Abort exceptions, taken to a PL1 mode

On taking a Data Abort exception to a PL1 mode:

- If the exception is on an instruction cache or branch predictor maintenance operation by VA, its reporting depends on the current translation table format. For more information about the registers used when reporting the exception, see *Data Abort on an instruction cache maintenance instruction by VA*.
- If the exception is generated by a Watchpoint debug event, then its reporting depends on whether the Watchpoint debug event is synchronous or asynchronous, and on the Debug architecture version. For more information, see *Data Abort on a Watchpoint exception* on page G4-3718.

Otherwise:

- The DFSR is updated with details of the fault, including the appropriate fault status code.

  If the Data Abort exception is synchronous, DFSR.WnR is updated to indicate whether the faulted instruction was a read or a write. However, if the fault is on a cache maintenance instruction, or on an address translation instruction, WnR is set to 1, to indicate a fault on a write instruction, and the CM bit is set to 1.

  DFSR.WnR is UNKNOWN on an asynchronous Data Abort exception.

  See the register description for more information about the returned fault information.

- If the Data Abort exception is
  - Synchronous, the DFAR is updated with the VA that caused the exception.
  - Asynchronous, the DFAR becomes UNKNOWN.

For all Data Abort exceptions, if the implementation includes EL3, the Security state of the PE in the mode to which the Data Abort exception is taken determines whether the Secure or Non-secure DFSR and DFAR are updated.

Data Abort on an instruction cache maintenance instruction by VA

If an instruction cache or branch predictor invalidation by VA operation generates a Data Abort exception that is taken to a PL1 mode, the DFAR is updated to hold the faulting VA. However, the reporting of the fault depends on the current translation table format:

Short-descriptor format

It is IMPLEMENTATION DEFINED which of the following is used when reporting the fault:

- The DFSR indicates an Instruction cache maintenance instruction fault, and the IFSR is valid and indicates the cause of the fault, a Translation fault or Access flag fault.
- The DFSR indicates the cause of the fault, a Translation fault or Access flag fault. The IFSR is UNKNOWN.

In either case:

- DFSR.WnR is set to 1.
- DFSR.CM is set to 1, to indicate a fault on a cache maintenance instruction.

Long-descriptor format

- DFSR.CM is set to 1, to indicates a fault on a cache maintenance instruction.
- DFSR.STATUS indicates the cause of the fault, a Translation or Access flag fault.
- DFSR.WnR is set to 1.
- The IFSR is UNKNOWN.

Data Abort on a Watchpoint exception

On taking a Data Abort exception caused by a watchpoint:

- DFSR.FS is updated to indicate a debug event.
- DFSR.{WnR, Domain} are UNKNOWN.
- DFAR is set to the address that generated the watchpoint

Note

- LR_abt indicates the address of the instruction that triggered the watchpoint.
- In some ARMv7 AArch32 implementations, the DBGWFAR is set to the address of the instruction that triggered the watchpoint. In ARMv8 this register is RES0.

A watchpointed address can be any byte-aligned address. The address reported in DFAR might not be the watchpointed address, and, for a watchpoint due to an operation other than a Data Cache maintenance instruction, can be any address between and including:

- The lowest address accessed by the instruction that triggered the watchpoint.
- The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated.

Note

In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.

The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.

Note

The IMPLEMENTATION DEFINED power-of-two size must be no larger than the block size of the AArch64 DC ZVA operation.

Prefetch Abort exceptions, taken to a PL1 mode

For a Prefetch Abort exception generated by an instruction fetch, the Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

- If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
- If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction, no Prefetch Abort exception is generated.

In addition, Software Breakpoint Instruction, Breakpoint, and Vector Catch exceptions, generate a Prefetch Abort exception, see *Breakpoint debug events and Vector Catch exception* on page H2-4399.

On taking a Prefetch Abort exception to a PL1 mode:

- The IFSR is updated with details of the fault, including the appropriate fault code. If appropriate, the fault code indicates that the exception was generated by a debug exception.

  See the register description for more information about the returned fault information.
- For a Prefetch Abort exception generated by an instruction fetch, the IFAR is updated with the VA that caused the exception.
- For a Prefetch Abort exception generated by a debug exception, the IFAR is UNKNOWN.

If the implementation includes EL3, the security state of the PE in the mode to which it takes the Prefetch Abort exception determines whether the exception updates the Secure or Non-secure IFSR and IFAR.

G4.13.3 Fault reporting in PL1 modes

The FSRs provide fault information, including an indication of the fault that occurred. The following subsections describe fault reporting in PL1 modes for each of the translation table formats:

- *PL1 fault reporting with the Short-descriptor translation table format*.
- *PL1 fault reporting with the Long-descriptor translation table format* on page G4-3721.

Reserved encodings in the IFSR and DFSR encodings tables on page G4-3722 gives some additional information about the encodings for both formats.

Summary of register updates on faults taken to PL1 modes on page G4-3722 shows which registers are updated on each of the reported faults.

Reporting of External aborts taken from Non-secure state to Monitor mode describes how the fault status register format is determined for those aborts. For all other aborts, the current translation table format determines the format of the fault status registers.

Reporting of External aborts taken from Non-secure state to Monitor mode

When an External abort is taken from Non-secure state to Monitor mode:

- For a Data Abort exception, the Secure DFSR and DFAR hold information about the abort.
- For a Prefetch Abort exception, the Secure IFSR and IFAR hold information about the abort.
- The abort does not affect the contents of the Non-secure copies of the fault reporting registers.

Normally, the current translation table format determines the format of the DFSR and IFSR. However, when SCR.EA is set to 1, to route external aborts to Monitor mode, and an external abort is taken from Non-secure state, this section defines the DFSR and IFSR format.

For an External abort taken from Non-secure state to Monitor mode, the DFSR or IFSR uses the format associated with the Long-descriptor translation table format, as described in *PL1 fault reporting with the Long-descriptor translation table format* on page G4-3721, if any of the following applies:

- The Secure TTBCR.EAE bit is set to 1.
- The External abort is synchronous and either:
  - It is taken from Hyp mode.
  - It is taken from a Non-secure PL1 mode, and the Non-secure TTBCR.EAE bit is set to 1.

Otherwise, the DFSR or IFSR uses the format associated with the Short-descriptor translation table format, as described in *PL1 fault reporting with the Short-descriptor translation table format*.

PL1 fault reporting with the Short-descriptor translation table format

This subsection describes the fault reporting for a fault taken to a PL1 when address translation is using the Short-descriptor translation table format.

On taking an exception, bit[9] of the FSR is RAZ, or set to 0, if the PE is using this FSR format.

An FSR encodes the fault in a 5-bit FS field, that comprises FSR[10, 3:0]. Table G4-26 on page G4-3720 shows the encoding of that field. *Summary of register updates on faults taken to PL1 modes* on page G4-3722 shows:

- Whether the corresponding FAR is updated on the fault. That is:
  - For a fault reported in the IFSR, whether the IFAR holds a valid address.
  - For a fault reported in the DFSR, whether the DFAR holds a valid address.
- For faults that update DFSR, whether DFSR.Domain is valid

When reading Table G4-26 on page G4-3720:

- FS values not shown in the table are reserved.

- FS values shown as DFSR only are reserved for the IFSR.

Table G4-26 FSR encodings when using the Short-descriptor translation table format

FS	Source		Notes
00001	Alignment fault		DFSR only. Fault on first lookup
00100	Fault on instruction cache maintenance		DFSR only
01100 01110	Synchronous external abort on translation table walk	First level Second level	-
11100 11110	Synchronous parity error on translation table walk	First level Second level	-
00101 00111	Translation fault	First level Second level	MMU fault
00011[a] 00110	Access flag fault	First level Second level	MMU fault
01001 01011	Domain fault	First level Second level	MMU fault
01101 01111	Permission fault	First level Second level	MMU fault
00010	Debug event		See Chapter G2 *AArch32 Self-hosted Debug*
01000	Synchronous external abort		-
10000	TLB conflict abort		See *TLB conflict aborts* on page G4-3688
10100	IMPLEMENTATION DEFINED		Lockdown
11010	IMPLEMENTATION DEFINED		Coprocessor abort
11001	Synchronous parity error on memory access		-
10110	Asynchronous external abort[b]		DFSR only
11000	Asynchronous parity error on memory access[c]		DFSR only

a. Previously, this encoding was a deprecated encoding for Alignment fault. The extensive changes in the memory model in VMSAv8-32 mean there should be no possibility of confusing the new use of this encoding with its previous use

b. Including asynchronous data external abort on translation table walk or instruction fetch.

c. Including asynchronous parity error on translation table walk.

The Domain field in the DFSR

The DFSR includes a Domain field. This is inherited from previous versions of the VMSA. The IFSR does not include a Domain field. *Summary of register updates on faults taken to PL1 modes* on page G4-3722 describes when DFSR.Domain is valid.

ARM deprecates any use of the Domain field in the DFSR. The Long-descriptor translation table format does not support a Domain field, and future versions of the ARM architecture might not support a Domain field in the Short-descriptor translation table format. ARM strongly recommends that new software does not use this field.

For both Data Abort exceptions and Prefetch Abort exceptions, software can find the domain information by performing a translation table read for the faulting address and extracting the Domain field from the translation table entry.

PL1 fault reporting with the Long-descriptor translation table format

This subsection describes the fault reporting for a fault taken to a PL1mode when address translation is using the Long-descriptor translation table format.

When the PE takes an exception, bit[9] of the FSR is set to 1 if the PE is using this FSR format.

The FSRs encode the fault in a 6-bit STATUS field, that comprises FSR[5:0]. Table G4-27 shows the encoding of that field. In addition:

- For a fault taken to a PL1 mode, *Summary of register updates on faults taken to PL1 modes* on page G4-3722 shows whether the corresponding FAR is updated on the fault. That is:
  - For a fault reported in the IFSR, whether the IFAR holds a valid address.
  - For a fault reported in the DFSR, whether the DFAR holds a valid address.
- For a fault taken to the Hyp mode, *Summary of register updates on exceptions taken to Hyp mode* on page G4-3734 shows what registers are updated on the fault.

Table G4-27 FSR encodings when using the Long-descriptor translation table format

STATUS[a]	Source	Notes
0001LL	Translation fault. LL bits indicate level[b].	MMU fault
0010LL	Access flag fault. LL bits indicate level[b].	MMU fault
0011LL	Permission fault. LL bits indicate level[b].	MMU fault
010000	Synchronous external abort.	-
011000	Synchronous parity error on memory access.	-
010001	Asynchronous external abort.	DFSR only
011001	Asynchronous parity error on memory access.	DFSR only
0101LL	Synchronous external abort on translation table walk. LL bits indicate level[b].	-
0111LL	Synchronous parity error on memory access on translation table walk. LL bits indicate level[b].	-
100001	Alignment fault.	Fault on first lookup
100010	Debug event.	See Chapter G2 *AArch32 Self-hosted Debug*
110000	TLB conflict abort.	See *TLB conflict aborts* on page G4-3688
110100	IMPLEMENTATION DEFINED.	Lockdown, DFSR only
111010	IMPLEMENTATION DEFINED.	Coprocessor abort, DFSR only
1111LL	Domain fault. LL bits indicate level[b].	MMU fault. 64-bit PAR only, First or second level only. Never used in DFSR, IFSR, or HSR[c]

a. STATUS values not shown in this table are reserved. STATUS values not supported in the IFSR or DFSR are reserved for the register or registers in which they are not supported.

b. See *The level associated with MMU faults* on page G4-3722.

c. A Domain fault can be reported using the Long-descriptor STATUS encodings only as a result of a fault on an address translation instruction. For more information see *MMU fault on an address translation instruction* on page G4-3741.

The level associated with MMU faults

For MMU faults, Table G4-28 shows how the LL bits in the xFSR.STATUS field encode the lookup level associated with the fault.

Table G4-28 Use of LL bits to encode the lookup level at which the fault occurred

LL bits	Meaning
00	Reserved.
01	First level.
10	Second level.
11	Third level. When xFSR.STATUS indicates a Domain fault, this value is reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because an stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a First level fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Reserved encodings in the IFSR and DFSR encodings tables

With both the Short-descriptor and the Long-descriptor FSR format, the fault encodings reserve a single encoding for each of:

- Cache and TLB lockdown faults. The details of these faults and any associated subsidiary registers are IMPLEMENTATION DEFINED.
- Aborts associated with coprocessors. The details of these faults are IMPLEMENTATION DEFINED.

G4.13.4 Summary of register updates on faults taken to PL1 modes

For faults that generate exceptions that are taken to a PL1 mode, Table G4-29 on page G4-3723 shows the registers affected by each fault. In this table:

- Yes indicates that the register is updated.
- UNK indicates that the fault makes the register value UNKNOWN.
- A null entry, -, indicates that the fault does not affect the register.

For faults that update the DFSR using the Short-descriptor format FSR encodings, Table G4-30 on page G4-3724 shows whether DFSR.Domain is valid.

Table G4-29 Effect of a fault taken to a PL1 mode on the reporting registers

Fault		IFSR	IFAR	DFSR	DFAR
Faults reported as Prefetch Abort exceptions:					
MMU fault, always synchronous.		Yes	Yes	-	-
Synchronous external abort on translation table walk.		Yes	Yes	-	-
Synchronous parity error on translation table walk.		Yes	Yes	-	-
Synchronous external abort.		Yes	Yes	-	-
Synchronous parity error on memory access.		Yes	Yes	-	-
TLB conflict abort.		Yes	Yes	-	-
Fault reported as Data Abort exception:					
Alignment fault, always synchronous.		-	-	Yes	Yes
MMU fault, always synchronous.		-	-	Yes	Yes
Fault on instruction cache maintenance, when using Long-descriptor translation table format[a].		UNK	-	Yes	Yes
Fault on instruction cache maintenance, when using Short descriptor translation table format[b].	*either*	Yes	-	Yes	Yes
	or	UNK	-	Yes	Yes
Synchronous external abort on translation table walk.		-	-	Yes	Yes
Synchronous parity error on translation table walk.		-	-	Yes	Yes
Synchronous external abort.		-	-	Yes	Yes
Synchronous parity error on memory access.		-	-	Yes	Yes
Asynchronous external abort.		-	-	Yes	UNK
Asynchronous parity error on memory access.		-	-	Yes	UNK
TLB conflict abort.		-	-	Yes	Yes
Debug exceptions:					
Breakpoint, Software Breakpoint Instruction, or Vector Catch[c].		Yes	UNK	-	-
Watchpoint[d].		-	-	Yes	Yes

a. When using the Long-descriptor translation table format, there is not a specific fault code for a fault on an instruction cache maintenance instruction. For more information see *Data Abort on an instruction cache maintenance instruction by VA* on page G4-3717.

b. The two lines of this entry show the alternative ways of reporting the fault when using the Short-descriptor translation table format. It is IMPLEMENTATION DEFINED which methods is used, see *Data Abort on an instruction cache maintenance instruction by VA* on page G4-3717.

c. Generates a Prefetch Abort exception.

d. Generates a Data Abort exception.

For those faults for which Table G4-29 on page G4-3723 shows that the DFSR is updated, if the fault is reported using the Short-descriptor FSR encodings, Table G4-30 shows whether DFSR.Domain is valid. In this table, UNK indicates that the fault makes DFSR.Domain UNKNOWN.

Table G4-30 Validity of Domain field on faults that update the DFSR when using the Short-descriptor encodings

DFSR.FS	Source		DFSR.Domain	Notes
00001	Alignment fault		UNK	-
00100	Fault on instruction cache maintenance instruction		UNK	-
01100 01110	Synchronous external abort on translation table walk	First level Second level	UNK Valid	-
11100 11110	Synchronous parity error on translation table walk	First level Second level	UNK Valid	-
00101 00111	Translation fault	First level Second level	UNK Valid	MMU fault
00011[a] 00110	Access flag fault	First level Second level	UNK Valid	MMU fault
01001 01011	Domain fault	First level Second level	Valid Valid	MMU fault
01101 01111	Permission fault	First level Second level	UNK UNK	MMU fault
01000	Synchronous external abort		UNK	-
10000	TLB conflict abort		UNK	-
11001	Synchronous parity error on memory access		UNK	-
10110	Asynchronous external abort[b]		UNK	-
11000	Asynchronous parity error on memory access[c]		UNK	-
00010	Watchpoint		UNK	

a. Previously, this encoding was a deprecated encoding for Alignment fault. The extensive changes in the memory model in VMSAv8-32 mean there should be no possibility of confusing the new use of this encoding with its previous use
b. Including asynchronous data external abort on translation table walk or instruction fetch.
c. Including asynchronous parity error on translation table walk.

G4.13.5 Reporting exceptions taken to Hyp mode

Hyp mode is the Non-secure EL2 mode. It is entered by taking an exception to Hyp mode.

Note

Software executing in Monitor mode, or at EL3 when EL3 is using AArch64, can perform an exception return to Hyp mode. This means Hyp mode can be entered either by taking an exception, or by a permitted exception return.

When EL2 is using AArch32, the following exceptions are taken to Hyp mode:

- Asynchronous external aborts, IRQ exceptions, and FIQ exceptions, from Non-secure PL0 and PL1 modes, if not routed to Secure Monitor mode, and if configured by the AMO, FMO or IMO bits. For more information see *Asynchronous exception routing controls* on page G1-3420.

- When HCR.TGE is set to 1, all exceptions that would be routed to Non-secure PL1 modes.

  For more information, see *Routing general exceptions to EL2* on page G1-3410.

- When HDCR.TDE is set to 1, any debug exception that would otherwise be taken to a Non-secure PL1 mode, see *Routing debug exceptions to EL2* on page G1-3411.

- The privilege rules for taking exceptions mean that any exception taken from Hyp mode, if not routed to EL3, must be taken to Hyp mode.

- Hypervisor Call exceptions, and Hyp Trap exceptions, are always taken to Hyp mode. These exceptions are supported only as part of EL2.

  When EL2 is implemented, various operations from Non-secure PL0 and PL1 modes can be *trapped* to Hyp mode, using the Hyp Trap exception. For more information, see *EL2 configurable instruction enables, disables, and traps* on page G1-3482.

These exceptions include any memory system fault that occurs:

- On a memory access from Hyp mode.
- On memory access from a Non-secure PL0 or PL1 mode:
  - On a stage 2 translation, from IPA to PA.
  - On the stage 2 translation of an address accessed in performing a stage 1 translation table walk.

Memory fault reporting in Hyp mode on page G4-3726 gives more information about these faults.

The following exceptions provide *syndrome* information in the HSR:

- Any synchronous exception taken to Hyp mode.

- Some exceptions taken from Debug state that would be taken to Hyp mode if the PE was not in Debug state, see *Exceptions in Debug state* on page H2-4425.

  Note

  - In Debug state, the PE does not change mode on taking an exception.
  - As *Exceptions in Debug state* on page H2-4425 describes, some other exceptions taken from Debug state make the HSR UNKNOWN.

The syndrome information in the HSR includes the fault status code otherwise provided by the fault status register, and extends the fault reporting compared to that available for an exception taken to a PL1 mode. For more information, see *Use of the HSR* on page G4-3728.

In addition, for a Debug exception taken to Hyp mode, DBGDSCRint.MOE or DBGDTRRXext.MOE shows what caused the Debug exception. This bit is valid regardless of whether the Debug exception was taken from Hyp mode or from another Non-secure mode.

Registers used for reporting exceptions taken to Hyp mode lists all of the registers used for exception reporting in Hyp mode.

Registers used for reporting exceptions taken to Hyp mode

The following registers are used for reporting exceptions taken to Hyp mode:

- The HSR holds syndrome information for the exception.
- The HDFAR holds the VA associated with a Data Abort exception.
- The HIFAR holds the VA associated with a Prefetch Abort exception.
- The HPFAR holds bits[39:12] of the IPA associated with a Prefetch Abort exception.

In addition, if implemented, the optional HADFSR and HAIFSR can provide additional fault information, see *Hyp Auxiliary Fault Syndrome Registers* on page G4-3726.

Hyp Auxiliary Fault Syndrome Registers

EL2 also defines encodings for the following Hyp Auxiliary Fault Syndrome Registers:

- The Hyp Auxiliary Data Fault Syndrome Register, HADFSR.
- The Hyp Auxiliary Instruction Fault Syndrome Register, HAIFSR.

An implementation can use these registers to return additional fault status information for aborts taken to Hyp mode. They are the Hyp mode equivalents of the registers described in *Auxiliary Fault Status Registers* on page G4-3716. An example use of these registers is to return more information for diagnosing parity errors.

The architectural requirements for the HADFSR and HAIFSR are:

- The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED.
- An implementation with no requirement for additional fault reporting can implement these registers as UNK/SBZP, but the architecture does not require it to do so.

Memory fault reporting in Hyp mode

Prefetch Abort and Data Abort exceptions taken to Hyp mode report memory faults. For these aborts, the HSR contains the following fault status information:

- The HSR.EC field indicates the type of abort, as Table G4-31 shows.
- The HSR.ISS field holds more information about the abort. In particular:
  - Bits[5:0] of this field hold the STATUS field for the abort, using the encodings defined in *PL1 fault reporting with the Long-descriptor translation table format* on page G4-3721.
  - Other subfields of the ISS give more information about the exception, equivalent to the information returned in the FSR for a memory fault reported at PL1.

  See the descriptions of the ISS fields for the memory faults, referenced from the *Syndrome description* column of Table G4-31, for information about the returned fault information.

Table G4-31 HSR.EC encodings for aborts taken to Hyp mode

HSR.EC	Abort	Syndrome description
0x20	Prefetch Abort taken from Non-secure PL0 or PL1 mode	*Prefetch Abort exceptions taken to Hyp mode* on page G4-3733
0x21	Prefetch Abort taken from Hyp mode	
0x24	Data Abort taken from Non-secure PL0 or PL1 mode	*Data Abort exceptions taken to Hyp mode* on page G4-3733
0x25	Data Abort taken from Hyp mode	

For more information, see *Use of the HSR* on page G4-3728.

A Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

- If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
- If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction that would abort if the PE attempted to execute it, no Prefetch Abort exception is generated.

Register updates on exception reporting in Hyp mode

The use of the HSR, and of the other registers listed in *Registers used for reporting exceptions taken to Hyp mode on page G4-3725*, depends on the cause of the Abort. In reporting these faults, in general:

- If the fault generates a synchronous Data Abort exception, the HDFAR holds the associated VA.
- If the fault generates a Prefetch Abort exception, the HIFAR holds the associated VA.
- In the following cases, the HPFAR holds the faulting IPA:
  - A Translation or Access flag fault on a stage 2 translation.
  - A fault on the stage 2 translation of an address accessed in a stage 1 translation table walk.

  In all other cases, the HPFAR is UNKNOWN.
- On a Data Abort exception that is taken to Hyp mode, the HIFAR is UNKNOWN.
- On a Prefetch Abort exception that is taken to Hyp mode, the HDFAR is UNKNOWN.

In addition, the reporting of particular aborts is as follows:

Abort on the stage 1 translation for a memory access from Hyp mode

The HDFAR or HIFAR holds the VA that caused the fault. The STATUS subfield of HSR.ISS indicates the type of fault, Translation, Address size, Access flag, or Permission. The HPFAR is UNKNOWN.

Abort on the stage 2 translation for a memory access from a Non-secure PL1 or PL0 mode

This includes aborts on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation. The HDFAR or HIFAR holds the VA that caused the fault. The STATUS subfield of HSR.ISS indicates the type of fault, Translation, Address size, Access flag, or Permission.

For any Access flag fault or Translation fault, and also for any Permission fault on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation, the HPFAR holds the IPA that caused the fault. Otherwise, the HPFAR is UNKNOWN.

Abort caused by a synchronous external abort, or synchronous parity error, and taken to Hyp mode

The HDFAR or HIFAR holds the VA that caused the fault. The HPFAR is UNKNOWN.

Data Abort caused by a Watchpoint exception and routed to Hyp mode because HDCR.TDE is set to 1

When HDCR.TDE is set to 1, a Watchpoint exception generated in a Non-secure PL1 or PL0 mode, that would otherwise generate a Data Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.

HDFAR is set to the address that generated the watchpoint.

Note

ELR_hyp indicates the address of the instruction that triggered the watchpoint.

A watchpointed address can be any byte-aligned address. The address reported in HDFAR might not be the watchpointed address, and, for a watchpoint due to an operation other than a Data Cache maintenance instruction, can be any address between and including:

- The lowest address accessed by the instruction that triggered the watchpoint.
- The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated.

Note

In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.

The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.

Note

The IMPLEMENTATION DEFINED power-of-two size must be no larger than the block size of the AArch64 DC ZVA operation.

See also *Watchpoint exceptions* on page G2-3550.

In all cases, HPFAR is UNKNOWN.

Prefetch Abort caused by a Software Breakpoint Instruction exception and taken to Hyp mode

This abort is generated if a BKPT instruction is executed in Hyp mode. The abort leaves the HIFAR and HPFAR UNKNOWN.

See also *Breakpoint debug events and Vector Catch exception* on page H2-4399.

Prefetch Abort caused by a Software Breakpoint Instruction, Breakpoint, or Vector Catch exception, and routed to Hyp mode because HDCR.TDE is set to 1

When HDCR.TDE is set to 1, a debug exception, generated in a Non-secure PL1 or PL0 mode, that would otherwise generate a Prefetch Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.

The abort leaves the HIFAR and HPFAR UNKNOWN. This is identical to the reporting of a Prefetch Abort exception caused by a Debug exception on a BKPT instruction that is executed in Hyp mode.

Note

The difference between these two cases is:

- The Debug exception on a BKPT instruction executed in Hyp mode generates a Prefetch Abort exception, taken to Hyp mode, and reported in the HSR using EC value 0x21.
- Aborts generated because HDCR.TDE is set to 1 generate a Hyp Trap exception, and are reported in the HSR using EC value 0x20.

G4.13.6 Use of the HSR

The HSR holds syndrome information for any synchronous exception taken to Hyp mode. Compared with the reporting of exceptions taken to PL1 modes, the HSR:

- Always provides details of the fault. The DFSR and IFSR are not used.
- Provides more extensive information, for a wider range of exceptions.

Note

IRQ and FIQ exceptions taken to Hyp mode do not report any syndrome information in the HSR.

HSR, Hyp Syndrome Register on page G5-3938 describes the HSR, this section summarizes the general form of the register, to show how it encodes exception syndrome information. The register comprises:

- A 6-bit Exception class field, EC, that indicates the cause of the exception.
- An instruction length bit, IL. When an exception is caused by trapping an instruction to Hyp mode, this bit indicates the length of the trapped instruction, as follows:

  0 16-bit instruction trapped.

  1 32-bit instruction trapped.

  In other cases the IL field is not valid and is field is RES1.
- An instruction specific syndrome field, ISS. Architecturally, this field could be defined independently for each defined Exception class (EC), but in practice several ISS formats are common to more than one EC.

  This field is not valid, UNK/SBZP, when the EC field is 0x00, indicating an exception with an unknown reason.

The format of the HSR depends on the value of the EC field, as follows:

EC == 0b000000 The remainder of the HSR, bits[25:0], is not valid and UNKNOWN. This is the Exception class described in *Exceptions with an unknown reason* on page G4-3731.

Non-zero EC value with HSR[31:30] == 0b00

The ISS part of the returned value includes the CV and COND fields described in *Encoding of ISS[24:20] when HSR[31:30] is 0b00*. Figure G4-25 shows the HSR format in this case.

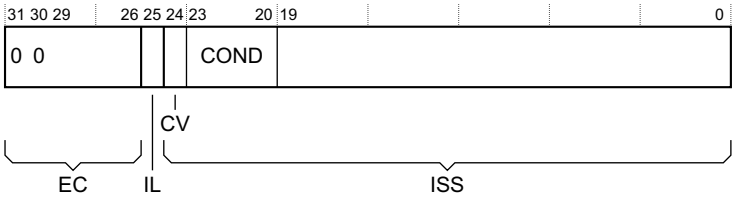

Figure G4-25 Format of the HSR when the ISS includes CV and COND fields

EC > 0b001111 There are no generic fields within the ISS. Figure G4-26 shows the HSR format in this case.

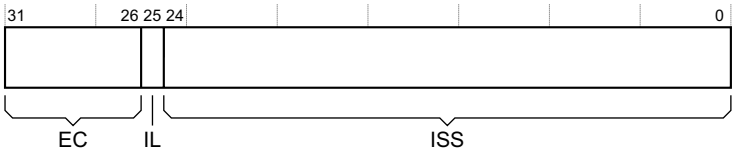

Figure G4-26 Format of the HSR when the ISS does not include a COND field

Encoding of ISS[24:20] when HSR[31:30] is `0b00`

For EC values that are nonzero and have the two most-significant bits `0b00`, ISS[24:20] provides the condition code field for the trapped instruction, together with a valid flag for this field. The encoding of this part of the ISS field is:

CV, ISS[24] Condition code valid. Possible values of this bit are:

- **0** The COND field is not valid.
- **1** The COND field is valid

COND, ISS[23:20]

The condition code for the trapped instruction. This field is valid only when CV is set to 1.

If CV is set to 0, this field is UNK/SBZP.

The full descriptions of the HSR.ISS formats give more information about the CV field.

Note

In some circumstances, it is IMPLEMENTATION DEFINED whether a conditional instruction that fails its condition code check generates an Undefined Instruction exception, see *Conditional execution of undefined instructions* on page G1-3430.

HSR exception classes

Table G4-32 shows the encoding of the HSR exception class field, EC. Values of EC not shown in the table are reserved. The table divides the EC values into three groups, relating to the interpretation of the associated ISS fields. For each EC value, the table references a subsection that gives information about the cause of the exception, for example the configuration required to enable the trap. The HSRdescription describes the associated HSR.ISS format.

Table G4-32 HSR.EC field encoding

EC	Exception class	ISS description, or notes
0b000000	Unknown reason	*Exceptions with an unknown reason* on page G4-3731.
Nonzero EC values with HSR[31:30] zero[a]		
0b000001	Trapped WFI or WFE instruction	*Exceptions caused by a trapped WFI or WFE instruction* on page G4-3731.
0b000011	Trapped MCR or MRC access to CP15	*Exceptions caused by a trapped MCR or MRC access* on page G4-3731.
0b000100	Trapped MCRR or MRRC access to CP15	*Exceptions caused by a trapped MCRR or MRRC access* on page G4-3732.
0b000101	Trapped MCR or MRC access to CP14	*Exceptions caused by a trapped MCR or MRC access* on page G4-3731.
0b000110	Trapped LDC or STC access to CP14	*Exceptions caused by a trapped LDC or STC access* on page G4-3732.
0b000111	HCPTR-trapped access to CP10 or CP11	*Exceptions caused by an HCPTR-trapped access to CP10 or CP11* on page G4-3732. Includes trap of use of Advanced SIMD functionality.
0b001000	Trapped MRC or VMRS access to CP10, for ID group traps	*Exceptions caused by a trapped MCR or MRC access* on page G4-3731. This trap is not taken if the HCPTR settings trap the access.
0b001100	Trapped MRRC access to CP14	*Exceptions caused by a trapped MCRR or MRRC access* on page G4-3732.
0b001110	Illegal exception return to AArch32 state	The ISS is RES0. For more information see *Illegal exception return and PC alignment fault exceptions* on page G4-3734.
EC values with HSR[31:30] nonzero		
0b010001	Supervisor Call exception routed to Hyp mode	*Hypervisor Call exceptions, and Supervisor Call exceptions routed to Hyp mode* on page G4-3732.
0b010010	Hypervisor Call	
0b010011	Trapped SMC instruction	*Exception caused by trapped SMC execution* on page G4-3733.
0b100000	Prefetch Abort routed to Hyp mode	*Prefetch Abort exceptions taken to Hyp mode* on page G4-3733.
0b100001	Prefetch Abort taken from Hyp mode	
0b101010	PC Alignment Exception.	The ISS is RES0. For more information see *Illegal exception return and PC alignment fault exceptions* on page G4-3734.
0b100100	Data Abort routed to Hyp mode	*Data Abort exceptions taken to Hyp mode* on page G4-3733.
0b100101	Data Abort taken from Hyp mode	

a. For more information see *Encoding of ISS[24:20] when HSR[31:30] is 0b00* on page G4-3729.

All EC encodings not shown in Table G4-31 on page G4-3726 are reserved by ARM.

Exceptions with an unknown reason

An HSR.EC value of 0x00 indicates an exception with an unknown reason. Any exception not covered by a nonzero EC value defined in Table G4-32 on page G4-3730 returns this value. When HSR.EC returns a value of 0x00, all other fields of HSR are invalid.

Undefined Instruction exception, when HCR.TGE is set to 1 on page G1-3410 describes the configuration settings for a trap that returns an HSR.EC value of 0b000000.

Exceptions caused by a trapped WFI or WFE instruction

This is the exception with EC value 0b000001.

The returned syndrome indicates whether the trapped instruction was a WFI or a WFE. *ISS encoding for an exception from a trapped WFI or WFE instruction* on page G5-3940 describes the format of this syndrome.

Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-3494 describes the configuration settings for this trap.

Exceptions caused by a trapped MCR or MRC access

These are the exceptions with the following EC values:

- 0b000011, trapped MRC or MCR access to CP15.
- 0b000101, trapped MRC or MCR access to CP14.
- 0b001000, trapped MRC or VMRS access to CP10.

The returned syndrome indicates the arguments of the trapped instruction. *ISS encoding for an exception from a trapped MCR or MRC access* on page G5-3941 describes the format of this syndrome.

The following sections describe configuration settings for traps that are reported using EC value 0x03:

- *Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers* on page G1-3485.
- *Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions* on page G1-3487.
- *Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions* on page G1-3488.
- *Traps to Hyp mode of Non-secure EL1 accesses to the Auxiliary Control Register* on page G1-3489.
- *Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations* on page G1-3490.
- *Traps to Hyp mode of Non-secure EL0 and EL1 reads of ID registers* on page G1-3491.
- *Trapping to Hyp mode of Non-secure EL1 accesses to the CPACR* on page G1-3496.
- *Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers* on page G1-3501.
- *General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to CP15 System registers* on page G1-3497.

The following sections describe configuration settings for traps that are reported using EC value 0x05:

- *ID group 0, Primary device identification registers* on page G1-3492.
- *Trapping CP14 accesses to trace registers* on page G1-3496.
- *Trapping CP14 accesses to Debug ROM registers* on page G1-3499.
- *Trapping CP14 accesses to powerdown debug registers* on page G1-3499.
- *Trapping general CP14 accesses to debug registers* on page G1-3500.

ID group 0, Primary device identification registers on page G1-3492 describes configuration settings for traps that are reported using EC value 0x08.

Exceptions caused by a trapped MCRR or MRRC access

These are the exceptions with the following EC values:

- 0b000100, trapped MRRC or MCRR access to CP15.
- 0b001100, trapped MRRC access to CP14.

The returned syndrome indicates the arguments of the trapped instruction. *ISS encoding for an exception from a trapped MCRR or MRRC access* on page G5-3943 describes the format of this syndrome.

The following sections describe configuration settings for traps that are reported using EC value 0x04:

- *Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers* on page G1-3485.
- *General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to CP15 System registers* on page G1-3497.

The following sections describe configuration settings for traps that are reported using EC value 0x0C:

- *Trapping CP14 accesses to trace registers* on page G1-3496.
- *Trapping CP14 accesses to Debug ROM registers* on page G1-3499.

Exceptions caused by a trapped LDC or STC access

This is the exception with EC value 0b000110.

The returned syndrome indicates the arguments of the trapped instruction. *ISS encoding for an exception from a trapped LDC or STC access to CP14* on page G5-3944 describes the format of this syndrome.

Note

The only architected uses of these instructions to access CP14 are:

- An STC to write to DBGDTRTXint.
- An LDC to read DBGDTRTXint.

Trapping general CP14 accesses to debug registers on page G1-3500 describes the configuration settings for the trap that is reported using EC value 0x06.

Exceptions caused by an HCPTR-trapped access to CP10 or CP11

This is the exception with EC value 0b000111.

The returned syndrome indicates whether the exception was caused by a trap on the use of Advanced SIMD functionality. *ISS encoding for an exception from an HCPTR-trapped access to CP10 or CP11* on page G5-3946 describes the format of this syndrome.

The following sections describe the configuration settings for the traps that are reported using EC value 0x07:

- *General trapping to Hyp mode of Non-secure accesses to the Advanced SIMD and floating-point registers* on page G1-3495.
- *Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality* on page G1-3495

Hypervisor Call exceptions, and Supervisor Call exceptions routed to Hyp mode

These are the exceptions with the following EC values:

- 0b010001, Supervisor Call exception taken to Hyp mode.
- 0b010010, Hypervisor Call exception.

Note

- A Supervisor Call exception is generated by executing an SVC instruction, see *SVC* on page F7-2891.
- A Hypervisor Call exception is generated by executing an HVC instruction, see *HVC* on page F7-3004.

The returned syndrome indicates the immediate value given as an argument to the instruction. *ISS encoding for an exception from HVC or SVC instruction execution* on page G5-3947 describes the format of this syndrome.

Note

The HVC instruction is unconditional, and a conditional SVC instruction generates a Supervisor Call exception that is routed to Hyp mode only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not include conditionality information.

Supervisor Call exception, when HCR.TGE is set to 1 on page G1-3410 describes the configuration settings for the trap reported with EC value 0x11.

Exception caused by trapped SMC execution

This is the exception with EC value 0b010011. When HSR.EC returns this value, the ISS field does not return any syndrome information, and is RES0.

Note

SMC instructions cannot be trapped if they fail their condition code check. Therefore, the syndrome information for this exception does not include conditionality information.

Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-3491 describes the configuration settings for this trap, for instructions executed in Non-secure PL1 modes.

Prefetch Abort exceptions taken to Hyp mode

These are the exceptions with the following EC values:

- 0b100000, for a Prefetch Abort exception taken from a mode other than Hyp mode and routed to Hyp mode.
- 0b100001, for a Prefetch Abort exception taken from Hyp mode.

The returned syndrome provides more information about the exception, including a fault code that indicates the cause of the exception. *ISS encoding for a Prefetch Abort exception* on page G5-3947 describes the format of this syndrome.

The following sections describe cases where Prefetch Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value 0x20:

- *Abort exceptions, when HCR.TGE is set to 1* on page G1-3411.
- *Routing debug exceptions to EL2* on page G1-3411.

Data Abort exceptions taken to Hyp mode

These are the exceptions with the following EC values:

- 0b100100, for a Data Abort exception taken from a mode other than Hyp mode and routed to Hyp mode.
- 0b100101, for a Data Abort exception taken from Hyp mode.

The returned syndrome provides more information about the exception, including a fault code that indicates the cause of the exception. *ISS encoding for a Data Abort exception* on page G5-3949 describes the format of this syndrome.

The following describe cases where Data Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value 0x24:

- *Abort exceptions, when HCR.TGE is set to 1* on page G1-3411.
- *Routing debug exceptions to EL2* on page G1-3411.
- *Hyp mode control of Non-secure access permissions* on page G4-3672.
- *Memory fault reporting in Hyp mode* on page G4-3726.

Illegal exception return and PC alignment fault exceptions

These are the exceptions with the following EC values:

- `0b001110`, for an illegal exception return to AArch32 state. This includes exceptions caused by an illegal Instruction set state. For more information see *Illegal exception returns to AArch32 state* on page G1-3413, *Illegal changes to the CPSR.M field* on page G1-3415, *Legal exception returns that set PSTATE.IL to 1* on page G1-3416, and *The Illegal Execution State exception* on page G1-3416.
- `0b101010`, for a PC alignment exception.

The ISS is RES0 for these exceptions.

There are no configurable traps or routing controls that can cause these exceptions.

G4.13.7 Summary of register updates on exceptions taken to Hyp mode

For memory system faults that generate exceptions that are taken to Hyp mode, Table G4-33 shows the registers affected by each fault. In this table:

- Yes indicates that the register is updated.
- UNK indicates that the fault makes the register value UNKNOWN.
- A null entry, -, indicates that the fault does not affect the register.

Table G4-33 Effect of an exception taken to Hyp mode on the reporting registers

Fault	HSR	HIFAR	HDFAR	HPFAR
Faults reported as Prefetch Abort exceptions:				
Address translation fault[a] at stage 1.	Yes	Yes	UNK	UNK
Address translation or Access flag fault[a] at stage 2.	Yes	Yes	UNK	Yes
Address translation fault[a] at stage 2.	Yes	Yes	UNK	UNK
Address translation stage 2 fault[a] on stage 1 translation.	Yes	Yes	UNK	Yes
Synchronous external abort on translation table walk.	Yes	Yes	UNK	UNK
Synchronous parity error on translation table walk.	Yes	Yes	UNK	UNK
Synchronous external abort.	Yes	Yes	UNK	UNK
Synchronous parity error on memory access.	Yes	Yes	UNK	UNK
TLB conflict abort.	Yes	Yes	UNK	UNK
Fault reported as Data Abort exception:				

Table G4-33 Effect of an exception taken to Hyp mode on the reporting registers (continued)

Fault	HSR	HIFAR	HDFAR	HPFAR
Alignment fault, always synchronous	Yes	UNK	Yes	UNK
Address translation fault[a] at stage 1.	Yes	UNK	Yes	UNK
Address translation Translation or Access flag fault[a] at stage 2.	Yes	UNK	Yes	Yes
Address translation Permission fault[a] at stage 2.	Yes	UNK	Yes	UNK
Address translation stage 2 fault[a] on stage 1 translation.	Yes	UNK	Yes	Yes
Synchronous external abort on translation table walk.	Yes	UNK	Yes	UNK
Synchronous parity error on translation table walk.	Yes	UNK	Yes	UNK
Synchronous external abort.	Yes	UNK	Yes	UNK
Synchronous parity error on memory access.	Yes	UNK	Yes	UNK
Asynchronous external abort.	Yes	UNK	UNK	UNK
Asynchronous parity error on memory access.	Yes	UNK	UNK	UNK
TLB conflict abort.	Yes	UNK	Yes	UNK
Debug exception:				
Software Breakpoint Instruction[b], generates a Prefetch Abort exception.	Yes	UNK	-	UNK
Debug exception routed to Hyp mode because HDCR.TDE is set to 1. Generates a Hyp Trap exception.				
Breakpoint Software Breakpoint Instruction or Vector Catch	Yes	UNK	-	UNK
Watchpoint	Yes	-	Yes	UNK

a. For more information see *Classification of MMU faults taken to Hyp mode*
b. All other debug exceptions are not permitted in Hyp mode.

Note

Unlike Table G4-29 on page G4-3723, the Hyp mode fault reporting table does not include an entry for a fault on an instruction cache maintenance instruction. That is because, when the fault is taken to Hyp mode, the reporting indicates the cause of the fault, for example a Translation fault, and ISS.CM is set to 1 to indicate that the fault was on a cache maintenance instruction, see *Data Abort exceptions taken to Hyp mode* on page G4-3733.

Classification of MMU faults taken to Hyp mode

This subsection gives more information about the MMU faults shown in Table G4-33 on page G4-3734.

Note

All MMU faults are synchronous.

The table uses the following descriptions for MMU faults taken to Hyp mode:

Address translation fault at stage 1

This is an address translation fault generated on a stage 1 translation performed in the Non-secure PL2 translation regime.

Address translation fault at stage 2

This is an address translation fault generated on a stage 2 translation performed in the Non-secure PL1&0 translation regime.

As the table shows, for the faults in this group:

- Translation and Access flag faults update the HPFAR
- Permission faults leave the HPFAR UNKNOWN.

Address translation stage 2 fault on a stage 1 translation

This is an address translation fault generated on the stage 2 translation of an address accessed in a stage 1 translation table walk performed in the Non-secure PL1&0 translation regime. For more information about these faults see *Stage 2 fault on a stage 1 translation table walk* on page G4-3710.

Figure G4-1 on page G4-3619 shows the different translation regimes and associated stages of translation.

G4.14 Virtual Address to Physical Address translation instructions

The system register space includes operations for *Virtual Address* (VA) to *Physical Address* (PA) translation. *Address translation instructions, functional group* on page G4-3796 summarizes these operations.

When using the Short-descriptor translation table format, all VA to PA translations take account of TEX remap when this is enabled, see *Short-descriptor format memory region attributes, with TEX remap* on page G4-3676.

A VA to PA translation operation returns the PA in the PAR. This is a 64-bit register, that can hold PAs of up to 40 bits.

The following sections give more information about these operations:

- *Naming of the address translation instructions, and operation summary*.
- *Encoding and availability of the address translation instructions* on page G4-3739.
- *Determining the PAR format* on page G4-3740.
- *Handling of faults and aborts during an address translation instruction* on page G4-3740.

G4.14.1 Naming of the address translation instructions, and operation summary

Some older documentation uses the original names for the address translation instructions that were included in the original ARMv7 documentation. Table G4-34 summarizes the operations that are available in AArch32 state, and relates the old operation names to the current names.

Table G4-34 Naming of address translation instructions

Name	Old name	Description
ATS1CPR, ATS1CPW, ATS1CUR, ATS1CUW	V2PCWPR, V2PCWPW, V2PCWUR, V2PCWUW	See *Address translation stage 1, current security state* on page G4-3738
ATS12NSOPR, ATS12NSOPW, ATS12NSOUR, ATS12NSOUW	V2POWPR, V2POWPW, V2POWUR, V2POWUW	See *Address translation stages 1 and 2, Non-secure state only* on page G4-3738
ATS1HR, ATS1HW	Not applicable[a]	See *Address translation stage 1, Hyp mode* on page G4-3738

a. Operations are part of EL2 and have no equivalent in the older descriptions.

In an implementation that does not include EL2, there is no distinction between stage 1 translations and stage 1 and 2 combined translations.

In the *stage 1 current state* and *stages 1 and 2 Non-secure state only* operations, the meanings of the last two letters of the names are:

PR PL1 mode, read operation.
PW PL1 mode, write operation.
UR User mode, read operation.
UW User mode, write operation.

Note

User mode can be described as an unprivileged mode. It is the only PL0 mode.

In the *stage 1 Hyp mode* operations, the last letter of the operation name is **R** for the read operation and **W** for the write operation.

The following sections describe the use and availability of these operations:

- *Address translation stage 1, current security state* on page G4-3738.
- *Address translation stages 1 and 2, Non-secure state only* on page G4-3738.
- *Address translation stage 1, Hyp mode* on page G4-3738.

Encoding and availability of the address translation instructions on page G4-3739 gives the encodings of the operations.

Address translation stage 1, current security state

These are the ATS1Cxx operations. Any VMSAv8-32 implementation supports these operations. They can be executed by any software executing at PL1 or higher, in either Security state.

These instructions perform the address translations of the PL1&0 translation regime.

In an implementation that includes EL2, when executed in Non-secure state, these operations return the IPA that is the output address of the stage 1 translation. Figure G4-1 on page G4-3619 shows the different translation regimes.

Note

The Non-secure PL1 and PL0 modes have no visibility of the stage 2 address translations, that can be defined only at PL2, and translate IPAs to be PAs.

See *Determining the PAR format* on page G4-3740 for the format used when returning the result of these operations.

Address translation stages 1 and 2, Non-secure state only

These are the ATS12NSOxx operations. A VMSAv8-32 implementation supports these operations only if it includes EL2. In an implementation that includes EL2, in AArch32 state, they can be executed:

- If the implementation includes EL3, by any software executing in Secure state at PL1.
- If the implementation includes EL2, by software executing in Non-secure state at PL2. This means by software executing in Hyp mode.

In an implementation that does not include EL2, but includes EL3, when EL3 is using AArch32 these instructions are not undefined but each instruction behaves in the same way as the equivalent ATSIC* instruction.

ARM deprecates use of these operations from any Secure PL1 mode other than Monitor mode.

In Secure state and in Non-secure Hyp mode these operations perform the translations made by the Non-secure PL1&0 translation regime.

These operations always return the PA and final attributes generated by the translation.That is, for an implementation that includes EL2, they return:

- The result of the two stages of address translation for the specified Non-secure input address.
- The memory attributes obtained by the combination of the stage 1 and stage 2 attributes.

Note

From Hyp mode, the ATS1Cxx and ATS12NSOxx operations both return the results of address translations that would be performed in the Non-secure modes other than Hyp mode. The difference is:

- The ATS1Cxx operations return the Non-secure PL1 view of these operations. That is, they return the IPA output address corresponding to the VA input address.
- The ATS12NSOxx operations return the EL2, or Hyp mode, view of these operations. That is, they return the PA output address corresponding to the VA input address, generated by two stages of translation.

See *Determining the PAR format* on page G4-3740 for the format used when returning the result of these operations.

Address translation stage 1, Hyp mode

These are the ATS1Hx operations. A VMSAv8-32 implementation supports these operations only if it includes EL2. They can be executed by:

- Software executing in Non-secure state at PL2. This means by software executing in Hyp mode.
- Software executing in Secure state in Monitor mode.

These operations are UNPREDICTABLE if used in a Secure PL1 mode other than Monitor mode.

These operations perform the translations made by the Non-secure EL2 translation regime. The operation takes a VA input address and returns a PA output address.

These operations always return a result in a 64-bit format PAR.

G4.14.2 Encoding and availability of the address translation instructions

Software executing at PL0 never has any visibility of the address translation instructions, but software executing at PL1 or higher can use the unprivileged address translation instructions to find the address translations used for memory accesses by software executing at PL0 and PL1.

Note

For information about translations when the stage of address translation is disabled see *The effects of disabling address translation stages on VMSAv8-32 behavior* on page G4-3625.

Table G4-35 shows the encodings for the address translation instructions, and their availability in different implementations in different PE modes and states.

Table G4-35 Address translation instructions in AArch32 state

opc1	CRm	opc2	Name	Type	Description
All VMSAv8-32 implementations, in all modes, at PL1 or higher					
0	c8	0	ATS1CPR	WO	PL1 stage 1 read translation, current state[a]
		1	ATS1CPW	WO	PL1 stage 1 write translation, current state[a]
		2	ATS1CUR	WO	Unprivileged stage 1 read translation, current state[a]
		3	ATS1CUW	WO	Unprivileged stage 1 write translation, current state[a]
Implementations that include EL2, in Non-secure Hyp mode and Secure PL1 modes					
0	c8	4	ATS12NSOPR	WO	Non-secure PL1 stage 1 and 2 read translation[b]
		5	ATS12NSOPW	WO	Non-secure PL1 stage 1 and 2 write translation[b]
		6	ATS12NSOUR	WO	Non-secure unprivileged stage 1 and 2 read translation[b]
		7	ATS12NSOUW	WO	Non-secure unprivileged stage 1 and 2 write translation[b]
Implementations that include EL2, in Non-secure Hyp mode and Secure Monitor mode					
4	c8	0	ATS1HR	WO	Hyp mode stage 1 read translation[c]
		1	ATS1HW	WO	Hyp mode stage 1 write translation[c]

a. For more information about these operations see *Address translation stage 1, current security state* on page G4-3738.
b. For more information about these operations see *Address translation stages 1 and 2, Non-secure state only* on page G4-3738.
c. For more information about these operations see *Address translation stage 1, Hyp mode* on page G4-3738.

The result of an operation is always returned in the PAR. The PAR is a RW register and:

- In all implementations, the 32-bit format PAR is accessed using an MCR or MRC instruction with CRn set to c7, CRm set to c4, and opc1 and opc2 both set to 0.
- The 64-bit format PAR is accessed using an MCRR or MRRC instruction with CRm set to c7, and opc1 set to 0.

Address translation instructions that are not available in a particular implementation are reserved and UNPREDICTABLE. For example, in an implementation that does not include EL3, the encodings with opc2 values of 4-7, and the encodings with an opc1 value of 4, are reserved and UNPREDICTABLE.

G4.14.3 Determining the PAR format

The PAR is a 64-bit register, that supports both 32-bit and 64-bit PAR formats. This section describes how the PAR format is determined, for returning a result from each of the groups of address translation instructions. The returned result might be the translated address, or might indicate a fault on the translation, see *Handling of faults and aborts during an address translation instruction*.

ATS1Cxx operations

Address translations for the current state. From modes other than Hyp mode:

- TTBCR.EAE determines whether the result is returned using the 32-bit or the 64-bit PAR format.
- If the implementation includes EL3, the translation performed is for the current security state and, depending on that state:
  - The Secure or Non-secure TTBCR.EAE determines the PAR format.
  - The result is returned to the Secure or Non-secure instance of the PAR

Operations from Hyp mode always return a result to the Non-secure PAR, using the 64-bit format.

ATS12NSOxx operations

Address translations for the Non-secure PL1 and PL0 modes. These operations return a result using the 64-bit PAR format if at least one of the following is true:

- The Non-secure TTBCR.EAE bit is set to 1.
- The implementation includes EL2, and the value of HCR.VM is 1.

Otherwise, the operation returns a result using the 32-bit PAR format.

Operations from a Secure PL1 mode return a result to the Secure PAR. Operations from Hyp mode return a result to the Non-secure PAR.

ATS1Hx operations

Address translations from Hyp mode. These operations always return a result using the 64-bit PAR format.

Operations from Secure Monitor mode return a result to the Secure PAR. Operations from Non-secure Hyp mode return a result to the Non-secure PAR.

G4.14.4 Handling of faults and aborts during an address translation instruction

When a stage of address translation is enabled, any corresponding address translation instruction requires a translation table lookup, and this might require a translation table walk. However, the input address for the translation might be a faulting address, either because:

- The translation table entries used for the translation indicate a fault.
- A stage 2 fault or an external abort occurs on the required translation table walk.

VMSAv8-32 memory aborts on page G4-3703 describes the faults that might occur on a translation table walk in AArch32 state.

How the fault is handled, and whether it generates an exception, depends on the cause of the fault, as described in:

- *MMU fault on an address translation instruction* on page G4-3741.
- *External abort during an address translation instruction* on page G4-3741.
- *Stage 2 fault on a current state address translation instruction* on page G4-3742.

MMU fault on an address translation instruction

In the following cases, an MMU fault on an address translation is reported in the PAR, and no abort is taken. This applies:

- For a faulting address translation instruction executed in Hyp mode, or in a Secure PL1 mode.
- For a faulting address translation instruction executed in a Non-secure PL1 mode, for cases where the fault would generate a stage 1 abort if it occurred on the on the equivalent load or store operation.

Using the PAR to report a fault on an address translation instruction gives more information about how these faults are reported.

Note

- The Domain fault encodings shown in Table G4-27 on page G4-3721 are used only for reporting a fault on an address translation instruction that uses the 64-bit PAR format. That is, they are used only in an implementation that includes EL2, and are used for reporting a Domain fault on either:
  - An ATS1Cxx operation from Hyp mode.
  - An ATS12NSOxx operation when HCR.VM is set to 1.

  These encodings are never used for fault reporting in the DFSR, IFSR, or HSR.
- For an address translation instruction executed in a Non-secure PL1 mode, for a fault that would generate a stage 2 abort if it occurred on the equivalent load or store operation, the stage 2 abort is generated as described in *Stage 2 fault on a current state address translation instruction* on page G4-3742.

Using the PAR to report a fault on an address translation instruction

For a fault on an address translation instruction for which no abort is taken, the PAR is updated with the following information, to indicate the fault:

- The fault code, that would normally be written to the Fault status register. The code used depends on the current translation table format, as described in either:
  - *PL1 fault reporting with the Short-descriptor translation table format* on page G4-3719.
  - *PL1 fault reporting with the Long-descriptor translation table format* on page G4-3721.

  See also the Note at the start of *Determining the PAR format* on page G4-3740 about the Domain fault encodings shown in Table G4-27 on page G4-3721.
- A status bit, that indicates that the translation operation failed.

The fault does not update any Fault Address Register.

External abort during an address translation instruction

As stated in *External abort on a translation table walk* on page G4-3713, an external abort on a translation table walk generates a Data Abort exception. The abort can be synchronous or asynchronous, and behaves as follows:

Synchronous external abort on a translation table walk

The fault status and fault address registers of the Security state to which the abort is taken are updated. The fault status register indicates the appropriate external abort on a Translation fault, and the fault address register indicates the input address for the translation.

The PAR is UNKNOWN.

Asynchronous external abort on a translation table walk

The fault status register of the Security state to which the abort is taken is updated, to indicate the asynchronous external abort. No fault address registers are updated.

The PAR is UNKNOWN.

Stage 2 fault on a current state address translation instruction

If the PE is in a Non-secure PL1 mode and performs one of the ATS1C** operations, then a fault in the stage 2 translation of an address accessed in a stage 1 translation table lookup generates an exception. This is equivalent to the case described in *Stage 2 fault on a stage 1 translation table walk* on page G4-3710. When this fault occurs on an ATS1C** address translation instruction:

- A Hyp Trap exception is taken to Hyp mode.
- The PAR is UNKNOWN.
- The HSR indicates that:
  - The fault occurred on a translation table walk.
  - The operation that faulted was a cache maintenance instruction.
- The HPFAR holds the IPA that faulted.
- The HDFAR holds the VA that the executing software supplied to the address translation instruction.

G4.15 About the System registers for VMSAv8-32

In AArch32 state, the System registers comprise:

- The registers accessed using the System Control Coprocessor interface, CP15.
- Registers accessed using the CP14 coprocessor interface, including:
  - Debug registers.
  - Trace registers.
  - Legacy execution environment registers.

Organization of the CP14 registers in VMSAv8-32 on page G4-3764 summarizes the CP14 registers, and indicates where the CP14 registers are described, either in this manual or in other architecture specifications.

Organization of the CP15 registers in VMSAv8-32 on page G4-3767 summarizes the CP15 registers, and indicates where in this manual the CP15 registers are described.

This section gives general information about the control registers, the CP14 and CP15 interfaces to these registers, and the conventions used in describing these registers.

Note

Many implementations include other interfaces to some functional groups of CP14 and CP15 registers, for example memory-mapped interfaces to the CP14 Debug registers. These are described in the appropriate sections of this manual.

This section is organized as follows:

- *About System register accesses*.
- *General behavior of System registers* on page G4-3744.
- *Classification of System registers* on page G4-3748.
- *Synchronization of changes to System registers* on page G4-3757.
- *Meaning of fixed bit values in register diagrams* on page G4-3762.

G4.15.1 About System register accesses

Most AArch32 System registers are 32 bits wide. *Accessing 32-bit control registers* describes how these registers are accessed.

A small number of the AArch32 System registers are 64 bits wide. *Accessing 64-bit control registers* on page G4-3744 describes how these registers are accessed.

Ordering of reads of System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that the data dependencies between the instructions, specified in *Synchronization of changes to System registers* on page G4-3757, are met.

Note

In particular, System registers holding self-incrementing counts, for example the Performance Monitors counters or the Generic Timer counter or timers, can be read *early*. This means that, for example, if a memory communication is used to communicate a read of the Generic Timer counter, an `ISB` must be inserted between the read of the memory location used for this communication and the read of the Generic Timer counter if it is required that the Generic Timer counter returns a count value that is later than the memory communication.

Accessing 32-bit control registers

Software accesses a 32-bit control register using the generic `MCR` and `MRC` coprocessor interface, specifying:

- A coprocessor identifier, coproc, identifying a valid coprocessor, as a value p0-p15, corresponding to CP0-CP15.

- Two coprocessor registers, CRn and CRm, as values in the range c0-c15, to specify a coprocessor register number. CRn specifies the primary coprocessor register.
- Two coprocessor-specific opcodes, opc1 and opc2, as values in the range 0-7.
- A general-purpose register to hold a 32-bit value to transfer to or from the coprocessor.

CP15 and CP14 provides the control registers. A PE access to a specific 32-bit control register uses:

- p15 to specify CP15, or p14 to specify CP14.
- A unique combination of CRn, opc1, CRm, and opc2, to specify the required control register.
- A general-purpose register for the transferred 32-bit value.

The PE accesses a 32-bit control register using:

- An `MCR` instruction to write to a control register, see *MCR, MCR2* on page F7-2631.
- An `MRC` instruction to read a control register, see *MCR, MCR2* on page F7-2631.

Accessing 64-bit control registers

Software accesses a 64-bit control register using the generic `MCRR` and `MRRC` coprocessor interface, specifying:

- A coprocessor identifier, coproc, identifying a valid coprocessor, as a value p0-p15, corresponding to CP0-CP15.
- A coprocessor register, CRm as a value in the range c0-c15, to specify a coprocessor register number. In this case, CRm specifies the primary coprocessor register, as a value c0-c15 to specify a coprocessor register number.
- A single coprocessor-specific opcode, opc1, as a value in the range 0-7.
- Two general-purpose registers to hold two 32-bit values to transfer to or from the coprocessor.

CP15 and CP14 provide the control registers. A PE access to a specific 64-bit System register uses:

- p15 to specify CP15, or p14 to specify CP14.
- A unique combination of CRm and opc1, to specify the required 64-bit System register.
- Two general-purpose registers, each holding 32 bits of the value to transfer.

Therefore, PE accesses a 64-bit control register using:

- An `MCRR` instruction to write to a control register, see *MCRR, MCRR2* on page F7-2633.
- An `MRRC` instruction to read a control register, see *MCRR, MCRR2* on page F7-2633.

When using a `MCRR` or `MRRC` instruction:

- Rt contains the least-significant 32 bits of the transferred value, and Rt2 contains the most-significant 32 bits of that value.
- The access is 64-bit atomic.

Some 64-bit registers also have an `MCR` and `MRC` encoding. The `MCR` and `MRC` encodings for these registers access the least significant 32 bits of the register. For example, to access the PAR, software can:

- Use the following instructions to access all 64 bits of the register:

```
MRRC p15, 0, <Rt>, <Rt2>, c7    ; Read 64-bit PAR into Rt (low word) and Rt2 (high word)
MCRR p15, 0, <Rt>, <Rt2>, c7    ; Write Rt (low word) and Rt2 (high word) to 64-bit PAR
```

- Use the following instructions to access the least-significant 32 bits of the register:

```
MRC p15, 0, <Rt>, c7, c4, 0    ; Read PAR[31:0] into Rt
MCR p15, 0, <Rt>, c7, c4, 0    ; Write Rt to PAR[31:0]
```

G4.15.2 General behavior of System registers

Except where indicated, System registers are 32-bits wide. As stated in *About System register accesses* on page G4-3743, there are some 64-bit registers, and these include cases where software can access either a 32-bit view or a 64-bit view of a register. The register summaries, and the individual register descriptions, identify the 64-bit registers and how they can be accessed.

The following sections give information about the general behavior of these registers. Unless otherwise indicated, information applies to both CP14 and CP15 registers:

- *Read-only bits in read/write registers*.
- *UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses*.
- *Read-only and write-only register encodings* on page G4-3747.
- *Reset behavior of CP14 and CP15 registers* on page G4-3747.

See also *About System register accesses* on page G4-3743 and *Meaning of fixed bit values in register diagrams* on page G4-3762.

Read-only bits in read/write registers

Some read/write registers include bits that are read-only. These bits ignore writes.

An example of this is the SCTLR.NMFI bit, SCTLR[27].

UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses

In AArch32 state the following operations are UNDEFINED:

- All `CDP`, `LDC` and `STC` operations to CP14 and CP15, except for the `LDC` access to DBGDTRTXint and the `STC` access to DBGDTRRXint specified in Table G4-46 on page G4-3766.
- All `MCRR` and `MRRC` operations to CP14 and CP15, except for those explicitly defined as accessing 64-bit CP14 and CP15 registers specified in Table G4-45 on page G4-3765 and Table G4-47 on page G4-3773.
- All `CDP2`, `MCR2`, `MRC2`, `MCRR2`, `MRRC2`, `LDC2` and `STC2` operations to CP14 and CP15.

Unless otherwise indicated in the individual register descriptions:

- Reserved fields in registers are RES0.
- Assigning a reserved value to a field can have an UNPREDICTABLE effect.

The following subsections give more information about UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses:

- *Accesses to unallocated CP14 and CP15 encodings*.
- *Additional rules for MCR and MRC accesses to CP14 and CP15 registers*.
- *Effects of EL3 and EL2 on CP15 register accesses* on page G4-3746.

Accesses to unallocated CP14 and CP15 encodings

In ARMv8-A, accesses to unallocated CP14 and CP15 register encodings are UNDEFINED.

Additional rules for MCR and MRC accesses to CP14 and CP15 registers

All `MCR` operations from the PC are UNPREDICTABLE for all coprocessors, including for CP14 and CP15.

All `MRC` operations to APSR_nzcv are UNPREDICTABLE for CP14 and CP15, except for the CP14 `MRC` operation to APSR_nzcv from DBGDSCRint.

For registers and operations that are accessible from a particular Privilege level, any attempt to access those registers from a lower Privilege level is UNDEFINED.

Some individual registers can be made inaccessible by setting configuration bits, possibly including IMPLEMENTATION DEFINED configuration bits, to disable access to the register. The effects of the architecturally-defined configuration bits are defined individually in this manual. Unless explicitly stated otherwise in this manual, setting a configuration bit to disable access to a register results in the register becoming UNDEFINED for `MRC` and `MCR` accesses.

See also *Read-only and write-only register encodings* on page G4-3747.

Effects of EL3 and EL2 on CP15 register accesses

EL2 and EL3 introduce classes of System registers, described in *Classification of System registers* on page G4-3748. Some of these classes of register are either:

- Accessible only from certain modes or states.
- Accessible from certain modes or states only when configuration settings permit the access.

Accesses to these registers that are not permitted are UNDEFINED, meaning execution of the register access instruction generates an Undefined Instruction exception.

Note

This section applies only to registers that are accessible from some modes and states. That is, it applies only to register access instructions using an encoding that, under some circumstances, would perform a valid register access.

The following register classes restrict access in this way:

Restricted access System registers

This register class is defined in any implementation that includes EL3.

Restricted access registers other than the NSACR are accessible only from Secure EL3 modes. All other accesses to these registers are UNDEFINED.

The NSACR is a special case of a Restricted access register and:

- The NSACR is:
  - Read/write accessible from Secure PL1 modes.
  - Is Read-only accessible from Non-secure PL2 and PL1 modes.
- All other accesses to the NSACR are UNDEFINED.

For more information, including behavior when EL3 is using AArch64 or is not implemented, see *Restricted access System registers* on page G4-3750.

Configurable access System registers

This register class is defined in any implementation that includes EL3.

Most Configurable access registers are accessible from Non-secure state only if control bits in the NSACR permit Non-secure access to the register. Otherwise, a Non-secure access to the register is UNDEFINED.

For other Configurable access registers, control bits in the NSACR control the behavior of bits or fields in the register when it is accessed from Non-secure state. That is, Non-secure accesses to the register are permitted, but the NSACR controls how they behave. The only architecturally-defined register of this type is the CPACR.

For more information, see *Configurable access System registers* on page G4-3750.

EL2-mode System registers

This register class is defined only in an implementation that includes EL2.

EL2-mode registers are accessible only from:

- The Non-secure EL2 mode, Hyp mode.
- Secure Monitor mode when SCR.NS is set to 1.

All other accesses to these registers are UNDEFINED.

For more information, see *Banked EL2-mode CP15 read/write registers* on page G4-3751 and *EL2-mode encodings for shared CP15 registers* on page G4-3752.

EL2-mode write-only operations

This register class is defined only in an implementation that includes EL2.

EL2-mode write-only operations are accessible only from:

- The Non-secure EL2 mode, Hyp mode.
- Secure Monitor mode, regardless of the value of SCR.NS.

Write accesses to these operations are:

- UNPREDICTABLE in Secure EL3 modes other than Monitor mode.
- UNDEFINED in Non-secure modes other than Hyp mode.

For more information, see *Banked EL2-mode CP15 write-only operations* on page G4-3753.

In addition, in any implementation that includes EL3, if write access to a register is disabled by the **CP15SDISABLE** signal then any MCR access to that register is UNDEFINED.

Read-only and write-only register encodings

Some System registers are *read-only* (RO) or *write-only* (WO). For example:

- Most identification registers are read-only.
- Most encodings that perform an operation, such as a cache maintenance instruction, are write-only.

If a particular Privilege level defines a register to be:

- RO, then any attempt to write to that register, at that Privilege level, is UNDEFINED. This means that any access to that register with L == 0 is UNDEFINED.
- WO, then any attempt to read from that register, at that Privilege level, is UNDEFINED. This means that any access to that register with L== 1 is UNDEFINED.

For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED.

Note

- This section applies only to registers that this manual defines as RO or WO. It does not apply to registers for which other access permissions are explicitly defined.
- Although the FPSID is a RO register, a write using the FPSID encoding is a valid *serializing* operation, see *Floating-point exception traps, serialization, and floating-point exception barriers* on page G1-3473. Such a write does not access the register.

Reset behavior of CP14 and CP15 registers

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for CP14 debug and trace registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of CP14 and CP15 registers, see:

- *Reset and debug* on page H8-4535, for the Debug CP14 registers.
- The appropriate Trace architecture specification, for the Trace CP14 registers.
- *Reset behavior of CP15 registers*.
- *Pseudocode details of resetting CP14 and CP15 registers* on page G4-3748.

Reset behavior of CP15 registers

On reset, the VMSAv8-32 architecture defines a required reset value for all or part of each of the following CP15 registers:

- The SCTLR, CPACR, TTBCR, and VBAR. If the implementation includes EL3, unless the register description says otherwise, the defined reset values apply only to the Secure instances of these registers, and the reset values of the corresponding bits are UNKNOWN in the Non-secure instances of the registers.
- In an implementation that includes EL3, when EL3 supports AArch32, the SCR and the NSACR.
- In an implementation that includes EL2, when EL2 supports AArch32, the VPIDR, VMPIDR, HCR, HDCR, HCPTR, HSTR, and VTTBR.
- In an implementation that includes the Performance Monitors Extension, the PMCR, the PMUSERENR, and the instance of PMXEVTYPER that relates to the cycle counter.
- In an implementation that includes the Generic Timer Extension, the CNTKCTL and CNTHCTL registers.

Note

As indicated in this subsubsection, in an implementation that includes EL3, unless this manual explicitly states otherwise, only the Secure instance of a Banked register is reset to the defined value. This means that software must program the Non-secure instance of the register with the required values. Typically, this programming is part of the PE boot sequence.

For details of the reset values of these registers see the register descriptions. If the description of a register or register field does not include its reset value then the architecture does not require that register or field to reset to a defined value, and software must treat the value as UNKNOWN after a reset.

The values of all other registers at reset are architecturally UNKNOWN. An implementation can assign an IMPLEMENTATION DEFINED reset value to a register whose reset value is architecturally UNKNOWN. After a reset, software must not rely on the value of any read/write register that does not have either an architecturally-defined reset value or an IMPLEMENTATION DEFINED reset value.

Pseudocode details of resetting CP14 and CP15 registers

The `ResetControlRegisters()` pseudocode function resets all CP14 and CP15 registers, and register fields, that have defined reset values, as described in this section.

Note

For CP14 debug and trace registers this function resets registers as defined for the appropriate level of reset.

G4.15.3 Classification of System registers

Features provided by EL3 and EL2 integrate with many features of the architecture. Therefore, the descriptions of the individual System registers include information about how these Exception levels affect the register. This section:

- Summarizes how EL3 and EL2 affect the implementation of the System registers, and the classification of those registers.
- Summarizes how EL3 controls access to the System registers.
- Describes an EL3 signal that can control access to some CP15 registers.

It contains the following subsections:

Note

EL3 defines the register classifications of Banked, Restricted access, Configurable, and Common. EL2 defines the EL2-mode classification. Some of these classifications can apply to some CP10 and CP11 coprocessor registers, as well as to the CP14 and CP15 System registers.

It is IMPLEMENTATION DEFINED whether each IMPLEMENTATION DEFINED register is Banked, Restricted access, Configurable, EL2-mode, or Common.

Banked System registers

In an implementation that includes EL3, some System registers are Banked. Banked System registers have two copies, one Secure and one Non-secure. The SCR.NS bit selects the Secure or Non-secure instance of the register. Table G4-36 shows which CP15 registers are Banked in this way, and the permitted access to each register. No CP14 registers are Banked.

Table G4-36 Banked CP15 registers

CRn[a]	Banked register	Permitted accesses[b]
c0	CSSELR, Cache Size Selection Register	Read/write only at EL1 or higher
c1	SCTLR, System Control Register[c]	Read/write only at EL1 or higher
	ACTLR, Auxiliary Control Register[d]	Read/write only at EL1 or higher
c2	TTBR0, Translation Table Base 0	Read/write only at EL1 or higher
	TTBR1, Translation Table Base 1	Read/write only at EL1 or higher
	TTBCR, Translation Table Base Control	Read/write only at EL1 or higher
c3	DACR, Domain Access Control Register	Read/write only at EL1 or higher
c5	DFSR, Data Fault Status Register	Read/write only at EL1 or higher
	IFSR, Instruction Fault Status Register	Read/write only at EL1 or higher
	ADFSR, Auxiliary Data Fault Status Register[d]	Read/write only at EL1 or higher
	AIFSR, Auxiliary Instruction Fault Status Register[d]	Read/write only at EL1 or higher
c6	DFAR, Data Fault Address Register	Read/write only at EL1 or higher
	IFAR, Instruction Fault Address Register	Read/write only at EL1 or higher
c7	PAR, Physical Address Register	Read/write only at EL1 or higher
c10	PRRR, Primary Region Remap Register	Read/write only at EL1 or higher
	NMRR, Normal Memory Remap Register	Read/write only at EL1 or higher
c12	VBAR, Vector Base Address Register	Read/write only at EL1 or higher
c13	FCSEIDR, FCSE PID Register[e]	Read/write only at EL1 or higher
	CONTEXTIDR, Context ID Register	Read/write only at EL1 or higher
	TPIDRURW, User Read/Write Thread ID	Read/write at all privilege levels, including EL0
	TPIDRURO, User Read-only Thread ID	Read-only at EL0 Read/write at EL1 or higher
	TPIDRPRW, EL1 only Thread ID	Read/write only at EL1 or higher

a. For accesses to 32-bit registers. More correctly, this is the primary coprocessor register.
b. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.
c. Some bits are common to the Secure and the Non-secure copies of the register, see *SCTLR, System Control Register* on page G5-4065.
d. Register is IMPLEMENTATION DEFINED.
e. Banked only in an implementation that includes the FCSE. The FCSE PID Register is RAZ/WI if the FCSE is not implemented.

A Banked CP15 register can contain a mixture of:

- Fields that are Banked.
- Fields that are read-only in Non-secure PL1 or PL2 modes but read/write in the Secure state.

The System Control Register SCTLR is an example of a register of that contains this mixture of fields.

The Secure copies of the Banked CP15 registers are sometimes referred to as the Secure Banked CP15 registers. The Non-secure copies of the Banked CP15 registers are sometimes referred to as the Non-secure Banked CP15 registers.

Restricted access System registers

In an implementation that includes EL3, some System registers are present only in the Secure security state. These are called *Restricted access* registers, and their read/write access permissions are:

- In Non-secure state, software cannot modify Restricted access registers.
- For the NSACR, in Non-secure state:
  - Software running at PL1 or higher can read the register.
  - Unprivileged software, meaning software running at PL0, cannot read the register.

  This means that Non-secure software running at PL1 or higher can read the access permissions for System registers that have Configurable access.

  If EL3 is using AArch64 then any read of the NSACR from Non-secure EL2 using AArch32, or Non-secure EL1 using AArch32, returns the value `0x00000C00`.
- For all other Restricted access registers, Non-secure software cannot read the register.

In an implementation that does not include EL3:

- SDER is implemented only in Secure state.
- Any read of the NSACR returns the value `0x00000C00`.
- All other accesses to Restricted access System registers are UNDEFINED.

Table G4-37 shows the Restricted access CP15 registers. There are no Restricted access CP14 registers.

Table G4-37 Restricted access CP15 registers

Register	Permitted accesses[a]
SCR, Secure Configuration	Read/write in Secure PL1 modes
SDCR, Secure Debug Configuration Register	Read/write in Secure PL1 modes
SDER, Secure Debug Enable	Read/write in Secure PL1 modes
NSACR, Non-Secure Access Control	Read/write in Secure PL1 modes Read-only in Non-secure PL1 and PL2 modes
MVBAR, Monitor Vector Base Address	Read/write in Secure PL1 modes

a. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.

Configurable access System registers

Secure software can configure the access to some System registers. These registers are called Configurable access registers, and the control can be:

- A bit in the control register determines whether the register is:
  - Accessible from Secure state only.
  - Accessible from both Secure and Non-secure states.

- A bit in the control register changes the accessibility of a register bit or field. For example, setting a bit in the control register might mean that a R/W field behaves as RAZ/WI when accessed from Non-secure state.

Bits in the NSACR control access.

In an AArch32 implementation that includes EL3:

- There are no Configurable access CP14 registers.
- The only required Configurable access CP15 register is the CPACR, Coprocessor Access Control Register.
- The following registers in the CP10 and CP11 register space are Configurable access:
  - Floating-point Status and Control Register, FPSCR
  - Floating-point Exception register, FPEXC.
  - Floating-point System ID register, FPSID.
  - Media and VFP Feature Register 0, MVFR0.
  - Media and VFP Feature Register 1, MVFR1.
  - Media and VFP Feature Register 2, MVFR2.

EL2-mode System registers

An implementation that includes EL2, when EL2 is using AArch32 it provides a number of registers for use in the EL2 mode, Hyp mode. As with other System register encodings, some of these register encodings provide write-only operations. When the implementation includes EL3 and EL3 is using AArch32, these registers are also accessible from Monitor mode when the value of SCR.NS is 1.

The following subsections describe the EL2-mode registers:

- *Banked EL2-mode CP15 read/write registers*.
- *EL2-mode encodings for shared CP15 registers* on page G4-3752.
- *Banked EL2-mode CP15 write-only operations* on page G4-3753.

There are no EL2-mode CP14 registers.

Banked EL2-mode CP15 read/write registers

Architecturally, these are an extension of the Banked registers described in *Banked System registers* on page G4-3749, where:

- The implementation does not implement the Secure instance of the register.
- The Non-secure instance of the register is accessible only at PL2, that is, only from Hyp mode.

Except for accesses to CNTVOFF in an implementation that includes EL3 but not EL2, the behavior of accesses to these registers is as follows:

- In Secure state, the registers can be accessed from Monitor mode when SCR.NS is set to 1, see *Access to registers from Monitor mode* on page G4-3756.
- The following accesses are UNDEFINED:
  - Accesses from Non-secure PL1 modes.
  - Accesses in Secure state when SCR.NS is set to 0.

In an implementation that includes EL3 but not EL2, the behavior of accesses to CNTVOFF is as follows:

- Any access from Secure Monitor mode is UNPREDICTABLE, regardless of the value of SCR.NS.
- All other accesses are UNDEFINED.

Note

Except for CNTVOFF, the Banked EL2-mode registers are part of EL2, meaning they are implemented only if the implementation includes EL2. However, conceptually, CNTVOFF is part of any implementation that includes the Generic Timer Extension, see *Status of the CNTVOFF register* on page D6-1791. This means the behavior of CNTVOFF in an implementation that includes the Generic Timer Extension but does not include EL2 is not covered by the general definition of the behavior of the Banked EL2-mode CP15 read/write registers.

Table G4-38 shows the EL2-mode CP15 read/write registers:

Table G4-38 Banked EL2-mode CP15 read/write registers

CRn or CRm[a]	Register	Width	Permitted accesses[b]
c0	VPIDR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	VMPIDR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c1	HSCTLR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	HACTLR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	HCR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	HDCR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	HCPTR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	HSTR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	HACR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c2	HTCR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	VTCR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	HTTBR	64-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	VTTBR	64-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c5	HADFSR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	HAIFSR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	HSR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c6	HPFAR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c10	HMAIR0	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	HMAIR1	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	HAMAIR0	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
	HAMAIR1	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c12	HVBAR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c13	HTPIDR	32-bit	Read/write. In Non-secure state, accessible only from Hyp mode
c14	CNTVOFF[c]	64-bit	Read/write. In Non-secure state, accessible only from Hyp mode

a. CRn for accesses to 32-bit registers, CRm for accesses to 64-bit registers. More correctly, this is the primary coprocessor register.
b. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.
c. Implemented only in an implementation that includes the Generic Timer Extension. See, also, the Note earlier in this section.

EL2-mode encodings for shared CP15 registers

Some Hyp mode registers share the Secure instance of an existing Banked register. In this case the implementation includes an encoding for the register that is accessible only in Hyp mode, or in Monitor mode when SCR.NS is set to 1.

For these registers, the following accesses are UNDEFINED:

- Accesses from Non-secure PL1 modes.

- Accesses in Secure state when SCR.NS is set to 0.

Table G4-39 lists the EL2-mode encodings for shared registers.

Table G4-39 EL2-mode CP15 register encodings for shared registers

CRn[a]	Register	Permitted accesses[b]	Shared register
c6	HDFAR	Read/write. In Non-secure state, accessible only from Hyp mode[c]	Secure DFAR
c6	HIFAR	Read/write. In Non-secure state, accessible only from Hyp mode[c]	Secure IFAR

a. For accesses to 32-bit registers. More correctly, this is the primary coprocessor register.
b. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.
c. Also accessible from Monitor mode when SCR.NS set to 1.

In Monitor mode, the Secure copies of these registers can be accessed either:

- Using the DFAR or IFAR encoding with SCR.NS set to 0.
- Using the HDFAR or HIFAR encoding with SCR.NS set to 1.

However, between accessing a register using one alias and accessing the register using the other alias, a *Context synchronization operation* is required to ensure the ordering of the accesses.

Banked EL2-mode CP15 write-only operations

Architecturally, these encodings are an extension of the Banked register encodings described in *Banked System registers* on page G4-3749, where:

- The implementation does not implement the operation in Secure state.
- In Non-secure state, the operation is accessible only at EL2, that is, only from Hyp mode.

In Secure state:

- These operations can be accessed from Monitor mode regardless of the value of SCR.NS, see *Access to registers from Monitor mode* on page G4-3756.
- Accesses to these operations are UNPREDICTABLE if executed in a Secure mode other than Monitor mode.

Accesses to these operations are UNDEFINED if accessed from a Non-secure PL1 mode.

Table G4-40 shows the EL2-mode CP15 write-only operations:

Table G4-40 Banked EL2-mode CP15 write-only operations

CRn	Register	Width	Permitted accesses[a]
c8	ATS1HR	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	ATS1HW	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	TLBIALLHIS	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	TLBIMVAHIS	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	TLBIALLNSNHIS	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	TLBIALLH	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	TLBIMVAH	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode
	TLBIALLNSNH	32-bit	Write-only. In Non-secure state, accessible only from Hyp mode

a. This section describes the behavior of write accesses that are not permitted. See also *Read-only and write-only register encodings* on page G4-3747.

For more information about these operations, see *Address translation stage 1, Hyp mode* on page G4-3738.

Common System registers

Some System registers and operations are common to the Secure and Non-secure Security states. These are described as the *Common access* registers, or simply as the *Common* registers. These registers include:

- Read-only registers that hold configuration information.
- Register encodings used for various memory system operations, rather than to access registers.
- The ISR.
- All CP14 registers.

Table G4-41 shows the Common CP15 System registers. These registers are not affected by whether EL3 is implemented.

Table G4-41 Common CP15 registers

CRn[a]	Register	Permitted accesses[b]
c0	MIDR, Main ID Register	Read-only, only at EL1 or higher
	CTR, Cache Type Register	Read-only, only at EL1 or higher
	TCMTR, TCM Type Register[c]	Read-only, only at EL1 or higher
	TLBTR, TLB Type Register[c]	Read-only, only at EL1 or higher
	MPIDR, Multiprocessor Affinity Register	Read-only, only at EL1 or higher
	REVIDR, Revision ID	Read-only, only at EL1 or higher
c0	ID_PFRx, Processor Feature Registers	Read-only, only at EL1 or higher
	ID_DFR0, Debug Feature Register 0	Read-only, only at EL1 or higher
	ID_AFR0, Auxiliary Feature Register 0	Read-only, only at EL1 or higher
	ID_MMFRx, Memory Model Feature Registers	Read-only, only at EL1 or higher
	ID_ISARx, Instruction Set Attribute Registers	Read-only, only at EL1 or higher
	CCSIDR, Cache Size ID Register	Read-only, only at EL1 or higher
	CLIDR, Cache Level ID Register	Read-only, only at EL1 or higher
	AIDR, Auxiliary ID Register[c]	Read-only, only at EL1 or higher
c7	Cache maintenance instruction	See *Cache maintenance instructions, functional group* on page G4-3794
	Address translation instructions	See *Address translation instructions, functional group* on page G4-3796
	Data barrier operations	Write-only at all privilege levels, including EL0
c8	TLB maintenance instructions	Write-only, only at EL1 or higher
c9	Performance monitors	See *Access permissions* on page D5-1777
c12	ISR, Interrupt Status Register	Read-only, only at EL1 or higher

a. For accesses to 32-bit registers. More correctly, this is the primary coprocessor register.
b. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.

c. Register or operation details are IMPLEMENTATION DEFINED.

Secure CP15 registers

The Secure CP15 registers comprise:

- The Secure copies of the Banked CP15 registers.
- The Restricted access CP15 registers.
- The Configurable access CP15 registers that are configured to be accessible only from Secure state.

In an implementation that includes EL3, the Non-secure CP15 registers are the CP15 registers other than the Secure CP15 registers.

The CP15SDISABLE input

EL3 provides an input signal, **CP15SDISABLE**, that disables write access to some of the Secure registers when asserted HIGH.

Note

The interaction between **CP15SDISABLE** and any IMPLEMENTATION DEFINED register is IMPLEMENTATION DEFINED.

Table G4-42 shows the registers and operations affected.

Table G4-42 Secure registers affected by CP15SDISABLE

CRn	Register name	Affected operation
c1	SCTLR, System Control Register	`MCR p15, 0, <Rt>, c1, c0, 0`
c2	TTBR0, Translation Table Base Register 0	`MCR p15, 0, <Rt>, c2, c0, 0`
	TTBCR, Translation Table Base Control Register	`MCR p15, 0, <Rt>, c2, c0, 2`
c3	DACR, Domain Access Control Register	`MCR p15, 0, <Rt>, c3, c0, 0`
c10	PRRR. Primary Region Remap Register	`MCR p15, 0, <Rt>, c10, c2, 0`
	NMRR, Normal Memory Remap Register	`MCR p15, 0, <Rt>, c10, c2, 1`
c12	VBAR, Vector Base Address Register	`MCR p15, 0, <Rt>, c12, c0, 0`
	MVBAR, Monitor Vector Base Address Register	`MCR p15, 0, <Rt>, c12, c0, 1`

On a reset by the external system, the **CP15SDISABLE** input signal must be taken LOW. This permits the Reset code to set up the configuration of EL3 features. When the input is asserted HIGH, any attempt to write to the Secure registers shown in Table G4-42 results in an Undefined Instruction exception.

The **CP15SDISABLE** input does not affect reading Secure registers, or reading or writing Non-secure registers. It is IMPLEMENTATION DEFINED how the input is changed and when changes to this input are reflected in the PE, and an implementation might not provide any mechanism for driving the **CP15SDISABLE** input HIGH. However, in an implementation in which the **CP15SDISABLE** input can be driven HIGH, changes in the state of **CP15SDISABLE** must be reflected as quickly as possible. Any change must occur before completion of a Instruction Synchronization Barrier operation, issued after the change, is visible to the PE with respect to instruction execution boundaries. Software must perform a Instruction Synchronization Barrier operation meeting the above conditions to ensure all subsequent instructions are affected by the change to **CP15SDISABLE**.

Use of **CP15SDISABLE** means key Secure features that are accessible only at PL1 can be locked in a known good state. This provides an additional level of overall system security. ARM expects control of **CP15SDISABLE** to reside in the system, in a block dedicated to security.

Access to registers from Monitor mode

When the PE is in Monitor mode, the PE is in Secure state regardless of the value of the SCR.NS bit. In Monitor mode, the SCR.NS bit determines whether valid uses of the MRC, MCR, MRRC and MCRR instructions access the Secure Banked CP15 registers or the Non-secure Banked CP15 registers. That is, when:

NS == 0 Common, Restricted access, and Secure Banked registers are accessed by CP15 MRC, MCR, MRRC and MCRR instructions.

If the implementation includes EL2, the registers listed in *Banked EL2-mode CP15 read/write registers* on page G4-3751 and *EL2-mode encodings for shared CP15 registers* on page G4-3752 are not accessible, and any attempt to access them generates an Undefined Instruction exception.

Note

The operations listed in *Banked EL2-mode CP15 write-only operations* on page G4-3753 are accessible in Monitor mode regardless of the value of SCR.NS.

CP15 operations use the Security state to determine all resources used, that is, all CP15-based operations are performed in Secure state.

NS == 1 Common, Restricted access and Non-secure Banked registers are accessed by CP15 MRC, MCR, MRRC and MCRR instructions.

If the implementation includes EL2, all the registers and operations listed in the subsections of *EL2-mode System registers* on page G4-3751 are accessible, using the MRC, MCR, MRRC, or MCRR instructions required to access them from Hyp mode.

CP15 operations use the Security state to determine all resources used, that is, all CP15-based operations are performed in Secure state.

The Security state determines whether the Secure or Non-secure Banked registers determine the control state.

Note

Where the contents of a register select the value accessed by an MRC or MCR access to a different register, then the register that is used for selection is being used as control state. For example, CSSELR selects the current CCSIDR, and therefore CSSELR is used as control state. Therefore, in Monitor mode:

- SCR.NS determines whether the Secure or Non-secure CSSELR is accessible.
- Because the PE is in Secure state, the Secure CSSELR selects the current CCSIDR.

G4.15.4 Synchronization of changes to System registers

In this section, *this PE* means the PE on which accesses are being synchronized.

Note

See *Definitions of direct and indirect reads and writes and their side-effects* on page G4-3760 for definitions of the terms *direct write*, *direct read*, *indirect write*, and *indirect read*.

A *direct write* to a System register might become visible at any point after the change to the register, but without a *Context synchronization operation* there is no guarantee that the change becomes visible.

Any direct write to a System register is guaranteed not to affect any instruction that appears, in program order, before the instruction that performed the direct write, and any direct write to a System register must be synchronized before any instruction that appears after the direct write, in program order, can rely on the effect of that write. The only exceptions to this are:

- All direct writes to the same register, using the same encoding, are guaranteed to occur in program order.
- All direct writes to a register are guaranteed to occur in program order relative to all direct reads of the same register using the same encoding.
- If an instruction that appears in program order before the direct write performs a memory access, such as a memory-mapped register access, that causes an indirect read or write to a register, that memory access is subject to the ARM ordering model. In this case, if permitted by the ARM ordering model, the instruction that appears in program order before the direct write can be affected by the direct write.

These rules mean that an instruction that writes to one of the address translation instructions described in *Virtual Address to Physical Address translation instructions* on page G4-3737 must be explicitly synchronized to guarantee that the result of the address translation instruction is visible in the PAR.

Note

In this case, the direct write to the encoding of the address translation instruction causes an *indirect write* to the PAR. Without a *Context synchronization operation* after the direct write there is no guarantee that the indirect write to the PAR is visible.

Conceptually, the explicit synchronization occurs as the first step of any *Context synchronization operation*. This means that if the operation uses state that had been changed but not synchronized before the operation occurred, the operation is guaranteed to use the state as if it had been synchronized.

Note

This explicit synchronization is applied as the first step of the execution of any instruction that causes the synchronization operation. This means it does not synchronize any effect of system registers that might affect the fetch and decode of the instructions that cause the operation, such as breakpoints or changes to translation tables.

Except for the register reads listed in *Registers with some architectural guarantee of ordering or observability* on page G4-3759, if no context synchronization operation is performed, direct reads of System registers can occur in any order.

Table G4-43 on page G4-3758 shows the synchronization requirement between two reads or writes that access the same System register. In the column headings, *First* and *Second* refer to:

- Program order, for any read or write caused by the execution of an instruction by this PE, other than a read or write caused by a memory access made by that instruction.
- The order of arrival of asynchronous reads or writes made by this PE relative to the execution of instructions by this PE.

In addition:

- For indirect reads or writes caused by an external agent, such as a debugger, the mechanism that determines the order of the reads or writes is defined by that external agent. The external agent can provide mechanisms that ensure that any read or write it makes arrives at the PE. These indirect reads and writes are asynchronous to software execution on the PE.
- For indirect reads or writes caused by memory-mapped reads or writes made by this PE, the ordering of the memory accesses is subject to the memory order model, including the effect of the memory type of the accessed memory address. This applies, for example, if this PE reads or writes one of its registers in a memory-mapped register interface.

  The mechanism for ensuring completion of these memory accesses, including ensuring the arrival of the asynchronous read or write at the PE, is defined by the system.

  Note

  Such accesses are likely to be given the a Device memory attribute, but requiring this is outside the scope of the architecture.
- For indirect reads or writes caused by autonomous asynchronous events that count, for example events caused by the passage of time, the events are ordered so that:
  — Counts progress monotonically.
  — The events arrive at the PE in finite time and without undue delay.

Table G4-43 Synchronization requirements for updates to System registers

First read or write	Second read or write	Context synchronization operation required
Direct read	Direct read	No
	Direct write	No
	Indirect read	No[a]
	Indirect write	No[a], but see text in this section for exceptions
Direct write	Direct read	No
	Direct write	No
	Indirect read	Yes[a]
	Indirect write	No, but see text in this section for exceptions
Indirect read	Direct read	No
	Direct write	No
	Indirect read	No
	Indirect write	No
Indirect write	Direct read	Yes, but see text in this section for exceptions
	Direct write	No, but see text in this section for exceptions
	Indirect read	Yes, but see text in this section for exceptions
	Indirect write	No, but see text in this section for exceptions

a. Although no synchronization is required between a Direct write and a Direct read, or between a Direct read and an Indirect write, this does not imply that a Direct read causes synchronization of a previous Direct write. This means that the sequence Direct write followed by Direct read followed by Indirect read, with no intervening context synchronization, does not guarantee that the Indirect read observes the result of the Direct write.

If the indirect write is to a register that *Registers with some architectural guarantee of ordering or observability* shows as having some guarantee of the visibility of an indirect writes, synchronization might not be required.

If a direct read or a direct write to a register is followed by an indirect write to that register that is caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the indirect write relative to the direct read or direct write.

If an indirect write caused by a direct write is followed by an indirect write caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the two indirect writes.

If a direct read causes an indirect write, synchronization is required to guarantee that the indirect write is visible to subsequent direct or indirect reads or writes. This synchronization must be performed after the direct read, before any subsequent direct or indirect read or write.

If a direct write causes an indirect write, synchronization is required to guarantee that the indirect write is visible to subsequent direct or indirect reads or writes. This synchronization must be performed after the direct write, before any subsequent direct or indirect read or write.

Note

Where a register has more that one encoding, a direct write to the register using a particular encoding is not an indirect write to the same register with a different encoding.

Where an indirect write is caused by the action of an external agent, such as a debugger, or by a memory-mapped read or write by the PE, then an indirect write by that agent to a register using a particular access mechanism, followed by an indirect read by that agent to the same register using the same access mechanism and address does not need synchronization.

For information about the additional synchronization requirements for memory-mapped registers, see *Synchronization requirements for System registers* on page D7-1794.

To guarantee the visibility of changes to some registers, additional operations might be required before the context synchronization operation. For such a register, the definition of the register identifies these additional requirements.

In this manual, unless the context indicates otherwise:

- *Accessing* a System register refers to a direct read or write of the register.
- *Using* a System register refers to an indirect read or write of the register.

Registers with some architectural guarantee of ordering or observability

For the registers for which Table G4-44 shows that the ordering of direct reads is guaranteed, multiple direct reads of a single register, using the same encoding, occur in program order without any explicit ordering.

For the registers for which Table G4-44 shows that some observability of indirect writes is guaranteed, an indirect write to the register caused by an external agent, an autonomous asynchronous event, or as a result of a memory-mapped write, is both:

- Observable to direct reads of the register, in finite time, without explicit synchronization.
- Observable to subsequent indirect reads of the register without explicit synchronization.

These two sets of registers are similar, as Table G4-44 shows:

Table G4-44 Registers with a guarantee of ordering or observability, VMSAv8-32

Register	Ordering of direct reads	Observability of indirect writes	Notes
ISR	Guaranteed	Guaranteed	Interrupt Status Register
DBGCLAIMCLR	-	Guaranteed	Debug claim registers
DBGCLAIMSET	Guaranteed	Guaranteed	

Table G4-44 Registers with a guarantee of ordering or observability, VMSAv8-32 (continued)

Register	Ordering of direct reads	Observability of indirect writes	Notes
DBGDTRRX	Guaranteed	Guaranteed	Debug Communication Channel registers
DBGDTRTX	Guaranteed	Guaranteed	
CNTPCT	Guaranteed	Guaranteed	Generic Timer Extension registers, if the implementation includes the extension
CNTP_TVAL	Guaranteed	Guaranteed	
CNTVCT	Guaranteed	Guaranteed	
CNTV_TVAL	Guaranteed	Guaranteed	
CNTHP_TVAL	Guaranteed	Guaranteed	
PMCCNTR	Guaranteed	Guaranteed	Performance Monitors Extension registers, if the implementation includes the extension
PMXEVCNTR	Guaranteed	Guaranteed	
PMOVSSET	Guaranteed	Guaranteed	

For the specified registers, the observability requirement is more demanding than the observability requirements for other registers. However, the possibility that direct reads can occur *early*, in the absence of context synchronization, described in *Ordering of reads of System registers* on page G4-3743, still applies to these registers.

In Debug state, additional synchronization requirements can apply to the registers shown in Table G4-44 on page G4-3759. For more information, see *Synchronization of DCC and ITR accesses* on page H4-4470.

Definitions of direct and indirect reads and writes and their side-effects

Direct and indirect reads and writes are defined as follows:

Direct read Is a read of a register, using an `MRC`, `MRC2`, `MRRC`, `MRRC2`, `LDC`, or `LDC2` instruction, that the architecture permits for the current PE state.

If a direct read of a register has a side-effect of changing the value of a register, the effect of a direct read on that register is defined to be an *indirect write*, and has the synchronization requirements of an indirect write. This means the indirect write is guaranteed to have occurred, and to be visible to subsequent direct or indirect reads and writes only if synchronization is performed after the direct read.

Note

The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases.

Direct write Is a write to a register, using an `MCR`, `MCR2`, `MCRR`, `MCRR2`, `STC`, or `STC2` instruction, that the architecture permits for the current PE state.

In the following cases, the side-effect of the direct write is defined to be an indirect write of the affected register, and has the synchronization requirements of an indirect write:

- If the direct write has a side-effect of changing the value of a register other than the register accessed by the direct write.
- If the direct write has a side-effect of changing the value of the register accessed by the direct write, so that the value in that register might not be the value that the direct write wrote to the register.

In both cases, this means that the indirect write is not guaranteed to be visible to subsequent direct or indirect reads and writes unless synchronization is performed after the direct write.

Note

- As an example of a direct write to a register having an effect that is an indirect write of that register, writing 1 to a PMCNTENCLR.P*x* bit is also an indirect write, because if the P*x* bit had the value 1 before the direct write, the side-effect of the write changes the value of that bit to 0.
- The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases.

  For example, writing 1 to a PMCNTENCLR.P*x* bit that is set to 1 also changes the corresponding PMCNTENSET.P*x* bit from 1 to 0. This means that the direct write to the PMCNTENCLR defines indirect writes to both itself and to the PMCNTENSET.

Indirect read Is a use of the register by an instruction to establish the operating conditions for the instruction. Examples of operating conditions that might be determined by an indirect read are the translation table base address, or whether a cache is enabled.

Indirect reads include situations where the value of one register determines what value is returned by a second register. This means that any read of the second register is an indirect read of the register that determines what value is returned.

Indirect reads also include:

- Reads of the System registers by external agents, such as debuggers, as described in *Debug registers* on page G5-4158.
- Memory-mapped reads of the System registers made by the PE on which the System registers are implemented.

Where an indirect read of a register has a side-effect of changing the value of a register, that change is defined to be an indirect write, and has the synchronization requirements of an indirect write.

Indirect write Is an update to the value of a register as a consequence of either:

- An exception, operation, or execution of an instruction that is not a direct write to that register.
- The asynchronous operation of some external agent.

This can include:

- The passage of time, as seen in counters or timers, including performance counters.
- The assertion of an interrupt.
- A write from an external agent, such as a debugger.

However, for some registers, the architecture gives some guarantee of visibility without any explicit synchronization, see *Registers with some architectural guarantee of ordering or observability* on page G4-3759.

Note

Taking an exception is a context-synchronizing operation. Therefore, any indirect write performed as part of an exception entry does not require additional synchronization. This includes the indirect writes to the registers that report the exception, as described in *Exception reporting in a VMSAv8-32 implementation* on page G4-3715.

G4.15.5 Meaning of fixed bit values in register diagrams

In register diagrams, fixed bits are indicated by one of following:

0 In any implementation:

- The bit must read as 0.
- Writes to the bit must be ignored.
- Software:
  - Can rely on the bit reading as 0.
  - Must use an SBZP policy to write to the bit.

(0) In AArch32 state there are a small number of cases where a bit is (0) in some contexts, and has a different defined behavior in other contexts. The meaning of (0) is modified for these bits. For a read/write register, this means:

If a register bit is (0) for all uses of the register

- The bit must read as 0.
- Writes to the bit must be ignored.
- Software:
  - Must not rely on the bit reading as 0.
  - Must use an SBZP policy to write to the bit.

If a register bit is (0) only for some uses of the register, when that bit is described as (0)

- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

  If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as (0), or as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit.
- Software:
  - Must not rely on the bit reading as 0.
  - Must use an SBZP policy to write to the bit.

Note

This definition applies only to bits that are defined as (0), or as RES0, for one use of a register, and are defined differently for another use of the register.

Fields that are more than one bit wide are sometimes described as RES0, instead of having each bit marked as (0).

In a read-only register, (0) or RES0 indicates that the bit reads as 0, but software must treat the bit as UNK.

In a write-only register, (0) indicates that software must treat the bit as SBZ.

1 In any implementation:

- The bit must read as 1.
- Writes to the bit must be ignored.
- Software:
  - Can rely on the bit reading as 1.
  - Must use an SBOP policy to write to the bit.

(1) In AArch32 state there are a small number of cases where a bit is (1) in some contexts, and has a different defined behavior in other contexts. The meaning of (1) is modified for these bits. For a read/write register, this means:

If a register bit is (1) for all uses of the register

- The bit must read as 1.
- Writes to the bit must be ignored.
- Software:
  - Must not rely on the bit reading as 1.
  - Must use an SBOP policy to write to the bit.

If a register bit is (1) only for some uses of the register, when that bit is described as (1)

- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

  If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A write to the bit must update a storage location associated with the bit.
- While the use of the register is such that the bit is described as (1), or as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit.
- Software:
  - Must not rely on the bit reading as 1.
  - Must use an SBOP policy to write to the bit.

Note

This definition applies only to bits that are defined as (1), or as RES1, for one use of a register, and are defined differently for another use of the register.

Fields that are more than one bit wide are sometimes described as RES1, instead of having each bit marked as (1).

In a read-only register, (1) indicates that the bit reads as 1, but software must treat the bit as UNK.

In a write-only register, (1) indicates that software must treat the bit as SBO.

G4.16 Organization of the CP14 registers in VMSAv8-32

The CP14 registers provide a number of distinct control functions, covering:

- Debug.
- Trace.
- Execution environment control, for identification of the trivial Jazelle implementation.

Because these functions are so distinct, the descriptions of these registers are distributed, as follows:

- In this manual *Debug registers* on page G5-4158 describes the Debug registers.
- The following ARM trace architecture specifications describe the Trace registers:
  - *Embedded Trace Macrocell Architecture Specification*.
  - *CoreSight Program Flow Trace Architecture Specification.*

This section summarizes the allocation of the CP14 registers between these different functions, and the CP14 register encodings that are reserved.

The CP14 32-bit register encodings are classified by the {CRn, opc1, CRm, opc2} values required to access them using an `MCR` or an `MRC` instruction. The CP14 64-bit register encodings are classified by the {opc1, CRm} values required to access them using an `MCRR` or an `MRRC` instruction. The opc1 value determines the primary allocation of these registers, as follows:

opc1==0 Debug registers.

opc1==1 Trace registers.

opc1==7 Jazelle registers. Jazelle registers are implemented as required for a trivial Jazelle implementation.

Other opc1 values

Reserved.

Note

Primary allocation of CP14 register function by opc1 value differs from the allocation of CP15 registers, where primary allocation is by CRn value.

For the Debug registers, Table G4-45 on page G4-3765 defines:

- The {CRn, opc1, CRm, opc2} values used for accessing the 32-bit registers using the `MRC` and `MCR` instructions.
- The {opc1, CRm} values used for accessing the 64-bit register using the `MRRC` instruction.

Some Debug registers can also be accessed using the `LDC` and `STC` instructions. Table G4-46 on page G4-3766 defines the {CRn} values used for accessing the registers using these instructions.

G4.16.1 CP14 interface instruction arguments

Table G4-45 shows the MCR, MRC, and MRRC instruction arguments required for accesses to each register than can be visible in the CP14 interface.

Table G4-45 Mapping of CP14 MCR, MRC, and MRRC instruction arguments to registers

CRn	opc1	CRm	opc2	Name	Width	Description
c0	0	c0	0	DBGDIDR	32-bit	Debug ID, or unallocated[a]
c0	0	c1	0	DBGDSCRint	32-bit	Debug Status and Control Register, Internal View
c0	0	c2	0	DBGDCCINT	32-bit	DCC Interrupt Enable Register
c0	0	c5	0	DBGDTRRXint	32-bit	Debug Data Transfer Register, Receive, Internal View
c0	0	c5	0	DBGDTRTXint	32-bit	Debug Data Transfer Register, Transmit, Internal View
c0	0	c6	0	-	32-bit	Legacy DBGWFAR, RES0
c0	0	c7	0	DBGVCR	32-bit	Debug Vector Catch Register
c0	0	c0	2	DBGDTRRXext	32-bit	Debug Data Transfer Register, Receive, External View
c0	0	c2	2	DBGDSCRext	32-bit	Debug Status and Control Register, External View
c0	0	c3	2	DBGDTRTXext	32-bit	Debug Data Transfer Register, Transmit, External View
c0	0	c6	2	DBGOSECCR	32-bit	Debug OS Lock Exception Catch Register
c0	0	c0-15[b]	4	DBGBVR<n>	32-bit	Debug Breakpoint Value Registers, n = 0-15
c0	0	c0-15[b]	5	DBGBCR<n>	32-bit	Debug Breakpoint Control Registers, n = 0-15
c0	0	c0-15[b]	6	DBGWVR<n>	32-bit	Debug Watchpoint Value Registers, n =0-15
c0	0	c0-15[b]	7	DBGWCR<n>	32-bit	Debug Watchpoint Control Registers, n = 0-15
c1	0	c0	0	DBGDRAR	32-bit	Debug ROM Address Register
-	0	c1	-		64-bit	
c1	0	c0-15[b]	1	DBGBXVR<n>	32-bit	Debug Breakpoint Extended Value Registers n = 0-15
c1	0	c0	4	DBGOSLAR	32-bit	Debug OS Lock Access Register
c1	0	c1	4	DBGOSLSR	32-bit	Debug OS Lock Status Register
c1	0	c3	4	DBGOSDLR	32-bit	Debug OS Double Lock Register
c1	0	c4	4	DBGPRCR	32-bit	Debug Power Control Register
c2	0	c0	0	DBGDSAR	32-bit	Debug Self Address Register or unallocated[a]
-	0	c2	-		64-bit	
c4	0	c0-15	0-3	-		IMPLEMENTATION DEFINED
c7	0	c8	6	DBGCLAIMSET	32-bit	Debug Claim Tag Set register

Table G4-45 Mapping of CP14 MCR, MRC, and MRRC instruction arguments to registers (continued)

CRn	opc1	CRm	opc2	Name	Width	Description
c7	0	c9	6	DBGCLAIMCLR	32-bit	Debug Claim Tag Clear register
c7	0	c14	6	DBGAUTHSTATUS	32-bit	Debug Authentication Status register
c7	0	c0	7	DBGDEVID2	32-bit	Debug Device ID register 2
c7	0	c1	7	DBGDEVID1	32-bit	Debug Device ID register 1
c7	0	c2	7	DBGDEVID	32-bit	Debug Device ID register
c8-c15	1	c0-c15	0-7	-	32-bit	Reserved for OPTIONAL Trace extension
All other encodings					32-bit	Unallocated

a. If EL1 is using AArch32 is not implemented this register is optional. See the register description for details.

b. Not implemented breakpoint and watchpoint register access instructions are unallocated. If EL2 is not implemented or breakpoint *n* is not context-aware, DBGBXVR<n> is unallocated. CRm encodes *n*, the breakpoint or watchpoint number.

Table G4-46 shows the LDC and STC instruction arguments required for accesses to each register than can be visible in the CP14 interface.

Table G4-46 Mapping of CP14 LDC and STC instruction arguments to registers

CRn	Instruction	Name	Width	Description
c5	LDC	DBGDTRTXint	32-bit	Debug Data Transfer Register, Transmit, Internal View
c5	STC	DBGDTRRXint	32-bit	Debug Data Transfer Register, Receive, Internal View

G4.17 Organization of the CP15 registers in VMSAv8-32

Previous documentation has described the CP15 registers in order of their primary coprocessor register number. More precisely, the ordered set of values {CRn, opc1, CRm, opc2} determined the register order. As the number of System registers has increased this ordering has become less appropriate. Also, it applies only to 32-bit registers, since 64-bit registers are identified only by {CRm, opc1}, making it difficult to include 32-bit and 64-bit versions of a single register in a common ordering scheme.

This document now:

- Groups the CP15 registers by functional group. For more information about this grouping in VMSAv8-32, including a summary of each functional group, see *Functional grouping of VMSAv8-32 System registers* on page G4-3786.
- Describes all of the System registers for VMSAv8-32, including the CP15 registers, in Chapter G5 *AArch32 System Register Descriptions*.

This section gives additional information about the organization of the CP15 registers in VMSAv8-32, as follows:

Register ordering by {CRn, opc1, CRm, opc2}

See:

- *CP15 32-bit register summary by coprocessor register number, CRn* on page G4-3768.
- *Full list of VMSAv8-32 CP15 registers, by coprocessor register number* on page G4-3773.

Note

The ordered listing of CP15 registers by the {CRn, opc1, CRm, opc2} encoding of the 32-bit registers is most likely to be useful to those implementing AArch32 state, and to those validating such implementations. However, otherwise, the grouping of registers by function is more logical.

Views of the registers, that depend on the current state of the PE

See *Views of the CP15 registers* on page G4-3783.

Note

The different register views are particularly significant in implementations that include EL2.

In addition, the indexes in Appendix J *Registers Index* include all of the CP15 registers.

G4.17.1 CP15 32-bit register summary by coprocessor register number, CRn

Figure G4-27 summarizes the grouping of CP15 registers by primary coprocessor register number for a VMSAv8-32 implementation.

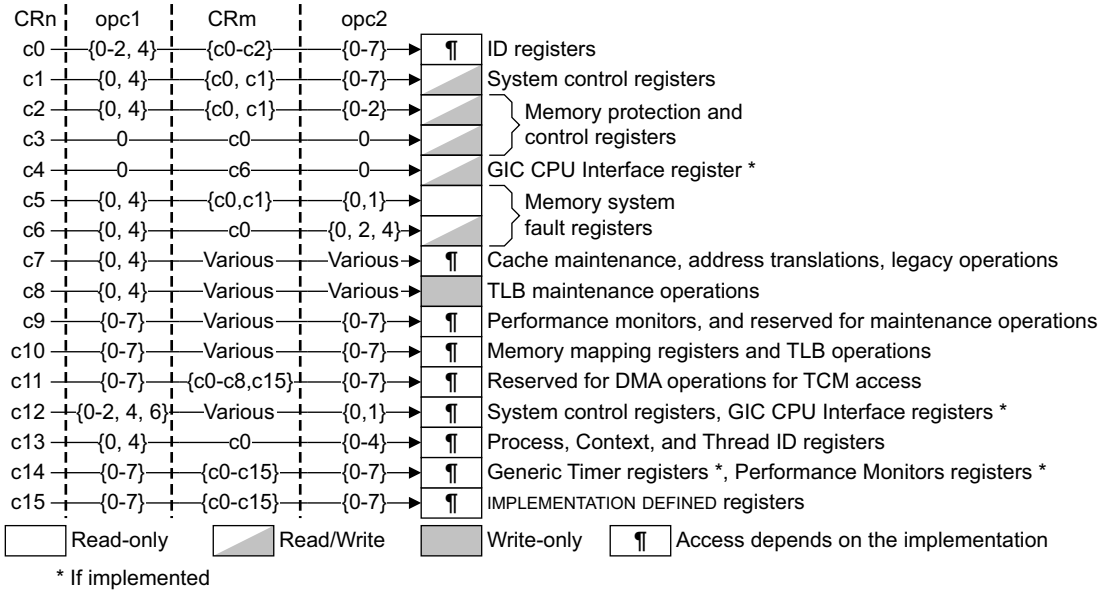

Figure G4-27 CP15 32-bit register grouping by primary coprocessor register, CRn

Note

- Figure G4-27 gives only an overview of the assigned encodings for 32-registers for each of the CP15 primary registers c0-c15. See the description of each primary register for the definition of the assigned and unassigned encodings for that register, including any dependencies on the implemented Exception levels.
- 64-bit registers in the CP15 encoding space use the same primary coprocessor register model, but in the 64-bit register read and write instructions, `MRRC` and `MCRR`, CRm identifies the primary coprocessor register.

The following sections give the register assignments for each of the CP15 primary registers, c0-c15:

- *VMSAv8-32 CP15 c0 register summary*.
- *VMSAv8-32 CP15 c1 register summary* on page G4-3769.
- *VMSAv8-32 CP15 c2 and c3 register summary* on page G4-3769
- *VMSAv8-32 CP15 c4 register summary* on page G4-3769.
- *VMSAv8-32 CP15 c5 and c6 register summary* on page G4-3769.
- *VMSAv8-32 CP15 c7 register summary* on page G4-3770.
- *VMSAv8-32 CP15 c8 register summary* on page G4-3770.
- *VMSAv8-32 CP15 c9 register summary* on page G4-3770.
- *VMSAv8-32 CP15 c10 register summary* on page G4-3771.
- *VMSAv8-32 CP15 c11 register summary* on page G4-3771.
- *VMSAv8-32 CP15 c12 register summary* on page G4-3771.
- *VMSAv8-32 CP15 c13 register summary* on page G4-3772.
- *VMSAv8-32 CP15 c14 register summary* on page G4-3772.
- *VMSAv8-32 CP15 c15 register summary* on page G4-3773.

VMSAv8-32 CP15 c0 register summary

The CP15 c0 registers provide device and feature identification.That is, they provide the register functional group described in *Identification registers, functional group* on page G4-3787.

Table G4-47 on page G4-3773 shows all of the architecturally required CP15 c0 registers. The behavior of CP15 c0 register encodings not shown in the table, and encodings that are part of an unimplemented Exception level, depends on the value of opc1, and possibly on the value of CRm and opc2, as follows:

opc1 == 0 All write accesses to the encodings are UNDEFINED.

For read accesses:

- The following encodings return an UNKNOWN value:
  - CRm == 3, opc2 == {0, 1, 2}.
  - CRm == {4, 6, 7}, opc2 == {0, 1}.
  - CRm == 5, opc2 == {0, 1, 4, 5}.
- All other encodings are RES0.

opc1 > 0 All accesses to the encodings are UNDEFINED.

See also *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

Note

Some of these registers were previously described as being part of the CPUID identification scheme, see *The CPUID identification scheme* on page G4-3788.

VMSAv8-32 CP15 c1 register summary

The CP15 c1 registers provide system control, including security and virtualization control. That is, they provide registers from the functional groups described in the following sections:

- *Other system control registers, functional group* on page G4-3788.
- *Virtualization registers, functional group* on page G4-3789.
- *Security registers, functional group* on page G4-3792.

Table G4-47 on page G4-3773 shows all of the architecturally required CP15 c1 registers. CP15 c1 register encodings not shown in the table, and encodings that are part of an unimplemented Exception level, are UNDEFINED, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

VMSAv8-32 CP15 c2 and c3 register summary

The CP15 c2 and c3 registers provide memory system control. That is, they provide registers from the functional group described in the section *Virtual memory control registers, functional group* on page G4-3788.

Table G4-47 on page G4-3773 shows all of the architecturally required CP15 c2 and c3 registers. CP15 c2 and c3 register encodings not shown in the table, and encodings that are part of an unimplemented Exception level, are UNDEFINED, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

VMSAv8-32 CP15 c4 register summary

In an implementation that includes the System register interface to the Generic Interrupt Control CPU interface:

- The CP15 c4 registers provide a register for this interface. That is, they provide a register from the functional group described in the section *Generic Interrupt Controller CPU interface registers, functional group* on page G4-3800.
- Table G4-47 on page G4-3773 shows all of the architecturally required CP15 c4 registers. CP15 c4 register encodings not shown in the table are UNDEFINED, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

In an implementation that does not include the System register interface to the Generic Interrupt Control CPU interface all CP15 c14 register encodings are UNDEFINED.

VMSAv8-32 CP15 c5 and c6 register summary

The CP15 c5 and c6 registers provide exception and fault handling. That is, they provide registers from the functional group described in the section *Exception and fault handling registers, functional group* on page G4-3792.

Table G4-47 on page G4-3773 shows all of the architecturally required CP15 c5 and c6 registers. CP15 c5 and c6 register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNDEFINED, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

VMSAv8-32 CP15 c7 register summary

The CP15 c7 registers provide system operations for cache maintenance, address translation, and some legacy operations. That is, they provide registers from the functional groups described in the following sections:

- *Cache maintenance instructions, functional group* on page G4-3794.
- *Address translation instructions, functional group* on page G4-3796.
- *Legacy feature registers, functional group* on page G4-3803.

Table G4-47 on page G4-3773 shows all of the architecturally required CP15 c7 registers. CP15 c7 register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNDEFINED, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

VMSAv8-32 CP15 c8 register summary

The CP15 c8 registers provide operations for TLB maintenance. That is, they provide registers from the functional groups described in *TLB maintenance instructions, functional group* on page G4-3795.

Table G4-47 on page G4-3773 shows all of the architecturally required CP15 c8 registers. CP15 c8 register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNDEFINED, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

VMSAv8-32 CP15 c9 register summary

The CP15 c9 registers provide:

- Registers for the OPTIONAL Performance Monitors Extension. That is, they provide registers from the functional group described in *Performance Monitors Extension registers, functional group* on page G4-3798.
- Reserved encodings for IMPLEMENTATION DEFINED memory system functions, in particular:
  - Cache control, including lockdown.
  - TCM control, including lockdown.
  - Branch predictor control.

  Note

  The reserved encodings permit implementations that are compatible with previous versions of the ARM architecture, in particular with the ARMv6 requirements.
- Reserved encodings for additional IMPLEMENTATION DEFINED performance monitors.

Figure G4-28 shows the VMSAv8-32 allocation of CP15 c9 register encodings.

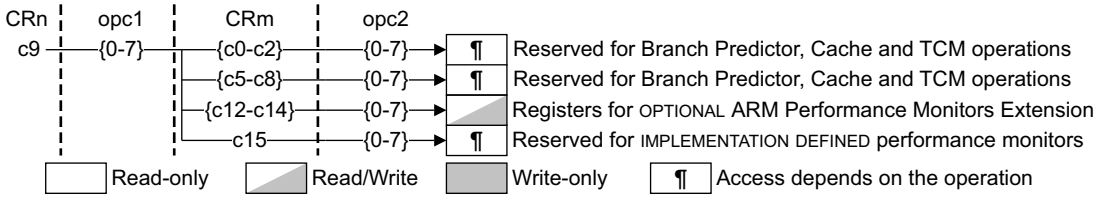

Figure G4-28 VMSAv8-32 CP15 c9 32-bit register encodings

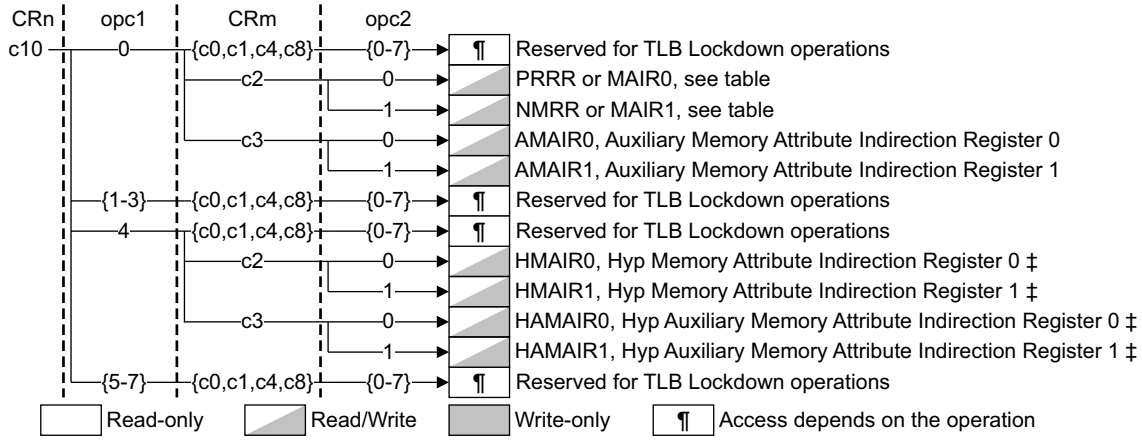
Table G4-47 on page G4-3773 shows all of the architecturally required CP15 c9 registers. Unimplemented CP15 c9 register encodings, including encodings that are part of an unimplemented Exception level, are UNDEFINED, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

VMSAv8-32 CP15 c10 register summary

The CP15 c10 registers provide:

- Virtual memory control registers. That is, they provide registers from the functional group described in *Virtual memory control registers, functional group* on page G4-3788.
- Reserved encodings for IMPLEMENTATION DEFINED TLB control functions, including lockdown.

Figure G4-29 shows the VMSAv8-32 allocation of CP15 c10 registers and reserved encodings.



‡ Implemented only as part of EL2

When using Short-descriptor translation table format	When using Long-descriptor translation table format
PRRR, Primary Region Remap Register	MAIR0, Memory Attribute Indirection Register 0
NMRR, Normal Memory Remap Register	MAIR1, Memory Attribute Indirection Register 1

Figure G4-29 VMSAv8-32 CP15 c10 32-bit register encodings

Table G4-47 on page G4-3773 shows all of the architecturally required CP15 c10 registers. Unimplemented CP15 c10 register encodings, including encodings that are part of an unimplemented Exception level, are UNDEFINED, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

VMSAv8-32 CP15 c11 register summary

The CP15 c11 registers provide some reserved encodings for IMPLEMENTATION DEFINED DMA operations to and from TCM. Figure G4-30 shows these reserved encodings:

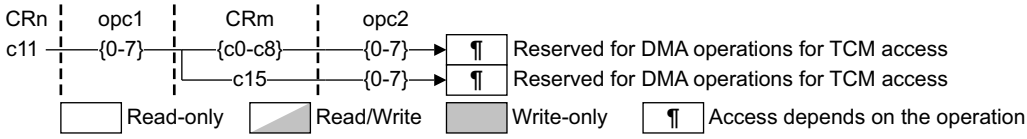


Figure G4-30 VMSAv8-32 reserved CP15 c11 encodings

CP15 c11 encodings not shown in Figure G4-30 are UNDEFINED, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

VMSAv8-32 CP15 c12 register summary

The CP15 c12 registers provide registers from the functional groups described in the following sections:

- *Exception and fault handling registers, functional group* on page G4-3792.
- *Virtualization registers, functional group* on page G4-3789.
- *Security registers, functional group* on page G4-3792.
- *Reset management registers, functional group* on page G4-3793.
- *Generic Interrupt Controller CPU interface registers, functional group* on page G4-3800.

Table G4-47 on page G4-3773 shows all of the architecturally required CP15 c12 registers. CP15 c12 register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNDEFINED, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

Note

Some CP15 c12 registers are in more than one functional group.

VMSAv8-32 CP15 c13 register summary

The CP15 c13 registers provide:

- An FCSE Process ID Register, that indicates that ARMv8 implementations do not include the FCSE.
- A Context ID Register.
- Software Thread ID Registers.

These registers are from the functional groups described in the following sections:

- *Virtual memory control registers, functional group* on page G4-3788.
- *Virtualization registers, functional group* on page G4-3789.
- *Thread and process ID registers, functional group* on page G4-3794.
- *Legacy feature registers, functional group* on page G4-3803.

Note

Some CP15 c12 registers are in more than one functional group.

Figure G4-31 shows these registers:

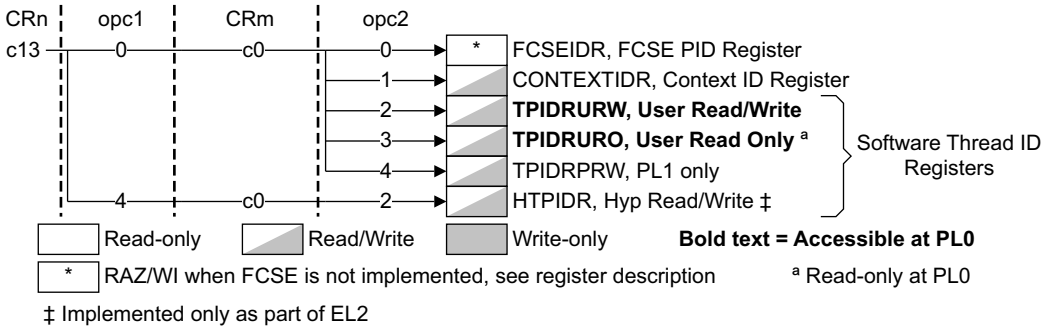

Figure G4-31 CP15 c13 registers in VMSAv8-32

Table G4-47 on page G4-3773 shows all of the architecturally required CP15 c13 registers. CP15 c13 register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNDEFINED, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

VMSAv8-32 CP15 c14 register summary

CP15 c14 is reserved for the System registers of the OPTIONAL Generic Timer Extension. For more information, see Chapter D6 *The Generic Timer*. On an implementation that does not include the Generic Timer, c14 is an unallocated CP15 primary register, see *UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses* on page G4-3745.

On an implementation that includes the Generic Timer Extension:

- The CP15 c14 registers provide Performance Monitors Extension and Generic Timer Extension registers. That is, they provide registers from the functional group described in the following sections:
  - *Performance Monitors Extension registers, functional group* on page G4-3798.
  - *Generic Timer Extension registers, functional group* on page G4-3800

- Table G4-47 shows all of the architecturally required CP15 c14 registers. CP15 c14 register encodings not shown in the table, and encodings that are part of an unimplemented Exception level are UNDEFINED, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

Note

Some CP15 c14 registers are also in the Virtualization group, see *Virtualization registers, functional group* on page G4-3789.

VMSAv8-32 CP15 c15 register summary

The CP15 c15 registers are reserved for IMPLEMENTATION DEFINED purposes. The architecture does not impose any restrictions on the use of these encodings. For more information, see *IMPLEMENTATION DEFINED registers, functional group* on page G4-3803.

G4.17.2 Full list of VMSAv8-32 CP15 registers, by coprocessor register number

Table G4-47 shows the CP15 registers in VMSAv8-32, in the order of the {CRn, opc1, CRm, opc2} values used in `MCR` or `MRC` accesses to the 32-bit registers:

- For `MCR` or `MRC` accesses to the 32-bit registers, CRn identifies the CP15 primary register used for the access.
- For `MCRR` or `MRRC` accesses to the 64-bit registers, CRm identifies the CP15 primary register used for the access. Table G4-47 lists the 64-bit registers with the 32-bit registers accessed using the same CP15 primary register number.

Table G4-47 Summary of VMSAv8-32 CP15 register descriptions, in coprocessor register number order

CRn	opc1	CRm	opc2	Name	Width	Description
c0	0	c0	0	MIDR	32-bit	Main ID Register
			1	CTR	32-bit	Cache Type Register

c15	0-7	c0-c15	0-7	-	32-bit	See *IMPLEMENTATION DEFINED registers, functional group* on page G4-3803

a. REVIDR is an optional register. If it is not implemented, the encoding with opc2 set to 6 is an alias of MIDR.

b. Implemented only as part of EL2, when EL2 is using AArch32. Otherwise, encoding is unallocated and UNPREDICTABLE, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

c. Implemented only as part of the EL3, when EL3 is using AArch32. Otherwise, as described in *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745, encoding is unallocated and:

UNDEFINED, for the registers accessed using CRn set to c12.

UNPREDICTABLE, for the register accessed using CRn values other than c12.

d. Introduced in ARMv8.

e. Introduced in ARMv8. Implemented only if the implementation includes the System registers interface to the Generic Interrupt Controller CPU interface.

f. This register is only accessible in Debug state.

g. When an implementation is using the Long descriptor translation table format these encodings access the MAIR0 and MAIR1registers. Otherwise, they access the PRRR and NMRR.

h. Introduced in ARMv8. Only one of RMR (at EL1), HRMR, and RMR (at EL3) is implemented, corresponding to the highest implemented Exception level, and the register is implemented only if that Exception level is using AArch32.

i. Implemented only as part of the Generic Timers Extension. Otherwise, encoding is unallocated and UNDEFINED, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

j. Implemented as RW only as part of the Generic Timers Extension on an implementation that includes EL2 and when EL2 is using AArch32. For more information see *Status of the CNTVOFF register* on page D6-1791.

G4.17.3 Views of the CP15 registers

The following sections summarize the different software views of the CP15 registers, for VMSAv8-32:

- *EL0 views of the CP15 registers*.
- *EL1 views of the CP15 registers* on page G4-3784.
- *Non-secure EL2 view of the CP15 registers* on page G4-3785.

EL0 views of the CP15 registers

Software executing at EL0, unprivileged, can access only a small subset of the CP15 registers, as Table G4-48 shows. This table excludes possible EL0 access to CP15 registers that are part of the following OPTIONAL extensions to the architecture:

- The Performance Monitors Extension, see *Possible EL0 access to the Performance Monitors Extension CP15 registers*.
- The Generic Timer Extension, see *Possible EL0 access to the Generic Timer Extension CP15 registers* on page G4-3784.

Table G4-48 CP15 registers accessible from EL0

CP15DMB	WO		
TPIDRURW	RW	*TPIDRURW, PL0 Read/Write Software Thread ID Register* on page G5-4135	-
TPIDRURO	RO	*TPIDRURO, PL0 Read-Only Software Thread ID Register* on page G5-4133	RW at EL1

Possible EL0 access to the Performance Monitors Extension CP15 registers

In a VMSAv8-32 implementation that includes the Performance Monitors Extension, when using CP15 to access the Performance Monitors registers:

- The PMUSERENR is RO from EL0.
- When:
  - The value of PMUSERENR.EN is 1, PMCNTENSET, PMCNTENCLR, PMOVSR, PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTYPER, PMXEVCNTR, PMUSERENR, PMOVSSET, PMEVCNTR<n>, PMEVTYPER<n>, and PMCCFILTR.are accessible by reads and writes from EL0.
  - The value of PMUSERENR.ER is 1, PMXEVCNTR and PMEVCNTR<n>.are accessible by reads and from EL0, and PMSELR is accessible by reads and writes from EL0.
  - The value of PMUSERENR.CR is 1, PMCCNTR is accessible by reads from EL0.
  - The value of PMUSERENR.SW is 1, PMSWINC is accessible by writes from EL0.

  In general, when the value of a PMUSERENR.{EN, ER, CR, SW} bit is 1, the enabled registers have the same access permissions from EL0 as they do from EL1.

For more information, see:

- *Traps to EL1 of EL0 accesses to Performance Monitors registers* on page D1-1466.
- Chapter D5 *The Performance Monitors Extension*, in particular *Access permissions* on page D5-1777.

Possible EL0 access to the Generic Timer Extension CP15 registers

In a VMSAv8-32 implementation that includes the Generic Timer Extension, when using CP15 to access the Generic Timer registers:

- If CNTKCTL.PL0PCTEN is set to 1, then if the physical counter register CNTPCT is accessible from EL1 it is also accessible from EL0. For more information see *Accessing the physical counter* on page D6-1786.
- If CNTKCTL.PL0PVTEN is set to 1, the virtual counter register CNTVCT is accessible from EL0. For more information, see *Accessing the virtual counter* on page D6-1787.
- If at least one of CNTKCTL.{PL0PCTEN, PL0PVTEN} is set to 1, the CNTFRQ register is RO from EL0.
- If:
  - CNTKCTL.PL0PTEN is set to 1, the physical timer registers CNTP_CTL, CNTP_CVAL, and CNTP_TVAL are accessible from EL0.
  - CNTKCTL.PL0VTEN is set to 1, the virtual timer registers CNTV_CTL, CNTV_CVAL, and CNTV_TVAL, are accessible from EL0.

  For more information, see *Accessing the timer registers* on page D6-1789.

EL1 views of the CP15 registers

Software executing at EL1 can access all CP15 registers, with the following exceptions:

Non-secure EL1 software

EL3 restricts or prevents access to some registers by Non-secure EL1 software. In particular:

- The Restricted access CP15 registers are either not accessible to Non-secure EL1 software, or are read-only to Non-secure EL1 software, see *Restricted access System registers* on page G4-3750
- Configuration settings determine whether Non-secure EL1 software can access the Configurable access CP15 registers, see *Configurable access System registers* on page G4-3750.

The individual register descriptions identify these access restrictions.

In an implementation that includes EL2, Non-secure EL1 software has no visibility of the EL2-mode registers summarized in *Banked EL2-mode CP15 read/write registers* on page G4-3751. The individual register descriptions identify these registers as EL2-mode registers.

Secure EL1 software

In general, Secure EL1 software has access to all CP15 registers. However:

- The **CP15SDISABLE** signal disables write access to a number of Secure registers, see *The CP15SDISABLE input* on page G4-3755.
- To access the EL2-mode registers, Secure EL1 software must move into Monitor mode, and set SCR.NS to 1.

  Banked EL2-mode CP15 read/write registers on page G4-3751 summarizes these registers.

The individual register descriptions identify:

- The registers affected by the **CP15SDISABLE** signal.
- The EL2-mode registers.

Non-secure EL2 view of the CP15 registers

Non-secure software executing at EL2 can access:

- The registers that are accessible to Non-secure software executing at EL1, as defined in *EL1 views of the CP15 registers* on page G4-3784. Access permissions for these registers are identical to those for Non-secure software executing at EL1.
- The EL2-mode registers summarized in *Banked EL2-mode CP15 read/write registers* on page G4-3751, and described in *Virtualization registers, functional group* on page G4-3789.

G4.18 Functional grouping of VMSAv8-32 System registers

This section describes how the System registers in an VMSAv8-32 implementation divide into functional groups.

General system control registers on page G5-3824 describes each of these registers.

Note

- Table G4-47 on page G4-3773 lists all of the VMSAv8-32 CP15 registers, ordered by:
  1. The CP15 primary register used when accessing the register. This is the CRn value for an access to a 32-bit register, or the CRm value for an access to a 64-bit register.
  2. The opc1 value used when accessing the register.
  3. For 32-bit registers, the {CRm, opc2} values used when accessing the register.
- The functional groups defined in this section mainly consist of the VMSAv8-32 registers, but include some additional System registers.
- Some registers belong to more than one functional group.

For other related information see:

- *The conceptual coprocessor interface and system control* on page G1-3463 for general information about the System Control Coprocessor, CP15 and the register access instructions `MRC` and `MCR`
- *About the System registers for VMSAv8-32* on page G4-3743 for general information about the CP15 registers for VMSAv8-32, including:
  - Their organization, both by CP15 primary registers c0 to c15, and by function.
  - Their general behavior.
  - The effect of not implementing some Exception levels on the registers.
  - Different views of the registers, that depend on the state of the PE.
  - Conventions used in describing the registers.

The remainder of this chapter, and *General system control registers* on page G5-3824, assumes you are familiar with *About the System registers for VMSAv8-32* on page G4-3743, and uses conventions and other information from that section without any explanation.

Each of the following sections summarizes a functional group of VMSAv8-32 System registers:

- *Identification registers, functional group* on page G4-3787.
- *Other system control registers, functional group* on page G4-3788.
- *Virtual memory control registers, functional group* on page G4-3788.
- *Virtualization registers, functional group* on page G4-3789.
- *Security registers, functional group* on page G4-3792.
- *Exception and fault handling registers, functional group* on page G4-3792.
- *Reset management registers, functional group* on page G4-3793.
- *Thread and process ID registers, functional group* on page G4-3794.
- *Cache maintenance instructions, functional group* on page G4-3794.
- *TLB maintenance instructions, functional group* on page G4-3795.
- *Address translation instructions, functional group* on page G4-3796.
- *Lockdown, DMA, and TCM features, functional group* on page G4-3798.
- *Performance Monitors Extension registers, functional group* on page G4-3798.
- *Generic Timer Extension registers, functional group* on page G4-3800.
- *Generic Interrupt Controller CPU interface registers, functional group* on page G4-3800.
- *Legacy feature registers, functional group* on page G4-3803.
- *IMPLEMENTATION DEFINED registers, functional group* on page G4-3803.
- *Floating-point registers, functional group* on page G4-3804.
- *Debug registers, functional group* on page G4-3804.

G4.18.1 Identification registers, functional group

Table G4-49 shows the VMSAv8-32 CP15 registers in the Identification registers functional group.

Table G4-49 Identification registers, VMSAv8-32

Name	CRn	opc1	CRm	opc2	Width	Type	Description
AIDR	c0	1	c0	7	32-bit	RO	Auxiliary ID Register, IMPLEMENTATION DEFINED

ID_MMFR1	c0	0	c1	5	32-bit	RO	Memory Model Feature Register 1[a]
ID_MMFR2	c0	0	c1	6	32-bit	RO	Memory Model Feature Register 2[a]
ID_MMFR3	c0	0	c1	7	32-bit	RO	Memory Model Feature Register 3[a]
ID_PFR0	c0	0	c1	0	32-bit	RO	Processor Feature Register 0[a]
ID_PFR1	c0	0	c1	1	32-bit	RO	Processor Feature Register 1[a]
MIDR	c0	0	c0	0	32-bit	RO	Main ID Register
MPIDR	c0	0	c0	5	32-bit	RO	Multiprocessor Affinity Register
REVIDR	c0	0	c0	6	32-bit	RO	Revision ID Register
TCMTR	c0	0	c0	2	32-bit	RO	TCM Type Register
TLBTR	c0	0	c0	3	32-bit	RO	TLB Type Register
VMPIDR	c0	4	c0	5	32-bit	RW	Virtualization Multiprocessor ID Register
VPIDR	c0	4	c0	5	32-bit	RW	Virtualization Processor ID Register

a. CPUID register, see *The CPUID identification scheme* on page G4-3788.

The other registers in this group are the FPSID, MVFR0, MVFR1, and MVFR2.

The JIDR holds legacy identification information.

The CPUID identification scheme

The ID_* registers were originally called the CPUID identification scheme registers. A footnote to Table G4-49 on page G4-3787 identifies these registers. However, functionally, there is no value in separating these registers from the slightly larger Identification registers functional group.

G4.18.2 Other system control registers, functional group

Table G4-50 shows the VMSAv8-32 CP15 registers in the Other System registers functional group.

Table G4-50 Other System registers, VMSAv8-32

Name	CRn	opc1	CRm	opc2	Width	Type	Description
ACTLR	c1	0	c0	1	32-bit	RW	Auxiliary Control Register, IMPLEMENTATION DEFINED
CPACR	c1	0	c0	2	32-bit	RW	Coprocessor Access Control Register
HACTLR	c1	4	c0	0	32-bit	RW	Hyp Auxiliary System Control Register, IMPLEMENTATION DEFINED
HSCTLR	c1	4	c0	0	32-bit	RW	Hyp System Control Register
SCTLR	c1	0	c0	0	32-bit	RW	System Control Register

The following sections summarize the System registers added by the corresponding Exception levels:

- *Security registers, functional group* on page G4-3792.
- *Virtualization registers, functional group* on page G4-3789.

G4.18.3 Virtual memory control registers, functional group

Table G4-51 shows the VMSAv8-32 CP15 registers in the Virtual memory control registers functional group.

Table G4-51 Virtual memory control registers

Name	CRn	opc1	CRm	opc2	Width	Type	Description
AMAIR0	c10	0	c3	0	32-bit	RW	Auxiliary Memory Attribute Indirection Register 0, IMPLEMENTATION DEFINED

NSACR	c1	0	c1	2	32-bit	RW	Non-Secure Access Control Register
RMR (at EL3)	c12	0	c0	2	32-bit	RW	Reset Management Register
SCR	c1	0	c1	0	32-bit	RW	Secure Configuration Register
SDER	c1	0	c1	1	32-bit	RW	Secure Debug Enable Register

All the encodings shown in Table G4-54 are unallocated and UNPREDICTABLE on an implementation that does not include EL3, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

G4.18.6 Exception and fault handling registers, functional group

Table G4-55 shows the VMSAv8-32 CP15 registers in the Exception and fault handling registers functional group.

Table G4-55 Exception and fault handling registers

Name	CRn	opc1	CRm	opc2	Width	Type	Description
ADFSR	c5	0	c1	0	32-bit	RW	Auxiliary Data Fault Status Register, IMPLEMENTATION DEFINED
AIFSR	c5	0	c1	1	32-bit	RW	Auxiliary Instruction Fault Status Register, IMPLEMENTATION DEFINED
DFAR	c6	0	c0	0	32-bit	RW	Data Fault Address Register

Table G4-55 Exception and fault handling registers (continued)

Name	CRn	opc1	CRm	opc2	Width	Type	Description
DFSR	c5	0	c0	0	32-bit	RW	Data Fault Status Register
HADFSR	c5	4	c1	0	32-bit	RW	Hyp Auxiliary Data Fault Status Register, IMPLEMENTATION DEFINED
HAIFSR	c5	4	c1	1	32-bit	RW	Hyp Auxiliary Instruction Fault Status Register, IMPLEMENTATION DEFINED
HDFAR	c6	4	c0	0	32-bit	RW	Hyp Data Fault Address Register
HIFAR	c6	4	c0	2	32-bit	RW	Hyp Instruction Fault Address Register
HPFAR	c6	4	c0	4	32-bit	RW	Hyp IPA Fault Address Register
HSR	c5	4	c2	0	32-bit	RW	Hyp Syndrome Register
HVBAR	c12	4	c0	1	32-bit	RW	Hyp Vector Base Address Register
IFAR	c6	0	c0	2	32-bit	RW	Instruction Fault Address Register
IFSR	c5	0	c0	1	32-bit	RW	Instruction Fault Status Register
ISR	c12	0	c1	0	32-bit	RO	Interrupt Status Register
MVBAR	c12	0	c0	1	32-bit	RW	Monitor Vector Base Address Register
RVBAR	c12	0	c0	1	32-bit	RW	Reset Vector Base Address Register
VBAR	c12	0	c0	0	32-bit	RW	Vector Base Address Register

The PE returns fault information using the fault status registers and the fault address registers. For details of how these registers are used see *Exception reporting in a VMSAv8-32 implementation* on page G4-3715.

Note

These registers also report information about debug exceptions. For more information see:

- *Data Abort exceptions, taken to a PL1 mode* on page G4-3717.
- *Prefetch Abort exceptions, taken to a PL1 mode* on page G4-3718.
- *Reporting exceptions taken to Hyp mode* on page G4-3724.

G4.18.7 Reset management registers, functional group

Table G4-56 shows the VMSAv8-32 CP15 registers in the Reset management registers functional group.

Table G4-56 Reset management registers

Name	CRn	opc1	CRm	opc2	Width	Type	Description
HRMR	c12	4	c0	2	32-bit	RW	Hyp Reset Management Register
RMR (at EL1)	c12	0	c0	2	32-bit	RW	Reset Management Register, EL1
RMR (at EL3)	c12	0	c0	2	32-bit	RW	Reset Management Register, EL3

G4.18.8 Thread and process ID registers, functional group

Table G4-57 shows the VMSAv8-32 Thread and process ID registers.

Table G4-57 VMSAv8-32 Thread and process ID registers

Name	CRn	opc1	CRm	opc2	Width	Type[a]	Description
HTPIDR[b]	c13	4	c0	2	32-bit	RW	Hyp Software Thread ID Register
TPIDRPRW	c13	0	c0	4	32-bit	RW	PL1 Software Thread ID Register
TPIDRURO	c13	0	c0	3	32-bit	RW, PL0	PL0 Read-Only Software Thread ID Register
TPIDRURW	c13	0	c0	2	32-bit	RW, PL0	PL0 Read/Write Software Thread ID Register

a. PL0 in a Type description indicates that the encoding is accessible by software executing at PL0. See the register description for more information.

b. Implemented only as part of EL2. Otherwise, encoding is unallocated and UNPREDICTABLE, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.

G4.18.9 Cache maintenance instructions, functional group

Table G4-58 shows the VMSAv8-32 Cache and branch predictor maintenance operations functional group.

Table G4-58 Cache and branch predictor maintenance operations

Name	CRn	opc1	CRm	opc2	Width	Type	Description	Limits[a]
BPIALL[b]	c7	0	c5	6	32-bit	WO	Branch predictor invalidate all	-
BPIALLIS[b]	c7	0	c1	6	32-bit	WO	Branch predictor invalidate all	IS
BPIMVA[b]	c7	0	c5	7	32-bit	WO	Branch predictor invalidate by VA	-
DCCIMVAC[b]	c7	0	c14	1	32-bit	WO	Data cache clean and invalidate by VA	PoC
DCCISW[b]	c7	0	c14	2	32-bit	WO	Data cache clean and invalidate by set/way	-
DCCMVAC[b]	c7	0	c10	1	32-bit	WO	Data cache clean by VA	PoC
DCCMVAU[b]	c7	0	c11	1	32-bit	WO	Data cache clean by VA	PoU
DCCSW[b]	c7	0	c10	2	32-bit	WO	Data cache clean by set/way	-
DCIMVAC[b]	c7	0	c6	1	32-bit	WO	Data cache invalidate by VA	PoC
DCISW[b]	c7	0	c6	2	32-bit	WO	Data cache invalidate by set/way	-
ICIALLU[b]	c7	0	c5	0	32-bit	WO	Instruction cache invalidate all	PoU
ICIALLUIS[b]	c7	0	c1	0	32-bit	WO	Instruction cache invalidate all	PoU, IS
ICIMVAU[b]	c7	0	c5	1	32-bit	WO	Instruction cache invalidate by VA	PoU

a. PoU = to Point of Unification, PoC = to Point of Coherence, IS = Inner Shareable.

b. The links in this column are to a summary of the operation, see *Cache maintenance instructions* on page G3-3589.

G4.18.10 TLB maintenance instructions, functional group

Table G4-59 shows the VMSAv8-32 TLB maintenance instructions functional group. *The scope of TLB maintenance instructions* on page G4-3696 describes the operations.

Table G4-59 TLB maintenance instructions

Name[a]	CRn	opc1	CRm	opc2	Width	Type	Description	Limits[b]
DTLBIALL[c]	c8	0	c6	0	32-bit	WO	Invalidate entire data TLB	-
DTLBIASID[c]	c8	0	c6	2	32-bit	WO	Invalidate data TLB by ASID	-
DTLBIMVA[c]	c8	0	c6	1	32-bit	WO	Invalidate data TLB entry by VA	-
ITLBIALL[c]	c8	0	c5	0	32-bit	WO	Invalidate entire instruction TLB	-
ITLBIASID[c]	c8	0	c5	2	32-bit	WO	Invalidate instruction TLB by ASID	-
ITLBIMVA[c]	c8	0	c5	1	32-bit	WO	Invalidate instruction TLB by VA	-
TLBIALL[d]	c8	0	c7	0	32-bit	WO	Invalidate entire unified TLB	-
TLBIALLH	c8	4	c7	0	32-bit	WO	Invalidate entire Hyp unified TLB	-
TLBIALLHIS	c8	4	c3	0	32-bit	WO	Invalidate entire Hyp unified TLB	IS
TLBIALLIS	c8	0	c3	0	32-bit	WO	Invalidate entire unified TLB	IS
TLBIALLNSNH	c8	4	c7	4	32-bit	WO	Invalidate entire Non-secure Non-Hyp unified TLB	-
TLBIALLNSNHIS	c8	4	c3	4	32-bit	WO	Invalidate entire Non-secure Non-Hyp unified TLB	IS
TLBIASID	c8	0	c7	2	32-bit	WO	Invalidate unified TLB by ASID	-
TLBIASIDIS	c8	0	c3	2	32-bit	WO	Invalidate unified TLB by ASID	IS
TLBIIPAS2	c8	4	c4	1	32-bit	WO	TLB Invalidate entry by IPA, Stage 2	-
TLBIIPAS2IS	c8	4	c0	1	32-bit	WO	TLB Invalidate entry by IPA, Stage 2, Inner Shareable	IS
TLBIIPAS2L	c8	4	c4	5	32-bit	WO	TLB Invalidate entry by IPA, Stage 2, Last level	-
TLBIIPAS2LIS	c8	4	c0	5	32-bit	WO	TLB Invalidate entry by IPA, Stage 2, Last level, Inner Shareable	IS
TLBIMVAA	c8	0	c7	3	32-bit	WO	Invalidate unified TLB by VA, all ASID	-
TLBIMVAAIS	c8	0	c3	3	32-bit	WO	Invalidate unified TLB by VA, all ASID	IS
TLBIMVAAL	c8	0	c7	7	32-bit	WO	TLB Invalidate entry by MVA, All ASID, Last level	-
TLBIMVAALIS	c8	0	c3	7	32-bit	WO	TLB Invalidate entry by MVA, All ASID, Last level, Inner Shareable	IS
TLBIMVA	c8	0	c7	1	32-bit	WO	Invalidate unified TLB by VA	-
TLBIMVAH	c8	4	c7	1	32-bit	WO	Invalidate Hyp unified TLB by VA	-

Table G4-59 TLB maintenance instructions (continued)

Name[a]	CRn	opc1	CRm	opc2	Width	Type	Description	Limits[b]
TLBIMVAHIS	c8	4	c3	1	32-bit	WO	Invalidate Hyp unified TLB by VA	IS
TLBIMVAIS	c8	0	c3	1	32-bit	WO	Invalidate unified TLB by VA	IS
TLBIMVAL	c8	0	c7	5	32-bit	WO	TLB Invalidate entry by MVA, Last level	-
TLBIMVALH	c8	4	c7	5	32-bit	WO	TLB Invalidate entry by MVA, Last level, Hyp mode	-
TLBIMVALHIS	c8	4	c3	5	32-bit	WO	TLB Invalidate entry by MVA, Last level, Hyp mode, Inner Shareable	IS
TLBIMVALIS	c8	0	c3	5	32-bit	WO	TLB Invalidate entry by MVA, Last level	IS

a. These links are to a summary of the operation, and *The scope of TLB maintenance instructions* on page G4-3696 describes the operation.
b. IS = Inner Shareable.
c. Deprecated. ARM deprecates use of operations that operate only on an Instruction TLB, or only on a Data TLB.
d. The mnemonics for the operations with CRm==c7, opc2=={0, 1, 2} were previously UTLBIALL, UTLBIMVA and UTLBIMASID.

G4.18.11 Address translation instructions, functional group

Table G4-60 shows the VMSAv8-32 Address translation instructions functional group.

Table G4-60 Address translation instructions

Name	CRn	opc1	CRm	opc2	Width	Type	Description
ATS12NSOPR[a, c]	c7	0	c8	4	32-bit	WO	Stages 1 and 2 Non-secure only EL1 read
ATS12NSOPW[a, c]	c7	0	c8	5	32-bit	WO	Stages 1 and 2 Non-secure only EL1 write
ATS12NSOUR[a, c]	c7	0	c8	6	32-bit	WO	Stages 1 and 2 Non-secure only unprivileged read
ATS12NSOUW[a, c]	c7	0	c8	7	32-bit	WO	Stages 1 and 2 Non-secure only unprivileged write
ATS1CPR[c]	c7	0	c8	0	32-bit	WO	Stage 1 Current state EL1 read
ATS1CPW[c]	c7	0	c8	1	32-bit	WO	Stage 1 Current state EL1 write
ATS1CUR[c]	c7	0	c8	2	32-bit	WO	Stage 1 Current state unprivileged read
ATS1CUW[c]	c7	0	c8	3	32-bit	WO	Stage 1 Current state unprivileged write
ATS1HR[b, c]	c7	4	c8	0	32-bit	WO	Stage 1 Hyp mode read
ATS1HW[b, c]	c7	4	c8	1	32-bit	WO	Stage 1 Hyp mode write
PAR	c7	0	c4	0	32-bit	RW	Physical Address Register
	-	0	c7	-	64-bit	RW	

a. Implemented only as part of EL3. Otherwise, encoding is unallocated and UNPREDICTABLE, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.
b. Implemented only as part of EL2. Otherwise, encoding is unallocated and UNPREDICTABLE, see *Accesses to unallocated CP14 and CP15 encodings* on page G4-3745.
c. These links are to a summary of the operation.

Virtual Address to Physical Address translation instructions on page G4-3737 describes these operations.

G4.18.12 Lockdown, DMA, and TCM features, functional group

Table G4-61 shows the VMSAv8-32 reserved encodings for the Lockdown, DMA, and TCM features registers functional group.

Table G4-61 Lockdown, DMA, and TCM features, VMSAv8-32

Name	CRn	opc1	CRm	Width	opc2	Type	Description
IMPLEMENTATION DEFINED	c9	0-7	c0-c2	32-bit	0-7	a	*VMSAv8-32 CP15 c9 register summary* on page G4-3770
			c5-c8	32-bit	0-7	a	
	c10	0	c0-c1	32-bit	0-7	a	*VMSAv8-32 CP15 c10 register summary* on page G4-3771
			c4	32-bit	0-7	a	
			c8	32-bit	0-7	a	
	c11	0-7	c0-c8	32-bit	0-7	a	*VMSAv8-32 CP15 c11 register summary* on page G4-3771
			c15	32-bit	0-7	a	

a. Access depends on the register or operation, and is IMPLEMENTATION DEFINED.

G4.18.13 Performance Monitors Extension registers, functional group

Table G4-62 shows the VMSAv8-32 Performance Monitors Extension registers functional group. See also *IMPLEMENTATION DEFINED performance monitors* on page G4-3799.

Table G4-62 Performance Monitors Extension registers

Name	CRn	opc1	CRm	opc2	Width	Description
PMCCFILTR	c14	0	c15	7	32-bit	Performance Monitors Cycle Count Filter Register
PMCCNTR	c9	0	c13	0	32-bit	Performance Monitors Cycle Count Register
PMCEID0	c9	0	c12	6	32-bit	Performance Monitors Common Event Identification register 0

PMOVSSET	c9	0	c14	3	32-bit	Performance Monitors Overflow Flag Status Set register
PMSELR	c9	0	c12	5	32-bit	Performance Monitors Event Counter Selection Register
PMSWINC	c9	0	c12	4	32-bit	Performance Monitors Software Increment register
PMUSERENR	c9	0	c14	0	32-bit	Performance Monitors User Enable Register
PMXEVCNTR	c9	0	c13	2	32-bit	Performance Monitors Event Count Register
PMXEVTYPER	c9	0	c13	1	32-bit	Performance Monitors Event Type Select Register

IMPLEMENTATION DEFINED performance monitors

VMSAv8-32 reserves some additional CP15 c9 encodings for optional additional IMPLEMENTATION DEFINED performance monitors. Table G4-63 shows the allocation of CP15 c9 encodings:

Table G4-63 Performance Monitors register encoding allocations in CP15 c9

CRn	opc1	CRm	opc2	Name	Width	Type	Description
c9	0-7	c12-c14	0-7	Performance Monitors Extension registers, see Table G4-62 on page G4-3798	32-bit	RW or RO[a]	*IMPLEMENTATION DEFINED performance monitors*
		c15	0-7	IMPLEMENTATION DEFINED	32-bit	[b]	

a. The table referenced in the *Name* entry shows the type of each of the OPTIONAL Performance Monitors Extension registers.

b. Access depends on the register or operation, and is IMPLEMENTATION DEFINED.

G4.18.14 Generic Timer Extension registers, functional group

AArch32 state reserves CP15 primary coprocessor register c14 for access to the Generic Timer Extension registers. For more information about these registers see *About the Generic Timer registers* on page D6-1791. Table G4-64 shows the VMSAv8-32 CP15 registers in the Generic Timer registers functional group.

Table G4-64 Generic Timer Extension registers

Name	CRn	opc1	CRm	opc2	Width	Type[a]	Description
CNTFRQ	c14	0	c0	0	32-bit	RW	Counter Frequency register
CNTHCTL	c14	4	c1	0	32-bit	RW	Timer EL2 Control register
CNTHP_CTL	c14	4	c2	1	32-bit	RW	EL2 Physical Timer Control register
CNTHP_CVAL	-	6	c14	-	64-bit	RW	EL2 Physical Timer CompareValue register
CNTHP_TVAL	c14	4	c2	0	32-bit	RW	EL2 Physical TimerValue register
CNTKCTL	c14	0	c1	0	32-bit	RW	Timer EL1 Control register
CNTP_CTL	c14	0	c2	1	32-bit	RW	EL1 Physical Timer Control register
CNTP_CVAL	-	2	c14	-	64-bit	RW	EL1 Physical Timer CompareValue register
CNTP_TVAL	c14	0	c2	0	32-bit	RW	EL1 Physical TimerValue register
CNTPCT	-	0	c14	-	64-bit	RW	Physical Count register
CNTV_CTL	c14	0	c3	1	32-bit	RW	Virtual Timer Control register
CNTV_CVAL	-	3	c14	-	64-bit	RW	Virtual Timer CompareValue register
CNTV_TVAL	c14	0	c3	0	32-bit	RW	Virtual TimerValue register
CNTVCT	-	1	c14	-	64-bit	RO	Virtual Count register
CNTVOFF[b]	-	4	c14	-	64-bit	RW	Virtual Offset register

a. See the register descriptions for more information. Accessibility can depend on configuration settings as well as on the current Exception level.

b. Implemented as RW only as part of the Generic Timers Extension on an implementation that includes EL2 and when EL2 is using AArch32. For more information see *Status of the CNTVOFF register* on page D6-1791.

G4.18.15 Generic Interrupt Controller CPU interface registers, functional group

Table G4-65 shows the VMSAv8-32 CP15 registers in the Generic Interrupt Controller CPU interface registers functional group.

Table G4-65 Generic Interrupt Controller CPU interface registers

Name	CRn	opc1	CRm	opc2	Width	Type	Description
ICC_AP0R0	c12	0	c8	4	32-bit	RW	Interrupt Controller Active Priorities Register (0,0)
ICC_AP0R1	c12	0	c8	5	32-bit	RW	Interrupt Controller Active Priorities Register (0,1)
ICC_AP0R2	c12	0	c8	6	32-bit	RW	Interrupt Controller Active Priorities Register (0,2)
ICC_AP0R3	c12	0	c8	7	32-bit	RW	Interrupt Controller Active Priorities Register (0,3)
ICC_AP1R0	c12	0	c9	0	32-bit	RW	Interrupt Controller Active Priorities Register (1,0)

G4.18.16 Legacy feature registers, functional group

Table G4-66 shows the VMSAv8-32 CP15 Legacy features registers.

Table G4-66 CP15 Legacy features registers

Name	CRn	opc1	CRm	opc2	Width	Type[a]	Description
CP15DMB	c7	0	c10	5	32-bit	WO, PL0	*Memory barriers* on page E2-2268
CP15DSB	c7	0	c10	4	32-bit	WO, PL0	
CP15ISB	c7	0	c5	4	32-bit	WO, PL0	
FCSEIDR	c13	0	c0	0	32-bit	[b]	FCSE Process ID Register

a. PL0 in a Type description indicates that the encoding is accessible by software executing at PL0. See the register description for more information.

b. In ARMv8, the PE does not implement the FCSEIDR, and therefore the register is RO. See the register description for more information.

Table G4-67 shows the VMSAv8-32 CP14 Legacy features registers.

Table G4-67 CP14 Legacy features registers

Name	CRn	opc1	CRm	opc2	Width	Type	Description
JIDR	c0	7	c0	0	32-bit	RO	Jazelle ID Register
JMCR	c2	7	c0	0	32-bit	RW	Jazelle Main Configuration Register
JOSCR	c1	7	c0	0	32-bit	RW	Jazelle OS Control Register

G4.18.17 IMPLEMENTATION DEFINED registers, functional group

AArch32 state reserves CP15 c15 for IMPLEMENTATION DEFINED purposes, and does not impose any restrictions on the use of the CP15 c15 encodings. The documentation of the ARM implementation must describe fully any registers implemented in CP15 c15. Normally, for processor implementations by ARM, this information is included in the *Technical Reference Manual* for the processor.

Typically, an implementation uses CP15 c15 to provide test features, and any required configuration options that are not covered by this manual.

In addition, VMSAv8-32 defines some encodings for IMPLEMENTATION DEFINED registers. Table G4-68 shows these registers.

Table G4-68 IMPLEMENTATION DEFINED registers with architecturally-defined encodings

Name	CRn	opc1	CRm	opc2	Width	Type	Description
ACTLR	c1	0	c0	1	32-bit	RW	Auxiliary Control Register
ADFSR	c5	0	c1	0	32-bit	RW	Auxiliary Data Fault Status Register
AIDR	c0	1	c0	7	32-bit	RO	Auxiliary ID Register
AIFSR	c5	0	c1	1	32-bit	RW	Auxiliary Instruction Fault Status Register
AMAIR0	c10	0	c3	0	32-bit	RW	Auxiliary Memory Attribute Indirection Register 0
AMAIR1	c10	0	c3	1	32-bit	RW	Auxiliary Memory Attribute Indirection Register 1
HACTLR	c1	4	c0	0	32-bit	RW	Hyp Auxiliary System Control Register

Table G4-68 IMPLEMENTATION DEFINED registers with architecturally-defined encodings (continued)

Name	CRn	opc1	CRm	opc2	Width	Type	Description
HADFSR	c5	4	c1	0	32-bit	RW	Hyp Auxiliary Data Fault Status Register
HAIFSR	c5	4	c1	1	32-bit	RW	Hyp Auxiliary Instruction Fault Status Register
HAMAIR0	c10	4	c3	0	32-bit	RW	Hyp Auxiliary Memory Attribute Indirection Register 0
HAMAIR1	c10	4	c3	1	32-bit	RW	Hyp Auxiliary Memory Attribute Indirection Register 1

See also *IMPLEMENTATION DEFINED performance monitors* on page G4-3799.

G4.18.18 Floating-point registers, functional group

Table G4-69 shows the VMSAv8-32 Floating-point registers. These registers are accesses using `MRS` and `MSR` instructions, see the register descriptions for more information.

Table G4-69 Floating-point registers

Name	Width	Type	Description
FPEXC	32-bit	RW	Floating-Point Exception Control register

SDER	c1	0	c1	1	32-bit	RW	Secure Debug Enable Register

~~Debug CP14 System register numbers~~

~~In AArch32 state, each debug register that is accessible using a System registers CP14 encoding can be assigned a register number, determined by the {CRn, opc2, CRm} values used to access the register. If the register is also accessible in a memory-mapped interface, then its offset in that interface is (4*(register_number)). Figure G4-32 shows this mapping from {CRn, opc2, CRm} values to the debug register number.~~

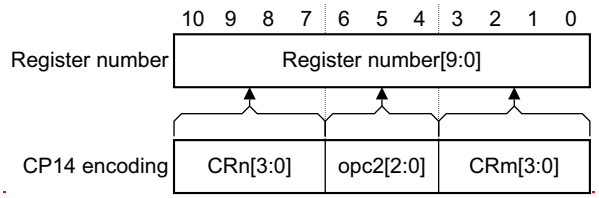

Figure G4-32 ~~Mapping from CP14 encoding to debug register number~~

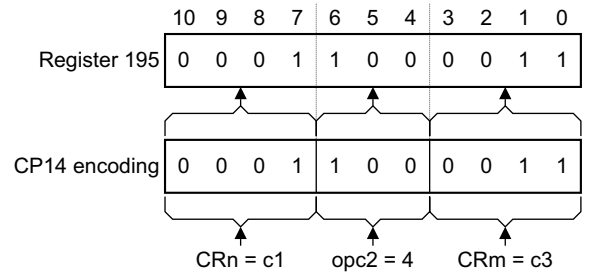
Note

~~The CP14 debug register encodings only use CRn values c0–c7, meaning bit[10] of the register number is 0.~~

~~Example G4-6 shows this encoding for debug register 195, DBGOSDLR.~~

Example G4-6 ~~CP14 encoding of debug register 195~~



G4.19 Pseudocode details of VMSAv8-32 memory system operations

This section contains pseudocode describing VMSAv8-32 memory operations. The following subsections describe the pseudocode functions:

- *Alignment fault*.
- *Address translation*.
- *Domain checking* on page G4-3809.
- *TLB operations* on page G4-3809.
- *Translation table walk* on page G4-3810.
- *Reporting syndrome information* on page G4-3821.
- *Calling the hypervisor* on page G4-3821.
- *Memory access decode when TEX remap is enabled* on page G4-3821.

See also the pseudocode for general memory system operations in *Pseudocode details of general memory system instructions* on page G3-3605.

G4.19.1 Alignment fault

The `AlignmentFault()` pseudocode function describes the generation of an Alignment fault Data Abort exception:

```
// AArch32.AlignmentFault()
// ========================

FaultRecord AArch32.AlignmentFault(AccType acctype, boolean iswrite, boolean secondstage)

    ipaddress = bits(40) UNKNOWN;
    domain = bits(4) UNKNOWN;
    level = integer UNKNOWN;
    extflag = bit UNKNOWN;
    debugmoe = bits(4) UNKNOWN;
    s2fs1walk = boolean UNKNOWN;

    return AArch32.CreateFaultRecord(Fault_Alignment, ipaddress,  domain, level, acctype, iswrite,
                                     extflag, debugmoe, secondstage, s2fs1walk);
```

See also *Abort exceptions* on page G3-3611.

G4.19.2 Address translation

The `TranslateAddress()` and `FullTranslate()` pseudocode functions describe a VMSAv8-32 address translation.

```
// AArch32.TranslateAddress()
// ==========================
// Main entry point for translating an address

AddressDescriptor AArch32.TranslateAddress(bits(32) vaddress, AccType acctype, boolean iswrite,
                                           boolean wasaligned, integer size)

    if PSTATE.EL == EL0 && !ELUsingAArch32(EL1) then
        return AArch64.TranslateAddress(ZeroExtend(vaddress, 64), acctype, iswrite, wasaligned,
                                        size);

    result = AArch32.FullTranslate(vaddress, acctype, iswrite, wasaligned, size);

    if !(acctype IN {AccType_PTW, AccType_IC, AccType_AT}) && !IsFault(result) then
        result.fault = AArch32.CheckDebug(vaddress, acctype, iswrite, size);

    return result;
```

The `FullTranslate()` function calls either:

- The function described in *Address translation when the stage 1 address translation is disabled* on page G4-3808.
- One of the functions described in *Translation table walk* on page G4-3810.

```
// AArch32.FullTranslate()
// =======================
// Perform both stage 1 and stage 2 translation walks for the current translation regime. The
// function used by Address Translation operations is similar except it uses the translation
// regime specified for the instruction.

AddressDescriptor AArch32.FullTranslate(bits(32) vaddress, AccType acctype, boolean iswrite,
                                        boolean wasaligned, integer size)

    // First Stage Translation
    S1 = AArch32.FirstStageTranslate(vaddress, acctype, iswrite, wasaligned, size);

    if !IsFault(S1) && HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} then
        s2fs1walk = FALSE;
        result = AArch32.SecondStageTranslate(S1, vaddress, acctype, iswrite, wasaligned, s2fs1walk,
                                              size);
    else
        result = S1;

    return result;
```

Stage 2 translation table walk on page G4-3818 describes the `CheckPermissionS2()` and `CombineS1S2Desc()` pseudocode functions.

Address translation when the stage 1 address translation is disabled

The `TranslateAddressS1Off()` pseudocode function describes the address translation performed when the stage 1 address translation is disabled.

```
// AArch32.TranslateAddressS1Off()
// ===============================
// Called for stage 1 translations when translation is disabled to supply a default translation.
// Note that there are additional constraints on instruction prefetching that are not described in
// this pseudocode.

TLBRecord AArch32.TranslateAddressS1Off(bits(32) vaddress, AccType acctype, boolean iswrite)
    assert ELUsingAArch32(TranslationRegime());

    TLBRecord result;

    if HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} then
        dc = (if ELUsingAArch32(EL2) then HCR.DC else HCR_EL2.DC);
        default_cacheable = (dc == '1');
    else
        default_cacheable = FALSE;

    if default_cacheable then
        // Use default cacheable settings
        result.addrdesc.memattrs.type = MemType_Normal;
        result.addrdesc.memattrs.device = DeviceType UNKNOWN;
        result.addrdesc.memattrs.inner.attrs = MemAttr_WB;      // Write-back
        result.addrdesc.memattrs.inner.hints = MemHint_RWA;
        result.addrdesc.memattrs.shareable = FALSE;
        result.addrdesc.memattrs.outershareable = FALSE;
        vm = (if ELUsingAArch32(EL2) then HCR.VM else HCR_EL2.VM);
        if vm != '1' then UNPREDICTABLE;
    elsif acctype != AccType_IFETCH then
        // Treat data as Device
        result.addrdesc.memattrs.type = MemType_Device;
        result.addrdesc.memattrs.device = DeviceType_nGnRnE;
        result.addrdesc.memattrs.inner = MemAttrHints UNKNOWN;
        result.addrdesc.memattrs.shareable = TRUE;
        result.addrdesc.memattrs.outershareable = TRUE;
    else
        // Instruction cacheability controlled by SCTLR/HSCTLR.I
        if PSTATE.EL == EL2 then
            cacheable = HSCTLR.I == '1';
```

```
        else
            cacheable = SCTLR.I == '1';
        result.addrdesc.memattrs.type = MemType_Normal;
        result.addrdesc.memattrs.device = DeviceType UNKNOWN;
        if cacheable then
            result.addrdesc.memattrs.inner.attrs = MemAttr_WT;
            result.addrdesc.memattrs.inner.hints = MemHint_RA;
        else
            result.addrdesc.memattrs.inner.attrs = MemAttr_NC;
            result.addrdesc.memattrs.inner.hints = MemHint_No;
        result.addrdesc.memattrs.shareable = TRUE;
        result.addrdesc.memattrs.outershareable = TRUE;

    result.addrdesc.memattrs.outer = result.addrdesc.memattrs.inner;

    result.perms.ap = bits(3) UNKNOWN;
    result.perms.xn = '0';
    result.perms.pxn = '0';

    result.nG = bit UNKNOWN;
    result.contiguous = boolean UNKNOWN;
    result.domain = bits(4) UNKNOWN;
    result.level = integer UNKNOWN;
    result.blocksize = integer UNKNOWN;
    result.addrdesc.paddress.physicaladdress = ZeroExtend(vaddress);
    result.addrdesc.paddress.NS = if IsSecure() then '0' else '1';
    result.addrdesc.fault = AArch32.NoFault();

    return result;
```

G4.19.3 Domain checking

The `CheckDomain()` pseudocode function describes domain checking:

```
// AArch32.CheckDomain()
// =====================

(boolean, FaultRecord) AArch32.CheckDomain(bits(4) domain, bits(32) vaddress, integer level,
                                           AccType acctype, boolean iswrite)

    index = 2 * UInt(domain);
    attrfield = DACR<index+1:index>;

    if attrfield == '10' then          // Reserved, maps to an allocated value
        // Reserved value maps to an allocated value
        (-, attrfield) = ConstrainUnpredictableBits();

    if attrfield == '00' then
        fault = AArch32.DomainFault(domain, level, acctype, iswrite);
    else
        fault = AArch32.NoFault();

    permissioncheck = (attrfield == '01');

    return (permissioncheck, fault);
```

G4.19.4 TLB operations

The `TLBRecord()` type represents the contents of a TLB entry:

```
type TLBRecord is (
    Permissions       perms,
    bit               nG,             // '0' = Global, '1' = not Global
    bits(4)           domain,         // AArch32 only
    boolean           contiguous,     // Contiguous bit from page table
    integer           level,          // In AArch32 Short-descriptort format, indicates Section/Page
    integer           blocksize,      // Describes size of memory translated in KBytes
```

```
    AddressDescriptor addrdesc
)
```

G4.19.5 Translation table walk

Because of the complexity of a translation table walk, the following sections describe the different cases:

- *Translation table walk using the Short-descriptor translation table format for stage 1*.
- *Translation table walk using the Long-descriptor translation table format for stage 1* on page G4-3813.
- *Stage 2 translation table walk* on page G4-3818.

Translation table walk using the Short-descriptor translation table format for stage 1

The TranslationTableWalkSD() pseudocode function describes the translation table walk when the stage 1 translation tables use the Short-descriptor format. It calls the function described in *Stage 2 translation table walk* on page G4-3818 if necessary:

```
// AArch32.TranslationTableWalkSD()
// ================================
// Returns a result of a translation table walk using the Short-descriptor format
//
// Implementations might cache information from memory in any number of non-coherent TLB
// caching structures, and so avoid memory accesses that have been expressed in this
// pseudocode. The use of such TLBs is not expressed in this pseudocode.

TLBRecord AArch32.TranslationTableWalkSD(bits(32) vaddress, AccType acctype, boolean iswrite,
                                         integer size)
    assert ELUsingAArch32(TranslationRegime());

    // This is only called when the MMU is enabled
    TLBRecord         result;
    AddressDescriptor l1descaddr;
    AddressDescriptor l2descaddr;
    bits(40)      outputaddress;

    // Variables for Abort functions
    ipaddress = bits(40) UNKNOWN;
    secondstage = FALSE;
    s2fs1walk = FALSE;

    // Default setting of the domain
    domain = bits(4) UNKNOWN;

    // Determine correct Translation Table Base Register to use.
    bits(64) ttbr;
    n = UInt(TTBCR.N);
    if n == 0 || IsZero(vaddress<31:(32-n)>) then
        ttbr = TTBR0;
        disabled = (TTBCR.PD0 == '1');
    else
        ttbr = TTBR1;
        disabled = (TTBCR.PD1 == '1');
        n = 0;  // TTBR1 translation always works like N=0 TTBR0 translation

    // Check this Translation Table Base Register is not disabled.
    if disabled then
        level = 1;
        result.addrdesc.fault = AArch32.TranslationFault(ipaddress, domain, level, acctype, iswrite,
                                                         secondstage, s2fs1walk);
        return result;

    // Obtain First level descriptor.
    l1descaddr.paddress.physicaladdress = ZeroExtend(ttbr<31:14-n>:vaddress<31-n:20>:'00');
    l1descaddr.paddress.NS = if IsSecure() then '0' else '1';
    IRGN = ttbr<0>:ttbr<6>;             // TTBR.IRGN
    RGN = ttbr<4:3>;                    // TTBR.RGN
```

```
SH = ttbr<1>:ttbr<5>;               // TTBR.S:TTBR.NOS
l1descaddr.memattrs = WalkAttrDecode(SH, RGN, IRGN);

if !HaveEL(EL2) || IsSecure()  then
    // if only 1 stage of translation
    l1descaddr2 = l1descaddr;
else
    l1descaddr2 = AArch32.SecondStageWalk(l1descaddr, vaddress, acctype, 4);

```

The `ShortConvertAttrsHints()` pseudocode function converts the Normal memory cacheability attribute, from the translation table base register or the translation table TEX field, into the separate cacheability attribute and cache allocation hint defined in a Long-descriptor translation table descriptor:

```
// ShortConvertAttrsHints()
// ========================
// Converts the short attribute fields for Normal memory as used in the TTBR and
// TEX fields to orthogonal attributes and hints

MemAttrHints ShortConvertAttrsHints(bits(2) RGN, AccType acctype)

    MemAttrHints result;
```

```
    if CacheDisabled(acctype) then     // Force Non-cacheable
        result.attrs = MemAttr_NC;
        result.hints = MemHint_No;
    else
        case RGN of
            when '00'                   // Non-cacheable (no allocate)
                result.attrs = MemAttr_NC;
                result.hints = MemHint_No;
            when '01'                   // Write-back, Read and Write allocate
                result.attrs = MemAttr_WB;
                result.hints = MemHint_RWA;
            when '10'                   // Write-through, Read allocate
                result.attrs = MemAttr_WT;
                result.hints = MemHint_RA;
            when '11'                   // Write-back, Read allocate
                result.attrs = MemAttr_WB;
                result.hints = MemHint_RA;

    result.transient = FALSE;

    return result;
```

Translation table walk using the Long-descriptor translation table format for stage 1

The `TranslationTableWalkLD()` pseudocode function describes the translation table walk when the stage 1 translation tables use the Long-descriptor format. It calls the function described in *Stage 2 translation table walk* on page G4-3818 if necessary:

```
// AArch32.TranslationTableWalkLD()
// ================================
// Returns a result of a translation table walk using the Long-descriptor format
//
// Implementations might cache information from memory in any number of non-coherent TLB
// caching structures, and so avoid memory accesses that have been expressed in this
// pseudocode. The use of such TLBs is not expressed in this pseudocode.

TLBRecord AArch32.TranslationTableWalkLD(bits(40) ipaddress, bits(32) vaddress,
                                         AccType acctype, boolean iswrite, boolean secondstage,
                                         boolean s2fs1walk, integer size)
    if !secondstage then
        assert ELUsingAArch32(TranslationRegime());
    else
        assert HaveEL(EL2) && !IsSecure() && ELUsingAArch32(EL2) && PSTATE.EL != EL2;

    TLBRecord result;
    AddressDescriptor descaddr;
    bits(64) baseregister;
    bits(40) inputaddr;        // Input Address is 'vaddress' for stage 1, 'ipaddress' for stage 2
    domain = bits(4) UNKNOWN;
    basefound = FALSE;

    descaddr.memattrs.type = MemType_Normal;

    // Determine parameters for the page table walk:
    //  grainsize = Log2(Size of Table)         - Size of Table is 4KB in AArch32
    //  stride = Log2(Address per Level)        - Bits of address consumed at each level
    constant integer grainsize = 12;            // Log2(4KB)

This function calls the `ConvertAttrsHints()` pseudocode function that is defined in *Translation table walk using the Short-descriptor translation table format for stage 1* on page G4-3810.

The `S1AttrDecode()` pseudocode function uses the MAIR0 and MAIR1 registers to decode the Attr[2:0] value from a stage 1 translation table descriptor:

```
// AArch32.S1AttrDecode()
// ======================
```

```
// Converts the Stage 1 attribute fields, using the MAIR, to orthogonal
// attributes and hints.

MemoryAttributes AArch32.S1AttrDecode(bits(2) SH, bits(3) attr, AccType acctype)

    MemoryAttributes mematTrs;

    if PSTATE.EL == EL2 then
        mair = HMAIR1:HMAIR0;
    else
        mair = MAIR1:MAIR0;
    index = 8 * UInt(attr);
    attrfield = mair<index+7:index>;

    if ((attrfield<7:4> != '0000' && attrfield<3:0> == '0000') ||
        (attrfield<7:4> == '0000' && attrfield<3:0> != 'xx00')) then
        // Reserved, maps to an allocated value
        (-, attrfield) = ConstrainUnpredictableBits();

    if attrfield<7:4> == '0000' then            // Device
        mematTrs.type = MemType_Device;
        mematTrs.inner = MemAttrHints UNKNOWN;
        mematTrs.outer = MemAttrHints UNKNOWN;
        mematTrs.shareable = TRUE;
        mematTrs.outershareable = TRUE;
        case attrfield<3:0> of
            when '0000'  mematTrs.device = DeviceType_nGnRnE;
            when '0100'  mematTrs.device = DeviceType_nGnRE;
            when '1000'  mematTrs.device = DeviceType_nGRE;
            when '1100'  mematTrs.device = DeviceType_GRE;
            otherwise    Unreachable();         // Reserved, handled above

    elsif attrfield<3:0> != '0000'  then        // Normal
        mematTrs.type = MemType_Normal;
        mematTrs.outer = LongConvertAttrsHints(attrfield<7:4>, acctype);
        mematTrs.inner = LongConvertAttrsHints(attrfield<3:0>, acctype);
        mematTrs.device = DeviceType UNKNOWN;
        mematTrs.shareable = SH<1> == '1';
        mematTrs.outershareable = SH == '10';

    else
        Unreachable();                          // Reserved, handled above

    return mematTrs;
```

The S2AttrDecode() pseudocode function decodes the Attr[3:0] value from a stage 2 translation table descriptor:

```
// S2AttrDecode()
// ==============
// Converts the Stage 2 attribute fields into orthogonal attributes and hints

MemoryAttributes S2AttrDecode(bits(2) SH, bits(4) attr, AccType acctype)

    MemoryAttributes mematTrs;

    if attr<3:2> == '00' then                    // Device
        mematTrs.type = MemType_Device;
        mematTrs.inner = MemAttrHints UNKNOWN;
        mematTrs.outer = MemAttrHints UNKNOWN;
        case attr<1:0> of
            when '00'  mematTrs.device = DeviceType_nGnRnE;
            when '01'  mematTrs.device = DeviceType_nGnRE;
            when '10'  mematTrs.device = DeviceType_nGRE;
            when '11'  mematTrs.device = DeviceType_GRE;
        mematTrs.shareable = TRUE;
        mematTrs.outershareable = TRUE;

    elsif attr<1:0> != '00' then                // Normal
```

```
        mematttrs.type = MemType_Normal;
        mematttrs.device = DeviceType UNKNOWN;
        mematttrs.outer = S2ConvertAttrsHints(attr<3:2>, acctype);
        mematttrs.inner = S2ConvertAttrsHints(attr<1:0>, acctype);
        mematttrs.shareable = SH<1> == '1';
        mematttrs.outershareable = SH == '10';

    else
        mematttrs = MemoryAttributes UNKNOWN;    // Reserved

    return mematttrs;
```

Stage 2 translation table walk

The SecondStageTranslate() pseudocode function describes the stage 2 translation table walk. Stage 2 translations tables always use the Long-descriptor format.

```
// AArch32.SecondStageTranslate()
// ==============================
// Perform a stage 2 translation walk. The function used by Address Translation operations is
// similar except it uses the translation regime specified for the instruction.

AddressDescriptor AArch32.SecondStageTranslate(AddressDescriptor S1, bits(32) vaddress,
                                               AccType acctype, boolean iswrite, boolean wasaligned,
                                               boolean s2fs1walk, integer size)
    assert HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1};
    assert IsZero(S1.paddress.physicaladdress<47:40>);

    if !ELUsingAArch32(EL2) then
        return AArch64.SecondStageTranslate(S1, ZeroExtend(vaddress, 64), acctype, iswrite,
                                            wasaligned, s2fs1walk, size);

    s2_enabled = HCR.VM == '1';
    secondstage = TRUE;

    if s2_enabled then                          // Second stage enabled
        ipaddress = S1.paddress.physicaladdress<39:0>;
        S2 = AArch32.TranslationTableWalkLD(ipaddress, vaddress, acctype, iswrite, secondstage,

        secondstage = TRUE;
        return AArch32.PermissionFault(ipaddress, domain, level, acctype, iswrite, secondstage,
                                       s2fs1walk);
    else
        return AArch32.NoFault();
```

The `CombineS1S2Desc()` pseudocode function combines the stage 1 and stage 2 access permissions:

```
// CombineS1S2Desc()
// =================
// Combines the address descriptors from stage 1 and stage 2

AddressDescriptor CombineS1S2Desc(AddressDescriptor s1desc, AddressDescriptor s2desc)

    AddressDescriptor result;

    result.paddress = s2desc.paddress;

    if IsFault(s1desc) || IsFault(s2desc) then
        result = if IsFault(s1desc) then s1desc else s2desc;
    elsif s2desc.mattrs.type == MemType_Device || s1desc.mattrs.type == MemType_Device then
        result.mattrs.type = MemType_Device;
        if s1desc.mattrs.type == MemType_Normal then
            result.mattrs.device = s2desc.mattrs.device;
        elsif s2desc.mattrs.type == MemType_Normal then
            result.mattrs.device = s1desc.mattrs.device;
        else                    // Both Device
            result.mattrs.device = CombineS1S2Device(s1desc.mattrs.device,
                                                     s2desc.mattrs.device);
        result.mattrs.inner = MemAttrHints UNKNOWN;
        result.mattrs.outer = MemAttrHints UNKNOWN;
        result.mattrs.shareable = TRUE;
        result.mattrs.outershareable = TRUE;
    else                        // Both Normal
        result.mattrs.type = MemType_Normal;
        result.mattrs.device = DeviceType UNKNOWN;
        result.mattrs.inner = CombineS1S2AttrHints(s1desc.mattrs.inner, s2desc.mattrs.inner);
        result.mattrs.outer = CombineS1S2AttrHints(s1desc.mattrs.outer, s2desc.mattrs.outer);
        if (result.mattrs.inner.attrs == MemAttr_NC &&
            result.mattrs.outer.attrs == MemAttr_NC) then
            // something Non-cacheable at each level is Outer Shareable
            result.mattrs.shareable = TRUE;
            result.mattrs.outershareable = TRUE;
        else
            result.mattrs.shareable = (s1desc.mattrs.shareable || s2desc.mattrs.shareable);
            result.mattrs.outershareable = (s1desc.mattrs.outershareable ||
                                            s2desc.mattrs.outershareable);
```

```
    return result;
```

G4.19.6 Reporting syndrome information

The ReportHypEntry() pseudocode function writes a syndrome value to the HSR:

```
// AArch32.ReportHypEntry()
// ========================
// Report syndrome information to Hyp mode registers.

AArch32.ReportHypEntry(ExceptionRecord exception)

    Exception type = exception.type;

    (ec,il) = AArch32.ExceptionClass(type);
    iss = exception.syndrome;

    // IL is not valid for Data Abort exceptions without valid instruction syndrome information
    if ec IN {0x24,0x25} && iss<24> == '0' then
        il = '1';

    HSR = ec<5:0>:il:iss;

    if type IN {Exception_InstructionAbort, Exception_PCAlignment} then
        HIFAR = exception.vaddress<31:0>;
        HDFAR = bits(32) UNKNOWN;
    elsif type == Exception_DataAbort then
        HIFAR = bits(32) UNKNOWN;
        HDFAR = exception.vaddress<31:0>;

    if exception.ipavalid then
        HPFAR<31:4> = exception.ipaddress<39:12>;

    return;
```

G4.19.7 Calling the hypervisor

The CallHypervisor() pseudocode function generates an HVC exception. Valid execution of the HVC instruction calls this function.

```
// AArch32.CallHypervisor()
// ========================
// Performs a HVC call

AArch32.CallHypervisor(bits(16) immediate)
    assert HaveEL(EL2);

    if !ELUsingAArch32(EL2) then
        AArch64.CallHypervisor(immediate);
    else
        AArch32.TakeHVCException(immediate);
```

G4.19.8 Memory access decode when TEX remap is enabled

When using the Short-descriptor translation table format, the function RemappedTEXDecode() decodes the texcb and S attributes derived from the translation tables when TEX remap is enabled. *Short-descriptor format memory region attributes, with TEX remap* on page G4-3676 shows the interpretation of the arguments.

```
// AArch32.RemappedTEXDecode()
// ===========================

MemoryAttributes AArch32.RemappedTEXDecode(bits(3) TEX, bit C, bit B, bit S, AccType acctype)

    MemoryAttributes mematttrs;
```

```
region = UInt(TEX<0>:C:B);          // TEX<2:1> are ignored in this mapping scheme
if region == 6 then
    mematTrs = MemoryAttributes IMPLEMENTATION_DEFINED;
else
    base = 2 * region;
    attrfield = PRRR<base+1:base>;

    if attrfield == '11' then       // Reserved, maps to allocated value
        (-, attrfield) = ConstrainUnpredictableBits();

    case attrfield of
        when '00'                   // Device-nGnRnE
            mematTrs.type = MemType_Device;
            mematTrs.device = DeviceType_nGnRnE;
            mematTrs.shareable = TRUE;
            mematTrs.outershareable = TRUE;
        when '01'                   // Device-nGnRE
            mematTrs.type = MemType_Device;
            mematTrs.device = DeviceType_nGnRE;
            mematTrs.shareable = TRUE;
            mematTrs.outershareable = TRUE;
        when '10'
            mematTrs.type = MemType_Normal;
            mematTrs.inner = ShortConvertAttrsHints(NMRR<base+1:base>, acctype);
            mematTrs.outer = ShortConvertAttrsHints(NMRR<base+17:base+16>, acctype);
            s_bit = if S == '0' then PRRR.NS0 else PRRR.NS1;
            mematTrs.shareable = (s_bit == '1');
            mematTrs.outershareable = (s_bit == '1' && PRRR<region+24> == '0');
        when '11'
            Unreachable();

// transient bits are not supported in this format
mematTrs.inner.transient = FALSE;
mematTrs.outer.transient = FALSE;

if mematTrs.type == MemType_Device then
    mematTrs.inner = MemAttrHints UNKNOWN;
    mematTrs.outer = MemAttrHints UNKNOWN;
else
    mematTrs.device = DeviceType UNKNOWN;

return mematTrs;
```

Chapter G5
AArch32 System Register Descriptions

This chapter describes each of the AArch32 System registers.

It contains the following sections:

G5.1 General system control registers

This section describes the system control registers in AArch32 state that are not part of one of the other listed groups.

G5.1.1 ACTLR, Auxiliary Control Register

The ACTLR characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options.

This register is part of:

- the Other system control registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ACTLR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as ACTLR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

ACTLR(NS) is architecturally mapped to AArch64 register ACTLR_EL1.

ACTLR(S) can be mapped to AArch64 register ACTLR_EL3, but this is not architecturally mandated.

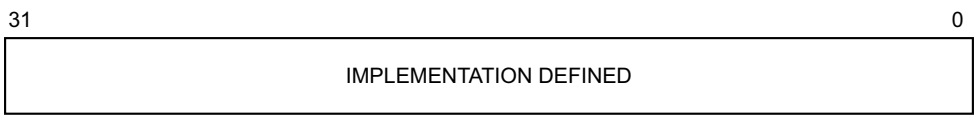
Some bits might define global configuration settings, and be common to the Secure and Non-secure copies of the register.

Attributes

ACTLR is a 32-bit register.

Field descriptions

The ACTLR bit assignments are:



Accessing the ACTLR

To access the ACTLR:

```
MRC p15,0,<Rt>,c1,c0,1 ; Read ACTLR into Rt
MCR p15,0,<Rt>,c1,c0,1 ; Write Rt to ACTLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0000	001

G5.1.2 ADFSR, Auxiliary Data Fault Status Register

The ADFSR characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for Data Abort exceptions taken to EL1 modes.

This register is part of:

- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ADFSR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as ADFSR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

ADFSR(NS) is architecturally mapped to AArch64 register AFSR0_EL1.

ADFSR(S) can be mapped to AArch64 register AFSR0_EL3, but this is not architecturally mandated.

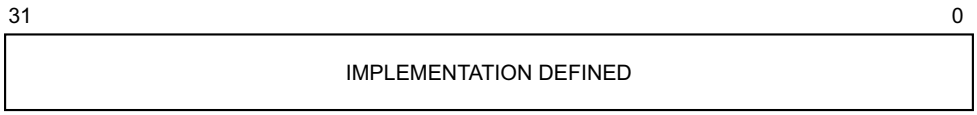
If EL3 is implemented and is using AArch32, this register also provides fault status information for Data Abort exceptions taken to EL3 modes.

Attributes

ADFSR is a 32-bit register.

Field descriptions

The ADFSR bit assignments are:



Accessing the ADFSR

To access the ADFSR:

```
MRC p15,0,<Rt>,c5,c1,0 ; Read ADFSR into Rt
MCR p15,0,<Rt>,c5,c1,0 ; Write Rt to ADFSR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0101	0001	000

G5.1.3 AIDR, Auxiliary ID Register

The AIDR characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED identification information.

This register is part of:

- the Identification registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

The value of this register must be used in conjunction with the value of MIDR.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

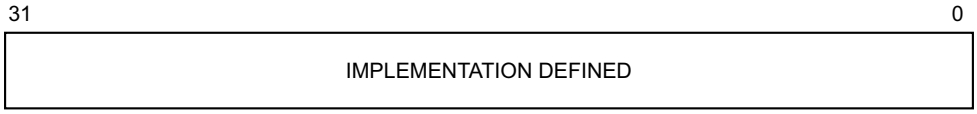
AIDR is architecturally mapped to AArch64 register AIDR_EL1.

Attributes

AIDR is a 32-bit register.

Field descriptions

The AIDR bit assignments are:



Bits [31:0]

IMPLEMENTATION DEFINED

Accessing the AIDR

To access the AIDR:

```
MRC p15,1,<Rt>,c0,c0,7 ; Read AIDR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	001	0000	0000	111

G5.1.4 AIFSR, Auxiliary Instruction Fault Status Register

The AIFSR characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for Prefetch Abort exceptions taken to EL1 modes.

This register is part of:

- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

When accessed as AIFSR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as AIFSR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

AIFSR(NS) is architecturally mapped to AArch64 register AFSR1_EL1.

AIFSR(S) can be mapped to AArch64 register AFSR1_EL3, but this is not architecturally mandated.

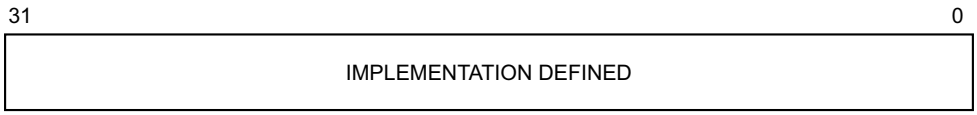
If EL3 is implemented and is using AArch32, this register also provides fault status information for Data Abort exceptions taken to EL3 modes.

Attributes

AIFSR is a 32-bit register.

Field descriptions

The AIFSR bit assignments are:



Accessing the AIFSR

To access the AIFSR:

```
MRC p15,0,<Rt>,c5,c1,1 ; Read AIFSR into Rt
MCR p15,0,<Rt>,c5,c1,1 ; Write Rt to AIFSR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0101	0001	001

G5.1.5 AMAIR0, Auxiliary Memory Attribute Indirection Register 0

The AMAIR0 characteristics are:

Purpose

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR0.

This register is part of:

- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

When accessed as AMAIR0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as AMAIR0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0. Otherwise, it is only valid when using the Long-descriptor translation table format.

If EL3 is implemented and is using AArch32:

- The Secure copy of the register gives the value for memory accesses from Secure state.
- The Non-secure copy of the register gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architected behavior specified by MAIR0 and MAIR1.

In a typical implementation, AMAIR0 and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

AMAIR0(NS) is architecturally mapped to AArch64 register AMAIR_EL1[31:0].

AMAIR0(S) can be mapped to AArch64 register AMAIR_EL3[31:0], but this is not architecturally mandated.

Write access to the Secure copy of AMAIR0 is disabled when the CP15SDISABLE signal is asserted HIGH.

Attributes

AMAIR0 is a 32-bit register.

Field descriptions

The AMAIR0 bit assignments are:

Accessing the AMAIR0

To access the AMAIR0:

```
MRC p15,0,<Rt>,c10,c3,0 ; Read AMAIR0 into Rt
MCR p15,0,<Rt>,c10,c3,0 ; Write Rt to AMAIR0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1010	0011	000

G5.1.6 AMAIR1, Auxiliary Memory Attribute Indirection Register 1

The AMAIR1 characteristics are:

Purpose

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR1.

This register is part of:

- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

When accessed as AMAIR1(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as AMAIR1(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0. Otherwise, it is only valid when using the Long-descriptor translation table format.

If EL3 is implemented and is using AArch32:

- The Secure copy of the register gives the value for memory accesses from Secure state.
- The Non-secure copy of the register gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architected behavior specified by MAIR0 and MAIR1.

In a typical implementation, AMAIR0 and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

AMAIR1(NS) is architecturally mapped to AArch64 register AMAIR_EL1[63:32].

AMAIR1(S) can be mapped to AArch64 register AMAIR_EL3[63:32], but this is not architecturally mandated.

Write access to the Secure copy of AMAIR1 is disabled when the CP15SDISABLE signal is asserted HIGH.

Attributes

AMAIR1 is a 32-bit register.

Field descriptions

The AMAIR1 bit assignments are:

Accessing the AMAIR1

To access the AMAIR1:

```
MRC p15,0,<Rt>,c10,c3,1 ; Read AMAIR1 into Rt
MCR p15,0,<Rt>,c10,c3,1 ; Write Rt to AMAIR1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1010	0011	001

G5.1.7 APSR, Application Program Status Register

The APSR characteristics are:

Purpose

Hold program status and control information.

This register is part of the Process state registers functional group.

Usage constraints

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

The APSR can be read using the MRS instruction and written using the MSR (immediate) or MSR (register) instructions. For more details on the instruction syntax, see .

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

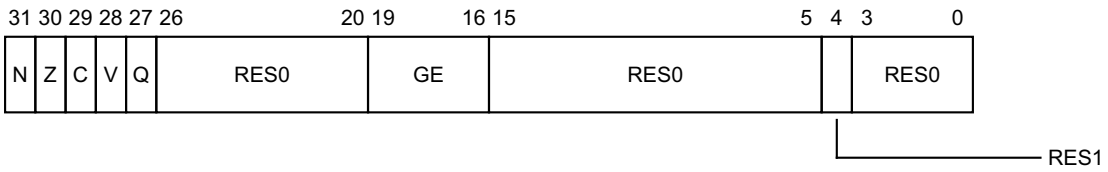
There are no configuration notes.

Attributes

APSR is a 32-bit register.

Field descriptions

The APSR bit assignments are:



N, bit [31]

Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then the processor sets N to 1 if the result was negative, and sets N to 0 if it was positive or zero.

Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

Bits [26:20]

Reserved, RES0.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

Bits [15:5]

Reserved, RES0.

Bit [4]

Reserved, RES1.

Bits [3:0]

Reserved, RES0.

G5.1.8 ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read

The ATS12NSOPR characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for PL1 and the Non-secure state, with permissions as if reading from the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO	WO

If EL3 is implemented and is using AArch64, any execution of ATS12NSOPR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

Configurations

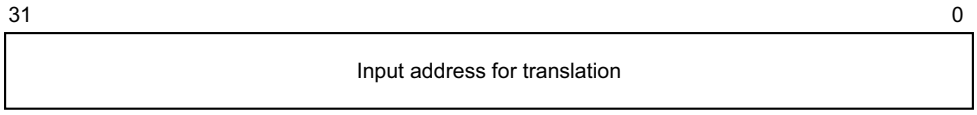
There are no configuration notes.

Attributes

ATS12NSOPR is a 32-bit system operation.

Field descriptions

The ATS12NSOPR input value bit assignments are:



Bits [31:0]

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

Performing the ATS12NSOPR operation

To perform the ATS12NSOPR operation:

```
MCR p15,0,<Rt>,c7,c8,4 ; ATS12NSOPR operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	100

G5.1.9 ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write

The ATS12NSOPW characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for PL1 and the Non-secure state, with permissions as if writing to the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO	WO

If EL3 is implemented and is using AArch64, any execution of ATS12NSOPW in Secure EL1 state in AArch32 is trapped as an exception to EL3.

Configurations

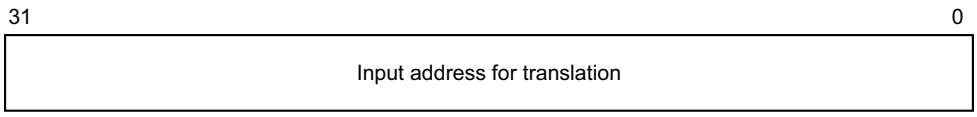
There are no configuration notes.

Attributes

ATS12NSOPW is a 32-bit system operation.

Field descriptions

The ATS12NSOPW input value bit assignments are:



Bits [31:0]

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

Performing the ATS12NSOPW operation

To perform the ATS12NSOPW operation:

```
MCR p15,0,<Rt>,c7,c8,5 ; ATS12NSOPW operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	101

G5.1.10 ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read

The ATS12NSOUR characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for PL0 and the Non-secure state, with permissions as if reading from the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO	WO

If EL3 is implemented and is using AArch64, any execution of ATS12NSOUR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

Configurations

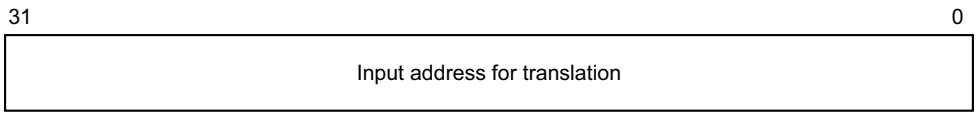
There are no configuration notes.

Attributes

ATS12NSOUR is a 32-bit system operation.

Field descriptions

The ATS12NSOUR input value bit assignments are:



Bits [31:0]

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

Performing the ATS12NSOUR operation

To perform the ATS12NSOUR operation:

```
MCR p15,0,<Rt>,c7,c8,6 ; ATS12NSOUR operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	110

G5.1.11 ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write

The ATS12NSOUW characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for PL0 and the Non-secure state, with permissions as if writing to the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO	WO

If EL3 is implemented and is using AArch64, any execution of ATS12NSOUW in Secure EL1 state in AArch32 is trapped as an exception to EL3.

Configurations

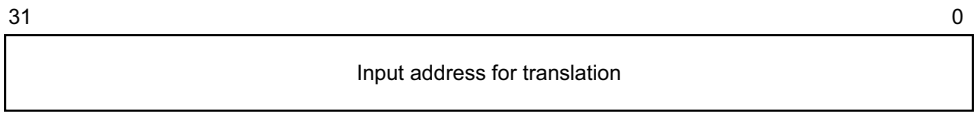
There are no configuration notes.

Attributes

ATS12NSOUW is a 32-bit system operation.

Field descriptions

The ATS12NSOUW input value bit assignments are:



Bits [31:0]

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

Performing the ATS12NSOUW operation

To perform the ATS12NSOUW operation:

```
MCR p15,0,<Rt>,c7,c8,7 ; ATS12NSOUW operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	111

G5.1.12 ATS1CPR, Address Translate Stage 1 Current state PL1 Read

The ATS1CPR characteristics are:

Purpose

Performs stage 1 address translation as defined for PL1 and the current security state, with permissions as if reading from the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

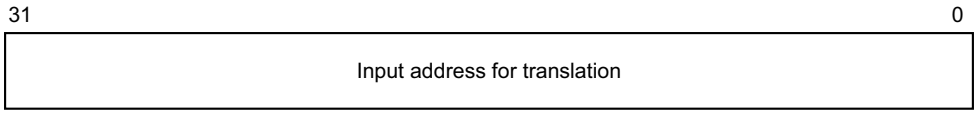
There are no configuration notes.

Attributes

ATS1CPR is a 32-bit system operation.

Field descriptions

The ATS1CPR input value bit assignments are:



Bits [31:0]

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Performing the ATS1CPR operation

To perform the ATS1CPR operation:

```
MCR p15,0,<Rt>,c7,c8,0 ; ATS1CPR operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	000

G5.1.13 ATS1CPW, Address Translate Stage 1 Current state PL1 Write

The ATS1CPW characteristics are:

Purpose

Performs stage 1 address translation as defined for PL1 and the current security state, with permissions as if writing to the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

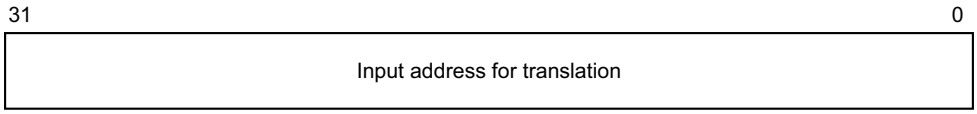
There are no configuration notes.

Attributes

ATS1CPW is a 32-bit system operation.

Field descriptions

The ATS1CPW input value bit assignments are:



Bits [31:0]

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Performing the ATS1CPW operation

To perform the ATS1CPW operation:

```
MCR p15,0,<Rt>,c7,c8,1 ; ATS1CPW operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	001

G5.1.14 ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read

The ATS1CUR characteristics are:

Purpose

Performs stage 1 address translation as defined for PL0 and the current security state, with permissions as if reading from the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

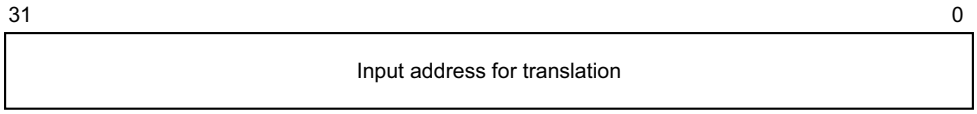
There are no configuration notes.

Attributes

ATS1CUR is a 32-bit system operation.

Field descriptions

The ATS1CUR input value bit assignments are:



Bits [31:0]

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Performing the ATS1CUR operation

To perform the ATS1CUR operation:

```
MCR p15,0,<Rt>,c7,c8,2 ; ATS1CUR operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	010

G5.1.15 ATS1CUW, Address Translate Stage 1 Current state Unprivileged Write

The ATS1CUW characteristics are:

Purpose

Performs stage 1 address translation as defined for PL0 and the current security state, with permissions as if writing to the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

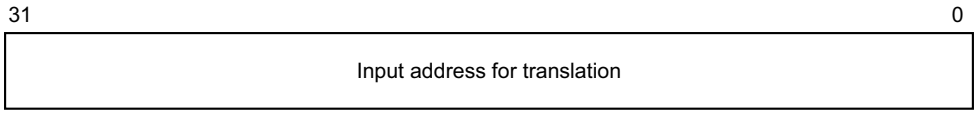
There are no configuration notes.

Attributes

ATS1CUW is a 32-bit system operation.

Field descriptions

The ATS1CUW input value bit assignments are:



Bits [31:0]

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Performing the ATS1CUW operation

To perform the ATS1CUW operation:

```
MCR p15,0,<Rt>,c7,c8,3 ; ATS1CUW operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1000	011

G5.1.16 ATS1HR, Address Translate Stage 1 Hyp mode Read

The ATS1HR characteristics are:

Purpose

Performs stage 1 address translation as defined for PL2 and the Non-secure state, with permissions as if reading from the given virtual address.

This register is part of:

- the Address translation instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

Configurations

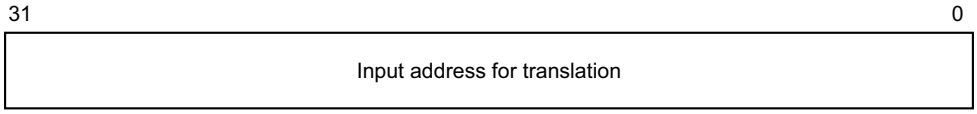
There are no configuration notes.

Attributes

ATS1HR is a 32-bit system operation.

Field descriptions

The ATS1HR input value bit assignments are:



Bits [31:0]

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. The resulting address is the PA that is the output address of the translation.

Performing the ATS1HR operation

To perform the ATS1HR operation:

```
MCR p15,4,<Rt>,c7,c8,0 ; ATS1HR operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0111	1000	000

G5.1.17 ATS1HW, Address Translate Stage 1 Hyp mode Write

The ATS1HW characteristics are:

Purpose

Performs stage 1 address translation as defined for PL2 and the Non-secure state, with permissions as if writing to the given virtual address.

This register is part of:

- the Address translation instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

Configurations

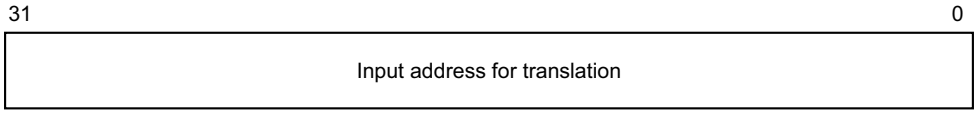
There are no configuration notes.

Attributes

ATS1HW is a 32-bit system operation.

Field descriptions

The ATS1HW input value bit assignments are:



Bits [31:0]

Input address for translation. The resulting address can be read from the PAR.

This instruction takes a VA as input. The resulting address is the PA that is the output address of the translation.

Performing the ATS1HW operation

To perform the ATS1HW operation:

```
MCR p15,4,<Rt>,c7,c8,1 ; ATS1HW operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0111	1000	001

G5.1.18 BPIALL, Branch Predictor Invalidate All

The BPIALL characteristics are:

Purpose

Invalidate all entries from branch predictors.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

There are no configuration notes.

Attributes

BPIALL is a 32-bit system operation.

Field descriptions

The BPIALL operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the BPIALL operation

To perform the BPIALL operation:

```
MCR p15,0,<Rt>,c7,c5,6 ; BPIALL operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0101	110

G5.1.19 BPIALLIS, Branch Predictor Invalidate All, Inner Shareable

The BPIALLIS characteristics are:

Purpose

Invalidate all entries from branch predictors Inner Shareable.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

There are no configuration notes.

Attributes

BPIALLIS is a 32-bit system operation.

Field descriptions

The BPIALLIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the BPIALLIS operation

To perform the BPIALLIS operation:

```
MCR p15,0,<Rt>,c7,c1,6 ; BPIALLIS operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0001	110

G5.1.20 BPIMVA, Branch Predictor Invalidate by VA

The BPIMVA characteristics are:

Purpose

Invalidate virtual address from branch predictors.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

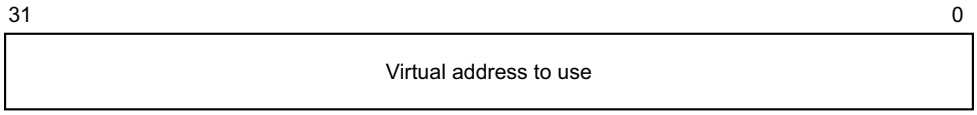
There are no configuration notes.

Attributes

BPIMVA is a 32-bit system operation.

Field descriptions

The BPIMVA input value bit assignments are:



Bits [31:0]

Virtual address to use.

Performing the BPIMVA operation

To perform the BPIMVA operation:

```
MCR p15,0,<Rt>,c7,c5,7 ; BPIMVA operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0101	111

G5.1.21 CCSIDR, Current Cache Size ID Register

The CCSIDR characteristics are:

Purpose

Provides information about the architecture of the cache.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

If CSSELR indicates a cache that is not implemented, then on a read of the CCSIDR the behavior is CONSTRAINED UNPREDICTABLE, see *Programming CSSELR.Level for a cache level that is not implemented* on page AppxA-4791

- The CCSIDR read is treated as NOP.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

CCSIDR is architecturally mapped to AArch64 register CCSIDR_EL1.

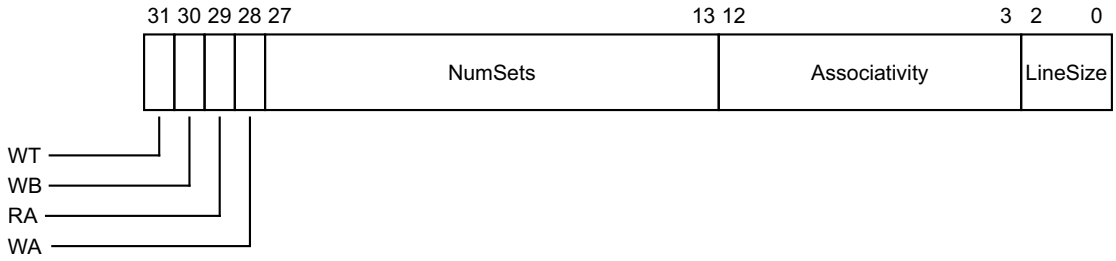
The implementation includes one CCSIDR for each cache that it can access. CSSELR and the security state select which Cache Size ID Register is accessible.

Attributes

CCSIDR is a 32-bit register.

Field descriptions

The CCSIDR bit assignments are:



WT, bit [31]

Indicates whether the selected cache level supports write-through. Permitted values are:

`0` Write-through not supported.

`1` Write-through supported.

WB, bit [30]

Indicates whether the selected cache level supports write-back. Permitted values are:

`0` Write-back not supported.

1 Write-back supported.

RA, bit [29]

Indicates whether the selected cache level supports read-allocation. Permitted values are:

0 Read-allocation not supported.

1 Read-allocation supported.

WA, bit [28]

Indicates whether the selected cache level supports write-allocation. Permitted values are:

0 Write-allocation not supported.

1 Write-allocation supported.

NumSets, bits [27:13]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Associativity, bits [12:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]

(Log_2(Number of bytes in cache line)) - 4. For example:

For a line length of 16 bytes: $Log_2(16) = 4$, LineSize entry = 0. This is the minimum line length.

For a line length of 32 bytes: $Log_2(32) = 5$, LineSize entry = 1.

Accessing the CCSIDR

To access the currently-selected CCSIDR:

```
MRC p15,1,<Rt>,c0,c0,0 ; Read CCSIDR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	001	0000	0000	000

G5.1.22 CLIDR, Cache Level ID Register

The CLIDR characteristics are:

Purpose

Identifies the type of cache, or caches, implemented at each level, up to a maximum of seven levels. Also identifies the Level of Coherency and Level of Unification for the cache hierarchy.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

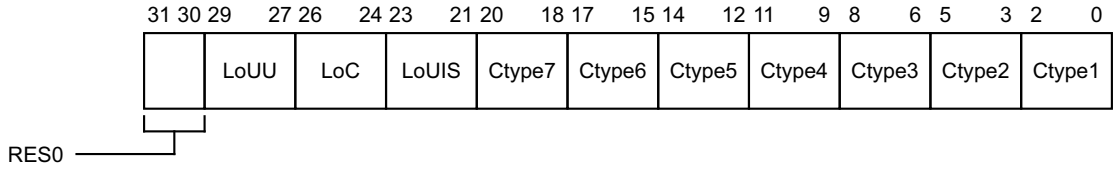
CLIDR is architecturally mapped to AArch64 register CLIDR_EL1.

Attributes

CLIDR is a 32-bit register.

Field descriptions

The CLIDR bit assignments are:



Bits [31:30]

Reserved, RES0.

LoUU, bits [29:27]

Level of Unification Uniprocessor for the cache hierarchy.

LoC, bits [26:24]

Level of Coherency for the cache hierarchy.

LoUIS, bits [23:21]

Level of Unification Inner Shareable for the cache hierarchy.

Ctype<n>, bits [3(n-1)+2:3(n-1)], for 3(n-1)+2:3(n-1) = 1 to 7

Cache Type fields. Indicate the type of cache implemented at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

`000` No cache.

`001` Instruction cache only.

`010` Data cache only.

`011` Separate instruction and data caches.

`100` Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of `000`, no caches exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of `000`, the values of Ctype4 to Ctype7 must be ignored.

Accessing the CLIDR

To access the CLIDR:

```
MRC p15,1,<Rt>,c0,c0,1 ; Read CLIDR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	001	0000	0000	001

G5.1.23 CONTEXTIDR, Context ID Register

The CONTEXTIDR characteristics are:

Purpose

Identifies the current Process Identifier and, when using the Short-descriptor translation table format, the Address Space Identifier.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as CONTEXTIDR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as CONTEXTIDR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

CONTEXTIDR(NS) is architecturally mapped to AArch64 register CONTEXTIDR_EL1.

The register format depends on whether address translation is using the Long-descriptor or the Short-descriptor translation table format.

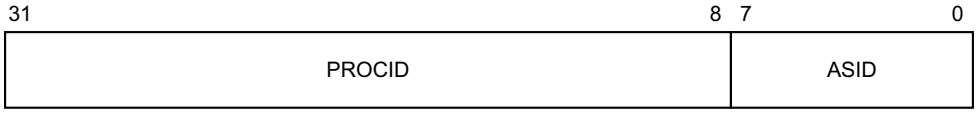
Attributes

CONTEXTIDR is a 32-bit register.

Field descriptions

The CONTEXTIDR bit assignments are:

When TTBCR.EAE==0:



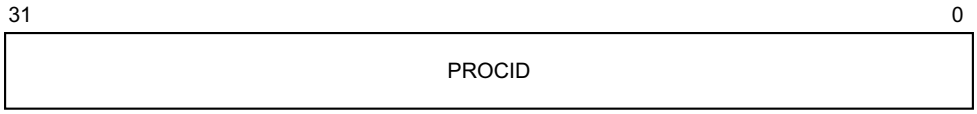
PROCID, bits [31:8]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

ASID, bits [7:0]

Address Space Identifier. This field is programmed with the value of the current ASID.

When TTBCR.EAE==1:



PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

Accessing the CONTEXTIDR

To access the CONTEXTIDR:

```
MRC p15,0,<Rt>,c13,c0,1 ; Read CONTEXTIDR into Rt
MCR p15,0,<Rt>,c13,c0,1 ; Write Rt to CONTEXTIDR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1101	0000	001

G5.1.24 CP15DMB, CP15 Data Memory Barrier operation

The CP15DMB characteristics are:

Purpose

Performs a Data Memory Barrier.

This register is part of the Legacy feature registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
WO	WO	WO	WO	WO	WO	WO

If SCTLR.CP15BEN is set to 0, this operation is disabled and its encoding is UNDEFINED.

ARM deprecates any use of this operation, and strongly recommends that software use the DMB instruction instead.

Configurations

There are no configuration notes.

Attributes

CP15DMB is a 32-bit system operation.

Field descriptions

The CP15DMB operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the CP15DMB operation

To perform the CP15DMB operation:

```
MCR p15,0,<Rt>,c7,c10,5 ; CP15DMB operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1010	101

G5.1.25 CP15DSB, CP15 Data Synchronization Barrier operation

The CP15DSB characteristics are:

Purpose

Performs a Data Synchronization Barrier.

This register is part of the Legacy feature registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
WO	WO	WO	WO	WO	WO	WO

If SCTLR.CP15BEN is set to 0, this operation is disabled and its encoding is UNDEFINED.

ARM deprecates any use of this operation, and strongly recommends that software use the DSB instruction instead.

Configurations

There are no configuration notes.

Attributes

CP15DSB is a 32-bit system operation.

Field descriptions

The CP15DSB operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the CP15DSB operation

To perform the CP15DSB operation:

```
MCR p15,0,<Rt>,c7,c10,4 ; CP15DSB operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1010	100

G5.1.26 CP15ISB, CP15 Instruction Synchronization Barrier operation

The CP15ISB characteristics are:

Purpose

Performs an Instruction Synchronization Barrier.

This register is part of the Legacy feature registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
WO	WO	WO	WO	WO	WO	WO

If SCTLR.CP15BEN is set to 0, this operation is disabled and its encoding is UNDEFINED.

ARM deprecates any use of this operation, and strongly recommends that software use the ISB instruction instead.

Configurations

There are no configuration notes.

Attributes

CP15ISB is a 32-bit system operation.

Field descriptions

The CP15ISB operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the CP15ISB operation

To perform the CP15ISB operation:

```
MCR p15,0,<Rt>,c7,c5,4 ; CP15ISB operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0101	100

G5.1.27 CPACR, Architectural Feature Access Control Register

The CPACR characteristics are:

Purpose

Controls access to Trace, Floating-point, and Advanced SIMD functionality.

This register is part of the Other system control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In an implementation that includes EL2, the CPACR has no effect on instructions executed at EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

CPACR is architecturally mapped to AArch64 register CPACR_EL1.

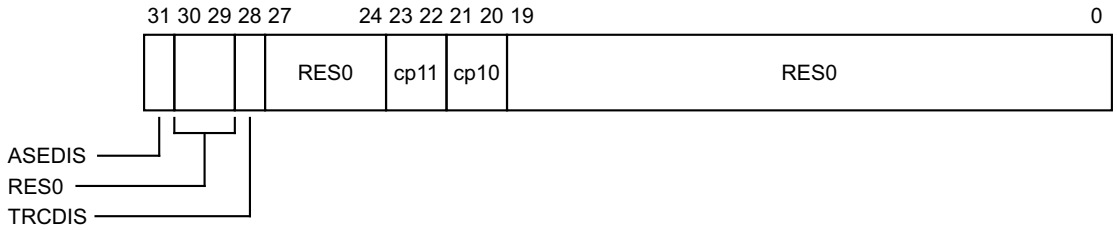
Bits in the NSACR control Non-secure access to the CPACR fields. See the field descriptions for more information.

Attributes

CPACR is a 32-bit register.

Field descriptions

The CPACR bit assignments are:



ASEDIS, bit [31]

Disable Advanced SIMD functionality:

`0` Does not cause any instructions to be UNDEFINED.

`1` All instruction encodings that are part of Advanced SIMD, but that are not VFPv3 or VFPv4 instructions, are UNDEFINED.

In Non-secure state, if EL3 is implemented and using AArch32 state and NSACR.NSASEDIS is set to 1, this bit is RAO/WI.

Resets to 0.

Bits [30:29]

Reserved, RES0.

TRCDIS, bit [28]

Disable CP14 access to trace registers:

0 Does not cause any instructions to be UNDEFINED.

1 Any MRC or MCR instruction with coproc set to 0b1110 and opc1 set to 0b001 is UNDEFINED.

In Non-secure state, if EL3 is implemented and using AArch32 state and NSACR.NSTRCDIS is set to 1, this bit is RAO/WI.

Reset value is architecturally UNKNOWN.

Bits [27:24]

Reserved, RES0.

cp<n>, bits [2n+1:2n], for 2n+1:2n = 10 to 11

Defines the access rights for coprocessors 10 and 11, which control the Floating-point and Advanced SIMD features. Possible values of the fields are:

00 Access denied. Any attempt to access Floating-point and Advanced SIMD registers or instructions generates an Undefined Instruction exception.

01 Access at EL1 only. Any attempt to access Floating-point and Advanced SIMD registers or instructions from software executing at EL0 generates an Undefined Instruction exception.

11 Full access.

The value 10 is reserved.

In Non-secure state, if NSACR.cp<n> is set to 0, this bit is RES0.

The Floating-point and Advanced SIMD features controlled by these fields are:

- VFP floating-point instructions.
- Advanced SIMD instructions (both integer and floating-point).
- Advanced SIMD and Floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- FPSCR, FPSID, MVFR0, MVFR1, MVFR2, FPEXC system registers.

If the cp11 and cp10 fields are set to different values, the behavior is CONSTRAINED UNPREDICTABLE, and is the same as if both fields were set to the value of cp10, in all respects other than the value read back by explicitly reading cp11.

Other coprocessors are not supported in ARMv8, so bits[27:24] and bits[19:0] are RES0.

Resets to 0.

Bits [19:0]

Reserved, RES0.

Accessing the CPACR

To access the CPACR:

```
MRC p15,0,<Rt>,c1,c0,2 ; Read CPACR into Rt
MCR p15,0,<Rt>,c1,c0,2 ; Write Rt to CPACR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0000	010

G5.1.28 CPSR, Current Program Status Register

The CPSR characteristics are:

Purpose

Holds processor status and control information.

This register is part of the Process state registers functional group.

Usage constraints

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

The CPSR can be read using the MRS instruction and written using the MSR (immediate) or MSR (register) instructions. For more details on the instruction syntax, see .

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

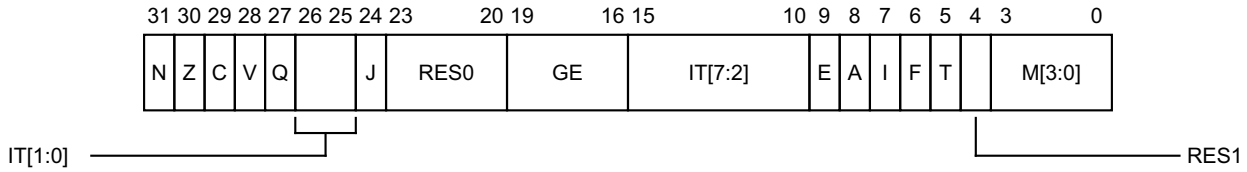
There are no configuration notes.

Attributes

CPSR is a 32-bit register.

Field descriptions

The CPSR bit assignments are:



N, bit [31]

Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then the processor sets N to 1 if the result was negative, and sets N to 0 if it was positive or zero.

Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:20]

Reserved, RES0.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Indicates the AArch32 instruction set state. Possible values of this bit are:

`0` A32 state.

`1` T32 state.

Bit [4]

Reserved, RES1.

M[3:0], bits [3:0]

Current processor mode. Possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0110`	Monitor
`0b0111`	Abort
`0b1010`	Hyp
`0b1011`	Undefined
`0b1111`	System

Other values are reserved.

G5.1.29 CSSELR, Cache Size Selection Register

The CSSELR characteristics are:

Purpose

Selects the current Cache Size ID Register, CCSIDR, by specifying the required cache level and the cache type (either instruction or data cache).

Note

The data cache argument must be used for a unified cache.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as CSSELR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as CSSELR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

If the CSSELR level field is programmed to a cache level that is not implemented, then a read of CSSELR is CONSTRAINED UNPREDICTABLE, and returns an UNKNOWN value in CSSELR.Level.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

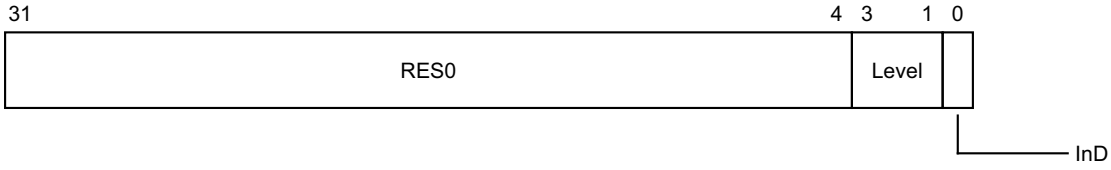
CSSELR(NS) is architecturally mapped to AArch64 register CSSELR_EL1.

Attributes

CSSELR is a 32-bit register.

Field descriptions

The CSSELR bit assignments are:



Bits [31:4]

Reserved, RES0.

Level, bits [3:1]

Cache level of required cache. Permitted values are from `0b000`, indicating Level 1 cache, to `0b110` indicating Level 7 cache.

InD, bit [0]

Instruction not Data bit. Permitted values are:

`0` Data or unified cache.

`1` Instruction cache.

Accessing the CSSELR

To access the CSSELR:

```
MRC p15,2,<Rt>,c0,c0,0 ; Read CSSELR into Rt
MCR p15,2,<Rt>,c0,c0,0 ; Write Rt to CSSELR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	010	0000	0000	000

G5.1.30 CTR, Cache Type Register

The CTR characteristics are:

Purpose

Provides information about the architecture of the caches.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

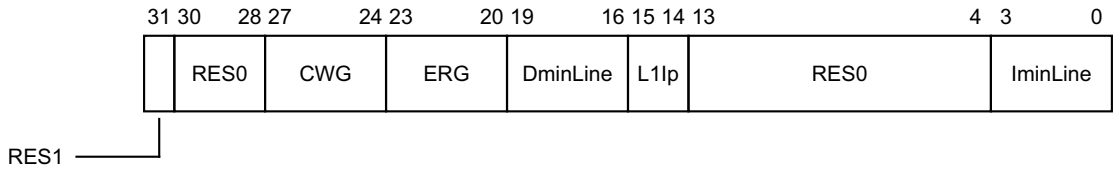
CTR is architecturally mapped to AArch64 register CTR_EL0.

Attributes

CTR is a 32-bit register.

Field descriptions

The CTR bit assignments are:



Bit [31]

Reserved, RES1.

Bits [30:28]

Reserved, RES0.

CWG, bits [27:24]

Cache Writeback Granule. Log_2 of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

A value of `0b0000` indicates that this register does not provide Cache Writeback Granule information and either:

- The architectural maximum of 512 words (2Kbytes) must be assumed.
- The Cache Writeback Granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than `0b1001` are reserved.

ERG, bits [23:20]

Exclusives Reservation Granule. Log_2 of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

A value of 0b0000 indicates that this register does not provide Exclusives Reservation Granule information and the architectural maximum of 512 words (2Kbytes) must be assumed.

Values greater than 0b1001 are reserved.

DminLine, bits [19:16]

Log_2 of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the processor.

L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:

01 ASID-tagged Virtual Index, Virtual Tag (AIVIVT)

10 Virtual Index, Physical Tag (VIPT)

11 Physical Index, Physical Tag (PIPT)

Other values are reserved.

Bits [13:4]

Reserved, RES0.

IminLine, bits [3:0]

Log_2 of the number of words in the smallest cache line of all the instruction caches that are controlled by the processor.

Accessing the CTR

To access the CTR:

```
MRC p15,0,<Rt>,c0,c0,1 ; Read CTR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0000	001

G5.1.31 DACR, Domain Access Control Register

The DACR characteristics are:

Purpose

Defines the access permission for each of the sixteen memory domains.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as DACR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as DACR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

DACR(NS) is architecturally mapped to AArch64 register DACR32_EL2.

DACR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

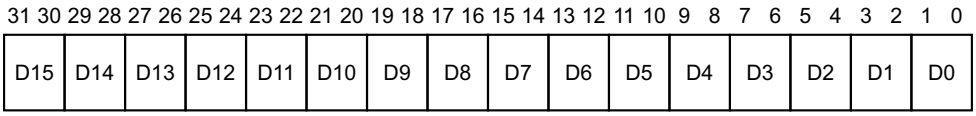
In an implementation that includes the Large Physical Address Extension, this register has no function when TTBCR.EAE is set to 1, to select the Long-descriptor translation table format.

Attributes

DACR is a 32-bit register.

Field descriptions

The DACR bit assignments are:



D<n>, bits [2n+1:2n], for 2n+1:2n = 0 to 15

Domain n access permission, where n = 0 to 15. Permitted values are:

`00` No access. Any access to the domain generates a Domain fault.

`01` Client. Accesses are checked against the permission bits in the translation tables.

`11` Manager. Accesses are not checked against the permission bits in the translation tables.

The value `10` is reserved.

Accessing the DACR

To access the DACR:

```
MRC p15,0,<Rt>,c3,c0,0 ; Read DACR into Rt
MCR p15,0,<Rt>,c3,c0,0 ; Write Rt to DACR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0011	0000	000

G5.1.32 DCCIMVAC, Data Cache line Clean and Invalidate by VA to PoC

The DCCIMVAC characteristics are:

Purpose

Clean and Invalidate data or unified cache line by virtual address to PoC.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

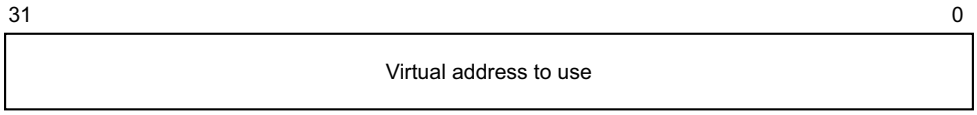
DCCIMVAC performs the same function as AArch64 operation DC CIVAC.

Attributes

DCCIMVAC is a 32-bit system operation.

Field descriptions

The DCCIMVAC input value bit assignments are:



Bits [31:0]

Virtual address to use.

Performing the DCCIMVAC operation

To perform the DCCIMVAC operation:

```
MCR p15,0,<Rt>,c7,c14,1 ; DCCIMVAC operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1110	001

G5.1.33 DCCISW, Data Cache line Clean and Invalidate by Set/Way

The DCCISW characteristics are:

Purpose

Clean and Invalidate data or unified cache line by set/way.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

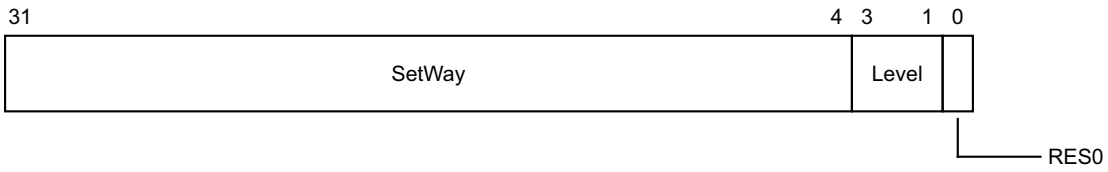
DCCISW performs the same function as AArch64 operation DC CISW.

Attributes

DCCISW is a 32-bit system operation.

Field descriptions

The DCCISW input value bit assignments are:



SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log_2(ASSOCIATIVITY), L = Log_2(LINELEN), B = (L + S), S = Log_2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Performing the DCCISW operation

To perform the DCCISW operation:

```
MCR p15,0,<Rt>,c7,c14,2 ; DCCISW operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1110	010

G5.1.34 DCCMVAC, Data Cache line Clean by VA to PoC

The DCCMVAC characteristics are:

Purpose

Clean data or unified cache line by virtual address to PoC.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

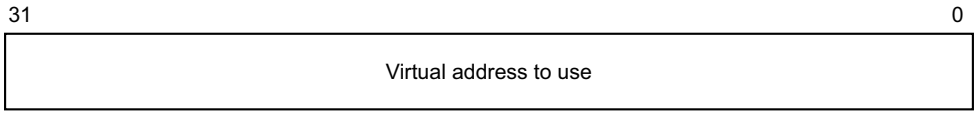
DCCMVAC performs the same function as AArch64 operation DC CVAC.

Attributes

DCCMVAC is a 32-bit system operation.

Field descriptions

The DCCMVAC input value bit assignments are:



Bits [31:0]

Virtual address to use.

Performing the DCCMVAC operation

To perform the DCCMVAC operation:

```
MCR p15,0,<Rt>,c7,c10,1 ; DCCMVAC operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1010	001

G5.1.35 DCCMVAU, Data Cache line Clean by VA to PoU

The DCCMVAU characteristics are:

Purpose

Clean data or unified cache line by virtual address to PoU.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

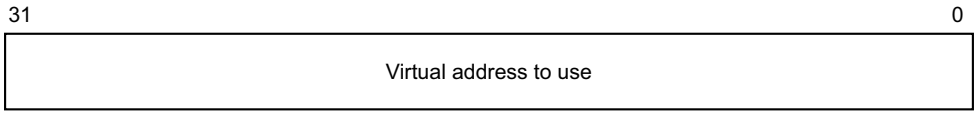
DCCMVAU performs the same function as AArch64 operation DC CVAU.

Attributes

DCCMVAU is a 32-bit system operation.

Field descriptions

The DCCMVAU input value bit assignments are:



Bits [31:0]

Virtual address to use.

Performing the DCCMVAU operation

To perform the DCCMVAU operation:

```
MCR p15,0,<Rt>,c7,c11,1 ; DCCMVAU operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1011	001

G5.1.36 DCCSW, Data Cache line Clean by Set/Way

The DCCSW characteristics are:

Purpose

Clean data or unified cache line by set/way.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

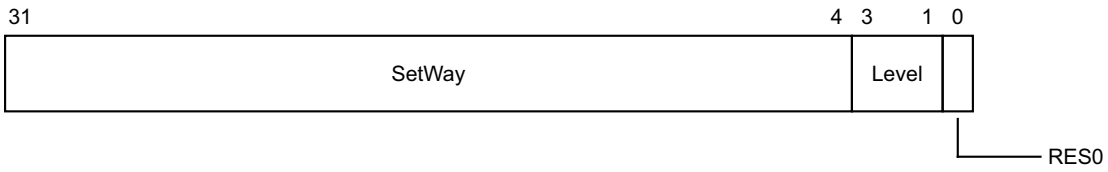
DCCSW performs the same function as AArch64 operation DC CSW.

Attributes

DCCSW is a 32-bit system operation.

Field descriptions

The DCCSW input value bit assignments are:



SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log_2(ASSOCIATIVITY), L = Log_2(LINELEN), B = (L + S), S = Log_2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Performing the DCCSW operation

To perform the DCCSW operation:

```
MCR p15,0,<Rt>,c7,c10,2 ; DCCSW operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	1010	010

G5.1.37 DCIMVAC, Data Cache line Invalidate by VA to PoC

The DCIMVAC characteristics are:

Purpose

Invalidate data or unified cache line by virtual address to PoC.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

At EL1, this operation must be performed as DCCIMVAC if all of the following apply:

- EL2 is implemented.
- HCR.VM is set to 1.
- SCR.NS is set to 1 or EL3 is not implemented.

Configurations

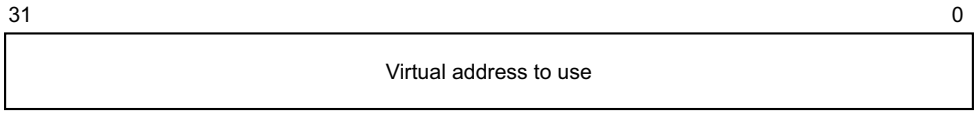
DCIMVAC performs the same function as AArch64 operation DC IVAC.

Attributes

DCIMVAC is a 32-bit system operation.

Field descriptions

The DCIMVAC input value bit assignments are:



Bits [31:0]

Virtual address to use.

Performing the DCIMVAC operation

To perform the DCIMVAC operation:

```
MCR p15,0,<Rt>,c7,c6,1 ; DCIMVAC operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0110	001

G5.1.38 DCISW, Data Cache line Invalidate by Set/Way

The DCISW characteristics are:

Purpose

Invalidate data or unified cache line by set/way.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

At EL1, this operation must be performed as DCCISW if all of the following apply:

- EL2 is implemented
- HCR.VM is set to 1
- SCR.NS is set to 1 or EL3 is not implemented.

Configurations

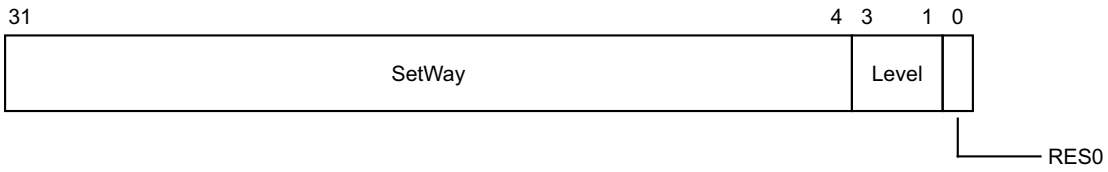
DCISW performs the same function as AArch64 operation DC ISW.

Attributes

DCISW is a 32-bit system operation.

Field descriptions

The DCISW input value bit assignments are:



SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log_2(ASSOCIATIVITY), L = Log_2(LINELEN), B = (L + S), S = Log_2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Performing the DCISW operation

To perform the DCISW operation:

```
MCR p15,0,<Rt>,c7,c6,2 ; DCISW operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0110	010

G5.1.39 DFAR, Data Fault Address Register

The DFAR characteristics are:

Purpose

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as DFAR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as DFAR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

DFAR(NS) is architecturally mapped to AArch64 register FAR_EL1[31:0].

DFAR(S) is architecturally mapped to AArch32 register HDFAR when EL2 is implemented.

DFAR(S) is architecturally mapped to AArch64 register FAR_EL2[31:0] when EL2 is implemented.

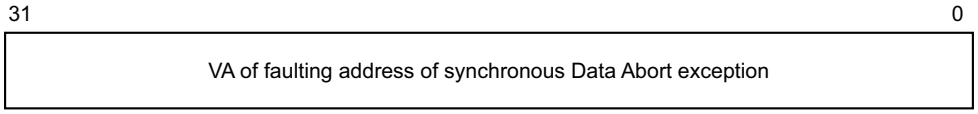
DFAR(S) can be mapped to AArch64 register FAR_EL3[31:0] when EL2 is not implemented, but this is not architecturally mandated.

Attributes

DFAR is a 32-bit register.

Field descriptions

The DFAR bit assignments are:



Bits [31:0]

VA of faulting address of synchronous Data Abort exception.

Accessing the DFAR

To access the DFAR:

```
MRC p15,0,<Rt>,c6,c0,0 ; Read DFAR into Rt
MCR p15,0,<Rt>,c6,c0,0 ; Write Rt to DFAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0110	0000	000

G5.1.40 DFSR, Data Fault Status Register

The DFSR characteristics are:

Purpose

Holds status information about the last data fault.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as DFSR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as DFSR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

DFSR(NS) is architecturally mapped to AArch64 register ESR_EL1.

DFSR(S) can be mapped to AArch64 register ESR_EL3, but this is not architecturally mandated.

The Large Physical Address Extension adds an alternative format for the register. If an implementation includes the Large Physical Address Extension then the current translation table format determines which format of the register is used.

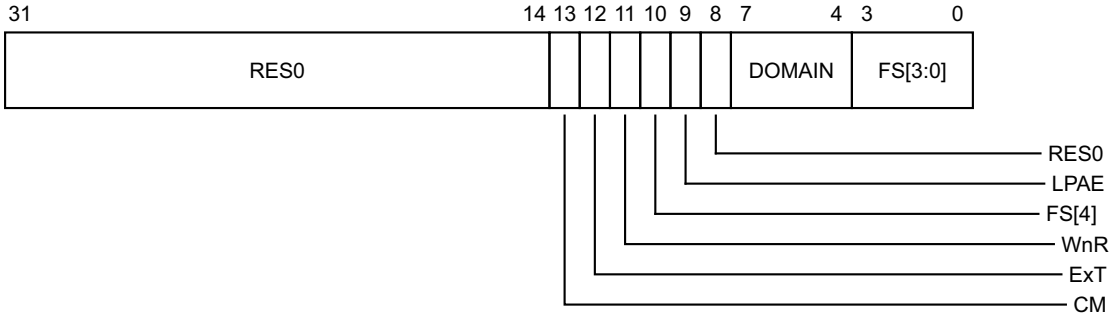
Attributes

DFSR is a 32-bit register.

Field descriptions

The DFSR bit assignments are:

When TTBCR.EAE==0:



Bits [31:14]

Reserved, RES0.

CM, bit [13]

Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance operation generated the fault. The possible values of this bit are:

0 Abort not caused by a cache maintenance operation.

1 Abort caused by a cache maintenance operation.

On an asynchronous fault, this bit is UNKNOWN.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

For aborts other than external aborts this bit always returns 0.

WnR, bit [11]

Write not Read bit. Indicates whether the abort was caused by a write or read access. The possible values of this bit are:

0 Abort caused by a read access.

1 Abort caused by a write access.

For faults on CP15 cache maintenance instructions, including the VA to PA translation instructions, this bit always returns a value of 1.

FS[4], bit [10]

See below for description of the FS field.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

0 Using the Short-descriptor translation table formats.

1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bit [8]

Reserved, RES0.

DOMAIN, bits [7:4]

Domain of the fault address. Use of this field is deprecated.

FS[3:0], bits [3:0]

Fault status bits. Interpreted with bit[10]. Possible values of the FS[4:0] field are:

00001 Alignment fault

00010 Debug event

00011 Access flag fault, first level

00100 Fault on instruction cache maintenance

00101 Translation fault, first level

00110 Access flag fault, second level

00111 Translation fault, second level

01000 Synchronous external abort

01001 Domain fault, first level

01011 Domain fault, second level

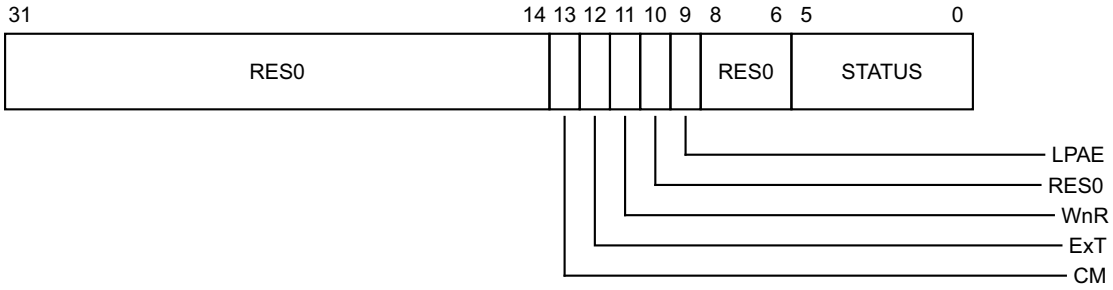
01100 Synchronous external abort on translation table walk, first level

01101 Permission fault, first level

01110	Synchronous external abort on translation table walk, second level
01111	Permission fault, second level
10000	TLB conflict abort
10100	IMPLEMENTATION DEFINED fault (Lockdown fault)
10101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
10110	Asynchronous external abort
11000	Asynchronous parity error on memory access
11001	Synchronous parity error on memory access
11100	Synchronous parity error on translation table walk, first level
11110	Synchronous parity error on translation table walk, second level

All other values are reserved.

When TTBCR.EAE==1:



Bits [31:14]

Reserved, RES0.

CM, bit [13]

Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance operation generated the fault. The possible values of this bit are:

0	Abort not caused by a cache maintenance operation.
1	Abort caused by a cache maintenance operation.

On an asynchronous fault, this bit is UNKNOWN.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

For aborts other than external aborts this bit always returns 0.

WnR, bit [11]

Write not Read bit. Indicates whether the abort was caused by a write or read access. The possible values of this bit are:

0	Abort caused by a read access.
1	Abort caused by a write access.

For faults on CP15 cache maintenance instructions, including the VA to PA translation instructions, this bit always returns a value of 1.

Bit [10]

Reserved, RES0.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

`0` Using the Short-descriptor translation table formats.

`1` Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:6]

Reserved, RES0.

STATUS, bits [5:0]

Fault status bits. Possible values of this field are:

`000000` Address size fault in TTBR0 or TTBR1

`000001` Address size fault, first level

`000010` Address size fault, second level

`000011` Address size fault, third level

`000101` Translation fault, first level

`000110` Translation fault, second level

`000111` Translation fault, third level

`001001` Access flag fault, first level

`001010` Access flag fault, second level

`001011` Access flag fault, third level

`001101` Permission fault, first level

`001110` Permission fault, second level

`001111` Permission fault, third level

`010000` Synchronous external abort

`010001` Asynchronous external abort

`010101` Synchronous external abort on translation table walk, first level

`010110` Synchronous external abort on translation table walk, second level

`010111` Synchronous external abort on translation table walk, third level

`011000` Synchronous parity error on memory access

`011001` Asynchronous parity error on memory access

`011101` Synchronous parity error on memory access on translation table walk, first level

`011110` Synchronous parity error on memory access on translation table walk, second level

`011111` Synchronous parity error on memory access on translation table walk, third level

`100001` Alignment fault

`100010` Debug event

`110000` TLB conflict abort

`110100` IMPLEMENTATION DEFINED fault (Lockdown fault)

`110101` IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.

- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because an MMU is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a First level fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Accessing the DFSR

To access the DFSR:

```
MRC p15,0,<Rt>,c5,c0,0 ; Read DFSR into Rt
MCR p15,0,<Rt>,c5,c0,0 ; Write Rt to DFSR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0101	0000	000

G5.1.41 DTLBIALL, Data TLB Invalidate All

The DTLBIALL characteristics are:

Purpose

Invalidate all PL1&0 regime stage 1 and 2 data TLB entries for the current VMID and the current security state.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

There are no configuration notes.

Attributes

DTLBIALL is a 32-bit system operation.

Field descriptions

The DTLBIALL operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the DTLBIALL operation

To perform the DTLBIALL operation:

```
MCR p15,0,<Rt>,c8,c6,0 ; DTLBIALL operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0110	000

G5.1.42 DTLBIASID, Data TLB Invalidate by ASID match

The DTLBIASID characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 data TLB entries for the given ASID, the current VMID, and the current security state.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

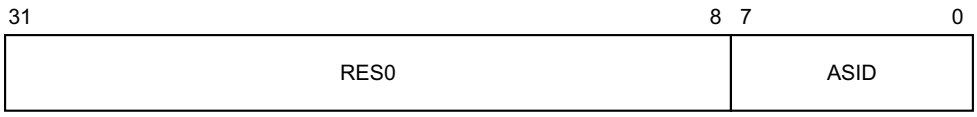
There are no configuration notes.

Attributes

DTLBIASID is a 32-bit system operation.

Field descriptions

The DTLBIASID input value bit assignments are:



Bits [31:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

Performing the DTLBIASID operation

To perform the DTLBIASID operation:

```
MCR p15,0,<Rt>,c8,c6,2 ; DTLBIASID operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0110	010

G5.1.43 DTLBIMVA, Data TLB Invalidate by VA

The DTLBIMVA characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 and 2 data TLB entries for the given VA and ASID, the current VMID, and the current security state.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

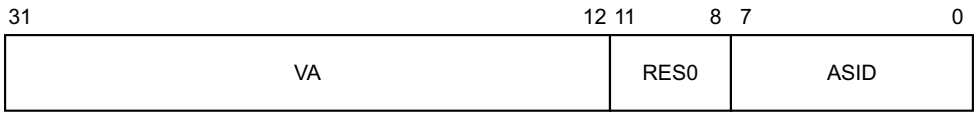
There are no configuration notes.

Attributes

DTLBIMVA is a 32-bit system operation.

Field descriptions

The DTLBIMVA input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Performing the DTLBIMVA operation

To perform the DTLBIMVA operation:

```
MCR p15,0,<Rt>,c8,c6,1 ; DTLBIMVA operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0110	001

G5.1.44 ELR_hyp, Exception Link Register (Hyp mode)

The ELR_hyp characteristics are:

Purpose

When taking an exception to Hyp mode, holds the address to return to.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	RW

Configurations

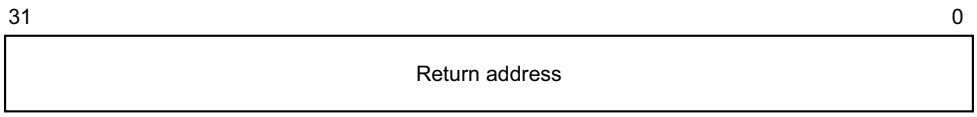
ELR_hyp is architecturally mapped to AArch64 register ELR_EL2.

Attributes

ELR_hyp is a 32-bit register.

Field descriptions

The ELR_hyp bit assignments are:



Bits [31:0]

Return address.

Accessing the ELR_hyp

To access the ELR_hyp:

```
MRS <Rd>, ELR_hyp ; Read ELR_hyp into Rd
MSR ELR_hyp, <Rd> ; Write Rd to ELR_hyp
```

Register access is encoded as follows:

m	m1	R
1	1110	0

G5.1.45 FCSEIDR, FCSE Process ID register

The FCSEIDR characteristics are:

Purpose

Identifies whether the Fast Context Switch Extension (FCSE) is implemented, and if it is, also identifies the current Process ID for the FCSE.

This register is part of the Legacy feature registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as FCSEIDR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as FCSEIDR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

In ARMv8, the FCSE is not implemented, so this register is RAZ/WI. Software can access this register to determine that the implementation does not include the FCSE.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

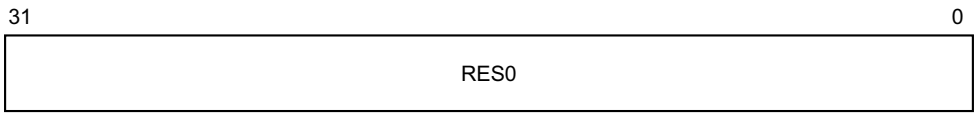
There are no configuration notes.

Attributes

FCSEIDR is a 32-bit register.

Field descriptions

The FCSEIDR bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the FCSEIDR

To access the FCSEIDR:

```
MRC p15,0,<Rt>,c13,c0,0 ; Read FCSEIDR into Rt
MCR p15,0,<Rt>,c13,c0,0 ; Write Rt to FCSEIDR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1101	0000	000

G5.1.46 FPEXC, Floating-Point Exception Control register

The FPEXC characteristics are:

Purpose

Provides a global enable for the Advanced SIMD and Floating-point operations, and indicates how the state of these is recorded.

This register is part of the Floating-point registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	Config-RW	RW	Config-RW	Config-RW	RW

Access to this register depends on the values of CPACR.{cp10,cp11}, NSACR.{cp10,cp11}, and HCPTR.{TCP10,TCP11}.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

FPEXC is architecturally mapped to AArch64 register FPEXC32_EL2.

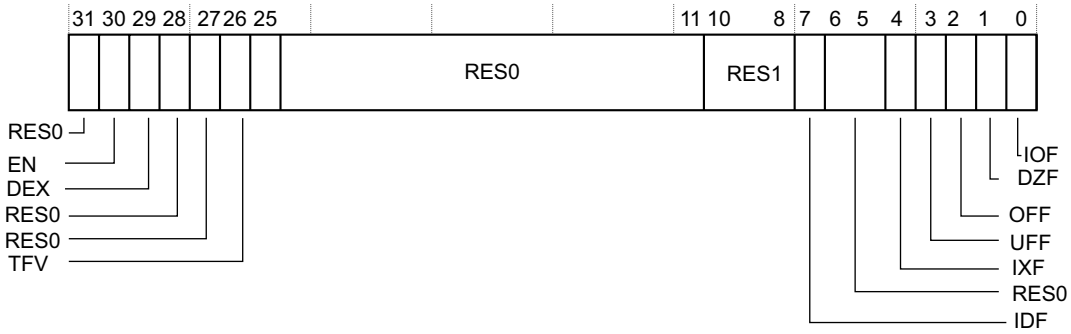
Implemented only if the implementation supports the Advanced SIMD and floating-point instructions.

Attributes

FPEXC is a 32-bit register.

Field descriptions

The FPEXC bit assignments are:



Bit [31]

Reserved, RES0

EN, bit [30]

Enable bit. A global enable for the Advanced SIMD and floating-point functionality:

0 The Advanced SIMD and floating-point functionality is disabled.

1 The Advanced SIMD and floating-point functionality is enabled and operates normally.

When executing in EL0 using AArch32 with EL1 using AArch64, the behavior is as if the FPEXC.EN bit is set to 1.

Resets to 0.

DEX, bit [29]

Defined synchronous instruction exception bit.

When a floating-point synchronous exception has occurred, if the exception was caused by an allocated floating-point instruction that is not implemented in hardware then it is IMPLEMENTATION DEFINED whether DEX is set to 0 or 1.

Otherwise, the meaning of this bit is:

`0` A synchronous exception occurred when processing an unallocated floating-point or Advanced SIMD instruction.

`1` A synchronous exception occurred on an allocated floating-point instruction that encountered an exceptional condition.

The exception-handling routine must clear DEX to 0.

In an implementation that does not require synchronous exception handling this bit is RES0.

Reset value is architecturally UNKNOWN.

Bit [28]

Reserved, RES0.

Bit [27]

Reserved, RES0.

TFV, bit [26]

Trapped Fault Valid bit. Indicates whether FPEXC bits[7, 4:0] indicate trapped exceptions:

`0` FPEXC bits[7, 4:0] are RES0.

`1` FPEXC bits[7, 4:0] indicate the presence of trapped exceptions that have occurred at the time of the exception. All trapped exceptions that occurred at the time of the exception have their bits set.

This bit has a fixed value and ignores writes.

Bits [25:11]

Reserved, RES0.

Bits [10:8]

Reserved, RES1.

IDF, bit [7]

Input Denormal trapped exception bit.

If FPEXC.TFV is 0, this bit is RES0.

If FPEXC.TFV is 1, this bit is the Input Denormal trapped exception bit, and indicates whether an Input Denormal exception occurred while FPSCR.IDE was 1:

`0` Input denormal exception has not occurred.

`1` Input denormal exception has occurred.

Input Denormal exceptions can occur only when FPSCR.FZ is 1.

This bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

Bits [6:5]

Reserved, RES0

IXF, bit [4]

Inexact trapped exception bit, or IMPLEMENTATION DEFINED.

If FPEXC.TFV is 0, this bit is RES0.

If FPEXC.TFV is 1, this bit is the Inexact trapped exception bit, and indicates whether an Inexact exception occurred while FPSCR.IXE was 1:

In this case, the meaning of this bit is:

0 Inexact exception has not occurred.

1 Inexact exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

UFF, bit [3]

Underflow trapped exception bit.

If FPEXC.TFV is 0, this bit is RES0.

If FPEXC.TFV is 1, this bit is the Underflow trapped exception bit, and indicates whether an Underflow exception occurred while FPSCR.UFE was 1:

0 Underflow exception has not occurred.

1 Underflow exception has occurred.

Underflow trapped exceptions can occur only when FPSCR.FZ is 0.

This bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

OFF, bit [2]

Overflow trapped exception bit.

If FPEXC.TFV is 0, this bit RES0.

If FPEXC.TFV is 1, this bit is the Overflow trapped exception bit, and indicates whether an Overflow exception occurred while FPSCR.OFE was 1:

0 Overflow exception has not occurred.

1 Overflow exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

DZF, bit [1]

Divide-by-zero trapped exception bit.

If FPEXC.TFV is 0, this bit is RES0.

If FPEXC.TFV is 1, this bit is the Divide-by-zero trapped exception bit, and indicates whether a Divide-by-zero exception occurred while FPSCR.DZE was 1:

0 Divide-by-zero exception has not occurred.

1 Divide-by-zero exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

IOF, bit [0]

Invalid Operation trapped exception bit.

If FPEXC.TFV is 0, this bit is RES0.

If FPEXC.TFV is 1, this bit is the Invalid Operation trapped exception bit, and indicates whether an Invalid Operation exception occurred while FPSCR.IOE was 1:

0 Invalid Operation exception has not occurred.

1 Invalid Operation exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

Reset value is architecturally UNKNOWN.

Accessing the FPEXC

To access the FPEXC:

```
VMRS <Rt>, FPEXC ; Read FPEXC into Rt
VMSR FPEXC, <Rt> ; Write Rt to FPEXC
```

Register access is encoded as follows:

spec_reg
1000

G5.1.47 FPSCR, Floating-Point Status and Control Register

The FPSCR characteristics are:

Purpose

Provides floating-point system status information and control.

This register is part of:

- the Special purpose registers functional group
- the Floating-point registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	Config-RW	RW	Config-RW	Config-RW	RW

Access to this register depends on the values of CPACR.{cp10,cp11}, NSACR.{cp10,cp11}, HCPTR.{TCP10,TCP11}, and FPEXC.EN.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

The named fields in this register map to the equivalent fields in the AArch64 FPCR and FPSR.

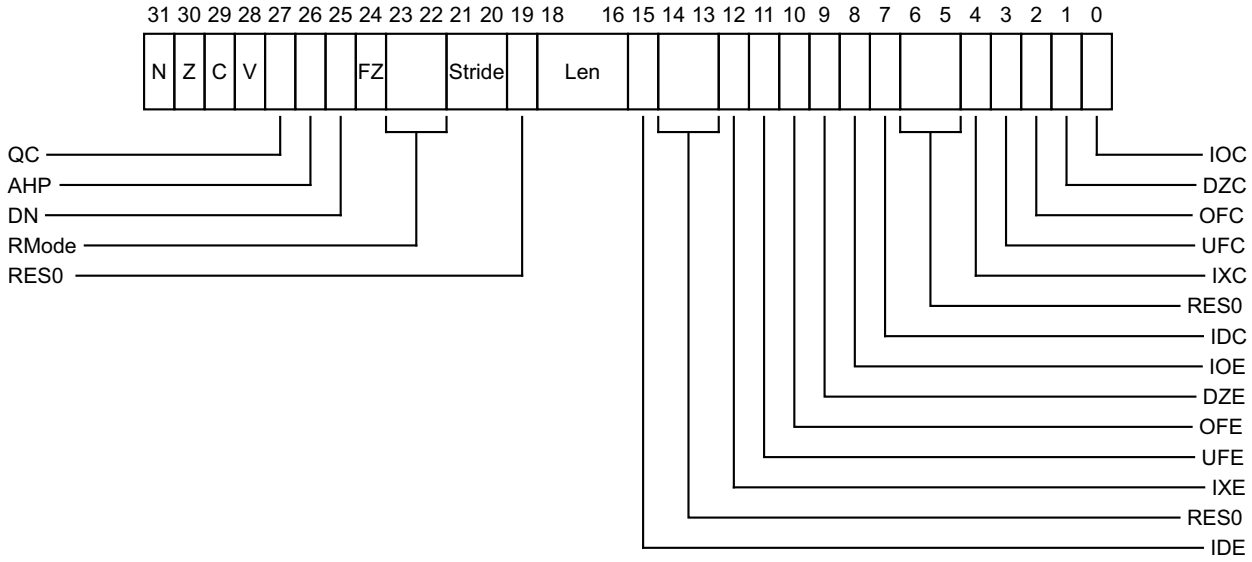
It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.

Attributes

FPSCR is a 32-bit register.

Field descriptions

The FPSCR bit assignments are:



N, bit [31]

Negative condition flag. This is updated by floating-point comparison operations.

Z, bit [30]

Zero condition flag. This is updated by floating-point comparison operations.

C, bit [29]

Carry condition flag. This is updated by floating-point comparison operations.

V, bit [28]

Overflow condition flag. This is updated by floating-point comparison operations.

QC, bit [27]

Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.

AHP, bit [26]

Alternative half-precision control bit:

0 IEEE half-precision format selected.

1 Alternative half-precision format selected.

DN, bit [25]

Default NaN mode control bit:

0 NaN operands propagate through to the output of a floating-point operation.

1 Any operation involving one or more NaNs returns the Default NaN.

The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Default NaN setting, regardless of the value of the DN bit.

FZ, bit [24]

Flush-to-zero mode control bit:

0 Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.

1 Flush-to-zero mode enabled.

The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Flush-to-zero setting, regardless of the value of the FZ bit.

RMode, bits [23:22]

Rounding Mode control field. The encoding of this field is:

00 Round to Nearest (RN) mode

01 Round towards Plus Infinity (RP) mode

10 Round towards Minus Infinity (RM) mode

11 Round towards Zero (RZ) mode.

The specified rounding mode is used by almost all scalar floating-point instructions. Advanced SIMD arithmetic always uses the Round to Nearest setting, regardless of the value of the RMode bits.

Stride, bits [21:20]

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.

ARM strongly recommends that software never sets this field to a value other than zero.

The value of this field is ignored when processing Advanced SIMD instructions.

Bit [19]

Reserved, RES0.

Len, bits [18:16]

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.

ARM strongly recommends that software never sets this field to a value other than zero.

The value of this field is ignored when processing Advanced SIMD instructions.

IDE, bit [15]

Input Denormal exception trap enable. Possible values are:

`0` Untrapped exception handling selected. If the floating-point exception occurs then the IDC bit is set to 1.

`1` Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IDC bit. The trap handling software can decide whether to set the IDC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

Bits [14:13]

Reserved, RES0.

IXE, bit [12]

Inexact exception trap enable. Possible values are:

`0` Untrapped exception handling selected. If the floating-point exception occurs then the IXC bit is set to 1.

`1` Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IXC bit. The trap handling software can decide whether to set the IXC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

UFE, bit [11]

Underflow exception trap enable. Possible values are:

`0` Untrapped exception handling selected. If the floating-point exception occurs then the UFC bit is set to 1.

`1` Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the UFC bit. The trap handling software can decide whether to set the UFC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

OFE, bit [10]

Overflow exception trap enable. Possible values are:

`0` Untrapped exception handling selected. If the floating-point exception occurs then the OFC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the OFC bit. The trap handling software can decide whether to set the OFC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

DZE, bit [9]

Division by Zero exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the DZC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the DZC bit. The trap handling software can decide whether to set the DZC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

IOE, bit [8]

Invalid Operation exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the IOC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IOC bit. The trap handling software can decide whether to set the IOC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

IDC, bit [7]

Input Denormal cumulative exception bit. This bit is set to 1 to indicate that the Input Denormal exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IDE bit.

Advanced SIMD instructions set this bit if the Input Denormal exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IDE bit.

Bits [6:5]

Reserved, RES0.

IXC, bit [4]

Inexact cumulative exception bit. This bit is set to 1 to indicate that the Inexact exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IXE bit.

Advanced SIMD instructions set this bit if the Inexact exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IXE bit.

UFC, bit [3]

Underflow cumulative exception bit. This bit is set to 1 to indicate that the Underflow exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the UFE bit.

Advanced SIMD instructions set this bit if the Underflow exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the UFE bit.

OFC, bit [2]

Overflow cumulative exception bit. This bit is set to 1 to indicate that the Overflow exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the OFE bit.

Advanced SIMD instructions set this bit if the Overflow exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the OFE bit.

DZC, bit [1]

Division by Zero cumulative exception bit. This bit is set to 1 to indicate that the Division by Zero exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the DZE bit.

Advanced SIMD instructions set this bit if the Division by Zero exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the DZE bit.

IOC, bit [0]

Invalid Operation cumulative exception bit. This bit is set to 1 to indicate that the Invalid Operation exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IOE bit.

Advanced SIMD instructions set this bit if the Invalid Operation exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IOE bit.

Accessing the FPSCR

To access the FPSCR:

```
VMRS <Rt>, FPSCR ; Read FPSCR into Rt
VMSR FPSCR, <Rt> ; Write Rt to FPSCR
```

Register access is encoded as follows:

spec_reg
0001

G5.1.48 FPSID, Floating-Point System ID register

The FPSID characteristics are:

Purpose

Provides top-level information about the floating-point implementation.

This register is part of:

- the Floating-point registers functional group
- the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	Config-RO	RO	Config-RO	Config-RO	RO

Access to this register depends on the values of CPACR.{cp10,cp11}, NSACR.{cp10,cp11}, and HCPTR.{TCP10,TCP11}.

This register largely duplicates information held in the MIDR. ARM deprecates use of FPSID.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

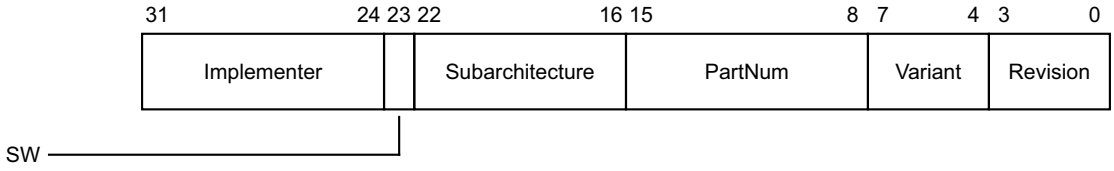
FPSID can be implemented in a system that provides only software emulation of the ARM floating-point instructions, and must be implemented if the implementation supports the Advanced SIMD and floating-point instructions.

Attributes

FPSID is a 32-bit register.

Field descriptions

The FPSID bit assignments are:



Implementer, bits [31:24]

Implementer codes are the same as those used for the MIDR.

For an implementation by ARM this field is `0x41`, the ASCII code for A.

SW, bit [23]

Software bit. This bit indicates whether a system provides only software emulation of the floating-point instructions that are provided:

`0` The system includes hardware support for the floating-point instructions.

`1` The system provides only software emulation of the floating-point instructions.

Subarchitecture, bits [22:16]

Subarchitecture version number. For an implementation by ARM, permitted values are:

`0000000` VFPv1 architecture with an IMPLEMENTATION DEFINED subarchitecture. Not permitted in an ARMv8 implementation.

`0000001` VFPv2 architecture with Common VFP subarchitecture v1. Not permitted in an ARMv8 implementation.

`0000010` VFPv3 architecture, or later, with Common VFP subarchitecture v2. Not permitted in an ARMv8 implementation.

`0000011` VFPv3 architecture, or later, with no subarchitecture, and no support for trap enable bits in FPSCR.

`0000100` VFPv3 architecture, or later, with Common VFP subarchitecture v3. and support for trap enable bits in FPSCR.

PartNum, bits [15:8]

An IMPLEMENTATION DEFINED part number for the floating-point implementation, assigned by the implementer.

Variant, bits [7:4]

An IMPLEMENTATION DEFINED variant number. Typically, this field distinguishes between different production variants of a single product.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the floating-point implementation.

Accessing the FPSID

To access the FPSID:

```
VMRS <Rt>, FPSID ; Read FPSID into Rt
```

G5.1.49 HACR, Hyp Auxiliary Configuration Register

The HACR characteristics are:

Purpose

Controls trapping to Hyp mode of IMPLEMENTATION DEFINED or IMPLEMENTATION SPECIFIC aspects of Non-secure EL1 or EL0 operation.

This register is part of the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

HACR is architecturally mapped to AArch64 register HACR_EL2.

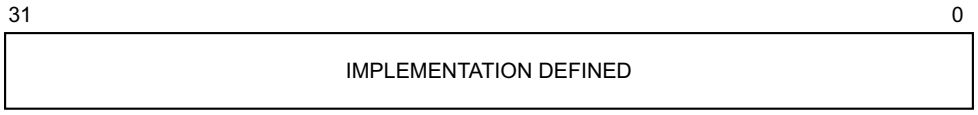
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HACR is a 32-bit register.

Field descriptions

The HACR bit assignments are:



Bits [31:0]

IMPLEMENTATION DEFINED

Accessing the HACR

To access the HACR:

```
MRC p15,4,<Rt>,c1,c1,7 ; Read HACR into Rt
MCR p15,4,<Rt>,c1,c1,7 ; Write Rt to HACR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0001	111

G5.1.50 HACTLR, Hyp Auxiliary Control Register

The HACTLR characteristics are:

Purpose

Controls IMPLEMENTATION DEFINED features of Hyp mode operation.

This register is part of:

- the Virtualization registers functional group
- the Other system control registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

HACTLR is architecturally mapped to AArch64 register ACTLR_EL2.

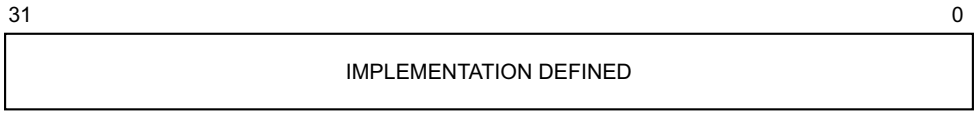
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HACTLR is a 32-bit register.

Field descriptions

The HACTLR bit assignments are:



Accessing the HACTLR

To access the HACTLR:

```
MRC p15,4,<Rt>,c1,c0,1 ; Read HACTLR into Rt
MCR p15,4,<Rt>,c1,c0,1 ; Write Rt to HACTLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0000	001

G5.1.51 HADFSR, Hyp Auxiliary Data Fault Status Register

The HADFSR characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED syndrome information for Data Abort exceptions taken to Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

HADFSR is architecturally mapped to AArch64 register AFSR0_EL2.

This is an optional register. An implementation that does not require this register can implement it as RES0.

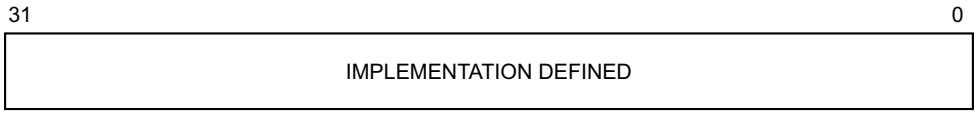
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HADFSR is a 32-bit register.

Field descriptions

The HADFSR bit assignments are:



Accessing the HADFSR

To access the HADFSR:

```
MRC p15,4,<Rt>,c5,c1,0 ; Read HADFSR into Rt
MCR p15,4,<Rt>,c5,c1,0 ; Write Rt to HADFSR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0101	0001	000

G5.1.52 HAIFSR, Hyp Auxiliary Instruction Fault Status Register

The HAIFSR characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED syndrome information for Prefetch Abort exceptions taken to Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

HAIFSR is architecturally mapped to AArch64 register AFSR1_EL2.

This is an optional register. An implementation that does not require this register can implement it as RES0.

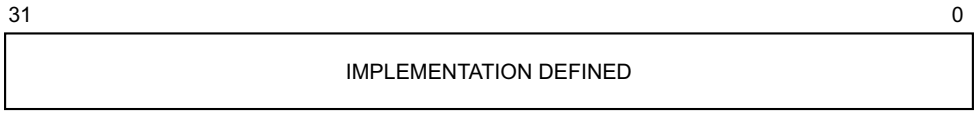
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HAIFSR is a 32-bit register.

Field descriptions

The HAIFSR bit assignments are:



Accessing the HAIFSR

To access the HAIFSR:

```
MRC p15,4,<Rt>,c5,c1,1 ; Read HAIFSR into Rt
MCR p15,4,<Rt>,c5,c1,1 ; Write Rt to HAIFSR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0101	0001	001

G5.1.53 HAMAIR0, Hyp Auxiliary Memory Attribute Indirection Register 0

The HAMAIR0 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory attribute encodings defined by HMAIR0. These IMPLEMENTATION DEFINED attributes can only provide additional qualifiers for the memory attribute encodings, and cannot change the memory attributes defined in HMAIR0.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0.

Configurations

HAMAIR0 is architecturally mapped to AArch64 register AMAIR_EL2[31:0].

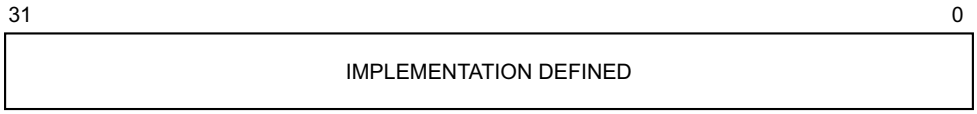
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HAMAIR0 is a 32-bit register.

Field descriptions

The HAMAIR0 bit assignments are:



Accessing the HAMAIR0

To access the HAMAIR0:

```
MRC p15,4,<Rt>,c10,c3,0 ; Read HAMAIR0 into Rt
MCR p15,4,<Rt>,c10,c3,0 ; Write Rt to HAMAIR0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1010	0011	000

G5.1.54 HAMAIR1, Hyp Auxiliary Memory Attribute Indirection Register 1

The HAMAIR1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory attribute encodings defined by HMAIR1. These IMPLEMENTATION DEFINED attributes can only provide additional qualifiers for the memory attribute encodings, and cannot change the memory attributes defined in HMAIR1.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0.

Configurations

HAMAIR1 is architecturally mapped to AArch64 register AMAIR_EL2[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HAMAIR1 is a 32-bit register.

Field descriptions

The HAMAIR1 bit assignments are:

Accessing the HAMAIR1

To access the HAMAIR1:

```
MRC p15,4,<Rt>,c10,c3,1 ; Read HAMAIR1 into Rt
MCR p15,4,<Rt>,c10,c3,1 ; Write Rt to HAMAIR1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1010	0011	001

G5.1.55 HCPTR, Hyp Architectural Feature Trap Register

The HCPTR characteristics are:

Purpose

Controls trapping to Hyp mode of Non-secure access, at EL1 or lower, to Trace, Floating Point, and Advanced SIMD functionality. Also controls access from Hyp mode to this functionality.

This register is part of the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

If a bit in the NSACR prohibits a Non-secure access, then the corresponding bit in the HCPTR behaves as RAO/WI for Non-secure accesses. See the bit descriptions for more information.

Configurations

HCPTR is architecturally mapped to AArch64 register CPTR_EL2.

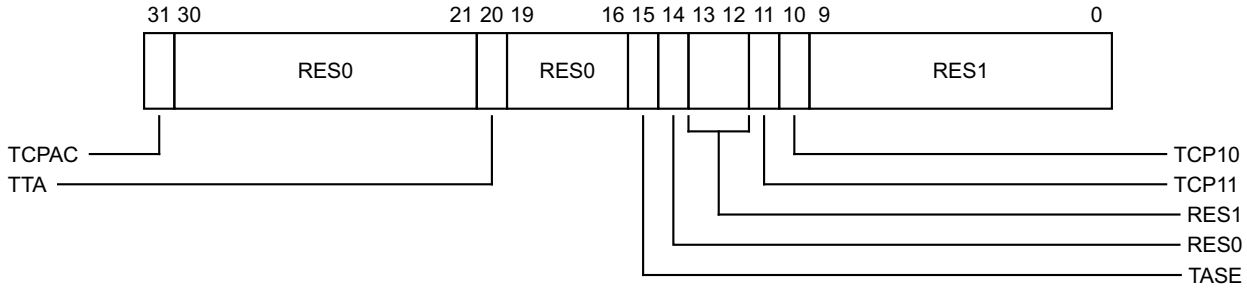
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HCPTR is a 32-bit register.

Field descriptions

The HCPTR bit assignments are:



TCPAC, bit [31]

Trap CPACR accesses. The possible values of this bit are:

`0` Has no effect on CPACR accesses.

`1` Trap valid Non-secure EL1 CPACR accesses to Hyp mode.

Resets to 0.

Bits [30:21]

Reserved, RES0.

TTA, bit [20]

Trap Trace Access. The possible values of this bit are:

`0` Has no effect on accesses to CP14 Trace registers.

1 Trap valid Non-secure EL0 and EL1 accesses to CP14 Trace registers to Hyp mode. Valid Hyp mode accesses to CP14 Trace registers generate an Undefined Instruction exception, taken in Hyp mode.

In an implementation that does not include Trace functionality, or does not include a CP14 interface to the Trace registers, it is IMPLEMENTATION DEFINED whether this bit:

- Is RAO/WI.
- Is RAZ/WI.
- Can be written from Hyp mode, and from Secure Monitor mode when SCR.NS is set to 1.

Resets to 0.

Bits [19:16]

Reserved, RES0.

TASE, bit [15]

Trap Advanced SIMD Extension use. The possible values of this bit are:

0 If the NSACR settings permit Non-secure use of the Advanced SIMD functionality then Hyp mode can access that functionality, regardless of any settings in the CPACR. This bit value has no effect on the possible use of the Advanced SIMD functionality from Non-secure EL1 and EL0 modes.

1 Trap valid Non-secure accesses to Advanced SIMD functionality to Hyp mode. Valid Hyp mode accesses to Advanced SIMD functionality generate an Undefined Instruction exception, taken in Hyp mode.

Resets to 0.

Bit [14]

Reserved, RES0.

Bits [13:12]

Reserved, RES1.

TCP<n>, bit [n], for n = 10 to 11

Trap coprocessor n (CP<n>). The possible values of each of these bits are:

0 If NSACR.cp<n> is set to 1, then Hyp mode can access CP<n>, regardless of the value of CPACR.cp<n>. This bit value has no effect on possible use of CP<n> from Non-secure EL1 and EL0 modes.

1 Trap valid Non-secure accesses to CP<n> to Hyp mode.

When TCP<n> is set to 1, any otherwise-valid access to CP<n> from:

- A Non-secure EL1 or EL0 mode is trapped to Hyp mode.
- Hyp mode generates an Undefined Instruction exception, taken in Hyp mode.

In an implementation that includes the Floating Point extension, the extension is controlled by coprocessors 10 and 11. If bits 11 and 10 are set to different values, the behavior is the same as if both bits were set to the value of bit 10, in all respects other than the value read back by explicitly reading bit 11.

Other coprocessors are not supported in ARMv8, so bits[13:12] and bits[9:0] are RES1.

Resets to 0.

Bits [9:0]

Reserved, RES1.

Accessing the HCPTR

To access the HCPTR:

```
MRC p15,4,<Rt>,c1,c1,2 ; Read HCPTR into Rt
MCR p15,4,<Rt>,c1,c1,2 ; Write Rt to HCPTR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0001	010

G5.1.56 HCR, Hyp Configuration Register

The HCR characteristics are:

Purpose

Provides configuration controls for virtualization, including defining whether various Non-secure operations are trapped to Hyp mode.

This register is part of the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

HCR is architecturally mapped to AArch64 register HCR_EL2[31:0].

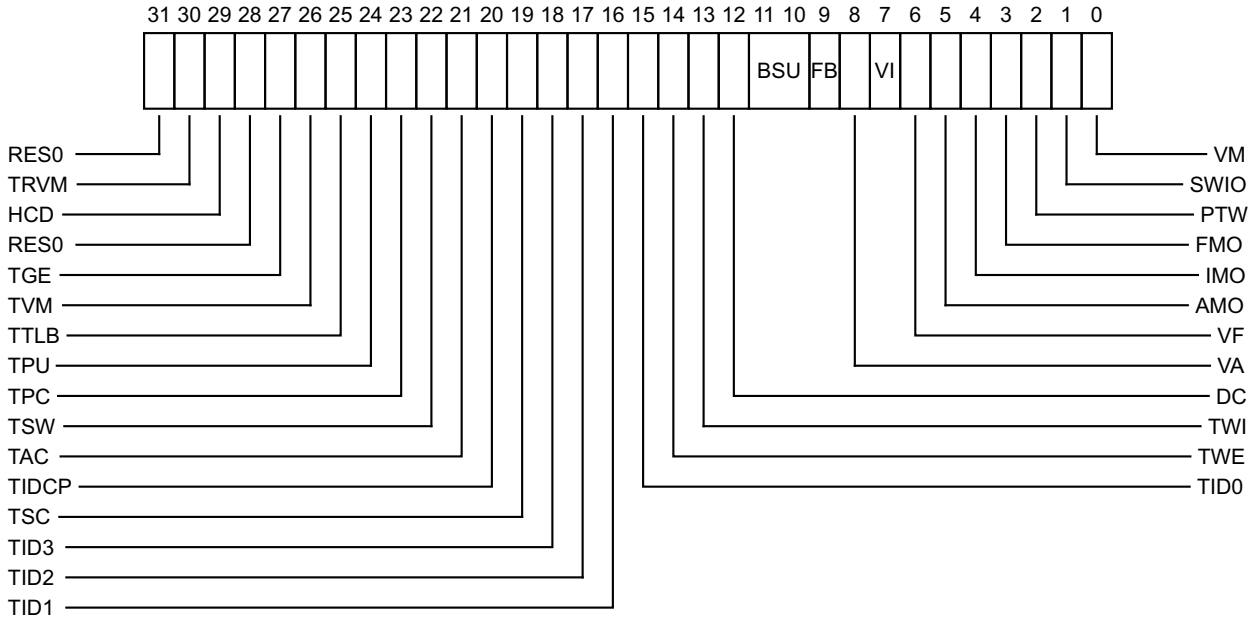
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HCR is a 32-bit register.

Field descriptions

The HCR bit assignments are:



Bit [31]

Reserved, RES0.

TRVM, bit [30]

Trap Read of Virtual Memory controls. When this bit is set to 1, this causes Reads to the EL1 virtual memory control registers from EL1 to be trapped to EL2. This covers the following registers:

SCTLR, TTBR0, TTBR1, TTBCR, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR/MAIR0, NMRR/MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

Resets to 0.

HCD, bit [29]

Hypervisor Call Disable, if EL3 is not implemented:

0 HVC instruction is enabled at EL1 or EL2.

1 HVC instruction is UNDEFINED at all exception levels.

If EL3 is implemented, this bit is RES0.

Resets to 0.

Bit [28]

Reserved, RES0.

TGE, bit [27]

Trap General Exceptions. If this bit is set to 1, and SCR.NS is set to 1, then:

- All exceptions that would be routed to EL1 are routed to EL2.
- The SCTLR.M bit is treated as being 0 regardless of its actual state other than for the purpose of reading the bit.
- The HCR.FMO, IMO, and AMO bits are treated as being 1 regardless of their actual state other than for the purpose of reading the bits.
- All virtual interrupts are disabled.
- Any implementation defined mechanisms for signalling virtual interrupts are disabled.
- An exception return to EL1 is treated as an illegal exception return.

Additionally, if HCR.TGE == 1, the HDCR.{TDRA,TDOSA,TDA} bits are ignored and the processor behaves as if they are set to 1, other than for the value read back from HDCR.

Resets to 0.

TVM, bit [26]

Trap Virtual Memory controls. When this bit is set to 1, this causes Writes to the EL1 virtual memory control registers from EL1 to be trapped to EL2. This covers the following registers:

SCTLR, TTBR0, TTBR1, TTBCR, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR/MAIR0, NMRR/MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

Resets to 0.

TTLB, bit [25]

Trap TLB maintenance instructions. When this bit is set to 1, this causes TLB maintenance instructions executed from EL1 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

TLBIALLIS, TLBIMVAIS, TLBIASIDIS, TLBIMVAAIS, TLBIALL, TLBIMVA, TLBIASID, DTLBIALL, DTLBIMVA, DTLBIASID, ITLBIALL, ITLBIMVA, ITLBIASID, TLBIMVAA, TLBIMVALIS, TLBIMVAALIS, TLBIMVAL, TLBIMVAAL.

Resets to 0.

TPU, bit [24]

Trap Cache maintenance instructions to Point of Unification. When this bit is set to 1, this causes Cache maintenance instructions to the point of unification executed from EL1 or EL0 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

ICIMVAU, ICIALLU, ICIALLUIS, DCCMVAU.

Resets to 0.

TPC, bit [23]

Trap Data/Unified Cache maintenance operations to Point of Coherency. When this bit is set to 1, this causes Data or Unified Cache maintenance instructions by address to the point of coherency executed from EL1 or EL0 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

DCIMVAC, DCCIMVAC, DCCMVAC.

Resets to 0.

TSW, bit [22]

Trap Data/Unified Cache maintenance operations by Set/Way. When this bit is set to 1, this causes Data or Unified Cache maintenance instructions by set/way executed from EL1 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

DCISW, DCCSW, DCCISW.

Resets to 0.

TAC, bit [21]

Trap ACTLR accesses. When this bit is set to 1, any valid Non-secure access to the ACTLR is trapped to Hyp mode.

Resets to 0.

TIDCP, bit [20]

Trap Implementation Dependent functionality. When this bit is set to 1, this causes accesses to the following instruction set space executed from EL1 to be trapped to EL2.

AArch32: MCR and MRC instructions as follows:

- All CP15, CRn==9, Opcode1 = {0-7}, CRm == {c0-c2, c5-c8}, opcode2 == {0-7}.
- All CP15, CRn==10, Opcode1 =={0-7}, CRm == {c0, c1, c4, c8}, opcode2 == {0-7}.
- All CP15, CRn==11, Opcode1=={0-7}, CRm == {c0-c8, c15}, opcode2 == {0-7}.

It is IMPLEMENTATION DEFINED whether any of this functionality accessed from EL0 is trapped to EL2 when the HCR.TIDCP bit is set. If it is not trapped to EL2, it results in an Undefined exception taken to EL1.

Resets to 0.

TSC, bit [19]

Trap SMC instruction. When this bit is set to 1, any attempt from a Non-secure EL1 mode to execute an SMC instruction, that passes its condition check if it is conditional, is trapped to Hyp mode.

Resets to 0.

TID3, bit [18]

Trap ID Group 3. When this bit is set to 1, this causes reads to the following registers executed from EL1 to be trapped to EL2:

ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0, ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5, MVFR0, MVFR1, MVFR2. Also MRC to any of the following encodings:

- CP15, CRn == 0, Opc1 == 0, CRm == {3-7}, Opc2 == {0,1}.
- CP15, CRn == 0, Opc1 == 0, CRm == 3, Opc2 == 2.
- CP15, CRn == 0, Opc1 == 0, CRm == 5, Opc2 == {4,5}.

Resets to 0.

TID2, bit [17]

Trap ID Group 2. When this bit is set to 1, this causes reads (or writes to CSSELR/CSSELR_EL1) to the following registers executed from EL1 or EL0 if not UNDEFINED to be trapped to EL2:

CTR, CCSIDR, CLIDR, CSSELR.

Resets to 0.

TID1, bit [16]

Trap ID Group 1. When this bit is set to 1, this causes reads to the following registers executed from EL1 to be trapped to EL2:

TCMTR, TLBTR, AIDR, REVIDR.

Resets to 0.

TID0, bit [15]

Trap ID Group 0. When this bit is set to 1, this causes reads to the following registers executed from EL1 or EL0 if not UNDEFINED to be trapped to EL2:

FPSID, JIDR.

Resets to 0.

TWE, bit [14]

Trap WFE. When this bit is set to 1, this causes execution of the WFE instruction from EL1 or EL0 to be trapped to EL2 if the instruction would otherwise cause suspension of execution (i.e. if the event register is not set).

Conditional WFE instructions that fail their condition are not trapped if this bit is set to 1.

Resets to 0.

TWI, bit [13]

Trap WFI. When this bit is set to 1, this causes execution of the WFI instruction from EL1 or EL0 to be trapped to EL2 if the instruction would otherwise cause suspension of execution (i.e. if there is not a pending WFI wakeup event).

Conditional WFI instructions that fail their condition are not trapped if this bit is set to 1.

Resets to 0.

DC, bit [12]

Default cacheable. When this bit is set to 1, and the Non-secure EL1 and EL0 stage 1 MMU is disabled, the memory type and attributes determined by the stage 1 translation is Normal, Non-shareable, Inner Write-Back Write-Allocate, Outer Write-Back Write-Allocate.

When this bit is 0 and the stage 1 MMU is disabled, the default memory attribute for Data accesses is Device-nGnRnE.

This bit is permitted to be cached in a TLB.

Resets to 0.

BSU, bits [11:10]

Barrier Shareability upgrade. The value in this field determines the minimum shareability domain that is applied to any barrier executed from EL1 or EL0:

00	No effect
01	Inner Shareable
10	Outer Shareable
11	Full system

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

Resets to 0.

FB, bit [9]

Force broadcast. When this bit is set to 1, this causes the following instructions to be broadcast within the Inner Shareable domain when executed from Non-secure EL1:

BPIALL, TLBIALL, TLBIMVA, TLBIASID, DTLBIALL, DTLBIMVA, DTLBIASID, ITLBIALL, ITLBIMVA, ITLBIASID, TLBIMVAA, ICIALLU, TLBIMVAL, TLBIMVAAL.

Resets to 0.

VA, bit [8]

Virtual Asynchronous Abort exception. When the AMO bit is set to 1, setting this bit to 1 generates a virtual Asynchronous Abort exception to the Guest OS, when the processor is executing in Non-secure state at EL0 or EL1.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

Resets to 0.

VI, bit [7]

Virtual IRQ exception. When the IMO bit is set to 1, setting this bit to 1 generates a virtual IRQ exception to the Guest OS, when the processor is executing in Non-secure state at EL0 or EL1.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

Resets to 0.

VF, bit [6]

Virtual FIQ exception. When the FMO bit is set to 1, setting this bit to 1 generates a virtual FIQ exception to the Guest OS, when the processor is executing in Non-secure state at EL0 or EL1.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

Resets to 0.

AMO, bit [5]

Asynchronous Abort Mask Override. When this bit is set to 1, it overrides the effect of CPSR.A, and enables virtual exception signalling by the VA bit.

Resets to 0.

IMO, bit [4]

IRQ Mask Override. When this bit is set to 1, it overrides the effect of CPSR.I, and enables virtual exception signalling by the VI bit.

Resets to 0.

FMO, bit [3]

FIQ Mask Override. When this bit is set to 1, it overrides the effect of CPSR.F, and enables virtual exception signalling by the VF bit.

Resets to 0.

PTW, bit [2]

Protected Table Walk. When this bit is set to 1, if the stage 2 translation of a translation table access made as part of a stage 1 translation table walk at EL0 or EL1 maps that translation table access to Strongly-ordered or Device memory, the access is faulted as a stage 2 Permission fault.

This bit is permitted to be cached in a TLB.

Resets to 0.

SWIO, bit [1]

Set/Way Invalidation Override. When this bit is set to 1, this causes EL1 execution of the data cache invalidate by set/way instruction to be treated as data cache clean and invalidate by set/way. That is, DCISW is executed as DCCISW.

As a result of changes to the behavior of DCISW, this bit is redundant in v8-A. It is permissible that an implementation makes this bit RES1.

Resets to 0.

VM, bit [0]

Virtualization MMU enable for EL1 and EL0 stage 2 address translation. Possible values of this bit are:

`0` EL1 and EL0 stage 2 address translation disabled.

`1` EL1 and EL0 stage 2 address translation enabled.

This bit is permitted to be cached in a TLB.

If the HCR.DC bit is set to 1, then the behavior of the processor when executing in a Non-secure mode other than Hyp mode is consistent with HCR.VM being 1, regardless of the actual value of HCR.VM, other than the value returned by an explicit read of HCR.VM.

Resets to 0.

Accessing the HCR

To access the HCR:

```
MRC p15,4,<Rt>,c1,c1,0 ; Read HCR into Rt
MCR p15,4,<Rt>,c1,c1,0 ; Write Rt to HCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0001	000

G5.1.57 HCR2, Hyp Configuration Register 2

The HCR2 characteristics are:

Purpose

Provides additional configuration controls for virtualization.

This register is part of the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

HCR2 is architecturally mapped to AArch64 register HCR_EL2[63:32].

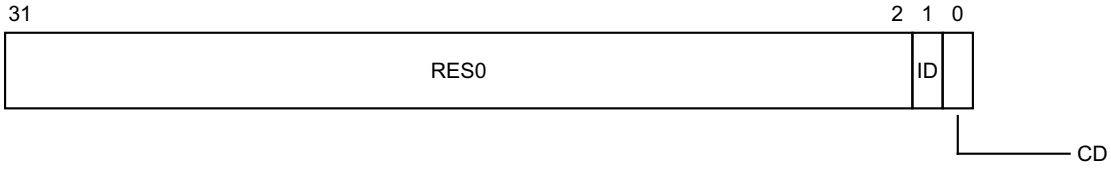
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HCR2 is a 32-bit register.

Field descriptions

The HCR2 bit assignments are:



Bits [31:2]

Reserved, RES0.

ID, bit [1]

Stage 2 Instruction cache disable. When HCR.VM==1, this forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable for the PL1&0 translation regime.

0 No effect on the stage 2 of the PL1&0 translation regime for instruction accesses.

1 Forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable for the PL1&0 translation regime.

This bit has no effect on the EL2 translation regime.

CD, bit [0]

Stage 2 Data cache disable. When HCR.VM==1, this forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the PL1&0 translation regime.

0 No effect on the stage 2 of the PL1&0 translation regime for data accesses and translation table walks.

1 Forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the PL1&0 translation regime.

This bit has no effect on the EL2 translation regime.

Accessing the HCR2

To access the HCR2:

```
MRC p15,4,<Rt>,c1,c1,4 ; Read HCR2 into Rt
MCR p15,4,<Rt>,c1,c1,4 ; Write Rt to HCR2
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0001	100

G5.1.58 HDFAR, Hyp Data Fault Address Register

The HDFAR characteristics are:

Purpose

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception that is taken to Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Any execution in a Non-secure PL1 mode, or in Secure state, makes the HDFAR UNKNOWN.

Configurations

HDFAR is architecturally mapped to AArch64 register FAR_EL2[31:0].

HDFAR is architecturally mapped to AArch32 register DFAR (S) when EL2 is implemented.

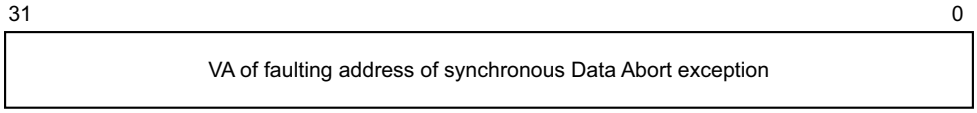
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HDFAR is a 32-bit register.

Field descriptions

The HDFAR bit assignments are:



Bits [31:0]

VA of faulting address of synchronous Data Abort exception.

Accessing the HDFAR

To access the HDFAR:

```
MRC p15,4,<Rt>,c6,c0,0 ; Read HDFAR into Rt
MCR p15,4,<Rt>,c6,c0,0 ; Write Rt to HDFAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0110	0000	000

G5.1.59 HIFAR, Hyp Instruction Fault Address Register

The HIFAR characteristics are:

Purpose

Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception that is taken to Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Any execution in a Non-secure PL1 mode, or in Secure state, makes the HIFAR UNKNOWN.

Configurations

HIFAR is architecturally mapped to AArch64 register FAR_EL2[63:32].

HIFAR is architecturally mapped to AArch32 register IFAR (S) when EL2 is implemented.

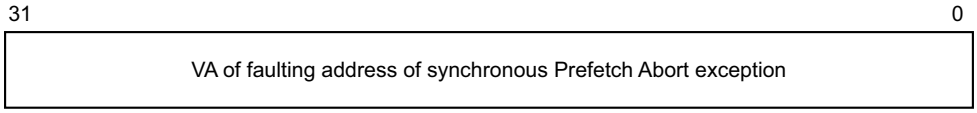
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HIFAR is a 32-bit register.

Field descriptions

The HIFAR bit assignments are:



Bits [31:0]

VA of faulting address of synchronous Prefetch Abort exception.

Accessing the HIFAR

To access the HIFAR:

```
MRC p15,4,<Rt>,c6,c0,2 ; Read HIFAR into Rt
MCR p15,4,<Rt>,c6,c0,2 ; Write Rt to HIFAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0110	0000	010

G5.1.60 HMAIR0, Hyp Memory Attribute Indirection Register 0

The HMAIR0 characteristics are:

Purpose

Along with HMAIR1, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

AttrIndx[2], from the translation table descriptor, selects the appropriate HMAIR: setting AttrIndx[2] to 0 selects HMAIR0.

Configurations

HMAIR0 is architecturally mapped to AArch64 register MAIR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

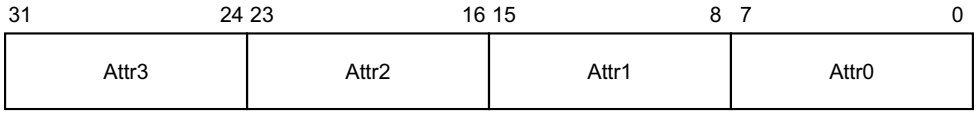
Attributes

HMAIR0 is a 32-bit register.

Field descriptions

The HMAIR0 bit assignments are:

When TTBCR.EAE==1:



Attr<n>, bits [8n+7:8n], for 8n+7:8n = 0 to 3

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
0000	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
00RW, RW not 00	Normal Memory, Outer Write-through transient
0100	Normal Memory, Outer Non-Cacheable
01RW, RW not 00	Normal Memory, Outer Write-back transient
10RW	Normal Memory, Outer Write-through non-transient
11RW	Normal Memory, Outer Write-back non-transient

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through transient
0100	Device-nGnRE memory	Normal memory, Inner Non-Cacheable
01RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back transient
1000	Device-nGRE memory	Normal Memory, Inner Write-through non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through non-transient
1100	Device-GRE memory	Normal Memory, Inner Write-back non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back non-transient

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.

ARMv7's Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	Do not allocate
1	Allocate

Accessing the HMAIR0

To access the HMAIR0:

```
MRC p15,4,<Rt>,c10,c2,0 ; Read HMAIR0 into Rt
MCR p15,4,<Rt>,c10,c2,0 ; Write Rt to HMAIR0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1010	0010	000

G5.1.61 HMAIR1, Hyp Memory Attribute Indirection Register 1

The HMAIR1 characteristics are:

Purpose

Along with HMAIR0, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

AttrIndx[2], from the translation table descriptor, selects the appropriate HMAIR: setting AttrIndx[2] to 1 selects HMAIR1.

Configurations

HMAIR1 is architecturally mapped to AArch64 register MAIR_EL2[63:32].

If EL2 is not implemented, this register is RES0 from EL3.

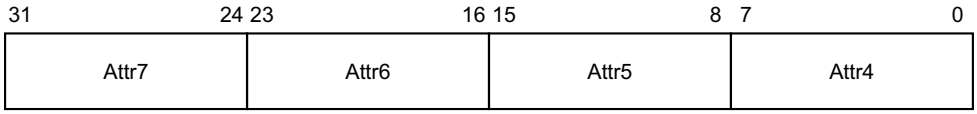
Attributes

HMAIR1 is a 32-bit register.

Field descriptions

The HMAIR1 bit assignments are:

When TTBCR.EAE==1:



Attr<n>, bits [8(n-4)+7:8(n-4)], for 8(n-4)+7:8(n-4) = 4 to 7

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
0000	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
00RW, RW not 00	Normal Memory, Outer Write-through transient
0100	Normal Memory, Outer Non-Cacheable
01RW, RW not 00	Normal Memory, Outer Write-back transient
10RW	Normal Memory, Outer Write-through non-transient
11RW	Normal Memory, Outer Write-back non-transient

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through transient
0100	Device-nGnRE memory	Normal memory, Inner Non-Cacheable
01RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back transient
1000	Device-nGRE memory	Normal Memory, Inner Write-through non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through non-transient
1100	Device-GRE memory	Normal Memory, Inner Write-back non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back non-transient

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.

ARMv7's Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	Do not allocate
1	Allocate

Accessing the HMAIR1

To access the HMAIR1:

```
MRC p15,4,<Rt>,c10,c2,1 ; Read HMAIR1 into Rt
MCR p15,4,<Rt>,c10,c2,1 ; Write Rt to HMAIR1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1010	0010	001

G5.1.62 HPFAR, Hyp IPA Fault Address Register

The HPFAR characteristics are:

Purpose

Holds the faulting IPA for some aborts on a stage 2 translation taken to Hyp mode.

This register is part of:

- the Exception and fault handling registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Execution in any Non-secure mode other than Hyp mode makes this register UNKNOWN.

Configurations

HPFAR is architecturally mapped to AArch64 register HPFAR_EL2[31:0].

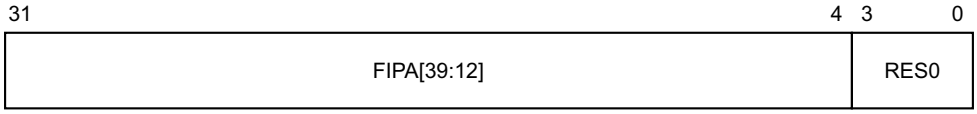
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HPFAR is a 32-bit register.

Field descriptions

The HPFAR bit assignments are:



FIPA[39:12], bits [31:4]

Bits [39:12] of the faulting intermediate physical address.

Bits [3:0]

Reserved, RES0.

Accessing the HPFAR

To access the HPFAR:

```
MRC p15,4,<Rt>,c6,c0,4 ; Read HPFAR into Rt
MCR p15,4,<Rt>,c6,c0,4 ; Write Rt to HPFAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0110	0000	100

G5.1.63 HRMR, Hyp Reset Management Register

The HRMR characteristics are:

Purpose

If EL2 is the highest exception level implemented, and is capable of using both AArch32 and AArch64, controls the Execution state that the processor boots into and allows request of a Warm reset.

This register is part of:

- the Virtualization registers functional group
- the Reset management registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1	EL2
-	-	RW

Configurations

HRMR is architecturally mapped to AArch64 register RMR_EL2.

Only implemented if the highest exception level implemented is EL2 and supports AArch32 and AArch64.

If EL2 is not the highest one implemented, then this register is not implemented and its encoding is UNDEFINED.

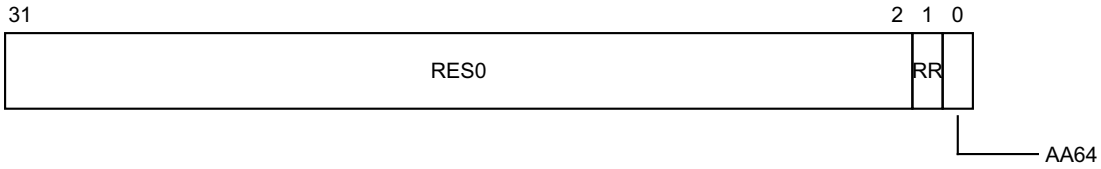
Attributes

HRMR is a 32-bit register when EL2 implemented, EL3 not implemented.

Field descriptions

The HRMR bit assignments are:

When EL2 implemented, EL3 not implemented:



Bits [31:2]

Reserved, RES0.

RR, bit [1]

When set to 1 this bit requests a Warm reset. The bit is strictly a request.

On Warm reset, the field resets to 0.

AA64, bit [0]

Determines which Execution state the processor boots into after a Warm reset:

0 AArch32.

1 AArch64.

The reset vector address on reset takes a choice between two IMP DEF values, depending on the value in the AA64 bit.

On Cold reset, the field resets to 0.

Accessing the HRMR

To access the HRMR when EL2 implemented, EL3 not implemented:

```
MRC p15,4,<Rt>,c12,c0,2 ; Read HRMR into Rt
MCR p15,4,<Rt>,c12,c0,2 ; Write Rt to HRMR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	0000	010

G5.1.64 HSCTLR, Hyp System Control Register

The HSCTLR characteristics are:

Purpose

Provides top level control of the system operation in Hyp mode. This register provides Hyp mode control of features controlled by the Banked SCTLR bits, and shows the values of the non-Banked SCTLR bits.

This register is part of:

- the Virtualization registers functional group
- the Other system control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

HSCTLR is architecturally mapped to AArch64 register SCTLR_EL2.

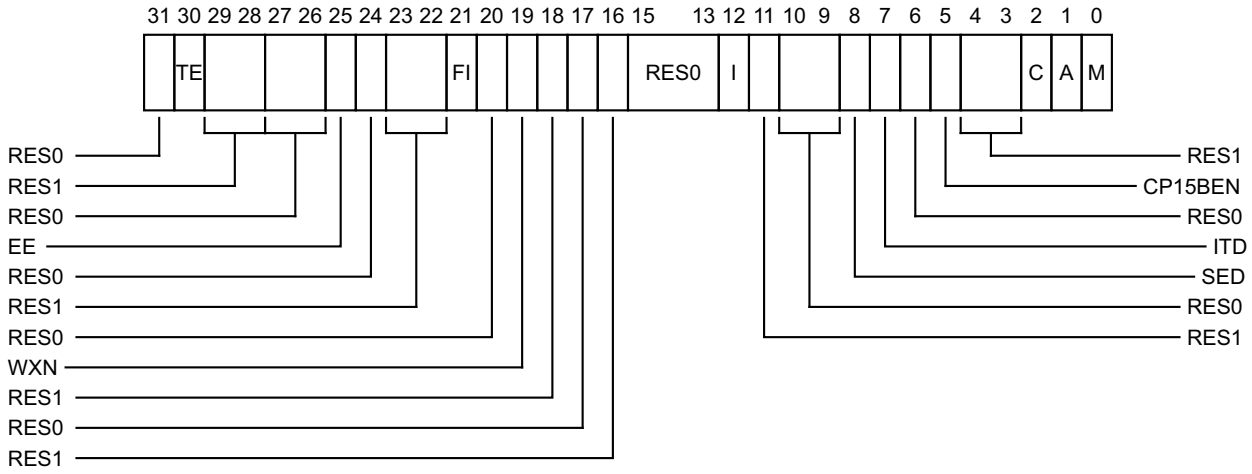
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HSCTLR is a 32-bit register.

Field descriptions

The HSCTLR bit assignments are:



Bit [31]

Reserved, RES0.

TE, bit [30]

T32 Exception Enable. This bit controls whether exceptions are taken in A32 or T32 state:

0 Exceptions, including reset, taken in A32 state.

1 Exceptions, including reset, taken in T32 state.

Reset value is architecturally UNKNOWN.

Bits [29:28]

Reserved, RES1.

Bits [27:26]

Reserved, RES0.

EE, bit [25]

Exception Endianness. The value of this bit defines the value of the CPSR.E bit on entry to an exception vector, including reset. This value also indicates the endianness of the translation table data for translation table lookups. The possible values of this bit are:

0 Little-endian.

1 Big-endian.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If this register is at the highest exception level implemented, field resets to an IMPLEMENTATION DEFINED value. Otherwise, its reset value is UNKNOWN.

Bit [24]

Reserved, RES0.

Bits [23:22]

Reserved, RES1.

FI, bit [21]

Fast interrupts configuration enable. This bit can be used to reduce interrupt latency in an implementation by disabling IMPLEMENTATION DEFINED performance features. The possible values of this bit are:

0 All performance features enabled.

1 Low interrupt latency configuration. Some performance features disabled.

Reset value is architecturally UNKNOWN.

Bit [20]

Reserved, RES0.

WXN, bit [19]

Write permission implies XN (Execute Never). This bit can be used to require all memory regions with write permission to be treated as XN. The possible values of this bit are:

0 Regions with write permission are not forced to XN.

1 Regions with write permission are forced to XN.

The WXN bit is permitted to be cached in a TLB.

Reset value is architecturally UNKNOWN.

Bit [18]

Reserved, RES1.

Bit [17]

Reserved, RES0.

Bit [16]

Reserved, RES1.

Bits [15:13]

Reserved, RES0.

I, bit [12]

Instruction cache enable. This is an enable bit for instruction caches at EL2:

0 Instruction caches disabled at EL2. If HSCTLR.M is set to 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal memory, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.

1 Instruction caches enabled at EL2. If HSCTLR.M is set to 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal memory, Outer Shareable, Inner Write-Through, Outer Write-Through.

When this bit is 0, all EL2 Normal memory instruction accesses are Non-cacheable.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

Bit [11]

Reserved, RES1.

Bits [10:9]

Reserved, RES0.

SED, bit [8]

SETEND Disable. The possible values of this bit are:

0 The SETEND instruction is available.

1 The SETEND instruction is UNALLOCATED.

If an implementation does not support mixed endian operation at EL2, this bit is RES1.

Reset value is architecturally UNKNOWN.

ITD, bit [7]

IT Disable. The possible values of this bit are:

0 The IT instruction functionality is available.

1 It is IMPLEMENTATION DEFINED whether the IT instruction is treated as either:

- A 16-bit instruction, which can only be followed by another 16-bit instruction.
- The first half of a 32-bit instruction.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

All encodings of the IT instruction with hw1[3:0]!=1000 are UNDEFINED and treated as unallocated.

All encodings of the subsequent instruction with the following values for hw1 are UNDEFINED (and treated as unallocated):

`11xxxxxxxxxxxxx`
All 32-bit instructions, B(2), B(1), Undefined, SVC, Load/Store multiple

`1x11xxxxxxxxxxx`
Miscellaneous 16-bit instructions

`1x100xxxxxxxxxx`
ADD Rd, PC, #imm

`01001xxxxxxxxxx`
LDR Rd, [PC, #imm]

`0100x1xxx1111xxx`
ADD(4),CMP(3), MOV, BX pc, BLX pc

010001xx1xxxx111

ADD(4),CMP(3), MOV (Note: this pattern also covers UNPREDICTABLE cases with BLX Rn)

Contrary to the standard treatment of conditional UNDEFINED instructions in the ARM architecture, in this case these instructions are always treated as UNDEFINED, regardless of whether the instruction would pass or fail its condition codes as a result of being in an IT block.

Reset value is architecturally UNKNOWN.

Bit [6]

Reserved, RES0.

CP15BEN, bit [5]

CP15 barrier enable. If implemented, this is an enable bit for the CP15 DMB, DSB, and ISB barrier operations at EL2:

0 CP15 barrier operations disabled at EL2. Their encodings are UNDEFINED.

1 CP15 barrier operations enabled at EL2.

If an implementation does not support the CP15 barrier operations, this bit is RES0.

Reset value is architecturally UNKNOWN.

Bits [4:3]

Reserved, RES1.

C, bit [2]

Cache enable. This is an enable bit for data and unified caches at EL2:

0 Data and unified caches disabled at EL2.

1 Data and unified caches enabled at EL2.

When this bit is 0, all EL2 Normal memory data accesses and all accesses to the EL2 translation tables are Non-cacheable.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking:

0 Alignment fault checking disabled.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

1 Alignment fault checking enabled.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

M, bit [0]

MMU enable for EL2 stage 1 address translation. Possible values of this bit are:

0 EL2 stage 1 address translation disabled.

1 EL2 stage 1 address translation enabled.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

Accessing the HSCTLR

To access the HSCTLR:

```
MRC p15,4,<Rt>,c1,c0,0 ; Read HSCTLR into Rt
MCR p15,4,<Rt>,c1,c0,0 ; Write Rt to HSCTLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0000	000

G5.1.65 HSR, Hyp Syndrome Register

The HSR characteristics are:

Purpose

Holds syndrome information for an exception taken to Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Execution in any Non-secure mode other than Hyp mode makes this register UNKNOWN.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of HSR is UNKNOWN. The value written to HSR must be consistent with a value that could be created as a result of an exception from the same exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that exception level, in order to avoid the possibility of a privilege violation.

Configurations

HSR is architecturally mapped to AArch64 register ESR_EL2.

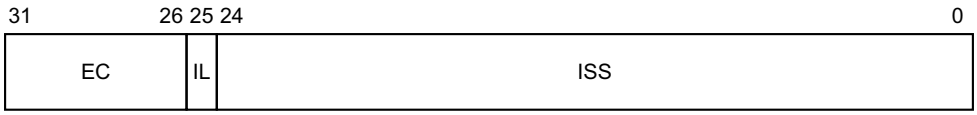
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HSR is a 32-bit register.

Field descriptions

The HSR bit assignments are:



EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about. Possible values of this field are:

`000000` Unknown reason.

See *ISS encoding for an exception with an unknown reason* on page G5-3940.

`000001` Trapped WFI or WFE instruction.

Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

See *ISS encoding for an exception from a trapped WFI or WFE instruction* on page G5-3940.

`000011` Trapped MCR or MRC access to CP15.

See *ISS encoding for an exception from a trapped MCR or MRC access* on page G5-3941.

`000100` Trapped MCRR or MRRC access to CP15.
See *ISS encoding for an exception from a trapped MCRR or MRRC access* on page G5-3943.

`000101` Trapped MCR or MRC access to CP14.
See *ISS encoding for an exception from a trapped MCR or MRC access* on page G5-3941.

`000110` Trapped LDC or STC access to CP14.
See *ISS encoding for an exception from a trapped LDC or STC access to CP14* on page G5-3944.

`000111` HCPTR-trapped access to CP0-CP13.
See *ISS encoding for an exception from an HCPTR-trapped access to CP10 or CP11* on page G5-3946.

`001000` Trapped MRC or VMRS access to CP10, for ID group traps.
See *ISS encoding for an exception from a trapped MCR or MRC access* on page G5-3941.

`001100` Trapped MRRC or MCRR access to CP14.
See *ISS encoding for an exception from a trapped MCRR or MRRC access* on page G5-3943.

`010001` SVC taken to Hyp mode.
See *ISS encoding for an exception from HVC or SVC instruction execution* on page G5-3947.

`010010` HVC executed.
See *ISS encoding for an exception from HVC or SVC instruction execution* on page G5-3947.

`010011` Trapped SMC instruction.
See *ISS encoding for an exception from SMC instruction execution* on page G5-3947.

`100000` Prefetch Abort routed to Hyp mode.
See *ISS encoding for a Prefetch Abort exception* on page G5-3947.

`100001` Prefetch Abort taken from Hyp mode.
See *ISS encoding for a Prefetch Abort exception* on page G5-3947.

`100010` PC Alignment Exception.
See *ISS encoding for an Illegal exception return or PC alignment fault exception* on page G5-3952.

`100100` Data Abort routed to Hyp mode.
See *ISS encoding for a Data Abort exception* on page G5-3949.

`100101` Data Abort taken from Hyp mode.
See *ISS encoding for a Data Abort exception* on page G5-3949.

Other values are reserved.

IL, bit [25]

Instruction Length. Indicates the size of the instruction that has been trapped to this exception level. Possible values of this bit are:

`0` 16-bit instruction trapped.

`1` 32-bit instruction trapped. This value also applies to the following exceptions:

- An SError interrupt.
- An Instruction Abort exception.
- A Misaligned PC exception.
- A Misaligned Stack Pointer exception.
- A Data Abort for which the value of the ISV bit is 0.

- An Illegal Execution State exception.
- Any debug exception except for Software Breakpoint Instruction exceptions. For Software Breakpoint Instruction exceptions, this bit has its standard meaning:

  `0` 16-bit T32 BKPT instruction.

  1 32-bit A32 BKPT instruction.
- An exception reported using EC value `0b000000`.

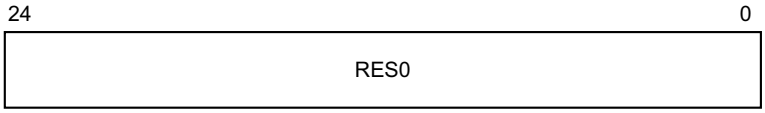
ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

The following subsubsections define each of the ISS formats.

ISS encoding for an exception with an unknown reason

These are exceptions with EC value `0b000000`. The ISS encoding for these exceptions is:



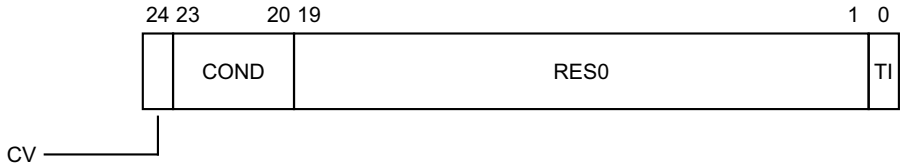
Bits [24:0]

Reserved, RES0.

See *Exceptions with an unknown reason* on page G4-3731 for more information about this Exception class.

ISS encoding for an exception from a trapped WFI or WFE instruction

These are exceptions with EC value `0b000001`. The ISS encoding for these exceptions is:



CV, bit [24]

Condition code valid. Possible values of this bit are:

`0` The COND field is not valid.

`1` The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to `0b1110`.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to `0b1110`, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

Bits [19:1]

Reserved, RES0.

TI, bit [0]

Trapped instruction. Possible values of this bit are:

`0` WFI trapped.

`1` WFE trapped.

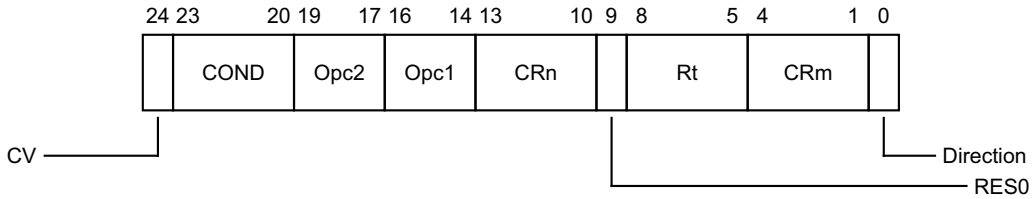
See *Exceptions caused by a trapped WFI or WFE instruction* on page G4-3731 for more information about this Exception class.

ISS encoding for an exception from a trapped MCR or MRC access

These are the exceptions with the following EC values:

- `0b000011`, trapped `MRC` or `MCR` access to CP15.
- `b000101`, trapped `MRC` or `MCR` access to CP14.
- `0b001000`, trapped `MRC` or `VMRS` access to CP10.

The ISS encoding for these exceptions is:



CV, bit [24]

Condition code valid. Possible values of this bit are:

`0` The COND field is not valid.

`1` The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to `0b1110`.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to `0b1110`, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value `0b000`.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value `0b111`.

CRn, bits [13:10]

The CRn value from the issued instruction, the coprocessor primary register value.

For a trapped VMRS access, holds the reg_field from the VMRS instruction encoding.

Bit [9]

Reserved, RES0.

Rt, bits [8:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

CRm, bits [4:1]

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value `0b0000`.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

`0` Write to coprocessor. MCR instruction.

`1` Read from coprocessor. MRC or VMRS instruction.

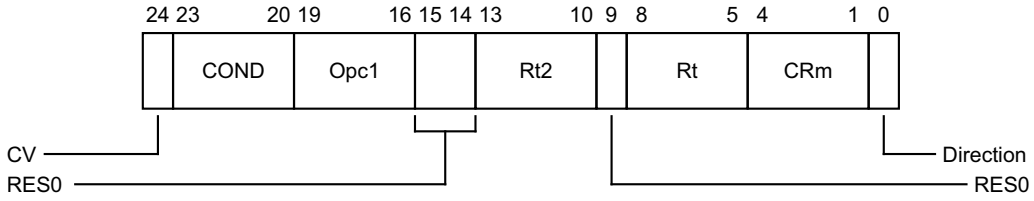
See *Exceptions caused by a trapped MCR or MRC access* on page G4-3731 for more information about this Exception class.

ISS encoding for an exception from a trapped MCRR or MRRC access

These are the exceptions with the following EC values:

- `0b000100`, trapped `MRRC` or `MCRR` access to CP15.
- `0b001100`, trapped `MRRC` access to CP14.

The ISS encoding for these exceptions is:



CV, bit [24]

Condition code valid. Possible values of this bit are:

`0` The COND field is not valid.

`1` The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to `0b1110`.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to `0b1110`, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

Opc1, bits [19:16]

The Opc1 value from the issued instruction.

Bits [15:14]

Reserved, RES0.

Rt2, bits [13:10]

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.

Bit [9]

Reserved, RES0.

Rt, bits [8:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

CRm, bits [4:1]

The CRm value from the issued instruction.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

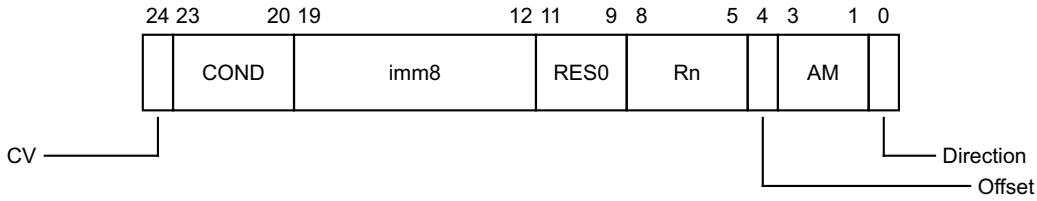
`0` Write to coprocessor. MCRR instruction.

`1` Read from coprocessor. MRRC instruction.

See *Exceptions caused by a trapped MCRR or MRRC access* on page G4-3732 for more information about this Exception class.

ISS encoding for an exception from a trapped LDC or STC access to CP14

These are exceptions with EC value `0b000110`. The ISS encoding for these exceptions is:



CV, bit [24]

Condition code valid. Possible values of this bit are:

`0` The COND field is not valid.

`1` The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to `0b1110`.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to `0b1110`, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.

- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

imm8, bits [19:12]

The immediate value from the issued instruction.

Bits [11:9]

Reserved, RES0.

Rn, bits [8:5]

The Rn value from the issued instruction. Valid only when the Direction field is 0, indicating a trapped STC instruction.

When the Direction field is 1, indicating a trapped LDC instruction, this field is RES0.

Offset, bit [4]

Indicates whether the offset is added or subtracted:

`0` Subtract offset.

`1` Add offset.

This bit corresponds to the U bit in the instruction encoding.

AM, bits [3:1]

Addressing mode. The permitted values of this field are:

`000` Immediate unindexed.

`001` Immediate post-indexed.

`010` Immediate offset.

`011` Immediate pre-indexed.

`100` Literal unindexed.
A32 instruction set only.
For a trapped LDC or STC T32 instruction, this encoding is reserved.

`110` Literal offset.
For the STC instruction, valid only in the A32 instruction set.
For a trapped STC T32 instruction, this encoding is reserved.

The values `0b101` and `0b111` are reserved.

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

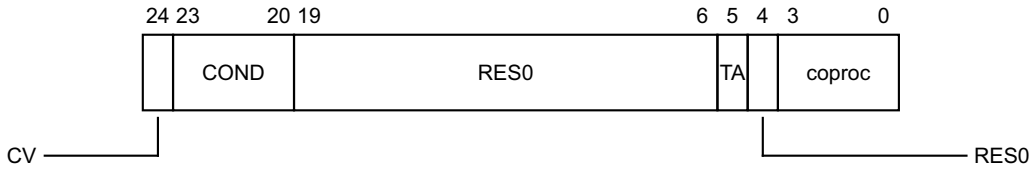
`0` Write to coprocessor. STC instruction.

`1` Read from coprocessor. LDC instruction.

See *Exceptions caused by a trapped LDC or STC access* on page G4-3732 for more information about this Exception class.

ISS encoding for an exception from an HCPTR-trapped access to CP10 or CP11

These are exceptions with EC value `0b000111`. The ISS encoding for these exceptions is:



CV, bit [24]

Condition code valid. Possible values of this bit are:

`0` The COND field is not valid.

`1` The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to `0b1110`.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to `0b1110`, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

Bits [19:6]

Reserved, RES0.

TA, bit [5]

Indicates trapped use of the Advanced SIMD functionality. The possible values of this bit are:

`0` Exception was not caused by trapped use of the Advanced SIMD functionality.

`1` Exception was caused by trapped use of the Advanced SIMD functionality.

Any use of an Advanced SIMD instruction that is trapped to Hyp mode because of a trap configured in the HCPTR sets this bit to 1.

Bit [4]

Reserved, RES0.

coproc, bits [3:0]

The number of the coprocessor accessed by the trapped operation, 0-13.

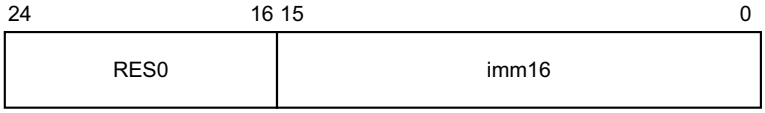
See *Exceptions caused by an HCPTR-trapped access to CP10 or CP11* on page G4-3732 for more information about this Exception class.

ISS encoding for an exception from HVC or SVC instruction execution

These are the exceptions with the following EC values:

- `0b010001`, Supervisor Call exception taken to Hyp mode.
- `0b010010`, Hypervisor Call exception.

The ISS encoding for these exceptions is:



Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction this is the value of the imm16 field of the issued instruction.

For an SVC instruction:

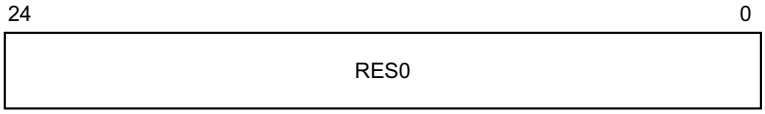
- If the instruction is unconditional, then:
  - For the 16-bit T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The HVC instruction is unconditional, and a conditional SVC instruction generates a Supervisor Call exception that is routed to Hyp mode only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not include conditionality information.

See *Hypervisor Call exceptions, and Supervisor Call exceptions routed to Hyp mode* on page G4-3732 for more information about this Exception class.

ISS encoding for an exception from SMC instruction execution

These are exceptions with EC value `0b010011`. The ISS encoding for these exceptions is:



Bits [24:0]

Reserved, RES0.

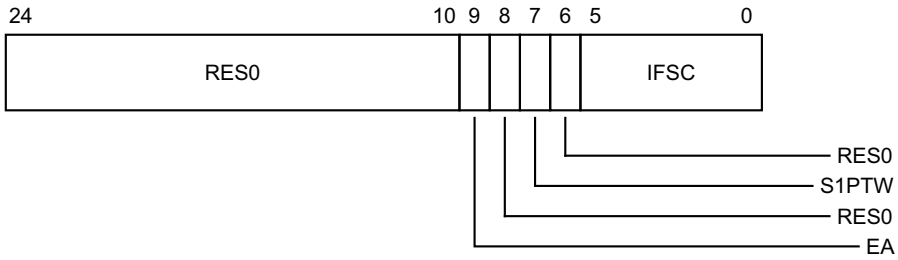
See *Exception caused by trapped SMC execution* on page G4-3733 for more information about this Exception class.

ISS encoding for a Prefetch Abort exception

These are the exceptions with the following EC values:

- `0b100000`, for a Prefetch Abort exception taken from a mode other than Hyp mode and routed to Hyp mode.
- `0b100001`, for a Prefetch Abort exception taken from Hyp mode.

The ISS encoding for these exceptions is:



Bits [24:10]

Reserved, RES0.

EA, bit [9]

External abort type. This bit can be provide an IMPLEMENTATION DEFINED classification of external aborts.

For any abort other than an External abort this bit returns a value of 0.

Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:

`0` Fault not on a stage 2 translation for a stage 1 translation table walk.

`1` Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For a stage 1 fault, this bit is RES0.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code. Possible values of this field are:

`000000` Address size fault, zeroth level of translation or translation table base register

`000001` Address size fault, first level

`000010` Address size fault, second level

`000011` Address size fault, third level

`000100` Translation fault, zeroth level

`000101` Translation fault, first level

`000110` Translation fault, second level

`000111` Translation fault, third level

`001001` Access flag fault, first level

`001010` Access flag fault, second level

`001011` Access flag fault, third level

`001101` Permission fault, first level

`001110` Permission fault, second level

`001111` Permission fault, third level

`010000` Synchronous external abort

`011000` Synchronous parity error on memory access

010100	Synchronous external abort on translation table walk, zeroth level
010101	Synchronous external abort on translation table walk, first level
010110	Synchronous external abort on translation table walk, second level
010111	Synchronous external abort on translation table walk, third level
011100	Synchronous parity error on memory access on translation table walk, zeroth level
011101	Synchronous parity error on memory access on translation table walk, first level
011110	Synchronous parity error on memory access on translation table walk, second level
011111	Synchronous parity error on memory access on translation table walk, third level
100001	Alignment fault
100010	Debug event
110000	TLB conflict abort
110100	IMPLEMENTATION DEFINED fault (Lockdown fault)

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault cased by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

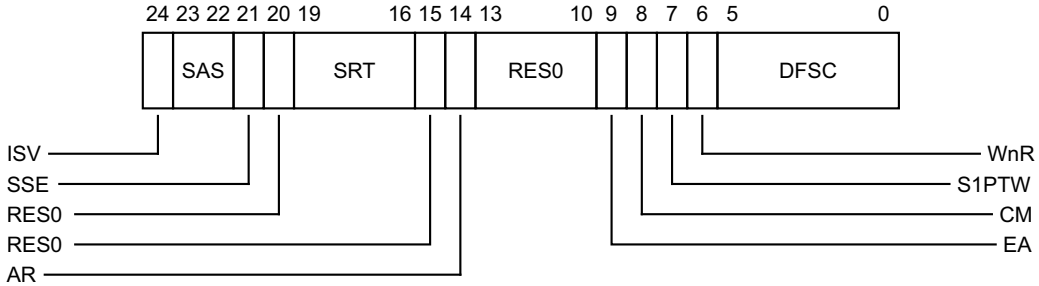
See *Prefetch Abort exceptions taken to Hyp mode* on page G4-3733 for more information about this Exception class.

ISS encoding for a Data Abort exception

These are the exceptions with the following EC values:

- 0b100100, for a Data Abort exception taken from a mode other than Hyp mode and routed to Hyp mode.
- 0b100101, for a Data Abort exception taken from Hyp mode.

The ISS encoding for these exceptions is:



ISV, bit [24]

Instruction syndrome valid. Indicates whether the rest of the syndrome information in this register is valid.

0	No valid instruction syndrome. ISS[23:16] are RES0.
1	ISS[24:16] hold a valid instruction syndrome.

This bit is 0 for all faults except those generated by a stage 2 translation. For Data Abort exceptions generated by a stage 2 translation, this bit is 1 and a valid instruction syndrome is returned, only if all of the following are true:

- The instruction that generated the Data Abort exception:
  - Is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT instruction.
  - Is not performing register writeback.
  - Is not using the PC as its source or destination register.

For ISS reporting, a stage 2 abort on a stage 1 translation table lookup is treated as a stage 1 Translation fault, and does not return a valid instruction syndrome.

It is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous external abort on stage 2 translation table walks.

In the A32 instruction set, LDR*T and STR*T instructions always perform register writeback and therefore never return a valid instruction syndrome.

SAS, bits [23:22]

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

`00` Byte

`01` Halfword

`10` Word

`11` Doubleword

SSE, bit [21]

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

`0` Sign-extension not required.

`1` Data item must be sign-extended.

For all other operations this bit is 0.

Bit [20]

Reserved, RES0.

SRT, bits [19:16]

Syndrome Register transfer. The register number of the Rt operand of the faulting instruction.

Bit [15]

Reserved, RES0.

AR, bit [14]

Acquire/Release. Possible values of this bit are:

`0` Instruction did not have acquire/release semantics.

`1` Instruction did have acquire/release semantics.

Bits [13:10]

Reserved, RES0.

EA, bit [9]

External abort type. This bit can be provide an IMPLEMENTATION DEFINED classification of external aborts.

For any abort other than an External abort this bit returns a value of 0.

CM, bit [8]

Cache maintenance. For a synchronous fault, identifies fault that comes from a cache maintenance or address translation operation. For synchronous faults, the possible values of this bit are:

`0` Fault not generated by a cache maintenance or address translation operation.

`1` Fault generated by a cache maintenance or address translation operation.

For asynchronous faults, this bit is 0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:

`0` Fault not on a stage 2 translation for a stage 1 translation table walk.

`1` Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For a stage 1 fault, this bit is RES0.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by a write or a read operation. The possible values of this bit are:

`0` Abort caused by a read operation.

`1` Abort caused by a write operation.

For faults on cache maintenance and address translation operations, this bit always returns a value of 1.

DFSC, bits [5:0]

Data Fault Status Code. Possible values of this field are:

`000000` Address size fault, zeroth level of translation or translation table base register

`000001` Address size fault, first level

`000010` Address size fault, second level

`000011` Address size fault, third level

`000100` Translation fault, zeroth level

`000101` Translation fault, first level

`000110` Translation fault, second level

`000111` Translation fault, third level

`001001` Access flag fault, first level

`001010` Access flag fault, second level

`001011` Access flag fault, third level

`001101` Permission fault, first level

`001110` Permission fault, second level

`001111` Permission fault, third level

`010000` Synchronous external abort

`011000` Synchronous parity error on memory access

`010001` Asynchronous external abort

`011001` Asynchronous parity error on memory access

`010100` Synchronous external abort on translation table walk, zeroth level

`010101` Synchronous external abort on translation table walk, first level

`010110` Synchronous external abort on translation table walk, second level

`010111` Synchronous external abort on translation table walk, third level

`011100` Synchronous parity error on memory access on translation table walk, zeroth level

011101	Synchronous parity error on memory access on translation table walk, first level
011110	Synchronous parity error on memory access on translation table walk, second level
011111	Synchronous parity error on memory access on translation table walk, third level
100001	Alignment fault
100010	Debug event
110000	TLB conflict abort
110100	IMPLEMENTATION DEFINED fault (Lockdown fault)
110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
111101	Section Domain Fault, used only for faults reported in the PAR_EL1
111110	Page Domain Fault, used only for faults reported in the PAR_EL1

All other values are reserved.

The lookup level associated with a fault is:

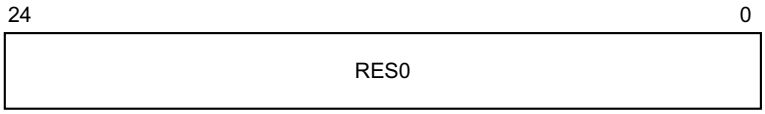
- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault cased by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

See *Data Abort exceptions taken to Hyp mode* on page G4-3733 for more information about this Exception class.

ISS encoding for an Illegal exception return or PC alignment fault exception

These are the exceptions with the following EC values:

- 0b001110, for an illegal exception return to AArch32 state. This includes exceptions caused by an illegal Instruction set state.
- 0b101010, for a PC alignment exception.



Bits [24:0]

Reserved, RES0.

See *Illegal exception return and PC alignment fault exceptions* on page G4-3734 for more information about this Exception class.

Accessing the HSR

To access the HSR:

```
MRC p15,4,<Rt>,c5,c2,0 ; Read HSR into Rt
MCR p15,4,<Rt>,c5,c2,0 ; Write Rt to HSR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0101	0010	000

G5.1.66 HSTR, Hyp System Trap Register

The HSTR characteristics are:

Purpose

Controls trapping to Hyp mode of Non-secure accesses, at EL1 or lower, of use of the CP15 primary coprocessor registers, {c0-c3,c5-c13,c15}.

This register is part of the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

HSTR is architecturally mapped to AArch64 register HSTR_EL2.

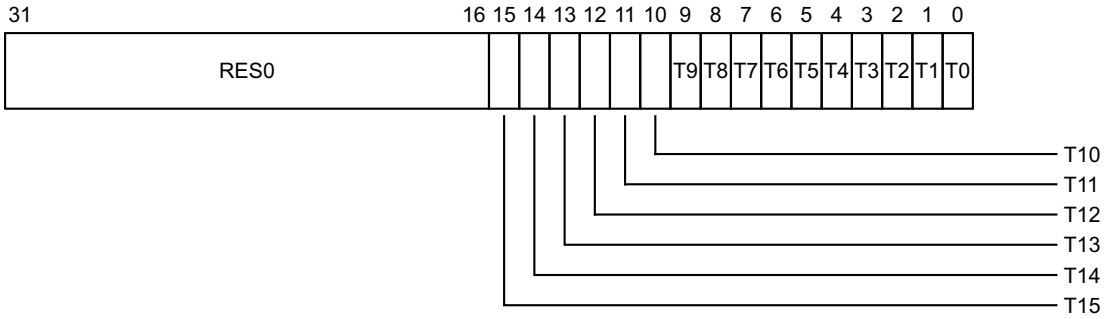
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HSTR is a 32-bit register.

Field descriptions

The HSTR bit assignments are:



Bits [31:16]

Reserved, RES0.

T<n>, bit [n], for n = 0 to 15

Trap coprocessor primary register. For each field T<n>, the possible values of this bit are:

`0` Has no effect on Non-secure accesses to CP15 coprocessor registers.

`1` Trap valid Non-secure accesses to coprocessor primary register c<n> to Hyp mode.

When T<n> is set to 1, any valid Non-secure access to CP15 primary coprocessor register c<n> is trapped to Hyp mode. For example, when T7 is set to 1:

- Any valid Non-secure 32-bit CP15 accesses, using MRC or MCR instructions with CRn==c7, are trapped to Hyp mode.
- Any valid Non-secure 64-bit CP15 accesses, using MRRC or MCRR instructions with CRm==c7, are trapped to Hyp mode.

Fields T14 and T4 are RES0.

Resets to 0.

Accessing the HSTR

To access the HSTR:

```
MRC p15,4,<Rt>,c1,c1,3 ; Read HSTR into Rt
MCR p15,4,<Rt>,c1,c1,3 ; Write Rt to HSTR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0001	011

G5.1.67 HTCR, Hyp Translation Control Register

The HTCR characteristics are:

Purpose

Controls translation table walks required for the stage 1 translation of memory accesses from Hyp mode, and holds cacheability and shareability information for the accesses.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Used in conjunction with HTTBR, that defines the translation table base address for the translations.

Configurations

HTCR is architecturally mapped to AArch64 register TCR_EL2.

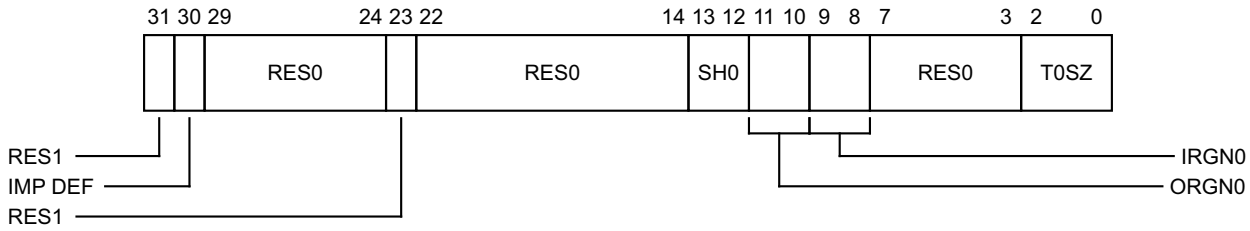
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HTCR is a 32-bit register.

Field descriptions

The HTCR bit assignments are:



Bit [31]

Reserved, RES1.

Bits [29:24]

Reserved, RES0.

Bit [23]

Reserved, RES1.

Bits [22:14]

Reserved, RES0.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0.

`00` Non-shareable

10 Outer Shareable

11 Inner Shareable

Other values are reserved.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0.

00 Normal memory, Outer Non-cacheable

01 Normal memory, Outer Write-Back Write-Allocate Cacheable

10 Normal memory, Outer Write-Through Cacheable

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0.

00 Normal memory, Inner Non-cacheable

01 Normal memory, Inner Write-Back Write-Allocate Cacheable

10 Normal memory, Inner Write-Through Cacheable

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

Bits [7:3]

Reserved, RES0.

T0SZ, bits [2:0]

The size offset of the memory region addressed by TTBR0. The region size is $2^{32-T0SZ}$ bytes.

Accessing the HTCR

To access the HTCR:

```
MRC p15,4,<Rt>,c2,c0,2 ; Read HTCR into Rt
MCR p15,4,<Rt>,c2,c0,2 ; Write Rt to HTCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0010	0000	010

G5.1.68 HTPIDR, Hyp Software Thread ID Register

The HTPIDR characteristics are:

Purpose

Provides a location where software running in Hyp mode can store thread identifying information that is not visible to Non-secure software executing at EL0 or EL1, for hypervisor management purposes.

This register is part of:

- the Virtualization registers functional group
- the Thread and process ID registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Processor hardware never updates this register.

Configurations

HTPIDR is architecturally mapped to AArch64 register TPIDR_EL2[31:0].

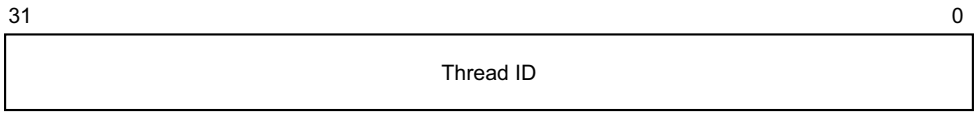
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HTPIDR is a 32-bit register.

Field descriptions

The HTPIDR bit assignments are:



Bits [31:0]

Thread ID. Thread identifying information stored by software running at this exception level.

Accessing the HTPIDR

To access the HTPIDR:

```
MRC p15,4,<Rt>,c13,c0,2 ; Read HTPIDR into Rt
MCR p15,4,<Rt>,c13,c0,2 ; Write Rt to HTPIDR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1101	0000	010

G5.1.69 HTTBR, Hyp Translation Table Base Register

The HTTBR characteristics are:

Purpose

Holds the base address of the translation table for the stage 1 translation of memory accesses from Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Used in conjunction with the HTCR.

Configurations

HTTBR is architecturally mapped to AArch64 register TTBR0_EL2.

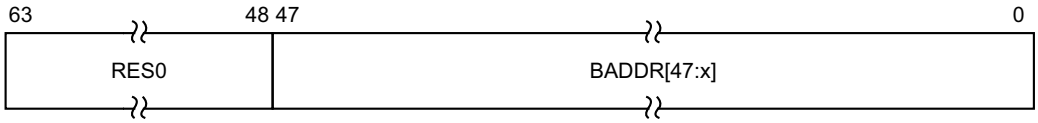
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HTTBR is a 64-bit register.

Field descriptions

The HTTBR bit assignments are:



Bits [63:48]

Reserved, RES0.

BADDR[47:x], bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of HTCR.T0SZ, and is calculated as follows:

- If HTCR.T0SZ is 0 or 1, x = 5 - HTCR.T0SZ.
- If HTCR.T0SZ is greater than 1, x = 14 - HTCR.T0SZ.

The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.

If bits [x-1:3] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:3] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

Accessing the HTTBR

To access the HTTBR:

```
MRRC p15,4,<Rt>,<Rt2>,c2 ; Read 64-bit HTTBR into Rt (low word) and Rt2 (high word)
MCRR p15,4,<Rt>,<Rt2>,c2 ; Write Rt (low word) and Rt2 (high word) to 64-bit HTTBR
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0100	0010

G5.1.70 HVBAR, Hyp Vector Base Address Register

The HVBAR characteristics are:

Purpose

Holds the exception base address for any exception that is taken to Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

HVBAR is architecturally mapped to AArch64 register VBAR_EL2[31:0].

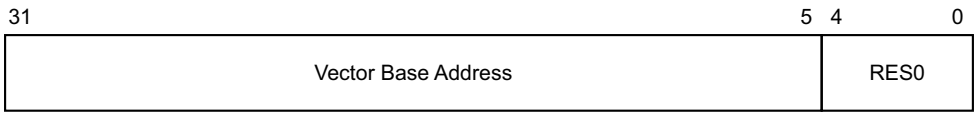
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HVBAR is a 32-bit register.

Field descriptions

The HVBAR bit assignments are:



Bits [31:5]

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken in this exception level. Bits[4:0] of an exception vector are the exception offset.

Bits [4:0]

Reserved, RES0.

Accessing the HVBAR

To access the HVBAR:

```
MRC p15,4,<Rt>,c12,c0,0 ; Read HVBAR into Rt
MCR p15,4,<Rt>,c12,c0,0 ; Write Rt to HVBAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	0000	000

G5.1.71 ICIALLU, Instruction Cache Invalidate All to PoU

The ICIALLU characteristics are:

Purpose

Invalidate all instruction caches to PoU. If branch predictors are architecturally visible, also flush branch predictors.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

ICIALLU performs the same function as AArch64 operation IC IALLU.

Attributes

ICIALLU is a 32-bit system operation.

Field descriptions

The ICIALLU operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the ICIALLU operation

To perform the ICIALLU operation:

```
MCR p15,0,<Rt>,c7,c5,0 ; ICIALLU operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0101	000

G5.1.72 ICIALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable

The ICIALLUIS characteristics are:

Purpose

Invalidate all instruction caches Inner Shareable to PoU. If branch predictors are architecturally visible, also flush branch predictors.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

ICIALLUIS performs the same function as AArch64 operation IC IALLUIS.

Attributes

ICIALLUIS is a 32-bit system operation.

Field descriptions

The ICIALLUIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the ICIALLUIS operation

To perform the ICIALLUIS operation:

```
MCR p15,0,<Rt>,c7,c1,0 ; ICIALLUIS operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0001	000

G5.1.73 ICIMVAU, Instruction Cache line Invalidate by VA to PoU

The ICIMVAU characteristics are:

Purpose

Invalidate instruction cache line by virtual address to PoU.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

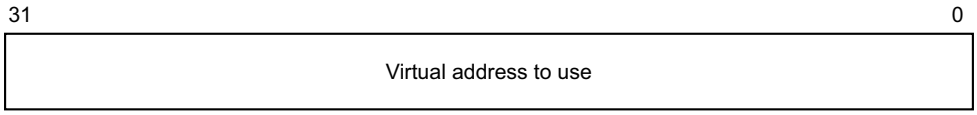
ICIMVAU performs the same function as AArch64 operation IC IVAU.

Attributes

ICIMVAU is a 32-bit system operation.

Field descriptions

The ICIMVAU input value bit assignments are:



Bits [31:0]

Virtual address to use.

Performing the ICIMVAU operation

To perform the ICIMVAU operation:

```
MCR p15,0,<Rt>,c7,c5,1 ; ICIMVAU operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0101	001

G5.1.74 ID_AFR0, Auxiliary Feature Register 0

The ID_AFR0 characteristics are:

Purpose

Provides information about the IMPLEMENTATION DEFINED features of the processor in AArch32.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with the Main ID Register, MIDR.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

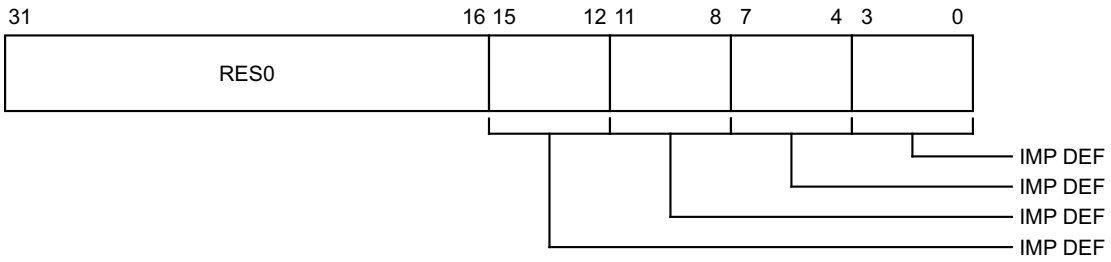
ID_AFR0 is architecturally mapped to AArch64 register ID_AFR0_EL1.

Attributes

ID_AFR0 is a 32-bit register.

Field descriptions

The ID_AFR0 bit assignments are:



Bits [31:16]

Reserved, RES0.

Bits [15:0]

IMPLEMENTATION DEFINED

Accessing the ID_AFR0

To access the ID_AFR0:

```
MRC p15,0,<Rt>,c0,c1,3 ; Read ID_AFR0 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0001	011

G5.1.75 ID_DFR0, Debug Feature Register 0

The ID_DFR0 characteristics are:

Purpose

Provides top level information about the debug system in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with the Main ID Register, MIDR.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

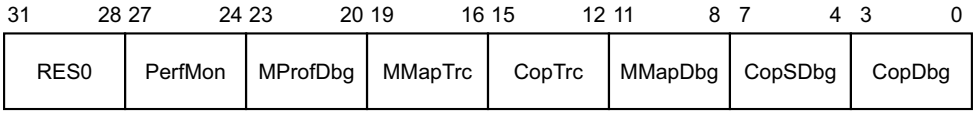
ID_DFR0 is architecturally mapped to AArch64 register ID_DFR0_EL1.

Attributes

ID_DFR0 is a 32-bit register.

Field descriptions

The ID_DFR0 bit assignments are:



Bits [31:28]

Reserved, RES0.

PerfMon, bits [27:24]

Performance Monitors. Support for coprocessor-based ARM Performance Monitors Extension, for A and R profile PEs. Possible values are:

`0000` Performance Monitors Extension system registers not implemented.

Note

`0000` means that either the Performance Monitors are not implemented or PMUv1 is implemented. PMUv1 is not permitted in ARMv8.

`0001` Support for Performance Monitors Extension version 1 (PMUv1) system registers. Not permitted in ARMv8.

`0010` Support for Performance Monitors Extension version 2 (PMUv2) system registers. Not permitted in ARMv8.

`0011` Support for Performance Monitors Extension version 3 (PMUv3) system registers.

`1111` IMPLEMENTATION DEFINED form of Performance Monitors system registers supported. PMUv3 not supported.

Note

1111 means that the Performance Monitors extension is not implemented, and an IMPLEMENTATION DEFINED form of performance monitors might be implemented. In ARMv8, this always means that an implementation defined form of performance monitors is implemented.

All other values are reserved.

MProfDbg, bits [23:20]

M Profile Debug. Support for memory-mapped debug model for M profile processors. Permitted values are:

0000 Not supported.

0001 Support for M profile Debug architecture, with memory-mapped access. Not supported in ARMv8.

All other values are reserved.

MMapTrc, bits [19:16]

Memory Mapped Trace. Support for memory-mapped trace model. Permitted values are:

0000 Not supported.

0001 Support for ARM trace architecture, with memory-mapped access.

All other values are reserved.

In the Trace registers, the ETMIDR gives more information about the implementation.

CopTrc, bits [15:12]

Coprocessor Trace. Support for coprocessor-based trace model. Permitted values are:

0000 Not supported.

0001 Support for ARM trace architecture, with CP14 access.

All other values are reserved.

In the Trace registers, the ETMIDR gives more information about the implementation.

MMapDbg, bits [11:8]

Memory Mapped Debug. Support for v7 memory-mapped debug model, for A and R profile PEs

0000 Not supported, or pre-ARMv6 implementation.

0100 Support for v7 Debug architecture, with memory-mapped access. Not supported in ARMv8.

0101 Support for v7.1 Debug architecture, with memory-mapped access. Not supported in ARMv8.

All other values are reserved.

In ARMv8-A this field is RES0. The optional memory map defined by ARMv8-A is not compatible with ARMv7-A.

CopSDbg, bits [7:4]

Coprocessor Secure Debug. Support for coprocessor-based Secure debug model.

0000 Not supported.

0011 Support for v6.1 Debug architecture, with CP14 access. Not supported in ARMv8.

0100 Support for v7 Debug architecture, with CP 14 access. Not supported in ARMv8.

0101 Support for v7.1 Debug architecture, with CP 14 access. Not supported in ARMv8.

0110 Support for v8 Debug architecture, with CP14 access.

All other values are reserved.

If the PE only supports Non-secure state, this field is 0000. Otherwise, this field reads the same as ID_DFR0[3:0].

CopDbg, bits [3:0]

Coprocessor Debug. Support for coprocessor based debug model, for A and R profile PEs. Permitted values are:

0000 Not supported. Not supported in an ARMv8 implementation.

0010 Support for v6 Debug architecture, with CP14 access. Not supported in ARMv8.

0011 Support for v6.1 Debug architecture, with CP14 access.Not supported in ARMv8.

0100 Support for v7 Debug architecture, with CP14 access.Not supported in ARMv8.

0101 Support for v7.1 Debug architecture, with CP14 access. Not supported in ARMv8.

0110 Support for v8-A debug architecture, with CP14 access.

All other values are reserved.

Accessing the ID_DFR0

To access the ID_DFR0:

```
MRC p15,0,<Rt>,c0,c1,2 ; Read ID_DFR0 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0001	010

G5.1.76 ID_ISAR0, Instruction Set Attribute Register 0

The ID_ISAR0 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

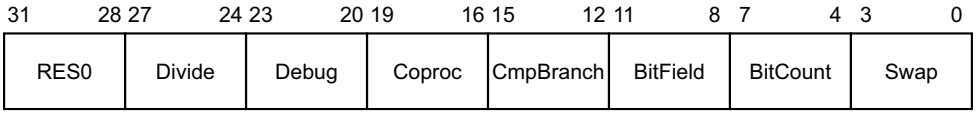
ID_ISAR0 is architecturally mapped to AArch64 register ID_ISAR0_EL1.

Attributes

ID_ISAR0 is a 32-bit register.

Field descriptions

The ID_ISAR0 bit assignments are:



Bits [31:28]

Reserved, RES0.

Divide, bits [27:24]

Indicates the implemented Divide instructions. Permitted values are:

`0000` None implemented. Not supported in ARMv8.

`0001` Adds SDIV and UDIV in the T32 instruction set. Not supported in ARMv8.

`0010` As for `0001`, and adds SDIV and UDIV in the A32 instruction set.

All other values are reserved.

Debug, bits [23:20]

Indicates the implemented Debug instructions. Permitted values are:

`0000` None implemented. Not supported in ARMv8.

`0001` Adds BKPT.

All other values are reserved.

Coproc, bits [19:16]

Indicates the implemented Coprocessor instructions. Permitted values are:

`0000` None implemented, except for instructions separately attributed by the architecture, including CP15, CP14, and Advanced SIMD and floating-point.

0001 Adds generic CDP, LDC, MCR, MRC, and STC. Not supported in ARMv8.

0010 As for 0001, and adds generic CDP2, LDC2, MCR2, MRC2, and STC2. Not supported in ARMv8.

0011 As for 0010, and adds generic MCRR and MRRC. Not supported in ARMv8

0100 As for 0011, and adds generic MCRR2 and MRRC2. Not supported in ARMv8

All other values are reserved.

CmpBranch, bits [15:12]

Indicates the implemented combined Compare and Branch instructions in the T32 instruction set. Permitted values are:

0000 None implemented. Not supported in ARMv8.

0001 Adds CBNZ and CBZ.

All other values are reserved.

BitField, bits [11:8]

Indicates the implemented BitField instructions. Permitted values are:

0000 None implemented. Not supported in ARMv8.

0001 Adds BFC, BFI, SBFX, and UBFX.

All other values are reserved.

BitCount, bits [7:4]

Indicates the implemented Bit Counting instructions. Permitted values are:

0000 None implemented. Not supported in ARMv8

0001 Adds CLZ.

All other values are reserved.

Swap, bits [3:0]

Indicates the implemented Swap instructions in the A32 instruction set. Permitted values are:

0000 None implemented.

0001 Adds SWP and SWPB. Not supported in ARMv8.

All other values are reserved.

Accessing the ID_ISAR0

To access the ID_ISAR0:

```
MRC p15,0,<Rt>,c0,c2,0 ; Read ID_ISAR0 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0010	000

G5.1.77 ID_ISAR1, Instruction Set Attribute Register 1

The ID_ISAR1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID_ISAR0, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

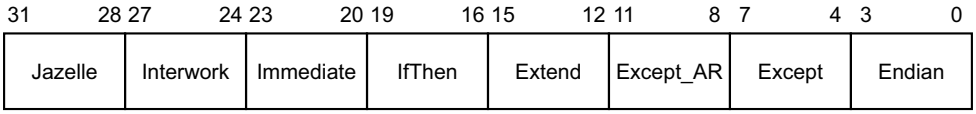
ID_ISAR1 is architecturally mapped to AArch64 register ID_ISAR1_EL1.

Attributes

ID_ISAR1 is a 32-bit register.

Field descriptions

The ID_ISAR1 bit assignments are:



Jazelle, bits [31:28]

Indicates the implemented Jazelle extension instructions. Permitted values are:

`0000` No support for Jazelle. Not supported in ARMv8.

`0001` Adds the BXJ instruction, and the J bit in the PSR. This setting might indicate a trivial implementation of the Jazelle extension.

All other values are reserved.

Interwork, bits [27:24]

Indicates the implemented Interworking instructions. Permitted values are:

`0000` None implemented. Not supported in ARMv8.

`0001` Adds the BX instruction, and the T bit in the PSR. Not supported in ARMv8.

`0010` As for `0001`, and adds the BLX instruction. PC loads have BX-like behavior. Not supported in ARMv8.

`0011` As for `0010`, and guarantees that data-processing instructions in the A32 instruction set with the PC as the destination and the S bit clear have BX-like behavior.

All other values are reserved.

Note

A value of 0000, 0001, or 0010, in this field does not guarantee that an ARM data-processing instruction with the PC as the destination and the S bit clear behaves like an old MOV PC instruction, ignoring bits[1:0] of the result. With these values of this field:

- If bits[1:0] of the result value are 0b00, then the PE remains in A32 state.
- If bits[1:0] are 0b01, 0b10, or 0b11, then the result must be treated as UNPREDICTABLE.

Immediate, bits [23:20]

Indicates the implemented data-processing instructions with long immediates. Permitted values are:

0000 None implemented. Not supported in ARMv8.

0001 Adds:

- The MOVT instruction.
- The MOV instruction encodings with zero-extended 16-bit immediates.
- The T32 ADD and SUB instruction encodings with zero-extended 12-bit immediates, and the other ADD, ADR, and SUB encodings cross-referenced by the pseudocode for those encodings.

All other values are reserved.

IfThen, bits [19:16]

Indicates the implemented If-Then instructions in the T32 instruction set. Permitted values are:

0000 None implemented. Not supported in ARMv8.

0001 Adds the IT instructions, and the IT bits in the PSRs.

All other values are reserved.

Extend, bits [15:12]

Indicates the implemented Extend instructions. Permitted values are:

0000 No base instruction set sign-extend or zero-extend instructions are implemented. Not supported in ARMv8.

0001 Adds the SXTB, SXTH, UXTB, and UXTH instructions. Not supported in ARMv8.

0010 As for 0001, and adds the SXTB16, SXTAB, SXTAB16, SXTAH, UXTB16, UXTAB, UXTAB16, and UXTAH instructions.

Note

In addition:

- The shift options on these instruction are available only if the ID_ISAR4.WithShifts attribute is 0b0011 or greater.
- The SXTAB16, SXTB16, UXTAB16, and UXTB16 instructions are implemented only if both:
  - The Extend attribute is 0b0010 or greater.
  - The ID_ISAR3.SIMD attribute is 0b0011 or greater.

All other values are reserved.

Except_AR, bits [11:8]

Indicates the implemented A and R profile exception-handling instructions. Permitted values are:

0000 None implemented. Not supported in ARMv8.

0001 Adds the SRS and RFE instructions, and the A and R profile forms of the CPS instruction.

All other values are reserved.

Except, bits [7:4]

Indicates the implemented exception-handling instructions in the A32 instruction set. Permitted values are:

`0000` Not implemented. This indicates that the User bank and Exception return forms of the LDM and STM instructions are not implemented. Not supported in ARMv8.

`0001` Adds the LDM (exception return), LDM (user registers), and STM (user registers) instruction versions.

All other values are reserved.

Endian, bits [3:0]

Indicates the implemented Endian instructions. Permitted values are:

`0000` None implemented. Not supported in ARMv8.

`0001` Adds the SETEND instruction, and the E bit in the PSRs.

All other values are reserved.

Accessing the ID_ISAR1

To access the ID_ISAR1:

```
MRC p15,0,<Rt>,c0,c2,1 ; Read ID_ISAR1 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0010	001

G5.1.78 ID_ISAR2, Instruction Set Attribute Register 2

The ID_ISAR2 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR3, ID_ISAR4, and ID_ISAR5.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

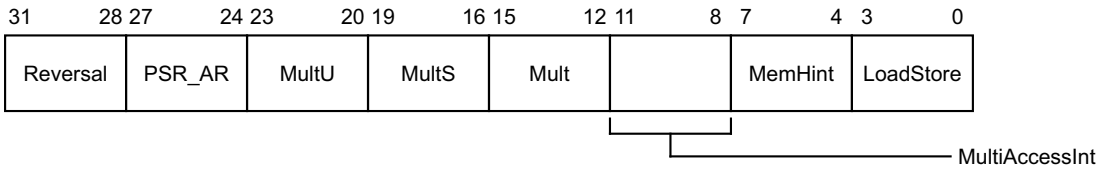
ID_ISAR2 is architecturally mapped to AArch64 register ID_ISAR2_EL1.

Attributes

ID_ISAR2 is a 32-bit register.

Field descriptions

The ID_ISAR2 bit assignments are:



Reversal, bits [31:28]

Indicates the implemented Reversal instructions. Permitted values are:

`0000` None implemented. Not supported in ARMv8.

`0001` Adds the REV, REV16, and REVSH instructions.Not supported in ARMv8.

`0010` As for `0001`, and adds the RBIT instruction.

All other values are reserved.

PSR_AR, bits [27:24]

Indicates the implemented A and R profile instructions to manipulate the PSR. Permitted values are:

`0000` None implemented. Not supported in ARMv8.

`0001` Adds the MRS and MSR instructions, and the exception return forms of data-processing instructions.

All other values are reserved.

Note

The exception return forms of the data-processing instructions are:

- In the A32 instruction set, data-processing instructions with the PC as the destination and the S bit set. These instructions might be affected by the WithShifts attribute.
- In the T32 instruction set, the SUBS PC,LR,#N instruction.

MultU, bits [23:20]

Indicates the implemented advanced unsigned Multiply instructions. Permitted values are:

`0000` None implemented. Not supported in ARMv8.

`0001` Adds the UMULL and UMLAL instructions. Not supported in ARMv8.

`0010` As for `0001`, and adds the UMAAL instruction.

All other values are reserved.

MultS, bits [19:16]

Indicates the implemented advanced signed Multiply instructions. Permitted values are:

`0000` None implemented. Not supported in ARMv8.

`0001` Adds the SMULL and SMLAL instructions. Not supported in ARMv8.

`0010` As for `0001`, and adds the SMLABB, SMLABT, SMLALBB, SMLALBT, SMLALTB, SMLALTT, SMLATB, SMLATT, SMLAWB, SMLAWT, SMULBB, SMULBT, SMULTB, SMULTT, SMULWB, and SMULWT instructions. Also adds the Q bit in the PSRs.Not supported in ARMv8.

`0011` As for `0010`, and adds the SMLAD, SMLADX, SMLALD, SMLALDX, SMLSD, SMLSDX, SMLSLD, SMLSLDX, SMMLA, SMMLAR, SMMLS, SMMLSR, SMMUL, SMMULR, SMUAD, SMUADX, SMUSD, and SMUSDX instructions.

All other values are reserved.

Mult, bits [15:12]

Indicates the implemented additional Multiply instructions. Permitted values are:

`0000` No additional instructions implemented. This means only MUL is implemented. Not supported in ARMv8.

`0001` Adds the MLA instruction. Not supported in ARMv8.

`0010` As for `0001`, and adds the MLS instruction.

All other values are reserved.

MultiAccessInt, bits [11:8]

Indicates the support for interruptible multi-access instructions. Permitted values are:

`0000` No support. This means the LDM and STM instructions are not interruptible.

`0001` LDM and STM instructions are restartable.

`0010` LDM and STM instructions are continuable. Not supported in ARMv8.

All other values are reserved.

MemHint, bits [7:4]

Indicates the implemented Memory Hint instructions. Permitted values are:

`0000` None implemented. Not supported in ARMv8.

`0001` Adds the PLD instruction. Not supported in ARMv8.

`0010` Adds the PLD instruction.

Note

0001 and 0010 have the same effect.

0011 As for 0001 and 0010, and adds the PLI instruction.

0100 As for 0011, and adds the PLDW instruction.

All other values are reserved.

LoadStore, bits [3:0]

Indicates the implemented additional load/store instructions. Permitted values are:

0000 No additional load/store instructions implemented. Not supported in ARMv8.

0001 Adds the LDRD and STRD instructions. Not supported in ARMv8.

0010 As for 0001, and adds the Load Acquire (LDAB, LDAH, LDA, LDAEXB, LDAEXH, LDAEX, LDAEXD) and Store Release (STLB, STLH, STL, STLEXB, STLEXH, STLEX, STLEXD) instructions.

All other values are reserved.

Accessing the ID_ISAR2

To access the ID_ISAR2:

```
MRC p15,0,<Rt>,c0,c2,2 ; Read ID_ISAR2 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0010	010

G5.1.79 ID_ISAR3, Instruction Set Attribute Register 3

The ID_ISAR3 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR4, and ID_ISAR5.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

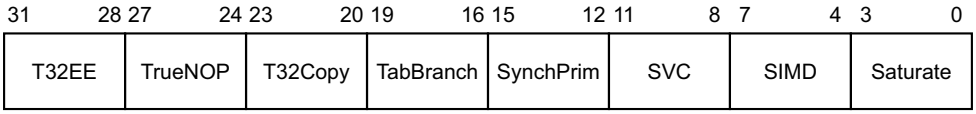
ID_ISAR3 is architecturally mapped to AArch64 register ID_ISAR3_EL1.

Attributes

ID_ISAR3 is a 32-bit register.

Field descriptions

The ID_ISAR3 bit assignments are:



T32EE, bits [31:28]

Indicates the implemented T32EE instructions. Permitted values are:

`0000` None implemented.

`0001` Adds the ENTERX and LEAVEX instructions, and modifies the load behavior to include null checking. Not supported in ARMv8.

All other values are reserved.

TrueNOP, bits [27:24]

Indicates the implemented explicit NOP instructions. Permitted values are:

`0000` None implemented. This means there are no NOP instructions that do not have any register dependencies. Not supported in ARMv8.

`0001` Adds explicit NOP instructions in both the T32 and A32 instruction sets. This also permits additional NOP-compatible hints.

All other values are reserved.

T32Copy, bits [23:20]

Indicates the support for T32 non flag-setting MOV instructions. Permitted values are:

`0000` Not supported. This means that in the T32 instruction set, encoding T1 of the MOV (register) instruction does not support a copy from a low register to a low register.

0001 Adds support for T32 instruction set encoding T1 of the MOV (register) instruction, copying from a low register to a low register. Not supported in ARMv8.

All other values are reserved.

TabBranch, bits [19:16]

Indicates the implemented Table Branch instructions in the T32 instruction set. Permitted values are:

0000 None implemented.

0001 Adds the TBB and TBH instructions. Not supported in ARMv8.

All other values are reserved.

SynchPrim, bits [15:12]

Used in conjunction with ID_ISAR4.SynchPrim_frac to indicate the implemented Synchronization Primitive instructions. Permitted values are:

0000 If SynchPrim_frac == 0000, no Synchronization Primitives implemented. Not supported in ARMv8.

0001 If SynchPrim_frac == 0000, adds the LDREX and STREX instructions. Not supported in ARMv8.

If SynchPrim_frac == 0011, also adds the CLREX, LDREXB, STREXB, and STREXH instructions. Not supported in ARMv8.

0010 If SynchPrim_frac == 0000, as for 0001and 0011, and also adds the LDREXD and STREXD instructions.

All other combinations of SynchPrim and SynchPrim_frac are reserved.

SVC, bits [11:8]

Indicates the implemented SVC instructions. Permitted values are:

0000 Not implemented. Not supported in ARMv8.

0001 Adds the SVC instruction.

All other values are reserved.

Note

The SVC instruction was called the SWI instruction in previous versions of the architecture.

SIMD, bits [7:4]

Indicates the implemented SIMD instructions. Permitted values are:

0000 None implemented. Not supported in ARMv8.

0001 Adds the SSAT and USAT instructions, and the Q bit in the PSRs. Not supported in ARMv8.

0011 As for 0001, and adds the PKHBT, PKHTB, QADD16, QADD8, QASX, QSUB16, QSUB8, QSAX, SADD16, SADD8, SASX, SEL, SHADD16, SHADD8, SHASX, SHSUB16, SHSUB8, SHSAX, SSAT16, SSUB16, SSUB8, SSAX, SXTAB16, SXTB16, UADD16, UADD8, UASX, UHADD16, UHADD8, UHASX, UHSUB16, UHSUB8, UHSAX, UQADD16, UQADD8, UQASX, UQSUB16, UQSUB8, UQSAX, USAD8, USADA8, USAT16, USUB16, USUB8, USAX, UXTAB16, and UXTB16 instructions. Also adds support for the GE[3:0] bits in the PSRs.

All other values are reserved.

Note

- The SXTAB16, SXTB16, UXTAB16, and UXTB16 instructions are implemented only if both:
  - The ID_ISAR1.Extend attribute is 0b0010 or greater.
  - The ID_ISAR3.SIMD attribute is 0b0011 or greater.
- The SIMD field relates only to implemented instructions that perform SIMD operations on the general-purpose registers. MVFR0, MVFR1, and MVFR2 give information about the SIMD instructions implemented by the optional Advanced SIMD functionality.

Saturate, bits [3:0]

Indicates the implemented Saturate instructions. Permitted values are:

0000 None implemented. This means no base instruction set saturate instructions are implemented. Not supported in ARMv8.

0001 Adds the QADD, QDADD, QDSUB, and QSUB instructions, and the Q bit in the PSRs.

All other values are reserved.

Accessing the ID_ISAR3

To access the ID_ISAR3:

```
MRC p15,0,<Rt>,c0,c2,3 ; Read ID_ISAR3 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0010	011

G5.1.80 ID_ISAR4, Instruction Set Attribute Register 4

The ID_ISAR4 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, and ID_ISAR5.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

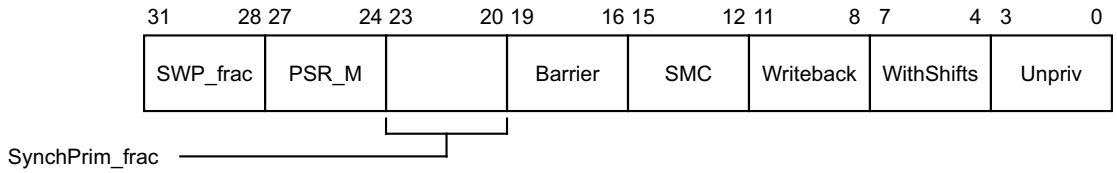
ID_ISAR4 is architecturally mapped to AArch64 register ID_ISAR4_EL1.

Attributes

ID_ISAR4 is a 32-bit register.

Field descriptions

The ID_ISAR4 bit assignments are:



SWP_frac, bits [31:28]

Indicates support for the memory system locking the bus for SWP or SWPB instructions. Permitted values are:

`0000` SWP or SWPB instructions not implemented.

`0001` SWP or SWPB implemented but only in a uniprocessor context. SWP and SWPB do not guarantee whether memory accesses from other masters can come between the load memory access and the store memory access of the SWP or SWPB. Not supported in ARMv8.

All other values are reserved. This field is valid only if the ID_ISAR0.Swap_instrs field is `0000`.

In v8-A this field is `0000`. The SWP and SWPB instructions are not supported in v8-A.

PSR_M, bits [27:24]

Indicates the implemented M profile instructions to modify the PSRs. Permitted values are:

`0000` None implemented.

`0001` Adds the M profile forms of the CPS, MRS, and MSR instructions. Not supported in ARMv8.

All other values are reserved.

SynchPrim_frac, bits [23:20]

Used in conjunction with ID_ISAR3.SynchPrim to indicate the implemented Synchronization Primitive instructions. Possible values are:

`0000` If SynchPrim == `0000`, no Synchronization Primitives implemented. Not supported in ARMv8.

If SynchPrim == `0001`, adds the LDREX and STREX instructions. Not supported in ARMv8.

If SynchPrim == `0010`, also adds the CLREX, LDREXB, LDREXH, STREXB, STREXH, LDREXD, and STREXD instructions. Not supported in ARMv8.

`0011` If SynchPrim == `0001`, adds the LDREX, STREX, CLREX, LDREXB, LDREXH, STREXB, and STREXH instructions.

All other combinations of SynchPrim and SynchPrim_frac are reserved.

Barrier, bits [19:16]

Indicates the implemented Barrier instructions in the A32 and T32 instruction sets. Permitted values are:

`0000` None implemented. Barrier operations are provided only as CP15 operations. Not permitted in ARMv8.

`0001` Adds the DMB, DSB, and ISB barrier instructions.

All other values are reserved.

SMC, bits [15:12]

Indicates the implemented SMC instructions. Permitted values are:

`0000` None implemented. Not permitted in ARMv8.

`0001` Adds the SMC instruction.

All other values are reserved.

Note

The SMC instruction was called the SMI instruction in previous versions of the architecture.

Writeback, bits [11:8]

Indicates the support for Writeback addressing modes. Permitted values are:

`0000` Basic support. Only the LDM, STM, PUSH, POP, SRS, and RFE instructions support writeback addressing modes. These instructions support all of their writeback addressing modes. Not supported in ARMv8.

`0001` Adds support for all of the writeback addressing modes.

All other values are reserved.

WithShifts, bits [7:4]

Indicates the support for instructions with shifts. Permitted values are:

`0000` Nonzero shifts supported only in MOV and shift instructions. Not supported in ARMv8.

`0001` Adds support for shifts of loads and stores over the range LSL 0-3. Not supported in ARMv8.

`0011` As for `0001`, and adds support for other constant shift options, both on load/store and other instructions. Not supported in ARMv8.

`0100` As for `0011`, and adds support for register-controlled shift options.

All other values are reserved.

Note

- Additions to the basic support indicated by the 0b0000 field value only apply when the encoding supports them. In particular, in the T32 instruction set there is no difference between the 0b0011 and 0b0100 levels of support.
- MOV instructions with shift options are treated as ASR, LSL, LSR, ROR, or RRX instructions.

Unpriv, bits [3:0]

Indicates the implemented unprivileged instructions. Permitted values are:

0000 None implemented. No T variant instructions are implemented. Not supported in ARMv8.

0001 Adds the LDRBT, LDRT, STRBT, and STRT instructions. Not supported in ARMv8.

0010 As for 0001, and adds the LDRHT, LDRSBT, LDRSHT, and STRHT instructions.

All other values are reserved.

Accessing the ID_ISAR4

To access the ID_ISAR4:

```
MRC p15,0,<Rt>,c0,c2,4 ; Read ID_ISAR4 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0010	100

G5.1.81 ID_ISAR5, Instruction Set Attribute Register 5

The ID_ISAR5 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, and ID_ISAR4.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

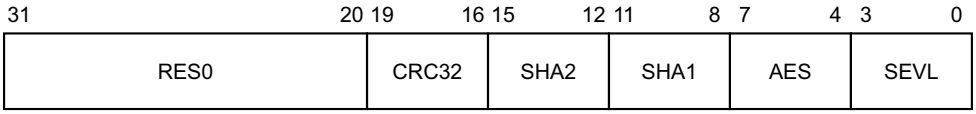
ID_ISAR5 is architecturally mapped to AArch64 register ID_ISAR5_EL1.

Attributes

ID_ISAR5 is a 32-bit register.

Field descriptions

The ID_ISAR5 bit assignments are:



Bits [31:20]

Reserved, RES0.

CRC32, bits [19:16]

Indicates whether CRC32 instructions are implemented in AArch32 state.

`0000` No CRC32 instructions implemented.

`0001` CRC32B, CRC32H, CRC32W, CRC32CB, CRC32CH, and CRC32CW instructions implemented.

All other values are reserved.

This field must have the same value as ID_AA64ISAR0_EL1.CRC32. The architecture requires that if CRC32 is supported in one Execution state, it must be supported in both Execution states.

SHA2, bits [15:12]

Indicates whether SHA2 instructions are implemented in AArch32 state.

`0000` No SHA2 instructions implemented.

`0001` SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 implemented.

All other values are reserved.

SHA1, bits [11:8]

Indicates whether SHA1 instructions are implemented in AArch32 state.

0000 No SHA1 instructions implemented.

0001 SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 implemented.

All other values are reserved.

AES, bits [7:4]

Indicates whether AES instructions are implemented in AArch32 state.

0000 No AES instructions implemented.

0001 AESE, AESD, AESMC, and AESIMC implemented.

0010 As for 0001, with the addition of PMULL/PMULL2 instructions operating on 64-bit data quantities.

All other values are reserved.

SEVL, bits [3:0]

Indicates whether the SEVL instruction is implemented in AArch32 state.

0000 SEVL is implemented as a NOP.

0001 SEVL is implemented as Send Event Local.

Accessing the ID_ISAR5

To access the ID_ISAR5:

```
MRC p15,0,<Rt>,c0,c2,5 ; Read ID_ISAR5 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0010	101

G5.1.82 ID_MMFR0, Memory Model Feature Register 0

The ID_MMFR0 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID_MMFR1, ID_MMFR2, and ID_MMFR3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

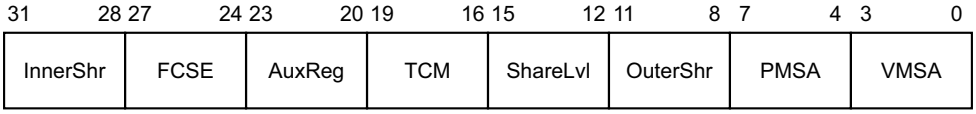
ID_MMFR0 is architecturally mapped to AArch64 register ID_MMFR0_EL1.

Attributes

ID_MMFR0 is a 32-bit register.

Field descriptions

The ID_MMFR0 bit assignments are:



InnerShr, bits [31:28]

Innermost Shareability. Indicates the innermost shareability domain implemented. Permitted values are:

`0000` Implemented as Non-cacheable.

`0001` Implemented with hardware coherency support.

1111 Shareability ignored.

All other values are reserved.

This field is valid only if the implementation distinguishes between Inner Shareable and Outer Shareable, by implementing two levels of shareability, as indicated by the value of the Shareability levels field, bits[15:12].

When the Shareability level field is zero, this field is UNKNOWN.

FCSE, bits [27:24]

Indicates whether the implementation includes the FCSE. Permitted values are:

`0000` Not supported.

`0001` Support for FCSE. No supported in ARMv8.

All other values are reserved.

The value of `0001` is only permitted when the VMSA field has a value greater than `0010`.

AuxReg, bits [23:20]

Auxiliary Registers. Indicates support for Auxiliary registers. Permitted values are:

`0000` None supported. Not supported in ARMv8.

`0001` Support for Auxiliary Control Register only. Not supported in ARMv8.

`0010` Support for Auxiliary Fault Status Registers (AIFSR and ADFSR) and Auxiliary Control Register.

All other values are reserved.

TCM, bits [19:16]

Indicates support for TCMs and associated DMAs. Permitted values are:

`0000` Not supported.

`0001` Support is IMPLEMENTATION DEFINED.

`0010` Support for TCM only, ARMv6 implementation. Not supported in ARMv8.

`0011` Support for TCM and DMA, ARMv6 implementation. Not supported in ARMv8.

All other values are reserved.

ShareLvl, bits [15:12]

Shareability Levels. Indicates the number of shareability levels implemented. Permitted values are:

`0000` One level of shareability implemented.

`0001` Two levels of shareability implemented.

All other values are reserved.

OuterShr, bits [11:8]

Outermost Shareability. Indicates the outermost shareability domain implemented. Permitted values are:

`0000` Implemented as Non-cacheable.

`0001` Implemented with hardware coherency support.

`1111` Shareability ignored.

All other values are reserved.

PMSA, bits [7:4]

Indicates support for a PMSA. Permitted values are:

`0000` Not supported.

`0001` Support for IMPLEMENTATION DEFINED PMSA. Not supported in ARMv8.

`0010` Support for PMSAv6, with a Cache Type Register implemented. Not supported in ARMv8.

`0011` Support for PMSAv7, with support for memory subsections. ARMv7-R profile. Not supported in ARMv8.

All other values are reserved.

When the PMSA field is set to a value other than `0000` the VMSA field must be set to `0000`.

VMSA, bits [3:0]

Indicates support for a VMSA. Permitted values are:

`0000` Not supported. Not supported in ARMv8.

`0001` Support for IMPLEMENTATION DEFINED VMSA. Not supported in ARMv8.

`0010` Support for VMSAv6, with Cache and TLB Type Registers implemented.

`0011` Support for VMSAv7, with support for remapping and the Access flag. ARMv7-A profile. Not supported in ARMv8.

0100 As for 0011, and adds support for the PXN bit in the Short-descriptor translation table format descriptors. Not supported in ARMv8.

0101 As for 0100, and adds support for the Long-descriptor translation table format.

All other values are reserved.

When the VMSA field is set to a value other than 0000 the PMSA field must be set to 0000.

Accessing the ID_MMFR0

To access the ID_MMFR0:

```
MRC p15,0,<Rt>,c0,c1,4 ; Read ID_MMFR0 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0001	100

G5.1.83 ID_MMFR1, Memory Model Feature Register 1

The ID_MMFR1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID_MMFR0, ID_MMFR2, and ID_MMFR3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

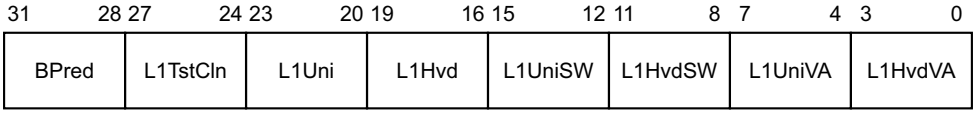
ID_MMFR1 is architecturally mapped to AArch64 register ID_MMFR1_EL1.

Attributes

ID_MMFR1 is a 32-bit register.

Field descriptions

The ID_MMFR1 bit assignments are:



BPred, bits [31:28]

Branch Predictor. Indicates branch predictor management requirements. Permitted values are:

`0000` No branch predictor, or no MMU present. Implies a fixed MPU configuration. Not supported in ARMv8.

`0001` Branch predictor requires flushing on:

- Enabling or disabling the MMU.
- Writing new data to instruction locations.
- Writing new mappings to the translation tables.
- Any change to the TTBR0, TTBR1, or TTBCR registers.
- Changes of FCSE ProcessID or ContextID.

Not supported in ARMv8.

`0010` Branch predictor requires flushing on:

- Enabling or disabling the MMU.
- Writing new data to instruction locations.
- Writing new mappings to the translation tables.
- Any change to the TTBR0, TTBR1, or TTBCR registers without a corresponding change to the FCSE ProcessID or ContextID.

Not supported in ARMv8.

0011 Branch predictor requires flushing only on writing new data to instruction locations. Not supported in ARMv8.

0100 For execution correctness, branch predictor requires no flushing at any time.

All other values are reserved.

Note

The branch predictor is described in some documentation as the Branch Target Buffer.

L1TstCln, bits [27:24]

Level 1 cache Test and Clean. Indicates the supported Level 1 data cache test and clean operations, for Harvard or unified cache implementations. Permitted values are:

0000 None supported. This is the required setting for ARMv7.

0001 Supported Level 1 data cache test and clean operations are:

- Test and clean data cache.

0010 As for 0001, and adds:

- Test, clean, and invalidate data cache.

All other values are reserved.

L1Uni, bits [23:20]

Level 1 Unified cache. Indicates the supported entire Level 1 cache maintenance operations, for a unified cache implementation. Permitted values are:

0000 None supported.

0001 Supported entire Level 1 cache operations are:

- Invalidate cache, including branch predictor if appropriate.
- Invalidate branch predictor, if appropriate.

Not supported in ARMv8.

0010 As for 0001, and adds:

- Clean cache, using a recursive model that uses the cache dirty status bit.
- Clean and invalidate cache, using a recursive model that uses the cache dirty status bit.

Not supported in ARMv8.

All other values are reserved.

If this field is set to a value other than 0000 then the L1 Harvard cache field, bits[19:16], must be set to 0000.

Note

ARMv8 requires a hierarchical cache implementation.

L1Hvd, bits [19:16]

Level 1 Harvard cache. Indicates the supported entire Level 1 cache maintenance operations, for a Harvard cache implementation. Permitted values are:

0000 None supported.

0001 Supported entire Level 1 cache operations are:

- Invalidate instruction cache, including branch predictor if appropriate.
- Invalidate branch predictor, if appropriate.

Not supported in ARMv8.

0010 As for 0001, and adds:

- Invalidate data cache.
- Invalidate data cache and instruction cache, including branch predictor if appropriate.

Not supported in ARMv8.

0011 As for 0010, and adds:

- Clean data cache, using a recursive model that uses the cache dirty status bit.
- Clean and invalidate data cache, using a recursive model that uses the cache dirty status bit.

Not supported in ARMv8.

All other values are reserved.

If this field is set to a value other than 0000 then the L1 unified cache field, bits[23:20], must be set to 0000.

Note

ARMv8 requires a hierarchical cache implementation.

L1UniSW, bits [15:12]

Level 1 Unified cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a unified cache implementation. Permitted values are:

0000 None supported.

0001 Supported Level 1 unified cache line maintenance operations by set/way are:

- Clean cache line by set/way.

Not supported in ARMv8.

0010 As for 0001, and adds:

- Clean and invalidate cache line by set/way.

Not supported in ARMv8.

0011 As for 0010, and adds:

- Invalidate cache line by set/way.

Not supported in ARMv8.

All other values are reserved.

If this field is set to a value other than 0000 then the L1 Harvard cache s/w field, bits[11:8], must be set to 0000.

Note

ARMv8 requires a hierarchical cache implementation.

L1HvdSW, bits [11:8]

Level 1 Harvard cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a Harvard cache implementation. Permitted values are:

0000 None supported.

0001 Supported Level 1 Harvard cache line maintenance operations by set/way are:

- Clean data cache line by set/way.
- Clean and invalidate data cache line by set/way.

Not supported in ARMv8.

0010 As for 0001, and adds:

- Invalidate data cache line by set/way.

Not supported in ARMv8.

0011 As for 0010, and adds:

- Invalidate instruction cache line by set/way.

Not supported in ARMv8.

All other values are reserved.

If this field is set to a value other than 0000 then the L1 unified cache s/w field, bits[15:12], must be set to 0000.

Note

ARMv8 requires a hierarchical cache implementation.

L1UniVA, bits [7:4]

Level 1 Unified cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a unified cache implementation. Permitted values are:

0000 None supported.

0001 Supported Level 1 unified cache line maintenance operations by VA are:

- Clean cache line by VA.
- Invalidate cache line by VA.
- Clean and invalidate cache line by VA.

Not supported in ARMv8.

0010 As for 0001, and adds:

- Invalidate branch predictor by VA, if branch predictor is implemented.

Not supported in ARMv8.

All other values are reserved.

If this field is set to a value other than 0000 then the L1 Harvard cache VA field, bits[3:0], must be set to 0000.

Note

ARMv8 requires a hierarchical cache implementation.

L1HvdVA, bits [3:0]

Level 1 Harvard cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a Harvard cache implementation. Permitted values are:

0000 None supported.

0001 Supported Level 1 Harvard cache line maintenance operations by VA are:

- Clean data cache line by VA.
- Invalidate data cache line by VA.
- Clean and invalidate data cache line by VA.
- Clean instruction cache line by VA.

Not supported in ARMv8.

0010 As for 0001, and adds:

- Invalidate branch predictor by VA, if branch predictor is implemented.

Not supported in ARMv8.

All other values are reserved.

If this field is set to a value other than 0000 then the L1 unified cache VA field, bits[7:4], must be set to 0000.

Note

ARMv8 requires a hierarchical cache implementation.

Accessing the ID_MMFR1

To access the ID_MMFR1:

```
MRC p15,0,<Rt>,c0,c1,5 ; Read ID_MMFR1 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0001	101

G5.1.84 ID_MMFR2, Memory Model Feature Register 2

The ID_MMFR2 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID_MMFR0, ID_MMFR1, and ID_MMFR3.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

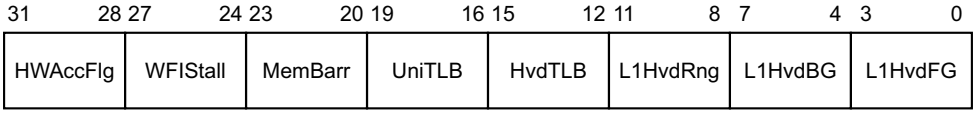
ID_MMFR2 is architecturally mapped to AArch64 register ID_MMFR2_EL1.

Attributes

ID_MMFR2 is a 32-bit register.

Field descriptions

The ID_MMFR2 bit assignments are:



HWAccFlg, bits [31:28]

Hardware Access Flag. Indicates support for a Hardware Access flag, as part of the VMSAv7 implementation. Permitted values are:

`0000` Not supported.

`0001` Support for VMSAv7 Access flag, updated in hardware. Not supported in ARMv8.

All other values are reserved.

On an ARMv7-R implementation this field must be `0000`.

WFI, bits [27:24]

Wait For Interrupt. Indicates the support for Wait For Interrupt (WFI). Permitted values are:

`0000` Not supported.

`0001` Support for WFI.

All other values are reserved.

MemBarr, bits [23:20]

Memory Barrier. Indicates the supported CP15 memory barrier operations:

`0000` None supported. Not supported in ARMv8.

`0001` Supported CP15 Memory barrier operations are:

- Data Synchronization Barrier (DSB), which in previous versions of the ARM architecture was named Data Write Barrier (DWB).

Not supported in ARMv8.

`0010` As for `0001`, and adds:

- Instruction Synchronization Barrier (ISB), which in previous versions of the ARM architecture was called Prefetch Flush.
- Data Memory Barrier (DMB).

All other values are reserved.

From ARMv7, ARM deprecates the use of these operations. ID_ISAR4.Barrier_instrs indicates the level of support for the preferred barrier instructions.

UniTLB, bits [19:16]

Unified TLB. Indicates the supported TLB maintenance operations, for a unified TLB implementation. Permitted values are:

`0000` Not supported. Not supported in ARMv8.

`0001` Supported unified TLB maintenance operations are:

- Invalidate all entries in the TLB.
- Invalidate TLB entry by VA.

Not supported in ARMv8.

`0010` As for `0001`, and adds:

- Invalidate TLB entries by ASID match.

Not supported in ARMv8.

`0011` As for `0010`, and adds:

- Invalidate instruction TLB and data TLB entries by VA All ASID. This is a shared unified TLB operation.

Not supported in ARMv8.

`0100` As for `0011`, and adds:

- Invalidate Hyp mode unified TLB entry by VA.
- Invalidate entire Non-secure PL1&0 unified TLB.
- Invalidate entire Hyp mode unified TLB.

Not supported in ARMv8.

`0101` As for `0100`, and adds the following operations: TLBIMVALIS, TLBIMVAALIS, TLBIMVALHIS, TLBIMVAL, TLBIMVAAL, TLBIMVALH.

Not supported in ARMv8.

`0110` As for `0101`, and adds the following operations: TLBIIPAS2IS, TLBIIPAS2LIS, TLBIIPAS2, TLBIIPAS2L.

All other values are reserved.

HvdTLB, bits [15:12]

Harvard TLB. Indicates the supported TLB maintenance operations, for a Harvard TLB implementation. Permitted values are:

`0000` If the Unified TLB field is not `0000`, then the meaning of this field is IMPLEMENTATION DEFINED. ARM deprecates the use of this field by software.

`0001` Supported Harvard TLB maintenance operations are:

- Invalidate all entries in the ITLB and the DTLB. This is a shared unified TLB operation.
- Invalidate all ITLB entries.
- Invalidate all DTLB entries.

- Invalidate ITLB entry by VA.
- Invalidate DTLB entry by VA.

Not supported in ARMv8.

0010 As for 0001, and adds:

- Invalidate ITLB and DTLB entries by ASID match. This is a shared unified TLB operation.
- Invalidate ITLB entries by ASID match.
- Invalidate DTLB entries by ASID match.

Not supported in ARMv8.

All other values are reserved.

Note

This field is defined only for legacy reasons. It is replaced by the Unified TLB field, bits [19:16], and it must be ignored by software if the Unified TLB field is not 0000.

L1HvdRng, bits [11:8]

Level 1 Harvard cache Range. Indicates the supported Level 1 cache maintenance range operations, for a Harvard cache implementation. Permitted values are:

0000 Not supported.

0001 Supported Level 1 Harvard cache maintenance range operations are:

- Invalidate data cache range by VA.
- Invalidate instruction cache range by VA.
- Clean data cache range by VA.
- Clean and invalidate data cache range by VA.

Not supported in ARMv8.

All other values are reserved.

L1HvdBG, bits [7:4]

Level 1 Harvard cache Background fetch. Indicates the supported Level 1 cache background fetch operations, for a Harvard cache implementation. When supported, background fetch operations are non-blocking operations. Permitted values are:

0000 Not supported.

0001 Supported Level 1 Harvard cache background fetch operations are:

- Fetch instruction cache range by VA.
- Fetch data cache range by VA.

Not supported in ARMv8.

All other values are reserved.

L1HvdFG, bits [3:0]

Level 1 Harvard cache Foreground fetch. Indicates the supported Level 1 cache foreground fetch operations, for a Harvard cache implementation. When supported, foreground fetch operations are blocking operations. Permitted values are:

0000 Not supported.

0001 Supported Level 1 Harvard cache foreground fetch operations are:

- Fetch instruction cache range by VA.
- Fetch data cache range by VA.

Not supported in ARMv8.

All other values are reserved.

Accessing the ID_MMFR2

To access the ID_MMFR2:

```
MRC p15,0,<Rt>,c0,c1,6 ; Read ID_MMFR2 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0001	110

G5.1.85 ID_MMFR3, Memory Model Feature Register 3

The ID_MMFR3 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID_MMFR0, ID_MMFR1, and ID_MMFR2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

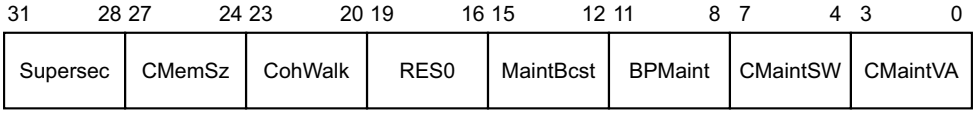
ID_MMFR3 is architecturally mapped to AArch64 register ID_MMFR3_EL1.

Attributes

ID_MMFR3 is a 32-bit register.

Field descriptions

The ID_MMFR3 bit assignments are:



Supersec, bits [31:28]

Supersections. On a VMSA implementation, indicates whether Supersections are supported. Permitted values are:

`0000` Supersections supported.

`1111` Supersections not supported. Not supported in ARMv8.

All other values are reserved.

The sense of this identification is reversed from the normal usage in the CPUID mechanism, with the value of zero indicating that the feature is supported.

CMemSz, bits [27:24]

Cached Memory Size. Indicates the physical memory size supported by the processor caches. Permitted values are:

`0000` 4GB, corresponding to a 32-bit physical address range.

`0001` 64GB, corresponding to a 36-bit physical address range.

`0010` 1TB or more, corresponding to a 40-bit or larger physical address range.

All other values are reserved.

CohWalk, bits [23:20]

Coherent Walk. Indicates whether Translation table updates require a clean to the point of unification. Permitted values are:

`0000` Updates to the translation tables require a clean to the point of unification to ensure visibility by subsequent translation table walks. Not supported in ARMv8.

`0001` Updates to the translation tables do not require a clean to the point of unification to ensure visibility by subsequent translation table walks.

All other values are reserved.

Bits [19:16]

Reserved, RES0.

MaintBcst, bits [15:12]

Maintenance Broadcast. Indicates whether Cache, TLB, and branch predictor operations are broadcast. Permitted values are:

`0000` Cache, TLB, and branch predictor operations only affect local structures. Not supported in ARMv8.

`0001` Cache and branch predictor operations affect structures according to shareability and defined behavior of instructions. TLB operations only affect local structures. Not supported in ARMv8.

`0010` Cache, TLB, and branch predictor operations affect structures according to shareability and defined behavior of instructions.

All other values are reserved.

BPMaint, bits [11:8]

Branch Predictor Maintenance. Indicates the supported branch predictor maintenance operations in an implementation with hierarchical cache maintenance operations. Permitted values are:

`0000` None supported. Not supported in ARMv8.

`0001` Supported branch predictor maintenance operations are:

- Invalidate all branch predictors.

Not supported in ARMv8.

`0010` As for `0001`, and adds:

- Invalidate branch predictors by VA.

All other values are reserved.

Note

ARMv8 requires a hierarchical cache implementation.

CMaintSW, bits [7:4]

Cache Maintenance by Set/Way. Indicates the supported cache maintenance operations by set/way, in an implementation with hierarchical caches. Permitted values are:

`0000` None supported. Not supported in ARMv8.

`0001` Supported hierarchical cache maintenance operations by set/way are:

- Invalidate data cache by set/way.
- Clean data cache by set/way.
- Clean and invalidate data cache by set/way.

All other values are reserved.

Note

- ARMv8 requires a hierarchical cache implementation.
- In a unified cache implementation, the data cache operations apply to the unified caches.

CMaintVA, bits [3:0]

Cache Maintenance by Virtual Address. Indicates the supported cache maintenance operations by VA, in an implementation with hierarchical caches. Permitted values are:

`0000` None supported. Not supported in ARMv8.

`0001` Supported hierarchical cache maintenance operations by VA are:

- Invalidate data cache by VA.
- Clean data cache by VA.
- Clean and invalidate data cache by VA.
- Invalidate instruction cache by VA.
- Invalidate all instruction cache entries.

All other values are reserved.

Note

- ARMv8 requires a hierarchical cache implementation.
- In a unified cache implementation, the data cache operations apply to the unified caches, and the instruction cache operations are not implemented.

Accessing the ID_MMFR3

To access the ID_MMFR3:

```
MRC p15,0,<Rt>,c0,c1,7 ; Read ID_MMFR3 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0001	111

G5.1.86 ID_PFR0, Processor Feature Register 0

The ID_PFR0 characteristics are:

Purpose

Gives top-level information about the instruction sets supported by the processor in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID_PFR1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

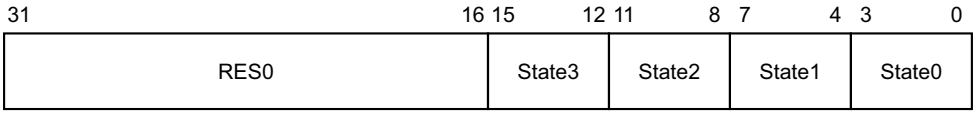
ID_PFR0 is architecturally mapped to AArch64 register ID_PFR0_EL1.

Attributes

ID_PFR0 is a 32-bit register.

Field descriptions

The ID_PFR0 bit assignments are:



Bits [31:16]

Reserved, RES0.

State3, bits [15:12]

T32EE instruction set support. Permitted values are:

`0000` Not implemented.

`0001` T32EE instruction set implemented. Not supported in ARMv8.

All other values are reserved.

The value of `0001` is only permitted when State1 == `0011`.

State2, bits [11:8]

Jazelle extension support. Permitted values are:

`0000` Not implemented. Not supported in ARMv8.

`0001` Jazelle extension implemented, without clearing of JOSCR.CV on exception entry.

`0010` Jazelle extension implemented, with clearing of JOSCR.CV on exception entry. Not supported in ARMv8.

All other values are reserved.

State1, bits [7:4]

T32 instruction set support. Permitted values are:

`0000` T32 instruction set not implemented. Not supported in ARMv8.

`0001` T32 encodings before the introduction of Thumb-2® technology implemented:

- All instructions are 16-bit.
- A BL or BLX is a pair of 16-bit instructions.
- 32-bit instructions other than BL and BLX cannot be encoded.

Not supported in ARMv8.

`0011` T32 encodings after the introduction of Thumb-2 technology implemented, for all 16-bit and 32-bit T32 basic instructions.

All other values are reserved.

State0, bits [3:0]

A32 instruction set support. Permitted values are:

`0000` A32 instruction set not implemented. Not supported in ARMv8.

`0001` A32 instruction set implemented.

All other values are reserved.

Accessing the ID_PFR0

To access the ID_PFR0:

```
MRC p15,0,<Rt>,c0,c1,0 ; Read ID_PFR0 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0001	000

G5.1.87 ID_PFR1, Processor Feature Register 1

The ID_PFR1 characteristics are:

Purpose

Gives information about the programmers' model and extensions support in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Must be interpreted with ID_PFR0.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

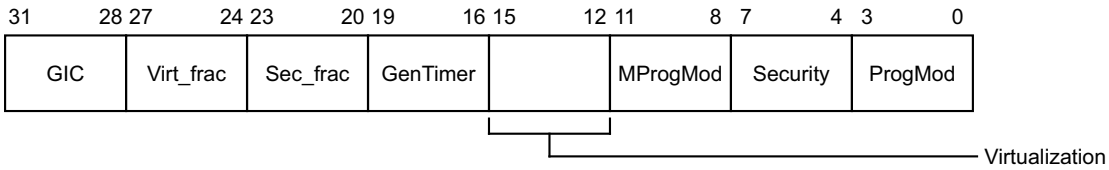
ID_PFR1 is architecturally mapped to AArch64 register ID_PFR1_EL1.

Attributes

ID_PFR1 is a 32-bit register.

Field descriptions

The ID_PFR1 bit assignments are:



GIC, bits [31:28]

GIC CP15 interface. Permitted values are:

`0000` No GIC CP15 registers are supported.

`0001` GICv3 CP15 registers are supported.

All other values are reserved.

Virt_frac, bits [27:24]

Virtualization fractional field. When the Virtualization field is `0000`, determines the support for features from the ARMv7 Virtualization Extensions. Permitted values are:

`0000` No features from the ARMv7 Virtualization Extensions are implemented. This value is not supported in ARMv8 if EL2 is not implemented and EL3 is implemented.

`0001` The SCR.SIF bit is implemented. The modifications to the SCR.AW and SCR.FW bits are part of the control of whether the CPSR.A and CPSR.F bits mask the corresponding aborts. The MSR (Banked register) and MRS (Banked register) instructions are implemented.

This value is permitted only when ID_PFR1.Security is not `0000`.

All other values are reserved.

This field is only valid when ID_PFR1[15:12] == 0, otherwise it holds the value `0000`.

Sec_frac, bits [23:20]

Security fractional field. When the Security field is `0000`, determines the support for features from the ARMv7 Security Extensions. Permitted values are:

`0000` No features from the ARMv7 Security Extensions are implemented. This value is not supported in ARMv8 if ID_PFR1 bits [7:4] are zero.

`0001` The implementation includes the VBAR, and the TCR.PD0 and TCR.PD1 bits.

`0010` As for `0001`, plus the ability to access Secure or Non-secure physical memory is supported.

All other values are reserved.

This field is only valid when ID_PFR1[7:4] == 0, otherwise it holds the value `0000`.

GenTimer, bits [19:16]

Generic Timer Extension support. Permitted values are:

`0000` Not implemented.

`0001` Generic Timer Extension implemented.

All other values are reserved.

Virtualization, bits [15:12]

Virtualization support. Permitted values are:

`0000` EL2 not implemented.

`0001` EL2 implemented.

All other values are reserved.

A value of `0001` implies implementation of the HVC, ERET, MRS (banked register), and MSR (banked register) instructions. The ID_ISARs do not identify whether these instructions are implemented.

MProgMod, bits [11:8]

M profile programmers' model support. Permitted values are:

`0000` Not supported.

`0010` Support for two-stack programmers' model. Not supported in ARMv8.

All other values are reserved.

Security, bits [7:4]

Security support. Permitted values are:

`0000` EL3 not implemented.

`0001` EL3 implemented.

This includes support for Monitor mode and the SMC instruction.

`0010` As for `0001`, and adds the ability to set the NSACR.RFR bit. Not permitted in v8-A as the NSACR.RFR bit is RES0.

All other values are reserved.

ProgMod, bits [3:0]

Support for the standard programmers' model for ARMv4 and later. Model must support User, FIQ, IRQ, Supervisor, Abort, Undefined, and System modes. Permitted values are:

`0000` Not supported. Not supported in ARMv8.

`0001` Supported.

All other values are reserved.

Accessing the ID_PFR1:

To access the ID_PFR1:

```
MRC p15,0,<Rt>,c0,c1,1 ; Read ID_PFR1 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0001	001

G5.1.88 IFAR, Instruction Fault Address Register

The IFAR characteristics are:

Purpose

Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as IFAR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as IFAR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

IFAR(NS) is architecturally mapped to AArch64 register FAR_EL1[63:32].

IFAR(S) is architecturally mapped to AArch32 register HIFAR when EL2 is implemented.

IFAR(S) is architecturally mapped to AArch64 register FAR_EL2[63:32] when EL2 is implemented.

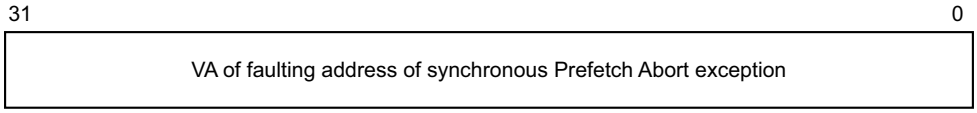
IFAR(S) can be mapped to AArch64 register FAR_EL3[63:32] when EL2 is not implemented, but this is not architecturally mandated.

Attributes

IFAR is a 32-bit register.

Field descriptions

The IFAR bit assignments are:



Bits [31:0]

VA of faulting address of synchronous Prefetch Abort exception.

Accessing the IFAR

To access the IFAR:

```
MRC p15,0,<Rt>,c6,c0,2 ; Read IFAR into Rt
MCR p15,0,<Rt>,c6,c0,2 ; Write Rt to IFAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0110	0000	010

G5.1.89 IFSR, Instruction Fault Status Register

The IFSR characteristics are:

Purpose

Holds status information about the last instruction fault.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as IFSR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as IFSR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

IFSR(NS) is architecturally mapped to AArch64 register IFSR32_EL2.

The Large Physical Address Extension adds an alternative format for the register. If an implementation includes the Large Physical Address Extension then the current translation table format determines which format of the register is used.

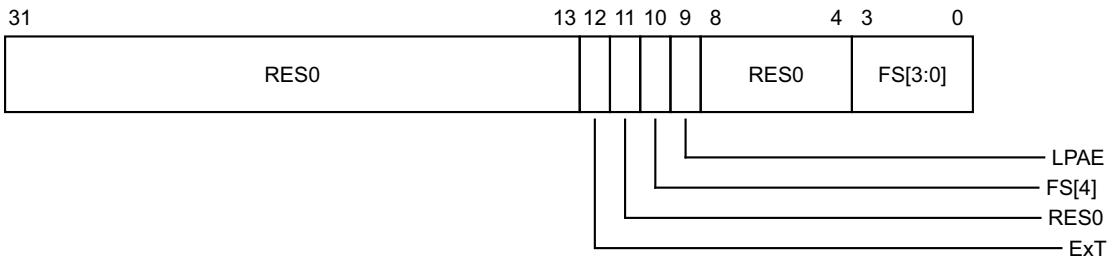
Attributes

IFSR is a 32-bit register.

Field descriptions

The IFSR bit assignments are:

When TTBCR.EAE==0:



Bits [31:13]

Reserved, RES0.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

For aborts other than external aborts this bit always returns 0.

Bit [11]

Reserved, RES0.

FS[4], bit [10]

See below for description of the FS field.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

0 Using the Short-descriptor translation table formats.

1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:4]

Reserved, RES0.

FS[3:0], bits [3:0]

Fault status bits. Interpreted with bit[10]. Possible values of the FS[4:0] field are:

00010 Debug event

00011 Access flag fault, first level

00101 Translation fault, first level

00110 Access flag fault, second level

00111 Translation fault, second level

01000 Synchronous external abort

01001 Domain fault, first level

01011 Domain fault, second level

01100 Synchronous external abort on translation table walk, first level

01101 Permission fault, first level

01110 Synchronous external abort on translation table walk, second level

01111 Permission fault, second level

10000 TLB conflict abort

10100 IMPLEMENTATION DEFINED fault (Lockdown fault)

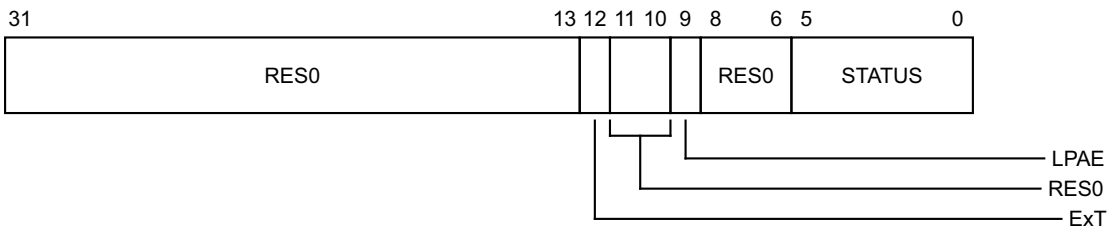
11001 Synchronous parity error on memory access

11100 Synchronous parity error on translation table walk, first level

11110 Synchronous parity error on translation table walk, second level

All other values are reserved.

When TTBCR.EAE==1:



Bits [31:13]

Reserved, RES0.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

For aborts other than external aborts this bit always returns 0.

Bits [11:10]

Reserved, RES0.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

`0` Using the Short-descriptor translation table formats.

`1` Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:6]

Reserved, RES0.

STATUS, bits [5:0]

Fault status bits. Possible values of this field are:

`000000` Address size fault in TTBR0 or TTBR1

`000001` Address size fault, first level

`000010` Address size fault, second level

`000011` Address size fault, third level

`000101` Translation fault, first level

`000110` Translation fault, second level

`000111` Translation fault, third level

`001001` Access flag fault, first level

`001010` Access flag fault, second level

`001011` Access flag fault, third level

`001101` Permission fault, first level

`001110` Permission fault, second level

`001111` Permission fault, third level

`010000` Synchronous external abort

`010101` Synchronous external abort on translation table walk, first level

`010110` Synchronous external abort on translation table walk, second level

`010111` Synchronous external abort on translation table walk, third level

`011000` Synchronous parity error on memory access

`011101` Synchronous parity error on memory access on translation table walk, first level

`011110` Synchronous parity error on memory access on translation table walk, second level

`011111` Synchronous parity error on memory access on translation table walk, third level

`100001` Alignment fault

`100010` Debug event

`110000` TLB conflict abort

`110100` IMPLEMENTATION DEFINED fault (Lockdown fault)

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because an MMU is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a First level fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Accessing the IFSR

To access the IFSR:

```
MRC p15,0,<Rt>,c5,c0,1 ; Read IFSR into Rt
MCR p15,0,<Rt>,c5,c0,1 ; Write Rt to IFSR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0101	0000	001

G5.1.90 ISR, Interrupt Status Register

The ISR characteristics are:

Purpose

Shows whether an IRQ, FIQ, or external abort is pending. If EL2 is implemented, an indicated pending abort might be a physical abort or a virtual abort.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

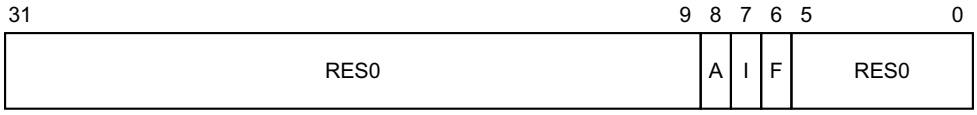
ISR is architecturally mapped to AArch64 register ISR_EL1.

Attributes

ISR is a 32-bit register.

Field descriptions

The ISR bit assignments are:



Bits [31:9]

Reserved, RES0.

A, bit [8]

External abort pending bit:

0 No pending external abort.

1 An external abort is pending.

I, bit [7]

IRQ pending bit. Indicates whether an IRQ interrupt is pending:

0 No pending IRQ.

1 An IRQ interrupt is pending.

F, bit [6]

FIQ pending bit. Indicates whether an FIQ interrupt is pending.

0 No pending FIQ.

1 An FIQ interrupt is pending.

Bits [5:0]

Reserved, RES0.

Accessing the ISR

To access the ISR:

```
MRC p15,0,<Rt>,c12,c1,0 ; Read ISR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	0001	000

G5.1.91 ITLBIALL, Instruction TLB Invalidate All

The ITLBIALL characteristics are:

Purpose

Invalidate all PL1&0 regime stage 1 and 2 instruction TLB entries for the current VMID and the current security state.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

There are no configuration notes.

Attributes

ITLBIALL is a 32-bit system operation.

Field descriptions

The ITLBIALL operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the ITLBIALL operation

To perform the ITLBIALL operation:

```
MCR p15,0,<Rt>,c8,c5,0 ; ITLBIALL operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0101	000

G5.1.92 ITLBIASID, Instruction TLB Invalidate by ASID match

The ITLBIASID characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 instruction TLB entries for the given ASID, the current VMID, and the current security state.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

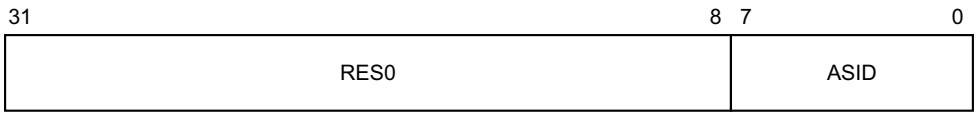
There are no configuration notes.

Attributes

ITLBIASID is a 32-bit system operation.

Field descriptions

The ITLBIASID input value bit assignments are:



Bits [31:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

Performing the ITLBIASID operation

To perform the ITLBIASID operation:

```
MCR p15,0,<Rt>,c8,c5,2 ; ITLBIASID operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0101	010

G5.1.93 ITLBIMVA, Instruction TLB Invalidate by VA

The ITLBIMVA characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 and 2 instruction TLB entries for the given VA and ASID, the current VMID, and the current security state.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

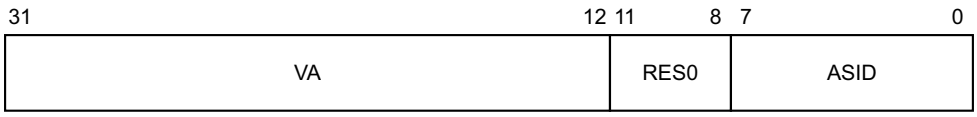
There are no configuration notes.

Attributes

ITLBIMVA is a 32-bit system operation.

Field descriptions

The ITLBIMVA input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Performing the ITLBIMVA operation

To perform the ITLBIMVA operation:

```
MCR p15,0,<Rt>,c8,c5,1 ; ITLBIMVA operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0101	001

G5.1.94 JIDR, Jazelle ID Register

The JIDR characteristics are:

Purpose

A Jazelle register, which identifies the Jazelle architecture and subarchitecture version.

This register is part of the Legacy feature registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RO	RO	RO	RO	RO	RO	RO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

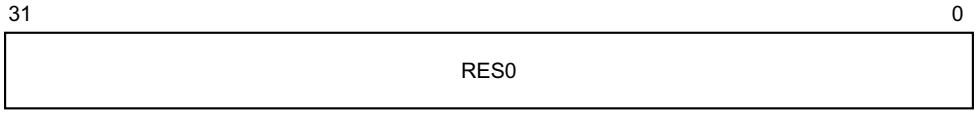
Implemented as RES0 in v8, which only contains a trivial implementation of the Jazelle Extension.

Attributes

JIDR is a 32-bit register.

Field descriptions

The JIDR bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the JIDR

To access the JIDR:

```
MRC p14,7,<Rt>,c0,c0,0 ; Read JIDR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	111	0000	0000	000

G5.1.95 JMCR, Jazelle Main Configuration Register

The JMCR characteristics are:

Purpose

A Jazelle register, which provides control of the Jazelle extension.

This register is part of the Legacy feature registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

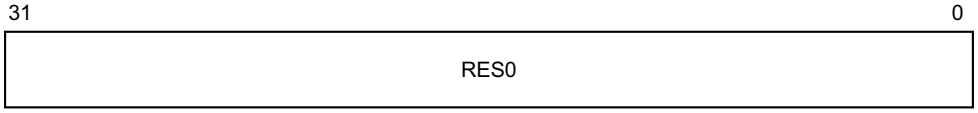
Implemented as RES0 in v8, which only contains a trivial implementation of the Jazelle Extension.

Attributes

JMCR is a 32-bit register.

Field descriptions

The JMCR bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the JMCR

To access the JMCR:

```
MRC p14,7,<Rt>,c2,c0,0 ; Read JMCR into Rt
MCR p14,7,<Rt>,c2,c0,0 ; Write Rt to JMCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	111	0010	0000	000

G5.1.96 JOSCR, Jazelle OS Control Register

The JOSCR characteristics are:

Purpose

A Jazelle register, which provides operating system control of the use of the Jazelle extension by processes and threads.

This register is part of the Legacy feature registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

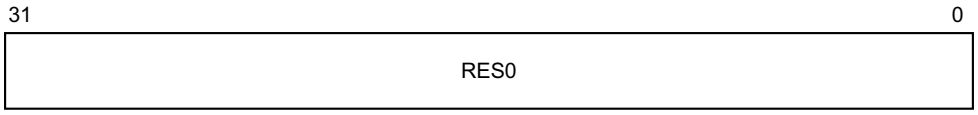
Implemented as RES0 in v8, which only contains a trivial implementation of the Jazelle Extension.

Attributes

JOSCR is a 32-bit register.

Field descriptions

The JOSCR bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the JOSCR

To access the JOSCR:

```
MRC p14,7,<Rt>,c1,c0,0 ; Read JOSCR into Rt
MCR p14,7,<Rt>,c1,c0,0 ; Write Rt to JOSCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	111	0001	0000	000

G5.1.97 MAIR0, Memory Attribute Indirection Register 0

The MAIR0 characteristics are:

Purpose

Along with MAIR1, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as MAIR0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as MAIR0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Only accessible when using the Long-descriptor translation table format.

AttrIndx[2], from the translation table descriptor, selects the appropriate MAIR: setting AttrIndx[2] to 0 selects MAIR0.

In an implementation that includes EL3:

- The Secure copy of the register gives the value for memory accesses from Secure state.
- The Non-secure copy of the register gives the value for memory accesses from Non-secure states other than Hyp mode.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

MAIR0(NS) is architecturally mapped to AArch64 register MAIR_EL1[31:0] when TTBCR.EAE==1.

MAIR0(S) can be mapped to AArch64 register MAIR_EL3[31:0] when TTBCR.EAE==1, but this is not architecturally mandated.

MAIR0 has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

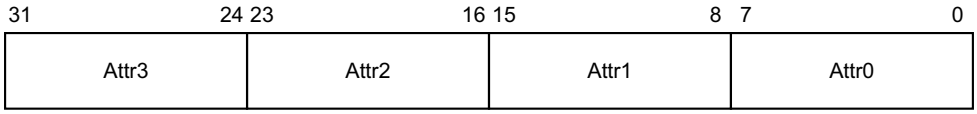
Attributes

MAIR0 is a 32-bit register when TTBCR.EAE==1.

Field descriptions

The MAIR0 bit assignments are:

When TTBCR.EAE==1:



Attr<n>, bits [8n+7:8n], for 8n+7:8n = 0 to 3

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
0000	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
00RW, RW not 00	Normal Memory, Outer Write-through transient
0100	Normal Memory, Outer Non-Cacheable
01RW, RW not 00	Normal Memory, Outer Write-back transient
10RW	Normal Memory, Outer Write-through non-transient
11RW	Normal Memory, Outer Write-back non-transient

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through transient
0100	Device-nGnRE memory	Normal memory, Inner Non-Cacheable
01RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back transient
1000	Device-nGRE memory	Normal Memory, Inner Write-through non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through non-transient
1100	Device-GRE memory	Normal Memory, Inner Write-back non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back non-transient

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.

ARMv7's Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	Do not allocate
1	Allocate

Accessing the MAIR0

To access the MAIR0 when TTBCR.EAE==1:

```
MRC p15,0,<Rt>,c10,c2,0 ; Read MAIR0 into Rt
MCR p15,0,<Rt>,c10,c2,0 ; Write Rt to MAIR0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1010	0010	000

G5.1.98 MAIR1, Memory Attribute Indirection Register 1

The MAIR1 characteristics are:

Purpose

Along with MAIR0, provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as MAIR1(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as MAIR1(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Only accessible when using the Long-descriptor translation table format.

AttrIndx[2], from the translation table descriptor, selects the appropriate MAIR: setting AttrIndx[2] to 1 selects MAIR1.

In an implementation that includes EL3:

- The Secure copy of the register gives the value for memory accesses from Secure state.
- The Non-secure copy of the register gives the value for memory accesses from Non-secure states other than Hyp mode.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

MAIR1(NS) is architecturally mapped to AArch64 register MAIR_EL1[63:32] when TTBCR.EAE==1.

MAIR1(S) can be mapped to AArch64 register MAIR_EL3[63:32] when TTBCR.EAE==1, but this is not architecturally mandated.

MAIR1 has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

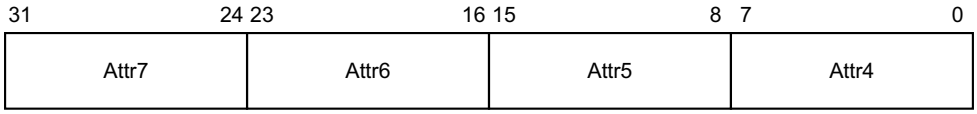
Attributes

MAIR1 is a 32-bit register when TTBCR.EAE==1.

Field descriptions

The MAIR1 bit assignments are:

When TTBCR.EAE==1:



Attr<n>, bits [8(n-4)+7:8(n-4)], for 8(n-4)+7:8(n-4) = 4 to 7

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIndx[2:0] gives the value of <n> in Attr<n>.
- AttrIndx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
`0000`	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
`00RW`, RW not `00`	Normal Memory, Outer Write-through transient
`0100`	Normal Memory, Outer Non-Cacheable
`01RW`, RW not `00`	Normal Memory, Outer Write-back transient
`10RW`	Normal Memory, Outer Write-through non-transient
`11RW`	Normal Memory, Outer Write-back non-transient

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
`0000`	Device-nGnRnE memory	UNPREDICTABLE
`00RW`, RW not `00`	UNPREDICTABLE	Normal Memory, Inner Write-through transient
`0100`	Device-nGnRE memory	Normal memory, Inner Non-Cacheable
`01RW`, RW not `00`	UNPREDICTABLE	Normal Memory, Inner Write-back transient
`1000`	Device-nGRE memory	Normal Memory, Inner Write-through non-transient (RW=00)
`10RW`, RW not `00`	UNPREDICTABLE	Normal Memory, Inner Write-through non-transient
`1100`	Device-GRE memory	Normal Memory, Inner Write-back non-transient (RW=00)
`11RW`, RW not `00`	UNPREDICTABLE	Normal Memory, Inner Write-back non-transient

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.

ARMv7's Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	Do not allocate
1	Allocate

Accessing the MAIR1

To access the MAIR1 when TTBCR.EAE==1:

```
MRC p15,0,<Rt>,c10,c2,1 ; Read MAIR1 into Rt
MCR p15,0,<Rt>,c10,c2,1 ; Write Rt to MAIR1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1010	0010	001

G5.1.99 MIDR, Main ID Register

The MIDR characteristics are:

Purpose

Provides identification information for the processor, including an implementer code for the device and a device ID number.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

If EL2 is implemented, reads of MIDR from EL1(NS) return the value from VPIDR.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

MIDR is architecturally mapped to AArch64 register MIDR_EL1.

MIDR is architecturally mapped to external register MIDR_EL1.

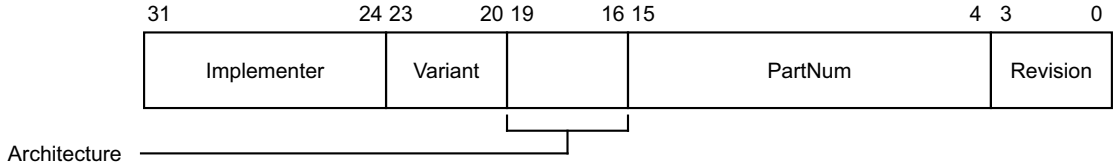
Some fields of MIDR are IMPLEMENTATION DEFINED. For details of the values of these fields for a particular ARMv8 implementation, and any implementation-specific significance of these values, see the product documentation.

Attributes

MIDR is a 32-bit register.

Field descriptions

The MIDR bit assignments are:



Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

Hex representation	ASCII representation	Implementer
0x41	A	ARM Limited
0x42	B	Broadcom Corporation
0x43	C	Cavium Inc.
0x44	D	Digital Equipment Corporation

Hex representation	ASCII representation	Implementer
0x49	I	Infineon Technologies AG
0x4D	M	Motorola or Freescale Semiconductor Inc.
0x4E	N	NVIDIA Corporation
0x50	P	Applied Micro Circuits Corporation
0x51	Q	Qualcomm Inc.
0x56	V	Marvell International Ltd.
0x69	i	Intel Corporation

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

Architecture, bits [19:16]

The permitted values of this field are:

0001 ARMv4

0010 ARMv4T

0011 ARMv5 (obsolete)

0100 ARMv5T

0101 ARMv5TE

0110 ARMv5TEJ

0111 ARMv6

1111 Defined by CPUID scheme

All other values are reserved.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

Processors implemented by ARM have an implementer code of 0x41.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

Note

For an ARM implementation, the MIDR is interpreted as follows:

Bits[31:24] Implementer code, must be 0x41

Bits[23:20] Major revision number, rX

Bits[19:16] Architecture code, must be 0xF

Bits[15:4] ARM part number

Bits[3:0] Minor revision number, pY

Accessing the MIDR

To access the MIDR:

```
MRC p15,0,<Rt>,c0,c0,0 ; Read MIDR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0000	000

G5.1.100 MPIDR, Multiprocessor Affinity Register

The MPIDR characteristics are:

Purpose

In a multiprocessor system, provides an additional processor identification mechanism for scheduling purposes.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

If EL2 is implemented, reads of MPIDR from EL1(NS) return the value from VMPIDR.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

MPIDR is architecturally mapped to AArch64 register MPIDR_EL1.

In a uniprocessor system ARM recommends that each Aff<n> field of this register returns a value of 0.

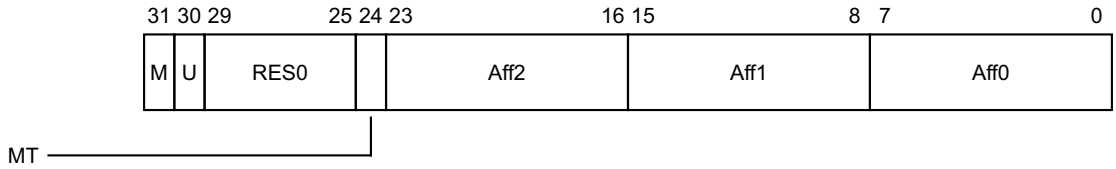
In the system as a whole, the assigned value of all the affinity fields in MPIDR for each PE must be unique.

Attributes

MPIDR is a 32-bit register.

Field descriptions

The MPIDR bit assignments are:



M, bit [31]

Indicates whether this implementation includes the Multiprocessing Extensions. The possible values of this bit are:

`0` This implementation does not include the Multiprocessing Extensions.

`1` This implementation includes the Multiprocessing Extensions.

In ARMv8-A this bit is reserved, RES1.

U, bit [30]

Indicates a Uniprocessor system, as distinct from processor 0 in a multiprocessor system. The possible values of this bit are:

`0` PE is part of a multiprocessor system.

`1` PE is part of a uniprocessor system.

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach. The possible values of this bit are:

0 Performance of PEs at the lowest affinity level is largely independent.

1 Performance of PEs at the lowest affinity level is very interdependent.

Aff2, bits [23:16]

Affinity level 2. The least significant affinity level field, for this processor in the system.

Aff1, bits [15:8]

Affinity level 1. The intermediate affinity level field, for this processor in the system.

Aff0, bits [7:0]

Affinity level 0. The most significant affinity level field, for this processor in the system.

Note

- The interpretation of these field is IMPLEMENTATION DEFINED, and must be documented as part of the documentation in of the multiprocessor system.
- The software mechanism to discover the total number of affinity numbers used at each level is IMPLEMENTATION DEFINED, and is part of the general system identification task.

Multi-threading approach to lowest affinity levels

If MPIDR.MT is set to 1, this indicates that the PEs at affinity level 0 are logical PEs, implemented using a multi-threading type approach. In such an approach, there can be a significant performance impact if a new thread is assigned to the PE with:

- A different affinity level 0 value to some other thread, referred to as the original thread.
- A pair of values for affinity levels 1 and 2 that are the same as the pair of values of the original thread.

In this situation, the performance of the original thread might be significantly reduced.

Note

In this description a thread always refers to a thread or a PE.

Accessing the MPIDR

To access the MPIDR:

```
MRC p15,0,<Rt>,c0,c0,5 ; Read MPIDR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0000	101

G5.1.101 MVBAR, Monitor Vector Base Address Register

The MVBAR characteristics are:

Purpose

Holds the exception base address for any exception that is taken to Monitor mode.

This register is part of:

- the Exception and fault handling registers functional group
- the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	RW	RW

Secure software must program the MVBAR with the required initial value as part of the processor boot sequence.

If EL3 is implemented and is using AArch64, any read or write to MVBAR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

If EL3 is not implemented, attempts to access MVBAR are UNDEFINED.

MVBAR is a Restricted access register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

The reset value of MVBAR, when resetting into EL3 using AArch32, is an IMPLEMENTATION DEFINED choice between the following:

- Either:
  - MVBAR[31:5] is an IMPLEMENTATION DEFINED value, which might be UNPREDICTABLE.
  - MVBAR[4:1] is RES0.
  - MVBAR[0] is 0.
- Or:
  - MVBAR[31:1] is an IMPLEMENTATION DEFINED value being the AArch32 reset address, bits[31:1].
  - MVBAR[0] is 1.

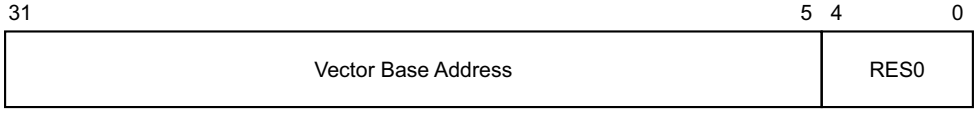
The reset value of MVBAR[0] can be used to distinguish between these two approaches.

Attributes

MVBAR is a 32-bit register.

Field descriptions

The MVBAR bit assignments are:



Bits [31:5]

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken in this exception level. Bits[4:0] of an exception vector are the exception offset.

Bits [4:0]

Reserved, RES0.

Accessing the MVBAR

To access the MVBAR:

```
MRC p15,0,<Rt>,c12,c0,1 ; Read MVBAR into Rt
MCR p15,0,<Rt>,c12,c0,1 ; Write Rt to MVBAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	0000	001

G5.1.102 MVFR0, Media and Floating-point Feature Register 0

The MVFR0 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point functionality.

This register is part of:

- the Floating-point registers functional group
- the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	Config-RO	RO	Config-RO	Config-RO	RO

Access to this register depends on the values of CPACR.{cp10,cp11}, NSACR.{cp10,cp11}, and HCPTR.{TCP10,TCP11}.

Must be interpreted with MVFR1 and MVFR2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

MVFR0 is architecturally mapped to AArch64 register MVFR0_EL1.

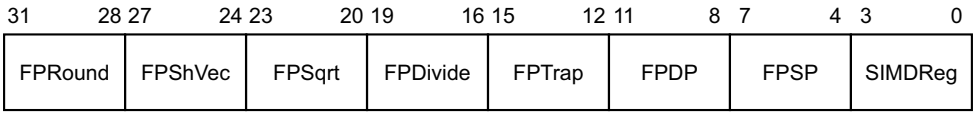
Implemented only if the implementation includes one or both of the Floating-point functionality or the Advanced SIMD functionality.

Attributes

MVFR0 is a 32-bit register.

Field descriptions

The MVFR0 bit assignments are:



FPRound, bits [31:28]

Floating-Point Rounding modes. Indicates the rounding modes supported by the floating-point hardware. Permitted values are:

`0000` Only Round to Nearest mode supported, except that Round towards Zero mode is supported for VCVT instructions that always use that rounding mode regardless of the FPSCR setting. Not supported in ARMv8.

`0001` All rounding modes supported.

All other values are reserved.

FPShVec, bits [27:24]

Short Vectors. Indicates the hardware support for VFP short vectors. Permitted values are:

`0000` Not supported.

`0001` Short vector operation supported. Not supported in ARMv8.

All other values are reserved.

FPSqrt, bits [23:20]

Square Root. Indicates the hardware support for floating-point square root operations. Permitted values are:

`0000` Not supported in hardware. Not supported in ARMv8.

`0001` Supported.

All other values are reserved.

The VSQRT.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VSQRT.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

FPDivide, bits [19:16]

Indicates the hardware support for floating-point divide operations. Permitted values are:

`0000` Not supported in hardware. Not supported in ARMv8.

`0001` Supported.

All other values are reserved.

The VDIV.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VDIV.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

FPTrap, bits [15:12]

Floating Point Exception Trapping. Indicates whether the floating-point hardware implementation supports exception trapping. Permitted values are:

`0000` Not supported.

`0001` Supported by the hardware. When exception trapping is supported, support code is needed to handle the trapped exceptions.

All other values are reserved.

A value of `0001` does not indicate that trapped exception handling is available. Because trapped exception handling requires support code, only the support code can provide this information.

FPDP, bits [11:8]

Double-precision. Indicates the hardware support for floating-point double-precision operations. Permitted values are:

`0000` Not supported in hardware. Not supported in ARMv8.

`0001` Supported, VFPv2. Not supported in ARMv8.

`0010` Supported, VFPv3, VFPv4, or ARMv8. VFPv3and ARMv8. add an instruction to load a double-precision floating-point constant, and conversions between double-precision and fixed-point values.

All other values are reserved.

A value of `0b0001` or `0b0010` indicates support for all floating-point double-precision instructions in the supported floating-point version, except that, in addition to this field being nonzero:

- VSQRT.F64 is only available if the Square root field is `0001`.
- VDIV.F64 is only available if the Divide field is `0001`.
- Conversion between double-precision and single-precision is only available if the single-precision field is nonzero.

FPSP, bits [7:4]

Single-precision. Indicates the hardware support for floating-point single-precision operations. Permitted values are:

`0000` Not supported in hardware. Not supported in ARMv8.

`0001` Supported, VFPv2. Not supported in ARMv8.

0010 Supported, VFPv3, VFPv4 or ARMv8. VFPv3and ARMv8 add an instruction to load a single-precision floating-point constant, and conversions between single-precision and fixed-point values.

All other values are reserved.

A value of 0b0001 or 0b0010 indicates support for all floating-point single-precision instructions in the supported floating-point version, except that, in addition to this field being nonzero:

- VSQRT.F32 is only available if the Square root field is 0001.
- VDIV.F32 is only available if the Divide field is 0001.
- Conversion between double-precision and single-precision is only available if the double-precision field is nonzero.

SIMDReg, bits [3:0]

Advanced SIMD registers. Indicates support for the Advanced SIMD register file. Permitted values are:

0000 Not supported.

0001 Supported, 16 x 64-bit registers. Not supported in ARMv8.

0010 Supported, 32 x 64-bit registers.

All other values are reserved.

If this field is nonzero:

- All VFP LDC, STC, MCR, and MRC instructions are supported.
- If the CPUID registers show that the MCRR and MRRC instructions are supported then the corresponding floating-point instructions are supported.

Accessing the MVFR0

To access the MVFR0:

```
VMRS <Rt>, MVFR0 ; Read MVFR0 into Rt
```

Register access is encoded as follows:

spec_reg
0111

G5.1.103 MVFR1, Media and Floating-point Feature Register 1

The MVFR1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and floating-point functionality.

This register is part of:

- the Floating-point registers functional group
- the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	Config-RO	RO	Config-RO	Config-RO	RO

Access to this register depends on the values of CPACR.{cp10,cp11}, NSACR.{cp10,cp11}, and HCPTR.{TCP10,TCP11}.

Must be interpreted with MVFR0 and MVFR2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

MVFR1 is architecturally mapped to AArch64 register MVFR1_EL1.

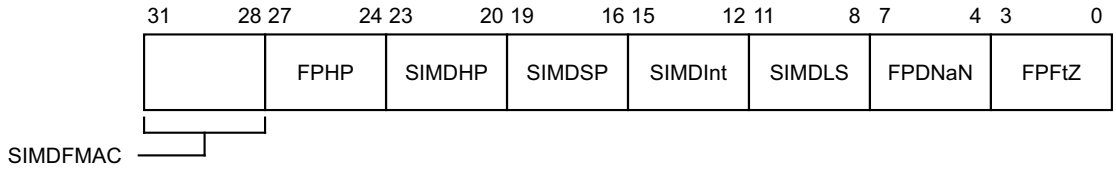
Implemented only if the implementation includes one or both of the Floating-point functionality or the Advanced SIMD functionality.

Attributes

MVFR1 is a 32-bit register.

Field descriptions

The MVFR1 bit assignments are:



SIMDFMAC, bits [31:28]

Advanced SIMD Fused Multiply-Accumulate. Indicates whether any implemented floating-point or Advanced SIMD functionality implements the fused multiply accumulate instructions. Permitted values are:

`0000` Not implemented. Not supported in ARMv8.

`0001` Implemented.

All other values are reserved.

If an implementation includes both the floating-point functionality and the Advanced SIMD functionality, both floating-point and Advanced SIMD must provide the same level of support for these instructions.

FPHP, bits [27:24]

Floating Point Half Precision. Indicates whether the floating-point functionality implements half-precision floating-point conversion instructions. Permitted values are:

`0000` Not implemented. Not supported in ARMv8.

`0001` Instructions to convert between half-precision and single-precision implemented. Not supported in ARMv8.

`0010` As for `0b0001`, and also instructions to convert between half-precision and double-precision implemented.

All other values are reserved.

SIMDHP, bits [23:20]

Advanced SIMD Half Precision. Indicates whether the Advanced SIMD functionality implements half-precision floating-point conversion instructions. Permitted values are:

`0000` Not implemented. Not supported in ARMv8.

`0001` Implemented. This value is permitted only if the SIMDSP field is `0001`.

All other values are reserved.

SIMDSP, bits [19:16]

Advanced SIMD single-precision. Indicates whether the Advanced SIMD functionality implements single-precision floating-point instructions. Permitted values are:

`0000` Not implemented. Not supported in ARMv8.

`0001` Implemented. This value is permitted only if the SIMDint field is `0001`.

All other values are reserved.

SIMDInt, bits [15:12]

Advanced SIMD Integer. Indicates whether the Advanced SIMD functionality implements integer instructions. Permitted values are:

`0000` Not implemented. Not supported in ARMv8.

`0001` Implemented.

All other values are reserved.

SIMDLS, bits [11:8]

Advanced SIMD Load/Store. Indicates whether the Advanced SIMD functionality implements load/store instructions. Permitted values are:

`0000` Not implemented. Not supported in ARMv8.

`0001` Implemented.

All other values are reserved.

FPDNaN, bits [7:4]

Default NaN mode. Indicates whether the floating-point hardware implementation supports only the Default NaN mode. Permitted values are:

`0000` Hardware supports only the Default NaN mode. Not supported in ARMv8.

`0001` Hardware supports propagation of NaN values.

All other values are reserved.

FPFtZ, bits [3:0]

Flush to Zero mode. Indicates whether the floating-point hardware implementation supports only the Flush-to-Zero mode of operation. Permitted values are:

`0000` Hardware supports only the Flush-to-Zero mode of operation. Not supported in ARMv8.

`0001` Hardware supports full denormalized number arithmetic.

All other values are reserved.

Accessing the MVFR1

To access the MVFR1:

```
VMRS <Rt>, MVFR1 ; Read MVFR1 into Rt
```

Register access is encoded as follows:

spec_reg
0110

G5.1.104 MVFR2, Media and Floating-point Feature Register 2

The MVFR2 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point functionality.

This register is part of:

- the Floating-point registers functional group
- the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	Config-RO	RO	Config-RO	Config-RO	RO

Access to this register depends on the values of CPACR.{cp10,cp11}, NSACR.{cp10,cp11}, and HCPTR.{TCP10,TCP11}.

Must be interpreted with MVFR0 and MVFR1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

MVFR2 is architecturally mapped to AArch64 register MVFR2_EL1.

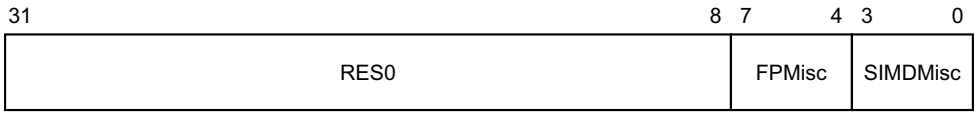
Implemented only if the implementation includes one or both of the floating-point functionality or the Advanced SIMD functionality.

Attributes

MVFR2 is a 32-bit register.

Field descriptions

The MVFR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

FPMisc, bits [7:4]

Indicates support for miscellaneous floating-point features.

`0000` No support for miscellaneous features. Not supported in ARMv8.

`0001` Support for floating-point selection. Not supported in ARMv8.

`0010` As `0001`, and Floating-point Conversion to Integer with Directed Rounding modes. Not supported in ARMv8.

`0011` As `0010`, and Floating-point Round to Integral Floating-point. Not supported in ARMv8.

`0100` As `0011`, and Floating-point MaxNum and MinNum.

All other values are reserved.

SIMDMisc, bits [3:0]

Indicates support for miscellaneous Advanced SIMD features.

`0000` No support for miscellaneous features. Not supported in ARMv8.

`0001` Floating-point Conversion to Integer with Directed Rounding modes. Not supported in ARMv8.

`0010` As `0001`, and Floating-point Round to Integral Floating-point. Not supported in ARMv8.

`0011` As `0010`, and Floating-point MaxNum and MinNum.

All other values are reserved.

Accessing the MVFR2

To access the MVFR2:

```
VMRS <Rt>, MVFR2 ; Read MVFR2 into Rt
```

Register access is encoded as follows:

spec_reg
0101

G5.1.105 NMRR, Normal Memory Remap Register

The NMRR characteristics are:

Purpose

Provides additional mapping controls for memory regions that are mapped as Normal memory by their entry in the PRRR.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as NMRR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as NMRR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Used in conjunction with the PRRR.

Only accessible when using the Short-descriptor translation table format.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

NMRR(NS) is architecturally mapped to AArch64 register MAIR_EL1[63:32] when TTBCR.EAE==0.

NMRR(S) can be mapped to AArch64 register MAIR_EL3[63:32] when TTBCR.EAE==0, but this is not architecturally mandated.

NMRR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

Attributes

NMRR is a 32-bit register when TTBCR.EAE==0.

Field descriptions

The NMRR bit assignments are:

When TTBCR.EAE==0:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OR7				OR6				OR5				OR4				OR3				OR2				OR1				OR0			
IR7				IR6				IR5				IR4				IR3				IR2				IR1				IR0			

OR<n>, bits [2n+17:2n+16], for 2n+17:2n+16 = 0 to 7

Outer Cacheable property mapping for memory attributes n, if the region is mapped as Normal memory by the PRRR.TR<n> entry. n is the value of the TEX[0], C, and B bits concatenated. The possible values of this field are:

00 Region is Non-cacheable.

01 Region is Write-Back, Write-Allocate.

10 Region is Write-Through, no Write-Allocate.

11 Region is Write-Back, no Write-Allocate.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination {TEX[0] = 1, C = 1, B = 0} is IMPLEMENTATION DEFINED.

IR<n>, bits [2n+1:2n], for 2n+1:2n = 0 to 7

Inner Cacheable property mapping for memory attributes n, if the region is mapped as Normal memory by the PRRR.TR<n> entry. n is the value of the TEX[0], C, and B bits concatenated. The possible values of this field are:

00 Region is Non-cacheable.

01 Region is Write-Back, Write-Allocate.

10 Region is Write-Through, no Write-Allocate.

11 Region is Write-Back, no Write-Allocate.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination {TEX[0] = 1, C = 1, B = 0} is IMPLEMENTATION DEFINED.

Accessing the NMRR

To access the NMRR when TTBCR.EAE==0:

```
MRC p15,0,<Rt>,c10,c2,1 ; Read NMRR into Rt
MCR p15,0,<Rt>,c10,c2,1 ; Write Rt to NMRR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1010	0010	001

G5.1.106 NSACR, Non-Secure Access Control Register

The NSACR characteristics are:

Purpose

Defines the Non-secure access permissions to coprocessors CP0 to CP13, and can include additional IMPLEMENTATION DEFINED bits that define Non-secure access permissions for IMPLEMENTATION DEFINED functionality.

This register is part of the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RW	RO	RW	RW

If EL3 is implemented and is using AArch64, any read or write to NSACR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

If EL3 is not implemented, this register is read-only from EL1.

NSACR is a Restricted access System register, see *Restricted access System registers* on page G4-3750.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

When EL3 is using AArch64, then any reads of the NSACR from Non-secure EL2 using AArch32 or Non-secure EL1 using AArch32 will return a fixed value of `0x00000C00`.

If EL3 is not implemented, then any reads of the NSACR from Non-secure EL2 using AArch32 or Secure or Non-secure EL1 using AArch32 will return a fixed value of `0x00000C00`.

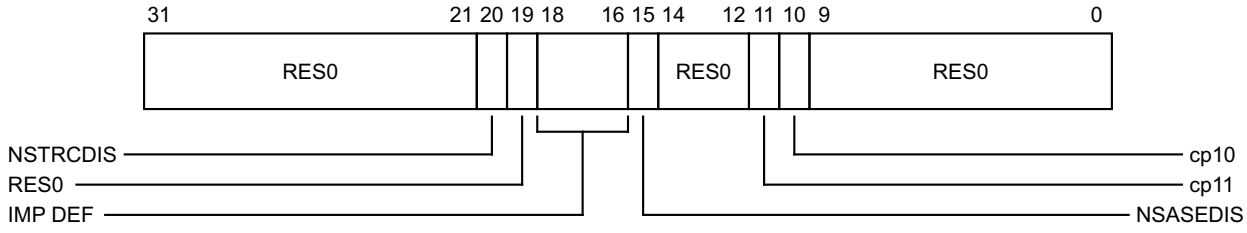
In AArch64, the NSACR functionality is replaced by the behavior in CPTR_EL3.

Attributes

NSACR is a 32-bit register.

Field descriptions

The NSACR bit assignments are:



Bits [31:21]

Reserved, RES0.

NSTRCDIS, bit [20]

Disable Non-secure access to CP14 trace registers. The implementation of this bit must correspond to the implementation of the CPACR.TRCDIS bit:

If CPACR.TRCDIS is RES0 then this bit is RES0.

If CPACR.TRCDIS is RW then this bit is RW and its possible values are:

0 This bit has no effect on the ability to write to CPACR.TRCDIS.

1 When executing in Non-secure state, CPACR.TRCDIS is RES1.

Bit [19]

Reserved, RES0.

NSASEDIS, bit [15]

Disable Non-secure Advanced SIMD functionality. The implementation of this bit must correspond to the implementation of the CPACR.ASEDIS bit.

If CPACR.ASEDIS is not RW then this bit is RES0.

If CPACR.ASEDIS is RW then this bit is RW and its possible values are:

0 This bit has no effect on the ability to write to CPACR.ASEDIS.

1 When executing in Non-secure state, CPACR.ASEDIS is RES1.

Bits [14:12]

Reserved, RES0.

cp<n>, bit [n], for n = 10 to 11

Enable Non-secure access to coprocessors 10 and 11, which control the Floating-point and Advanced SIMD features. Possible values of the fields are:

0 Coprocessor <n> can be accessed only from Secure state. Any attempt to access coprocessor <n> in Non-secure state results in an Undefined Instruction exception. If the processor is in Non-secure state, the corresponding bits in the CPACR ignore writes and read as 00, access denied.

1 Coprocessor <n> can be accessed from any security state.

If Non-secure access to a coprocessor is enabled, the CPACR must be checked to determine the level of access that is permitted.

The Floating-point and Advanced SIMD features controlled by these fields are:

- VFP floating-point instructions.
- Advanced SIMD instructions (both integer and floating-point).
- Advanced SIMD and Floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- FPSCR, FPSID, MVFR0, MVFR1, MVFR2, FPEXC system registers.

If the cp11 and cp10 fields are set to different values, the behavior is CONSTRAINED UNPREDICTABLE, and is the same as if both fields were set to the value of cp10, in all respects other than the value read back by explicitly reading cp11.

Other coprocessors are not supported in ARMv8, so bits[13:12] and bits[9:0] are RES0.

Bits [9:0]

Reserved, RES0.

Accessing the NSACR

To access the NSACR:

```
MRC p15,0,<Rt>,c1,c1,2 ; Read NSACR into Rt
MCR p15,0,<Rt>,c1,c1,2 ; Write Rt to NSACR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0001	010

G5.1.107 PAR, Physical Address Register

The PAR characteristics are:

Purpose

Receives the PA from any address translation operation.

This register is part of the Address translation instructions functional group.

Usage constraints

This register is accessible as shown below:

When accessed as PAR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as PAR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

An implementation that does not support a cacheability attribute can report its corresponding behavior instead of the actual value in the translation table entry.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

PAR(NS) is architecturally mapped to AArch64 register PAR_EL1.

The PAR returns a 32-bit value:

- When the PE is not in Hyp mode and is using the Short-descriptor translation table format.
- When in Hyp mode for the ATS12NSO instruction when the value of HCR.VM is 0 and the value of TTBCR.EAE is 0.

In these cases, PAR[63:32] is RES0.

Otherwise, the PAR returns a 64-bit value. This means it returns a 64-bit value in the following cases:

- When using the Long-descriptor translation table format.
- If the stage 1 MMU is disabled and TTBCR.EAE is set to 1.
- In an implementation that includes EL2, for the result of an ATS1Cxx operation performed from Hyp mode.

Attributes

When the PE is in a mode other than Hyp mode, TTBCR.EAE selects the translation table format.

Field descriptions

The PAR bit assignments are:

For all register layouts:

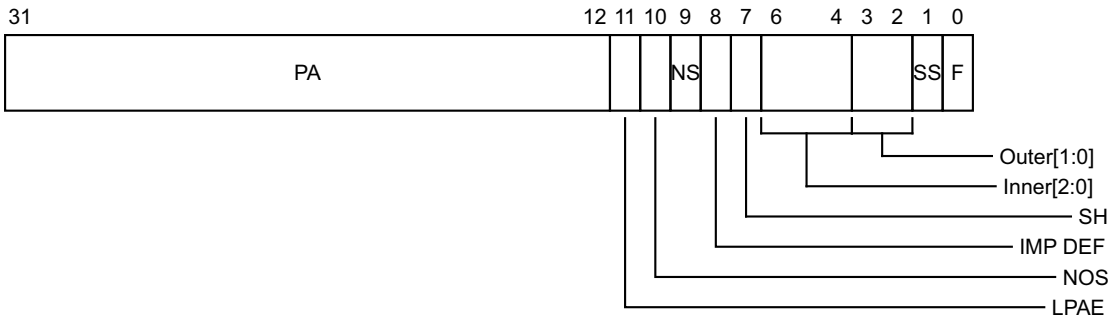
F, bit [0]

Indicates whether the conversion completed successfully.

`0` VA to PA conversion completed successfully.

`1` VA to PA conversion aborted.

When TTBCR.EAE==0, PAR.F==0:



PA, bits [31:12]

Physical Address. The physical address corresponding to the supplied virtual address. This field returns address bits[31:12].

LPAE, bit [11]

When updating the PAR with the result of a translation operation, this bit is set as follows:

`0` Indicates use of the Short-descriptor translation table formats. This indicates that the PAR returns a 32-bit value.

`1` Indicates use of the Long-descriptor translation table formats. This indicates that the PAR returns a 64-bit value.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

NOS, bit [10]

Not Outer Shareable attribute for the region. Indicates whether Shareable physical memory is Outer Shareable:

`0` Memory is Outer Shareable.

`1` Memory is not Outer Shareable.

NS, bit [9]

Non-secure. The NS attribute for a translation table entry read from Secure state.

This bit is UNKNOWN for a translation table entry read from Non-secure state.

SH, bit [7]

Shareable attribute for the region. Indicates whether the physical memory is Shareable:

`0` Memory is Non-shareable.

`1` Memory is Shareable.

Inner[2:0], bits [6:4]

Inner memory attributes for the region. Permitted values are:

`000` Non-cacheable.

`001` Strongly-ordered.

`011` Device.

`101` Write-Back, Write-Allocate.

`110` Write-Through.

`111` Write-Back, no Write-Allocate.

The values `010` and `100` are reserved.

An implementation that does not support all of the defined attributes can return the behavior that the cache supports, instead of the value in the translation table entry.

Outer[1:0], bits [3:2]

Outer memory attributes for the region. Permitted values are:

`00` Non-cacheable.

`01` Write-Back, Write-Allocate.

`10` Write-Through, no Write-Allocate.

`11` Write-Back, no Write-Allocate.

An implementation that does not support all of the defined attributes can return the behavior that the cache supports, instead of the value in the translation table entry.

SS, bit [1]

Supersection. Used to indicate if the result is a Supersection:

`0` Page is not a Supersection. That is, PAR[31:12] contains PA[31:12], regardless of the page size.

`1` Page is part of a Supersection:

- PAR[31:24] contains PA[31:24].
- PAR[23:16] contains PA[39:32].
- PAR[15:12] contains `0b0000`.

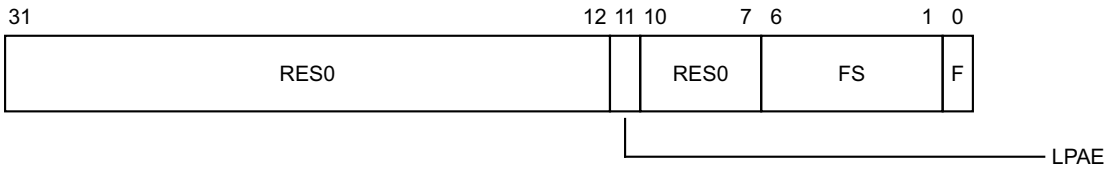
If an implementation supports less than 40 bits of physical address, the bits in the PAR field that correspond to physical address bits that are not implemented are UNKNOWN.

F, bit [0]

Indicates whether the conversion completed successfully.

`0` VA to PA conversion completed successfully.

When TTBCR.EAE==0, PAR.F==1:



Bits [31:12]

Reserved, RES0.

LPAE, bit [11]

When updating the PAR with the result of a translation operation, this bit is set as follows:

`0` Indicates use of the Short-descriptor translation table formats. This indicates that the PAR returns a 32-bit value.

`1` Indicates use of the Long-descriptor translation table formats. This indicates that the PAR returns a 64-bit value.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [10:7]

Reserved, RES0.

FS, bits [6:1]

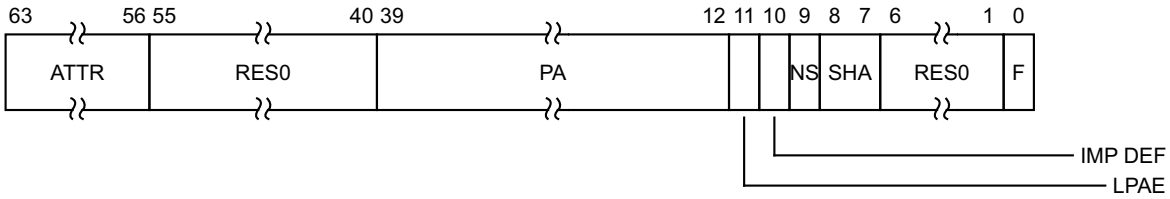
Fault status bits. Bits [12,10,3:0] from the DFSR, indicating the source of the abort.

F, bit [0]

Indicates whether the conversion completed successfully.

0 VA to PA conversion aborted.

When TTBCR.EAE==1, PAR.F==0:



ATTR, bits [63:56]

Memory attributes for the returned PA, as indicated by the translation table entry. This field uses the same encoding as the Attr<n> fields in MAIR0 and MAIR1.

Bits [55:40]

Reserved, RES0.

PA, bits [39:12]

Physical Address. The physical address corresponding to the supplied virtual address. This field returns address bits[39:12].

LPAE, bit [11]

When updating the PAR with the result of a translation operation, this bit is set as follows:

0 Indicates use of the Short-descriptor translation table formats. This indicates that the PAR returns a 32-bit value.

1 Indicates use of the Long-descriptor translation table formats. This indicates that the PAR returns a 64-bit value.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

NS, bit [9]

Non-secure. The NS attribute for a translation table entry read from Secure state.

This bit is UNKNOWN for a translation table entry read from Non-secure state.

SHA, bits [8:7]

Shareability attribute, from the translation table entry for the returned PA. Permitted values are:

00 Non-shareable.

10 Outer Shareable.

11 Inner Shareable.

The value 01 is reserved.

Note: this takes the value 10 for:

- Any type of Device memory.
- Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.

Bits [6:1]

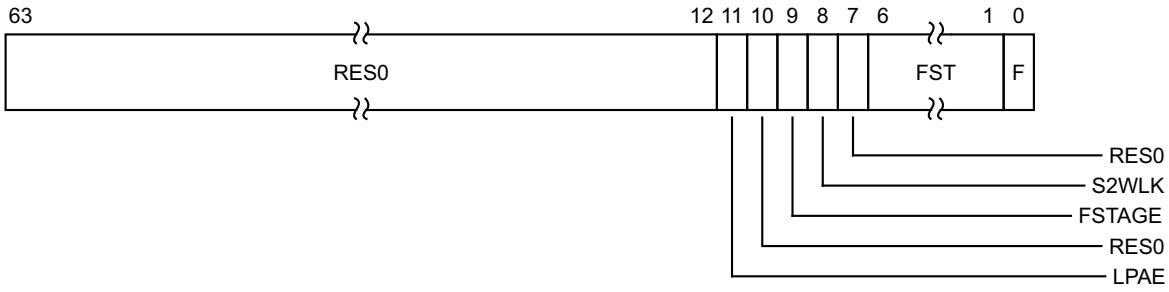
Reserved, RES0.

F, bit [0]

Indicates whether the conversion completed successfully.

0 VA to PA conversion completed successfully.

When TTBCR.EAE==1, PAR.F==1:



Bits [63:12]

Reserved, RES0.

LPAE, bit [11]

When updating the PAR with the result of a translation operation, this bit is set as follows:

0 Indicates use of the Short-descriptor translation table formats. This indicates that the PAR returns a 32-bit value.

1 Indicates use of the Long-descriptor translation table formats. This indicates that the PAR returns a 64-bit value.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bit [10]

Reserved, RES0.

FSTAGE, bit [9]

Indicates the translation stage at which the translation aborted:

0 Translation aborted because of a fault in the stage 1 translation.

1 Translation aborted because of a fault in the stage 2 translation.

S2WLK, bit [8]

If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.

Bit [7]

Reserved, RES0.

FST, bits [6:1]

Fault status field. Values are as in the DFSR.STATUS and IFSR.STATUS fields (when using the Long-descriptor translation table format).

F, bit [0]

Indicates whether the conversion completed successfully.

1 VA to PA conversion aborted.

Accessing the PAR

To access the PAR when TTBCR.EAE==0:

```
MRC p15,0,<Rt>,c7,c4,0 ; Read PAR into Rt
MCR p15,0,<Rt>,c7,c4,0 ; Write Rt to PAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0111	0100	000

To access the PAR when TTBCR.EAE==1:

```
MRRC p15,0,<Rt>,<Rt2>,c7 ; Read 64-bit PAR into Rt (low word) and Rt2 (high word)
MCRR p15,0,<Rt>,<Rt2>,c7 ; Write Rt (low word) and Rt2 (high word) to 64-bit PAR
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0000	0111

G5.1.108 PRRR, Primary Region Remap Register

The PRRR characteristics are:

Purpose

Controls the top level mapping of the TEX[0], C, and B memory region attributes.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as PRRR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as PRRR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Only accessible when using the Short-descriptor translation table format.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

PRRR(NS) is architecturally mapped to AArch64 register MAIR_EL1[31:0] when TTBCR.EAE==0.

PRRR(S) can be mapped to AArch64 register MAIR_EL3[31:0] when TTBCR.EAE==0, but this is not architecturally mandated.

PRRR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

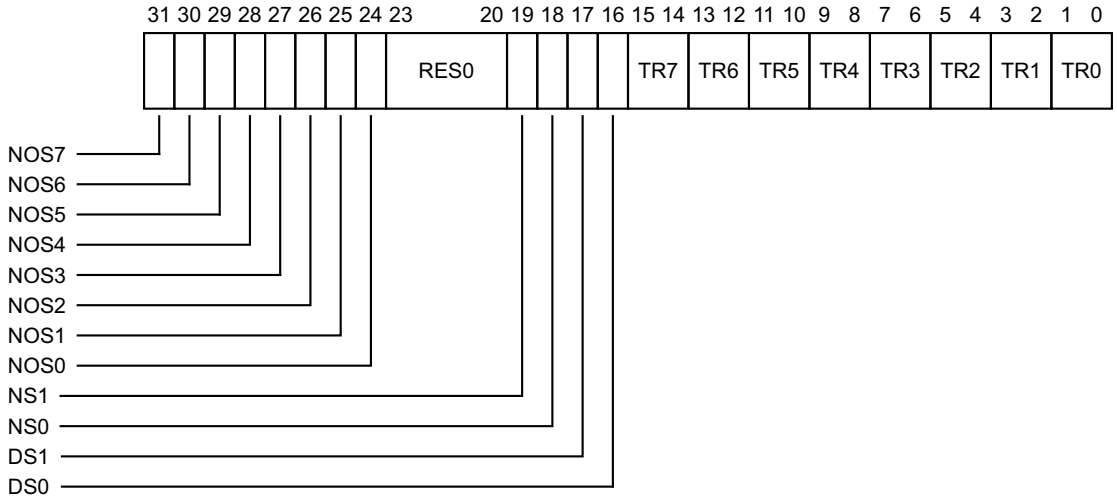
Attributes

PRRR is a 32-bit register when TTBCR.EAE==0.

Field descriptions

The PRRR bit assignments are:

When TTBCR.EAE==0:



NOS<n>, bit [n+24], for n+24 = 0 to 7

NOS<n> is the Outer Shareable property mapping for memory attributes n, if the region is mapped as Normal or Device memory that is Shareable. n is the value of the TEX[0], C, and B bits concatenated. The possible values of each NOS<n> bit are:

`0` Memory region is Outer Shareable.

`1` Memory region is Inner Shareable.

The value of this bit is ignored if the region is Normal or Device memory that is not Shareable.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination {TEX[0] = 1, C = 1, B = 0} is IMPLEMENTATION DEFINED.

If the implementation does not distinguish between Inner Shareable and Outer Shareable then these bits are reserved and are RES0.

Bits [23:20]

Reserved, RES0.

NS1, bit [19]

Mapping of S = 1 attribute for Normal memory. This bit gives the mapped Shareable attribute for a region of memory that:

- Is mapped as Normal memory.
- Has the S bit set to 1.

The possible values of this bit are:

`0` Region is not Shareable.

`1` Region is Shareable.

NS0, bit [18]

Mapping of S = 0 attribute for Normal memory. This bit gives the mapped Shareable attribute for a region of memory that:

- Is mapped as Normal memory.
- Has the S bit set to 0.

The possible values of this bit are:

0 Region is not Shareable.

1 Region is Shareable.

DS1, bit [17]

Mapping of S = 1 attribute for Device memory. This bit gives the mapped Shareable attribute for a region of memory that:

- Is mapped as Device memory.
- Has the S bit set to 1.

The possible values of this bit are:

0 Region is not Shareable.

1 Region is Shareable.

DS0, bit [16]

Mapping of S = 0 attribute for Device memory. This bit gives the mapped Shareable attribute for a region of memory that:

- Is mapped as Device memory.
- Has the S bit set to 0.

The possible values of this bit are:

0 Region is not Shareable.

1 Region is Shareable.

TR<n>, bits [2n+1:2n], for 2n+1:2n = 0 to 7

TR<n> is the primary TEX mapping for memory attributes n, and defines the mapped memory type for a region with attributes n. n is the value of the TEX[0], C, and B bits concatenated. The possible values of this field are:

00 Device-nGnRnE memory

01 Device-nGnRE memory

10 Normal memory

The value 11 is reserved.

The meaning of the field with n = 6 is IMPLEMENTATION DEFINED and might differ from the meaning given here. This is because the meaning of the attribute combination {TEX[0] = 1, C = 1, B = 0} is IMPLEMENTATION DEFINED.

Accessing the PRRR

To access the PRRR when TTBCR.EAE==0:

```
MRC p15,0,<Rt>,c10,c2,0 ; Read PRRR into Rt
MCR p15,0,<Rt>,c10,c2,0 ; Write Rt to PRRR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1010	0010	000

G5.1.109 REVIDR, Revision ID Register

The REVIDR characteristics are:

Purpose

Provides implementation-specific minor revision information.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

REVIDR is architecturally mapped to AArch64 register REVIDR_EL1.

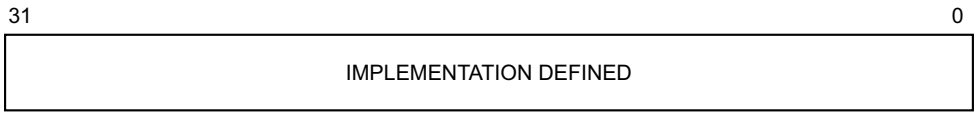
If REVIDR has the same value as MIDR, then its content has no significance.

Attributes

REVIDR is a 32-bit register.

Field descriptions

The REVIDR bit assignments are:



Bits [31:0]

IMPLEMENTATION DEFINED

Accessing the REVIDR

To access the REVIDR:

```
MRC p15,0,<Rt>,c0,c0,6 ; Read REVIDR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0000	110

G5.1.110 RMR (at EL1), Reset Management Register

The RMR (at EL1) characteristics are:

Purpose

If this register's exception level is the highest exception level implemented, and is capable of using both AArch32 and AArch64, controls the Execution state that the processor boots into and allows request of a Warm reset.

This register is part of the Reset management registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1
-	RW

If EL3 is implemented, the AArch32 view of the RMR register is subject to CP15SDISABLE, which prevents writing to this register when the CP15SDISABLE signal is asserted.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

RMR (at EL1) is architecturally mapped to AArch64 register RMR_EL1.

RMR is implemented at EL1 only if EL1 is the highest Exception level implemented, and is capable of using both AArch32 and AArch64.

If RMR is not implemented at EL1 then its encoding is UNDEFINED at EL1.

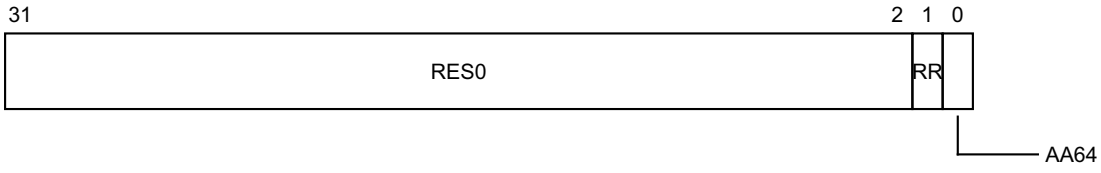
Attributes

RMR (at EL1) is a 32-bit register when EL2 and EL3 not implemented.

Field descriptions

The RMR (at EL1) bit assignments are:

When EL2 and EL3 not implemented:



Bits [31:2]

Reserved, RES0.

RR, bit [1]

When set to 1 this bit requests a Warm reset. The bit is strictly a request.

On Warm reset, the field resets to 0.

AA64, bit [0]

Determines which Execution state the processor boots into after a Warm reset:

0 AArch32.

1 AArch64.

The reset vector address on reset takes a choice between two IMP DEF values, depending on the value in the AA64 bit.

On Cold reset, the field resets to 0.

Accessing the RMR (at EL1)

To access the RMR (at EL1) when EL2 and EL3 not implemented:

```
MRC p15,0,<Rt>,c12,c0,2 ; Read RMR into Rt
MCR p15,0,<Rt>,c12,c0,2 ; Write Rt to RMR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	0000	010

G5.1.111 RMR (at EL3), Reset Management Register

The RMR (at EL3) characteristics are:

Purpose

If this register's exception level is the highest exception level implemented, and is capable of using both AArch32 and AArch64, controls the Execution state that the processor boots into and allows request of a Warm reset.

This register is part of the Reset management registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW	RW

If EL3 is implemented, the AArch32 view of the RMR register is subject to CP15SDISABLE, which prevents writing to this register when the CP15SDISABLE signal is asserted.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

RMR (at EL3) is architecturally mapped to AArch64 register RMR_EL3.

RMR is implemented at EL3 only if EL3 is capable of using both AArch32 and AArch64.

If RMR is not implemented at EL3 then its encoding is UNDEFINED at EL3.

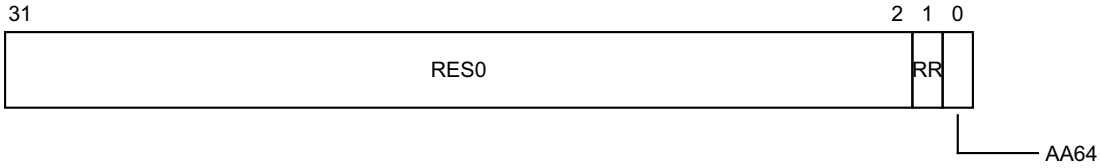
Attributes

RMR (at EL3) is a 32-bit register when EL3 implemented.

Field descriptions

The RMR (at EL3) bit assignments are:

When EL3 implemented:



Bits [31:2]

Reserved, RES0.

RR, bit [1]

When set to 1 this bit requests a Warm reset. The bit is strictly a request.

On Warm reset, the field resets to 0.

AA64, bit [0]

Determines which Execution state the processor boots into after a Warm reset:

0. AArch32.

1. AArch64.

The reset vector address on reset takes a choice between two IMP DEF values, depending on the value in the AA64 bit.

On Cold reset, the field resets to 0.

Accessing the RMR (at EL3)

To access the RMR (at EL3) when EL3 implemented:

```
MRC p15,0,<Rt>,c12,c0,2 ; Read RMR into Rt
MCR p15,0,<Rt>,c12,c0,2 ; Write Rt to RMR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	0000	010

G5.1.112 RVBAR, Reset Vector Base Address Register

The RVBAR characteristics are:

Purpose

If EL3 is not implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch32 state.

This register is part of the Reset management registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1	EL2
-	Config-RO	Config-RO

This register can only be read at the highest exception level implemented. It is UNDEFINED at all other exception levels.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

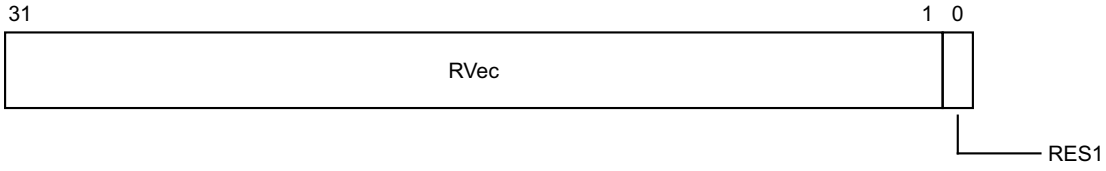
This register is only implemented if the highest exception level implemented is capable of using AArch32, and is not EL3.

Attributes

RVBAR is a 32-bit register.

Field descriptions

The RVBAR bit assignments are:



RVec, bits [31:1]

Bits [31:1] of the IMPLEMENTATION DEFINED AArch32 reset address.

Bit [0]

Reserved, RES1.

Accessing the RVBAR

To access the RVBAR:

```
MRC p15,0,<Rt>,c12,c0,1 ; Read RVBAR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	0000	001

G5.1.113 SCR, Secure Configuration Register

The SCR characteristics are:

Purpose

Defines the configuration of the current security state. It specifies:

- The security state, either Secure or Non-secure.
- What mode the processor branches to if an IRQ, FIQ, or External Abort occurs.
- Whether the CPSR.F or CPSR.A bits can be modified when SCR.NS==1.

This register is part of the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	RW	RW

If EL3 is implemented and is using AArch64, any read or write to SCR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

If EL3 is not implemented, attempts to access SCR are UNDEFINED.

SCR is a Restricted access System register, see *Restricted access System registers* on page G4-3750.

Configurations

This register is only accessible in Secure state.

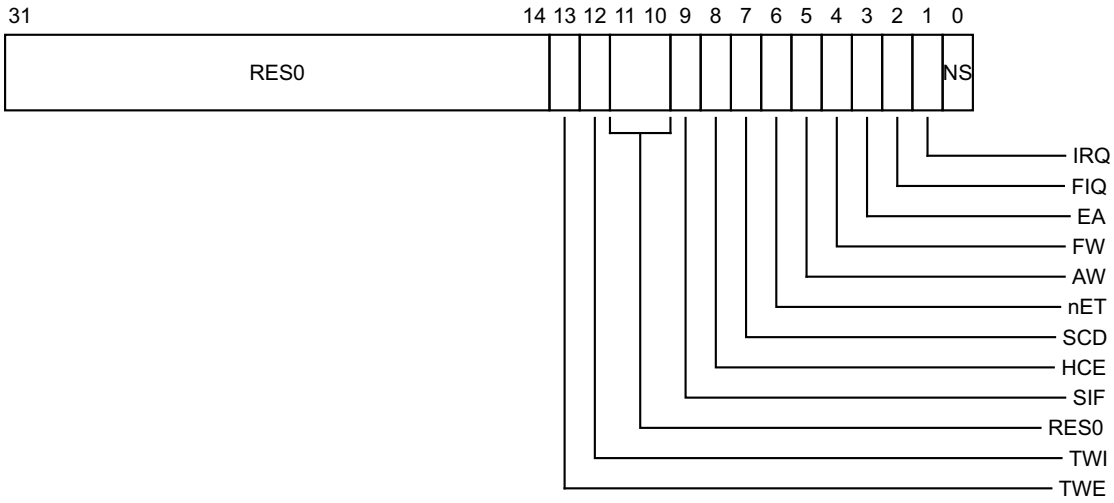
SCR can be mapped to AArch64 register SCR_EL3, but this is not architecturally mandated.

Attributes

SCR is a 32-bit register.

Field descriptions

The SCR bit assignments are:



Bits [31:14]

Reserved, RES0.

TWE, bit [13]

Trap WFE. The possible values of this bit are:

0 WFE instructions are not trapped.

1 A WFE instruction executed in any mode other than Monitor mode is trapped to Monitor mode, using the Monitor Trap exception, if the instruction would otherwise cause suspension of execution. This means the instruction is trapped only if the event register is not set, there is not a pending WFE wakeup event, and the instruction does not cause another exception.

Conditional WFE instructions that fail their condition do not cause an exception by this mechanism.

Resets to 0.

TWI, bit [12]

Trap WFI. The possible values of this bit are:

0 WFI instructions are not trapped.

1 A WFI instruction executed in any mode other than Monitor mode is trapped to Monitor mode, using the Monitor Trap exception, if the instruction would otherwise cause suspension of execution.

Conditional WFI instructions that fail their condition do not cause an exception by this mechanism.

Resets to 0.

Bits [11:10]

Reserved, RES0.

SIF, bit [9]

Secure instruction fetch. When the processor is in Secure state, this bit disables instruction fetch from Non-secure memory. The possible values for this bit are:

0 Secure state instruction fetches from Non-secure memory are permitted.

1 Secure state instruction fetches from Non-secure memory are not permitted.

This bit is permitted to be cached in a TLB.

Resets to 0.

HCE, bit [8]

Hypervisor Call enable. This bit enables use of the HVC instruction from Non-secure EL1 modes. The possible values of this bit are:

0 HVC instruction is UNDEFINED in Non-secure EL1 modes, and either UNDEFINED or a NOP in Hyp mode, depending on the implementation.

1 HVC instruction is enabled in Non-secure EL1 modes, and performs a Hypervisor Call.

If EL3 is implemented but EL2 is not implemented, this bit is RES0.

Resets to 0.

SCD, bit [7]

Secure Monitor Call disable. Makes the SMC instruction UNDEFINED in Non-secure state. The possible values of this bit are:

0 SMC executes normally in Non-secure state, performing a Secure Monitor Call.

1 SMC instruction is either UNDEFINED or a NOP in Non-secure state, depending on the implementation.

A trap of the SMC instruction to Hyp mode takes priority over the value of this bit.

Resets to 0.

nET, bit [6]

Not Early Termination. This bit disables early termination. The possible values of this bit are:

0 Early termination permitted. Execution time of data operations can depend on the data values.

1 Disable early termination. The number of cycles required for data operations is forced to be independent of the data values.

This IMPLEMENTATION DEFINED mechanism can disable data dependent timing optimizations from multiplies and data operations. It can provide system support against information leakage that might be exploited by timing correlation types of attack.

Resets to 0.

AW, bit [5]

When the value of SCR.EA is 1 and the value of HCR.AMO is 0, this bit controls whether CPSR.A masks an external abort taken from Non-secure state, and the possible values of this bit are:

0 External aborts taken from Non-secure state are not masked by CPSR.A, and are taken to EL3.

External aborts taken from Secure state are masked by CPSR.A.

1 External aborts taken from either security state are masked by CPSR.A. When CPSR.A is 0, the abort is taken to EL3.

When SCR.EA is 0 or HCR.AMO is 1, this bit has no effect.

Resets to 0.

FW, bit [4]

When the value of SCR.FIQ is 1 and the value of HCR.FMO is 0, this bit controls whether CPSR.F masks an FIQ interrupt taken from Non-secure state, and the possible values of this bit are:

0 An FIQ taken from Non-secure state is not masked by CPSR.F, and is taken to EL3.

An FIQ taken from Secure state is masked by CPSR.F.

1 An FIQ taken from either security state is masked by CPSR.F. When CPSR.F is 0, the FIQ is taken to EL3.

When SCR.FIQ is 0 or HCR.FMO is 1, this bit has no effect.

Resets to 0.

EA, bit [3]

External Abort handler. This bit controls which mode takes external aborts. The possible values of this bit are:

0 External aborts taken in Abort mode.

1 External aborts taken in Monitor mode.

Resets to 0.

FIQ, bit [2]

FIQ handler. This bit controls which mode takes FIQ exceptions. The possible values of this bit are:

0 FIQs taken in FIQ mode.

1 FIQs taken in Monitor mode.

Resets to 0.

IRQ, bit [1]

IRQ handler. This bit controls which mode takes IRQ exceptions. The possible values of this bit are:

0 IRQs taken in IRQ mode.

1 IRQs taken in Monitor mode.

Resets to 0.

NS, bit [0]

Non-secure bit. Except when the processor is in Monitor mode, this bit determines the security state of the processor:

`0` Processor is in Secure state.

`1` Processor is in Non-secure state.

If the HCR.TGE bit is set, an attempt to change from a Secure Kernel mode to a Non-secure Kernel mode by changing the SCR.NS bit from 0 to 1 will result in the SCR.NS bit remaining as 0.

Resets to 0.

Accessing the SCR

To access the SCR:

```
MRC p15,0,<Rt>,c1,c1,0 ; Read SCR into Rt
MCR p15,0,<Rt>,c1,c1,0 ; Write Rt to SCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0001	000

G5.1.114 SCTLR, System Control Register

The SCTLR characteristics are:

Purpose

Provides the top level control of the system, including its memory system.

This register is part of the Other system control registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as SCTLR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as SCTLR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Some bits in the register are read-only. These bits relate to non-configurable features of an implementation, and are provided for compatibility with previous versions of the architecture.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

SCTLR(NS) is architecturally mapped to AArch64 register SCTLR_EL1.

SCTLR(S) can be mapped to AArch64 register SCTLR_EL3, but this is not architecturally mandated.

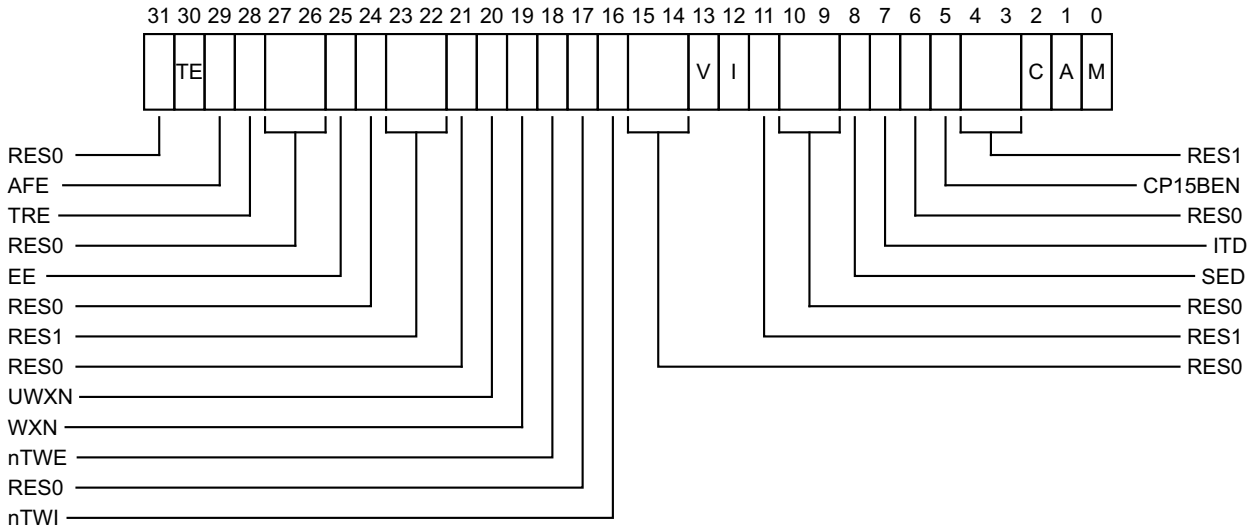
SCTLR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

Attributes

SCTLR is a 32-bit register.

Field descriptions

The SCTLR bit assignments are:



Bit [31]

Reserved, RES0.

TE, bit [30]

T32 Exception Enable. This bit controls whether exceptions are taken in A32 or T32 state:

0 Exceptions, including reset, taken in A32 state.

1 Exceptions, including reset, taken in T32 state.

For the Secure copy of this register, the field resets to a value that is configurable by either input signal or pin setting.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

AFE, bit [29]

Access Flag Enable. When using the Short-descriptor translation table format, this bit enables use of the AP[0] bit in the translation descriptors as the Access flag, and restricts access permissions in the translation descriptors to the simplified model. The possible values of this bit are:

0 In the translation table descriptors, AP[0] is an access permissions bit. The full range of access permissions is supported. No Access flag is implemented.

1 In the translation table descriptors, AP[0] is the Access flag. Only the simplified model for access permissions is supported.

When using the Long-descriptor translation table format, the VMSA behaves as if this bit is set to 1, regardless of the value of this bit.

The AFE bit is permitted to be cached in a TLB.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

TRE, bit [28]

TEX remap enable. This bit enables remapping of the TEX[2:1] bits for use as two translation table bits that can be managed by the operating system. Enabling this remapping also changes the scheme used to describe the memory region attributes in the VMSA. The possible values of this bit are:

0 TEX remap disabled. TEX[2:0] are used, with the C and B bits, to describe the memory region attributes.

1 TEX remap enabled. TEX[2:1] are reassigned for use as bits managed by the operating system. The TEX[0], C, and B bits are used to describe the memory region attributes, with the MMU remap registers.

The TRE bit is permitted to be cached in a TLB.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

Bits [27:26]

Reserved, RES0.

EE, bit [25]

Exception Endianness. The value of this bit defines the value of the CPSR.E bit on entry to an exception vector, including reset. This value also indicates the endianness of the translation table data for translation table lookups. The possible values of this bit are:

0 Little-endian.

1 Big-endian.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

For the Secure copy of this register, the field resets to a value that is configurable by either input signal or pin setting.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

Bit [24]

Reserved, RES0.

Bits [23:22]

Reserved, RES1.

Bit [21]

Reserved, RES0.

UWXN, bit [20]

Unprivileged write permission implies EL1 XN (Execute Never). This bit can be used to require all memory regions with unprivileged write permissions to be treated as XN for accesses from software executing at EL1. The possible values of this bit are:

0 Regions with unprivileged write permission are not forced to XN.

1 Regions with unprivileged write permission are forced to XN for accesses from software executing at EL1.

The UWXN bit is permitted to be cached in a TLB.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

WXN, bit [19]

Write permission implies XN (Execute Never). This bit can be used to require all memory regions with write permission to be treated as XN. The possible values of this bit are:

0 Regions with write permission are not forced to XN.

1 Regions with write permission are forced to XN.

The WXN bit is permitted to be cached in a TLB.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

nTWE, bit [18]

Not trap WFE. Possible values of this bit are:

`0` If a WFE instruction executed at EL0 would cause execution to be suspended, such as if the event register is not set and there is not a pending WFE wakeup event, it is treated as UNDEFINED.

`1` WFE instructions are executed as normal.

Conditional WFE instructions that fail their condition do not cause an exception if this bit is 0.

For the Secure copy of this register, the field resets to 1.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

Bit [17]

Reserved, RES0.

nTWI, bit [16]

Not trap WFI. Possible values of this bit are:

`0` If a WFI instruction executed at EL0 would cause execution to be suspended, such as if there is not a pending WFI wakeup event, it is treated as UNDEFINED.

`1` WFI instructions are executed as normal.

Conditional WFI instructions that fail their condition do not cause an exception if this bit is 0.

For the Secure copy of this register, the field resets to 1.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

Bits [15:14]

Reserved, RES0.

V, bit [13]

Vectors bit. This bit selects the base address of the exception vectors:

`0` Normal exception vectors, base address `0x00000000`. In an implementation that includes EL3, this base address can be re-mapped.

`1` High exception vectors (Hivecs), base address `0xFFFF0000`. This base address is never remapped.

For the Secure copy of this register, the field resets to a value that is configurable by either input signal or pin setting.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

I, bit [12]

Instruction cache enable. This is a global enable bit for instruction caches:

`0` Instruction caches disabled. If SCTLR.M is set to 0, instruction accesses from stage 1 of the PL1&0 translation regime are to Normal memory, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.

`1` Instruction caches enabled. If SCTLR.M is set to 0, instruction accesses from stage 1 of the PL1&0 translation regime are to Normal memory, Outer Shareable, Inner Write-Through, Outer Write-Through.

When this bit is 0, all Normal memory instruction accesses are Non-cacheable.

If the HCR.DC bit is set to 1, then the Non-secure stage 1 PL1&0 translation regime is Cacheable regardless of the value of this bit.

For the Secure copy of this register, the field if this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

Bit [11]

Reserved, RES1.

Bits [10:9]

Reserved, RES0.

SED, bit [8]

SETEND Disable. The possible values of this bit are:

0 The SETEND instruction is available.

1 The SETEND instruction is UNALLOCATED.

If an implementation does not support mixed endian operation, this bit is RES1.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

ITD, bit [7]

IT Disable. The possible values of this bit are:

0 The IT instruction functionality is available.

1 It is IMPLEMENTATION DEFINED whether the IT instruction is treated as either:

- A 16-bit instruction, which can only be followed by another 16-bit instruction.
- The first half of a 32-bit instruction.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

All encodings of the IT instruction with hw1[3:0]!=1000 are UNDEFINED and treated as unallocated.

All encodings of the subsequent instruction with the following values for hw1 are UNDEFINED (and treated as unallocated):

`11xxxxxxxxxxxxx`
: All 32-bit instructions, B(2), B(1), Undefined, SVC, Load/Store multiple

`1x11xxxxxxxxxxx`
: Miscellaneous 16-bit instructions

`1x100xxxxxxxxxx`
: ADD Rd, PC, #imm

`01001xxxxxxxxxx`
: LDR Rd, [PC, #imm]

`0100x1xxx1111xxx`
: ADD(4),CMP(3), MOV, BX pc, BLX pc

`010001xx1xxxx111`
: ADD(4),CMP(3), MOV (Note: this pattern also covers UNPREDICTABLE cases with BLX Rn)

Contrary to the standard treatment of conditional UNDEFINED instructions in the ARM architecture, in this case these instructions are always treated as UNDEFINED, regardless of whether the instruction would pass or fail its condition codes as a result of being in an IT block.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

Bit [6]

Reserved, RES0.

CP15BEN, bit [5]

CP15 barrier enable. If implemented, this is an enable bit for the CP15 DMB, DSB, and ISB barrier operations at EL0 and EL1:

0 CP15 barrier operations disabled at EL0 and EL1. Their encodings are UNDEFINED.

1 CP15 barrier operations enabled at EL0 and EL1.

If an implementation does not support the CP15 barrier operations, this bit is RES0.

For the Secure copy of this register, the field resets to 1.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

Bits [4:3]

Reserved, RES1.

C, bit [2]

Cache enable. This is a global enable bit for data and unified caches:

0 Data and unified caches disabled.

1 Data and unified caches enabled.

When this bit is 0, all Normal memory data accesses and all accesses to the PL1&0 stage 1 translation tables are Non-cacheable.

If the HCR.DC bit is set to 1, then the Non-secure stage 1 PL1&0 translation regime is Cacheable regardless of the value of the SCTLR.C bit.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking:

0 Alignment fault checking disabled.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

1 Alignment fault checking enabled.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

M, bit [0]

MMU enable for EL1 and EL0 stage 1 address translation. Possible values of this bit are:

0 EL1 and EL0 stage 1 address translation disabled.

1 EL1 and EL0 stage 1 address translation enabled.

If the HCR.DC bit is set to 1, then the behavior of the processor when executing in a Non-secure mode other than Hyp mode is consistent with SCTLR.M being 0, regardless of the actual value of SCTLR.M, other than the value returned by an explicit read of SCTLR.M.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

Accessing the SCTLR

To access the SCTLR:

```
MRC p15,0,<Rt>,c1,c0,0 ; Read SCTLR into Rt
MCR p15,0,<Rt>,c1,c0,0 ; Write Rt to SCTLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0000	000

G5.1.115 SPSR, Saved Program Status Register

The SPSR characteristics are:

Purpose

Holds the saved processor state for the current mode.

Usage constraints

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

The SPSR can be read using the MRS instruction and written using the MSR (immediate) or MSR (register) instructions. For more details on the instruction syntax, see .

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

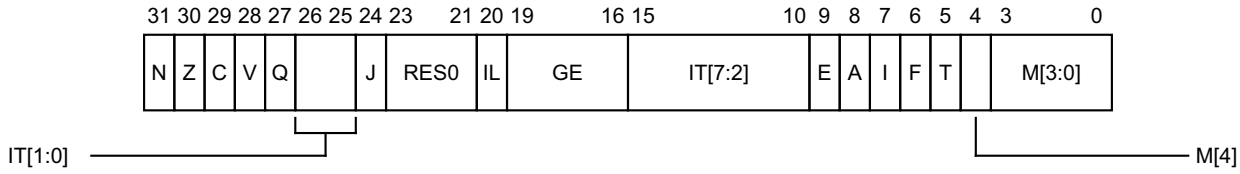
There are no configuration notes.

Attributes

SPSR is a 32-bit register.

Field descriptions

The SPSR bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to the current mode, and copied to CPSR.N on executing an exception return operation in the current mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to the current mode, and copied to CPSR.Z on executing an exception return operation in the current mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to the current mode, and copied to CPSR.C on executing an exception return operation in the current mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to the current mode, and copied to CPSR.V on executing an exception return operation in the current mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to the current mode, and copied to CPSR.Q on executing an exception return operation in the current mode.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

G5.1.116 SPSR_abt, Saved Program Status Register (Abort mode)

The SPSR_abt characteristics are:

Purpose

Holds the saved processor state when an exception is taken to Abort mode.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS, !ABT)	EL1 (S, !ABT)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

This register is only accessible at EL1 in modes other than Abort mode. In Abort mode, it is accessible as the current SPSR.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

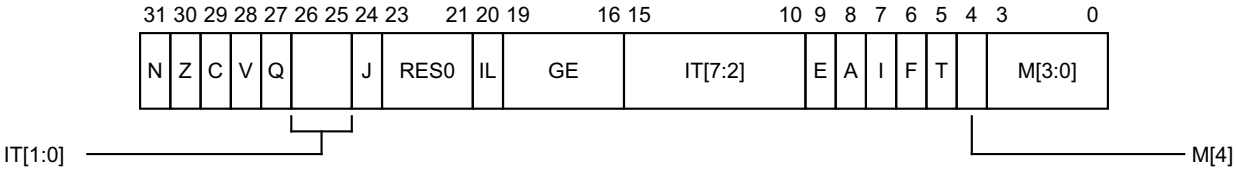
SPSR_abt is architecturally mapped to AArch64 register SPSR_abt.

Attributes

SPSR_abt is a 32-bit register.

Field descriptions

The SPSR_abt bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Abort mode, and copied to CPSR.N on executing an exception return operation in Abort mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Abort mode, and copied to CPSR.Z on executing an exception return operation in Abort mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Abort mode, and copied to CPSR.C on executing an exception return operation in Abort mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Abort mode, and copied to CPSR.V on executing an exception return operation in Abort mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to Abort mode, and copied to CPSR.Q on executing an exception return operation in Abort mode.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved.

Accessing the SPSR_abt

To access the SPSR_abt:

```
MRS <Rd>, SPSR_abt ; Read SPSR_abt into Rd
MSR SPSR_abt, <Rd> ; Write Rd to SPSR_abt
```

Register access is encoded as follows:

m	m1	R
1	0100	1

G5.1.117 SPSR_fiq, Saved Program Status Register (FIQ mode)

The SPSR_fiq characteristics are:

Purpose

Holds the saved processor state when an exception is taken to FIQ mode.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS, !FIQ)	EL1 (S, !FIQ)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

This register is only accessible at EL1 in modes other than FIQ mode. In FIQ mode, it is accessible as the current SPSR.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

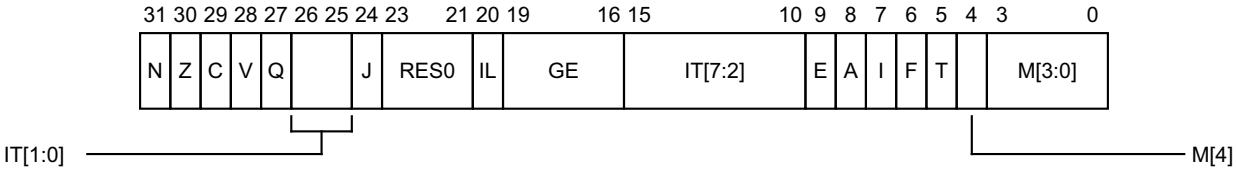
SPSR_fiq is architecturally mapped to AArch64 register SPSR_fiq.

Attributes

SPSR_fiq is a 32-bit register.

Field descriptions

The SPSR_fiq bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to FIQ mode, and copied to CPSR.N on executing an exception return operation in FIQ mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to FIQ mode, and copied to CPSR.Z on executing an exception return operation in FIQ mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to FIQ mode, and copied to CPSR.C on executing an exception return operation in FIQ mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to FIQ mode, and copied to CPSR.V on executing an exception return operation in FIQ mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to FIQ mode, and copied to CPSR.Q on executing an exception return operation in FIQ mode.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved.

Accessing the SPSR_fiq

To access the SPSR_fiq:

```
MRS <Rd>, SPSR_fiq ; Read SPSR_fiq into Rd
MSR SPSR_fiq, <Rd> ; Write Rd to SPSR_fiq
```

Register access is encoded as follows:

m	m1	R
0	1110	1

G5.1.118 SPSR_hyp, Saved Program Status Register (Hyp mode)

The SPSR_hyp characteristics are:

Purpose

Holds the saved processor state when an exception is taken to Hyp mode.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

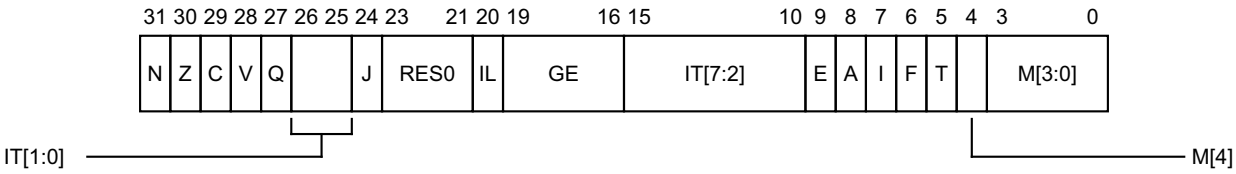
SPSR_hyp is architecturally mapped to AArch64 register SPSR_EL2.

Attributes

SPSR_hyp is a 32-bit register.

Field descriptions

The SPSR_hyp bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Hyp mode, and copied to CPSR.N on executing an exception return operation in Hyp mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Hyp mode, and copied to CPSR.Z on executing an exception return operation in Hyp mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Hyp mode, and copied to CPSR.C on executing an exception return operation in Hyp mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Hyp mode, and copied to CPSR.V on executing an exception return operation in Hyp mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to Hyp mode, and copied to CPSR.Q on executing an exception return operation in Hyp mode.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

Accessing the SPSR_hyp

To access the SPSR_hyp:

```
MRS <Rd>, SPSR_hyp ; Read SPSR_hyp into Rd
MSR SPSR_hyp, <Rd> ; Write Rd to SPSR_hyp
```

Register access is encoded as follows:

m	m1	R
1	1110	1

G5.1.119 SPSR_irq, Saved Program Status Register (IRQ mode)

The SPSR_irq characteristics are:

Purpose

Holds the saved processor state when an exception is taken to IRQ mode.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS, !IRQ)	EL1 (S, !IRQ)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

This register is only accessible at EL1 in modes other than IRQ mode. In IRQ mode, it is accessible as the current SPSR.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

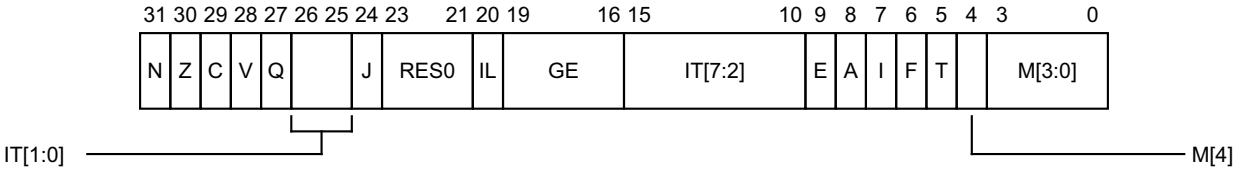
SPSR_irq is architecturally mapped to AArch64 register SPSR_irq.

Attributes

SPSR_irq is a 32-bit register.

Field descriptions

The SPSR_irq bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to IRQ mode, and copied to CPSR.N on executing an exception return operation in IRQ mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to IRQ mode, and copied to CPSR.Z on executing an exception return operation in IRQ mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to IRQ mode, and copied to CPSR.C on executing an exception return operation in IRQ mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to IRQ mode, and copied to CPSR.V on executing an exception return operation in IRQ mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to IRQ mode, and copied to CPSR.Q on executing an exception return operation in IRQ mode.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved.

Accessing the SPSR_irq

To access the SPSR_irq:

```
MRS <Rd>, SPSR_irq ; Read SPSR_irq into Rd
MSR SPSR_irq, <Rd> ; Write Rd to SPSR_irq
```

Register access is encoded as follows:

m	m1	R
1	0000	1

G5.1.120 SPSR_mon, Saved Program Status Register (Monitor mode)

The SPSR_mon characteristics are:

Purpose

Holds the saved processor state when an exception is taken to Monitor mode.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	-

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

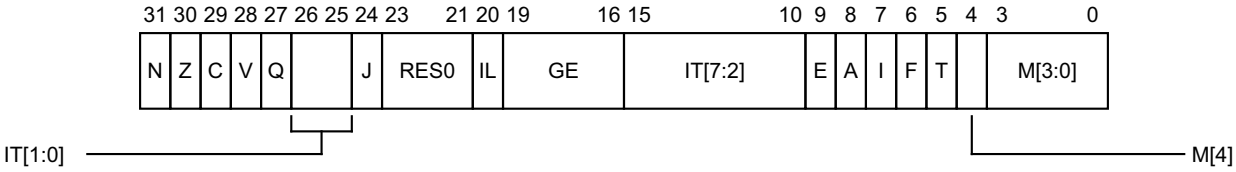
SPSR_mon can be mapped to AArch64 register SPSR_EL3, but this is not architecturally mandated.

Attributes

SPSR_mon is a 32-bit register.

Field descriptions

The SPSR_mon bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Monitor mode, and copied to CPSR.N on executing an exception return operation in Monitor mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Monitor mode, and copied to CPSR.Z on executing an exception return operation in Monitor mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Monitor mode, and copied to CPSR.C on executing an exception return operation in Monitor mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Monitor mode, and copied to CPSR.V on executing an exception return operation in Monitor mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to Monitor mode, and copied to CPSR.Q on executing an exception return operation in Monitor mode.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

Accessing the SPSR_mon

To access the SPSR_mon:

```
MRS <Rd>, SPSR_mon ; Read SPSR_mon into Rd
MSR SPSR_mon, <Rd> ; Write Rd to SPSR_mon
```

Register access is encoded as follows:

m	m1	R
1	1100	1

G5.1.121 SPSR_svc, Saved Program Status Register (Sup. Call mode)

The SPSR_svc characteristics are:

Purpose

Holds the saved processor state when an exception is taken to Supervisor mode.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS, !SVC)	EL1 (S, !SVC)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

This register is only accessible at EL1 in modes other than Supervisor mode. In Supervisor mode, it is accessible as the current SPSR.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

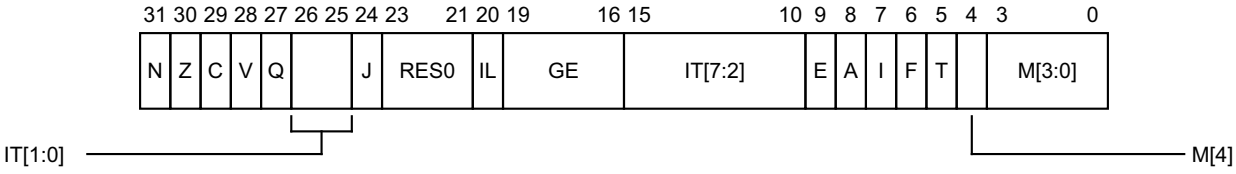
SPSR_svc is architecturally mapped to AArch64 register SPSR_EL1.

Attributes

SPSR_svc is a 32-bit register.

Field descriptions

The SPSR_svc bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Supervisor mode, and copied to CPSR.N on executing an exception return operation in Supervisor mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Supervisor mode, and copied to CPSR.Z on executing an exception return operation in Supervisor mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Supervisor mode, and copied to CPSR.C on executing an exception return operation in Supervisor mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Supervisor mode, and copied to CPSR.V on executing an exception return operation in Supervisor mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to Supervisor mode, and copied to CPSR.Q on executing an exception return operation in Supervisor mode.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved.

Accessing the SPSR_svc

To access the SPSR_svc:

```
MRS <Rd>, SPSR_svc ; Read SPSR_svc into Rd
MSR SPSR_svc, <Rd> ; Write Rd to SPSR_svc
```

Register access is encoded as follows:

m	m1	R
1	0010	1

G5.1.122 SPSR_und, Saved Program Status Register (Undefined mode)

The SPSR_und characteristics are:

Purpose

Holds the saved processor state when an exception is taken to Undefined mode.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS, !UND)	EL1 (S, !UND)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

This register is only accessible at EL1 in modes other than Undefined mode. In Undefined mode, it is accessible as the current SPSR.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

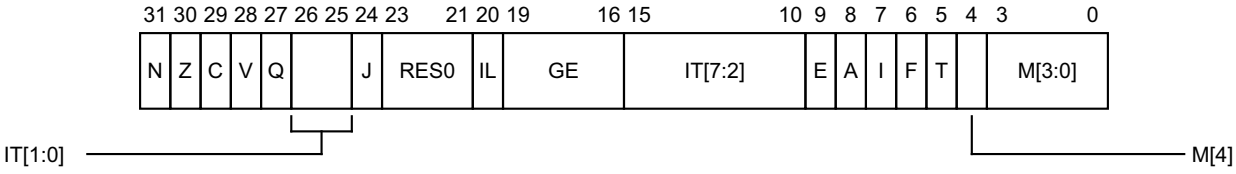
SPSR_und is architecturally mapped to AArch64 register SPSR_und.

Attributes

SPSR_und is a 32-bit register.

Field descriptions

The SPSR_und bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Undefined mode, and copied to CPSR.N on executing an exception return operation in Undefined mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Undefined mode, and copied to CPSR.Z on executing an exception return operation in Undefined mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Undefined mode, and copied to CPSR.C on executing an exception return operation in Undefined mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Undefined mode, and copied to CPSR.V on executing an exception return operation in Undefined mode.

Q, bit [27]

Set to the value of CPSR.Q on taking an exception to Undefined mode, and copied to CPSR.Q on executing an exception return operation in Undefined mode.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
0b0111	Abort
0b1011	Undefined
0b1111	System

Other values are reserved.

Accessing the SPSR_und

To access the SPSR_und:

```
MRS <Rd>, SPSR_und ; Read SPSR_und into Rd
MSR SPSR_und, <Rd> ; Write Rd to SPSR_und
```

Register access is encoded as follows:

m	m1	R
1	0110	1

G5.1.123 TCMTR, TCM Type Register

The TCMTR characteristics are:

Purpose

Provides information about the implementation of the TCM.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Configurations

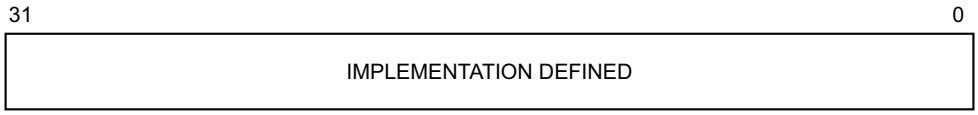
There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

TCMTR is a 32-bit register.

Field descriptions

The TCMTR bit assignments are:



Bits [31:0]

IMPLEMENTATION DEFINED

Accessing the TCMTR

To access the TCMTR:

```
MRC p15,0,<Rt>,c0,c0,2 ; Read TCMTR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0000	010

G5.1.124 TLBIALL, TLB Invalidate All

The TLBIALL characteristics are:

Purpose

Invalidate all PL1&0 regime stage 1 and 2 TLB entries for the current VMID and the current security state.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

There are no configuration notes.

Attributes

TLBIALL is a 32-bit system operation.

Field descriptions

The TLBIALL operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBIALL operation

To perform the TLBIALL operation:

```
MCR p15,0,<Rt>,c8,c7,0 ; TLBIALL operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	000

G5.1.125 TLBIALLH, TLB Invalidate All, Hyp mode

The TLBIALLH characteristics are:

Purpose

Invalidate all PL2 regime stage 1 TLB entries for the Non-secure state.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

Configurations

There are no configuration notes.

Attributes

TLBIALLH is a 32-bit system operation.

Field descriptions

The TLBIALLH operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBIALLH operation

To perform the TLBIALLH operation:

```
MCR p15,4,<Rt>,c8,c7,0 ; TLBIALLH operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0111	000

G5.1.126 TLBIALLHIS, TLB Invalidate All, Hyp mode, Inner Shareable

The TLBIALLHIS characteristics are:

Purpose

Invalidate all PL2 regime stage 1 TLB entries for the Non-secure state, on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

Configurations

There are no configuration notes.

Attributes

TLBIALLHIS is a 32-bit system operation.

Field descriptions

The TLBIALLHIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBIALLHIS operation

To perform the TLBIALLHIS operation:

```
MCR p15,4,<Rt>,c8,c3,0 ; TLBIALLHIS operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0011	000

G5.1.127 TLBIALLIS, TLB Invalidate All, Inner Shareable

The TLBIALLIS characteristics are:

Purpose

Invalidate all PL1&0 regime stage 1 and 2 TLB entries for the current VMID and the current security state, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

There are no configuration notes.

Attributes

TLBIALLIS is a 32-bit system operation.

Field descriptions

The TLBIALLIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBIALLIS operation

To perform the TLBIALLIS operation:

```
MCR p15,0,<Rt>,c8,c3,0 ; TLBIALLIS operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	000

G5.1.128 TLBIALLNSNH, TLB Invalidate All, Non-Secure Non-Hyp

The TLBIALLNSNH characteristics are:

Purpose

Invalidate all Non-secure PL1&0 regime stage 1 and 2 TLB entries.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

Configurations

There are no configuration notes.

Attributes

TLBIALLNSNH is a 32-bit system operation.

Field descriptions

The TLBIALLNSNH operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBIALLNSNH operation

To perform the TLBIALLNSNH operation:

```
MCR p15,4,<Rt>,c8,c7,4 ; TLBIALLNSNH operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0111	100

G5.1.129 TLBIALLNSNHIS, TLB Invalidate All, Non-Secure Non-Hyp, Inner Shareable

The TLBIALLNSNHIS characteristics are:

Purpose

Invalidate all Non-secure PL1&0 regime stage 1 and 2 TLB entries, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

Configurations

There are no configuration notes.

Attributes

TLBIALLNSNHIS is a 32-bit system operation.

Field descriptions

The TLBIALLNSNHIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBIALLNSNHIS operation

To perform the TLBIALLNSNHIS operation:

```
MCR p15,4,<Rt>,c8,c3,4 ; TLBIALLNSNHIS operation, ignoring the value in Rt
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0011	100

G5.1.130 TLBIASID, TLB Invalidate by ASID match

The TLBIASID characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 TLB entries for the given ASID, the current VMID, and the current security state.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

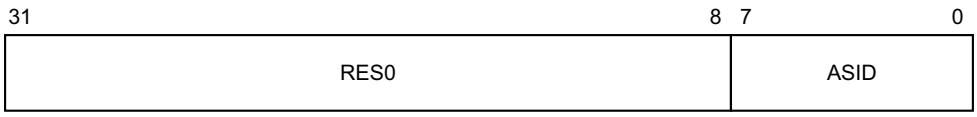
There are no configuration notes.

Attributes

TLBIASID is a 32-bit system operation.

Field descriptions

The TLBIASID input value bit assignments are:



Bits [31:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

Performing the TLBIASID operation

To perform the TLBIASID operation:

```
MCR p15,0,<Rt>,c8,c7,2 ; TLBIASID operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	010

G5.1.131 TLBIASIDIS, TLB Invalidate by ASID match, Inner Shareable

The TLBIASIDIS characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 TLB entries for the given ASID, the current VMID, and the current security state, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

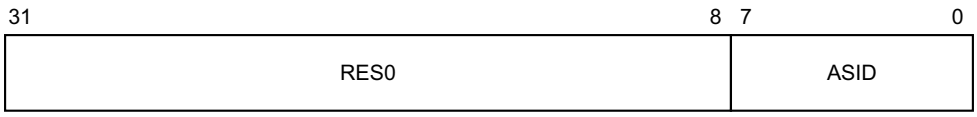
There are no configuration notes.

Attributes

TLBIASIDIS is a 32-bit system operation.

Field descriptions

The TLBIASIDIS input value bit assignments are:



Bits [31:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

Performing the TLBIASIDIS operation

To perform the TLBIASIDIS operation:

```
MCR p15,0,<Rt>,c8,c3,2 ; TLBIASIDIS operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	010

G5.1.132 TLBIIPAS2, TLB Invalidate by Intermediate Physical Address, Stage 2

The TLBIIPAS2 characteristics are:

Purpose

Invalidate PL1&0 regime stage 2 TLB entries for the given IPA, the current VMID, and the Non-secure state.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO	WO

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

Configurations

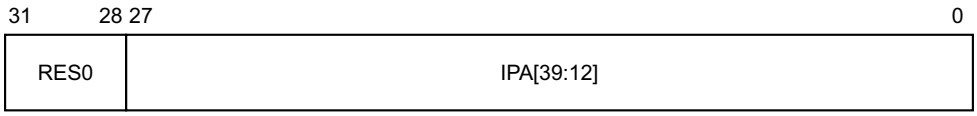
This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIIPAS2 is a 32-bit system operation.

Field descriptions

The TLBIIPAS2 input value bit assignments are:



Bits [31:28]

Reserved, RES0.

IPA[39:12], bits [27:0]

Bits[39:12] of the intermediate physical address to match.

Performing the TLBIIPAS2 operation

To perform the TLBIIPAS2 operation:

```
MCR p15,4,<Rt>,c8,c4,1 ; TLBIIPAS2 operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0100	001

G5.1.133 TLBIIPAS2IS, TLB Invalidate by Intermediate Physical Address, Stage 2, Inner Shareable

The TLBIIPAS2IS characteristics are:

Purpose

Invalidate PL1&0 regime stage 2 TLB entries for the given IPA, the current VMID, and the Non-secure state, on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO	WO

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

Configurations

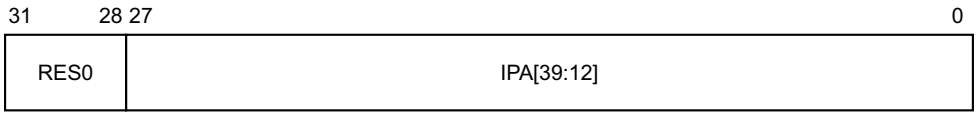
This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIIPAS2IS is a 32-bit system operation.

Field descriptions

The TLBIIPAS2IS input value bit assignments are:



Bits [31:28]

Reserved, RES0.

IPA[39:12], bits [27:0]

Bits[39:12] of the intermediate physical address to match.

Performing the TLBIIPAS2IS operation

To perform the TLBIIPAS2IS operation:

```
MCR p15,4,<Rt>,c8,c0,1 ; TLBIIPAS2IS operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0000	001

G5.1.134 TLBIIPAS2L, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level

The TLBIIPAS2L characteristics are:

Purpose

Invalidate PL1&0 regime stage 2 TLB entries for the last level of translation, the given IPA, the current VMID, and the Non-secure state.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO	WO

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

Configurations

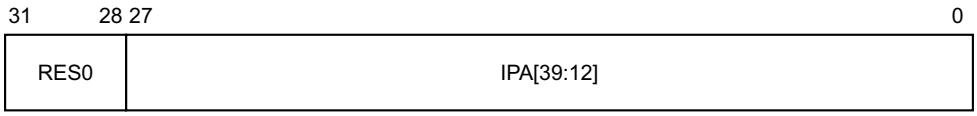
This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIIPAS2L is a 32-bit system operation.

Field descriptions

The TLBIIPAS2L input value bit assignments are:



Bits [31:28]

Reserved, RES0.

IPA[39:12], bits [27:0]

Bits[39:12] of the intermediate physical address to match.

Performing the TLBIIPAS2L operation

To perform the TLBIIPAS2L operation:

```
MCR p15,4,<Rt>,c8,c4,5 ; TLBIIPAS2L operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0100	101

G5.1.135 TLBIIPAS2LIS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, Inner Shareable

The TLBIIPAS2LIS characteristics are:

Purpose

Invalidate PL1&0 regime stage 2 TLB entries for the last level of translation, the given IPA, the current VMID, and the Non-secure state, on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO	WO

This instruction is a NOP when executed in Monitor mode with SCR.NS==0, and is UNPREDICTABLE when executed in any AArch32 Secure privileged mode other than Monitor mode.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

Configurations

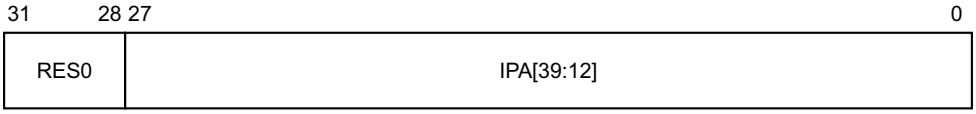
This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIIPAS2LIS is a 32-bit system operation.

Field descriptions

The TLBIIPAS2LIS input value bit assignments are:



Bits [31:28]

Reserved, RES0.

IPA[39:12], bits [27:0]

Bits[39:12] of the intermediate physical address to match.

Performing the TLBIIPAS2LIS operation

To perform the TLBIIPAS2LIS operation:

```
MCR p15,4,<Rt>,c8,c0,5 ; TLBIIPAS2LIS operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0000	101

G5.1.136 TLBIMVA, TLB Invalidate by VA

The TLBIMVA characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 and 2 TLB entries for the given VA and ASID, the current VMID, and the current security state.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

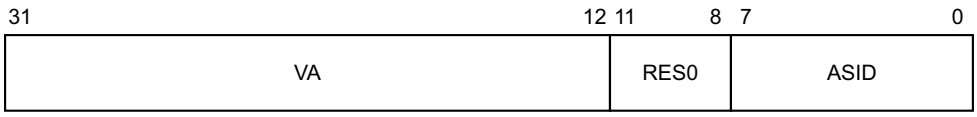
There are no configuration notes.

Attributes

TLBIMVA is a 32-bit system operation.

Field descriptions

The TLBIMVA input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Performing the TLBIMVA operation

To perform the TLBIMVA operation:

```
MCR p15,0,<Rt>,c8,c7,1 ; TLBIMVA operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	001

G5.1.137 TLBIMVAA, TLB Invalidate by VA, All ASID

The TLBIMVAA characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 TLB entries for the given VA, the current VMID, and the current security state.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

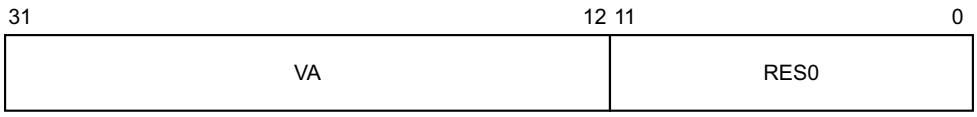
There are no configuration notes.

Attributes

TLBIMVAA is a 32-bit system operation.

Field descriptions

The TLBIMVAA input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

Bits [11:0]

Reserved, RES0.

Performing the TLBIMVAA operation

To perform the TLBIMVAA operation:

```
MCR p15,0,<Rt>,c8,c7,3 ; TLBIMVAA operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	011

G5.1.138 TLBIMVAAIS, TLB Invalidate by VA, All ASID, Inner Shareable

The TLBIMVAAIS characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 TLB entries for the given VA, the current VMID, and the current security state, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

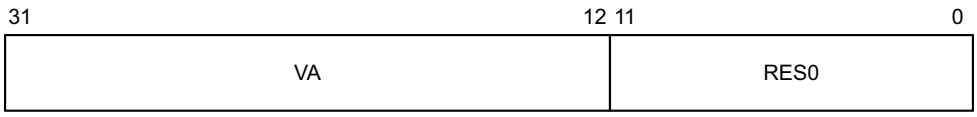
There are no configuration notes.

Attributes

TLBIMVAAIS is a 32-bit system operation.

Field descriptions

The TLBIMVAAIS input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

Bits [11:0]

Reserved, RES0.

Performing the TLBIMVAAIS operation

To perform the TLBIMVAAIS operation:

```
MCR p15,0,<Rt>,c8,c3,3 ; TLBIMVAAIS operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	011

G5.1.139 TLBIMVAAL, TLB Invalidate by VA, All ASID, Last level

The TLBIMVAAL characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA, the current VMID, and the current security state.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

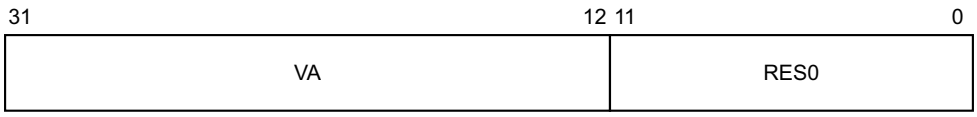
This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVAAL is a 32-bit system operation.

Field descriptions

The TLBIMVAAL input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

Bits [11:0]

Reserved, RES0.

Performing the TLBIMVAAL operation

To perform the TLBIMVAAL operation:

```
MCR p15,0,<Rt>,c8,c7,7 ; TLBIMVAAL operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	111

G5.1.140 TLBIMVAALIS, TLB Invalidate by VA, All ASID, Last level, Inner Shareable

The TLBIMVAALIS characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA, the current VMID, and the current security state, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

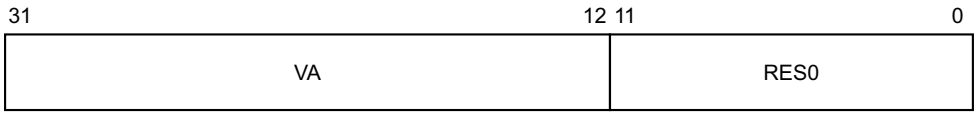
This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVAALIS is a 32-bit system operation.

Field descriptions

The TLBIMVAALIS input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any unlocked TLB entries that match the VA will be affected by this operation, regardless of the ASID.

Bits [11:0]

Reserved, RES0.

Performing the TLBIMVAALIS operation

To perform the TLBIMVAALIS operation:

```
MCR p15,0,<Rt>,c8,c3,7 ; TLBIMVAALIS operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	111

G5.1.141 TLBIMVAH, TLB Invalidate by VA, Hyp mode

The TLBIMVAH characteristics are:

Purpose

Invalidate PL2 regime stage 1 TLB entries for the given VA and the Non-secure state.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

Configurations

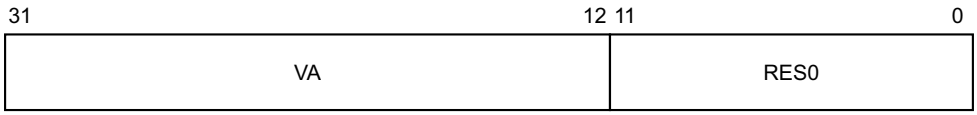
There are no configuration notes.

Attributes

TLBIMVAH is a 32-bit system operation.

Field descriptions

The TLBIMVAH input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:0]

Reserved, RES0.

Performing the TLBIMVAH operation

To perform the TLBIMVAH operation:

```
MCR p15,4,<Rt>,c8,c7,1 ; TLBIMVAH operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0111	001

G5.1.142 TLBIMVAHIS, TLB Invalidate by VA, Hyp mode, Inner Shareable

The TLBIMVAHIS characteristics are:

Purpose

Invalidate PL2 regime stage 1 TLB entries for the given VA and the Non-secure state on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

Configurations

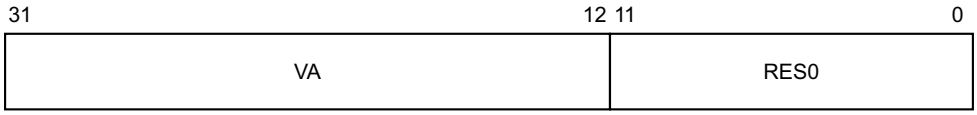
There are no configuration notes.

Attributes

TLBIMVAHIS is a 32-bit system operation.

Field descriptions

The TLBIMVAHIS input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:0]

Reserved, RES0.

Performing the TLBIMVAHIS operation

To perform the TLBIMVAHIS operation:

```
MCR p15,4,<Rt>,c8,c3,1 ; TLBIMVAHIS operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0011	001

G5.1.143 TLBIMVAIS, TLB Invalidate by VA, Inner Shareable

The TLBIMVAIS characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 and 2 TLB entries for the given VA and ASID, the current VMID, and the current security state, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

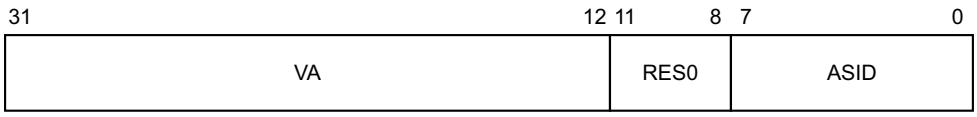
There are no configuration notes.

Attributes

TLBIMVAIS is a 32-bit system operation.

Field descriptions

The TLBIMVAIS input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Performing the TLBIMVAIS operation

To perform the TLBIMVAIS operation:

```
MCR p15,0,<Rt>,c8,c3,1 ; TLBIMVAIS operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	001

G5.1.144 TLBIMVAL, TLB Invalidate by VA, Last level

The TLBIMVAL characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 and 2 TLB entries for the last level of translation table walk, the given VA and ASID, the current VMID, and the current security state.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

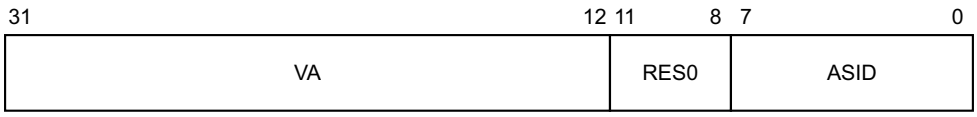
This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVAL is a 32-bit system operation.

Field descriptions

The TLBIMVAL input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Performing the TLBIMVAL operation

To perform the TLBIMVAL operation:

```
MCR p15,0,<Rt>,c8,c7,5 ; TLBIMVAL operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0111	101

G5.1.145 TLBIMVALH, TLB Invalidate by VA, Last level, Hyp mode

The TLBIMVALH characteristics are:

Purpose

Invalidate PL2 regime stage 1 TLB entries for the last level of translation table walk, the given VA, and the Non-secure state.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

Configurations

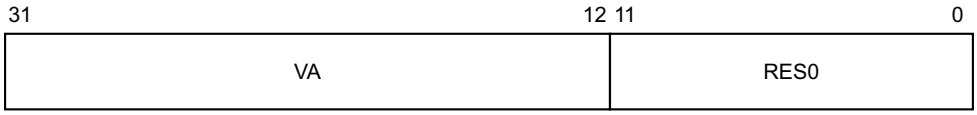
This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVALH is a 32-bit system operation.

Field descriptions

The TLBIMVALH input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:0]

Reserved, RES0.

Performing the TLBIMVALH operation

To perform the TLBIMVALH operation:

```
MCR p15,4,<Rt>,c8,c7,5 ; TLBIMVALH operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0111	101

G5.1.146 TLBIMVALHIS, TLB Invalidate by VA, Last level, Hyp mode, Inner Shareable

The TLBIMVALHIS characteristics are:

Purpose

Invalidate PL2 regime stage 1 TLB entries for the last level of translation table walk, the given VA, and the Non-secure state on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0, Mon)	EL3 (SCR.NS=0, !Mon)
-	-	-	-	WO	WO	WO	UNPREDICTABLE

If this operation is executed at Secure EL3 not in Monitor mode, the result is CONSTRAINED UNPREDICTABLE and may be one of the following:

- The operation is UNDEFINED.
- The operation is treated as a NOP.
- The operation is executed as if it had been executed in Monitor mode.

Configurations

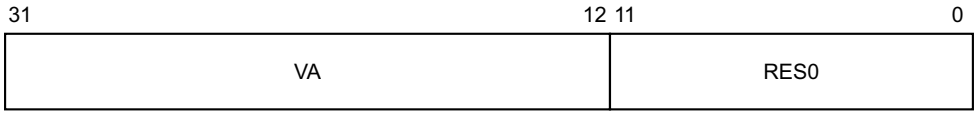
This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVALHIS is a 32-bit system operation.

Field descriptions

The TLBIMVALHIS input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:0]

Reserved, RES0.

Performing the TLBIMVALHIS operation

To perform the TLBIMVALHIS operation:

```
MCR p15,4,<Rt>,c8,c3,5 ; TLBIMVALHIS operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1000	0011	101

G5.1.147 TLBIMVALIS, TLB Invalidate by VA, Last level, Inner Shareable

The TLBIMVALIS characteristics are:

Purpose

Invalidate PL1&0 regime stage 1 and 2 TLB entries for the last level of translation table walk, the given VA and ASID, the current VMID, and the current security state, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

Configurations

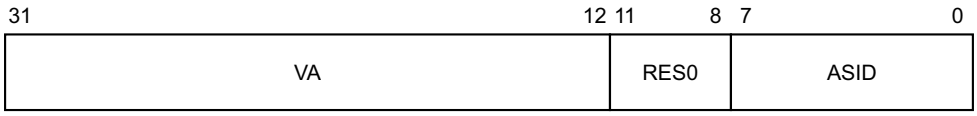
This operation is not implemented in architecture versions before ARMv8.

Attributes

TLBIMVALIS is a 32-bit system operation.

Field descriptions

The TLBIMVALIS input value bit assignments are:



VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Performing the TLBIMVALIS operation

To perform the TLBIMVALIS operation:

```
MCR p15,0,<Rt>,c8,c3,5 ; TLBIMVALIS operation
```

The operation is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1000	0011	101

G5.1.148 TLBTR, TLB Type Register

The TLBTR characteristics are:

Purpose

Provides information about the TLB implementation. The register must define whether the implementation provides separate instruction and data TLBs, or a unified TLB. Normally, the IMPLEMENTATION DEFINED information in this register includes the number of lockable entries in the TLB.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Configurations

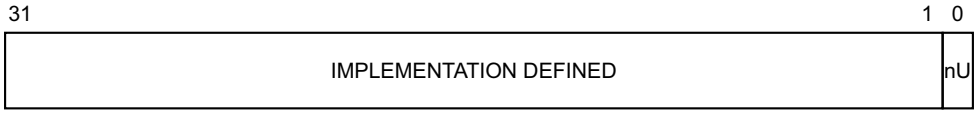
There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

TLBTR is a 32-bit register.

Field descriptions

The TLBTR bit assignments are:



Bits [31:1]

IMPLEMENTATION DEFINED

nU, bit [0]

Not Unified TLB. Indicates whether the implementation has a unified TLB:

`0` Unified TLB.

`1` Separate Instruction and Data TLBs.

Accessing the TLBTR

To access the TLBTR:

```
MRC p15,0,<Rt>,c0,c0,3 ; Read TLBTR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0000	0000	011

G5.1.149 TPIDRPRW, PL1 Software Thread ID Register

The TPIDRPRW characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is not visible to software executing at EL0, for OS management purposes.

This register is part of the Thread and process ID registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as TPIDRPRW(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as TPIDRPRW(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Processor hardware never updates this register.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

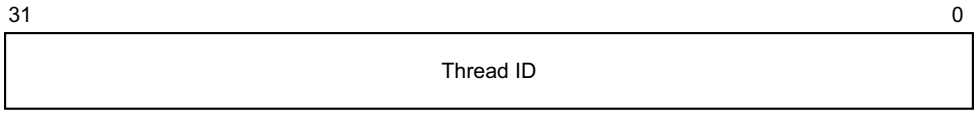
TPIDRPRW(NS) is architecturally mapped to AArch64 register TPIDR_EL1[31:0].

Attributes

TPIDRPRW is a 32-bit register.

Field descriptions

The TPIDRPRW bit assignments are:



Bits [31:0]

Thread ID. Thread identifying information stored by software running at this exception level.

Accessing the TPIDRPRW

To access the TPIDRPRW:

```
MRC p15,0,<Rt>,c13,c0,4 ; Read TPIDRPRW into Rt
MCR p15,0,<Rt>,c13,c0,4 ; Write Rt to TPIDRPRW
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1101	0000	100

G5.1.150 TPIDRURO, PL0 Read-Only Software Thread ID Register

The TPIDRURO characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes.

This register is part of the Thread and process ID registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as TPIDRURO(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	-	RW	-	-	RW

When accessed as TPIDRURO(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RO	-	RW	-	RW	RW	-

Processor hardware never updates this register.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

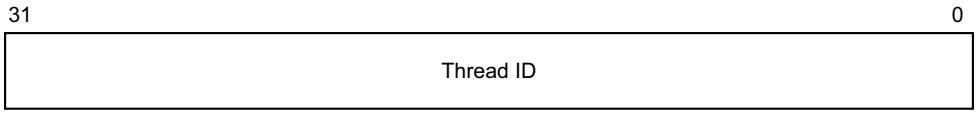
TPIDRURO(NS) is architecturally mapped to AArch64 register TPIDRRO_EL0[31:0].

Attributes

TPIDRURO is a 32-bit register.

Field descriptions

The TPIDRURO bit assignments are:



Bits [31:0]

Thread ID. Thread identifying information stored by software running at this exception level.

Accessing the TPIDRURO

To access the TPIDRURO:

```
MRC p15,0,<Rt>,c13,c0,3 ; Read TPIDRURO into Rt
MCR p15,0,<Rt>,c13,c0,3 ; Write Rt to TPIDRURO
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1101	0000	011

G5.1.151 TPIDRURW, PL0 Read/Write Software Thread ID Register

The TPIDRURW characteristics are:

Purpose

Provides a location where software executing at EL0 can store thread identifying information, for OS management purposes.

This register is part of the Thread and process ID registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as TPIDRURW(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	-	RW	-	-	RW

When accessed as TPIDRURW(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	-	RW	-	RW	RW	-

Processor hardware never updates this register.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

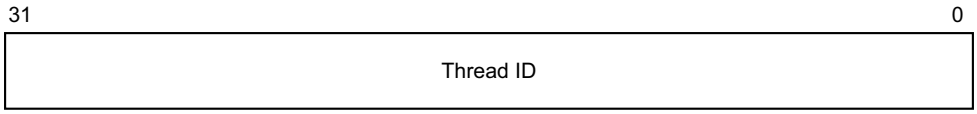
TPIDRURW(NS) is architecturally mapped to AArch64 register TPIDR_EL0[31:0].

Attributes

TPIDRURW is a 32-bit register.

Field descriptions

The TPIDRURW bit assignments are:



Bits [31:0]

Thread ID. Thread identifying information stored by software running at this exception level.

Accessing the TPIDRURW

To access the TPIDRURW:

```
MRC p15,0,<Rt>,c13,c0,2 ; Read TPIDRURW into Rt
MCR p15,0,<Rt>,c13,c0,2 ; Write Rt to TPIDRURW
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1101	0000	010

G5.1.152 TTBCR, Translation Table Base Control Register

The TTBCR characteristics are:

Purpose

Determines which of the Translation Table Base Registers defined the base address for a translation table walk required for the stage 1 translation of a memory access from any mode other than Hyp mode. Also controls the translation table format and, when using the Long-descriptor translation table format, holds cacheability and shareability information.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as TTBCR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as TTBCR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

TTBCR(NS) is architecturally mapped to AArch64 register TCR_EL1[31:0].

TTBCR(S) can be mapped to AArch64 register TCR_EL3[31:0], but this is not architecturally mandated.

The Large Physical Address Extension adds an alternative format for the register. If an implementation includes the Large Physical Address Extension then the current translation table format determines which format of the register is used.

TTBCR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

Attributes

TTBCR is a 32-bit register.

Field descriptions

The TTBCR bit assignments are:

For all register layouts:

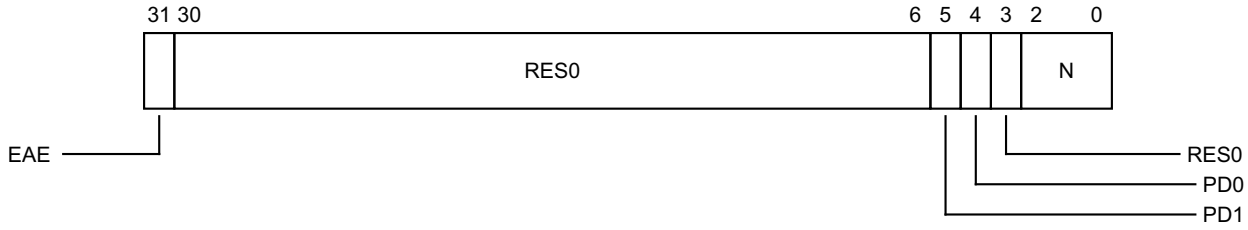
EAE, bit [31]

Extended Address Enable. The meanings of the possible values of this bit are:

`0` Use the 32-bit translation system, with the Short-descriptor translation table format.

`1` Use the 40-bit translation system, with the Long-descriptor translation table format.

When TTBCR.EAE==0:



EAE, bit [31]

Extended Address Enable. The meanings of the possible values of this bit are:

`0` Use the 32-bit translation system, with the Short-descriptor translation table format.

Resets to 0.

Bits [30:6]

Reserved, RES0.

PD1, bit [5]

Translation table walk disable for translations using TTBR1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1. The encoding of this bit is:

`0` Perform translation table walks using TTBR1.

`1` A TLB miss on an address that is translated using TTBR1 generates a Translation fault. No translation table walk is performed.

Resets to 0.

PD0, bit [4]

Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss for an address that is translated using TTBR0. The encoding of this bit is:

`0` Perform translation table walks using TTBR0.

`1` A TLB miss on an address that is translated using TTBR0 generates a Translation fault. No translation table walk is performed.

Resets to 0.

Bit [3]

Reserved, RES0.

N, bits [2:0]

Indicate the width of the base address held in TTBR0. In TTBR0, the base address field is bits[31:14-N]. The value of N also determines:

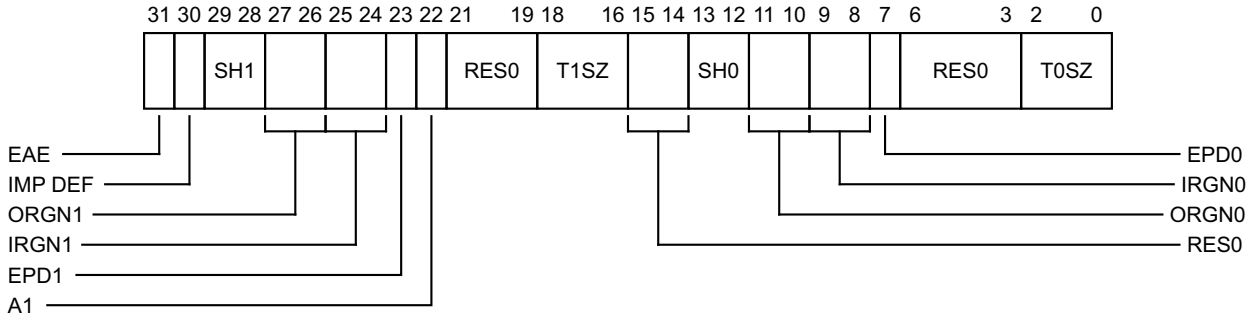
- Whether TTBR0 or TTBR1 is used as the base address for translation table walks.
- The size of the translation table pointed to by TTBR0.

N can take any value from 0 to 7, that is, from `0b000` to `0b111`.

When N has its reset value of 0, the translation table base is compatible with ARMv5 and ARMv6.

Resets to 0.

When TTBCR.EAE==1:



EAE, bit [31]

Extended Address Enable. The meanings of the possible values of this bit are:

1 Use the 40-bit translation system, with the Long-descriptor translation table format.

Resets to 0.

SH1, bits [29:28]

Shareability attribute for memory associated with translation table walks using TTBR1.

00 Non-shareable

10 Outer Shareable

11 Inner Shareable

Other values are reserved.

Resets to 0.

ORGN1, bits [27:26]

Outer cacheability attribute for memory associated with translation table walks using TTBR1.

00 Normal memory, Outer Non-cacheable

01 Normal memory, Outer Write-Back Write-Allocate Cacheable

10 Normal memory, Outer Write-Through Cacheable

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

Resets to 0.

IRGN1, bits [25:24]

Inner cacheability attribute for memory associated with translation table walks using TTBR1.

00 Normal memory, Inner Non-cacheable

01 Normal memory, Inner Write-Back Write-Allocate Cacheable

10 Normal memory, Inner Write-Through Cacheable

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

Resets to 0.

EPD1, bit [23]

Translation table walk disable for translations using TTBR1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1. The encoding of this bit is:

0 Perform translation table walks using TTBR1.

1 A TLB miss on an address that is translated using TTBR1 generates a Translation fault. No translation table walk is performed.

Resets to 0.

A1, bit [22]

Selects whether TTBR0 or TTBR1 defines the ASID. The encoding of this bit is:

0 TTBR0.ASID defines the ASID.

1 TTBR1.ASID defines the ASID.

Resets to 0.

Bits [21:19]

Reserved, RES0.

T1SZ, bits [18:16]

The size offset of the memory region addressed by TTBR1. The region size is $2^{32-T1SZ}$ bytes.

Resets to 0.

Bits [15:14]

Reserved, RES0.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0.

00 Non-shareable

10 Outer Shareable

11 Inner Shareable

Other values are reserved.

Resets to 0.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0.

00 Normal memory, Outer Non-cacheable

01 Normal memory, Outer Write-Back Write-Allocate Cacheable

10 Normal memory, Outer Write-Through Cacheable

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

Resets to 0.

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0.

00 Normal memory, Inner Non-cacheable

01 Normal memory, Inner Write-Back Write-Allocate Cacheable

10 Normal memory, Inner Write-Through Cacheable

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

Resets to 0.

EPD0, bit [7]

Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0. The encoding of this bit is:

0 Perform translation table walks using TTBR0.

1 A TLB miss on an address that is translated using TTBR0 generates a Translation fault. No translation table walk is performed.

Resets to 0.

Bits [6:3]

Reserved, RES0.

T0SZ, bits [2:0]

The size offset of the memory region addressed by TTBR0. The region size is $2^{32-T0SZ}$ bytes.

Resets to 0.

Accessing the TTBCR

To access the TTBCR:

```
MRC p15,0,<Rt>,c2,c0,2 ; Read TTBCR into Rt
MCR p15,0,<Rt>,c2,c0,2 ; Write Rt to TTBCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0010	0000	010

G5.1.153 TTBR0, Translation Table Base Register 0

The TTBR0 characteristics are:

Purpose

Holds the base address of translation table 0, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses from modes other than Hyp mode.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as TTBR0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as TTBR0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Used in conjunction with the TTBCR. When the 64-bit TTBR0 format is used, cacheability and shareability information is held in the TTBCR, not in TTBR0.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

TTBR0(NS) is architecturally mapped to AArch64 register TTBR0_EL1.

TTBR0(S) can be mapped to AArch64 register TTBR0_EL3, but this is not architecturally mandated.

The Large Physical Address Extension extends TTBR0 to a 64-bit register. In an implementation that includes the Large Physical Address Extension, TTBCR.EAE determines which TTBR0 format is used:

`EAE==0` 32-bit format is used. TTBR0[63:32] are ignored.

`EAE==1` 64-bit format is used.

TTBR0 has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

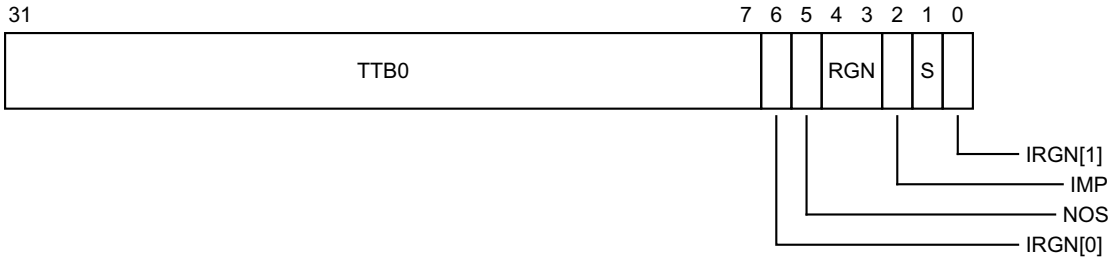
Attributes

TTBR0 is a 32-bit register when TTBCR.EAE==0 and a 64-bit register when TTBCR.EAE==1.

Field descriptions

The TTBR0 bit assignments are:

When TTBCR.EAE==0:



TTB0, bits [31:7]

Translation table base 0 address, bits[31:x], where x is 14-(TTBCR.N). Bits [x-1:7] are RES0.

The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.

If bits [x-1:7] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:7] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

IRGN[0], bit [6]

See IRGN[1] below for description of the IRGN field.

NOS, bit [5]

Not Outer Shareable bit. Indicates the Outer Shareable attribute for the memory associated with a translation table walk that has the Shareable attribute, indicated by TTBR0.S == 1:

0 Outer Shareable

1 Inner Shareable.

This bit is ignored when TTBR0.S == 0.

RGN, bits [4:3]

Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:

00 Normal memory, Outer Non-cacheable.

01 Normal memory, Outer Write-Back Write-Allocate Cacheable.

10 Normal memory, Outer Write-Through Cacheable.

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable.

IMP, bit [2]

The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is UNK/SBZP.

S, bit [1]

Shareable bit. Indicates the Shareable attribute for the memory associated with the translation table walks:

0 Non-shareable

1 Shareable.

IRGN[1], bit [0]

Inner region bits. Indicates the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:

`00` Normal memory, Inner Non-cacheable.

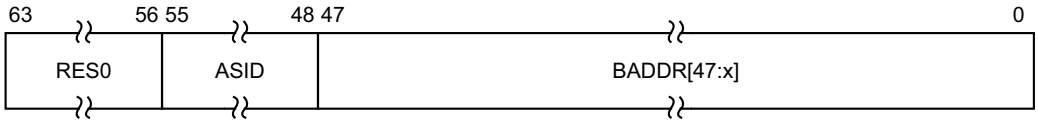
`01` Normal memory, Inner Write-Back Write-Allocate Cacheable.

`10` Normal memory, Inner Write-Through Cacheable.

`11` Normal memory, Inner Write-Back no Write-Allocate Cacheable.

The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 or later without the Multiprocessing Extensions can run unmodified on an implementation that includes the Multiprocessing Extensions.

When TTBCR.EAE==1:



Bits [63:56]

Reserved, RES0.

ASID, bits [55:48]

An ASID for the translation table base address. The TTBCR.A1 field selects either TTBR0.ASID or TTBR1.ASID.

BADDR[47:x], bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of TTBCR.T0SZ, and is calculated as follows:

- If TTBCR.T0SZ is 0 or 1, x = 5 - TTBCR.T0SZ.
- If TTBCR.T0SZ is greater than 1, x = 14 - TTBCR.T0SZ.

The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.

If bits [x-1:3] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:3] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

Accessing the TTBR0

To access the TTBR0 when TTBCR.EAE==0:

```
MRC p15,0,<Rt>,c2,c0,0 ; Read TTBR0 into Rt
MCR p15,0,<Rt>,c2,c0,0 ; Write Rt to TTBR0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0010	0000	000

To access the TTBR0 when TTBCR.EAE==1:

```
MRRC p15,0,<Rt>,<Rt2>,c2 ; Read 64-bit TTBR0 into Rt (low word) and Rt2 (high word)
MCRR p15,0,<Rt>,<Rt2>,c2 ; Write Rt (low word) and Rt2 (high word) to 64-bit TTBR0
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0000	0010

G5.1.154 TTBR1, Translation Table Base Register 1

The TTBR1 characteristics are:

Purpose

Holds the base address of translation table 1, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses from modes other than Hyp mode.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as TTBR1(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as TTBR1(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Used in conjunction with the TTBCR. When the 64-bit TTBR1 format is used, cacheability and shareability information is held in the TTBCR, not in TTBR1.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

TTBR1(NS) is architecturally mapped to AArch64 register TTBR1_EL1.

The Large Physical Address Extension extends TTBR1 to a 64-bit register. In an implementation that includes the Large Physical Address Extension, TTBCR.EAE determines which TTBR1 format is used:

`EAE==0` 32-bit format is used. TTBR1[63:32] are ignored.

`EAE==1` 64-bit format is used.

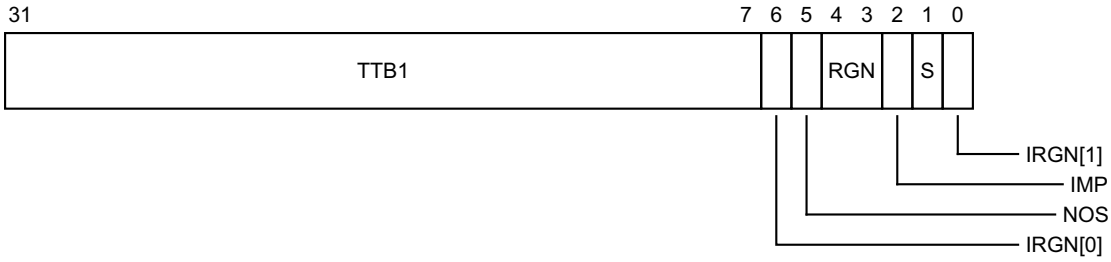
Attributes

TTBR1 is a 32-bit register when TTBCR.EAE==0 and a 64-bit register when TTBCR.EAE==1.

Field descriptions

The TTBR1 bit assignments are:

When TTBCR.EAE==0:



TTB1, bits [31:7]

Translation table base 1 address, bits[31:x], where x is 14-(TTBCR.N). Bits [x-1:7] are RES0.

The translation table must be aligned on a 16KByte boundary.

If bits [x-1:7] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:7] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

IRGN[0], bit [6]

See IRGN[1] below for description of the IRGN field.

NOS, bit [5]

Not Outer Shareable bit. Indicates the Outer Shareable attribute for the memory associated with a translation table walk that has the Shareable attribute, indicated by TTBR0.S == 1:

0 Outer Shareable

1 Inner Shareable.

This bit is ignored when TTBR0.S == 0.

RGN, bits [4:3]

Region bits. Indicates the Outer cacheability attributes for the memory associated with the translation table walks:

00 Normal memory, Outer Non-cacheable.

01 Normal memory, Outer Write-Back Write-Allocate Cacheable.

10 Normal memory, Outer Write-Through Cacheable.

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable.

IMP, bit [2]

The effect of this bit is IMPLEMENTATION DEFINED. If the translation table implementation does not include any IMPLEMENTATION DEFINED features this bit is UNK/SBZP.

S, bit [1]

Shareable bit. Indicates the Shareable attribute for the memory associated with the translation table walks:

0 Non-shareable

1 Shareable.

IRGN[1], bit [0]

Inner region bits. Indicates the Inner Cacheability attributes for the memory associated with the translation table walks. The possible values of IRGN[1:0] are:

`00` Normal memory, Inner Non-cacheable.

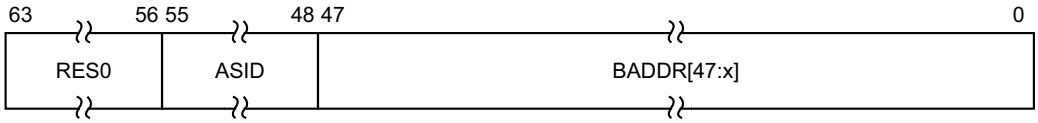
`01` Normal memory, Inner Write-Back Write-Allocate Cacheable.

`10` Normal memory, Inner Write-Through Cacheable.

`11` Normal memory, Inner Write-Back no Write-Allocate Cacheable.

The encoding of the IRGN bits is counter-intuitive, with register bit[6] being IRGN[0] and register bit[0] being IRGN[1]. This encoding is chosen to give a consistent encoding of memory region types and to ensure that software written for ARMv7 or later without the Multiprocessing Extensions can run unmodified on an implementation that includes the Multiprocessing Extensions.

When TTBCR.EAE==1:



Bits [63:56]

Reserved, RES0.

ASID, bits [55:48]

An ASID for the translation table base address. The TTBCR.A1 field selects either TTBR0.ASID or TTBR1.ASID.

BADDR[47:x], bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of TTBCR.T1SZ, and is calculated as follows:

- If TTBCR.T1SZ is 0 or 1, x = 5 - TTBCR.T1SZ.
- If TTBCR.T1SZ is greater than 1, x = 14 - TTBCR.T1SZ.

The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.

If bits [x-1:3] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:3] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

Accessing the TTBR1

To access the TTBR1 when TTBCR.EAE==0:

```
MRC p15,0,<Rt>,c2,c0,1 ; Read TTBR1 into Rt
MCR p15,0,<Rt>,c2,c0,1 ; Write Rt to TTBR1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0010	0000	001

To access the TTBR1 when TTBCR.EAE==1:

```
MRRC p15,1,<Rt>,<Rt2>,c2 ; Read 64-bit TTBR1 into Rt (low word) and Rt2 (high word)
MCRR p15,1,<Rt>,<Rt2>,c2 ; Write Rt (low word) and Rt2 (high word) to 64-bit TTBR1
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0001	0010

G5.1.155 VBAR, Vector Base Address Register

The VBAR characteristics are:

Purpose

When high exception vectors are not selected, holds the exception base address for exceptions that are not taken to Monitor mode or to Hyp mode.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as VBAR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as VBAR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Software must program the Non-secure copy of the register with the required initial value as part of the processor boot sequence.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

VBAR(NS) is architecturally mapped to AArch64 register VBAR_EL1[31:0].

VBAR(S) can be mapped to AArch64 register VBAR_EL3[31:0], but this is not architecturally mandated.

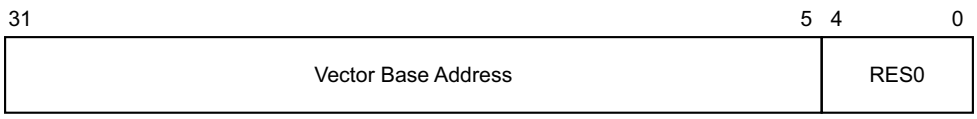
VBAR has write access to the Secure copy of the register disabled when the CP15SDISABLE signal is asserted HIGH.

Attributes

VBAR is a 32-bit register.

Field descriptions

The VBAR bit assignments are:



Bits [31:5]

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken in this exception level. Bits[4:0] of an exception vector are the exception offset.

For the Secure copy of this register, the field resets to 0.

For the Non-secure copy of this register, the field reset value is architecturally UNKNOWN.

Bits [4:0]

Reserved, RES0.

Accessing the VBAR

To access the VBAR:

```
MRC p15,0,<Rt>,c12,c0,0 ; Read VBAR into Rt
MCR p15,0,<Rt>,c12,c0,0 ; Write Rt to VBAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	0000	000

G5.1.156 VMPIDR, Virtualization Multiprocessor ID Register

The VMPIDR characteristics are:

Purpose

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by Non-secure EL1 reads of MPIDR.

This register is part of:

- the Identification registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Note

This register is accessible from EL1 as MPIDR.

Configurations

VMPIDR is architecturally mapped to AArch64 register VMPIDR_EL2[31:0].

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

VMPIDR is a 32-bit register.

For an interpretation of the values in this register, see MPIDR.

Accessing the VMPIDR

To access the VMPIDR:

```
MRC p15,4,<Rt>,c0,c0,5 ; Read VMPIDR into Rt
MCR p15,4,<Rt>,c0,c0,5 ; Write Rt to VMPIDR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0000	0000	101

G5.1.157 VPIDR, Virtualization Processor ID Register

The VPIDR characteristics are:

Purpose

Holds the value of the Virtualization Processor ID. This is the value returned by Non-secure EL1 reads of MIDR.

This register is part of:

- the Virtualization registers functional group
- the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Note

This register is accessible from EL1 as MIDR.

Configurations

VPIDR is architecturally mapped to AArch64 register VPIDR_EL2.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

VPIDR is a 32-bit register.

For an interpretation of the values in this register, see MIDR.

Accessing the VPIDR

To access the VPIDR:

```
MRC p15,4,<Rt>,c0,c0,0 ; Read VPIDR into Rt
MCR p15,4,<Rt>,c0,c0,0 ; Write Rt to VPIDR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0000	0000	000

G5.1.158 VTCR, Virtualization Translation Control Register

The VTCR characteristics are:

Purpose

Controls the translation table walks required for the stage 2 translation of memory accesses from Non-secure modes other than Hyp mode, and holds cacheability and shareability information for the accesses.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Used in conjunction with VTTBR, that defines the translation table base address for the translations.

Configurations

VTCR is architecturally mapped to AArch64 register VTCR_EL2.

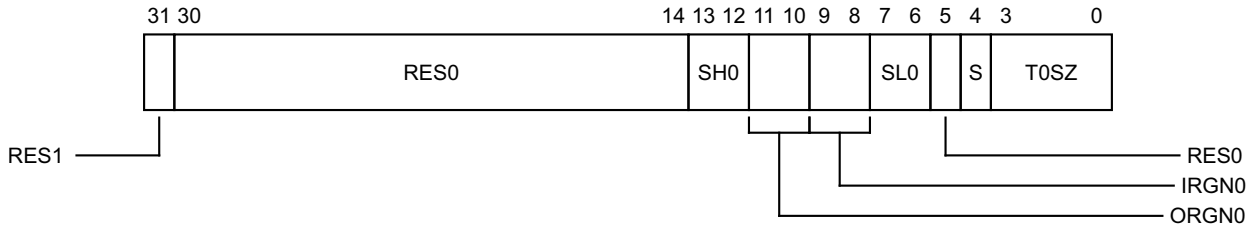
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

VTCR is a 32-bit register.

Field descriptions

The VTCR bit assignments are:



Bit [31]

Reserved, RES1.

Bits [30:14]

Reserved, RES0.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0.

00 Non-shareable

10 Outer Shareable

11 Inner Shareable

Other values are reserved.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0.

00 Normal memory, Outer Non-cacheable

01 Normal memory, Outer Write-Back Write-Allocate Cacheable

10 Normal memory, Outer Write-Through Cacheable

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0.

00 Normal memory, Inner Non-cacheable

01 Normal memory, Inner Write-Back Write-Allocate Cacheable

10 Normal memory, Inner Write-Through Cacheable

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

SL0, bits [7:6]

Starting level for translation table walks using VTTBR.

00 Start at second level

01 Start at first level

Other values are reserved.

If the stage 2 input address size, as programmed in VTCR.T0SZ, is out of range with respect to the starting level at the time of a translation walk that uses the stage 2 translation, then a second stage level 1 translation fault is generated.

Bit [5]

Reserved, RES0.

S, bit [4]

Sign extension bit. This bit must be programmed to the value of T0SZ[3]. If it is not, then the stage 2 T0SZ value is treated as an UNKNOWN value within the legal range that can be programmed.

T0SZ, bits [3:0]

The size offset of the memory region addressed by TTBR0. The region size is $2^{32-T0SZ}$ bytes.

Accessing the VTCR

To access the VTCR:

```
MRC p15,4,<Rt>,c2,c1,2 ; Read VTCR into Rt
MCR p15,4,<Rt>,c2,c1,2 ; Write Rt to VTCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0010	0001	010

G5.1.159 VTTBR, Virtualization Translation Table Base Register

The VTTBR characteristics are:

Purpose

Holds the base address of the translation table for the stage 2 translation of memory accesses from Non-secure modes other than Hyp mode.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Used in conjunction with the VTCR.

Configurations

VTTBR is architecturally mapped to AArch64 register VTTBR_EL2.

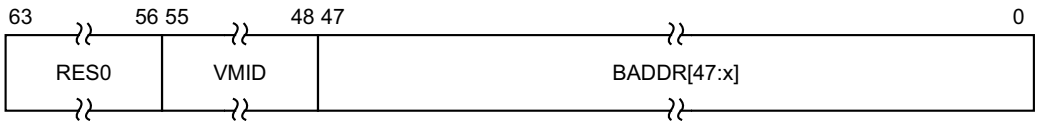
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

VTTBR is a 64-bit register.

Field descriptions

The VTTBR bit assignments are:



Bits [63:56]

Reserved, RES0.

VMID, bits [55:48]

The VMID for the translation table.

Resets to 0.

BADDR[47:x], bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of VTCR.T0SZ, and is calculated as follows:

- If VTCR.T0SZ is 0 or 1, x = 5 - VTCR.T0SZ.
- If VTCR.T0SZ is greater than 1, x = 14 - VTCR.T0SZ.

The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.

If bits [x-1:3] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:3] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

Reset value is architecturally UNKNOWN.

Accessing the VTTBR

To access the VTTBR:

```
MRRC p15,6,<Rt>,<Rt2>,c2 ; Read 64-bit VTTBR into Rt (low word) and Rt2 (high word)
MCRR p15,6,<Rt>,<Rt2>,c2 ; Write Rt (low word) and Rt2 (high word) to 64-bit VTTBR
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0110	0010

G5.2 Debug registers

This section describes each of the Debug registers in AArch32 state.

G5.2.1 DBGAUTHSTATUS, Debug Authentication Status register

The DBGAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGAUTHSTATUS is architecturally mapped to AArch64 register DBGAUTHSTATUS_EL1.

DBGAUTHSTATUS is architecturally mapped to external register DBGAUTHSTATUS_EL1.

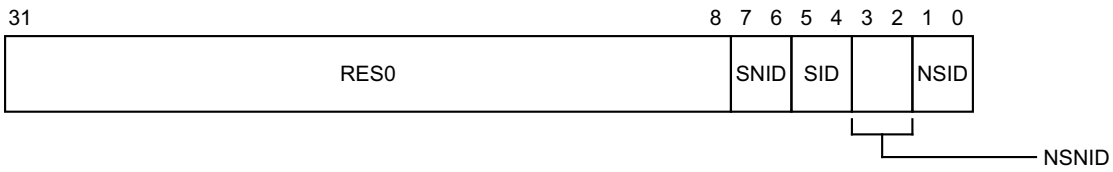
This register is required in all implementations.

Attributes

DBGAUTHSTATUS is a 32-bit register.

Field descriptions

The DBGAUTHSTATUS bit assignments are:



Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Secure non-invasive debug. Possible values of this field are:

`00` Not implemented. EL3 is not implemented and the processor is Non-secure.

`10` Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.

`11` Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the processor is Non-secure.

10 Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSNID, bits [3:2]

Non-secure non-invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the processor is Secure.

10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the processor is Secure.

10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

Other values are reserved.

Accessing the DBGAUTHSTATUS register

To access the DBGAUTHSTATUS register:

```
MRC p14,0,<Rt>,c7,c14,6 ; Read DBGAUTHSTATUS into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	1110	110

G5.2.2 DBGBCR<n>, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n> characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>, where n is 0 to 15. If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<n> can be associated with a Breakpoint Extended Value Register DBGBXVR<n> for VMID matching.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

When the E field is zero, all the other fields in the register are ignored.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGBCR<n> is architecturally mapped to AArch64 register DBGBCR<n>_EL1.

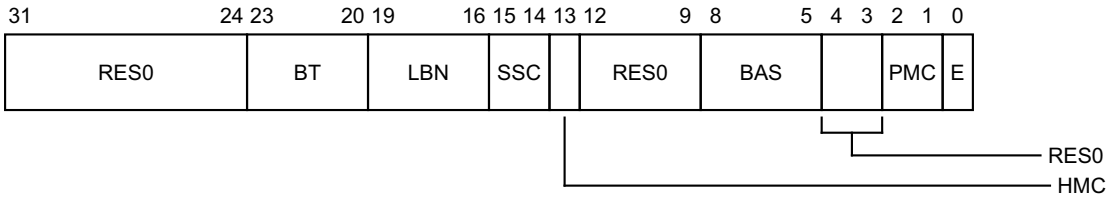
DBGBCR<n> is architecturally mapped to external register DBGBCR<n>_EL1.

Attributes

DBGBCR<n> is a 32-bit register.

Field descriptions

The DBGBCR<n> bit assignments are:



Bits [31:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type. Possible values are:

`0000` Unlinked instruction address match.

`0001` Linked instruction address match.

`0010` Unlinked context ID match.

`0011` Linked context ID match

`0100` Unlinked instruction address mismatch.

`0101` Linked instruction address mismatch.

`1000` Unlinked VMID match.

1001 Linked VMID match.

1010 Unlinked VMID and context ID match.

1011 Linked VMID and context ID match.

The field breaks down as follows:

- BT[3:1]: Base type.

  000 Match address. DBGBVR<n> is the address of an instruction.

  010 Mismatch address. Behaves as type 000 if in an AArch64 translation, or if Halting debug is enabled and halting is allowed. Otherwise, DBGBVR<n> is the address of an instruction to be stepped.

  001 Match context ID. DBGBVR<n> is a context ID.

  100 Match VMID. DBGBXVR<n>[7:0] is a VMID.

  101 Match VMID and context ID. DBGBVR<n> is a context ID, and DBGBXVR<n>[7:0] is a VMID.

- BT[0]: Enable linking.

If the breakpoint is not context-aware, BT[3] and BT[1] are RES0. If EL2 is not implemented, BT[3] is RES0. If EL1 using AArch32 is not implemented, BT[2] is RES0.

The values 011x and 11xx are reserved, but must behave as if the breakpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

On Cold reset, the field reset value is architecturally UNKNOWN.

LBN, bits [19:16]

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

On Cold reset, the field reset value is architecturally UNKNOWN.

SSC, bits [15:14]

Security state control. Determines the security states under which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [12:9]

Reserved, RES0.

BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state. In an AArch64-only implementation, this field is reserved, RES1. Otherwise:

- BAS[2] and BAS[0] are read/write.
- BAS[3] and BAS[1] are read-only copies of BAS[2] and BAS[0] respectively.

The values 0011 and 1100 are only supported if AArch32 is supported at any exception level.

The permitted values depend on the breakpoint type.

For Address match breakpoints:

BAS	Match instruction at	Constraint for debuggers
0011	DBGBVR<n>	Use for T32 instructions.
1100	DBGBVR<n>+2	Use for T32 instructions.
1111	DBGBVR<n>	Use for A32 instructions.

0000 is reserved and must behave as if the breakpoint is disabled or map to a permitted value.

For Address mismatch breakpoints in an AArch32 stage 1 translation regime:

BAS	Step instruction at	Constraint for debuggers
0000	-	Use for a match anywhere breakpoint.
0011	DBGBVR<n>	Use for stepping T32 instructions.
1100	DBGBVR<n>+2	Use for stepping T32 instructions.
1111	DBGBVR<n>	Use for stepping A32 instructions.

For Context matching breakpoints, this field is RES1 and ignored.

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the exception level or levels at which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

E, bit [0]

Enable breakpoint DBGBVR<n>. Possible values are:

0 Breakpoint disabled.

1 Breakpoint enabled.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGBCR<n>

To access the DBGBCR<n>:

```
MRC p14,0,<Rt>,c0,<CRm>,5 ; Read DBGBCR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c0,<CRm>,5 ; Write Rt to DBGBCR<n>, where n is in the range 0 to 15
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	n<3:0>	101

G5.2.3 DBGBVR<n>, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n> characteristics are:

Purpose

Holds a value for use in breakpoint matching, either the virtual address of an instruction or a context ID. Forms breakpoint n together with control register DBGBCR<n>, where n is 0 to 15. If EL2 is implemented and this breakpoint supports Context matching, DBGBVR<n> can be associated with a Breakpoint Extended Value Register DBGBXVR<n> for VMID matching.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Some breakpoints might not support Context ID comparison. For more information, see the description of the DBGDIDR.CTX_CMPs field.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGBVR<n> is architecturally mapped to AArch64 register DBGBVR<n>_EL1[31:0].

DBGBVR<n> is architecturally mapped to external register DBGBVR<n>_EL1[31:0].

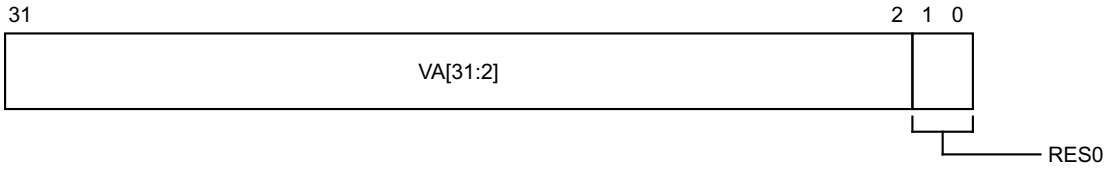
Attributes

DBGBVR<n> is a 32-bit register.

Field descriptions

The DBGBVR<n> bit assignments are:

When DBGBCR<n>.BT==0b0x0x:



VA[31:2], bits [31:2]

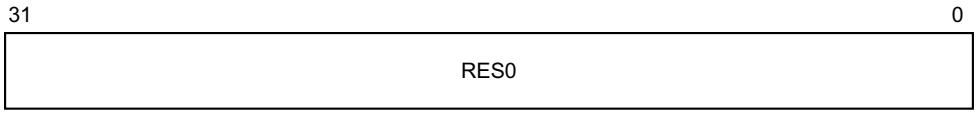
Bits[31:2] of the address value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

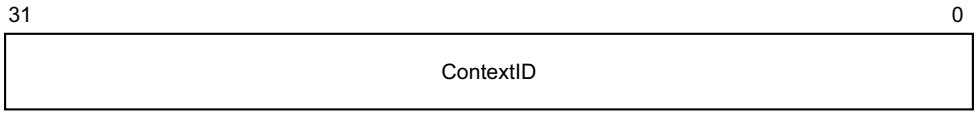
When DBGBCR<n>.BT==0b1x0x:



Bits [31:0]

Reserved, RES0.

When DBGBCR<n>.BT==0xxx1x:



ContextID, bits [31:0]

Context ID value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGBVR<n>

To access the DBGBVR<n>:

```
MRC p14,0,<Rt>,c0,<CRm>,4 ; Read DBGBVR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c0,<CRm>,4 ; Write Rt to DBGBVR<n>, where n is in the range 0 to 15
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	n<3:0>	100

G5.2.4 DBGBXVR<n>, Debug Breakpoint Extended Value Registers, n = 0 - 15

The DBGBXVR<n> characteristics are:

Purpose

Holds a value for use in breakpoint matching, to support VMID matching. Used in conjunction with a control register DBGBCR<n> and a value register DBGBVR<n>, where n is 0 to 15. Used if EL2 is implemented and breakpoint n supports Context matching.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGBXVR<n> is architecturally mapped to AArch64 register DBGBVR<n>_EL1[63:32].

DBGBXVR<n> is architecturally mapped to external register DBGBVR<n>_EL1[63:32].

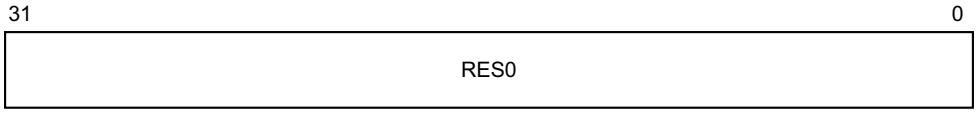
Attributes

DBGBXVR<n> is a 32-bit register.

Field descriptions

The DBGBXVR<n> bit assignments are:

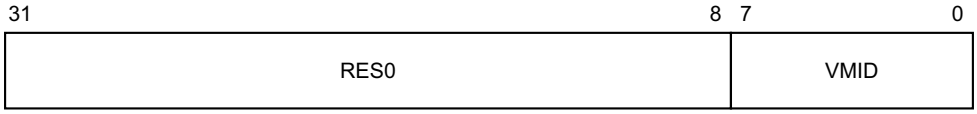
When DBGBCR<n>.BT==0b0xxx:



Bits [31:0]

Reserved, RES0.

When DBGBCR<n>.BT==0b1xxx and EL2 implemented:



Bits [31:8]

Reserved, RES0.

VMID, bits [7:0]

VMID value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGBXVR<n>

To access the DBGBXVR<n>:

```
MRC p14,0,<Rt>,c1,<CRm>,1 ; Read DBGBXVR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c1,<CRm>,1 ; Write Rt to DBGBXVR<n>, where n is in the range 0 to 15
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	n<3:0>	001

G5.2.5 DBGCLAIMCLR, Debug Claim Tag Clear register

The DBGCLAIMCLR characteristics are:

Purpose

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

The architecture does not define any functionality for the CLAIM bits.

Used in conjunction with the DBGCLAIMSET register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGCLAIMCLR is architecturally mapped to AArch64 register DBGCLAIMCLR_EL1.

DBGCLAIMCLR is architecturally mapped to external register DBGCLAIMCLR_EL1.

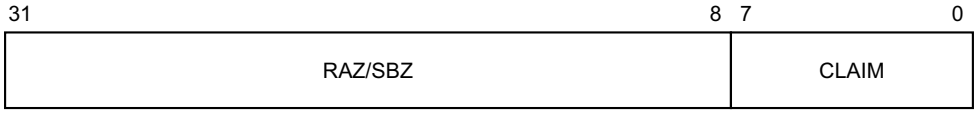
This register is required in all implementations. An implementation must include 8 CLAIM tag bits.

Attributes

DBGCLAIMCLR is a 32-bit register.

Field descriptions

The DBGCLAIMCLR bit assignments are:



Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Claim clear bits. Reading this field returns the current value of the CLAIM bits.

Writing a 1 to one of these bits clears the corresponding CLAIM bit to 0. This is an indirect write to the CLAIM bits.

A single write operation can clear multiple bits to 0. Writing 0 to one of these bits has no effect.

On Cold reset, the field resets to 0.

Accessing the DBGCLAIMCLR register

To access the DBGCLAIMCLR register:

```
MRC p14,0,<Rt>,c7,c9,6 ; Read DBGCLAIMCLR into Rt
MCR p14,0,<Rt>,c7,c9,6 ; Write Rt to DBGCLAIMCLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	1001	110

G5.2.6 DBGCLAIMSET, Debug Claim Tag Set register

The DBGCLAIMSET characteristics are:

Purpose

Used by software to set CLAIM bits to 1.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

The architecture does not define any functionality for the CLAIM bits.

Used in conjunction with the DBGCLAIMCLR register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGCLAIMSET is architecturally mapped to AArch64 register DBGCLAIMSET_EL1.

DBGCLAIMSET is architecturally mapped to external register DBGCLAIMSET_EL1.

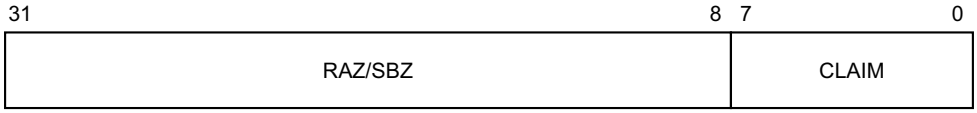
This register is required in all implementations. An implementation must include 8 CLAIM tag bits.

Attributes

DBGCLAIMSET is a 32-bit register.

Field descriptions

The DBGCLAIMSET bit assignments are:



Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Claim set bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM bit to 1. This is an indirect write to the CLAIM bits.

A single write operation can set multiple bits to 1. Writing 0 to one of these bits has no effect.

Accessing the DBGCLAIMSET register

To access the DBGCLAIMSET register:

```
MRC p14,0,<Rt>,c7,c8,6 ; Read DBGCLAIMSET into Rt
MCR p14,0,<Rt>,c7,c8,6 ; Write Rt to DBGCLAIMSET
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	1000	110

G5.2.7 DBGDCCINT, DCC Interrupt Enable Register

The DBGDCCINT characteristics are:

Purpose

Enables interrupt requests to be signaled based on the DCC status flags.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

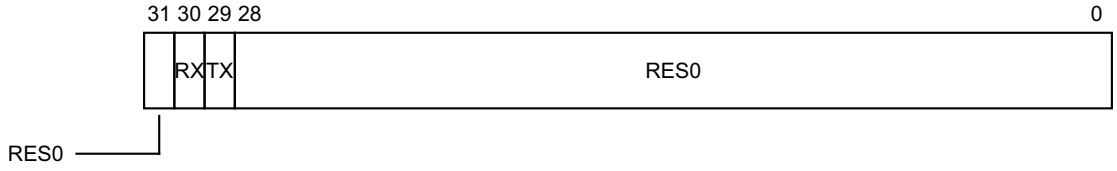
DBGDCCINT is architecturally mapped to AArch64 register MDCCINT_EL1.

Attributes

DBGDCCINT is a 32-bit register.

Field descriptions

The DBGDCCINT bit assignments are:



Bit [31]

Reserved, RES0.

RX, bit [30]

DCC interrupt request enable control for DTRRX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

`0` No interrupt request generated by DTRRX.

`1` Interrupt request will be generated on RXfull == 1.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

On Warm reset, the field resets to 0.

TX, bit [29]

DCC interrupt request enable control for DTRTX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

0 . No interrupt request generated by DTRTX.

1 . Interrupt request will be generated on TXfull == 0.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

On Warm reset, the field resets to 0.

Bits [28:0]

Reserved, RES0.

Accessing the DBGDCCINT register

To access the DBGDCCINT register:

```
MRC p14,0,<Rt>,c0,c2,0 ; Read DBGDCCINT into Rt
MCR p14,0,<Rt>,c0,c2,0 ; Write Rt to DBGDCCINT
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0010	000

G5.2.8 DBGDEVID, Debug Device ID register 0

The DBGDEVID characteristics are:

Purpose

Adds to the information given by the DBGDIDR by describing other features of the debug implementation.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

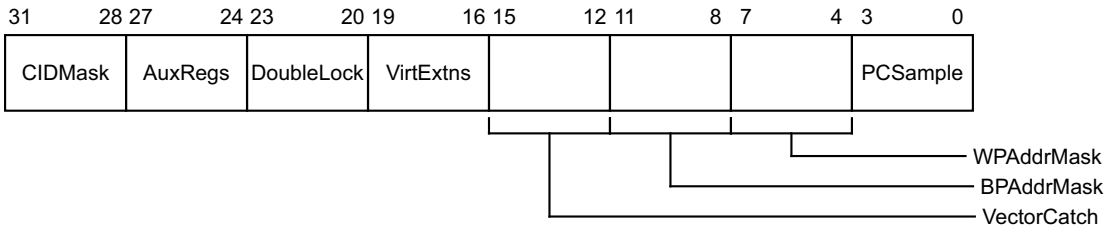
This register is required in all implementations.

Attributes

DBGDEVID is a 32-bit register.

Field descriptions

The DBGDEVID bit assignments are:



CIDMask, bits [31:28]

Indicates the level of support for the Context ID matching breakpoint masking capability. Permitted values of this field are:

`0000` Context ID masking is not implemented.

`0001` Context ID masking is implemented.

All other values are reserved. The value of this for v8-A is `0000`.

AuxRegs, bits [27:24]

Indicates support for Auxiliary registers. Permitted values for this field are:

`0000` None supported.

`0001` Support for External Debug Auxiliary Control Register, EDACR.

All other values are reserved.

DoubleLock, bits [23:20]

Indicates the presence of the DBGOSDLR, OS Double Lock Register. Permitted values of this field are:

`0000` The DBGOSDLR is not present.

0001 The DBGOSDLR is present.

All other values are reserved. The value of this for v8-A is 0001.

VirtExtns, bits [19:16]

Indicates whether EL2 is implemented. Permitted values of this field are:

0000 EL2 is not implemented.

0001 EL2 is implemented.

All other values are reserved.

VectorCatch, bits [15:12]

Defines the form of Vector catch debug event implemented. Permitted values of this field are:

0000 Address matching vector catch debug event implemented.

0001 Exception matching vector catch debug event implemented.

All other values are reserved.

BPAddrMask, bits [11:8]

Indicates the level of support for the IVA matching breakpoint masking capability. Permitted values of this field are:

0000 Breakpoint address matching may be implemented. If not implemented, DBGBCR<n>[28:24] is RAZ/WI.

0001 Breakpoint address matching is implemented.

1111 Breakpoint address matching is not implemented. DBGBCR<n>[28:24] is RES0.

All other values are reserved. The value of this for v8-A is 1111.

WPAddrMask, bits [7:4]

Indicates the level of support for the data VA matching watchpoint masking capability. Permitted values of this field are:

0000 Watchpoint address matching may be implemented. If not implemented, DBGWCR<n>.MASK (Address mask) is RAZ/WI.

0001 Watchpoint address matching is implemented.

1111 Watchpoint address matching is not implemented. DBGWCR<n>.MASK (Address mask) is RES0.

All other values are reserved. The value of this for v8-A is 0001.

PCSample, bits [3:0]

Indicates the level of Sample-based profiling support using external debug registers 40 through 43. Permitted values of this field in v8-A are:

0000 Architecture-defined form of Sample-based profiling not implemented.

0010 EDPCSR and EDCIDSR are implemented (only permitted if EL3 and EL2 are not implemented).

0011 EDPCSR, EDCIDSR, and EDVIDSR are implemented.

All other values are reserved.

Accessing the DBGDEVID register

To access the DBGDEVID register:

```
MRC p14,0,<Rt>,c7,c2,7 ; Read DBGDEVID into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	0010	111

G5.2.9 DBGDEVID1, Debug Device ID register 1

The DBGDEVID1 characteristics are:

Purpose

Adds to the information given by the DBGDIDR by describing other features of the debug implementation.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

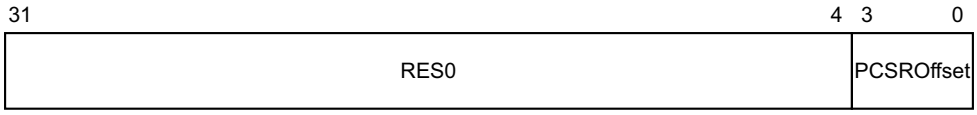
This register is required in all implementations.

Attributes

DBGDEVID1 is a 32-bit register.

Field descriptions

The DBGDEVID1 bit assignments are:



Bits [31:4]

Reserved, RES0.

PCSROffset, bits [3:0]

This field indicates the offset applied to PC samples returned by reads of EDPCSR. Permitted values of this field in v8-A are:

`0000` EDPCSR not implemented.

In v7-A, this field being `0000` can also mean that EDPCSR is implemented and that values returned by reads have an offset applied and indicate the instruction set state. This is not a permitted implementation for v8-A.

`0010` EDPCSR implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state.

Accessing the DBGDEVID1 register

To access the DBGDEVID1 register:

```
MRC p14,0,<Rt>,c7,c1,7 ; Read DBGDEVID1 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	0001	111

G5.2.10 DBGDEVID2, Debug Device ID register 2

The DBGDEVID2 characteristics are:

Purpose

Reserved for future descriptions of features of the debug implementation.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

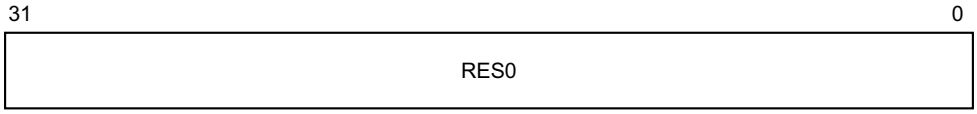
There are no configuration notes.

Attributes

DBGDEVID2 is a 32-bit register.

Field descriptions

The DBGDEVID2 bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the DBGDEVID2 register

To access the DBGDEVID2 register:

```
MRC p14,0,<Rt>,c7,c0,7 ; Read DBGDEVID2 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0111	0000	111

G5.2.11 DBGDIDR, Debug ID Register

The DBGDIDR characteristics are:

Purpose

Specifies which version of the Debug architecture is implemented, and some features of the debug implementation.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 if DBGDSCRext.UDCCdis is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

This register is required in all implementations.

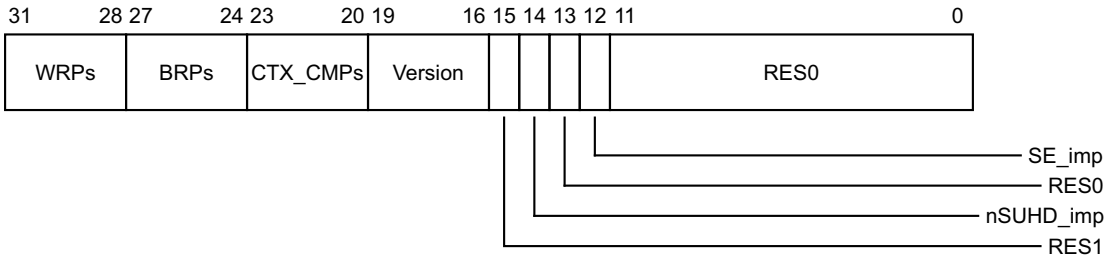
If external debug over powerdown is implemented, this register can be implemented in either or both power domains.

Attributes

DBGDIDR is a 32-bit register.

Field descriptions

The DBGDIDR bit assignments are:



WRPs, bits [31:28]

The number of watchpoints implemented, minus 1.

Permitted values of this field are from `0b0001` for 2 implemented watchpoints, to `0b1111` for 16 implemented watchpoints.

The value of `0b0000` is reserved.

If AArch64 is implemented, this field has the same value as ID_AA64DFR0_EL1.WRPs.

BRPs, bits [27:24]

The number of breakpoints implemented, minus 1.

Permitted values of this field are from `0b0001` for 2 implemented breakpoint, to `0b1111` for 16 implemented breakpoints.

The value of 0b0000 is reserved.

If AArch64 is implemented, this field has the same value as ID_AA64DFR0_EL1.BRPs.

CTX_CMPs, bits [23:20]

The number of breakpoints that can be used for Context matching, minus 1.

Permitted values of this field are from 0b0000 for 1 Context matching breakpoint, to 0b1111 for 16 Context matching breakpoints.

The Context matching breakpoints must be the highest addressed breakpoints. For example, if six breakpoints are implemented and two are Context matching breakpoints, they must be breakpoints 4 and 5.

If AArch64 is implemented, this field has the same value as ID_AA64DFR0_EL1.CTX_CMPs.

Version, bits [19:16]

The Debug architecture version. The permitted values of this field are:

0001 ARMv6, v6 Debug architecture

0010 ARMv6, v6.1 Debug architecture

0011 ARMv7, v7 Debug architecture, with baseline CP14 registers implemented

0100 ARMv7, v7 Debug architecture, with all CP14 registers implemented

0101 ARMv7, v7.1 Debug architecture.

0110 ARMv8, v8 Debug architecture.

All other values are reserved.

Bit [15]

Reserved, RES1.

nSUHD_imp, bit [14]

In v7-A, was Secure User Halting Debug not implemented.

The value of this bit must match the value of the SE_imp bit.

Bit [13]

Reserved, RES0.

SE_imp, bit [12]

EL3 implemented. The meanings of the values of this bit are:

0 EL3 not implemented.

1 EL3 implemented.

The value of this bit must match the value of the nSUHD_imp bit.

Bits [11:0]

Reserved, RES0.

Accessing the DBGDIDR

To access the DBGDIDR:

```
MRC p14,0,<Rt>,c0,c0,0 ; Read DBGDIDR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0000	000

G5.2.12 DBGDRAR, Debug ROM Address Register

The DBGDRAR characteristics are:

Purpose

Defines the base physical address of a memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system. However, if this processor is the only memory-mapped debug component in the system, or the only memory mapped-debug component visible to this processor, this register defines the base physical address of this processor's debug registers.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 if DBGDSCRext.UDCCdis is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGDRAR is architecturally mapped to AArch64 register MDRAR_EL1.

This register is required in all implementations.

If no memory-mapped debug components are implemented, DBGDRAR.Valid is RES0.

DBGDRAR is accessible either as a 64-bit register (using MRRC) or a 32-bit register (using MRC).

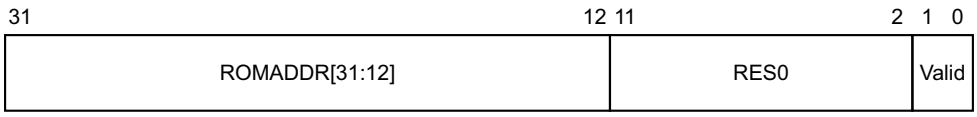
Attributes

DBGDRAR is a 32-bit register when accessing the 32-bit version and a 64-bit register when accessing the 64-bit version.

Field descriptions

The DBGDRAR bit assignments are:

When accessing the 32-bit version:



ROMADDR[31:12], bits [31:12]

Bits[31:12] of the ROM table physical address. Bits [11:0] of the address are zero.

Bits [11:2]

Reserved, RES0.

Valid, bits [1:0]

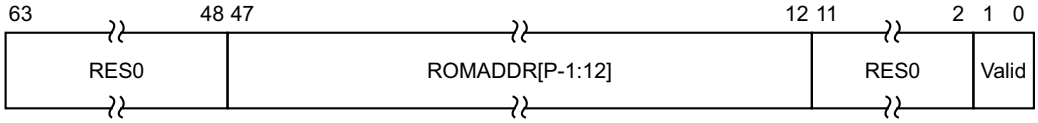
This field indicates whether the ROM Table address is valid. The permitted values of this field are:

`00` ROM Table address is not valid

11 ROM Table address is valid.

Other values are reserved.

When accessing the 64-bit version:



Bits [63:48]

Reserved, RES0.

ROMADDR[P-1:12], bits [47:12]

Bits[P-1:12] of the ROM table physical address, where P is the physical address size in bits (up to 48 bits) as stored in ID_AA64MMFR0_EL1. If P is less than 48, bits[47:P] of this register are RES0.

Bits [11:0] of the ROM table physical address are zero.

If EL3 is implemented, ROMADDR is an address in Non-secure memory. Whether the ROM table is also accessible in Secure memory is IMPLEMENTATION DEFINED.

ARM recommends that bits [P-1:32] are zero in systems that support AArch32 at the highest exception level.

Bits [11:2]

Reserved, RES0.

Valid, bits [1:0]

This field indicates whether the ROM Table address is valid. The permitted values of this field are:

00 ROM Table address is not valid

11 ROM Table address is valid.

Other values are reserved.

Accessing the DBGDRAR

To access the DBGDRAR when accessing the 32-bit version:

```
MRC p14,0,<Rt>,c1,c0,0 ; Read DBGDRAR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	0000	000

To access the DBGDRAR when accessing the 64-bit version:

```
MRRC p14,0,<Rt>,<Rt2>,c1 ; Read 64-bit DBGDRAR into Rt (low word) and Rt2 (high word)
```

Register access is encoded as follows:

coproc	opc1	CRm
1110	0000	0001

G5.2.13 DBGDSAR, Debug Self Address Register

The DBGDSAR characteristics are:

Purpose

Previously defined the offset from the base address defined in DBGDRAR of the physical base address of the debug registers for the processor. Is now deprecated and RAZ.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 if DBGDSCRext.UDCCdis is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

There are no configuration notes.

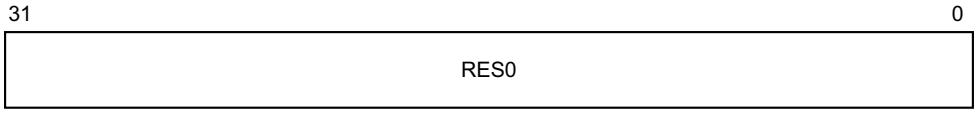
Attributes

DBGDSAR is a 32-bit register when accessing the 32-bit version and a 64-bit register when accessing the 64-bit version.

Field descriptions

The DBGDSAR bit assignments are:

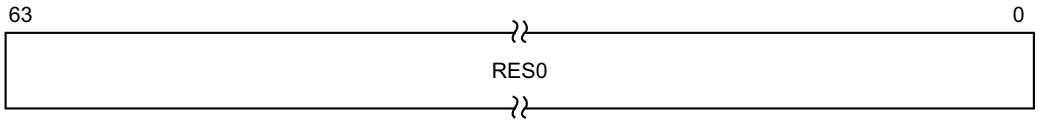
When accessing the 32-bit version:



Bits [31:0]

Reserved, RES0.

When accessing the 64-bit version:



Bits [63:0]

Reserved, RES0.

Accessing the DBGDSAR

To access the DBGDSAR when accessing the 32-bit version:

```
MRC p14,0,<Rt>,c2,c0,0 ; Read DBGDSAR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0010	0000	000

To access the DBGDSAR when accessing the 64-bit version:

```
MRRC p14,0,<Rt>,<Rt2>,c2 ; Read 64-bit DBGDSAR into Rt (low word) and Rt2 (high word)
```

Register access is encoded as follows:

coproc	opc1	CRm
1110	0000	0010

G5.2.14 DBGDSCRext, Debug Status and Control Register, External View

The DBGDSCRext characteristics are:

Purpose

Main control register for the debug implementation.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGDSCRext is architecturally mapped to AArch64 register MDSCR_EL1.

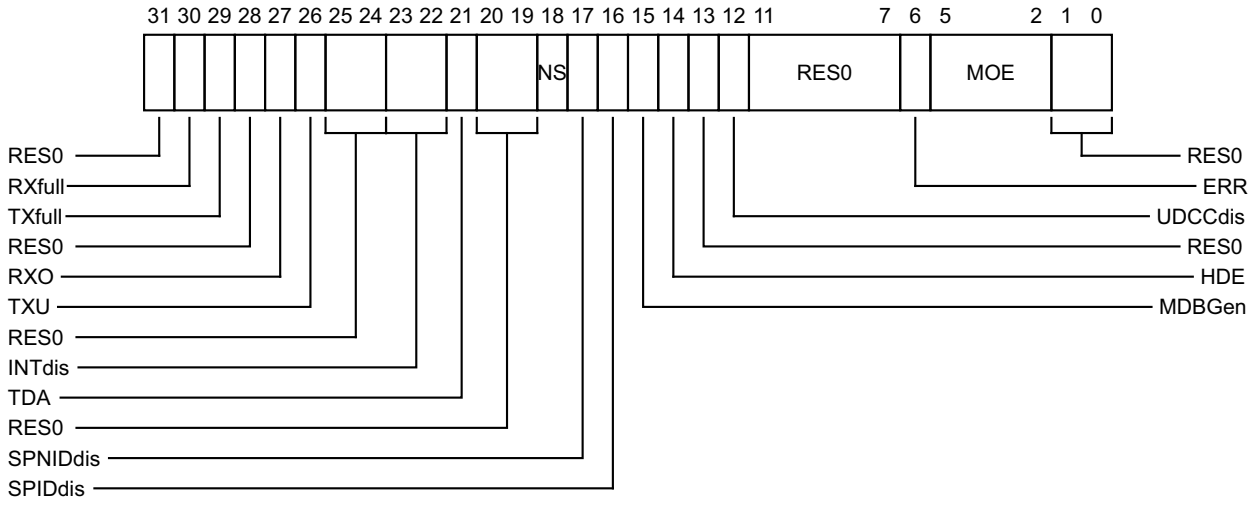
This register is required in all implementations.

Attributes

DBGDSCRext is a 32-bit register.

Field descriptions

The DBGDSCRext bit assignments are:



Bit [31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. Used for save/restore of EDSCR.RXfull.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

ARM deprecates use of this bit other than for save/restore. Use DBGDSCRint to access the DTRRX full status.

TXfull, bit [29]

DTRTX full. Used for save/restore of EDSCR.TXfull.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

ARM deprecates use of this bit other than for save/restore. Use DBGDSCRint to access the DTRTX full status.

Bit [28]

Reserved, RES0.

RXO, bit [27]

Used for save/restore of EDSCR.RXO.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

TXU, bit [26]

Used for save/restore of EDSCR.TXU.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

Bits [25:24]

Reserved, RES0.

INTdis, bits [23:22]

Used for save/restore of EDSCR.INTdis.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this field is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this field is RW.

TDA, bit [21]

Used for save/restore of EDSCR.TDA.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

Bits [20:19]

Reserved, RES0.

NS, bit [18]

Non-secure status. Returns the inverse of IsSecure(). This bit is RO.

ARM deprecates use of this field.

On Warm reset, the field reset value is architecturally UNKNOWN.

SPNIDdis, bit [17]

Secure privileged profiling disabled status bit. This bit is RO and reflects the value of ProfilingProhibited(TRUE,EL1). Permitted values are:

`0` Profiling allowed in Secure privileged modes.

`1` Profiling prohibited in Secure privileged modes.

ARM deprecates use of this field.

On Warm reset, the field reset value is architecturally UNKNOWN.

SPIDdis, bit [16]

Secure privileged AArch32 invasive self-hosted debug disabled status bit. This bit is RO and returns the inverse of DebugSPD32(). Permitted values are:

`0` Self-hosted debug enabled in Secure privileged AArch32 modes.

`1` Self-hosted debug disabled in Secure privileged AArch32 modes.

ARM deprecates use of this field.

On Warm reset, the field reset value is architecturally UNKNOWN.

MDBGen, bit [15]

Monitor debug events enable. Enable Breakpoint, Watchpoint, and Vector catch debug exceptions.

`0` Breakpoint, Watchpoint, and Vector catch debug exceptions disabled.

`1` Breakpoint, Watchpoint, and Vector catch debug exceptions enabled.

On Warm reset, the field resets to 0.

HDE, bit [14]

Used for save/restore of EDSCR.HDE.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [13]

Reserved, RES0.

UDCCdis, bit [12]

User mode access to Debug Communications Channel disable. When set, then any EL0 access to DBGDIDR, DBGDRAR, DBGDSAR, DBGDSCRint, DBGDTRTXint, or DBGDTRRXint is trapped to EL1.

On Warm reset, the field resets to 0.

Bits [11:7]

Reserved, RES0.

ERR, bit [6]

Used for save/restore of EDSCR.ERR.

When DBGOSLSR.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When DBGOSLSR.OSLK == 1 (the OS lock is locked), this bit is RW.

On Warm reset, the field reset value is architecturally UNKNOWN.

MOE, bits [5:2]

Method of Entry for debug exception. When a debug exception is taken to an exception level using AArch32, this field is set to indicate the event that caused the exception:

`0001` Breakpoint

`0011` Software breakpoint (BKPT) instruction

`0101` Vector catch

`1010` Watchpoint

On Warm reset, the field reset value is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

Accessing the DBGDSCRext

To access the DBGDSCRext:

```
MRC p14,0,<Rt>,c0,c2,2 ; Read DBGDSCRext into Rt
MCR p14,0,<Rt>,c0,c2,2 ; Write Rt to DBGDSCRext
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0010	010

G5.2.15 DBGDSCRint, Debug Status and Control Register, Internal View

The DBGDSCRint characteristics are:

Purpose

Main control register for the debug implementation. This is an internal, read-only view.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register can be read at EL0 when DBGDSCRext.UDCCdis is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGDSCRint is architecturally mapped to AArch64 register MDCCSR_EL0.

This register is required in all implementations.

DBGDSCRint.{NS, SPNIDdis, SPIDdis, MDBGen, UDCCdis, MOE} are UNKNOWN when the register is accessed at EL0. However, although these values are not accessible at EL0 by instructions that are neither UNPREDICTABLE nor return UNKNOWN values, it is permissible for an implementation to return the values of DBGDSCRext.{NS, SPNIDdis, SPIDdis, MDBGen, UDCCdis, MOE} for these fields at EL0.

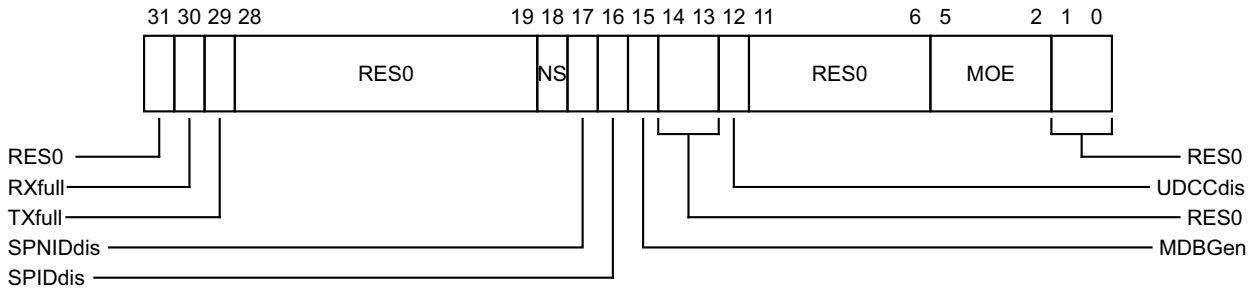
It is also permissible for an implementation to return the same values as defined for a read of DBGDSCRint at EL1 or above. (This is the case even if the implementation does not support AArch32 at EL1 or above.)

Attributes

DBGDSCRint is a 32-bit register.

Field descriptions

The DBGDSCRint bit assignments are:



Bit [31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. Read-only view of the equivalent bit in the EDSCR.

TXfull, bit [29]

DTRTX full. Read-only view of the equivalent bit in the EDSCR.

Bits [28:19]

Reserved, RES0.

NS, bit [18]

Non-secure status.

Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

SPNIDdis, bit [17]

Secure privileged non-invasive debug disable.

Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

SPIDdis, bit [16]

Secure privileged invasive debug disable.

Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

MDBGen, bit [15]

Monitor debug events enable.

Read-only view of the equivalent bit in the DBGDSCRext.

Bits [14:13]

Reserved, RES0.

UDCCdis, bit [12]

User mode access to Debug Communications Channel disable.

Read-only view of the equivalent bit in the DBGDSCRext. ARM deprecates use of this field.

Bits [11:6]

Reserved, RES0.

MOE, bits [5:2]

Method of Entry for debug exception. When a debug exception is taken to an exception level using AArch32, this field is set to indicate the event that caused the exception:

`0001` Breakpoint

`0011` Software breakpoint (BKPT) instruction

`0101` Vector catch

`1010` Watchpoint

Read-only view of the equivalent bit in the DBGDSCRext.

Bits [1:0]

Reserved, RES0.

Accessing the DBGDSCRint

To access the DBGDSCRint:

```
MRC p14,0,<Rt>,c0,c1,0 ; Read DBGDSCRint into Rt, where Rt can be R0-R14 or APSR_nzcv.
                       ; The last form writes bits[31:28] of the transferred value to the N, Z, C and V
                       ; condition flags and is specified by setting the RT field of the encoding to
                       ; 0b1111.
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0001	000

G5.2.16 DBGDTRRXext, Debug Data Transfer Register, Receive, External View

The DBGDTRRXext characteristics are:

Purpose

Used for save/restore of DBGDTRRXint. It is a component of the Debug Communications Channel.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

ARM deprecates reads and writes of DBGDTRRXext through the CP14 interface when the OS lock is unlocked.

If EDSCR.ITE == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGDTRRXext is architecturally mapped to AArch64 register OSDTRRX_EL1.

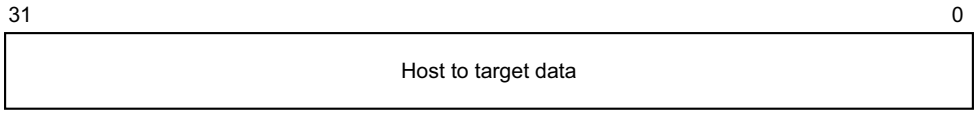
This register is required in all implementations.

Attributes

DBGDTRRXext is a 32-bit register.

Field descriptions

The DBGDTRRXext bit assignments are:



Bits [31:0]

Host to target data. One word of data for transfer from the debug host to the debug target.

For the full behavior of the Debug Communications Channel, see The Debug Communication Channel and Instruction Transfer Register.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGDTRRXext

To access the DBGDTRRXext:

```
MRC p14,0,<Rt>,c0,c0,2 ; Read DBGDTRRXext into Rt
MCR p14,0,<Rt>,c0,c0,2 ; Write Rt to DBGDTRRXext
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0000	010

G5.2.17 DBGDTRRXint, Debug Data Transfer Register, Receive, Internal View

The DBGDTRRXint characteristics are:

Purpose

Transfers data from an external host to the ARM processor. For example, it is used by a debugger transferring commands and data to a debug target. It is a component of the Debug Communications Channel.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register can be read at EL0 when DBGDSCRint.UDCCdis is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

If EDSCR.ITE == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGDTRRXint is architecturally mapped to AArch64 register DBGDTRRX_EL0.

DBGDTRRXint is architecturally mapped to external register DBGDTRRX_EL0.

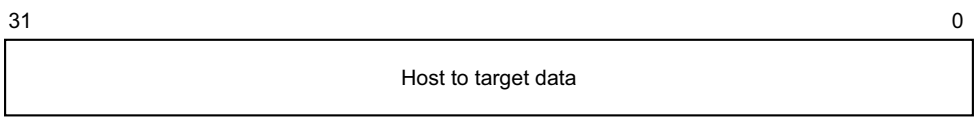
This register is required in all implementations.

Attributes

DBGDTRRXint is a 32-bit register.

Field descriptions

The DBGDTRRXint bit assignments are:



Bits [31:0]

Host to target data. One word of data for transfer from the debug host to the debug target.

For the full behavior of the Debug Communications Channel, see The Debug Communication Channel and Instruction Transfer Register.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGDTRRXint

To access the DBGDTRRXint:

```
MRC p14,0,<Rt>,c0,c5,0 ; Read DBGDTRRXint into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0101	000

G5.2.18 DBGDTRTXext, Debug Data Transfer Register, Transmit, External View

The DBGDTRTXext characteristics are:

Purpose

Used for save/restore of DBGDTRTXint. It is a component of the Debug Communication Channel.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

ARM deprecates reads and writes of DBGDTRTXext through the CP14 interface when the OS Lock is unlocked.

If EDSCR.ITE == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGDTRTXext is architecturally mapped to AArch64 register OSDTRTX_EL1.

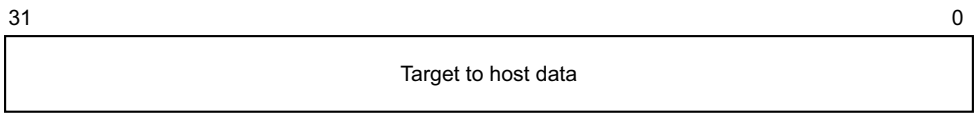
This register is required in all implementations.

Attributes

DBGDTRTXext is a 32-bit register.

Field descriptions

The DBGDTRTXext bit assignments are:



Bits [31:0]

Target to host data. One word of data for transfer from the debug target to the debug host.

For the full behavior of the Debug Communications Channel, see The Debug Communication Channel and Instruction Transfer Register.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGDTRTXext

To access the DBGDTRTXext:

```
MRC p14,0,<Rt>,c0,c3,2 ; Read DBGDTRTXext into Rt
MCR p14,0,<Rt>,c0,c3,2 ; Write Rt to DBGDTRTXext
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0011	010

G5.2.19 DBGDTRTXint, Debug Data Transfer Register, Transmit, Internal View

The DBGDTRTXint characteristics are:

Purpose

Transfers data from the ARM processor to an external host. For example, it is used by a debug target to transfer data to the debugger. It is a component of the Debug Communication Channel.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-WO	Config-WO	WO	WO	WO	WO	WO

This register can be written at EL0 when DBGDSCRint.UDCCdis is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

If EDSCR.ITE == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGDTRTXint is architecturally mapped to AArch64 register DBGDTRTX_EL0.

DBGDTRTXint is architecturally mapped to external register DBGDTRTX_EL0.

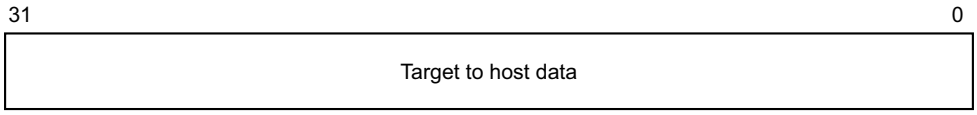
This register is required in all implementations.

Attributes

DBGDTRTXint is a 32-bit register.

Field descriptions

The DBGDTRTXint bit assignments are:



Bits [31:0]

Target to host data. One word of data for transfer from the debug target to the debug host.

For the full behavior of the Debug Communications Channel, see The Debug Communication Channel and Instruction Transfer Register.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGDTRTXint

To access the DBGDTRTXint:

```
MCR p14,0,<Rt>,c0,c5,0 ; Write Rt to DBGDTRTXint
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0101	000

G5.2.20 DBGOSDLR, Debug OS Double Lock Register

The DBGOSDLR characteristics are:

Purpose

Locks out the external debug interface.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

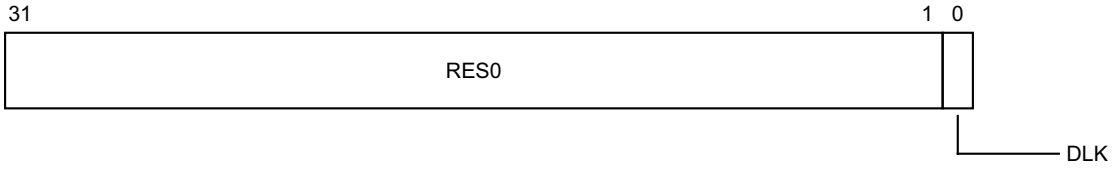
DBGOSDLR is architecturally mapped to AArch64 register OSDLR_EL1.

Attributes

DBGOSDLR is a 32-bit register.

Field descriptions

The DBGOSDLR bit assignments are:



Bits [31:1]

Reserved, RES0.

DLK, bit [0]

OS Double Lock control bit. Possible values are:

`0` OS Double Lock unlocked.

`1` OS Double Lock locked, if DBGPRCR.CORENPDRQ (Core no power-down request) bit is set to 0 and the processor is in Non-debug state.

On Warm reset, the field resets to 0.

Accessing the DBGOSDLR

To access the DBGOSDLR:

```
MRC p14,0,<Rt>,c1,c3,4 ; Read DBGOSDLR into Rt
MCR p14,0,<Rt>,c1,c3,4 ; Write Rt to DBGOSDLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	0011	100

G5.2.21 DBGOSECCR, Debug OS Lock Exception Catch Control Register

The DBGOSECCR characteristics are:

Purpose

Provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGOSECCR is architecturally mapped to AArch64 register OSECCR_EL1.

DBGOSECCR is architecturally mapped to external register EDECCR.

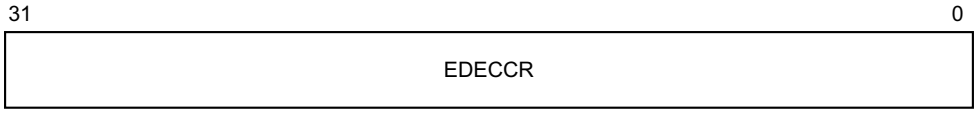
Attributes

DBGOSECCR is a 32-bit register.

Field descriptions

The DBGOSECCR bit assignments are:

When OSLSR.OSLK==1:



EDECCR, bits [31:0]

Used for save/restore to EDECCR over powerdown.

Accessing the DBGOSECCR

To access the DBGOSECCR:

```
MRC p14,0,<Rt>,c0,c6,2 ; Read DBGOSECCR into Rt
MCR p14,0,<Rt>,c0,c6,2 ; Write Rt to DBGOSECCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0110	010

G5.2.22 DBGOSLAR, Debug OS Lock Access Register

The DBGOSLAR characteristics are:

Purpose

Provides a lock for the debug registers. The OS lock also disables some Software debug events.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGOSLAR is architecturally mapped to AArch64 register OSLAR_EL1.

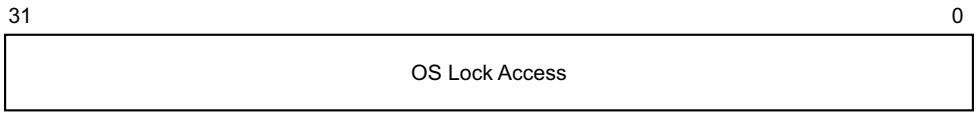
DBGOSLAR is architecturally mapped to external register OSLAR_EL1.

Attributes

DBGOSLAR is a 32-bit register.

Field descriptions

The DBGOSLAR bit assignments are:



Bits [31:0]

OS Lock Access. Writing the value `0xC5ACCE55` to the DBGOSLAR sets the OS lock to 1. Writing any other value sets the OS lock to 0.

Use DBGOSLSR.OSLK to check the current status of the lock.

Accessing the DBGOSLAR

To access the DBGOSLAR:

```
MCR p14,0,<Rt>,c1,c0,4 ; Write Rt to DBGOSLAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	0000	100

G5.2.23 DBGOSLSR, Debug OS Lock Status Register

The DBGOSLSR characteristics are:

Purpose

Provides status information for the OS lock.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGOSLSR is architecturally mapped to AArch64 register OSLSR_EL1.

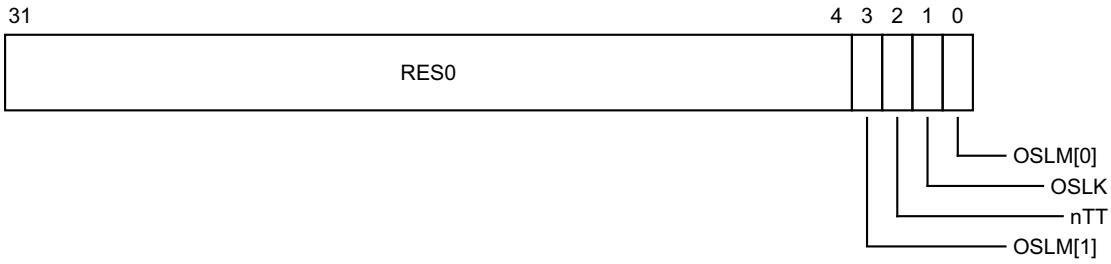
The OS lock status is also visible in the external debug interface through EDPRSR.

Attributes

DBGOSLSR is a 32-bit register.

Field descriptions

The DBGOSLSR bit assignments are:



Bits [31:4]

Reserved, RES0.

OSLM[1], bit [3]

See below for description of the OSLM field.

nTT, bit [2]

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

OSLK, bit [1]

OS Lock Status. The possible values are:

`0` OS lock unlocked.

`1` OS lock locked.

The OS Lock is locked and unlocked by writing to the OS Lock Access Register.

On Cold reset, the field resets to 1.

OSLM[0], bit [0]

OS lock model implemented. Identifies the form of OS save and restore mechanism implemented. In v8-A these bits are as follows:

`10` OS lock implemented. DBGOSSRR not implemented.

All other values are reserved.

Accessing the DBGOSLSR

To access the DBGOSLSR:

```
MRC p14,0,<Rt>,c1,c1,4 ; Read DBGOSLSR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	0001	100

G5.2.24 DBGPRCR, Debug Power Control Register

The DBGPRCR characteristics are:

Purpose

Controls behavior of processor on power-down request.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGPRCR is architecturally mapped to AArch64 register DBGPRCR_EL1.

This register is required in all implementations.

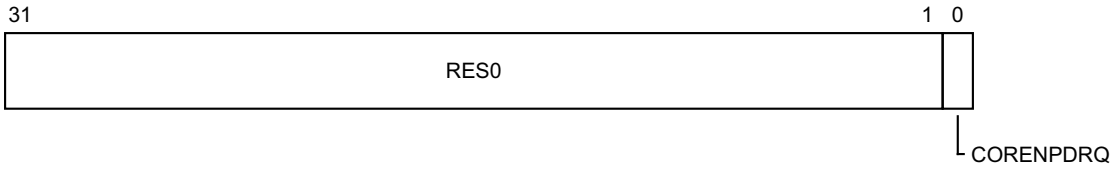
Bit [0] of this register is mapped to EDPRCR.CORENPDRQ, bit [0] of the external view of this register. The other bits in these registers are not mapped to each other.

Attributes

DBGPRCR is a 32-bit register.

Field descriptions

The DBGPRCR bit assignments are:



Bits [31:1]

Reserved, RES0.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:

`0` On a powerdown request, the system powers down the Core power domain.

`1` On a powerdown request, the system emulates powerdown of the Core power domain. In this emulation mode the Core power domain is not actually powered down.

On Cold reset, the field resets to the value of EDPRCR.COREPURQ.

Accessing the DBGPRCR

To access the DBGPRCR:

```
MRC p14,0,<Rt>,c1,c4,4 ; Read DBGPRCR into Rt
MCR p14,0,<Rt>,c1,c4,4 ; Write Rt to DBGPRCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0001	0100	100

G5.2.25 DBGVCR, Debug Vector Catch Register

The DBGVCR characteristics are:

Purpose

Controls Vector catch debug events.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGVCR is architecturally mapped to AArch64 register DBGVCR32_EL2.

This register is required in all implementations.

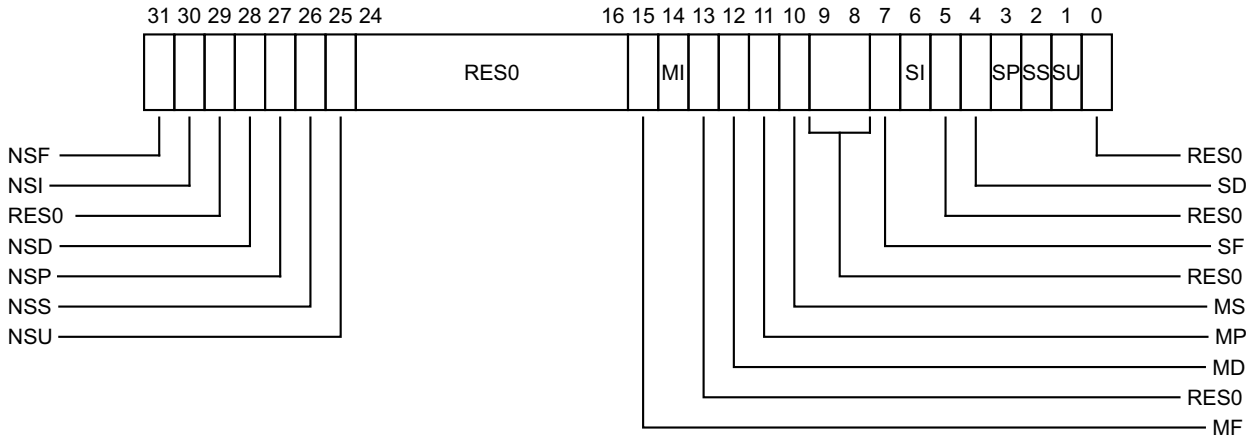
Attributes

DBGVCR is a 32-bit register.

Field descriptions

The DBGVCR bit assignments are:

When EL3 implemented and using AArch32:



NSF, bit [31]

FIQ vector catch enable in Non-secure state.

The exception vector offset is `0x1C`.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSI, bit [30]

IRQ vector catch enable in Non-secure state.

The exception vector offset is `0x18`.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [29]

Reserved, RES0.

NSD, bit [28]

Data Abort vector catch enable in Non-secure state.

The exception vector offset is `0x10`.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSP, bit [27]

Prefetch Abort vector catch enable in Non-secure state.

The exception vector offset is `0x0C`.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSS, bit [26]

Supervisor Call (SVC) vector catch enable in Non-secure state.

The exception vector offset is `0x08`.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSU, bit [25]

Undefined Instruction vector catch enable in Non-secure state.

The exception vector offset is `0x04`.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bits [24:16]

Reserved, RES0.

MF, bit [15]

FIQ vector catch enable in Monitor mode.

The exception vector offset is `0x1C`.

On Warm reset, the field reset value is architecturally UNKNOWN.

MI, bit [14]

IRQ vector catch enable in Monitor mode.

The exception vector offset is `0x18`.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [13]

Reserved, RES0.

MD, bit [12]

Data Abort vector catch enable in Monitor mode.

The exception vector offset is `0x10`.

On Warm reset, the field reset value is architecturally UNKNOWN.

MP, bit [11]

Prefetch Abort vector catch enable in Monitor mode.

The exception vector offset is `0x0C`.

On Warm reset, the field reset value is architecturally UNKNOWN.

MS, bit [10]

Secure Monitor Call (SMC) vector catch enable in Monitor mode.

The exception vector offset is 0x08.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bits [9:8]

Reserved, RES0.

SF, bit [7]

FIQ vector catch enable in Secure state.

The exception vector offset is 0x1C.

On Warm reset, the field reset value is architecturally UNKNOWN.

SI, bit [6]

IRQ vector catch enable in Secure state.

The exception vector offset is 0x18.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

SD, bit [4]

Data Abort vector catch enable in Secure state.

The exception vector offset is 0x10.

On Warm reset, the field reset value is architecturally UNKNOWN.

SP, bit [3]

Prefetch Abort vector catch enable in Secure state.

The exception vector offset is 0x0C.

On Warm reset, the field reset value is architecturally UNKNOWN.

SS, bit [2]

Supervisor Call (SVC) vector catch enable in Secure state.

The exception vector offset is 0x08.

On Warm reset, the field reset value is architecturally UNKNOWN.

SU, bit [1]

Undefined Instruction vector catch enable in Secure state.

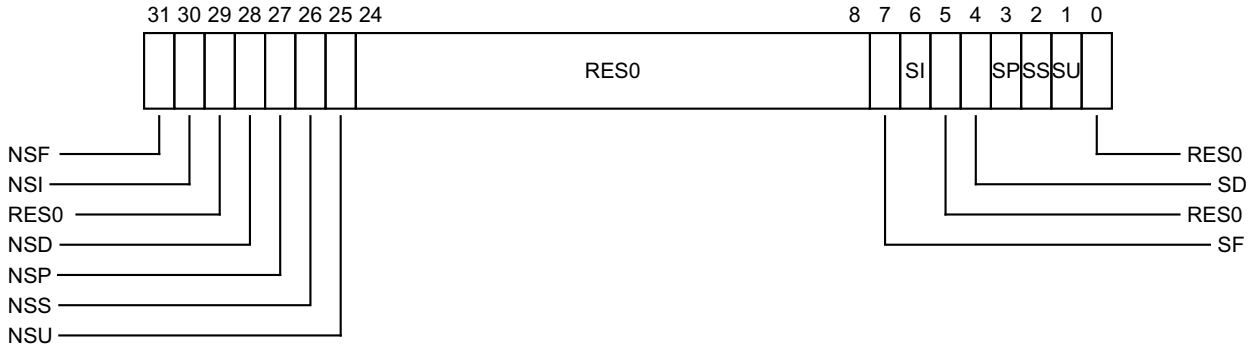
The exception vector offset is 0x04.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

When EL3 implemented and using AArch64:



NSF, bit [31]

FIQ vector catch enable in Non-secure state.

The exception vector offset is `0x1C`.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSI, bit [30]

IRQ vector catch enable in Non-secure state.

The exception vector offset is `0x18`.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [29]

Reserved, RES0.

NSD, bit [28]

Data Abort vector catch enable in Non-secure state.

The exception vector offset is `0x10`.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSP, bit [27]

Prefetch Abort vector catch enable in Non-secure state.

The exception vector offset is `0x0C`.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSS, bit [26]

Supervisor Call (SVC) vector catch enable in Non-secure state.

The exception vector offset is `0x08`.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSU, bit [25]

Undefined Instruction vector catch enable in Non-secure state.

The exception vector offset is `0x04`.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bits [24:8]

Reserved, RES0.

SF, bit [7]

FIQ vector catch enable in Secure state.

The exception vector offset is 0x1C.

On Warm reset, the field reset value is architecturally UNKNOWN.

SI, bit [6]

IRQ vector catch enable in Secure state.

The exception vector offset is 0x18.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

SD, bit [4]

Data Abort vector catch enable in Secure state.

The exception vector offset is 0x10.

On Warm reset, the field reset value is architecturally UNKNOWN.

SP, bit [3]

Prefetch Abort vector catch enable in Secure state.

The exception vector offset is 0x0C.

On Warm reset, the field reset value is architecturally UNKNOWN.

SS, bit [2]

Supervisor Call (SVC) vector catch enable in Secure state.

The exception vector offset is 0x08.

On Warm reset, the field reset value is architecturally UNKNOWN.

SU, bit [1]

Undefined Instruction vector catch enable in Secure state.

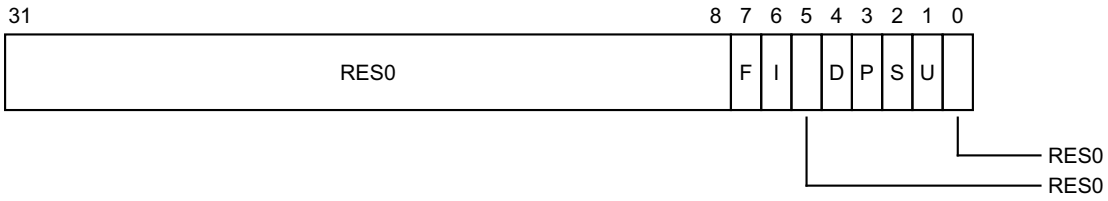
The exception vector offset is 0x04.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

When EL3 not implemented:



Bits [31:8]

Reserved, RES0.

F, bit [7]

FIQ vector catch enable.

The exception vector offset is 0x1C.

On Warm reset, the field reset value is architecturally UNKNOWN.

I, bit [6]

IRQ vector catch enable.

The exception vector offset is `0x18`.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

D, bit [4]

Data Abort vector catch enable.

The exception vector offset is `0x10`.

On Warm reset, the field reset value is architecturally UNKNOWN.

P, bit [3]

Prefetch Abort vector catch enable.

The exception vector offset `0x0C`.

On Warm reset, the field reset value is architecturally UNKNOWN.

S, bit [2]

Supervisor Call (SVC) vector catch enable.

The exception vector offset is `0x08`.

On Warm reset, the field reset value is architecturally UNKNOWN.

U, bit [1]

Undefined Instruction vector catch enable.

The exception vector offset is `0x04`.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

Accessing the DBGVCR

To access the DBGVCR:

```
MRC p14,0,<Rt>,c0,c7,0 ; Read DBGVCR into Rt
MCR p14,0,<Rt>,c0,c7,0 ; Write Rt to DBGVCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0111	000

G5.2.26 DBGWCR<n>, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n> characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>, where n is 0 to 15.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

When the E field is zero, all the other fields in the register are ignored.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGWCR<n> is architecturally mapped to AArch64 register DBGWCR<n>_EL1.

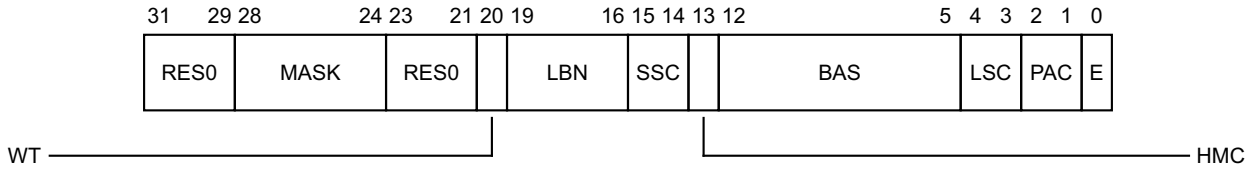
DBGWCR<n> is architecturally mapped to external register DBGWCR<n>_EL1.

Attributes

DBGWCR<n> is a 32-bit register.

Field descriptions

The DBGWCR<n> bit assignments are:



Bits [31:29]

Reserved, RES0.

MASK, bits [28:24]

Address mask. Only objects up to 2GB can be watched using a single mask.

`00000` No mask.

`00001` Reserved.

`00010` Reserved.

Other values mask the corresponding number of address bits, from `0b00011` masking 3 address bits (`0x00000007` mask for address) to `0b11111` masking 31 address bits (`0x7FFFFFFF` mask for address).

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [23:21]

Reserved, RES0.

WT, bit [20]

Watchpoint type. Possible values are:

`0` Unlinked data address match.

`1` Linked data address match.

On Cold reset, the field reset value is architecturally UNKNOWN.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

On Cold reset, the field reset value is architecturally UNKNOWN.

SSC, bits [15:14]

Security state control. Determines the security states under which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n> is being watched.

BAS	Description
xxxxxxx1	Match byte at DBGWVR<n>
xxxxxx1x	Match byte at DBGWVR<n>+1
xxxxx1xx	Match byte at DBGWVR<n>+2
xxxx1xxx	Match byte at DBGWVR<n>+3

In cases where DBGWVR<n> addresses a double-word:

BAS	Description, if DBGWVR<n>[2] == 0
xxx1xxxx	Match byte at DBGWVR<n>+4
xx1xxxxx	Match byte at DBGWVR<n>+5
x1xxxxxx	Match byte at DBGWVR<n>+6
1xxxxxxx	Match byte at DBGWVR<n>+7

If DBGWVR<n>[2] == 1, only BAS[3:0] is used. ARM deprecates setting DBGWVR<n> == 1.

The valid values for BAS are `0b0000000`, or a binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software.

If BAS is zero, no bytes are watched by this watchpoint.

Ignored if E is 0.

On Cold reset, the field reset value is architecturally UNKNOWN.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

01 Match instructions that load from a watchpointed address.

10 Match instructions that store to a watchpointed address.

11 Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

Ignored if E is 0.

On Cold reset, the field reset value is architecturally UNKNOWN.

PAC, bits [2:1]

Privilege of access control. Determines the exception level or levels at which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

E, bit [0]

Enable watchpoint n. Possible values are:

0 Watchpoint disabled.

1 Watchpoint enabled.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGWCR<n>

To access the DBGWCR<n>:

```
MRC p14,0,<Rt>,c0,<CRm>,7 ; Read DBGWCR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c0,<CRm>,7 ; Write Rt to DBGWCR<n>, where n is in the range 0 to 15
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	n<3:0>	111

G5.2.27 DBGWFAR, Debug Watchpoint Fault Address Register

The DBGWFAR characteristics are:

Purpose

Previously returned information about the address of the instruction that accessed a watchpointed address. Is now deprecated and RAZ.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

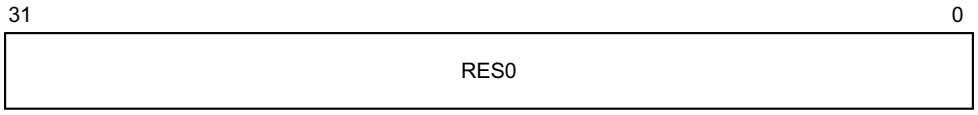
There are no configuration notes.

Attributes

DBGWFAR is a 32-bit register.

Field descriptions

The DBGWFAR bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the DBGWFAR

To access the DBGWFAR:

```
MRC p14,0,<Rt>,c0,c6,0 ; Read DBGWFAR into Rt
MCR p14,0,<Rt>,c0,c6,0 ; Write Rt to DBGWFAR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	0110	000

G5.2.28 DBGWVR<n>, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n> characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>, where n is 0 to 15.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

DBGWVR<n> is architecturally mapped to AArch64 register DBGWVR<n>_EL1[31:0].

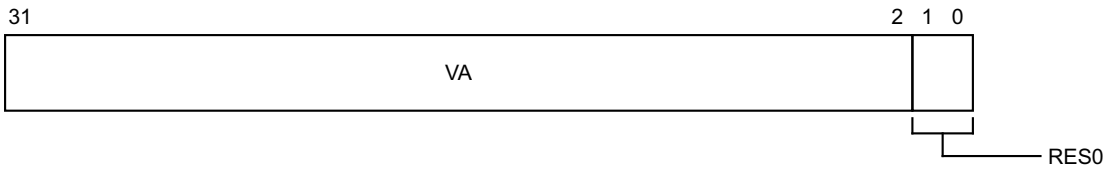
DBGWVR<n> is architecturally mapped to external register DBGWVR<n>_EL1[31:0].

Attributes

DBGWVR<n> is a 32-bit register.

Field descriptions

The DBGWVR<n> bit assignments are:



VA, bits [31:2]

Bits[31:2] of the address value for comparison.

ARM deprecates setting DBGWVR<n>[2] == 1.

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

Accessing the DBGWVR<n>

To access the DBGWVR<n>:

```
MRC p14,0,<Rt>,c0,<CRm>,6 ; Read DBGWVR<n> into Rt, where n is in the range 0 to 15
MCR p14,0,<Rt>,c0,<CRm>,6 ; Write Rt to DBGWVR<n>, where n is in the range 0 to 15
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1110	000	0000	n<3:0>	110

G5.2.29 DLR, Debug Link Register

The DLR characteristics are:

Purpose

In Debug state, holds the address to restart from.

This register is part of:

- the Debug registers functional group
- the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW	RW

Access to this register is from Debug state only. During normal execution this register is UNALLOCATED.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

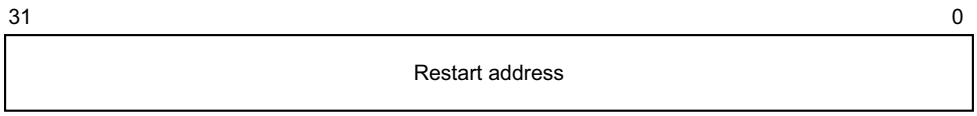
DLR is architecturally mapped to AArch64 register DLR_EL0[31:0].

Attributes

DLR is a 32-bit register.

Field descriptions

The DLR bit assignments are:



Bits [31:0]

Restart address.

Accessing the DLR

To access the DLR:

```
MRC p15,3,<Rt>,c4,c5,1 ; Read DLR into Rt
MCR p15,3,<Rt>,c4,c5,1 ; Write Rt to DLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	011	0100	0101	001

G5.2.30 DSPSR, Debug Saved Program Status Register

The DSPSR characteristics are:

Purpose

Holds the saved processor state on entry to Debug state.

This register is part of:

- the Debug registers functional group
- the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW	RW

Access to this register is from Debug state only. During normal execution this register is UNDEFINED.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

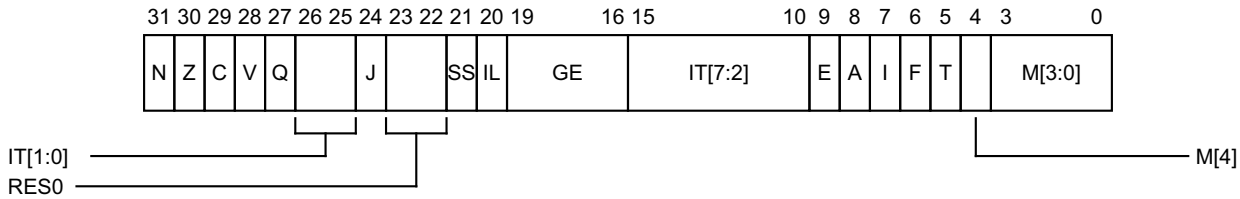
DSPSR is architecturally mapped to AArch64 register DSPSR_EL0.

Attributes

DSPSR is a 32-bit register.

Field descriptions

The DSPSR bit assignments are:



N, bit [31]

Set to the value of CPSR.N on entering Debug state, and copied to CPSR.N on exiting Debug state.

Z, bit [30]

Set to the value of CPSR.Z on entering Debug state, and copied to CPSR.Z on exiting Debug state.

C, bit [29]

Set to the value of CPSR.C on entering Debug state, and copied to CPSR.C on exiting Debug state.

V, bit [28]

Set to the value of CPSR.V on entering Debug state, and copied to CPSR.V on exiting Debug state.

Q, bit [27]

Set to the value of CPSR.Q on entering Debug state, and copied to CPSR.Q on exiting Debug state.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:22]

Reserved, RES0.

SS, bit [21]

Software step. Indicates whether software step was enabled when Debug state was entered.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before Debug state was entered.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the Debug state entry was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that Debug state was entered from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0110`	Monitor (only valid in Secure state, if EL3 is implemented and can use AArch32)
`0b0111`	Abort
`0b1010`	Hyp
`0b1011`	Undefined
`0b1111`	System

Other values are reserved.

Accessing the DSPSR

To access the DSPSR:

```
MRC p15,3,<Rt>,c4,c5,0 ; Read DSPSR into Rt
MCR p15,3,<Rt>,c4,c5,0 ; Write Rt to DSPSR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	011	0100	0101	000

G5.2.31 HDCR, Hyp Debug Control Register

The HDCR characteristics are:

Purpose

Controls the trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to functions provided by the debug and trace architectures and the Performance Monitors extension.

This register is part of:

- the Debug registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

HDCR is architecturally mapped to AArch64 register MDCR_EL2.

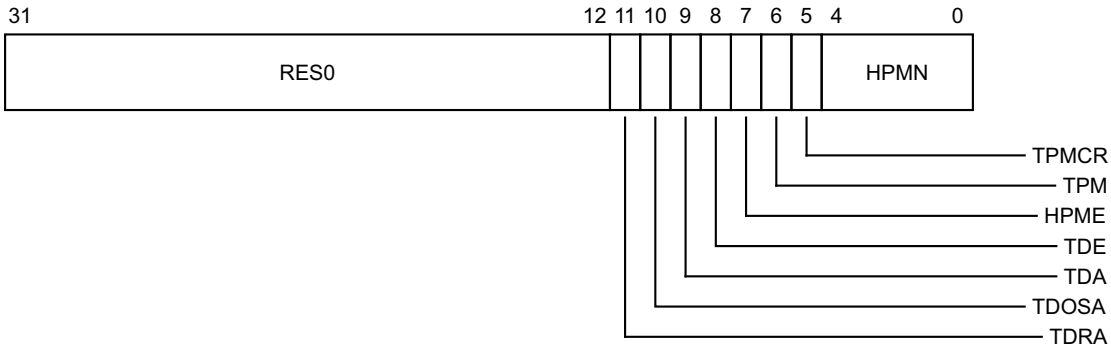
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HDCR is a 32-bit register.

Field descriptions

The HDCR bit assignments are:



Bits [31:12]

Reserved, RES0.

TDRA, bit [11]

Trap debug ROM address register access. The possible values of this bit are:

`0` Has no effect on accesses to debug ROM address registers from EL1 and EL0.

`1` Trap valid Non-secure EL1 and EL0 access to debug ROM address registers to Hyp mode.

When this bit is set to 1, any valid Non-secure access to the DBGDRAR or DBGDSAR is trapped to Hyp mode.

If HCR.TGE == 1 or HDCR.TDE == 1, the behavior is CONSTRAINED UNPREDICTABLE, and this bit is ignored and treated as though it is 1 other than for the value read back from HDCR.

On Warm reset, the field resets to 0.

TDOSA, bit [10]

Trap debug OS-related register access. The possible values of this bit are:

0 Has no effect on accesses to CP14 debug registers.

1 Trap valid Non-secure accesses to CP14 OS-related debug registers to Hyp mode.

When this bit is set to 1, any valid Non-secure CP14 access to DBGOSLAR, DBGOSLSR, DBGOSDLR, or DBGPRCR is trapped to Hyp mode.

If HCR.TGE == 1 or HDCR.TDE == 1, then this bit is ignored and treated as though it is 1 other than for the value read back from HDCR.

On Warm reset, the field resets to 0.

TDA, bit [9]

Trap debug access. The possible values of this bit are:

0 Has no effect on accesses to CP14 Debug registers.

1 Trap valid Non-secure accesses to CP14 Debug registers to Hyp mode.

When this bit is set to 1, any valid access to the CP14 Debug registers, other than the registers trapped by the TDRA and TDOSA bits, is trapped to Hyp mode.

If HCR.TGE == 1 or HDCR.TDE == 1, then this bit is ignored and treated as though it is 1 other than for the value read back from HDCR.

On Warm reset, the field resets to 0.

TDE, bit [8]

Trap Debug exceptions. The possible values of this bit are:

0 Has no effect on Debug exceptions.

1 Route Non-secure Debug exceptions to Hyp mode.

When this bit is set to 1, any Debug exception taken in Non-secure state is routed to Hyp mode.

If HCR.TGE == 1, then this bit is ignored and treated as though it is 1 other than for the value read back from HDCR.

On Warm reset, the field resets to 0.

HPME, bit [7]

Hypervisor Performance Monitors Enable. The possible values of this bit are:

0 Hyp mode Performance Monitors disabled.

1 Hyp mode Performance Monitors enabled.

When this bit is set to 1, the Performance Monitors counters that are reserved for use from Hyp mode or Secure state are enabled. For more information see the description of the HPMN field.

If the Performance Monitors extension is not implemented, this field is RES0.

On Warm reset, the field reset value is architecturally UNKNOWN.

TPM, bit [6]

Trap Performance Monitors accesses. The possible values of this bit are:

0 Has no effect on Performance Monitors accesses.

1 Trap valid Non-secure Performance Monitors accesses to Hyp mode.

If the Performance Monitors extension is not implemented, this field is RES0.

On Warm reset, the field resets to 0.

TPMCR, bit [5]

Trap PMCR accesses. The possible values of this bit are:

`0` Has no effect on PMCR accesses.

`1` Trap valid Non-secure PMCR accesses to Hyp mode.

If the Performance Monitors extension is not implemented, this field is RES0.

On Warm reset, the field resets to 0.

HPMN, bits [4:0]

Defines the number of Performance Monitors counters that are accessible from Non-secure EL1 modes, and from Non-secure EL0 modes if unprivileged access is enabled.

If the Performance Monitors extension is not implemented, this field is RES0.

In Non-secure state, HPMN divides the Performance Monitors counters as follows. If software is accessing Performance Monitors counter n then, in Non-secure state:

- If n is in the range 0<=n<HPMN, the counter is accessible from EL1 and EL2, and from EL0 if unprivileged access to the counters is enabled. PMCR.E enables the operation of counters in this range.
- If n is in the range HPMN<=n<PMCR.N, the counter is accessible only from EL2. HDCR.HPME enables the operation of counters in this range.

If this field is set to 0, or to a value larger than PMCR.N, then the behavior in Non-secure EL0 and EL1 is CONSTRAINED UNPREDICTABLE, and one of the following must happen:

- The number of counters accessible is an UNKNOWN non-zero value less than PMCR.N.
- There is no access to any counters.

For reads of HDCR.HPMN by EL2 or higher, if this field is set to 0 or to a value larger than PMCR.N, the processor must return a CONSTRAINED UNPREDICTABLE value being one of:

- PMCR.N.
- The value that was written to HDCR.HPMN.
- (The value that was written to HDCR.HPMN) modulo 2^h, where h is the smallest number of bits required for a value in the range 0 to PMCR.N.

On Warm reset, the field resets to an IMPLEMENTATION DEFINED value.

Accessing the HDCR

To access the HDCR:

```
MRC p15,4,<Rt>,c1,c1,1 ; Read HDCR into Rt
MCR p15,4,<Rt>,c1,c1,1 ; Write Rt to HDCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	0001	0001	001

G5.2.32 SDCR, Secure Debug Configuration Register

The SDCR characteristics are:

Purpose

Controls debug and performance monitors functionality in Secure state.

This register is part of:

- the Debug registers functional group
- the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	RW	RW

If EL3 is implemented and is using AArch64, any read or write to SDCR in Secure EL1 state in AArch32 is trapped as an exception to EL3.

If EL3 is not implemented, attempts to access SDCR are UNDEFINED.

SDCR is a Restricted access System register, see *Restricted access System registers* on page G4-3750.

Configurations

This register is only accessible in Secure state.

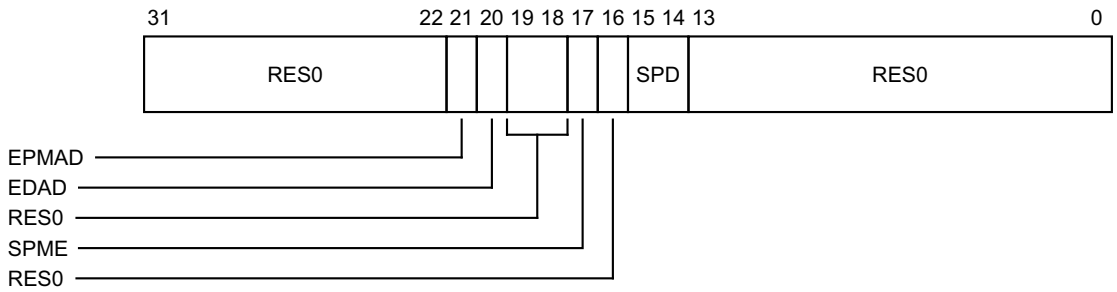
SDCR can be mapped to AArch64 register MDCR_EL3, but this is not architecturally mandated.

Attributes

SDCR is a 32-bit register.

Field descriptions

The SDCR bit assignments are:



Bits [31:22]

Reserved, RES0.

EPMAD, bit [21]

External debugger access to Performance Monitors registers disabled. This disables access to these registers by an external debugger:

0 Access to Performance Monitors registers from external debugger is permitted.

1 Access to Performance Monitors registers from external debugger is disabled, unless overridden by authentication interface.

On Warm reset, the field resets to 0.

EDAD, bit [20]

External debugger access to breakpoint and watchpoint registers disabled. This disables access to these registers by an external debugger:

0 Access to breakpoint and watchpoint registers from external debugger is permitted.

1 Access to breakpoint and watchpoint registers from external debugger is disabled, unless overridden by authentication interface.

On Warm reset, the field resets to 0.

Bits [19:18]

Reserved, RES0.

SPME, bit [17]

Secure performance monitors enable. This allows event counting in Secure state:

0 Event counting prohibited in Secure state, unless overridden by the authentication interface.

1 Event counting allowed in Secure state.

On Warm reset, the field resets to 0.

Bit [16]

Reserved, RES0.

SPD, bits [15:14]

AArch32 secure privileged debug. Enables or disables debug exceptions from Secure state, other than Software breakpoint instructions. Valid values for this field are:

00 Legacy mode. Debug exceptions from Secure EL1 are enabled by the authentication interface.

10 Secure privileged debug disabled. Debug exceptions from Secure EL1 are disabled.

11 Secure privileged debug enabled. Debug exceptions from Secure EL1 are enabled.

Other values are reserved.

If debug exceptions from Secure EL1 are enabled, then debug exceptions from Secure EL0 are also enabled.

Otherwise, debug exceptions from Secure EL0 are enabled only if SDER32_EL3.SUIDEN == 1.

Ignored in Non-secure state. Debug exceptions from Software breakpoint instruction debug events are always enabled.

On Warm reset, the field resets to 0.

Bits [13:0]

Reserved, RES0.

Accessing the SDCR

To access the SDCR:

```
MRC p15,0,<Rt>,c1,c3,1 ; Read SDCR into Rt
MCR p15,0,<Rt>,c1,c3,1 ; Write Rt to SDCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0011	001

G5.2.33 SDER, Secure Debug Enable Register

The SDER characteristics are:

Purpose

Controls invasive and non-invasive debug in the Secure EL0 mode.

This register is part of:

- the Debug registers functional group
- the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	RW	RW

Configurations

This register is only accessible in Secure state.

SDER is architecturally mapped to AArch64 register SDER32_EL3.

If EL3 is not implemented and EL1 supports AArch32, SDER is implemented only if the processor is Secure.

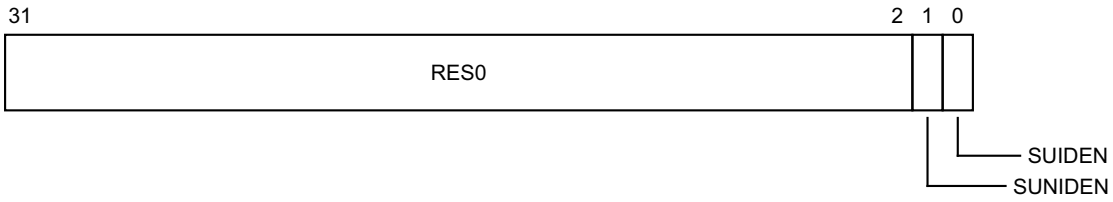
SDER is a Restricted access System register. See *Restricted access System registers* on page G4-3750.

Attributes

SDER is a 32-bit register.

Field descriptions

The SDER bit assignments are:



Bits [31:2]

Reserved, RES0.

SUNIDEN, bit [1]

Secure User Non-Invasive Debug Enable:

0 Non-invasive debug not permitted in Secure EL0 mode.

1 Non-invasive debug permitted in Secure EL0 mode.

On Warm reset, the field resets to 0.

SUIDEN, bit [0]

Secure User Invasive Debug Enable:

0 Invasive debug not permitted in Secure EL0 mode.

1 Invasive debug permitted in Secure EL0 mode.

On Warm reset, the field resets to 0.

Accessing the SDER

To access the SDER:

```
MRC p15,0,<Rt>,c1,c1,1 ; Read SDER into Rt
MCR p15,0,<Rt>,c1,c1,1 ; Write Rt to SDER
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0001	0001	001

G5.3 Performance Monitors registers

This section lists the Performance Monitors registers in AArch32 state.

G5.3.1 PMCCFILTR, Performance Monitors Cycle Count Filter Register

The PMCCFILTR characteristics are:

Purpose

Determines the modes in which the Cycle Counter, PMCCNTR, increments.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

PMCCFILTR can also be accessed by using PMXEVTYPER with PMSELR.SEL set to `0b11111`.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMCCFILTR is architecturally mapped to AArch64 register PMCCFILTR_EL0.

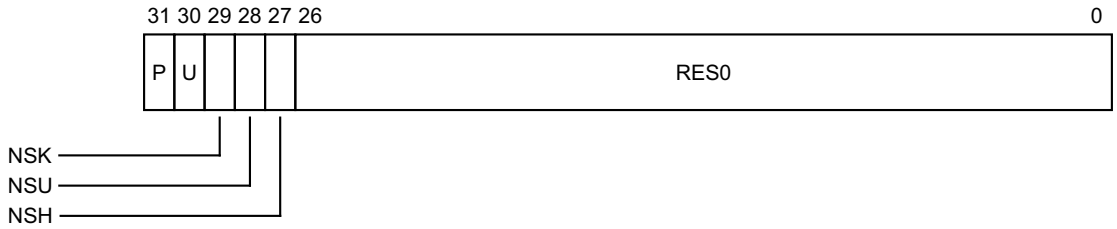
PMCCFILTR is architecturally mapped to external register PMCCFILTR_EL0.

Attributes

PMCCFILTR is a 32-bit register.

Field descriptions

The PMCCFILTR bit assignments are:



P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

`0` Count cycles in EL1.

`1` Do not count cycles in EL1.

On Warm reset, the field resets to 0.

U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

0 Count cycles in EL0.

1 Do not count cycles in EL0.

On Warm reset, the field resets to 0.

NSK, bit [29]

Non-secure kernel modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

On Warm reset, the field resets to 0.

NSU, bit [28]

Non-secure user modes filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

On Warm reset, the field resets to 0.

NSH, bit [27]

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count cycles in EL2.

1 Count cycles in EL2.

On Warm reset, the field resets to 0.

Bits [26:0]

Reserved, RES0.

Accessing the PMCCFILTR

To access the PMCCFILTR:

```
MRC p15,0,<Rt>,c14,c15,7 ; Read PMCCFILTR into Rt
MCR p15,0,<Rt>,c14,c15,7 ; Write Rt to PMCCFILTR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	1111	111

G5.3.2 PMCCNTR, Performance Monitors Cycle Count Register

The PMCCNTR characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR.EN or PMUSERENR.CR is set to 1.

The PMCR.{LC, D} bits configure whether PMCCNTR increments every clock cycle, or once every 64 clock cycles.

PMCCFILTR determines the modes and states in which the PMCCNTR can increment.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMCCNTR is architecturally mapped to AArch64 register PMCCNTR_EL0 when accessing as a 64-bit register.

PMCCNTR is architecturally mapped to external register PMCCNTR_EL0.

PMCCNTR is architecturally mapped to AArch64 register PMCCNTR_EL0[31:0].

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONSTRAINED UNPREDICTABLE whether or not PMCCNTR continues to increment when clocks are stopped by WFI and WFE instructions.

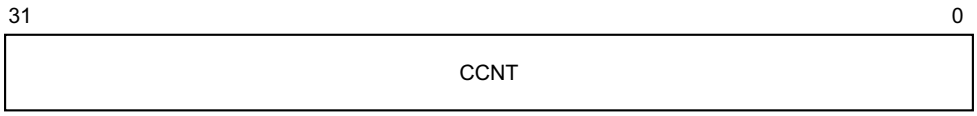
Attributes

PMCCNTR is a 32-bit register when accessing as a 32-bit register and a 64-bit register when accessing as a 64-bit register.

Field descriptions

The PMCCNTR bit assignments are:

When accessing as a 32-bit register:



CCNT, bits [31:0]

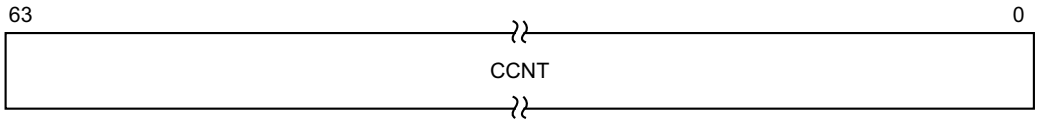
Cycle count. Depending on the values of PMCR.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

This field can be reset to zero by writing 1 to PMCR.C.

On Warm reset, the field reset value is architecturally UNKNOWN.

When accessing as a 64-bit register:



CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

This field can be reset to zero by writing 1 to PMCR.C.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMCCNTR

To access the PMCCNTR when accessing as a 32-bit register:

```
MRC p15,0,<Rt>,c9,c13,0 ; Read PMCCNTR into Rt
MCR p15,0,<Rt>,c9,c13,0 ; Write Rt to PMCCNTR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1101	000

To access the PMCCNTR when accessing as a 64-bit register:

```
MRRC p15,0,<Rt>,<Rt2>,c9 ; Read 64-bit PMCCNTR into Rt (low word) and Rt2 (high word)
MCRR p15,0,<Rt>,<Rt2>,c9 ; Write Rt (low word) and Rt2 (high word) to 64-bit PMCCNTR
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0000	1001

G5.3.3 PMCEID0, Performance Monitors Common Event Identification register 0

The PMCEID0 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMCEID0 is architecturally mapped to AArch64 register PMCEID0_EL0.

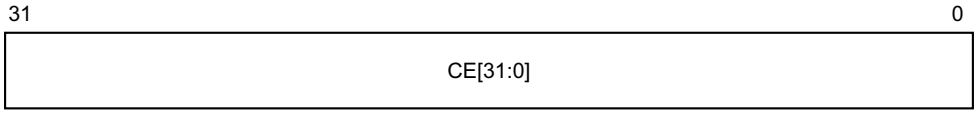
PMCEID0 is architecturally mapped to external register PMCEID0_EL0.

Attributes

PMCEID0 is a 32-bit register.

Field descriptions

The PMCEID0 bit assignments are:



CE[31:0], bits [31:0]

Common architectural and microarchitectural feature events that can be counted by the PMU event counters.

For each bit described in the following table, the event is implemented if the bit is set to 1, or not implemented if the bit is set to 0.

Bit	Event number	Event mnemonic
31	0x01F	L1D_CACHE_ALLOCATE
30	0x01E	CHAIN
29	0x01D	BUS_CYCLES
28	0x01C	TTBR_WRITE_RETIRED
27	0x01B	INST_SPEC
26	0x01A	MEMORY_ERROR

Bit	Event number	Event mnemonic
25	0x019	BUS_ACCESS
24	0x018	L2D_CACHE_WB
23	0x017	L2D_CACHE_REFILL
22	0x016	L2D_CACHE
21	0x015	L1D_CACHE_WB
20	0x014	L1I_CACHE
19	0x013	MEM_ACCESS
18	0x012	BR_PRED
17	0x011	CPU_CYCLES
16	0x010	BR_MIS_PRED
15	0x00F	UNALIGNED_LDST_RETIRED
14	0x00E	BR_RETURN_RETIRED
13	0x00D	BR_IMMED_RETIRED
12	0x00C	PC_WRITE_RETIRED
11	0x00B	CID_WRITE_RETIRED
10	0x00A	EXC_RETURN
9	0x009	EXC_TAKEN
8	0x008	INST_RETIRED
7	0x007	ST_RETIRED
6	0x006	LD_RETIRED
5	0x005	L1D_TLB_REFILL
4	0x004	L1D_CACHE
3	0x003	L1D_CACHE_REFILL
2	0x002	L1I_TLB_REFILL
1	0x001	L1I_CACHE_REFILL
0	0x000	SW_INCR

Accessing the PMCEID0

To access the PMCEID0:

```
MRC p15,0,<Rt>,c9,c12,6 ; Read PMCEID0 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	110

G5.3.4 PMCEID1, Performance Monitors Common Event Identification register 1

The PMCEID1 characteristics are:

Purpose

Reserved for future indication of which common architectural and common microarchitectural feature events are implemented.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMCEID1 is architecturally mapped to AArch64 register PMCEID1_EL0.

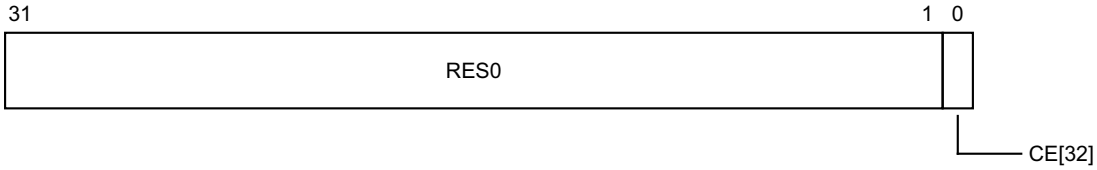
PMCEID1 is architecturally mapped to external register PMCEID1_EL0.

Attributes

PMCEID1 is a 32-bit register.

Field descriptions

The PMCEID1 bit assignments are:



Bits [31:1]

Reserved, RES0.

CE[32], bit [0]

Common architectural and microarchitectural feature events that can be counted by the PMU event counters.

For the bit described in the following table, the event is implemented if the bit is set to 1, or not implemented if the bit is set to 0.

Bit	Event number	Event mnemonic
0	0x020	L2D_CACHE_ALLOCATE

Accessing the PMCEID1

To access the PMCEID1:

```
MRC p15,0,<Rt>,c9,c12,7 ; Read PMCEID1 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	111

G5.3.5 PMCNTENCLR, Performance Monitors Count Enable Clear register

The PMCNTENCLR characteristics are:

Purpose

Disables the Cycle Count Register, PMCCNTR, and any implemented event counters PMEVCNTR<x>. Reading this register shows which counters are enabled.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMCNTENCLR. See the description of the Px bit.

PMCNTENCLR is used in conjunction with the PMCNTENSET register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMCNTENCLR is architecturally mapped to AArch64 register PMCNTENCLR_EL0.

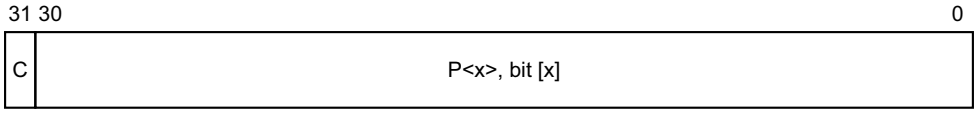
PMCNTENCLR is architecturally mapped to external register PMCNTENCLR_EL0.

Attributes

PMCNTENCLR is a 32-bit register.

Field descriptions

The PMCNTENCLR bit assignments are:



C, bit [31]

PMCCNTR disable bit. Disables the cycle counter register. Possible values are:

`0` When read, means the cycle counter is disabled. When written, has no effect.

`1` When read, means the cycle counter is enabled. When written, disables the cycle counter.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<x>, bit [x], for x = 0 to 30

Event counter disable bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Possible values of each bit are:

0 When read, means that PMEVCNTR<x> is disabled. When written, has no effect.

1 When read, means that PMEVCNTR<x> is enabled. When written, disables PMEVCNTR<x>.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMCNTENCLR

To access the PMCNTENCLR:

```
MRC p15,0,<Rt>,c9,c12,2 ; Read PMCNTENCLR into Rt
MCR p15,0,<Rt>,c9,c12,2 ; Write Rt to PMCNTENCLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	010

G5.3.6 PMCNTENSET, Performance Monitors Count Enable Set register

The PMCNTENSET characteristics are:

Purpose

Enables the Cycle Count Register, PMCCNTR, and any implemented event counters PMEVCNTR<x>. Reading this register shows which counters are enabled.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMCNTENSET. See the description of the Px bit.

PMCNTENSET is used in conjunction with the PMCNTENCLR register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMCNTENSET is architecturally mapped to AArch64 register PMCNTENSET_EL0.

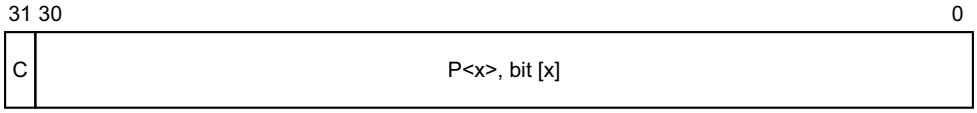
PMCNTENSET is architecturally mapped to external register PMCNTENSET_EL0.

Attributes

PMCNTENSET is a 32-bit register.

Field descriptions

The PMCNTENSET bit assignments are:



C, bit [31]

PMCCNTR enable bit. Enables the cycle counter register. Possible values are:

`0` When read, means the cycle counter is disabled. When written, has no effect.

`1` When read, means the cycle counter is enabled. When written, enables the cycle counter.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<x>, bit [x], for x = 0 to 30

Event counter enable bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Possible values of each bit are:

`0` When read, means that PMEVCNTR<x> is disabled. When written, has no effect.

1 When read, means that PMEVCNTR<x> event counter is enabled. When written, enables PMEVCNTR<x>.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMCNTENSET

To access the PMCNTENSET:

```
MRC p15,0,<Rt>,c9,c12,1 ; Read PMCNTENSET into Rt
MCR p15,0,<Rt>,c9,c12,1 ; Write Rt to PMCNTENSET
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	001

G5.3.7 PMCR, Performance Monitors Control Register

The PMCR characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMCR is architecturally mapped to AArch64 register PMCR_EL0.

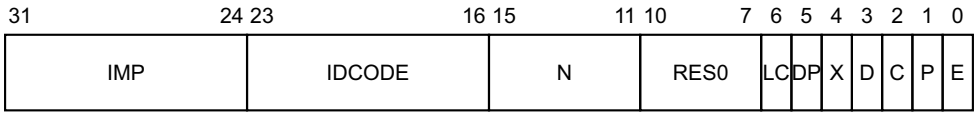
PMCR is architecturally mapped to external register PMCR_EL0.

Attributes

PMCR is a 32-bit register.

Field descriptions

The PMCR bit assignments are:



IMP, bits [31:24]

Implementer code. This field is RO with an IMPLEMENTATION DEFINED value.

The implementer codes are allocated by ARM. Values have the same interpretation as bits [31:24] of the MIDR.

IDCODE, bits [23:16]

Identification code. This field is RO with an IMPLEMENTATION DEFINED value.

Each implementer must maintain a list of identification codes that is specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.

N, bits [15:11]

Number of event counters. This field is RO with an IMPLEMENTATION DEFINED value that indicates the number of counters implemented.

The value of this field is the number of counters implemented, from `0b00000` for no counters to `0b11111` for 31 counters.

An implementation can implement only the Cycle Count Register, PMCCNTR. This is indicated by a value of `0b00000` for the N field.

Bits [10:7]

Reserved, RES0.

LC, bit [6]

Long cycle counter enable. Determines which PMCCNTR bit generates an overflow recorded by PMOVSR[31].

0 Cycle counter overflow on increment that changes PMCCNTR[31] from 1 to 0.

1 Cycle counter overflow on increment that changes PMCCNTR[63] from 1 to 0.

ARM deprecates use of PMCR.LC = 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

0 PMCCNTR, if enabled, counts when event counting is prohibited.

1 PMCCNTR does not count when event counting is prohibited.

Event counting is prohibited when ProfilingProhibited(IsSecure(),PSTATE.EL) == TRUE.

This bit is RW.

On Warm reset, the field resets to 0.

X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

0 Do not export events.

1 Export events where not prohibited.

This bit is used to permit events to be exported to another debug device, such as an OPTIONAL trace extension, over an event bus. If the implementation does not include such an event bus, this bit is RAZ/WI.

This bit does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the processor.

If the implementation does not include an exported event stream, this bit is RAZ/WI. Otherwise this bit is RW.

On Warm reset, the field resets to 0.

D, bit [3]

Clock divider. The possible values of this bit are:

0 When enabled, PMCCNTR counts every clock cycle.

1 When enabled, PMCCNTR counts once every 64 clock cycles.

This bit is RW.

If PMCR.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.

ARM deprecates use of PMCR.D = 1.

On Warm reset, the field resets to 0.

C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

0 No action.

1 Reset PMCCNTR to zero.

This bit is always RAZ.

Resetting PMCCNTR does not clear the PMCCNTR overflow bit to 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

`0` No action.

`1` Reset all event counters accessible in the current EL, not including PMCCNTR, to zero.

This bit is always RAZ.

In Non-secure EL0 and EL1, if EL2 is implemented, a write of 1 to this bit does not reset event counters that HDCR.HPMN reserves for EL2 use.

In EL2 and EL3, a write of 1 to this bit resets all the event counters.

Resetting the event counters does not clear any overflow bits to 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

E, bit [0]

Enable. The possible values of this bit are:

`0` All counters, including PMCCNTR, are disabled.

`1` All counters are enabled by PMCNTENSET.

This bit is RW.

In Non-secure EL0 and EL1, if EL2 is implemented, this bit does not affect the operation of event counters that HDCR.HPMN reserves for EL2 use.

On Warm reset, the field resets to 0.

Accessing the PMCR

To access the PMCR:

```
MRC p15,0,<Rt>,c9,c12,0 ; Read PMCR into Rt
MCR p15,0,<Rt>,c9,c12,0 ; Write Rt to PMCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	000

G5.3.8 PMEVCNTR<n>, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n> characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register can be read at EL0 when PMUSERENR.EN or PMUSERENR.ER is set to 1, and can be written at EL0 when PMUSERENR.ER is set to 1.

PMEVCNTR<n> can also be accessed by using PMXEVCNTR with PMSELR.SEL set to n.

If <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVCNTR<n> are CONSTRAINED UNPREDICTABLE, and must behave as one of the following:

- UNALLOCATED.
- RAZ/WI.
- A NOP.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMEVCNTR<n> is architecturally mapped to AArch64 register PMEVCNTR<n>_EL0.

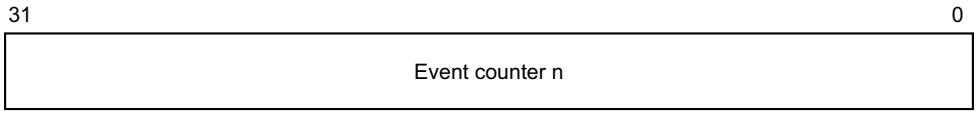
PMEVCNTR<n> is architecturally mapped to external register PMEVCNTR<n>_EL0.

Attributes

PMEVCNTR<n> is a 32-bit register.

Field descriptions

The PMEVCNTR<n> bit assignments are:



Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMEVCNTR<n>

To access the PMEVCNTR<n>:

```
MRC p15,0,<Rt>,c14,<CRm>,<opc2> ; Read PMEVCNTR<n> into Rt, where n is in the range 0 to 30
MCR p15,0,<Rt>,c14,<CRm>,<opc2> ; Write Rt to PMEVCNTR<n>, where n is in the range 0 to 30
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	10:n<4:3>	n<2:0>

G5.3.9 PMEVTYPER<n>, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n> characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

PMEVTYPER<n> can also be accessed by using PMXEVTYPER with PMSELR.SEL set to n.

If <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVTYPER<n> are CONSTRAINED UNPREDICTABLE, and must behave as one of the following:

- UNALLOCATED.
- RAZ/WI.
- A `NOP`.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMEVTYPER<n> is architecturally mapped to AArch64 register PMEVTYPER<n>_EL0.

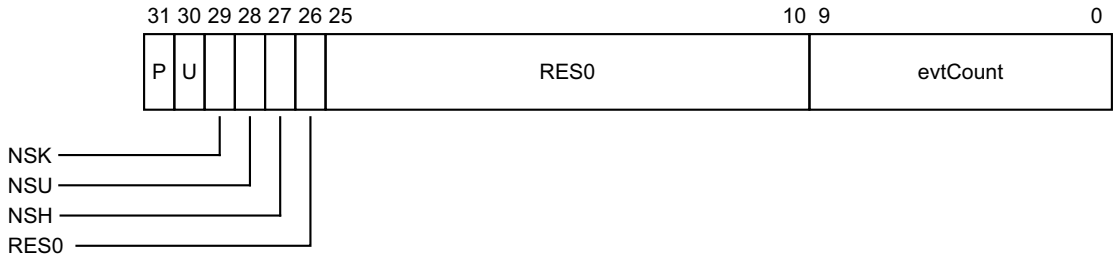
PMEVTYPER<n> is architecturally mapped to external register PMEVTYPER<n>_EL0.

Attributes

PMEVTYPER<n> is a 32-bit register.

Field descriptions

The PMEVTYPER<n> bit assignments are:



P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

`0` Count events in EL1.

`1` Do not count events in EL1.

On Warm reset, the field reset value is architecturally UNKNOWN.

U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

0 Count events in EL0.

1 Do not count events in EL0.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSK, bit [29]

Non-secure kernel modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSU, bit [28]

Non-secure user modes filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted.

Otherwise, events in Non-secure EL0 are not counted.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSH, bit [27]

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count events in EL2.

1 Count events in EL2.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [26]

Reserved, RES0.

Bits [25:10]

Reserved, RES0.

evtCount, bits [9:0]

Event to count. The event number of the event that is counted by event counter PMEVCNTR<n>.

Software must program this field with an event defined by the processor or a common event defined by the architecture.

If evtCount is programmed to an event that is reserved or not implemented, the behavior depends on the event type.

For common architectural and microarchitectural events:

- No events are counted.
- The value read back on evtCount is the value written.

For IMPLEMENTATION DEFINED events:

- It is UNPREDICTABLE what event, if any, is counted. UNPREDICTABLE in this case means the event must not expose privileged information.
- The value read back on evtCount is an UNKNOWN value with the same effect.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMEVTYPER<n>

To access the PMEVTYPER<n>:

```
MRC p15,0,<Rt>,c14,<CRm>,<opc2> ; Read PMEVTYPER<n> into Rt, where n is in the range 0 to 30
MCR p15,0,<Rt>,c14,<CRm>,<opc2> ; Write Rt to PMEVTYPER<n>, where n is in the range 0 to 30
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	11:n<4:3>	n<2:0>

G5.3.10 PMINTENCLR, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR characteristics are:

Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR, and the event counters PMEVCNTR<n>. Reading the register shows which overflow interrupt requests are enabled.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMINTENCLR. See the description of the P<x> bit.

PMINTENCLR is used in conjunction with the PMINTENSET register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMINTENCLR is architecturally mapped to AArch64 register PMINTENCLR_EL1.

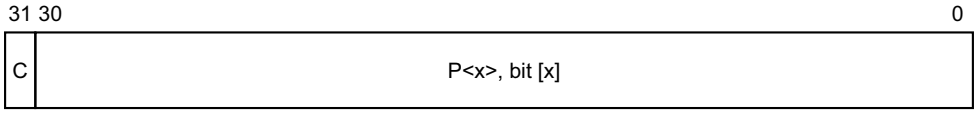
PMINTENCLR is architecturally mapped to external register PMINTENCLR_EL1.

Attributes

PMINTENCLR is a 32-bit register.

Field descriptions

The PMINTENCLR bit assignments are:



C, bit [31]

PMCCNTR overflow interrupt request disable bit. Possible values are:

`0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`1` When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<x>, bit [x], for x = 0 to 30

Event counter overflow interrupt request disable bit for PMEVCNTR<x>.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Bits [30:N] are RAZ/WI.

Possible values are:

0 When read, means that the PMEVCNTR<x> event counter interrupt request is disabled. When written, has no effect.

1 When read, means that the PMEVCNTR<x> event counter interrupt request is enabled. When written, disables the PMEVCNTR<x> interrupt request.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMINTENCLR

To access the PMINTENCLR:

```
MRC p15,0,<Rt>,c9,c14,2 ; Read PMINTENCLR into Rt
MCR p15,0,<Rt>,c9,c14,2 ; Write Rt to PMINTENCLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1110	010

G5.3.11 PMINTENSET, Performance Monitors Interrupt Enable Set register

The PMINTENSET characteristics are:

Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR, and the event counters PMEVCNTR<n>. Reading the register shows which overflow interrupt requests are enabled.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMINTENSET. See the description of the P<x> bit.

PMINTENSET is used in conjunction with the PMINTENCLR register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMINTENSET is architecturally mapped to AArch64 register PMINTENSET_EL1.

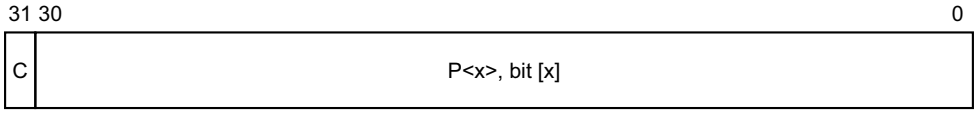
PMINTENSET is architecturally mapped to external register PMINTENSET_EL1.

Attributes

PMINTENSET is a 32-bit register.

Field descriptions

The PMINTENSET bit assignments are:



C, bit [31]

PMCCNTR overflow interrupt request enable bit. Possible values are:

`0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`1` When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<x>, bit [x], for x = 0 to 30

Event counter overflow interrupt request enable bit for PMEVCNTR<x>.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Bits [30:N] are RAZ/WI.

Possible values are:

0 When read, means that the PMEVCNTR<x> event counter interrupt request is disabled. When written, has no effect.

1 When read, means that the PMEVCNTR<x> event counter interrupt request is enabled. When written, enables the PMEVCNTR<x> interrupt request.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMINTENSET

To access the PMINTENSET:

```
MRC p15,0,<Rt>,c9,c14,1 ; Read PMINTENSET into Rt
MCR p15,0,<Rt>,c9,c14,1 ; Write Rt to PMINTENSET
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1110	001

G5.3.12 PMOVSR, Performance Monitors Overflow Flag Status Register

The PMOVSR characteristics are:

Purpose

Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR, and each of the implemented event counters PMEVCNTR<x>. Writing to this register clears these bits.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMOVSR. See the description of the Px bit.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMOVSR is architecturally mapped to AArch64 register PMOVSCLR_EL0.

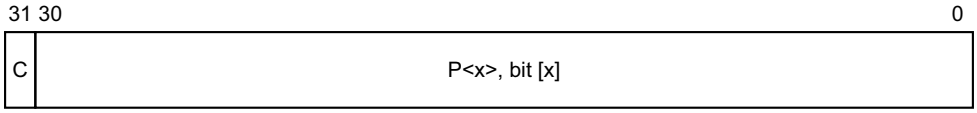
PMOVSR is architecturally mapped to external register PMOVSCLR_EL0.

Attributes

PMOVSR is a 32-bit register.

Field descriptions

The PMOVSR bit assignments are:



C, bit [31]

PMCCNTR overflow bit. Possible values are:

`0` When read, means the cycle counter has not overflowed. When written, has no effect.

`1` When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.

PMCR.LC is used to control from which bit of PMCCNTR (bit 31 or bit 63) an overflow is detected.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<x>, bit [x], for x = 0 to 30

Event counter overflow clear bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Possible values of each bit are:

0 When read, means that PMEVCNTR<x> has not overflowed. When written, has no effect.

1 When read, means that PMEVCNTR<x> has overflowed. When written, clears the PMEVCNTR<x> overflow bit to 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMOVSR

To access the PMOVSR:

```
MRC p15,0,<Rt>,c9,c12,3 ; Read PMOVSR into Rt
MCR p15,0,<Rt>,c9,c12,3 ; Write Rt to PMOVSR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	011

G5.3.13 PMOVSSET, Performance Monitors Overflow Flag Status Set register

The PMOVSSET characteristics are:

Purpose

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR, and each of the implemented event counters PMEVCNTR<x>.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMOVSSET. See the description of the Px bit.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMOVSSET is architecturally mapped to AArch64 register PMOVSSET_EL0.

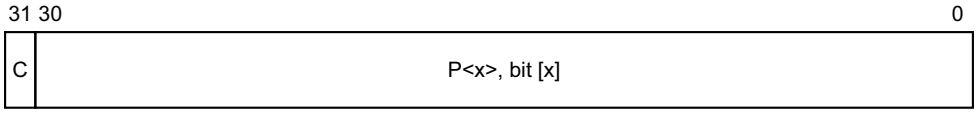
PMOVSSET is architecturally mapped to external register PMOVSSET_EL0.

Attributes

PMOVSSET is a 32-bit register.

Field descriptions

The PMOVSSET bit assignments are:



C, bit [31]

PMCCNTR overflow bit. Possible values are:

`0` When read, means the cycle counter has not overflowed. When written, has no effect.

`1` When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<x>, bit [x], for x = 0 to 30

Event counter overflow set bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

Possible values are:

0 When read, means that PMEVCNTR<x> has not overflowed. When written, has no effect.

1 When read, means that PMEVCNTR<x> has overflowed. When written, sets the PMEVCNTR<x> overflow bit to 1.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMOVSSET

To access the PMOVSSET:

```
MRC p15,0,<Rt>,c9,c14,3 ; Read PMOVSSET into Rt
MCR p15,0,<Rt>,c9,c14,3 ; Write Rt to PMOVSSET
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1110	011

G5.3.14 PMSELR, Performance Monitors Event Counter Selection Register

The PMSELR characteristics are:

Purpose

Selects the current event counter PMEVCNTR<x> or the cycle counter, CCNT.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR.EN or PMUSERENR.ER is set to 1.

PMSELR is used in conjunction with PMXEVTYPER to determine the event that increments a selected event counter, and the modes and states in which the selected counter increments.

It is also used in conjunction with PMXEVCNTR, to determine the value of a selected event counter.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

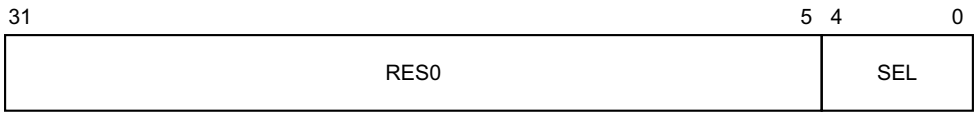
PMSELR is architecturally mapped to AArch64 register PMSELR_EL0.

Attributes

PMSELR is a 32-bit register.

Field descriptions

The PMSELR bit assignments are:



Bits [31:5]

Reserved, RES0.

SEL, bits [4:0]

Selects event counter, PMEVCNTR<x>, where x is the value held in this field. This value identifies which event counter is accessed when a subsequent access to PMXEVTYPER or PMXEVCNTR occurs.

This field can take any value from 0 (`0b00000`) to (PMCR.N)-1, or 31 (`0b11111`).

When PMSELR.SEL is `0b11111` it selects the cycle counter and:

- A read of the PMXEVTYPER returns the value of PMCCFILTR.
- A write of the PMXEVTYPER writes to PMCCFILTR.
- A read or write of PMXEVCNTR has CONSTRAINED UNPREDICTABLE effects, that can be one of the following:
  - Access to PMXEVCNTR is UNDEFINED.
  - Access to PMXEVCNTR behaves as a NOP.

— Access to PMXEVCNTR behaves as if the register is RAZ/WI.

— Access to PMXEVCNTR behaves as if the PMSELR.SEL field contains an UNKNOWN value.

If this field is set to a value greater than or equal to the number of implemented counters, but not equal to 31, the results of access to PMXEVTYPER or PMXEVCNTR are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Access to PMXEVTYPER or PMXEVCNTR is UNDEFINED.
- Access to PMXEVTYPER or PMXEVCNTR behaves as a NOP.
- Access to PMXEVTYPER or PMXEVCNTR behaves as if the register is RAZ/WI.
- Access to PMXEVTYPER or PMXEVCNTR behaves as if the PMSELR.SEL field contains an UNKNOWN value.
- Access to PMXEVTYPER or PMXEVCNTR behaves as if the PMSELR.SEL field contains 0b11111.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMSELR

To access the PMSELR:

```
MRC p15,0,<Rt>,c9,c12,5 ; Read PMSELR into Rt
MCR p15,0,<Rt>,c9,c12,5 ; Write Rt to PMSELR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	101

G5.3.15 PMSWINC, Performance Monitors Software Increment register

The PMSWINC characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event `0x00`.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-WO	Config-WO	WO	WO	WO	WO	WO

This register is accessible at EL0 when PMUSERENR.EN or PMUSERENR.SW is set to 1.

If EL2 is implemented, in Non-secure EL1 and EL0 modes, the value of HDCR.HPMN can change the behavior of accesses to PMSWINC. See the description of the Px bit.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

PMSWINC is architecturally mapped to AArch64 register PMSWINC_EL0.

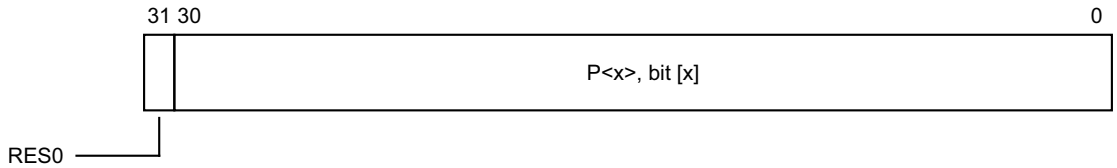
PMSWINC is architecturally mapped to external register PMSWINC_EL0.

Attributes

PMSWINC is a 32-bit register.

Field descriptions

The PMSWINC bit assignments are:



Bit [31]

Reserved, RES0.

P<x>, bit [x], for x = 0 to 30

Event counter software increment bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in HDCR.HPMN. Otherwise, N is the value in PMCR.N.

The effects of writing to this bit are:

`0` No action. The write to this bit is ignored.

`1` If PMEVCNTR<x> is enabled and configured to count the software increment event, increments PMEVCNTR<x> by 1. If PMEVCNTR<x> is disabled, or not configured to count the software increment event, the write to this bit is ignored.

Accessing the PMSWINC

To access the PMSWINC:

```
MCR p15,0,<Rt>,c9,c12,4 ; Write Rt to PMSWINC
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1100	100

G5.3.16 PMUSERENR, Performance Monitors User Enable Register

The PMUSERENR characteristics are:

Purpose

Enables or disables User mode access to the Performance Monitors.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RO	RO	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

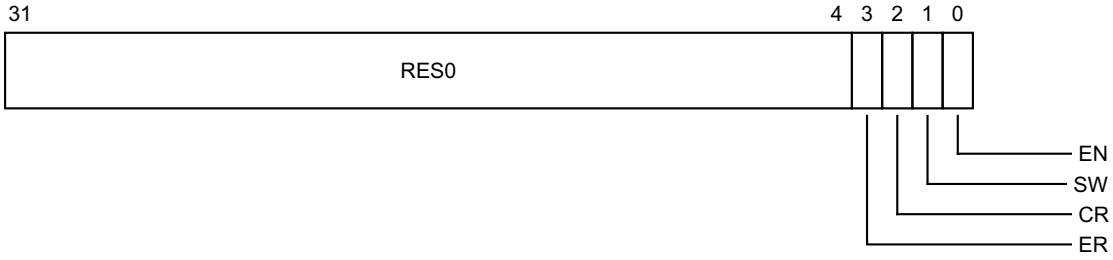
PMUSERENR is architecturally mapped to AArch64 register PMUSERENR_EL0.

Attributes

PMUSERENR is a 32-bit register.

Field descriptions

The PMUSERENR bit assignments are:



Bits [31:4]

Reserved, RES0.

ER, bit [3]

Event counter read enable. The possible values of this bit are:

0 EL0 read access to PMXEVCNTR / PMEVCNTR<n> and read/write access to PMSELR disabled if PMUSERENR.EN is also 0.

1 EL0 read access to PMXEVCNTR / PMEVCNTR<n> and read/write access to PMSELR enabled.

On Warm reset, the field resets to 0.

CR, bit [2]

Cycle counter read enable. The possible values of this bit are:

0 EL0 read access to PMCCNTR disabled if PMUSERENR.EN is also 0.

1 EL0 read access to PMCCNTR enabled.

On Warm reset, the field resets to 0.

SW, bit [1]

Software Increment write enable. The possible values of this bit are:

0 EL0 write access to PMSWINC disabled if PMUSERENR.EN is also 0.

1 EL0 write access to PMSWINC enabled.

On Warm reset, the field resets to 0.

EN, bit [0]

EL0 access enable bit. The possible values of this bit are:

0 EL0 access to the Performance Monitors disabled.

1 EL0 access to the Performance Monitors enabled. Can access all PMU registers at EL0, except for writes to PMUSERENR and reads/writes of PMINTENSET and PMINTENCLR.

On Warm reset, the field resets to 0.

Accessing the PMUSERENR

To access the PMUSERENR:

```
MRC p15,0,<Rt>,c9,c14,0 ; Read PMUSERENR into Rt
MCR p15,0,<Rt>,c9,c14,0 ; Write Rt to PMUSERENR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1110	000

G5.3.17 PMXEVCNTR, Performance Monitors Selected Event Count Register

The PMXEVCNTR characteristics are:

Purpose

Reads or writes the value of the selected event counter, PMEVCNTR<x>. PMSELR.SEL determines which event counter is selected.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register can be read at EL0 when PMUSERENR.EN or PMUSERENR.ER is set to 1, and can be written at EL0 when PMUSERENR.ER is set to 1.

If PMSELR.SEL selects a counter that is not accessible then reads and writes of PMXEVCNTR are CONSTRAINED UNPREDICTABLE, and must behave as one of the following:

- UNALLOCATED.
- RAZ/WI.
- A NOP.
- As if PMSELR.SEL has an UNKNOWN value less than the number of counters accessible at the current exception level and security state.
- As if PMSELR.SEL is 31.
- If the counter is implemented but not accessible at the current exception level and security state, generate a System Register Trap or CP14 Register Trap exception taken to EL2.

This applies:

- If PMSELR.SEL is larger than the number of implemented counters.
- In an implementation that includes EL2, in Non-secure EL1 and EL0 modes, if PMSELR.SEL >= HDCR.HPMN.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

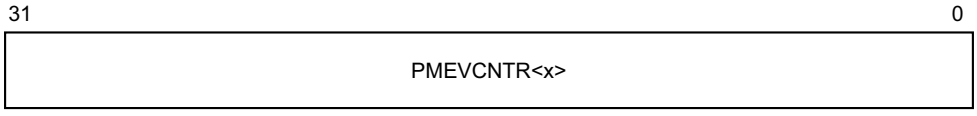
PMXEVCNTR is architecturally mapped to AArch64 register PMXEVCNTR_EL0.

Attributes

PMXEVCNTR is a 32-bit register.

Field descriptions

The PMXEVCNTR bit assignments are:



PMEVCNTR<x>, bits [31:0]

Value of the selected event counter, PMEVCNTR<x>, where x is the value stored in PMSELR.SEL.

Accessing the PMXEVCNTR

To access the PMXEVCNTR:

```
MRC p15,0,<Rt>,c9,c13,2 ; Read PMXEVCNTR into Rt
MCR p15,0,<Rt>,c9,c13,2 ; Write Rt to PMXEVCNTR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1101	010

G5.3.18 PMXEVTYPER, Performance Monitors Selected Event Type Register

The PMXEVTYPER characteristics are:

Purpose

When PMSELR.SEL selects an event counter, this accesses a PMEVTYPER<n> register. When PMSELR.SEL selects the cycle counter, this accesses PMCCFILTR.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR.EN is set to 1.

If PMSELR.SEL selects a counter that is not accessible then reads and writes of PMXEVTYPER are CONSTRAINED UNPREDICTABLE, and must behave as one of the following:

- UNALLOCATED.
- RAZ/WI.
- A NOP.
- As if PMSELR.SEL has an UNKNOWN value less than the number of counters accessible at the current exception level and security state.
- As if PMSELR.SEL is 31.
- If the counter is implemented but not accessible at the current exception level and security state, generate a System Register Trap or CP14 Register Trap exception taken to EL2.

This applies:

- If PMSELR.SEL is larger than the number of implemented counters.
- In an implementation that includes EL2, in Non-secure EL1 and EL0 modes, if PMSELR.SEL >= HDCR.HPMN.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

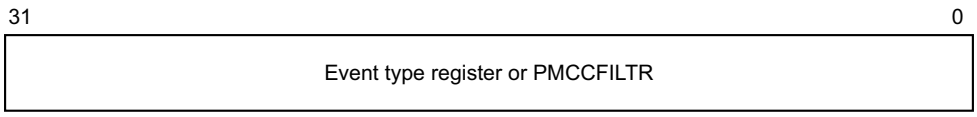
PMXEVTYPER is architecturally mapped to AArch64 register PMXEVTYPER_EL0.

Attributes

PMXEVTYPER is a 32-bit register.

Field descriptions

The PMXEVTYPER bit assignments are:



Bits [31:0]

Event type register or PMCCFILTR.

When PMSELR.SEL == 31, this register accesses PMCCFILTR.

Otherwise, this register accesses PMEVTYPER<n> where n is the value in PMSELR.SEL.

Accessing the PMXEVTYPER

To access the PMXEVTYPER:

```
MRC p15,0,<Rt>,c9,c13,1 ; Read PMXEVTYPER into Rt
MCR p15,0,<Rt>,c9,c13,1 ; Write Rt to PMXEVTYPER
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1001	1101	001

G5.4 Generic Timer registers

This section lists the Generic Timer registers in AArch32 state.

G5.4.1 CNTFRQ, Counter-timer Frequency register

The CNTFRQ characteristics are:

Purpose

Holds the clock frequency of the system counter.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RW

Can only be written at the highest exception level implemented. For example, if EL3 is the highest implemented exception level, CNTFRQ can only be written at EL3.

If EL3 is using AArch64, write access to CNTFRQ in AArch32 at Secure EL1 is UNDEFINED.

This register is accessible and read-only at EL0 when CNTKCTL.EL0PCTEN or CNTKCTL.EL0VCTEN is set to 1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

CNTFRQ is architecturally mapped to AArch64 register CNTFRQ_EL0.

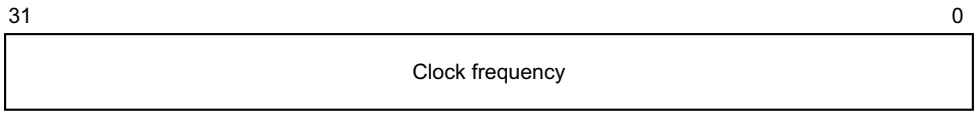
CNTFRQ is architecturally mapped to external register CNTFRQ.

Attributes

CNTFRQ is a 32-bit register.

Field descriptions

The CNTFRQ bit assignments are:



Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

Accessing the CNTFRQ register

To access the CNTFRQ:

```
MRC p15,0,<Rt>,c14,c0,0 ; Read CNTFRQ into Rt
MCR p15,0,<Rt>,c14,c0,0 ; Write Rt to CNTFRQ
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0000	000

G5.4.2 CNTHCTL, Counter-timer Hyp Control register

The CNTHCTL characteristics are:

Purpose

Controls the generation of an event stream from the physical counter, and access from Non-secure EL1 modes to the physical counter and the Non-secure EL1 physical timer.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

CNTHCTL is architecturally mapped to AArch64 register CNTHCTL_EL2.

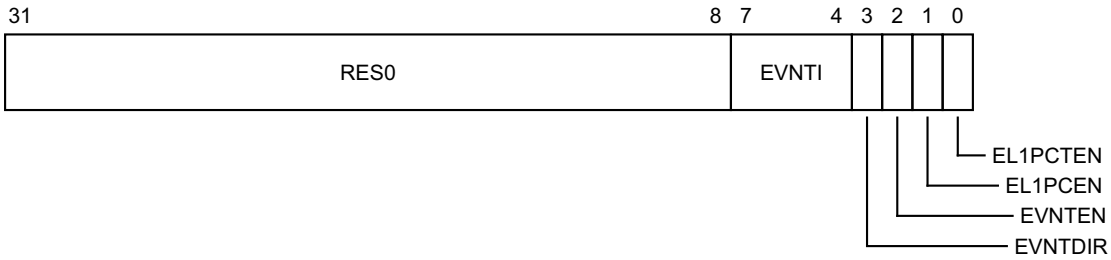
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

CNTHCTL is a 32-bit register.

Field descriptions

The CNTHCTL bit assignments are:



Bits [31:8]

Reserved, RES0.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the corresponding counter register (CNTPCT or CNTVCT) is the trigger for the event stream generated from that counter, when that stream is enabled.

Reset value is architecturally UNKNOWN.

EVNTDIR, bit [3]

Controls which transition of the counter register (CNTPCT or CNTVCT) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

`0` A 0 to 1 transition of the trigger bit triggers an event.

`1` A 1 to 0 transition of the trigger bit triggers an event.

Reset value is architecturally UNKNOWN.

EVNTEN, bit [2]

Enables the generation of an event stream from the corresponding counter:

0 Disables the event stream.

1 Enables the event stream.

Resets to 0.

EL1PCEN, bit [1]

Controls whether the Non-secure copies of the physical timer registers are accessible from Non-secure EL1 and EL0 modes:

0 The Non-secure CNTP_CVAL, CNTP_TVAL, and CNTP_CTL registers are not accessible from Non-secure EL1 and EL0 modes.

1 The Non-secure CNTP_CVAL, CNTP_TVAL, and CNTP_CTL registers are accessible from Non-secure EL1 and EL0 modes.

If EL3 is implemented and EL2 is not implemented, this bit is treated as if it is 1 for all purposes other than reading the register.

Resets to 1.

EL1PCTEN, bit [0]

Controls whether the physical counter, CNTPCT, is accessible from Non-secure EL1 and EL0 modes:

0 The CNTPCT register is not accessible from Non-secure EL1 and EL0 modes.

1 The CNTPCT register is accessible from Non-secure EL1 and EL0 modes.

If EL3 is implemented and EL2 is not implemented, this bit is treated as if it is 1 for all purposes other than reading the register.

Resets to 1.

Accessing the CNTHCTL

To access the CNTHCTL:

```
MRC p15,4,<Rt>,c14,c1,0 ; Read CNTHCTL into Rt
MCR p15,4,<Rt>,c14,c1,0 ; Write Rt to CNTHCTL
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1110	0001	000

G5.4.3 CNTHP_CTL, Counter-timer Hyp Physical Timer Control register

The CNTHP_CTL characteristics are:

Purpose

Control register for the Hyp mode physical timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

CNTHP_CTL is architecturally mapped to AArch64 register CNTHP_CTL_EL2.

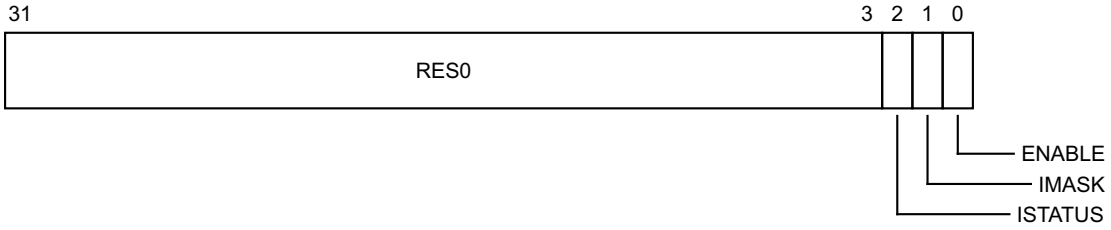
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

CNTHP_CTL is a 32-bit register.

Field descriptions

The CNTHP_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer interrupt. This bit is read-only. Permitted values are:

`0` Interrupt not asserted.

`1` Interrupt asserted.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

Reset value is architecturally UNKNOWN.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0` Timer interrupt is not masked.

`1` Timer interrupt is masked.

Reset value is architecturally UNKNOWN.

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0` Timer disabled.

`1` Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

Resets to 0.

Accessing the CNTHP_CTL

To access the CNTHP_CTL:

```
MRC p15,4,<Rt>,c14,c2,1 ; Read CNTHP_CTL into Rt
MCR p15,4,<Rt>,c14,c2,1 ; Write Rt to CNTHP_CTL
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1110	0010	001

G5.4.4 CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register

The CNTHP_CVAL characteristics are:

Purpose

Holds the compare value for the Hyp mode physical timer.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

CNTHP_CVAL is architecturally mapped to AArch64 register CNTHP_CVAL_EL2.

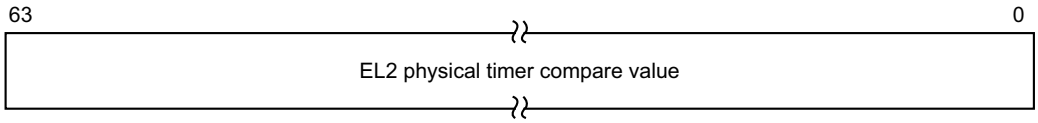
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

CNTHP_CVAL is a 64-bit register.

Field descriptions

The CNTHP_CVAL bit assignments are:



Bits [63:0]

EL2 physical timer compare value.

Accessing the CNTHP_CVAL

To access the CNTHP_CVAL:

```
MRRC p15,6,<Rt>,<Rt2>,c14 ; Read 64-bit CNTHP_CVAL into Rt (low word) and Rt2 (high word)
MCRR p15,6,<Rt>,<Rt2>,c14 ; Write Rt (low word) and Rt2 (high word) to 64-bit CNTHP_CVAL
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0110	1110

G5.4.5 CNTHP_TVAL, Counter-timer Hyp Physical Timer TimerValue register

The CNTHP_TVAL characteristics are:

Purpose

Holds the timer value for the Hyp mode physical timer.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

CNTHP_TVAL is architecturally mapped to AArch64 register CNTHP_TVAL_EL2.

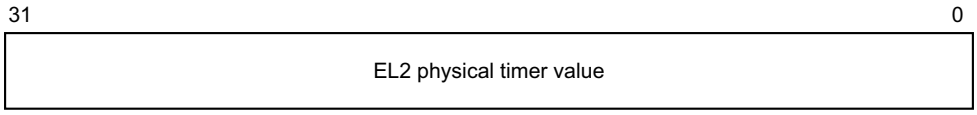
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

CNTHP_TVAL is a 32-bit register.

Field descriptions

The CNTHP_TVAL bit assignments are:



Bits [31:0]

EL2 physical timer value.

Accessing the CNTHP_TVAL

To access the CNTHP_TVAL:

```
MRC p15,4,<Rt>,c14,c2,0 ; Read CNTHP_TVAL into Rt
MCR p15,4,<Rt>,c14,c2,0 ; Write Rt to CNTHP_TVAL
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1110	0010	000

G5.4.6 CNTKCTL, Counter-timer Kernel Control register

The CNTKCTL characteristics are:

Purpose

Controls the generation of an event stream from the virtual counter, and access from EL0 modes to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

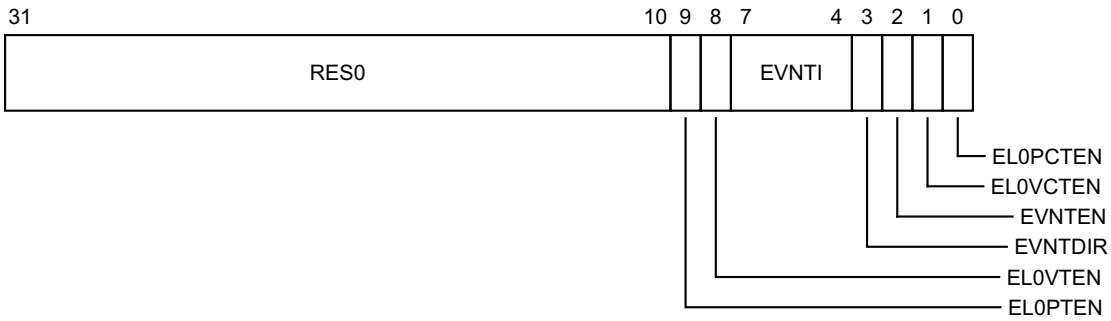
CNTKCTL is architecturally mapped to AArch64 register CNTKCTL_EL1.

Attributes

CNTKCTL is a 32-bit register.

Field descriptions

The CNTKCTL bit assignments are:



Bits [31:10]

Reserved, RES0.

EL0PTEN, bit [9]

Controls whether the physical timer registers are accessible from EL0 modes:

`0` The CNTP_CVAL, CNTP_CTL, and CNTP_TVAL registers are not accessible from EL0.

`1` The CNTP_CVAL, CNTP_CTL, and CNTP_TVAL registers are accessible from EL0.

Resets to 0.

EL0VTEN, bit [8]

Controls whether the virtual timer registers are accessible from EL0 modes:

`0` The CNTV_CVAL, CNTV_CTL, and CNTV_TVAL registers are not accessible from EL0.

1 The CNTV_CVAL, CNTV_CTL, and CNTV_TVAL registers are accessible from EL0.

Resets to 0.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the corresponding counter register (CNTPCT or CNTVCT) is the trigger for the event stream generated from that counter, when that stream is enabled.

Reset value is architecturally UNKNOWN.

EVNTDIR, bit [3]

Controls which transition of the counter register (CNTPCT or CNTVCT) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

0 A 0 to 1 transition of the trigger bit triggers an event.

1 A 1 to 0 transition of the trigger bit triggers an event.

Reset value is architecturally UNKNOWN.

EVNTEN, bit [2]

Enables the generation of an event stream from the corresponding counter:

0 Disables the event stream.

1 Enables the event stream.

Resets to 0.

EL0VCTEN, bit [1]

Controls whether the virtual counter, CNTVCT, and the frequency register CNTFRQ, are accessible from EL0 modes:

0 CNTVCT is not accessible from EL0. If EL0PCTEN is set to 0, CNTFRQ is not accessible from EL0.

1 CNTVCT and CNTFRQ are accessible from EL0.

Resets to 0.

EL0PCTEN, bit [0]

Controls whether the physical counter, CNTPCT, and the frequency register CNTFRQ, are accessible from EL0 modes:

0 CNTPCT is not accessible from EL0 modes. If EL0VCTEN is set to 0, CNTFRQ is not accessible from EL0.

1 CNTPCT and CNTFRQ are accessible from EL0.

Resets to 0.

Accessing the CNTKCTL

To access the CNTKCTL:

```
MRC p15,0,<Rt>,c14,c1,0 ; Read CNTKCTL into Rt
MCR p15,0,<Rt>,c14,c1,0 ; Write Rt to CNTKCTL
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0001	000

G5.4.7 CNTP_CTL, Counter-timer Physical Timer Control register

The CNTP_CTL characteristics are:

Purpose

Control register for the EL1 physical timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as CNTP_CTL(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	Config-RW	-	RW	-	-	RW

When accessed as CNTP_CTL(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	-	Config-RW	-	RW	RW	-

This register is accessible at EL0 when CNTKCTL.EL0PTEN is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when CNTHCTL.EL1PCEN is set to 1.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

CNTP_CTL(NS) is architecturally mapped to AArch64 register CNTP_CTL_EL0.

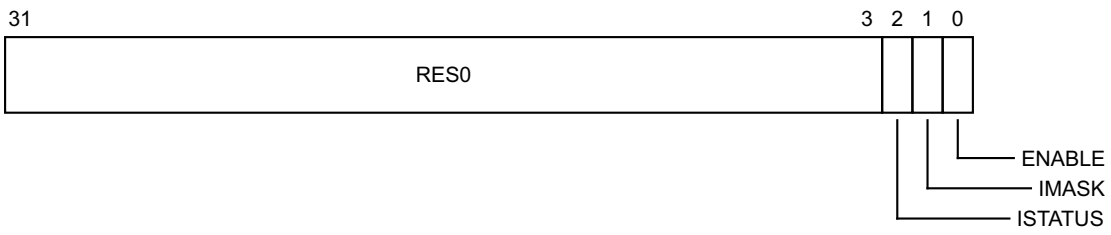
CNTP_CTL is architecturally mapped to external register CNTP_CTL.

Attributes

CNTP_CTL is a 32-bit register.

Field descriptions

The CNTP_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer interrupt. This bit is read-only. Permitted values are:

`0` Interrupt not asserted.

1 Interrupt asserted.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

Reset value is architecturally UNKNOWN.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

0 Timer interrupt is not masked.

1 Timer interrupt is masked.

Reset value is architecturally UNKNOWN.

ENABLE, bit [0]

Enables the timer. Permitted values are:

0 Timer disabled.

1 Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

Resets to 0.

Accessing the CNTP_CTL

To access the CNTP_CTL:

```
MRC p15,0,<Rt>,c14,c2,1 ; Read CNTP_CTL into Rt
MCR p15,0,<Rt>,c14,c2,1 ; Write Rt to CNTP_CTL
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0010	001

G5.4.8 CNTP_CVAL, Counter-timer Physical Timer CompareValue register

The CNTP_CVAL characteristics are:

Purpose

Holds the compare value for the EL1 physical timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as CNTP_CVAL(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	Config-RW	-	RW	-	-	RW

When accessed as CNTP_CVAL(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	-	Config-RW	-	RW	RW	-

This register is accessible at EL0 when CNTKCTL.EL0PTEN is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when CNTHCTL.EL1PCEN is set to 1.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

CNTP_CVAL(NS) is architecturally mapped to AArch64 register CNTP_CVAL_EL0.

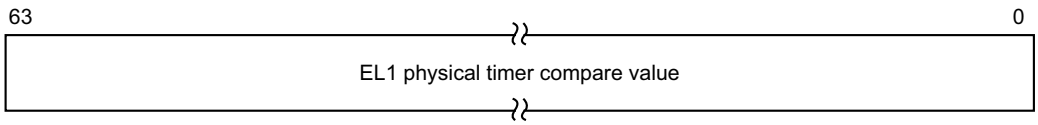
CNTP_CVAL is architecturally mapped to external register CNTP_CVAL.

Attributes

CNTP_CVAL is a 64-bit register.

Field descriptions

The CNTP_CVAL bit assignments are:



Bits [63:0]

EL1 physical timer compare value.

Accessing the CNTP_CVAL

To access the CNTP_CVAL:

```
MRRC p15,2,<Rt>,<Rt2>,c14 ; Read 64-bit CNTP_CVAL into Rt (low word) and Rt2 (high word)
MCRR p15,2,<Rt>,<Rt2>,c14 ; Write Rt (low word) and Rt2 (high word) to 64-bit CNTP_CVAL
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0010	1110

G5.4.9 CNTP_TVAL, Counter-timer Physical Timer TimerValue register

The CNTP_TVAL characteristics are:

Purpose

Holds the timer value for the EL1 physical timer. This provides a 32-bit downcounter.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as CNTP_TVAL(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	Config-RW	-	RW	-	-	RW

When accessed as CNTP_TVAL(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	-	Config-RW	-	RW	RW	-

This register is accessible at EL0 when CNTKCTL.EL0PTEN is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when CNTHCTL.EL1PCEN is set to 1.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

CNTP_TVAL(NS) is architecturally mapped to AArch64 register CNTP_TVAL_EL0.

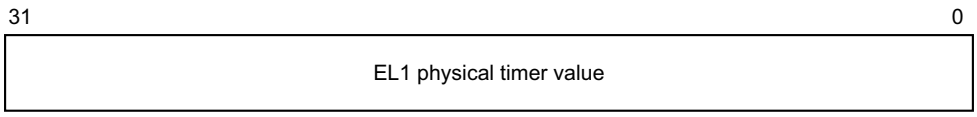
CNTP_TVAL is architecturally mapped to external register CNTP_TVAL.

Attributes

CNTP_TVAL is a 32-bit register.

Field descriptions

The CNTP_TVAL bit assignments are:



Bits [31:0]

EL1 physical timer value.

Accessing the CNTP_TVAL

To access the CNTP_TVAL:

```
MRC p15,0,<Rt>,c14,c2,0 ; Read CNTP_TVAL into Rt
MCR p15,0,<Rt>,c14,c2,0 ; Write Rt to CNTP_TVAL
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0010	000

G5.4.10 CNTPCT, Counter-timer Physical Count register

The CNTPCT characteristics are:

Purpose

Holds the 64-bit physical count value.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	Config-RO	RO	RO	RO	RO

This register is accessible at EL0 when CNTKCTL.EL0PCTEN is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when CNTHCTL.EL1PCTEN is set to 1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

CNTPCT is architecturally mapped to AArch64 register CNTPCT_EL0.

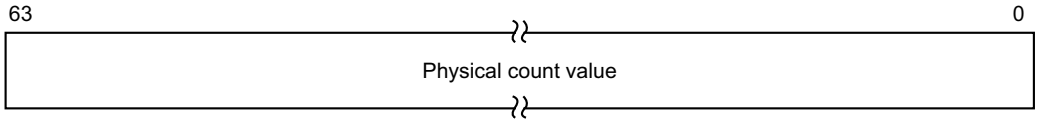
CNTPCT is architecturally mapped to external register CNTPCT.

Attributes

CNTPCT is a 64-bit register.

Field descriptions

The CNTPCT bit assignments are:



Bits [63:0]

Physical count value.

Accessing the CNTPCT

To access the CNTPCT:

```
MRRC p15,0,<Rt>,<Rt2>,c14 ; Read 64-bit CNTPCT into Rt (low word) and Rt2 (high word)
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0000	1110

G5.4.11 CNTV_CTL, Counter-timer Virtual Timer Control register

The CNTV_CTL characteristics are:

Purpose

Control register for the virtual timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when CNTKCTL.EL0VTEN is set to 1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

CNTV_CTL is architecturally mapped to AArch64 register CNTV_CTL_EL0.

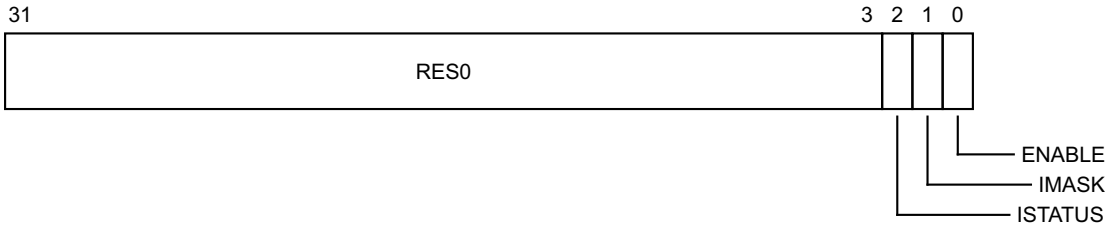
CNTV_CTL is architecturally mapped to external register CNTV_CTL.

Attributes

CNTV_CTL is a 32-bit register.

Field descriptions

The CNTV_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer interrupt. This bit is read-only. Permitted values are:

`0` Interrupt not asserted.

`1` Interrupt asserted.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

Reset value is architecturally UNKNOWN.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0` Timer interrupt is not masked.

`1` Timer interrupt is masked.

Reset value is architecturally UNKNOWN.

ENABLE, bit [0]

Enables the timer. Permitted values are:

0 Timer disabled.

1 Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

Resets to 0.

Accessing the CNTV_CTL

To access the CNTV_CTL:

```
MRC p15,0,<Rt>,c14,c3,1 ; Read CNTV_CTL into Rt
MCR p15,0,<Rt>,c14,c3,1 ; Write Rt to CNTV_CTL
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0011	001

G5.4.12 CNTV_CVAL, Counter-timer Virtual Timer CompareValue register

The CNTV_CVAL characteristics are:

Purpose

Holds the compare value for the virtual timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when CNTKCTL.EL0VTEN is set to 1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

CNTV_CVAL is architecturally mapped to AArch64 register CNTV_CVAL_EL0.

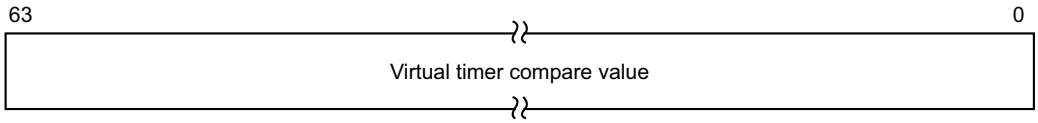
CNTV_CVAL is architecturally mapped to external register CNTV_CVAL.

Attributes

CNTV_CVAL is a 64-bit register.

Field descriptions

The CNTV_CVAL bit assignments are:



Bits [63:0]

Virtual timer compare value.

Accessing the CNTV_CVAL

To access the CNTV_CVAL:

```
MRRC p15,3,<Rt>,<Rt2>,c14 ; Read 64-bit CNTV_CVAL into Rt (low word) and Rt2 (high word)
MCRR p15,3,<Rt>,<Rt2>,c14 ; Write Rt (low word) and Rt2 (high word) to 64-bit CNTV_CVAL
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0011	1110

G5.4.13 CNTV_TVAL, Counter-timer Virtual Timer TimerValue register

The CNTV_TVAL characteristics are:

Purpose

Holds the timer value for the virtual timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when CNTKCTL.EL0VTEN is set to 1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

CNTV_TVAL is architecturally mapped to AArch64 register CNTV_TVAL_EL0.

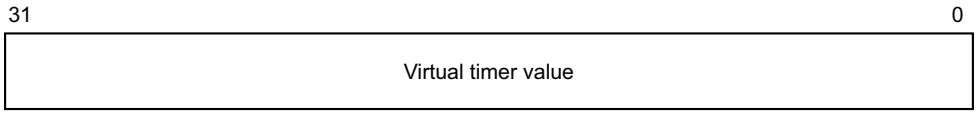
CNTV_TVAL is architecturally mapped to external register CNTV_TVAL.

Attributes

CNTV_TVAL is a 32-bit register.

Field descriptions

The CNTV_TVAL bit assignments are:



Bits [31:0]

Virtual timer value.

Accessing the CNTV_TVAL

To access the CNTV_TVAL:

```
MRC p15,0,<Rt>,c14,c3,0 ; Read CNTV_TVAL into Rt
MCR p15,0,<Rt>,c14,c3,0 ; Write Rt to CNTV_TVAL
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1110	0011	000

G5.4.14 CNTVCT, Counter-timer Virtual Count register

The CNTVCT characteristics are:

Purpose

Holds the 64-bit virtual count value.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 when CNTKCTL.EL0VCTEN is set to 1.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

CNTVCT is architecturally mapped to AArch64 register CNTVCT_EL0.

CNTVCT is architecturally mapped to external register CNTVCT.

The virtual count value is equal to the physical count value visible in CNTPCT minus the virtual offset visible in CNTVOFF.

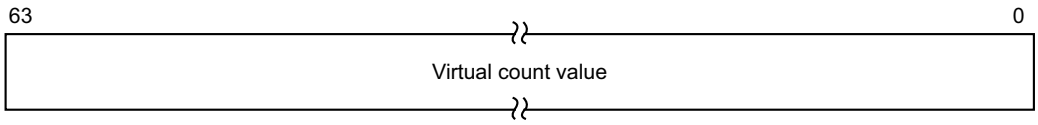
When EL2 is not implemented, CNTVOFF is RES0, and the value of this register is the same as the value of CNTPCT.

Attributes

CNTVCT is a 64-bit register.

Field descriptions

The CNTVCT bit assignments are:



Bits [63:0]

Virtual count value.

Accessing the CNTVCT

To access the CNTVCT:

```
MRRC p15,1,<Rt>,<Rt2>,c14 ; Read 64-bit CNTVCT into Rt (low word) and Rt2 (high word)
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0001	1110

G5.4.15 CNTVOFF, Counter-timer Virtual Offset register

The CNTVOFF characteristics are:

Purpose

Holds the 64-bit virtual offset.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

CNTVOFF is architecturally mapped to AArch64 register CNTVOFF_EL2.

CNTVOFF is architecturally mapped to external register CNTVOFF.

CNTVOFF is architecturally mapped to external register CNTVOFF<n>.

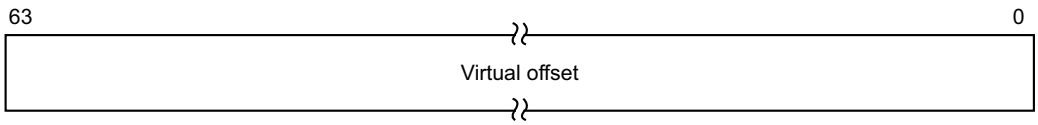
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

CNTVOFF is a 64-bit register.

Field descriptions

The CNTVOFF bit assignments are:



Bits [63:0]

Virtual offset.

Accessing the CNTVOFF

To access the CNTVOFF:

```
MRRC p15,4,<Rt>,<Rt2>,c14 ; Read 64-bit CNTVOFF into Rt (low word) and Rt2 (high word)
MCRR p15,4,<Rt>,<Rt2>,c14 ; Write Rt (low word) and Rt2 (high word) to 64-bit CNTVOFF
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0100	1110

G5.5 Generic Interrupt Controller CPU interface registers

This section describes the GIC CPU interface registers in AArch32 state.

G5.5.1 ICC_AP0R0, Interrupt Controller Active Priorities Register (0,0)

The ICC_AP0R0 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

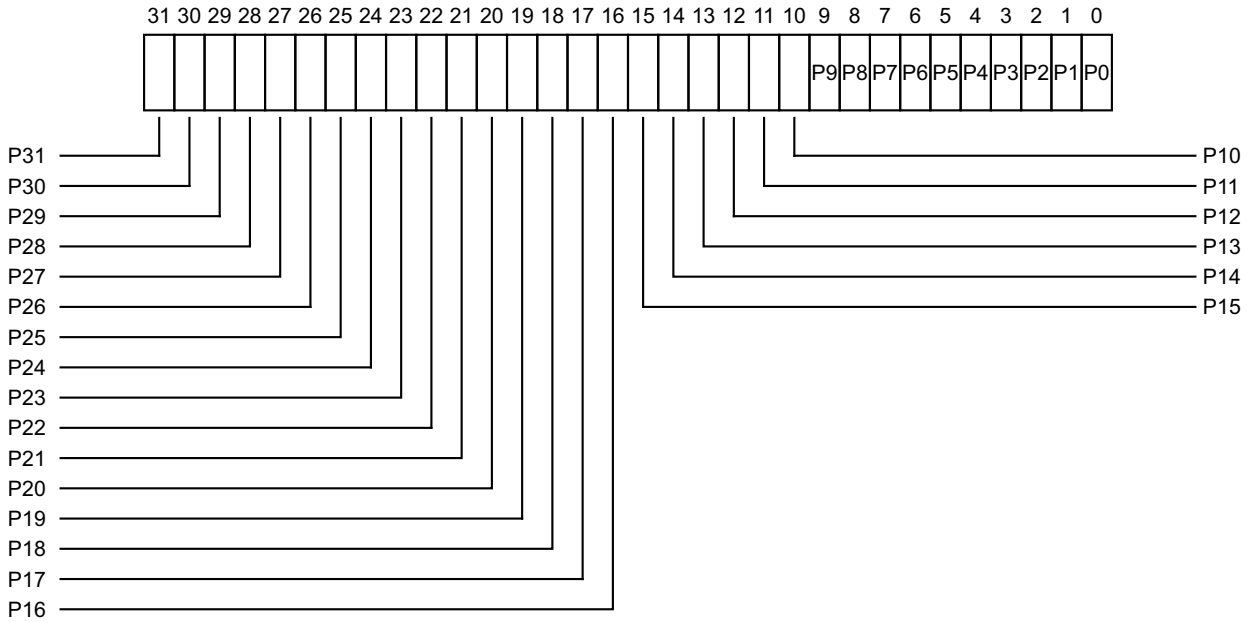
ICC_AP0R0 is architecturally mapped to AArch64 register ICC_AP0R0_EL1.

Attributes

ICC_AP0R0 is a 32-bit register.

Field descriptions

The ICC_AP0R0 bit assignments are:



P<n>, bit [n], for n = 0 to 31

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP0R0

To access the ICC_AP0R0:

```
MRC p15,0,<Rt>,c12,c8,4 ; Read ICC_AP0R0 into Rt
MCR p15,0,<Rt>,c12,c8,4 ; Write Rt to ICC_AP0R0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1000	100

G5.5.2 ICC_AP0R1, Interrupt Controller Active Priorities Register (0,1)

The ICC_AP0R1 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

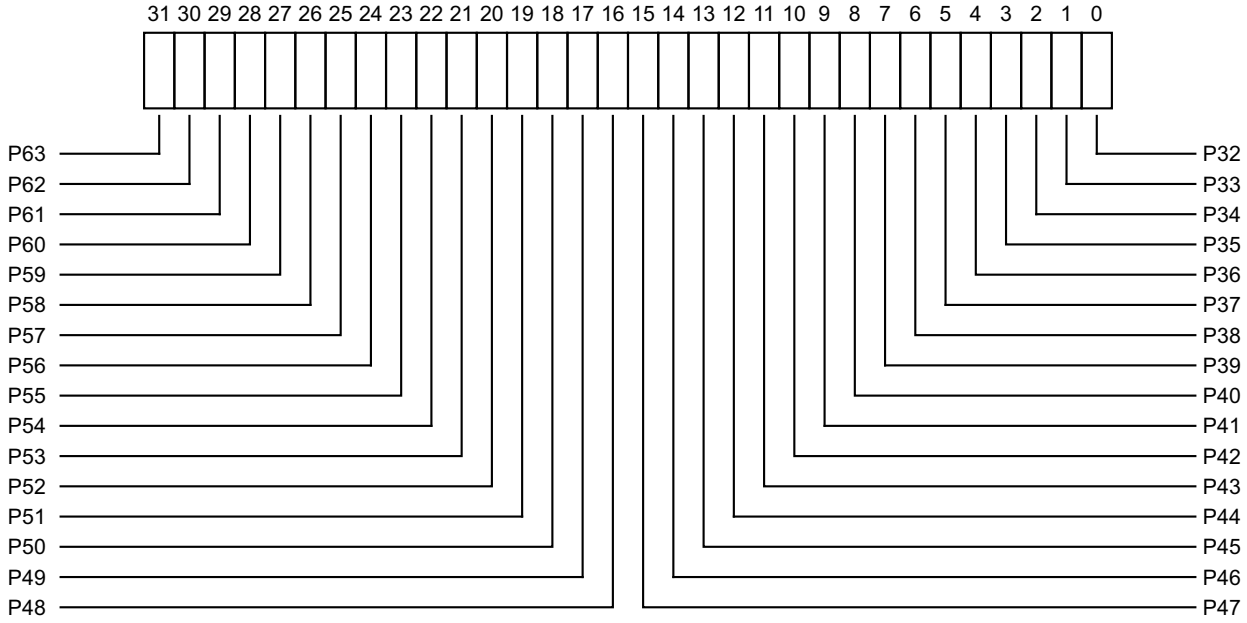
ICC_AP0R1 is architecturally mapped to AArch64 register ICC_AP0R1_EL1.

Attributes

ICC_AP0R1 is a 32-bit register.

Field descriptions

The ICC_AP0R1 bit assignments are:



P<n>, bit [(n-32)], for (n-32) = 32 to 63

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP0R1

To access the ICC_AP0R1:

```
MRC p15,0,<Rt>,c12,c8,5 ; Read ICC_AP0R1 into Rt
MCR p15,0,<Rt>,c12,c8,5 ; Write Rt to ICC_AP0R1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1000	101

G5.5.3 ICC_AP0R2, Interrupt Controller Active Priorities Register (0,2)

The ICC_AP0R2 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

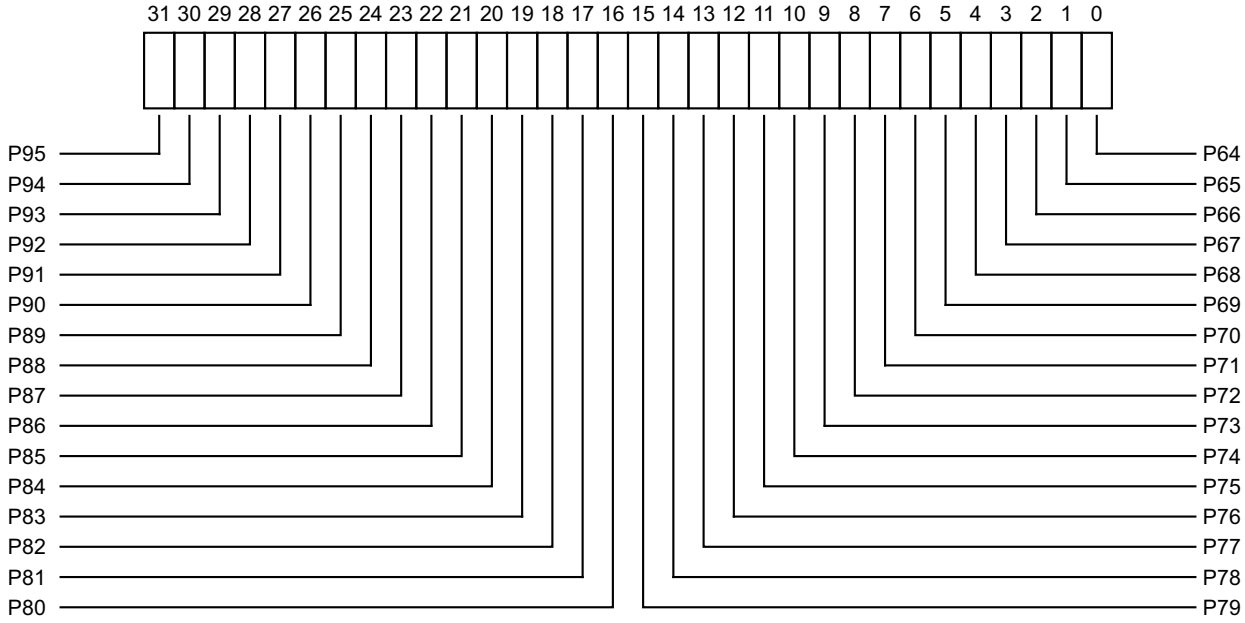
ICC_AP0R2 is architecturally mapped to AArch64 register ICC_AP0R2_EL1.

Attributes

ICC_AP0R2 is a 32-bit register.

Field descriptions

The ICC_AP0R2 bit assignments are:



P<n>, bit [(n-64)], for (n-64) = 64 to 95

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP0R2

To access the ICC_AP0R2:

```
MRC p15,0,<Rt>,c12,c8,6 ; Read ICC_AP0R2 into Rt
MCR p15,0,<Rt>,c12,c8,6 ; Write Rt to ICC_AP0R2
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1000	110

G5.5.4 ICC_AP0R3, Interrupt Controller Active Priorities Register (0,3)

The ICC_AP0R3 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

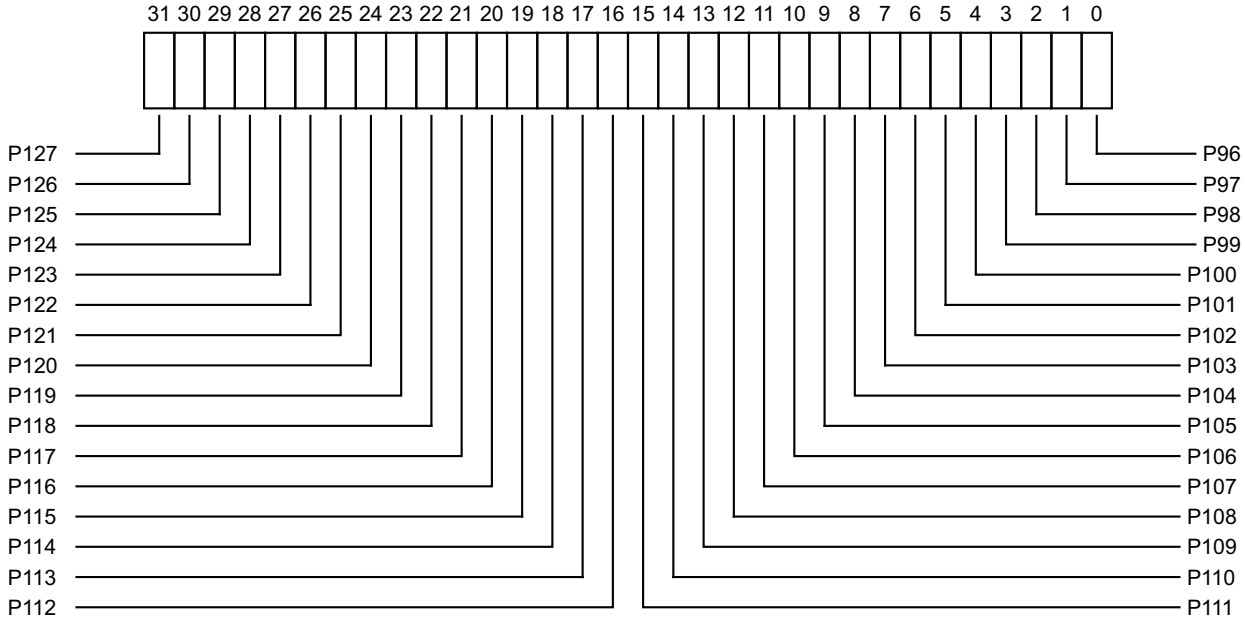
ICC_AP0R3 is architecturally mapped to AArch64 register ICC_AP0R3_EL1.

Attributes

ICC_AP0R3 is a 32-bit register.

Field descriptions

The ICC_AP0R3 bit assignments are:



P<n>, bit [(n-96)], for (n-96) = 96 to 127

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP0R3

To access the ICC_AP0R3:

```
MRC p15,0,<Rt>,c12,c8,7 ; Read ICC_AP0R3 into Rt
MCR p15,0,<Rt>,c12,c8,7 ; Write Rt to ICC_AP0R3
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1000	111

G5.5.5 ICC_AP1R0, Interrupt Controller Active Priorities Register (1,0)

The ICC_AP1R0 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

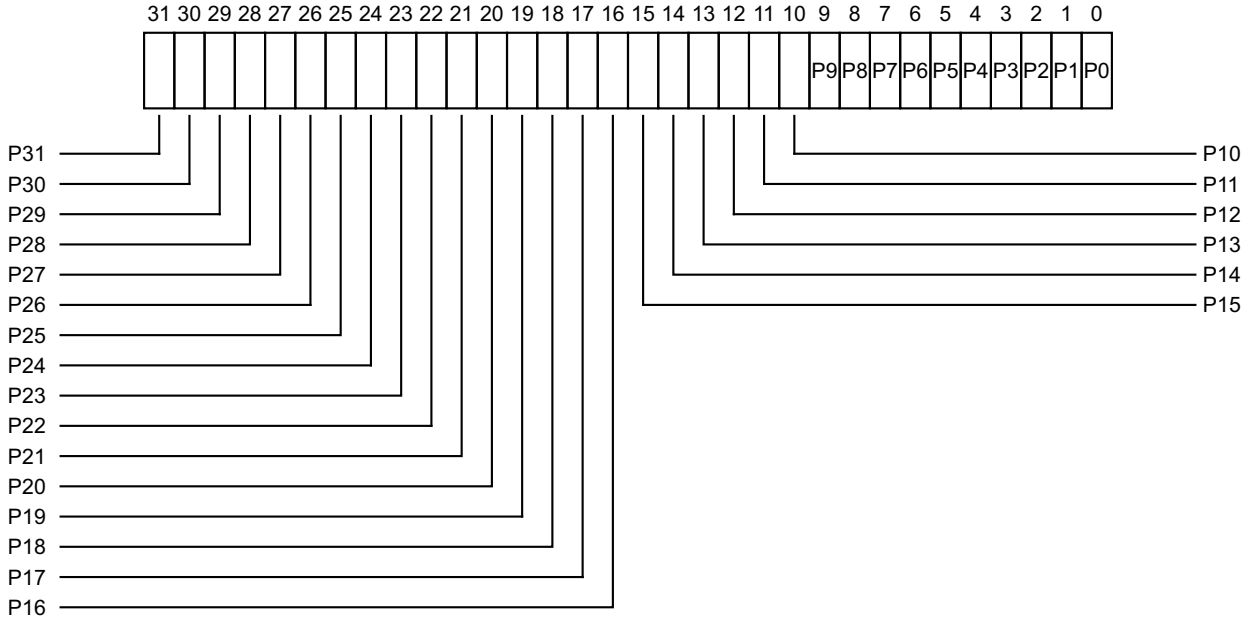
ICC_AP1R0 is architecturally mapped to AArch64 register ICC_AP1R0_EL1.

Attributes

ICC_AP1R0 is a 32-bit register.

Field descriptions

The ICC_AP1R0 bit assignments are:



P<n>, bit [n], for n = 0 to 31

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP1R0

To access the ICC_AP1R0:

```
MRC p15,0,<Rt>,c12,c9,0 ; Read ICC_AP1R0 into Rt
MCR p15,0,<Rt>,c12,c9,0 ; Write Rt to ICC_AP1R0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1001	000

G5.5.6 ICC_AP1R1, Interrupt Controller Active Priorities Register (1,1)

The ICC_AP1R1 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

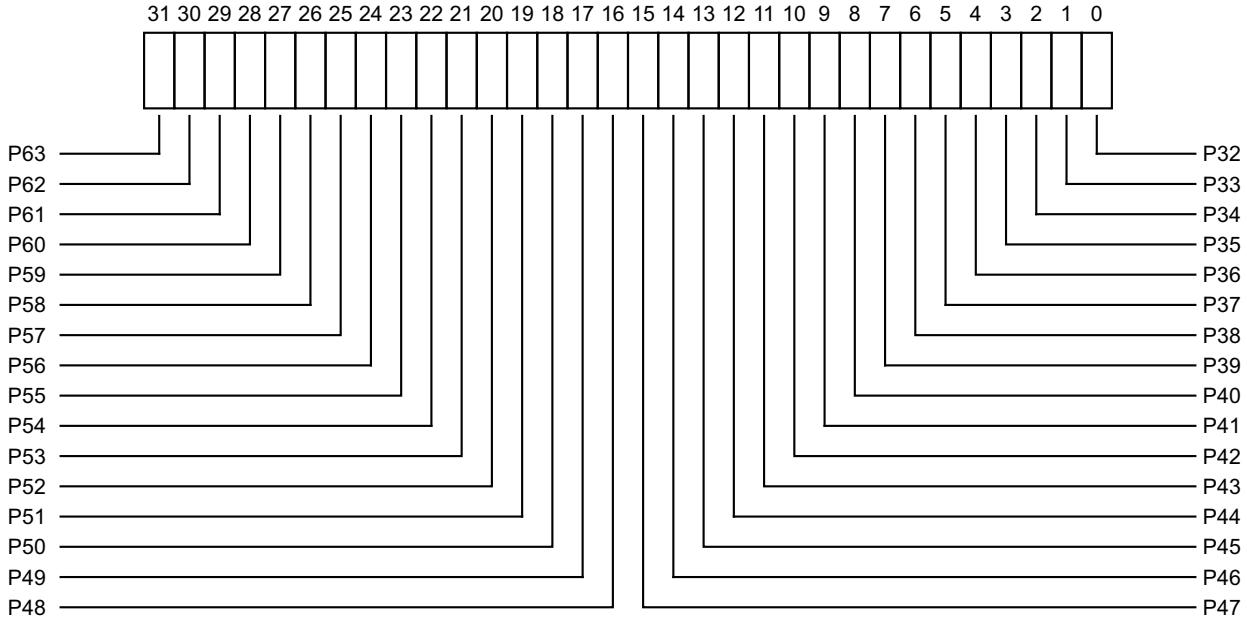
ICC_AP1R1 is architecturally mapped to AArch64 register ICC_AP1R1_EL1.

Attributes

ICC_AP1R1 is a 32-bit register.

Field descriptions

The ICC_AP1R1 bit assignments are:



P<n>, bit [(n-32)], for (n-32) = 32 to 63

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP1R1

To access the ICC_AP1R1:

```
MRC p15,0,<Rt>,c12,c9,1 ; Read ICC_AP1R1 into Rt
MCR p15,0,<Rt>,c12,c9,1 ; Write Rt to ICC_AP1R1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1001	001

G5.5.7 ICC_AP1R2, Interrupt Controller Active Priorities Register (1,2)

The ICC_AP1R2 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

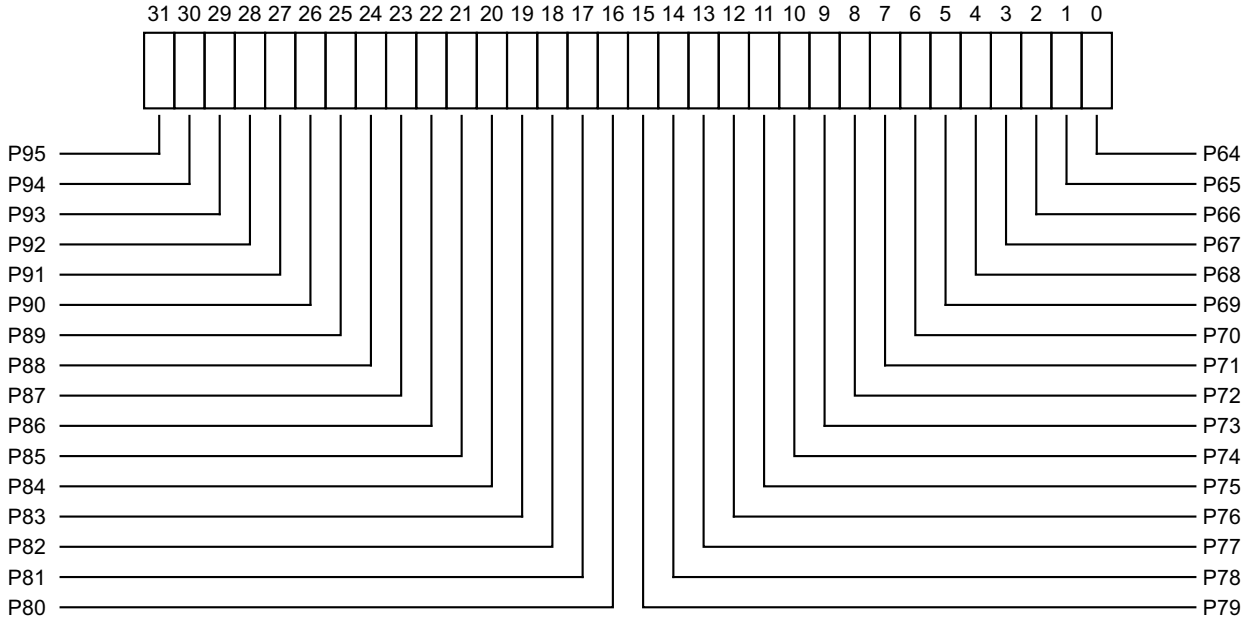
ICC_AP1R2 is architecturally mapped to AArch64 register ICC_AP1R2_EL1.

Attributes

ICC_AP1R2 is a 32-bit register.

Field descriptions

The ICC_AP1R2 bit assignments are:



P<n>, bit [(n-64)], for (n-64) = 64 to 95

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP1R2

To access the ICC_AP1R2:

```
MRC p15,0,<Rt>,c12,c9,2 ; Read ICC_AP1R2 into Rt
MCR p15,0,<Rt>,c12,c9,2 ; Write Rt to ICC_AP1R2
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1001	010

G5.5.8 ICC_AP1R3, Interrupt Controller Active Priorities Register (1,3)

The ICC_AP1R3 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

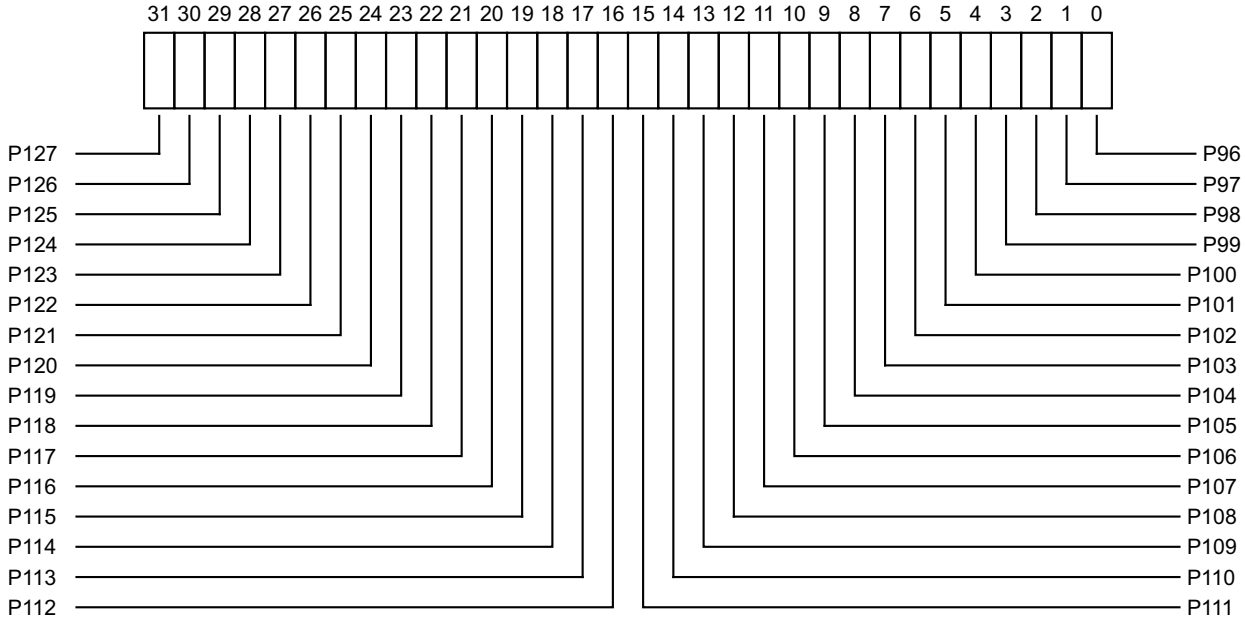
ICC_AP1R3 is architecturally mapped to AArch64 register ICC_AP1R3_EL1.

Attributes

ICC_AP1R3 is a 32-bit register.

Field descriptions

The ICC_AP1R3 bit assignments are:



P<n>, bit [(n-96)], for (n-96) = 96 to 127

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP1R3

To access the ICC_AP1R3:

```
MRC p15,0,<Rt>,c12,c9,3 ; Read ICC_AP1R3 into Rt
MCR p15,0,<Rt>,c12,c9,3 ; Write Rt to ICC_AP1R3
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1001	011

G5.5.9 ICC_ASGI1R, Interrupt Controller Alias Software Generated Interrupt group 1 Register

The ICC_ASGI1R characteristics are:

Purpose

Provides software the ability to generate group 1 SGIs for the other security state.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_ASGI1R(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	-	-	WO

When accessed as ICC_ASGI1R(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	-	WO	WO	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

ICC_ASGI1R(S) is architecturally mapped to AArch64 register ICC_ASGI1R_EL1 (S).

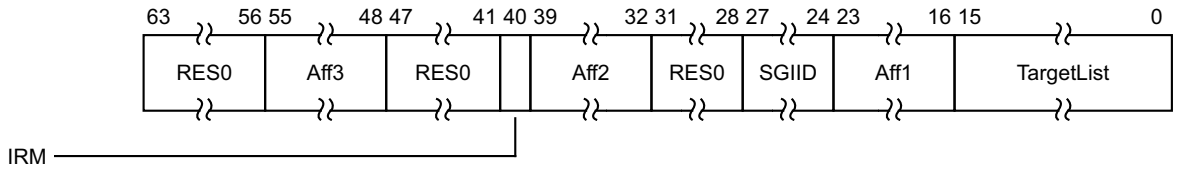
ICC_ASGI1R(NS) is architecturally mapped to AArch64 register ICC_ASGI1R_EL1 (NS).

Attributes

ICC_ASGI1R is a 64-bit register.

Field descriptions

The ICC_ASGI1R bit assignments are:



Bits [63:56]

Reserved, RES0.

Aff3, bits [55:48]

The affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [47:41]

Reserved, RES0.

IRM, bit [40]

Interrupt Routing Mode. Determines how the generated interrupts should be distributed to processors. Possible values are:

`0` Interrupts routed to the processors specified by a.b.c.{target list}. In this routing, a, b, and c are the values of fields Aff3, Aff2, and Aff1 respectively.

`1` Interrupts routed to all processors in the system, excluding self.

Aff2, bits [39:32]

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [31:28]

Reserved, RES0.

SGIID, bits [27:24]

SGI Interrupt ID.

Aff1, bits [23:16]

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated.

TargetList, bits [15:0]

Target List. The set of processors for which SGI interrupts will be generated. Each bit corresponds to the processor within a cluster with an Affinity 0 value equal to the bit number.

If a bit is 1 and the bit does not correspond to a valid target processor, the bit must be ignored by the Distributor. In such cases, a Distributor may optionally generate an SError interrupt.

This restricts distribution of SGIs to the first 16 processors of an affinity 1 cluster.

Accessing the ICC_ASGI1R

To access the ICC_ASGI1R:

```
MCRR p15,1,<Rt>,<Rt2>,c12 ; Write Rt (low word) and Rt2 (high word) to 64-bit ICC_ASGI1R
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0001	1100

G5.5.10 ICC_BPR0, Interrupt Controller Binary Point Register 0

The ICC_BPR0 characteristics are:

Purpose

Defines the point at which the priority value fields split into two parts, the group priority field and the subpriority field. The group priority field is used to determine interrupt preemption.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_BPR0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as ICC_BPR0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

In Secure state, this register is the binary point register for Group 0 interrupts. In Non-secure state, this is the BPR for Group 1 interrupts.

The minimum binary point value is IMPLEMENTATION DEFINED in the range:

- 0-3 if the implementation supports one security state, and for the Secure copy of the register if the implementation supports two security states.
- 1-4 for the Non-secure copy of the register.

An attempt to program the binary point field to a value less than the minimum value sets the field to the minimum value. On a reset, the binary point field is set to the minimum supported value.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

ICC_BPR0(S) is architecturally mapped to AArch64 register ICC_BPR0_EL1 (S).

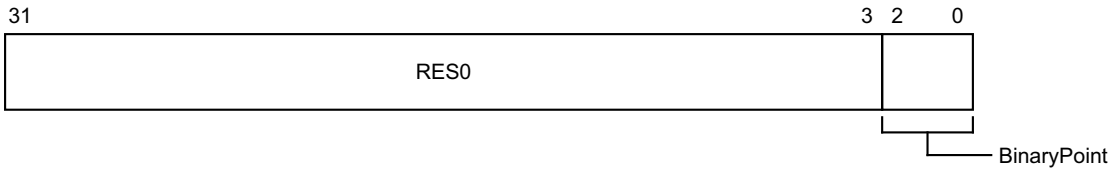
ICC_BPR0(NS) is architecturally mapped to AArch64 register ICC_BPR0_EL1 (NS).

Attributes

ICC_BPR0 is a 32-bit register.

Field descriptions

The ICC_BPR0 bit assignments are:



Bits [31:3]

Reserved, RES0.

BinaryPoint, bits [2:0]

The value of this field controls how the 8-bit interrupt priority field is split into a group priority field, used to determine interrupt preemption, and a subpriority field. This is done as follows:

Binary point value	Group priority field	Subpriority field	Field with binary point
0	[7:1]	[0]	ggggggg.s
1	[7:2]	[1:0]	gggggg.ss
2	[7:3]	[2:0]	ggggg.sss
3	[7:4]	[3:0]	gggg.ssss
4	[7:5]	[4:0]	ggg.sssss
5	[7:6]	[5:0]	gg.ssssss
6	[7]	[6:0]	g.sssssss
7	No preemption	[7:0]	.ssssssss

Accessing the ICC_BPR0

To access the ICC_BPR0:

```
MRC p15,0,<Rt>,c12,c8,3 ; Read ICC_BPR0 into Rt
MCR p15,0,<Rt>,c12,c8,3 ; Write Rt to ICC_BPR0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1000	011

G5.5.11 ICC_BPR1, Interrupt Controller Binary Point Register 1

The ICC_BPR1 characteristics are:

Purpose

Defines the point at which the priority value fields split into two parts, the group priority field and the subpriority field. The group priority field is used to determine Group 1 interrupt preemption.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

This register is an alias of the Non-secure view of ICC_BPR0, and a Secure access to this register is identical to a Non-secure access to ICC_BPR0.

The minimum binary point value is IMPLEMENTATION DEFINED in the range 1-4.

An attempt to program the binary point field to a value less than the minimum value sets the field to the minimum value. On a reset, the binary point field is set to the minimum supported value.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

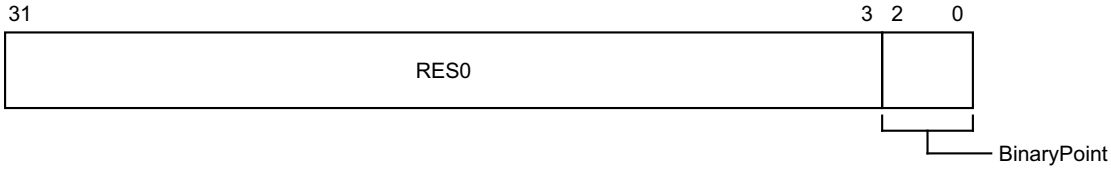
ICC_BPR1 is architecturally mapped to AArch64 register ICC_BPR1_EL1.

Attributes

ICC_BPR1 is a 32-bit register.

Field descriptions

The ICC_BPR1 bit assignments are:



Bits [31:3]

Reserved, RES0.

BinaryPoint, bits [2:0]

The value of this field controls how the 8-bit interrupt priority field is split into a group priority field, used to determine interrupt preemption, and a subpriority field. This is done as follows:

Binary point value	Group priority field	Subpriority field	Field with binary point
0	[7:1]	[0]	ggggggg.s
1	[7:2]	[1:0]	gggggg.ss
2	[7:3]	[2:0]	ggggg.sss

Binary point value	Group priority field	Subpriority field	Field with binary point
3	[7:4]	[3:0]	gggg.ssss
4	[7:5]	[4:0]	ggg.sssss
5	[7:6]	[5:0]	gg.ssssss
6	[7]	[6:0]	g.sssssss
7	No preemption	[7:0]	.ssssssss

Accessing the ICC_BPR1

To access the ICC_BPR1:

```
MRC p15,0,<Rt>,c12,c12,3 ; Read ICC_BPR1 into Rt
MCR p15,0,<Rt>,c12,c12,3 ; Write Rt to ICC_BPR1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1100	011

G5.5.12 ICC_CTLR, Interrupt Controller Control Register

The ICC_CTLR characteristics are:

Purpose

Controls aspects of the behavior of the GIC CPU interface and provides information about the features implemented.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_CTLR(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as ICC_CTLR(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

ICC_CTLR(S) is architecturally mapped to AArch64 register ICC_CTLR_EL1 (S).

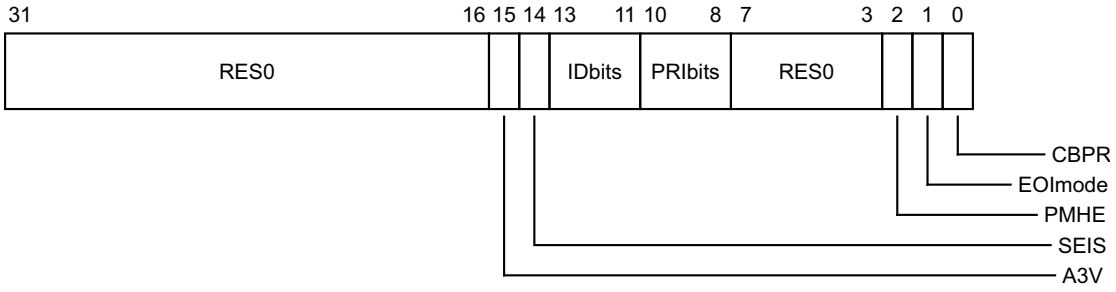
ICC_CTLR(NS) is architecturally mapped to AArch64 register ICC_CTLR_EL1 (NS).

Attributes

ICC_CTLR is a 32-bit register.

Field descriptions

The ICC_CTLR bit assignments are:



Bits [31:16]

Reserved, RES0.

A3V, bit [15]

Affinity 3 Valid. Read-only. Possible values are:

0 The CPU interface logic only supports zero values of Affinity 3 in SGI generation system registers.

1 The CPU interface logic supports non-zero values of Affinity 3 in SGI generation system registers.

Virtual accesses return the value from ICH_VTR.A3V.

SEIS, bit [14]

SEI Support. Read-only. Indicates whether the CPU interface supports local generation of SEIs:

0 The CPU interface logic does not support local generation of SEIs by the CPU interface.

1 The CPU interface logic supports local generation of SEIs by the CPU interface.

Virtual accesses return the value from ICH_VTR.SEIS.

IDbits, bits [13:11]

The number of physical interrupt identifier bits supported:

000 16 bits.

001 24 bits.

All other values are reserved.

Virtual accesses return the value from ICH_VTR.IDbits.

Reset value is architecturally UNKNOWN.

PRIbits, bits [10:8]

The number of priority bits implemented, minus one. Read-only.

Virtual accesses return the value from ICH_VTR.PRIbits.

Bits [7:3]

Reserved, RES0.

PMHE, bit [2]

Priority Mask Hint Enable.

If EL3 is present and GICD_CTLR.DS == 0, this bit is a read-only alias of ICC_MCTLR.PMHE.

If EL3 is present and GICD_CTLR.DS == 1, this bit is writable at EL1 and EL2.

Resets to 0.

EOImode, bit [1]

Alias of ICC_MCTLR.EOImode_EL1{S,NS} as appropriate to the current security state.

Virtual accesses modify ICH_VMCR.VEOIM.

Reset value is architecturally UNKNOWN.

CBPR, bit [0]

Common Binary Point Register.

If EL3 is present and GICD_CTLR.DS == 0, this bit is a read-only alias of ICC_MCTLR.CBPR_EL1{S,NS} as appropriate.

If EL3 is not present, this field resets to zero.

If EL3 is present and GICD_CTLR.DS == 1, this bit is writable at EL1 and EL2.

Virtual accesses modify ICH_VMCR.VCBPR. An access is virtual when accessed at non-secure EL1 and either of FIQ or IRQ has been virtualized. That is, when (SCR.NS == '1' && (HCR.FMO == '1' || HCR.IMO == '1')).

Accessing the ICC_CTLR

To access the ICC_CTLR:

```
MRC p15,0,<Rt>,c12,c12,4 ; Read ICC_CTLR into Rt
MCR p15,0,<Rt>,c12,c12,4 ; Write Rt to ICC_CTLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1100	100

G5.5.13 ICC_DIR, Interrupt Controller Deactivate Interrupt Register

The ICC_DIR characteristics are:

Purpose

When interrupt priority drop is separated from interrupt deactivation, a write to this register deactivates the specified interrupt.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

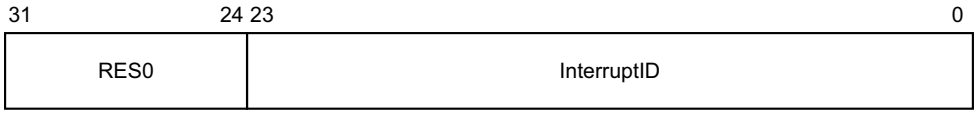
ICC_DIR is architecturally mapped to AArch64 register ICC_DIR_EL1.

Attributes

ICC_DIR is a 32-bit register.

Field descriptions

The ICC_DIR bit assignments are:



Bits [31:24]

Reserved, RES0.

InterruptID, bits [23:0]

The interrupt ID.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_DIR

To access the ICC_DIR:

```
MCR p15,0,<Rt>,c12,c11,1 ; Write Rt to ICC_DIR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1011	001

G5.5.14 ICC_EOIR0, Interrupt Controller End Of Interrupt Register 0

The ICC_EOIR0 characteristics are:

Purpose

A processor writes to this register to inform the CPU interface that it has completed the processing of the specified interrupt.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_EOIR0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	-	-	WO

When accessed as ICC_EOIR0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	-	WO	WO	-

A write to this register must correspond to the most recent valid read from an Interrupt Acknowledge Register. A valid read is a read that returns a valid interrupt ID, that is not a spurious interrupt ID.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

ICC_EOIR0(S) is architecturally mapped to AArch64 register ICC_EOIR0_EL1 (S).

ICC_EOIR0(NS) is architecturally mapped to AArch64 register ICC_EOIR0_EL1 (NS).

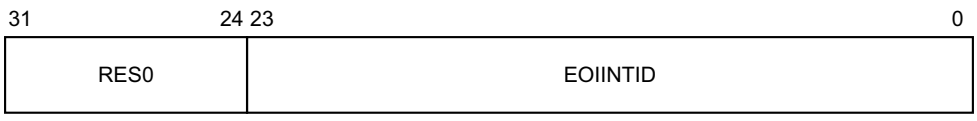
In Secure state, this register is the end of interrupt register for Group 0 interrupts. In Non-secure state, this is the EOIR for Group 1 interrupts.

Attributes

ICC_EOIR0 is a 32-bit register.

Field descriptions

The ICC_EOIR0 bit assignments are:



Bits [31:24]

Reserved, RES0.

EOIINTID, bits [23:0]

The InterruptID value from the corresponding GICC_IAR access.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_EOIR0

To access the ICC_EOIR0:

```
MCR p15,0,<Rt>,c12,c8,1 ; Write Rt to ICC_EOIR0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1000	001

G5.5.15 ICC_EOIR1, Interrupt Controller End Of Interrupt Register 1

The ICC_EOIR1 characteristics are:

Purpose

A processor writes to this register to inform the CPU interface that it has completed the processing of the specified Group 1 interrupt.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

A write to this register must correspond to the most recent valid read from an Interrupt Acknowledge Register. A valid read is a read that returns a valid interrupt ID, that is not a spurious interrupt ID.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

ICC_EOIR1 is architecturally mapped to AArch64 register ICC_EOIR1_EL1.

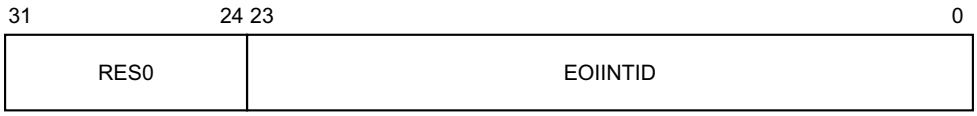
This register is an alias of the Non-secure view of ICC_EOIR0, and a Secure access to this register is identical to a Non-secure access to ICC_EOIR0.

Attributes

ICC_EOIR1 is a 32-bit register.

Field descriptions

The ICC_EOIR1 bit assignments are:



Bits [31:24]

Reserved, RES0.

EOIINTID, bits [23:0]

The InterruptID value from the corresponding GICC_IAR access.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_EOIR1

To access the ICC_EOIR1:

```
MCR p15,0,<Rt>,c12,c12,1 ; Write Rt to ICC_EOIR1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1100	001

G5.5.16 ICC_HPPIR0, Interrupt Controller Highest Priority Pending Interrupt Register 0

The ICC_HPPIR0 characteristics are:

Purpose

Indicates the Interrupt ID, and processor ID if appropriate, of the highest priority pending interrupt on the CPU interface.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_HPPIR0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RO	-	-	RO

When accessed as ICC_HPPIR0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	-	RO	RO	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

ICC_HPPIR0(S) is architecturally mapped to AArch64 register ICC_HPPIR0_EL1 (S).

ICC_HPPIR0(NS) is architecturally mapped to AArch64 register ICC_HPPIR0_EL1 (NS).

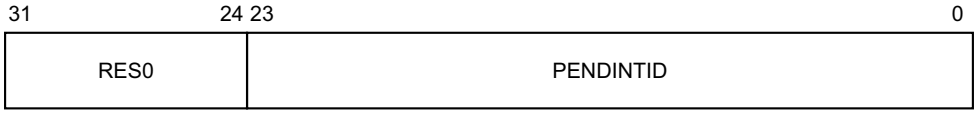
In Secure state, this register is the highest priority pending interrupt register for Group 0 interrupts. In Non-secure state, this is the HPPIR for Group 1 interrupts.

Attributes

ICC_HPPIR0 is a 32-bit register.

Field descriptions

The ICC_HPPIR0 bit assignments are:



Bits [31:24]

Reserved, RES0.

PENDINTID, bits [23:0]

The interrupt ID of the highest priority pending interrupt.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_HPPIR0

To access the ICC_HPPIR0:

```
MRC p15,0,<Rt>,c12,c8,2 ; Read ICC_HPPIR0 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1000	010

G5.5.17 ICC_HPPIR1, Interrupt Controller Highest Priority Pending Interrupt Register 1

The ICC_HPPIR1 characteristics are:

Purpose

If the highest priority pending interrupt on the CPU interface is a Group 1 interrupt, returns the interrupt ID of that interrupt. Otherwise, returns a spurious interrupt ID of 1023.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

ICC_HPPIR1 is architecturally mapped to AArch64 register ICC_HPPIR1_EL1.

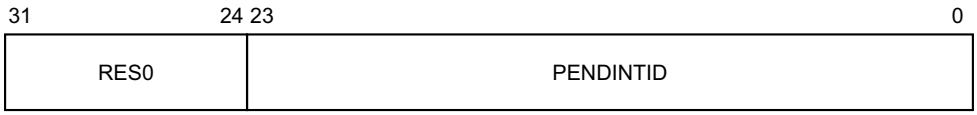
This register is an alias of the Non-secure view of ICC_HPPIR0, and a Secure access to this register is identical to a Non-secure access to ICC_HPPIR0.

Attributes

ICC_HPPIR1 is a 32-bit register.

Field descriptions

The ICC_HPPIR1 bit assignments are:



Bits [31:24]

Reserved, RES0.

PENDINTID, bits [23:0]

The interrupt ID of the highest priority pending interrupt.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_HPPIR1

To access the ICC_HPPIR1:

```
MRC p15,0,<Rt>,c12,c12,2 ; Read ICC_HPPIR1 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1100	010

G5.5.18 ICC_HSRE, Interrupt Controller Hyp System Register Enable register

The ICC_HSRE characteristics are:

Purpose

Controls whether the system register interface or the memory mapped interface to the GIC CPU interface is used for EL2.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	RW

If EL3 is present and ICC_MSRE.Enable is 0, EL2 accesses to this register will trap to EL3.

Configurations

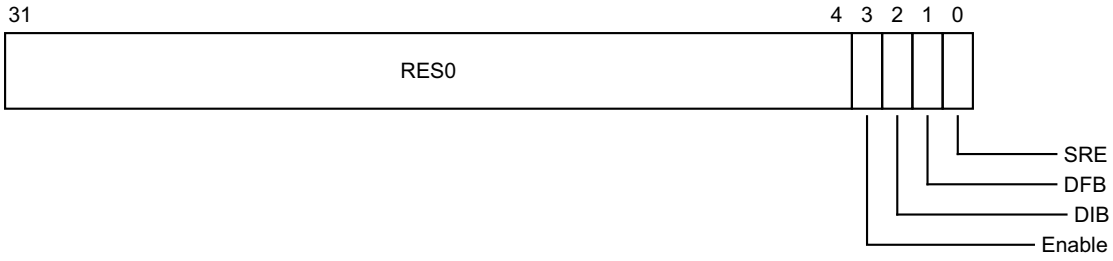
ICC_HSRE is architecturally mapped to AArch64 register ICC_SRE_EL2.

Attributes

ICC_HSRE is a 32-bit register.

Field descriptions

The ICC_HSRE bit assignments are:



Bits [31:4]

Reserved, RES0.

Enable, bit [3]

Enable. Enables lower exception level access to ICC_SRE_EL1.

0 Non-secure EL1 accesses to ICC_SRE_EL1 trap to EL2.

1 Non-secure EL1 accesses to ICC_SRE_EL1 are permitted if EL3 is not present or ICC_SRE_EL3.Enable is 1, otherwise Non-secure EL1 accesses to ICC_SRE_EL1 trap to EL3.

Resets to 0.

DIB, bit [2]

Disable IRQ bypass.

If EL3 is present and GICD_CTLR.DS is 0, this field is a read-only alias of ICC_MSRE.DIB.

Resets to 0.

DFB, bit [1]

Disable FIQ bypass.

If EL3 is present and GICD_CTLR.DS is 0, this field is a read-only alias of ICC_MSRE.DFB.

Resets to 0.

SRE, bit [0]

System Register Enable.

`0` The memory mapped interface must be used. Access at EL2 to any ICH_* system register, or any EL1 or EL2 ICC_* register other than ICC_SRE or ICC_HSRE, results in an Undefined exception.

`1` The system register interface to the ICH_* registers and the EL1 and EL2 ICC_* registers is enabled for EL2.

`0` The memory mapped interface must be used. Access at EL2 to any ICH_* system register, or any EL1 or EL2 ICC_* register other than ICC_SRE_EL1 or ICC_SRE_EL2, results in an Undefined exception.

`1` The system register interface to the ICH_* registers and the EL1 and EL2 ICC_* registers is enabled for EL2.

System Register Enable.

Resets to 0.

Accessing the ICC_HSRE

To access the ICC_HSRE:

```
MRC p15,4,<Rt>,c12,c9,5 ; Read ICC_HSRE into Rt
MCR p15,4,<Rt>,c12,c9,5 ; Write Rt to ICC_HSRE
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1001	101

G5.5.19 ICC_IAR0, Interrupt Controller Interrupt Acknowledge Register 0

The ICC_IAR0 characteristics are:

Purpose

The processor reads this register to obtain the interrupt ID of the signaled interrupt. This read acts as an acknowledge for the interrupt.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_IAR0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RO	-	-	RO

When accessed as ICC_IAR0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	-	RO	RO	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

ICC_IAR0(S) is architecturally mapped to AArch64 register ICC_IAR0_EL1 (S).

ICC_IAR0(NS) is architecturally mapped to AArch64 register ICC_IAR0_EL1 (NS).

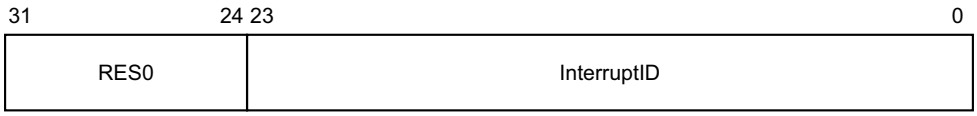
In Secure state, this register is the interrupt acknowledge register for Group 0 interrupts. In Non-secure state, this is the IAR for Group 1 interrupts.

Attributes

ICC_IAR0 is a 32-bit register.

Field descriptions

The ICC_IAR0 bit assignments are:



Bits [31:24]

Reserved, RES0.

InterruptID, bits [23:0]

The ID of the signaled interrupt. IDs 1020 to 1023 are reserved and convey additional information such as spurious interrupts.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_IAR0

To access the ICC_IAR0:

```
MRC p15,0,<Rt>,c12,c8,0 ; Read ICC_IAR0 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1000	000

G5.5.20 ICC_IAR1, Interrupt Controller Interrupt Acknowledge Register 1

The ICC_IAR1 characteristics are:

Purpose

The processor reads this register to obtain the interrupt ID of the signaled Group 1 interrupt. This read acts as an acknowledge for the interrupt.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

ICC_IAR1 is architecturally mapped to AArch64 register ICC_IAR1_EL1.

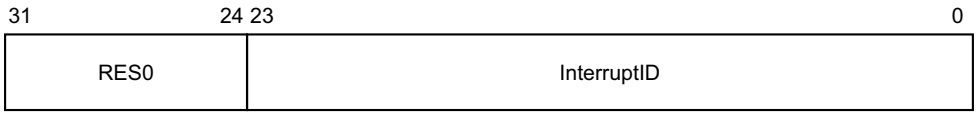
This register is an alias of the Non-secure view of ICC_IAR0, and a Secure access to this register is identical to a Non-secure access to ICC_IAR0.

Attributes

ICC_IAR1 is a 32-bit register.

Field descriptions

The ICC_IAR1 bit assignments are:



Bits [31:24]

Reserved, RES0.

InterruptID, bits [23:0]

The ID of the signaled interrupt. IDs 1020 to 1023 are reserved and convey additional information such as spurious interrupts.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_IAR1

To access the ICC_IAR1:

```
MRC p15,0,<Rt>,c12,c12,0 ; Read ICC_IAR1 into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1100	000

G5.5.21 ICC_IGRPEN0, Interrupt Controller Interrupt Group 0 Enable register

The ICC_IGRPEN0 characteristics are:

Purpose

Controls whether Group 0 interrupts are enabled or not.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_IGRPEN0(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as ICC_IGRPEN0(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

The lowest exception level at which this register may be accessed is governed by the exception level to which FIQ is routed. This routing depends on SCR.FIQ, SCR.NS and HCR.FMO.

If an interrupt is pending within the CPU interface when Enable becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different processor.

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

ICC_IGRPEN0(S) is architecturally mapped to AArch64 register ICC_IGRPEN0_EL1 (S).

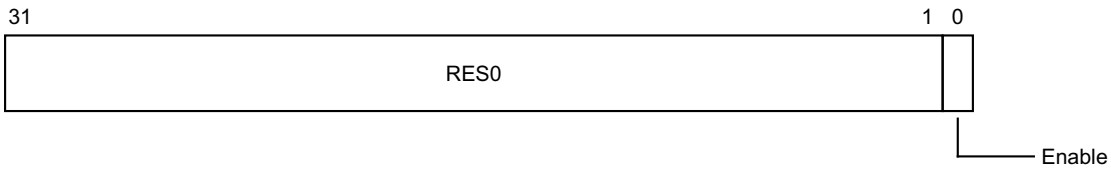
ICC_IGRPEN0(NS) is architecturally mapped to AArch64 register ICC_IGRPEN0_EL1 (NS).

Attributes

ICC_IGRPEN0 is a 32-bit register.

Field descriptions

The ICC_IGRPEN0 bit assignments are:



Bits [31:1]

Reserved, RES0.

Accessing the ICC_IGRPEN0

To access the ICC_IGRPEN0:

```
MRC p15,0,<Rt>,c12,c12,6 ; Read ICC_IGRPEN0 into Rt
MCR p15,0,<Rt>,c12,c12,6 ; Write Rt to ICC_IGRPEN0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1100	110

G5.5.22 ICC_IGRPEN1, Interrupt Controller Interrupt Group 1 Enable register

The ICC_IGRPEN1 characteristics are:

Purpose

Controls whether Group 1 interrupts are enabled for the current security state.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

The lowest exception level at which this register may be accessed is governed by the exception level to which FIQ is routed. This routing depends on SCR.FIQ, SCR.NS and HCR.FMO.

If an interrupt is pending within the CPU interface when Enable becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different processor.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

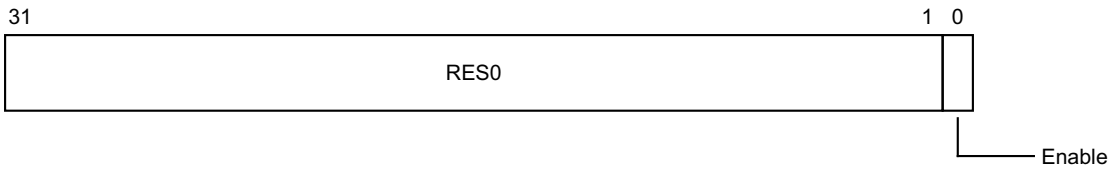
ICC_IGRPEN1 is architecturally mapped to AArch64 register ICC_IGRPEN1_EL1.

Attributes

ICC_IGRPEN1 is a 32-bit register.

Field descriptions

The ICC_IGRPEN1 bit assignments are:



Bits [31:1]

Reserved, RES0.

Accessing the ICC_IGRPEN1

To access the ICC_IGRPEN1:

```
MRC p15,0,<Rt>,c12,c12,7 ; Read ICC_IGRPEN1 into Rt
MCR p15,0,<Rt>,c12,c12,7 ; Write Rt to ICC_IGRPEN1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1100	111

G5.5.23 ICC_MCTLR, Interrupt Controller Monitor Control Register

The ICC_MCTLR characteristics are:

Purpose

Controls aspects of the behavior of the GIC CPU interface and provides information about the features implemented.

This register is part of:

- the GIC registers functional group
- the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

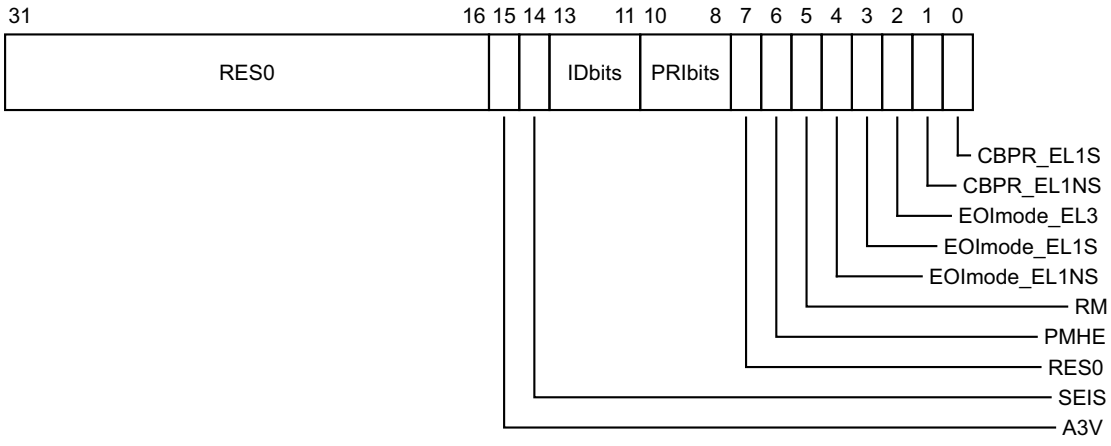
ICC_MCTLR is architecturally mapped to AArch64 register ICC_CTLR_EL3.

Attributes

ICC_MCTLR is a 32-bit register.

Field descriptions

The ICC_MCTLR bit assignments are:



Bits [31:16]

Reserved, RES0.

A3V, bit [15]

Affinity 3 Valid. Read-only. Possible values are:

`0` The CPU interface logic only supports zero values of Affinity 3 in SGI generation system registers.

`1` The CPU interface logic supports non-zero values of Affinity 3 in SGI generation system registers.

Virtual accesses return the value from ICH_VTR.A3V.

SEIS, bit [14]

SEI Support. Read-only. Indicates whether the CPU interface supports generation of SEIs:

0 The CPU interface logic does not support generation of SEIs.

1 The CPU interface logic supports generation of SEIs.

Virtual accesses return the value from ICH_VTR.SEIS.

IDbits, bits [13:11]

The number of physical interrupt identifier bits supported:

000 16 bits.

001 24 bits.

All other values are reserved.

Reset value is architecturally UNKNOWN.

PRIbits, bits [10:8]

The number of priority bits implemented, minus one. Read-only.

Bit [7]

Reserved, RES0.

PMHE, bit [6]

Priority Mask Hint Enable.

When set, enables use of the PMR as a hint for interrupt distribution.

Resets to 0.

RM, bit [5]

Routing Modifier. This bit is used to modify the behavior of ICC_IAR0 and ICC_IAR1 such that systems with legacy secure software may be supported correctly.

0 Reading ICC_IAR0 and ICC_IAR1 at EL3 acknowledges interrupts normally.

1 Reading ICC_IAR0 and ICC_IAR1 at EL3 returns special values:

- Reading ICC_IAR0 at EL3 returns ID 1020, indicating the interrupt should be handled at Secure EL1.
- Reading ICC_IAR1 at EL3 returns ID 1021, indicating the interrupt should be handled at Non-secure EL1 or EL2.

Reset value is architecturally UNKNOWN.

EOImode_EL1NS, bit [4]

EOI mode for interrupts handled at non-secure EL1 and EL2.

Reset value is architecturally UNKNOWN.

EOImode_EL1S, bit [3]

EOI mode for interrupts handled at secure EL1.

Reset value is architecturally UNKNOWN.

EOImode_EL3, bit [2]

EOI mode for interrupts handled at EL3.

Reset value is architecturally UNKNOWN.

CBPR_EL1NS, bit [1]

When set, non-secure accesses to GICC_BPR and ICC_BPR1 access the state of ICC_BPR0. ICC_BPR0 is used to determine the preemption group for Non-secure Group 1 interrupts.

Reset value is architecturally UNKNOWN.

CBPR_EL1S, bit [0]

When set, secure EL1 accesses to ICC_BPR1 access the state of ICC_BPR0. ICC_BPR0 is used to determine the preemption group for Secure Group 1 interrupts.

Reset value is architecturally UNKNOWN.

Accessing the ICC_MCTLR

To access the ICC_MCTLR:

```
MRC p15,6,<Rt>,c12,c12,4 ; Read ICC_MCTLR into Rt
MCR p15,6,<Rt>,c12,c12,4 ; Write Rt to ICC_MCTLR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	110	1100	1100	100

G5.5.24 ICC_MGRPEN1, Interrupt Controller Monitor Interrupt Group 1 Enable register

The ICC_MGRPEN1 characteristics are:

Purpose

Controls whether Group 1 interrupts are enabled or not.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW	RW

If an interrupt is pending within the CPU interface when an Enable bit becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different processor.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

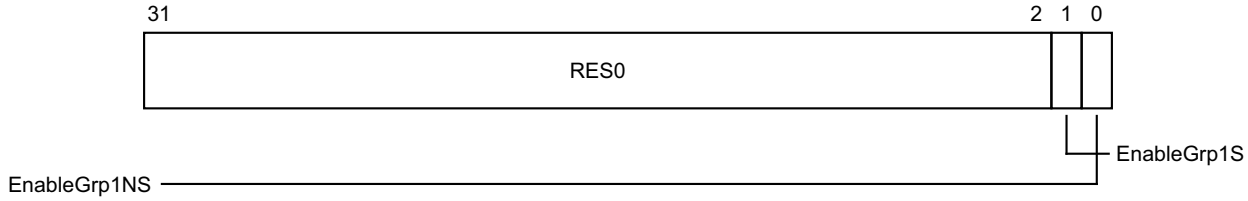
ICC_MGRPEN1 is architecturally mapped to AArch64 register ICC_IGRPEN1_EL3.

Attributes

ICC_MGRPEN1 is a 32-bit register.

Field descriptions

The ICC_MGRPEN1 bit assignments are:



Bits [31:2]

Reserved, RES0.

EnableGrp1S, bit [1]

Enables Group 1 interrupts for the Secure state.

0 Group 1 interrupts are disabled for the Secure state.

1 Group 1 interrupts are enabled for the Secure state.

Resets to 0.

EnableGrp1NS, bit [0]

Enables Group 1 interrupts for the Non-secure state.

0 Group 1 interrupts are disabled for the Non-secure state.

1 Group 1 interrupts are enabled for the Non-secure state.

Resets to 0.

Accessing the ICC_MGRPEN1

To access the ICC_MGRPEN1:

```
MRC p15,6,<Rt>,c12,c12,7 ; Read ICC_MGRPEN1 into Rt
MCR p15,6,<Rt>,c12,c12,7 ; Write Rt to ICC_MGRPEN1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	110	1100	1100	111

G5.5.25 ICC_MSRE, Interrupt Controller Monitor System Register Enable register

The ICC_MSRE characteristics are:

Purpose

Controls whether the system register interface or the memory mapped interface to the GIC CPU interface is used for EL2.

This register is part of:

- the GIC registers functional group
- the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	-	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

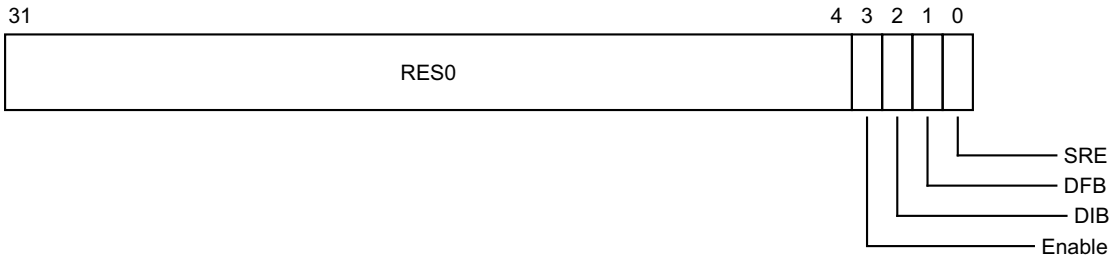
ICC_MSRE is architecturally mapped to AArch64 register ICC_SRE_EL3.

Attributes

ICC_MSRE is a 32-bit register.

Field descriptions

The ICC_MSRE bit assignments are:



Bits [31:4]

Reserved, RES0.

Enable, bit [3]

Enable. Enables lower exception level access to ICC_SRE_EL1 and ICC_SRE_EL2.

0 EL1 and EL2 accesses to ICC_SRE_EL1 or ICC_SRE_EL2 trap to EL3.

1 EL2 accesses to ICC_SRE_EL2 are permitted. If the Enable bit of ICC_SRE_EL2 is 1, then EL1 accesses to ICC_SRE_EL1 are also permitted.

Resets to 0.

DIB, bit [2]

Disable IRQ bypass.

Resets to 0.

DFB, bit [1]

Disable FIQ bypass.

Resets to 0.

SRE, bit [0]

System Register Enable.

0 The memory mapped interface must be used. Access at EL3 to any ICH_* system register, or any EL1, EL2, or EL3 ICC_* register other than ICC_SRE, ICC_HSRE, or ICC_MSRE, results in an Undefined exception.

1 The system register interface to the ICH_* registers and the EL1, EL2, and EL3 ICC_* registers is enabled for EL3.

Resets to 0.

Accessing the ICC_MSRE

To access the ICC_MSRE:

```
MRC p15,6,<Rt>,c12,c12,5 ; Read ICC_MSRE into Rt
MCR p15,6,<Rt>,c12,c12,5 ; Write Rt to ICC_MSRE
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	110	1100	1100	101

G5.5.26 ICC_PMR, Interrupt Controller Interrupt Priority Mask Register

The ICC_PMR characteristics are:

Purpose

Provides an interrupt priority filter. Only interrupts with higher priority than the value in this register are signaled to the processor.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

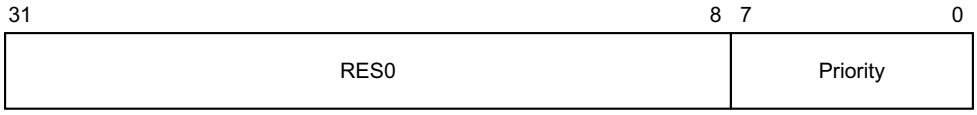
ICC_PMR is architecturally mapped to AArch64 register ICC_PMR_EL1.

Attributes

ICC_PMR is a 32-bit register.

Field descriptions

The ICC_PMR bit assignments are:



Bits [31:8]

Reserved, RES0.

Priority, bits [7:0]

The priority mask level for the CPU interface. If the priority of an interrupt is higher than the value indicated by this field, the interface signals the interrupt to the processor.

If the GIC supports fewer than 256 priority levels then some bits are RAZ/WI, as follows:

`128 supported levels`Bit [0] = 0.

`64 supported levels`Bits [1:0] = `0b00`.

`32 supported levels`Bits [2:0] = `0b000`.

`16 supported levels`Bits [3:0] = `0b0000`.

The possible priority field values are as follows:

Implemented priority bits	Possible priority field values	Number of priority levels
[7:0]	0x00-0xFF (0-255), all values	256
[7:1]	0x00-0xFE (0-254), even values only	128
[7:2]	0x00-0xFC (0-252), in steps of 4	64
[7:3]	0x00-0xF8 (0-248), in steps of 8	32
[7:4]	0x00-0xF0 (0-240), in steps of 16	16

Accessing the ICC_PMR

To access the ICC_PMR:

```
MRC p15,0,<Rt>,c4,c6,0 ; Read ICC_PMR into Rt
MCR p15,0,<Rt>,c4,c6,0 ; Write Rt to ICC_PMR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	0100	0110	000

G5.5.27 ICC_RPR, Interrupt Controller Running Priority Register

The ICC_RPR characteristics are:

Purpose

Indicates the Running priority of the CPU interface.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RO	RO	RO	RO	RO

If there is no active interrupt on the CPU interface, the value returned is the Idle priority.

Software cannot determine the number of implemented priority bits from a read of this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

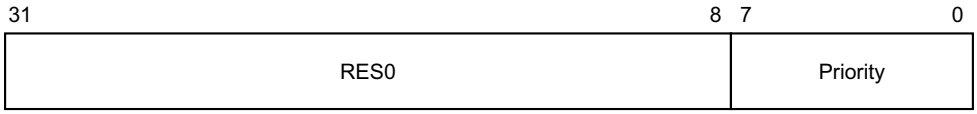
ICC_RPR is architecturally mapped to AArch64 register ICC_RPR_EL1.

Attributes

ICC_RPR is a 32-bit register.

Field descriptions

The ICC_RPR bit assignments are:



Bits [31:8]

Reserved, RES0.

Priority, bits [7:0]

The current running priority on the CPU interface. This is the priority of the current active interrupt.

Accessing the ICC_RPR

To access the ICC_RPR:

```
MRC p15,0,<Rt>,c12,c11,3 ; Read ICC_RPR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1011	011

G5.5.28 ICC_SEIEN, Interrupt Controller System Error Interrupt Enable register

The ICC_SEIEN characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED controls for SError Interrupts generated by bus message.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	RW	RW	RW	RW

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

ICC_SEIEN is architecturally mapped to AArch64 register ICC_SEIEN_EL1.

Attributes

ICC_SEIEN is a 32-bit register.

Field descriptions

The ICC_SEIEN bit assignments are:

Accessing the ICC_SEIEN

To access the ICC_SEIEN:

```
MRC p15,0,<Rt>,c12,c13,0 ; Read ICC_SEIEN into Rt
MCR p15,0,<Rt>,c12,c13,0 ; Write Rt to ICC_SEIEN
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1101	000

G5.5.29 ICC_SGI0R, Interrupt Controller Software Generated Interrupt group 0 Register

The ICC_SGI0R characteristics are:

Purpose

Provides software the ability to generate secure group 0 SGIs, including from the Non-secure state when permitted by GICR_NSACR.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	WO	WO	WO	WO

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

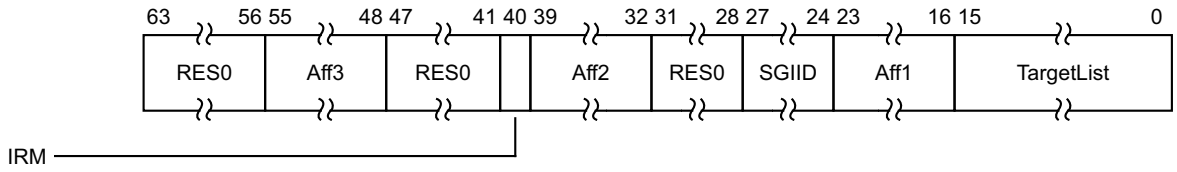
ICC_SGI0R is architecturally mapped to AArch64 register ICC_SGI0R_EL1.

Attributes

ICC_SGI0R is a 64-bit register.

Field descriptions

The ICC_SGI0R bit assignments are:



Bits [63:56]

Reserved, RES0.

Aff3, bits [55:48]

The affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [47:41]

Reserved, RES0.

IRM, bit [40]

Interrupt Routing Mode. Determines how the generated interrupts should be distributed to processors. Possible values are:

`0` Interrupts routed to the processors specified by a.b.c.{target list}. In this routing, a, b, and c are the values of fields Aff3, Aff2, and Aff1 respectively.

`1` Interrupts routed to all processors in the system, excluding self.

Aff2, bits [39:32]

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [31:28]

Reserved, RES0.

SGIID, bits [27:24]

SGI Interrupt ID.

Aff1, bits [23:16]

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated.

TargetList, bits [15:0]

Target List. The set of processors for which SGI interrupts will be generated. Each bit corresponds to the processor within a cluster with an Affinity 0 value equal to the bit number.

If a bit is 1 and the bit does not correspond to a valid target processor, the bit must be ignored by the Distributor. In such cases, a Distributor may optionally generate an SError interrupt.

This restricts distribution of SGIs to the first 16 processors of an affinity 1 cluster.

Accessing the ICC_SGI0R

To access the ICC_SGI0R:

```
MCRR p15,2,<Rt>,<Rt2>,c12 ; Write Rt (low word) and Rt2 (high word) to 64-bit ICC_SGI0R
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0010	1100

G5.5.30 ICC_SGI1R, Interrupt Controller Software Generated Interrupt group 1 Register

The ICC_SGI1R characteristics are:

Purpose

Provides software the ability to generate group 1 SGIs for the current security state.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_SGI1R(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	-	-	WO

When accessed as ICC_SGI1R(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	WO	-	WO	WO	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

ICC_SGI1R(S) is architecturally mapped to AArch64 register ICC_SGI1R_EL1 (S).

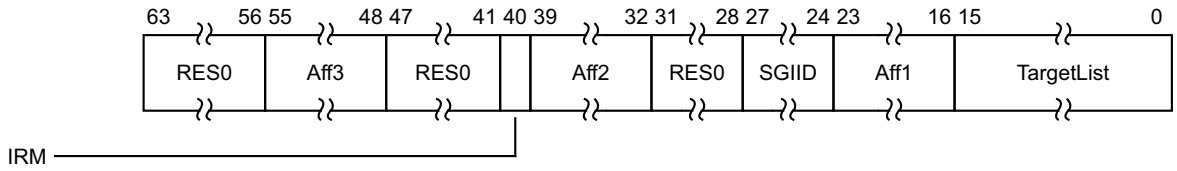
ICC_SGI1R(NS) is architecturally mapped to AArch64 register ICC_SGI1R_EL1 (NS).

Attributes

ICC_SGI1R is a 64-bit register.

Field descriptions

The ICC_SGI1R bit assignments are:



Bits [63:56]

Reserved, RES0.

Aff3, bits [55:48]

The affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [47:41]

Reserved, RES0.

IRM, bit [40]

Interrupt Routing Mode. Determines how the generated interrupts should be distributed to processors. Possible values are:

`0` Interrupts routed to the processors specified by a.b.c.{target list}. In this routing, a, b, and c are the values of fields Aff3, Aff2, and Aff1 respectively.

`1` Interrupts routed to all processors in the system, excluding self.

Aff2, bits [39:32]

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [31:28]

Reserved, RES0.

SGIID, bits [27:24]

SGI Interrupt ID.

Aff1, bits [23:16]

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated.

TargetList, bits [15:0]

Target List. The set of processors for which SGI interrupts will be generated. Each bit corresponds to the processor within a cluster with an Affinity 0 value equal to the bit number.

If a bit is 1 and the bit does not correspond to a valid target processor, the bit must be ignored by the Distributor. In such cases, a Distributor may optionally generate an SError interrupt.

This restricts distribution of SGIs to the first 16 processors of an affinity 1 cluster.

Accessing the ICC_SGI1R

To access the ICC_SGI1R:

```
MCRR p15,0,<Rt>,<Rt2>,c12 ; Write Rt (low word) and Rt2 (high word) to 64-bit ICC_SGI1R
```

Register access is encoded as follows:

coproc	opc1	CRm
1111	0000	1100

G5.5.31 ICC_SRE, Interrupt Controller System Register Enable register

The ICC_SRE characteristics are:

Purpose

Controls whether the system register interface or the memory mapped interface to the GIC CPU interface is used for EL0 and EL1.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_SRE(S):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	-	-	RW

When accessed as ICC_SRE(NS):

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	RW	-	RW	RW	-

Configurations

If EL3 is using AArch32, there are separate Secure and Non-secure instances of this register.

ICC_SRE(S) is architecturally mapped to AArch64 register ICC_SRE_EL1 (S).

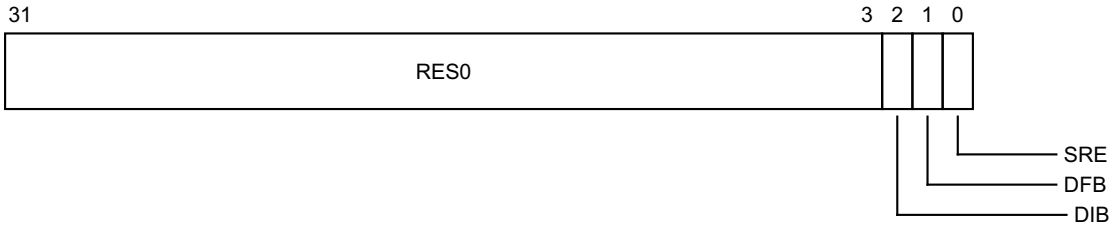
ICC_SRE(NS) is architecturally mapped to AArch64 register ICC_SRE_EL1 (NS).

Attributes

ICC_SRE is a 32-bit register.

Field descriptions

The ICC_SRE bit assignments are:



Bits [31:3]

Reserved, RES0.

DIB, bit [2]

Disable IRQ bypass.

If EL3 is present, this field is a read-only alias of ICC_MSRE.DIB.

If EL3 is not present and EL2 is present, this field is a read-only alias of ICC_HSRE.DIB.

Resets to 0.

DFB, bit [1]

Disable FIQ bypass.

If EL3 is present, this field is a read-only alias of ICC_MSRE.DFB.

If EL3 is not present and EL2 is present, this field is a read-only alias of ICC_HSRE.DFB.

Resets to 0.

SRE, bit [0]

System Register Enable.

0 The memory mapped interface must be used. Access at EL1 to any ICC_* system register other than ICC_SRE results in an Undefined exception.

1 The system register interface for the current security state is enabled.

Virtual accesses modify ICH_VMCR.VSRE.

Resets to 0.

Accessing the ICC_SRE

To access the ICC_SRE:

```
MRC p15,0,<Rt>,c12,c12,5 ; Read ICC_SRE into Rt
MCR p15,0,<Rt>,c12,c12,5 ; Write Rt to ICC_SRE
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	000	1100	1100	101

G5.5.32 ICH_AP0R0, Interrupt Controller Hyp Active Priorities Register (0,0)

The ICH_AP0R0 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

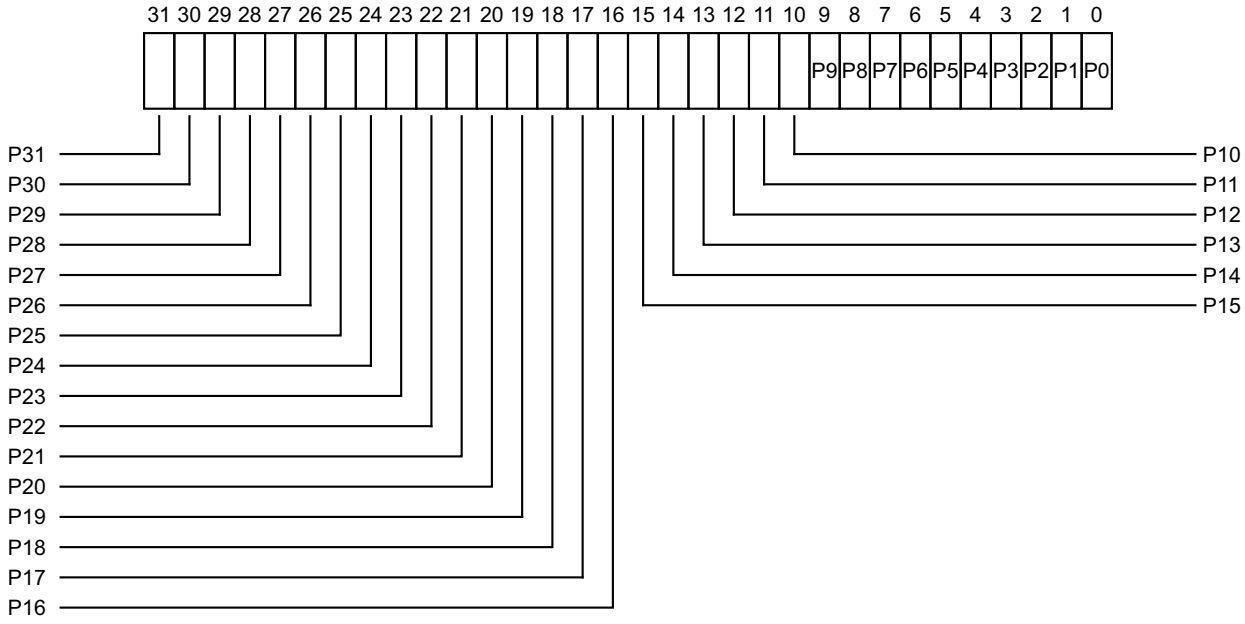
ICH_AP0R0 is architecturally mapped to AArch64 register ICH_AP0R0_EL2.

Attributes

ICH_AP0R0 is a 32-bit register.

Field descriptions

The ICH_AP0R0 bit assignments are:



P<n>, bit [n], for n = 0 to 31

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP0R0

To access the ICH_AP0R0:

```
MRC p15,4,<Rt>,c12,c8,0 ; Read ICH_AP0R0 into Rt
MCR p15,4,<Rt>,c12,c8,0 ; Write Rt to ICH_AP0R0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1000	000

G5.5.33 ICH_AP0R1, Interrupt Controller Hyp Active Priorities Register (0,1)

The ICH_AP0R1 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

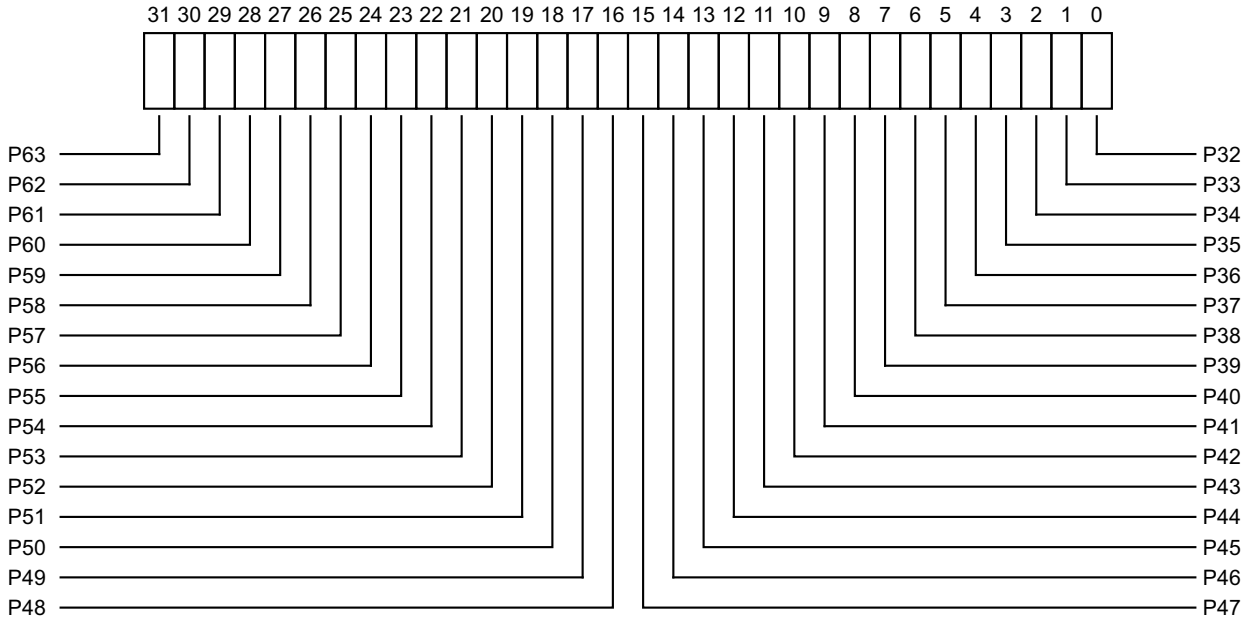
ICH_AP0R1 is architecturally mapped to AArch64 register ICH_AP0R1_EL2.

Attributes

ICH_AP0R1 is a 32-bit register.

Field descriptions

The ICH_AP0R1 bit assignments are:



P<n>, bit [(n-32)], for (n-32) = 32 to 63

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP0R1

To access the ICH_AP0R1:

```
MRC p15,4,<Rt>,c12,c8,1 ; Read ICH_AP0R1 into Rt
MCR p15,4,<Rt>,c12,c8,1 ; Write Rt to ICH_AP0R1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1000	001

G5.5.34 ICH_AP0R2, Interrupt Controller Hyp Active Priorities Register (0,2)

The ICH_AP0R2 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

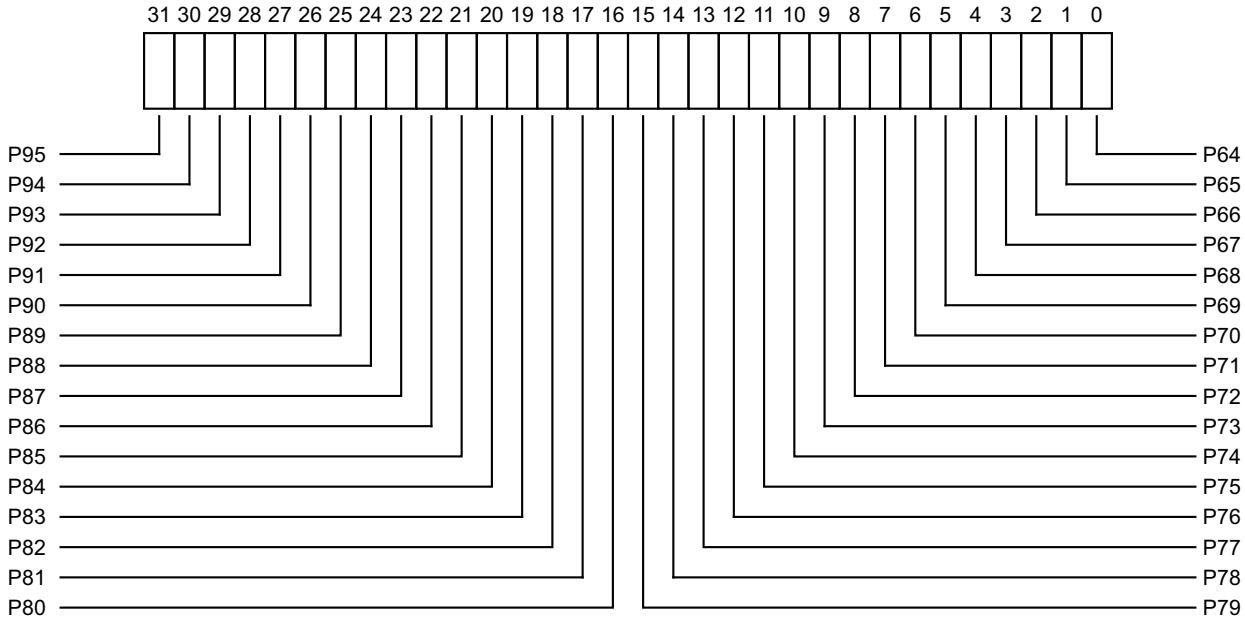
ICH_AP0R2 is architecturally mapped to AArch64 register ICH_AP0R2_EL2.

Attributes

ICH_AP0R2 is a 32-bit register.

Field descriptions

The ICH_AP0R2 bit assignments are:



P<n>, bit [(n-64)], for (n-64) = 64 to 95

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP0R2

To access the ICH_AP0R2:

```
MRC p15,4,<Rt>,c12,c8,2 ; Read ICH_AP0R2 into Rt
MCR p15,4,<Rt>,c12,c8,2 ; Write Rt to ICH_AP0R2
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1000	010

G5.5.35 ICH_AP0R3, Interrupt Controller Hyp Active Priorities Register (0,3)

The ICH_AP0R3 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

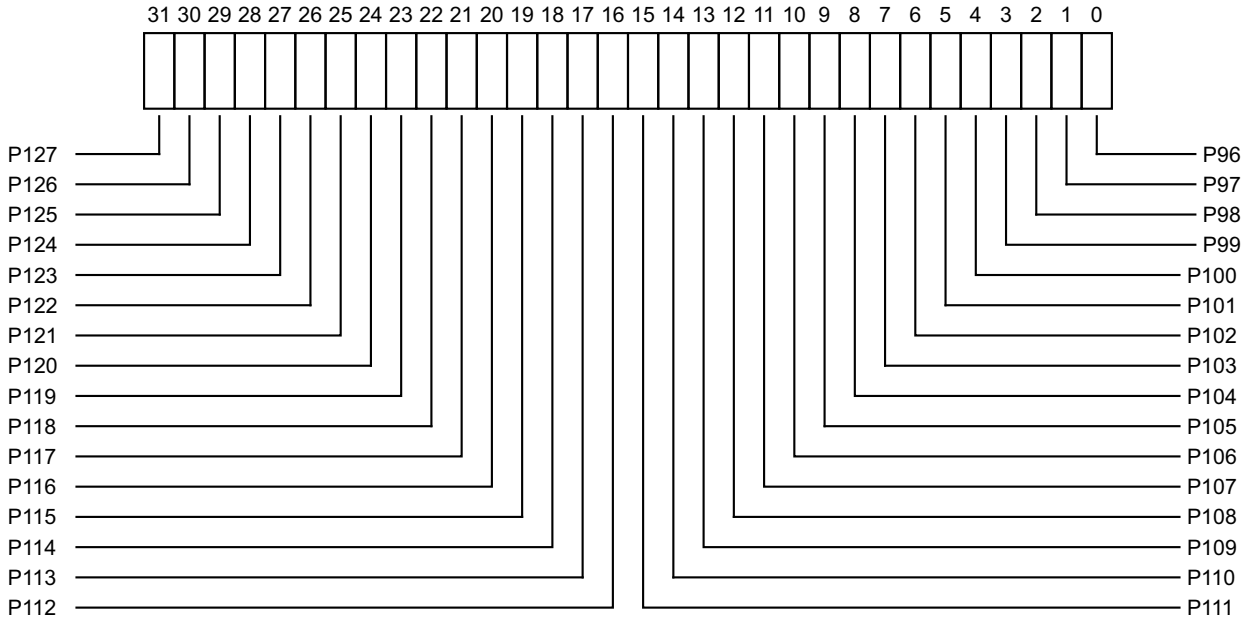
ICH_AP0R3 is architecturally mapped to AArch64 register ICH_AP0R3_EL2.

Attributes

ICH_AP0R3 is a 32-bit register.

Field descriptions

The ICH_AP0R3 bit assignments are:



P<n>, bit [(n-96)], for (n-96) = 96 to 127

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP0R3

To access the ICH_AP0R3:

```
MRC p15,4,<Rt>,c12,c8,3 ; Read ICH_AP0R3 into Rt
MCR p15,4,<Rt>,c12,c8,3 ; Write Rt to ICH_AP0R3
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1000	011

G5.5.36 ICH_AP1R0, Interrupt Controller Hyp Active Priorities Register (1,0)

The ICH_AP1R0 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

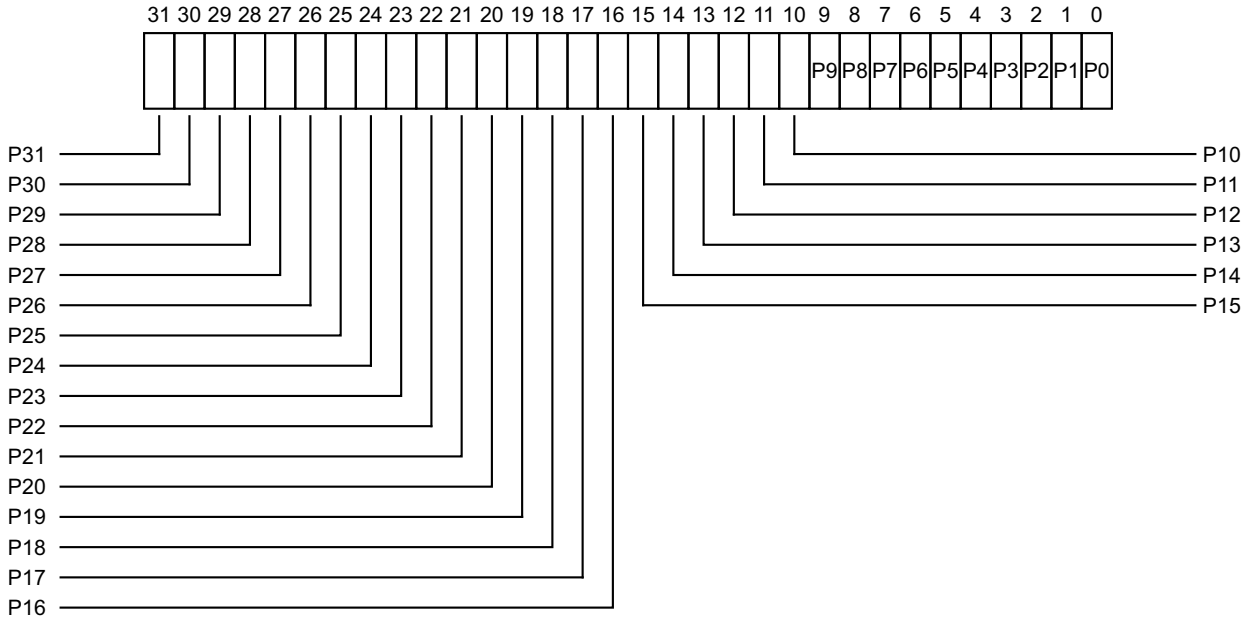
ICH_AP1R0 is architecturally mapped to AArch64 register ICH_AP1R0_EL2.

Attributes

ICH_AP1R0 is a 32-bit register.

Field descriptions

The ICH_AP1R0 bit assignments are:



P<n>, bit [n], for n = 0 to 31

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP1R0

To access the ICH_AP1R0:

```
MRC p15,4,<Rt>,c12,c9,0 ; Read ICH_AP1R0 into Rt
MCR p15,4,<Rt>,c12,c9,0 ; Write Rt to ICH_AP1R0
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1001	000

G5.5.37 ICH_AP1R1, Interrupt Controller Hyp Active Priorities Register (1,1)

The ICH_AP1R1 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

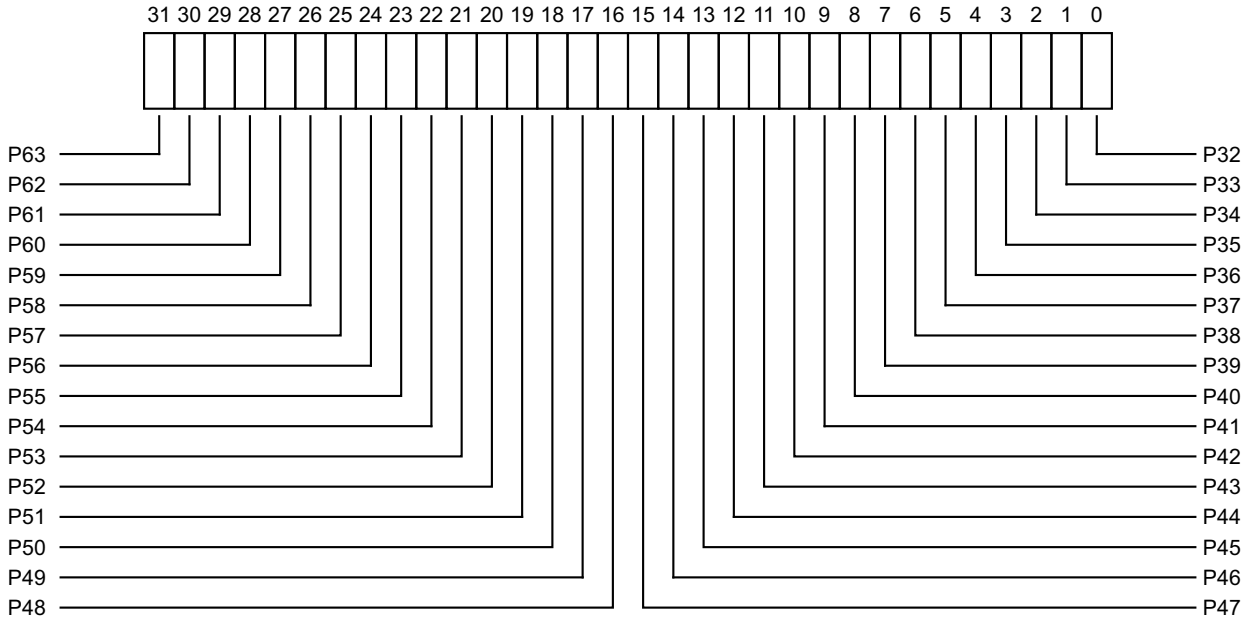
ICH_AP1R1 is architecturally mapped to AArch64 register ICH_AP1R1_EL2.

Attributes

ICH_AP1R1 is a 32-bit register.

Field descriptions

The ICH_AP1R1 bit assignments are:



P<n>, bit [(n-32)], for (n-32) = 32 to 63

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP1R1

To access the ICH_AP1R1:

```
MRC p15,4,<Rt>,c12,c9,1 ; Read ICH_AP1R1 into Rt
MCR p15,4,<Rt>,c12,c9,1 ; Write Rt to ICH_AP1R1
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1001	001

G5.5.38 ICH_AP1R2, Interrupt Controller Hyp Active Priorities Register (1,2)

The ICH_AP1R2 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

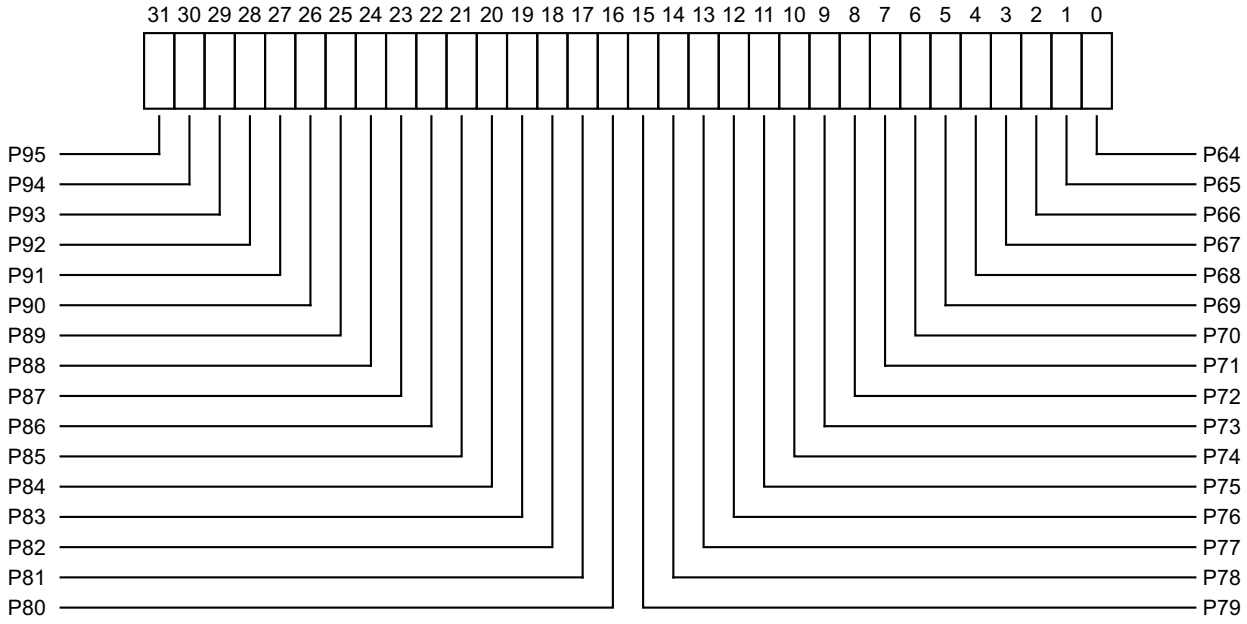
ICH_AP1R2 is architecturally mapped to AArch64 register ICH_AP1R2_EL2.

Attributes

ICH_AP1R2 is a 32-bit register.

Field descriptions

The ICH_AP1R2 bit assignments are:



P<n>, bit [(n-64)], for (n-64) = 64 to 95

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP1R2

To access the ICH_AP1R2:

```
MRC p15,4,<Rt>,c12,c9,2 ; Read ICH_AP1R2 into Rt
MCR p15,4,<Rt>,c12,c9,2 ; Write Rt to ICH_AP1R2
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1001	010

G5.5.39 ICH_AP1R3, Interrupt Controller Hyp Active Priorities Register (1,3)

The ICH_AP1R3 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

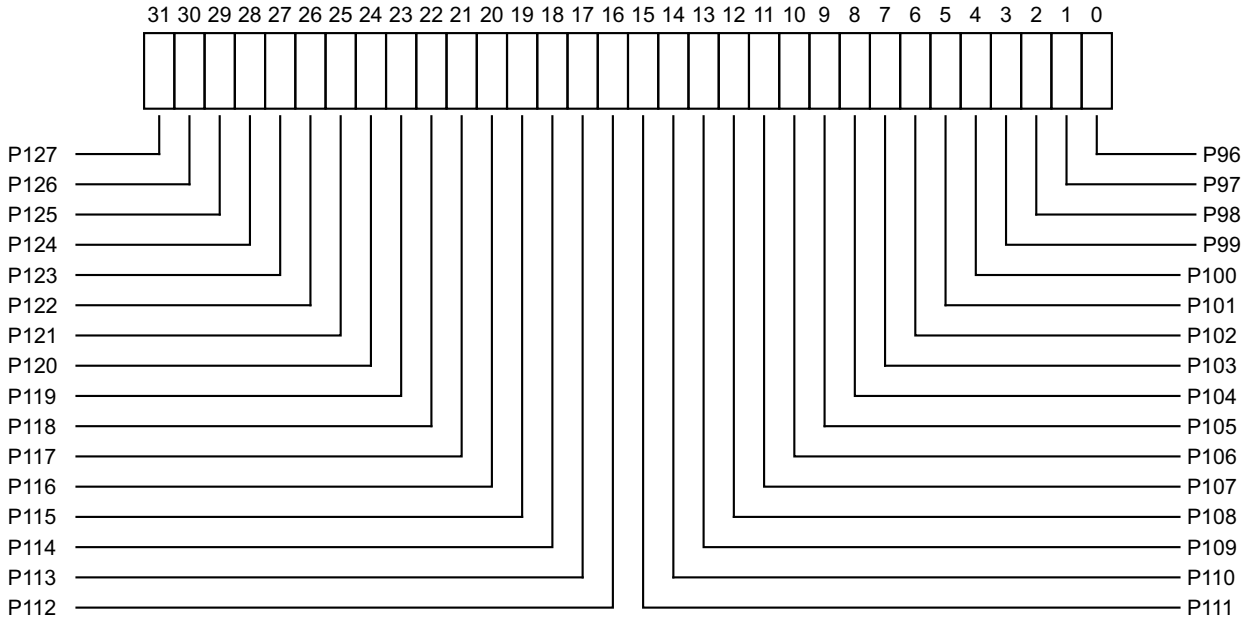
ICH_AP1R3 is architecturally mapped to AArch64 register ICH_AP1R3_EL2.

Attributes

ICH_AP1R3 is a 32-bit register.

Field descriptions

The ICH_AP1R3 bit assignments are:



P<n>, bit [(n-96)], for (n-96) = 96 to 127

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP1R3

To access the ICH_AP1R3:

```
MRC p15,4,<Rt>,c12,c9,3 ; Read ICH_AP1R3 into Rt
MCR p15,4,<Rt>,c12,c9,3 ; Write Rt to ICH_AP1R3
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1001	011

G5.5.40 ICH_EISR, Interrupt Controller End of Interrupt Status Register

The ICH_EISR characteristics are:

Purpose

When a maintenance interrupt is received, this register helps determine which List registers have outstanding EOI interrupts that require servicing.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RO	RO	-

Configurations

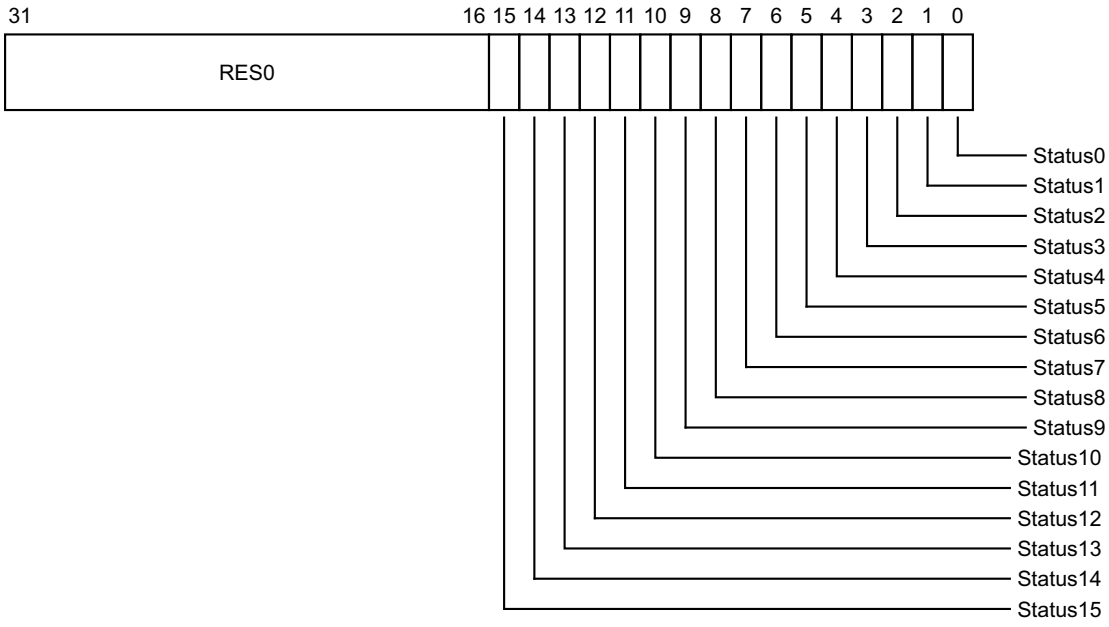
ICH_EISR is architecturally mapped to AArch64 register ICH_EISR_EL2.

Attributes

ICH_EISR is a 32-bit register.

Field descriptions

The ICH_EISR bit assignments are:



Bits [31:16]

Reserved, RES0.

Status<n>, bit [n], for n = 0 to 15

EOI status bit for List register <n>:

`0` List register <n>, ICH_LR<n>_EL2, does not have an EOI.

`1` List register <n>, ICH_LR<n>_EL2, has an EOI.

For any ICH_LR<n>_EL2, the corresponding status bit is set to 1 if ICH_LR<n>_EL2.State is `0b00` and ICH_LR<n>_EL2.HW is 0 and ICH_LR<n>_EL2.EOI is 1.

Accessing the ICH_EISR

To access the ICH_EISR:

```
MRC p15,4,<Rt>,c12,c11,3 ; Read ICH_EISR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1011	011

G5.5.41 ICH_ELSR, Interrupt Controller Empty List Register Status Register

The ICH_ELSR characteristics are:

Purpose

This register can be used to locate a usable List register when the hypervisor is delivering an interrupt to a Guest OS.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RO	RO	-

Configurations

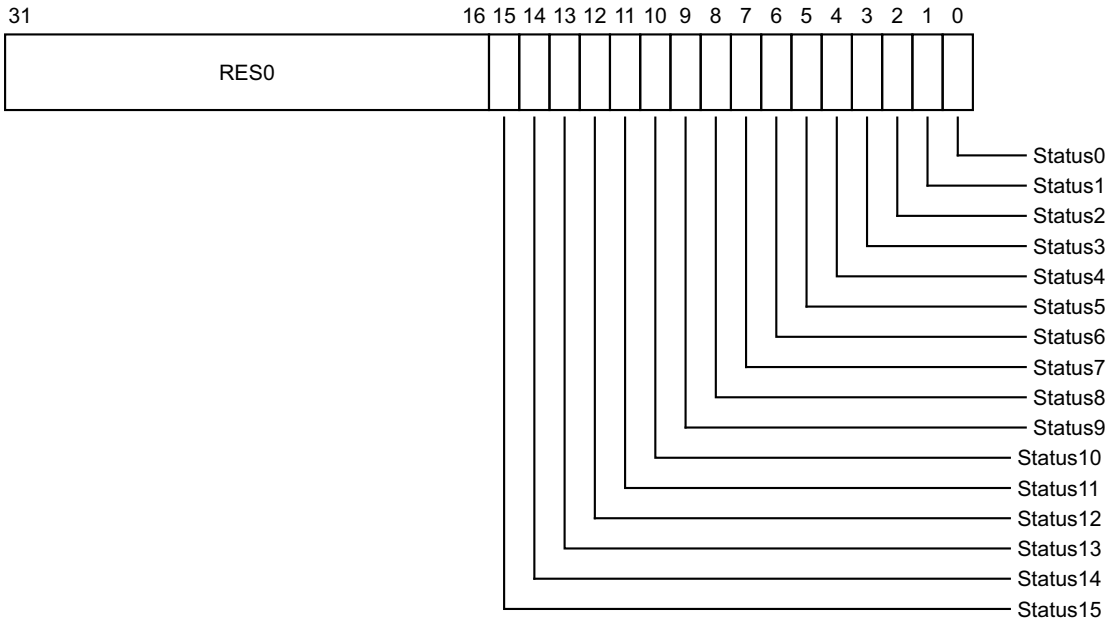
ICH_ELSR is architecturally mapped to AArch64 register ICH_ELSR_EL2.

Attributes

ICH_ELSR is a 32-bit register.

Field descriptions

The ICH_ELSR bit assignments are:



Bits [31:16]

Reserved, RES0.

Status<n>, bit [n], for n = 0 to 15

Status bit for List register <n>, ICH_LR<n>_EL2:

`0` List register ICH_LR<n>_EL2, if implemented, contains a valid interrupt. Using this List register can result in overwriting a valid interrupt.

`1` List register ICH_LR<n>_EL2 does not contain a valid interrupt. The List register is empty and can be used without overwriting a valid interrupt or losing an EOI maintenance interrupt.

For any ICH_LR<n>_EL2, the corresponding status bit is set to 1 if ICH_LR<n>_EL2.State is `0b00` and either ICH_LR<n>_EL2.HW is 1 or ICH_LR<n>_EL2.EOI is 0.

Accessing the ICH_ELSR

To access the ICH_ELSR:

```
MRC p15,4,<Rt>,c12,c11,5 ; Read ICH_ELSR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1011	101

G5.5.42 ICH_HCR, Interrupt Controller Hyp Control Register

The ICH_HCR characteristics are:

Purpose

Controls the environment for guest operating systems.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

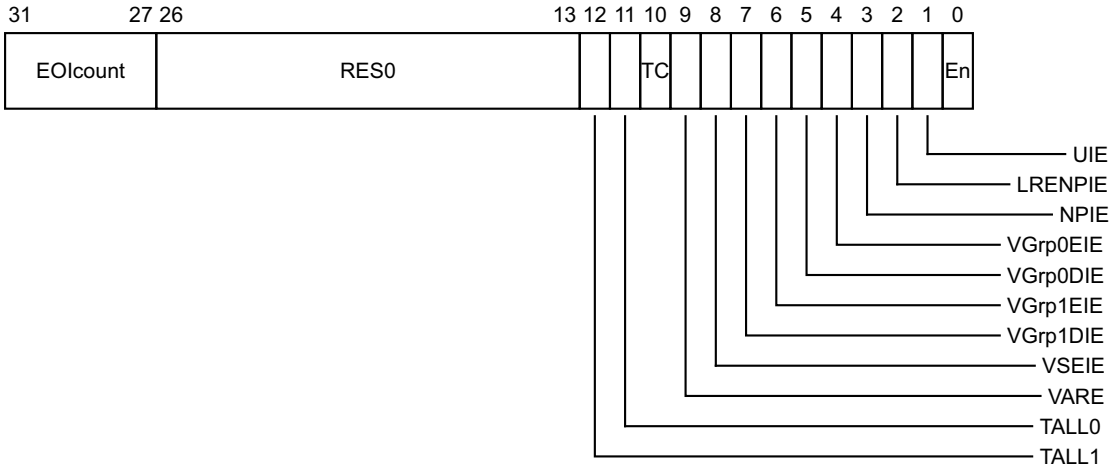
ICH_HCR is architecturally mapped to AArch64 register ICH_HCR_EL2.

Attributes

ICH_HCR is a 32-bit register.

Field descriptions

The ICH_HCR bit assignments are:



EOIcount, bits [31:27]

Counts the number of EOIs received that do not have a corresponding entry in the List registers. The virtual CPU interface increments this field automatically when a matching EOI is received.

EOIs that do not clear a bit in one of the Active Priorities registers ICH_APmRn do not cause an increment.

Although not possible under correct operation, if an EOI occurs when the value of this field is 31, this field wraps to 0.

The maintenance interrupt is asserted whenever this field is non-zero and the LRENPIE bit is set to 1.

Bits [26:13]

Reserved, RES0.

TALL1, bit [12]

Trap all Non-secure EL1 accesses to ICC_* system registers for group 1 interrupts to EL2.

0 Non-Secure EL1 accesses to ICC_* registers for group 1 interrupts proceed as normal.

1 Any Non-secure EL1 accesses to ICC_* registers for group 1 interrupts trap to EL2.

TALL0, bit [11]

Trap all Non-secure EL1 accesses to ICC_* system registers for group 0 interrupts to EL2.

0 Non-Secure EL1 accesses to ICC_* registers for group 0 interrupts proceed as normal.

1 Any Non-secure EL1 accesses to ICC_* registers for group 0 interrupts trap to EL2.

TC, bit [10]

Trap all Non-secure El1 accesses to system registers that are common to group 0 and group 1 to EL2.

0 Non-secure EL1 accesses to common registers proceed as normal.

1 Any Non-secure EL1 accesses to common registers trap to EL2.

This affects ICC_DIR, ICC_PMR, and ICC_RPR.

VARE, bit [9]

Virtual ARE.

0 The guest operating system does not use affinity routing and expects a Source CPU ID for SGIs.

1 The guest operating system uses affinity routing.

When VARE is 0, the guest operating system does not support LPIs and software must ensure that no LPIs are presented to the guest either using the List registers or from the Distributor.

VSEIE, bit [8]

Virtual SEI Enable. Enables the signaling of a maintenance interrupt when performing a virtual access to a system register and a condition that would result in an (optional) SEI for a physical access is detected.

0 VSEIE maintenance interrupt is disabled.

1 VSEIE maintenance interrupt is enabled.

VGrp1DIE, bit [7]

VM Disable Group 1 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 1 interrupts from the virtual CPU interface to the connected virtual machine is disabled:

0 Maintenance interrupt disabled.

1 Maintenance interrupt signaled while GICV_CTLR.EnableGrp1 is set to 0.

VGrp1EIE, bit [6]

VM Enable Group 1 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 1 interrupts from the virtual CPU interface to the connected virtual machine is enabled:

0 Maintenance interrupt disabled.

1 Maintenance interrupt signaled while GICV_CTLR.EnableGrp1 is set to 1.

VGrp0DIE, bit [5]

VM Disable Group 0 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 0 interrupts from the virtual CPU interface to the connected virtual machine is disabled:

0 Maintenance interrupt disabled.

1 Maintenance interrupt signaled while GICV_CTLR.EnableGrp0 is set to 0.

VGrp0EIE, bit [4]

VM Enable Group 0 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 0 interrupts from the virtual CPU interface to the connected virtual machine is enabled:

0 Maintenance interrupt disabled.

1 Maintenance interrupt signaled while GICV_CTLR.EnableGrp0 is set to 1.

NPIE, bit [3]

No Pending Interrupt Enable. Enables the signaling of a maintenance interrupt while no pending interrupts are present in the List registers:

0 Maintenance interrupt disabled.

1 Maintenance interrupt signaled while the List registers contain no interrupts in the pending state.

LRENPIE, bit [2]

List Register Entry Not Present Interrupt Enable. Enables the signaling of a maintenance interrupt while the virtual CPU interface does not have a corresponding valid List register entry for an EOI request:

0 Maintenance interrupt disabled.

1 A maintenance interrupt is asserted while the EOIcount field is not 0.

UIE, bit [1]

Underflow Interrupt Enable. Enables the signaling of a maintenance interrupt when the List registers are empty, or hold only one valid entry:

0 Maintenance interrupt disabled.

1 A maintenance interrupt is asserted if none, or only one, of the List register entries is marked as a valid interrupt.

En, bit [0]

Enable. Global enable bit for the virtual CPU interface:

0 Virtual CPU interface operation disabled.

1 Virtual CPU interface operation enabled.

When this field is set to 0:

- The virtual CPU interface does not signal any maintenance interrupts.
- The virtual CPU interface does not signal any virtual interrupts.
- A read of GICV_IAR or GICV_AIAR returns a spurious interrupt ID.

Accessing the ICH_HCR

To access the ICH_HCR:

```
MRC p15,4,<Rt>,c12,c11,0 ; Read ICH_HCR into Rt
MCR p15,4,<Rt>,c12,c11,0 ; Write Rt to ICH_HCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1011	000

G5.5.43 ICH_LRC<n>, Interrupt Controller List Registers, n = 0 - 15

The ICH_LRC<n> characteristics are:

Purpose

Provides interrupt context information for the virtual CPU interface.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

ICH_LR<n> and ICH_LRC<n> may be updated independently.

Configurations

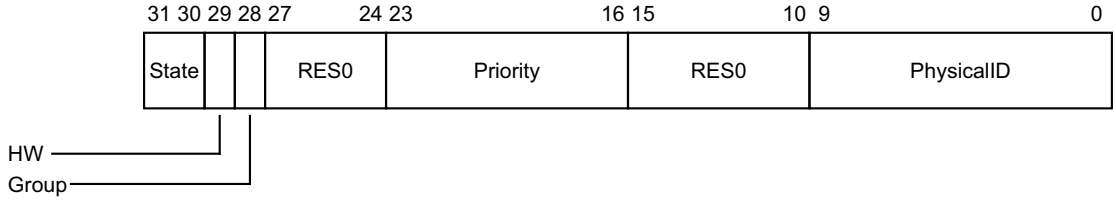
ICH_LRC<n> is architecturally mapped to AArch64 register ICH_LR<n>_EL2[63:32].

Attributes

ICH_LRC<n> is a 32-bit register.

Field descriptions

The ICH_LRC<n> bit assignments are:



State, bits [31:30]

The state of the interrupt:

`00` Invalid

`01` Pending

`10` Active

11 Pending and active.

The GIC updates these state bits as virtual interrupts proceed through the interrupt life cycle. Entries in the invalid state are ignored, except for the purpose of generating virtual maintenance interrupts.

For hardware interrupts, the pending and active state is held in the physical Distributor rather than the virtual CPU interface. A hypervisor must only use the pending and active state for software originated interrupts, which are typically associated with virtual devices, or SGIs.

HW, bit [29]

Indicates whether this virtual interrupt is a hardware interrupt, meaning that it corresponds to a physical interrupt. Deactivation of the virtual interrupt also causes the deactivation of the physical interrupt with the ID that the PhysicalID field indicates.

`0` The interrupt is triggered entirely in software. No notification is sent to the Distributor when the virtual interrupt is deactivated.

`1` The interrupt is a hardware interrupt. A deactivate interrupt request is sent to the Distributor when the virtual interrupt is deactivated, using the PhysicalID field from this register to indicate the physical interrupt ID.

If GICV_CTLR.EOImode is 0, this request corresponds to a write to the GICV_EOIR or GICV_AEOIR, otherwise it corresponds to a write to the GICV_DIR.

Bits [27:24]

Reserved, RES0.

Priority, bits [23:16]

The priority of this interrupt.

It is IMPLEMENTATION DEFINED how many bits of priority are implemented, though at least five bits must be implemented. Unimplemented bits are RES0 and start from bit [48] up to bit [50]. The number of implemented bits can be discovered from ICH_VTR_EL2.PRIbits, and determines how many GICH_APR<n> registers exist.

Bits [15:10]

Reserved, RES0.

PhysicalID, bits [9:0]

Physical ID, for hardware interrupts.

When HW is 0 (i.e. there is no corresponding physical interrupt), some of these bits have a special meaning:

`Bit [39]` EOI. When this bit is 1, a maintenance interrupt is asserted to signal EOI when the interrupt state is invalid, which typically occurs when the interrupt is deactivated.

`Bits [38:32]`Reserved, RES0.

A hardware physical identifier is only required in List Registers for interrupts that require an EOI or Deactivate. This means only 10 bits of Physical ID are required, regardless of the number specified by ICC_CTLR_EL1.IDbits.

Accessing the ICH_LRC<n>

To access the ICH_LRC<n>:

```
MRC p15,4,<Rt>,c12,<CRm>,<opc2> ; Read ICH_LRC<n> into Rt, where n is in the range 0 to 15
MCR p15,4,<Rt>,c12,<CRm>,<opc2> ; Write Rt to ICH_LRC<n>, where n is in the range 0 to 15
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	111:n<3>	n<2:0>

G5.5.44 ICH_LR<n>, Interrupt Controller List Registers, n = 0 - 15

The ICH_LR<n> characteristics are:

Purpose

Provides interrupt context information for the virtual CPU interface.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

ICH_LR<n> and ICH_LRC<n> may be updated independently.

Configurations

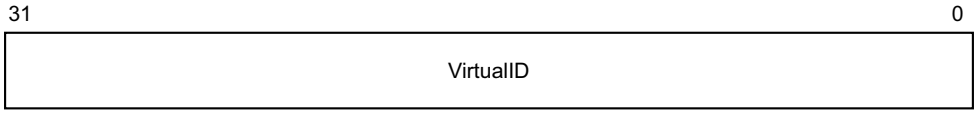
ICH_LR<n> is architecturally mapped to AArch64 register ICH_LR<n>_EL2[31:0].

Attributes

ICH_LR<n> is a 32-bit register.

Field descriptions

The ICH_LR<n> bit assignments are:



VirtualID, bits [31:0]

Virtual ID of the interrupt.

When VARE is zero, software must ensure the correct Source CPU ID is provided in bits [12:10].

Software must ensure there is only a single valid entry for a given VirtualID.

It is IMPLEMENTATION DEFINED how many bits are implemented, though at least 16 bits must be implemented. Unimplemented bits are RES0. The number of implemented bits can be discovered from ICH_VTR_EL2.IDbits.

Accessing the ICH_LR<n>

To access the ICH_LR<n>:

```
MRC p15,4,<Rt>,c12,<CRm>,<opc2> ; Read ICH_LR<n> into Rt, where n is in the range 0 to 15
MCR p15,4,<Rt>,c12,<CRm>,<opc2> ; Write Rt to ICH_LR<n>, where n is in the range 0 to 15
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	110:n<3>	n<2:0>

G5.5.45 ICH_MISR, Interrupt Controller Maintenance Interrupt State Register

The ICH_MISR characteristics are:

Purpose

Indicates which maintenance interrupts are asserted.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RO	RO	-

Configurations

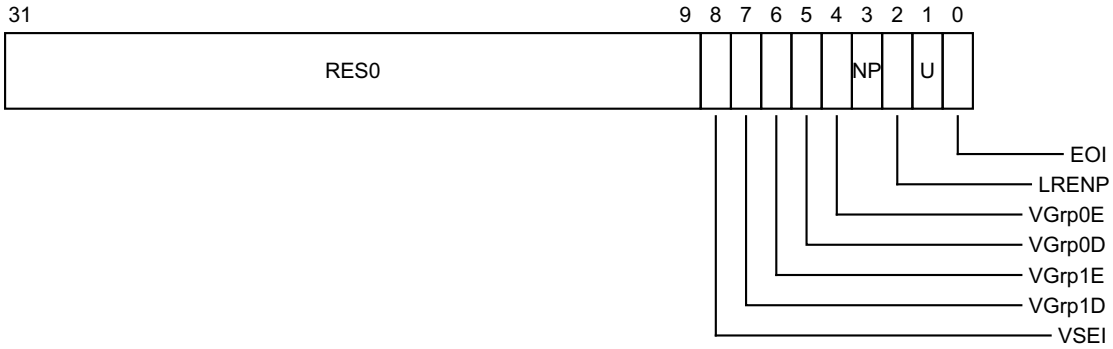
ICH_MISR is architecturally mapped to AArch64 register ICH_MISR_EL2.

Attributes

ICH_MISR is a 32-bit register.

Field descriptions

The ICH_MISR bit assignments are:



Bits [31:9]

Reserved, RES0.

VSEI, bit [8]

Virtual SEI. Set to 1 when a condition that would result in generation of an SEI is detected during a virtual access to an ICC_* system register.

VGrp1D, bit [7]

Disabled Group 1 maintenance interrupt.

Asserted whenever ICH_HCR_EL2.VGrp1DIE is 1 and ICH_VMCR_EL2.VMGrp1En is 0.

VGrp1E, bit [6]

Enabled Group 1 maintenance interrupt.

Asserted whenever ICH_HCR_EL2.VGrp1EIE is 1 and ICH_VMCR_EL2.VMGrp1En is 1.

VGrp0D, bit [5]

Disabled Group 0 maintenance interrupt.

Asserted whenever ICH_HCR_EL2.VGrp0DIE is 1 and ICH_VMCR_EL2.VMGrp0En is 0.

VGrp0E, bit [4]

Enabled Group 0 maintenance interrupt.

Asserted whenever ICH_HCR_EL2.VGrp0EIE is 1 and ICH_VMCR_EL2.VMGrp0En is 1.

NP, bit [3]

No Pending maintenance interrupt.

Asserted whenever ICH_HCR_EL2.NPIE is 1 and no List register is in pending state.

LRENP, bit [2]

List Register Entry Not Present maintenance interrupt.

Asserted whenever ICH_HCR_EL2.LRENPIE is 1 and ICH_HCR_EL2.EOIcount is non-zero.

U, bit [1]

Underflow maintenance interrupt.

Asserted whenever ICH_HCR_EL2.UIE is 1 and if none, or only one, of the List register entries are marked as a valid interrupt, that is, if the corresponding ICH_LR<n>_EL2.State bits do not equal `0x0`.

EOI, bit [0]

EOI maintenance interrupt.

Asserted whenever at least one List register is asserting an EOI interrupt. That is, when at least one bit in ICH_EISR0_EL1 or ICH_EISR1_EL1 is 1.

Accessing the ICH_MISR

To access the ICH_MISR:

```
MRC p15,4,<Rt>,c12,c11,2 ; Read ICH_MISR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1011	010

G5.5.46 ICH_VMCR, Interrupt Controller Virtual Machine Control Register

The ICH_VMCR characteristics are:

Purpose

Enables the hypervisor to save and restore the virtual machine view of the GIC state.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

When EL2 is using system register access, EL1 using either system register or memory-mapped access must be supported.

Configurations

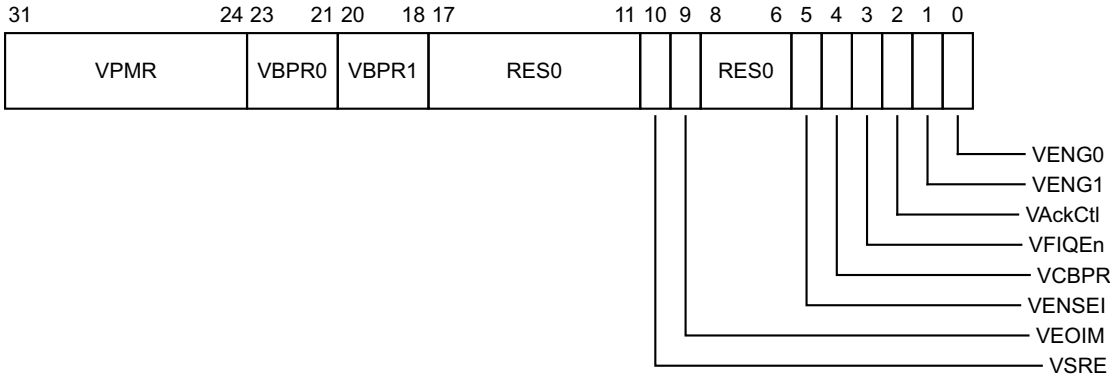
ICH_VMCR is architecturally mapped to AArch64 register ICH_VMCR_EL2.

Attributes

ICH_VMCR is a 32-bit register.

Field descriptions

The ICH_VMCR bit assignments are:



VPMR, bits [31:24]

Virtual Priority Mask.

Visible to the guest OS as ICC_PMR_EL1 / GICV_PMR.

VBPR0, bits [23:21]

Virtual BPR0.

Visible to the guest OS as ICC_BPR0_EL1 / GICV_BPR.

VBPR1, bits [20:18]

Virtual BPR1.

Visible to the guest OS as ICC_BPR1_EL1 / GICV_ABPR.

Bits [17:11]

Reserved, RES0.

VSRE, bit [10]

Virtual SRE.

Visible to the guest OS as ICC_SRE_EL1.SRE.

If EL2 is not configured to use system registers, this bit is treated as if it is 0.

VEOIM, bit [9]

Virtual EOImode.

Visible to the guest OS as ICC_CTLR_EL1.EOImode / GICV_CTLR.EOImode.

Bits [8:6]

Reserved, RES0.

VENSEI, bit [5]

IMPLEMENTATION DEFINED control of Virtual SEIs.

If an implementation does not have functionality associated with this bit, ARM recommends that the bit is RES0.

VCBPR, bit [4]

Virtual CBPR.

Visible to the guest OS as ICC_CTLR_EL1.CBPR / GICV_CTLR.CBPR.

VFIQEn, bit [3]

Virtual FIQ enable.

Visible to the guest OS as GICV_CTLR.FIQEn.

VAckCtl, bit [2]

Virtual AckCtl.

Visible to the guest OS as GICV_CTLR.AckCtl.

VENG1, bit [1]

Virtual group 1 interrupt enable.

Visible to the guest OS as ICC_IGRPEN1_EL1.Enable / GICV_CTLR.EnableGrp1.

VENG0, bit [0]

Virtual group 0 interrupt enable.

Visible to the guest OS as ICC_IGRPEN0_EL1.Enable / GICV_CTLR.EnableGrp0.

Accessing the ICH_VMCR

To access the ICH_VMCR:

```
MRC p15,4,<Rt>,c12,c11,7 ; Read ICH_VMCR into Rt
MCR p15,4,<Rt>,c12,c11,7 ; Write Rt to ICH_VMCR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1011	111

G5.5.47 ICH_VSEIR, Interrupt Controller Virtual System Error Interrupt Register

The ICH_VSEIR characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED generation of virtual SError interrupts.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW	-

Configurations

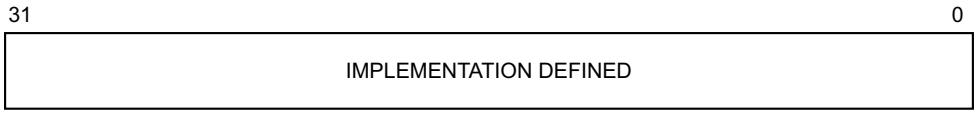
ICH_VSEIR is architecturally mapped to AArch64 register ICH_VSEIR_EL2.

Attributes

ICH_VSEIR is a 32-bit register.

Field descriptions

The ICH_VSEIR bit assignments are:



Accessing the ICH_VSEIR

To access the ICH_VSEIR:

```
MRC p15,4,<Rt>,c12,c9,4 ; Read ICH_VSEIR into Rt
MCR p15,4,<Rt>,c12,c9,4 ; Write Rt to ICH_VSEIR
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1001	100

G5.5.48 ICH_VTR, Interrupt Controller VGIC Type Register

The ICH_VTR characteristics are:

Purpose

Describes the number of implemented virtual priority bits and List registers.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0 (NS)	EL0 (S)	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RO	RO	-

Configurations

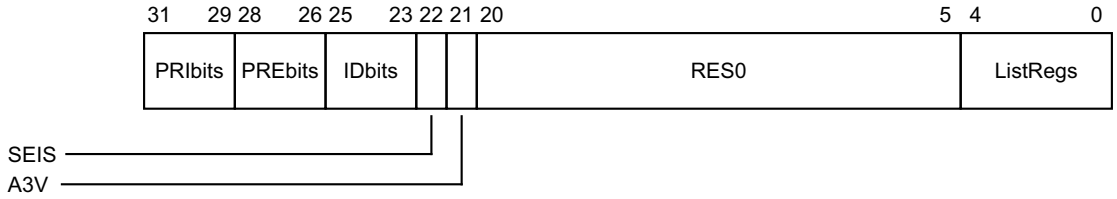
ICH_VTR is architecturally mapped to AArch64 register ICH_VTR_EL2.

Attributes

ICH_VTR is a 32-bit register.

Field descriptions

The ICH_VTR bit assignments are:



PRIbits, bits [31:29]

The number of virtual priority bits implemented, minus one.

PREbits, bits [28:26]

The number of virtual preemption bits implemented, minus one.

IDbits, bits [25:23]

The number of virtual interrupt identifier bits supported:

`000` 16 bits.

`001` 24 bits.

All other values are reserved.

SEIS, bit [22]

SEI Support. Indicates whether the virtual CPU interface supports generation of SEIs:

`0` The virtual CPU interface logic does not support generation of SEIs.

`1` The virtual CPU interface logic supports generation of SEIs.

Virtual system errors may still be generated by writing to ICH_VSEIR_EL2 regardless of the value of this field.

A3V, bit [21]

Affinity 3 Valid. Possible values are:

`0` The virtual CPU interface logic only supports zero values of Affinity 3 in SGI generation system registers.

`1` The virtual CPU interface logic supports non-zero values of Affinity 3 in SGI generation system registers.

Bits [20:5]

Reserved, RES0.

ListRegs, bits [4:0]

The number of implemented List registers, minus one. For example, a value of `0b01111` indicates that the maximum of 16 List registers are implemented.

Accessing the ICH_VTR

To access the ICH_VTR:

```
MRC p15,4,<Rt>,c12,c11,1 ; Read ICH_VTR into Rt
```

Register access is encoded as follows:

coproc	opc1	CRn	CRm	opc2
1111	100	1100	1011	001

Part H
External Debug

Chapter H1
Introduction to External Debug

This chapter introduces the external debug components of ARMv8. It contains the following sections:

- *Introduction to external debug* on page H1-4390.
- *External debug* on page H1-4391.

Note

For information about self-hosted debug, see Chapter D2 *AArch64 Self-hosted Debug* and Chapter G2 *AArch32 Self-hosted Debug*.

H1.1 Introduction to external debug

ARMv8 supports both:

Self-hosted debug

The PE itself hosts a debugger. That is, developers developing software to run on the PE use debugger software running on the same PE.

External debug

The debugger is external to the PE. The debugging might be either on-chip, for example in a second PE, or off-chip, for example a JTAG debugger. External debug is particularly useful for:

- Hardware bring-up. That is, debugging during development when a system is first powered up and not all of the software functionality is available.
- PEs that are deeply embedded inside systems.

To support external debug, the ARM architecture defines required features that are called *external debug features.*

Note

When the description of external debug in this part of the manual describes a debugger as controlling external debug this might be a second on-chip PE or a processor in an off-chip device such as a JTAG debugger.

H1.2 External debug

The following halting debug events are available in ARMv8:

- *Halting Step debug event* on page H3-4438:
  - The debugger can use this resource to make the PE step through code one line at a time.
- *Halt Instruction debug event* on page H3-4448:
  - This might occur when software executes the Halting software breakpoint instruction, `HLT`.
- *Exception Catch debug event* on page H3-4449:
  - This can be programmed to occur on all entries to a given Exception level.
- *External Debug Request debug event* on page H3-4452:
  - An embedded cross-trigger can signal this debug event.
- *OS Unlock Catch debug event* on page H3-4453:
  - This might occur when the state of the OS Lock changes from locked to unlocked.
- *Reset Catch debug event* on page H3-4454:
  - This might occur when the PE exits reset state.
- *Software Access debug event* on page H3-4455:
  - This can be programmed to occur when software tries to access the Breakpoint Value registers, the Breakpoint Control registers, the Watchpoint value registers, or the Watchpoint Control registers. It caused a trap to Debug state.

Halting debug events allow an external debugger to halt the PE. Breakpoints and watchpoints can also halt the PE. The PE then enters Debug state. When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state:
  - The ITR contains a single register, EDITR, and associated flow-control flags.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger:
  - The DCC includes the data transfer registers, DTRRX and DTRTX, and associated flow-control flags.
  - Although the DCC is an essential part of Debug state operation, it can also be used in Non-debug state.
- The PE cannot service any interrupts in Debug state.

Chapter H2 *Debug State* describes Debug state in more detail.

Chapter H2
Debug State

This chapter describes Debug state. It contains the following sections:

- *About Debug state* on page H2-4394.
- *Halting the PE on debug events* on page H2-4395.
- *Entering Debug state* on page H2-4403.
- *Behavior in Debug state* on page H2-4407.
- *Exiting Debug state* on page H2-4433.

Note

Table J-1 on page AppxJ-5170 disambiguates the general register references used in this chapter.

H2.1 About Debug state

In external debug, debug events allow an external debugger to halt the PE. The PE then enters Debug state. When the PE is in Debug state:

- It stops executing instructions from the location indicated by the program counter, and is instead controlled through the external debug interface.
- The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state.
- The *Debug Communications Channel*, DCC, passes data between the PE and the debugger.

The PE cannot service any interrupts in Debug state.

H2.2 Halting the PE on debug events

For details of debug events see *Introduction to Halting debug events* on page H3-4436 and *Breakpoint and Watchpoint debug events* on page H2-4396.

On a debug event, the PE must do one of the following:

- Enter Debug state.
- Pend the debug event.
- Generate a debug exception.
- Ignore the debug event.

This behavior depends on both:

- Whether halting is allowed by the current state of the debug authentication interface. See *Halting allowed and halting prohibited*.
- The type of debug event and the programming of the debug control registers.
  - See *Halting debug events* for all Halting debug events.
  - See *Breakpoint and Watchpoint debug events* on page H2-4396 for Breakpoint and Watchpoint debug events.

See also *Other debug exceptions* on page H2-4397.

This means that behavior can be UNPREDICTABLE if the conditions change. See *Synchronization and Halting debug events* on page H3-4456.

Summary of debug events and possible outcomes on page H3-4436 summarizes the possible outcomes of each type of debug event.

H2.2.1 Halting allowed and halting prohibited

Halting can be either allowed or prohibited:

- Halting is always prohibited in Debug state.
- Halting is always prohibited when `DoubleLockStatus()` == TRUE.
  - This means that OS Double Lock is locked, that is EDPRSR.DLK == 1.
- Halting is also controlled by the IMPLEMENTATION DEFINED authentication interface, and is prohibited when either:
  - The PE is in Non-secure state and `ExternalInvasiveDebugEnabled()` == FALSE.
  - The PE is in Secure state and `ExternalSecureInvasiveDebugEnabled()` == FALSE.

  Note

  See Appendix B *Recommended External Debug Interface* for more information on these functions.
- Otherwise, halting is allowed.

See *Pseudocode details of Halting on debug events* on page H2-4401.

H2.2.2 Halting debug events

When a Halting debug event is generated, it causes entry to Debug state if both:

- Halting is allowed. See *Halting allowed and halting prohibited*.
- The Halting debug event is either:
  - A Halt Instruction debug event when Halting debug is enabled. This means that EDSCR.HDE == 1.
  - Not a Halt Instruction debug event.

Note

— An Halt Instruction debug event is the only Halting debug event that relies on EDSCR.HDE == 1. This is to prevent malicious code from causing an entry Debug state. EDSCR.HDE == 0 on a Cold reset.

— Halting on Breakpoint and Watchpoint Software debug events is also controlled by EDSCR.HDE. See *Breakpoint and Watchpoint debug events*.

— EDSCR.HDE can be written by software when the OS Lock is locked. Privileged code can use SDCR.TDOSA and HDCR.TDOSA to trap writes to these registers.

If a Halting debug event does not generate entry to Debug state because the conditions listed in this section do not hold, then:

- If the Halting debug event is a Halt Instruction debug event, it generates an Undefined Instruction exception.
- If the Halting debug event is an Exception Catch debug event or a Software Access debug event, it is ignored.
- In all other cases the Halting debug event is pended, meaning that:
  - The pending Halting debug event is recorded in EDESR.
  - The pending Halting debug event is taken when halting is allowed. See *Pending Halting debug events* on page H3-4456.

Pending Halting debug events are discarded by a Cold reset. The debugger can also force a pending event to be dropped by writing to EDESR. *Summary of actions from debug events* on page H2-4400 summarizes the possible outcome for each type of Debug event.

Note

Halting debug events never generate Debug exceptions.

H2.2.3 Breakpoint and Watchpoint debug events

A breakpoint or watchpoint generates an entry to Debug state if all of the following conditions hold:

- Halting debug is enabled, that is EDSCR.HDE == 1.
- Halting is allowed. See *Halting allowed and halting prohibited* on page H2-4395.
- The OS Lock is unlocked, that is OSLSR.OSLK == 0.

The Address Mismatch breakpoint type is reserved when all of these conditions are met.

MDSCR_EL1.MDE or DBGDSCRext.MDBGen is ignored when determining whether to enter Debug state. A breakpoint or watchpoint that generates entry to Debug state is a Breakpoint or Watchpoint debug event and does not generate a debug exception.

A breakpoint or watchpoint that does not generate an entry to Debug state either:

- Generates a Breakpoint or Watchpoint exception.
- Is ignored.

Note

EDSCR.HDE is ignored when determining whether to generate a debug exception. The debug exception is suppressed only if the PE enters Debug state. This means that the use of Halting-debug mode in Non-secure state does not affect the Exception model in Secure state.

See Chapter D2 *AArch64 Self-hosted Debug*, Chapter G2 *AArch32 Self-hosted Debug*, and the Note in *Other debug exceptions* on page H2-4397.

H2.2.4 Other debug exceptions

The following events never generate entry to Debug state:

- Software Breakpoint Instruction exceptions.
- Software Step exceptions.
- Vector Catch exceptions.

The behavior of these events is unchanged when Halting debug mode is enabled, that is when EDSCR.HDE == 1. This means that these events can do one of the following:

- They can generate a debug exception.
- They can be ignored.

For additional information, see Chapter D2 *AArch64 Self-hosted Debug* and Chapter G2 *AArch32 Self-hosted Debug*.

H2.2.5 Debug state entry and debug event prioritization

The architecture does not define when asynchronous Halting debug events are taken, and therefore the prioritization of asynchronous debug events is IMPLEMENTATION DEFINED.

Synchronous Halting debug events do have a priority order.

The following are synchronous Halting debug events:

- Halting Step debug event.
- Halt Instruction debug event.
- Exception Catch debug event.
- Software Access debug event.
- Reset Catch debug event.

Each of these synchronous Halting debug events is treated as a synchronous exception generated by an instruction, or by the taking of an exception or reset. That is, the synchronous Halting debug event must be taken before any subsequent instructions are executed. Reset Catch debug events must be taken before the PE executes the instruction at the reset vector.

Note

Reset Catch and Exception Catch debug events can be generated asynchronously, because they can result from an asynchronous exception. However, if halting is allowed after the asynchronous exception has been processed, the Reset Catch or Exception Catch debug event is taken synchronously.

The Halting Step debug event is generated by the instruction after the stepped instruction. Therefore, if the stepped instruction generates any other synchronous exceptions or debug events, these are taken first.

OS Unlock Catch debug events are always pended and taken asynchronously.

Halting Step debug events and Reset Catch debug events might be pended and taken asynchronously at a later time.

The following list shows how the events are prioritized, with -2 being the highest priority.

Note

The priority numbering is the same as the numbering for AArch64 synchronous exception priorities listed in *Synchronous exception types, routing and priorities* on page D1-1447. The Debug events in this section with a negative priority are a higher priority than any synchronous exception. The debug events with fractional priorities have a priority between two or more exceptions.

The priority for synchronous debug events is as follows:

-2 Reset Catch debug event. See *Reset Catch debug event* on page H3-4454.

This debug event has a higher priority than the synchronous exceptions listed in *Synchronous exception types, routing and priorities* on page D1-1447.

-1	Exception Catch debug event. See *Exception Catch debug event* on page H3-4449. This debug event can be assigned one of two priorities. When it has a priority of -1, it has a higher priority than the synchronous exceptions listed in the Exception model. See *Exception Catch debug event* on page H3-4449.
0	Halting Step debug event. See *Halting Step debug event* on page H3-4438. This debug event has a higher priority than the synchronous exceptions listed in the Exception model.
1	Software Step debug event. See *Software Step exceptions* on page D2-1579.
1.5	Exception Catch debug event. See *Exception Catch debug event* on page H3-4449. This debug event can be assigned one of two priorities, -1 or 1.5. See *Exception Catch debug event* on page H3-4449.
2 - 3	These events are not debug events.
4	Breakpoint exception or debug event or Address Matching Vector Catch exception. See *Breakpoint exceptions* on page D2-1546, and *Vector Catch exceptions* on page G2-3564. These two debug events have the same priority.
5 - 13	These events are not debug events.
14	Halt Instruction debug event. See *Halt Instruction debug event* on page H3-4448.
15 - 19	These events are not debug events.
19.5	Software Access debug event. See *Software Access debug event* on page H3-4455.
20 - 21	These events are not debug events.
22	Watchpoint exception or debug event. See *Watchpoint exceptions* on page D2-1564 for exceptions taken from AArch64 state, or *Watchpoint exceptions* on page G2-3550 for exceptions taken from AArch32 state.

For Reset Catch debug events and Halting Step debug events the priorities listed in this section only apply when halting is allowed at the time the event is generated. This means that the event is taken synchronously and not pended.

The prioritization of asynchronous Halting debug events, including pending Halting debug events taken asynchronously, is IMPLEMENTATION DEFINED. See *Taking Halting debug events asynchronously* on page H3-4457.

For more information on the prioritization of exceptions see *Synchronous exception types, routing and priorities* on page D1-1447.

Debug state entry and Software Step

When Software Step is active, a debug event that causes entry to Debug state behaves like an exception taken to an Exception level above the debug target Exception level. That is:

- If the instruction that is stepped generates a synchronous debug event that causes entry to Debug state, or an asynchronous debug event is taken before the step completes, the PE enters Debug state with DSPSR.SS set to 1.
- A pending Halting debug event or an asynchronous debug event can be taken after the step has completed. In this case the PE enters Debug state with DSPSR.SS set to 0.

In addition:

- If the instruction that is stepped generates an exception trapped by an Exception Catch debug event, the PE enters Debug state at the exception vector with DSPSR.SS set to 0. This is because PSTATE.SS is set to 0 by taking the exception.

- If the PE is reset, PSTATE.SS is reset to 0. If the following debug events are enabled, the PE enters Debug state with DSPSR.SS set to 0:
  - Reset Catch debug event at the reset Exception level.
  - Exception Catch debug event at the reset Exception level.
  - Halting Step debug event.
- If Halting Step is also active, then Halting Step and Software Step operate in parallel and can both become active-pending. In this case Halting step has a higher priority than Software step. This means that the PE enters Debug state and DSPSR.SS is set to 0.

Breakpoint debug events and Vector Catch exception

An Address Matching Vector Catch exception has the same priority as a Breakpoint debug event. See *Synchronous exception prioritization* on page D1-1448.

The prioritization of these events is unchanged even if the breakpoint generates entry to Debug state instead of a Breakpoint exception. This means that if a single instruction generates both an Address Matching Vector Catch exception and a Breakpoint debug event, there is a CONSTRAINED UNPREDICTABLE choice of:

- The PE entering Debug state due to the Breakpoint debug event.
- A Vector Catch exception.

This only applies if all of the following are true:

- Halting debug is enabled.
- Halting is allowed.
- The OS Lock is unlocked.

An Exception Trapping Vector Catch exception must be generated immediately following the exception that generated it. This means that it does not appear in the priority table.

H2.2.6 Forcing entry to Debug state

Entry to Debug state is normally precise, meaning that the PE cannot enter Debug state if it can neither complete nor abandon all currently executing instructions and leave the PE in a precise state.

A debugger can write a value of 1 to EDRCR.CBRRQ to allow imprecise entry to Debug state. An External Debug Request debug event must be pending before writing 1 to this bit. Support for this feature is OPTIONAL and it is IMPLEMENTATION DEFINED when it is effective at forcing entry to Debug state.

The PE ignores writes to this bit if either:

- External debugging is not enabled, meaning `ExternalInvasiveDebugEnabled()` == FALSE.
- Secure external debugging is not enabled, meaning `ExternalSecureInvasiveDebugEnabled()` == FALSE, and either:
  - EL3 is not implemented and the PE is Secure.
  - EL3 is implemented.

Example H2-1 shows how entry to Debug state can be forced.

Example H2-1 Forcing entry to Debug state

The debugger pends an External Debug Request debug event through the CTI to halt a program that has stopped responding. However, the memory system is not responding and a memory access instruction cannot complete. This means that Debug state cannot be entered precisely. The debugger writes a value of 1 to EDRCR.CBRRQ. The PE cancels all outstanding memory accesses and enters Debug state. As some instructions might not have completed correctly, entry to Debug state is imprecise.

When Debug state is entered imprecisely, all memory access instructions executed through the ITR have UNPREDICTABLE behavior. The value of all registers is UNKNOWN, but might be useful for diagnostic purposes.

H2.2.7 Summary of actions from debug events

Table H2-1 shows the Software and Halting debug events. In Table H2-1 the columns have the following meaning:

Debug event type

This means the type of debug event where:

Other software means one of:

- *Software Step exceptions* on page D2-1579.
- *Software Breakpoint Instruction exceptions* on page D2-1544.
- *Vector Catch exceptions* on page D2-1578for AArch64 state or *Vector Catch exceptions* on page G2-3564 for AArch32 state.

Other Halting means one of the following:

- *Halting Step debug event* on page H3-4438.
- *External Debug Request debug event* on page H3-4452.
- *Reset Catch debug event* on page H3-4454.
- *OS Unlock Catch debug event* on page H3-4453.

Other debug events are referred to explicitly.

Authentication

This means halting is allowed by the IMPLEMENTATION DEFINED external authentication interface. It is the result of one of the following pseudocode functions:

In Secure state

`ExternalSecureInvasiveDebugEnabled()`.

In Non-secure state

`ExternalInvasiveDebugEnabled()`.

DLK This is the value of EDPRSR.DLK. It indicates whether the OS Double Lock is locked, `DoubleLockStatus()` == TRUE.

OSLK This is the value of OSLSR.OSLK. It indicates whether the OS Lock is locked.

HDE This is the value of EDSCR.HDE. It indicates whether Halting debug is enabled.

The letter X in Table H2-1 indicates that the value can be either 0 or 1.

Table H2-1 Debug authentication for external debug

Debug event type	Authentication	DLK	OSLK	HDE	Behavior
Other software	X	X	X	X	Handled by the Exception model

Table H2-1 Debug authentication for external debug (continued)

Debug event type	Authentication	DLK	OSLK	HDE	Behavior
Breakpoint or Watchpoint debug event	X	1	X	X	Handled by the Exception model (ignored)
	X	0	1	X	Handled by the Exception model (ignored)
	FALSE	0	0	X	Handled by the Exception model
	TRUE	0	0	0	Handled by the Exception model
	TRUE	0	0	1	Entry to Debug state
Halt Instruction debug event	FALSE	X	X	X	UNDEFINED
	TRUE	1	X	X	UNDEFINED
	TRUE	0	X	0	UNDEFINED
	TRUE	0	X	1	Entry to Debug state
Exception Catch debug event	FALSE	X	X	X	Ignored
	TRUE	1	X	X	Ignored
	TRUE	0	X	X	Entry to Debug state
Software Access debug event	FALSE	X	X	X	Ignored
	TRUE	1	X	X	Ignored
	TRUE	0	1	X	Ignored
	TRUE	0	0	X	Entry to Debug state
Other Halting	FALSE	X	X	X	Ignored
	TRUE	1	X	X	Debug event is pended
	TRUE	0	X	X	Entry to Debug state

H2.2.8 Pseudocode details of Halting on debug events

The following pseudocode outlines the `Halting()`, `Restarting()`, `HaltingAllowed()`, and `HaltOnBreakpointOrWatchpoint()`functions.

```
// Halted()
// ========

boolean Halted()
    return !(EDSCR.STATUS IN {'000001', '000010'});                    // Halted

// Restarting()
// ============

boolean Restarting()
    return EDSCR.STATUS == '000001';                                   // Restarting

// HaltingAllowed()
// ================
// Returns TRUE if halting is currently allowed, FALSE if halting is prohibited.
```

```
boolean HaltingAllowed()
    if Halted() || DoubleLockStatus() then
        return FALSE;
    elsif IsSecure() then
        return ExternalSecureInvasiveDebugEnabled();
    else
        return ExternalInvasiveDebugEnabled();

// HaltOnBreakpointOrWatchpoint()
// ==============================
// Returns TRUE if the Breakpoint and Watchpoint debug events should be considered for Debug
// state entry, FALSE if they should be considered for a debug exception.

boolean HaltOnBreakpointOrWatchpoint()
    return HaltingAllowed() && EDSCR.HDE == '1' && OSLSR_EL1.OSLK == '0';
```

H2.3 Entering Debug state

On entry to Debug state the preferred restart address and PSTATE are saved in DLR and DSPSR. The PE remains in the mode and security state from which it entered Debug state.

If EDRCR.CBRRQ has a value of 0, entry to Debug state is precise. If EDRCR.CBRRQ has a value of 1, then imprecise entry to Debug state is permitted.

If a Watchpoint debug event causes an entry to Debug state, the address of the access that generated the Watchpoint debug event is recorded in EDWAR. See *Determining the memory location that caused a Watchpoint exception* on page D2-1571 for an exception taken from AArch64 state, or *Determining the memory location that caused a Watchpoint exception* on page G2-3557 for an exception taken from AArch32 state.

Other than the effect on PSTATE and EDSCR, entry to Debug state is not a *Context synchronization operation*. The effects of entry to Debug state on PSTATE and EDSCR are synchronized.

H2.3.1 Entering Debug state from AArch32 state

When entering Debug state from AArch32 state, the PE remains in AArch32 state. In AArch32 Debug state the PE executes T32 instructions, regardless of the values of PSTATE.{J,T} before entering Debug state.

To allow the debugger to determine the state of the PE, the current Execution state for all four Exception levels can be read from EDSCR.RW, and the current Exception level can be read from EDSCR.EL.

The current endianness state, PSTATE.E, is unchanged on entry to Debug state.

Note

- If EL1 is using AArch32 state, the current endianness state can differ from that indicated by SCTLR.EE.
- If EL2 is using AArch32 state, the current endianness state can differ from that indicated by HSCTLR.EE.
- On entry to Debug state from AArch32 state, PSTATE.SS is copied to DSPSR.SS, even though the PE remains in AArch32 state.

See also *Effect of entering Debug state on PSTATE* on page H2-4404.

H2.3.2 Effect of entering Debug state on DLR and DSPSR

DLR is set to the preferred restart address for the debug event, and depends on the event type. The value of PSTATE is saved in DSPSR. For entry to Debug state from AArch32 state, the values saved in DSPSR.IT are always correct for the preferred restart address.

For synchronous Halting debug events, the preferred restart address is the address of the instruction that generated the debug event.

For asynchronous Halting debug events, including pending Halting debug events taken asynchronously, the preferred restart address is the address of the first instruction that must be executed on exit from Debug state.

This means that:

- For Breakpoint and Watchpoint debug events, the preferred restart address is the same as the preferred return address for a debug exception, as described in Chapter D2 *AArch64 Self-hosted Debug* and Chapter G2 *AArch32 Self-hosted Debug*.
- For Halt Instruction debug events DLR is set to the address of the `HLT` instruction and DSPSR.IT is correct for the `HLT` instruction.
- For Software Access debug events, DLR is set to the address of the accessing instruction and DSPSR.IT is correct for this instruction.
- For Halting Step debug events taken synchronously, DLR and DSPSR are set as the ELR and SPSR would be set for a Software Step exception. This is usually the address of, and PSTATE for, the instruction after the one that was stepped.

- For Exception Catch debug events, DLR is set to the address of the exception vector the PE would have started fetching from. This is UNKNOWN if the VBAR for the Exception level has never been initialized. DSPSR records the value of PSTATE after taking the exception. The exception catch occurs after ELR_ELx and SPSR_ELx are set, and the debugger can use these registers to determine where in the application program the exception occurred.
- Reset Catch debug events taken synchronously behave like Exception Catch debug events.
- For pending Halting debug events and External Debug Request debug events, DLR is set to the address of the first instruction that must be executed on exit from Debug state and DSPSR.IT is correct for this instruction. See *Pending Halting debug events* on page H3-4456.

Normally DLR is aligned according to the instruction set state indicated in DSPSR. However, a debug event might be taken at a point where the PC is not aligned.

H2.3.3 Effect of entering Debug state on system registers, the Event register, and exclusive monitors

Entering Debug state has no effect on system registers other than DLR and DSPSR. In particular, ESRs, FARs, and FSRs are not updated on entering Debug state. SCR is unchanged, even when entering Debug state from EL3.

Entering Debug state has no architecturally-defined effect on the Event Register and exclusive monitors.

Note

Entry to Debug state might set the Event Register or clear the exclusive monitors, or both. However, this is not a requirement, and debuggers must not rely on any implementation specific behavior.

Unless otherwise described in this reference manual, instructions executed in Debug state have their architecturally-defined effects on the system registers, the Event register, and exclusive monitors.

H2.3.4 Effect of entering Debug state on PSTATE

The effect of an entry to Debug state on PSTATE is described in *Entering Debug state* on page H2-4403 and *Entering Debug state from AArch32 state* on page H2-4403.

PSTATE.{E, M, nRW, EL, SP} are unchanged on entry to Debug state.

PSTATE.IL is cleared to 0 on entry to Debug state, after being saved in DSPSR_EL0.

The other PSTATE fields are ignored and not observable in Debug state:

- PSTATE.{N, Z, C, V, Q, GE} are unchanged.
- PSTATE.{IT, J, T, SS, D, A, I, F} are set to UNKNOWN values, after being saved in DSPSR_EL0.

For more information see *Process state (PSTATE) in Debug state* on page H2-4407.

H2.3.5 Entering Debug state during loads and stores

The PE can enter Debug state during instructions that perform a sequence of memory accesses, as opposed to a single single-copy atomic access, because of a Watchpoint debug event. The effect of entering Debug state on such an instruction is the same as taking a Data Abort exception during such an instruction.

In addition, when executing in AArch64 state, the PE can enter Debug state during instructions that perform a sequence of memory accesses because of an External Debug Request debug event. The effect of entering Debug state on such an instruction is the same as taking an interrupt exception during such an instruction.

This applies to all memory types.

H2.3.6 Pseudocode details for entering Debug state

The following pseudocode shows the definition of the `DebugHalt()` function.

```
constant bits(6) DebugHalt_Breakpoint      = '000111';
```

```
constant bits(6) DebugHalt_EDBGRQ          = '010011';
constant bits(6) DebugHalt_Step_Normal     = '011011';
constant bits(6) DebugHalt_Step_Exclusive  = '011111';
constant bits(6) DebugHalt_OSUnlockCatch   = '100011';
constant bits(6) DebugHalt_ResetCatch      = '100111';
constant bits(6) DebugHalt_Watchpoint      = '101011';
constant bits(6) DebugHalt_HaltInstruction = '101111';
constant bits(6) DebugHalt_SoftwareAccess  = '110011';
constant bits(6) DebugHalt_ExceptionCatch  = '110111';
constant bits(6) DebugHalt_Step_NoSyndrome = '111011';
```

The pseudocode for the UpdateEDSCRFields() function is as follows:

```
// UpdateEDSCRFields()
// ===================
// Update EDSCR processor state fields

UpdateEDSCRFields()

    if !Halted() then
        EDSCR.EL = '00';
        EDSCR.NS = bit UNKNOWN;
        EDSCR.RW = '1111';
    else
        EDSCR.EL = PSTATE.EL;
        EDSCR.NS = if IsSecure() then '0' else '1';
        EDSCR.RW<1> = (if ELUsingAArch32(EL1) then '0' else '1');
        if PSTATE.EL != EL0 then
            EDSCR.RW<0> = EDSCR.RW<1>;
        else
            EDSCR.RW<0> = (if UsingAArch32() then '0' else '1');
        if !HaveEL(EL2) || SCR_GEN[].NS == '0' then
            EDSCR.RW<2> = EDSCR.RW<1>;
        else
            EDSCR.RW<2> = (if ELUsingAArch32(EL2) then '0' else '1');
        if !HaveEL(EL3) then
            EDSCR.RW<3> = EDSCR.RW<2>;
        else
            EDSCR.RW<3> = (if ELUsingAArch32(EL3) then '0' else '1');

    return;
```

The pseudocode for the `Halt()` function is as follows:

```
// Halt()
// ======

Halt(bits(6) reason)

    CTI_SignalEvent(CrossTriggerIn_CrossHalt);  // Trigger other cores to halt

    DLR_EL0 = ThisInstrAddr();
    DSPSR_EL0 = GetPSRFromPSTATE();
    DSPSR_EL0.SS = PSTATE.SS;                   // Always save PSTATE.SS

    EDSCR.ITE = '1';  EDSCR.ITO = '0';
    if IsSecure() then
        EDSCR.SDD = '0';                        // If entered in Secure state, allow debug
    elsif HaveEL(EL3) then
        EDSCR.SDD = (if ExternalSecureInvasiveDebugEnabled() then '0' else '1');
    else
        assert EDSCR.SDD == '1';                // Otherwise EDSCR.SDD is RES1
    EDSCR.MA = '0';

    // PSTATE.{SS,D,A,I,F} are not observable and ignored in Debug state, so behave as if
    // UNKNOWN. PSTATE.{N,Z,C,V,Q,GE} are also not observable, but since these are not changed on
    // exception entry, this function also leaves them unchanged. PSTATE.{E,M,nRW,EL,SP} are
```

```
// unchanged. PSTATE.IL is set to 0.
if UsingAArch32() then
    PSTATE.<SS,A,I,F> = bits(4) UNKNOWN;
    //  In AArch32, all instructions are T32 and unconditional.
    PSTATE.IT = '00000000';  PSTATE.<J,T> = '01';
else
    PSTATE.<SS,D,A,I,F> = bits(5) UNKNOWN;
PSTATE.IL = '0';

StopInstructionPrefetchAndEnableITR();
EDSCR.STATUS = reason;                      // Signal entered Debug state
UpdateEDSCRFields();                        // Update EDSCR processor state flags.

return;
```

H2.4 Behavior in Debug state

Instructions are executed in Debug state from the Instruction Transfer Register, ITR. The debugger controls which instructions are executed in Debug state by writing the instructions to the External Debug Instruction Transfer register, EDITR. The Execution state of the PE determines which instruction set is executed:

- If the PE is in AArch64 state it executes A64 instructions.
- If the PE is in AArch32 state it executes T32 instructions.

The PE does not execute A32 instructions in Debug state.

Some instructions are available only in Debug state. See *Debug state instructions, DCPS, DRPS, MRS, MSR* on page H2-4421. In Non-debug state these instructions are UNDEFINED.

H2.4.1 Process state (PSTATE) in Debug state

PSTATE.{N, Z, C, V, Q, GE, IT, J, T, SS, D, A, I, F} are all ignored in Debug state:

- There are no conditional instruction in Debug state.
- In AArch32 state, the PE only executes T32 instructions and PSTATE.IT is ignored.
- Asynchronous exceptions and debug events are ignored.
- Software step is inactive.

Instructions executed in Debug state indirectly read PSTATE.{IL, E, M, nRW, EL, SP} as they would in Non-debug state.

H2.4.2 Executing instructions in Debug state

The instructions executed in Debug state must be either A64 instructions or T32 instructions, depending on the current Execution state.

Each instruction falls into one of the following groups:

- Debug state instructions. These are instructions that are changed in Debug state. See *A64 instructions that are changed in Debug state* and *T32 instructions that are changed in Debug state* on page H2-4412.
- Instructions that are unchanged in Debug state. See *A64 instructions that are unchanged in Debug state* on page H2-4408 and *T32 instructions that are unchanged in Debug state* on page H2-4412.
- Instructions that are UNPREDICTABLE in Debug state. See *A64 instructions that are UNPREDICTABLE in Debug state* on page H2-4409 and *T32 instructions that are UNPREDICTABLE in Debug state* on page H2-4414.

All T32 instructions are treated as unconditional, regardless of PSTATE.IT. See *Process state (PSTATE) in Debug state*.

If EDSCR.SDD == 1 then an instruction executed in Non-secure state cannot cause entry into Secure state. See *Security in Debug state* on page H2-4420

Executing A64 instructions in Debug state

The following sections describe the behavior of the A64 instructions in Debug state:

- *A64 instructions that are changed in Debug state*.
- *A64 instructions that are unchanged in Debug state* on page H2-4408.
- *A64 instructions that are UNPREDICTABLE in Debug state* on page H2-4409.

A64 instructions that are changed in Debug state

The following A64 instructions are defined in Debug state, but are UNDEFINED in Non-debug state:

- `DCPS`

Note

`DCPS` can be UNDEFINED in certain conditions in Debug state. See *DCPS* on page H2-4422.

- DRPS
- MRS (DLR_EL0), MRS (DSPSR_EL0), MSR (DLR_EL0), MSR (DSPSR_EL0)

For more information see *Debug state instructions, DCPS, DRPS, MRS, MSR* on page H2-4421.

A64 instructions that are unchanged in Debug state

The following list shows the instructions that are unchanged in Debug state:

Any instruction that is UNDEFINED in Non-debug state

This list of instructions excludes:

- Any instruction listed in *A64 instructions that are changed in Debug state* on page H2-4407.
- Any instruction listed in *A64 instructions that are UNPREDICTABLE in Debug state* on page H2-4409 that is UNDEFINED because an enable or disable bit is not RES0 or RES1

Instructions that move System or Special registers to or from a general-purpose register

This list of instructions:

- Includes the instructions to transfer a general-purpose register to or from the DTR, which can be executed at any Exception level.
- Excludes PSTATE access instructions.

These instructions are:

- MRS <special_reg>, MSR <special_reg>

  Note

  This does not include NZCV, DAIF, DAIFSet, DAIFClr, SPSel, and CurrentEL.

- MRS <system_reg>, MSR <system_reg>

Floating-point moves between a SIMD&FP register and a general-purpose register

These instructions are:

- FMOV (between a general-purpose register and a single-precision register).
- FMOV (between a general-purpose register and a double-precision register).
- FMOV (between a general-purpose register and a SIMD element).

SIMD moves between a SIMD&FP register and a general-purpose register

These instructions are:

- INS (from a general-purpose register to a SIMD element).
- UMOV (from a SIMD element to a general-purpose register).

Barriers

These instructions are:

- ISB.
- DSB.
- DMB.

Memory access instructions at various access sizes

The following constraints apply:

- General purpose-registers only.
- One of the following addressing modes:
  - Unscaled (9-bit signed) immediate offset.
  - Immediate (9-bit signed) post-indexed.
  - Immediate (9-bit signed) pre-indexed.

  - Unprivileged (9-bit signed).
- Not literal.
- One of the following types:
  - (Single) register.
  - Exclusive.
  - Exclusive pair.
  - Acquire/Release.
  - Acquire/Release Exclusive.
  - Acquire/Release Exclusive pair.
- 32-bit and 64-bit target register variants.

These instructions are:

- `LDR`, `LDRB`, `LDRH`, `LDRSB`, `LDRSH`, `LDRSW` (immediate, not literal).
- `LDUR`, `LDURB`, `LDURH`, `LDURSB`, `LDURSH`, `LDURSW` (immediate).
- `LDTR`, `LDTRB`, `LDTRH`, `LDTRSB`, `LDTRSH`, `LDTRSW` (immediate).
- `LDAR`, `LDARB`, `LDARH`, `LDXR`, `LDXRB`, `LDXRH`, `LDAXR`, `LDAXRB`, `LDAXRH`.
- `LDXP`, `LDAXP`.
- `STR`, `STRB`, `STRH` (immediate).
- `STUR`, `STURB`, `STURH` (immediate).
- `STTR`,`STTRB`, `STTRH` (immediate).
- `STLR`, `STLRB`, `STLRH`, `STXR`, `STXRB`, `STXRH`, `STLXR`, `STLXRB`, `STLXRH`.
- `STXP`, `STLXP`.

Move to general-purpose register and between the stack-pointer and a general-purpose register

These instructions are:

- `MOVZ`, `MOVN`, `MOVK` (immediate).
- `MOV` (between a general-purpose register and the SP).

Cache maintenance, Send Event, NOP, and Clear Exclusive

These instructions are:

- `IC`.
- `DC`.
- `TLBI`.
- `AT`.
- `SEV`, `SEVL`.
- `NOP` (no operation hint).
- `CLREX`.

A64 instructions that are UNPREDICTABLE in Debug state

This subsection describes all instruction not listed in either:

- *A64 instructions that are changed in Debug state* on page H2-4407.
- *A64 instructions that are unchanged in Debug state* on page H2-4408.

These instructions are CONSTRAINED UNPREDICTABLE in Debug state. In general, the permissible behaviors are:

- The instruction generates an Undefined Instruction exception.
- The instruction executes as a `NOP`.
- If the instruction reads the PC or PSTATE, it uses an UNKNOWN value.

- If the instruction modifies the PC or PSTATE, other than by advancing the PC to the sequentially next instruction, it sets DLR_EL0 and DSPSR_EL0 to UNKNOWN values.
- If the instruction is similar to a Debug state instruction, it executes as that Debug state instruction.
- The instruction has the same behavior as in Non-debug state.

The following list shows the permissible behaviors for A64 instruction in Debug state. An instruction might appear multiple times in the list, in which case the choice of permissible behaviors is any of those listed. An example of this is `CCMP`.

Exception-generating instructions

These instructions are:

- `SVC`.
- `HVC`.
- `SMC`.
- `BRK`.
- `HLT`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- `SVC` behaves as `DCPS1`.
- `HVC` behaves as `DCPS2`.
- `SMC` behaves as `DCPS3`.
- They generate the exception the instruction would generate in Non-debug state. The exception is taken as described in *Exceptions in Debug state* on page H2-4425

Note

`SMC` must not generate a Secure Monitor Call exception from Non-secure state if EDSCR.SDD is set to 1.

Exception return and related instructions

These instructions are:

- `ERET`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as `DRPS` instead of performing an exception return, using UNKNOWN ELR and SPSR values.
- They set DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

Instructions that explicitly write to the PC (branches)

These instructions are:

- `B`, `B.cond`, `BL`, `BLR`, `BR`, `CBZ`, `CBNZ`, `RET`, `TBZ`, `TBNZ`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They set DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

Instructions that read the PC

These instructions are:

- `LDR` (literal), `LDRSW` (literal).
- `ADR`, `ADRP`.
- `PRFM` (literal).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They read an UNKNOWN value for the PC operand.

Instructions that explicitly modify PSTATE (other than `DCPS` and `DRPS`)

These instructions are:

- `MSR DAIFSet` (immediate), `MSR DAIFClr` (immediate), `MSR SPSel` (immediate).
- `MSR NZCV` (register), `MSR DAIF` (register), `MSR SPSel` (register).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They set DSPSR_EL0 and DLR_EL0 to UNKNOWN values.

Instruction that read the NZCV condition flags or other PSTATE fields

These instructions are:

- `CSEL`, `CSINC`, `CSINV`, `CSNEG`, `CCMN`, `CCMP`, `FCSEL`, `FCCMP`, `FCCMPE`.
- `ADC`, `ADCS`,`SBC`, `SBCS`.
- `MRS NZCV`, `MRS DAIF`, `MRS SPSel`, `MRS CurrentEL`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- For the conditional operations and those using the PSTATE.C flags, they use an UNKNOWN value for the flag.
- For the `MRS` operations, they return an UNKNOWN value.

Instructions that explicitly modify the PSTATE NZCV condition flags

These instructions are:

- `ADDS`, `SUBS`, `ADCS`, `SBCS`, `ANDS`, `BICS`, `CCMN`, `CCMP`.
- `FCMP`, `FCMPE`. `FCCMP`, `FCCMPE`.
- `MSR NZCV` (register).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They set DSPSR_EL0 and DLR_EL0 to UNKNOWN values.
- They generate an exception if the instruction would generate an exception in Non-debug state.

Instructions that suspend execution

These instructions are:

- `WFE`, `WFI`

These instructions behave in one of the following ways:

- Are UNDEFINED.
- Execute as a NOP.
- Generate an exception if the corresponding instruction would be trapped in Non-debug state.

Note

This means that these instructions must not suspend execution.

All other instructions

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a NOP.
- They have the same behavior as in Non-debug state.

Note

This includes instructions defined as UNPREDICTABLE in Non-debug state. These instructions are UNPREDICTABLE in Debug state.

Executing T32 instructions in Debug state

The following sections describe the behavior of the T32 instructions in Debug state:

- *T32 instructions that are changed in Debug state*.
- *T32 instructions that are unchanged in Debug state*.
- *T32 instructions that are UNPREDICTABLE in Debug state* on page H2-4414.

T32 instructions that are changed in Debug state

The following T32 instructions are defined in Debug state, but are UNDEFINED in Non-debug state:

- DCPS

  Note

  DCPS can be UNDEFINED in certain conditions in Debug state. See *DCPS* on page H2-4422.

- MRC p15,3,<Rt>,c4,c5,0 (DSPSR)
- MCR p15,3,<Rt>,c4,c5,0 (DSPSR)
- MRC p15,3,<Rt>,c4,c5,1 (DLR)
- MCR p15,3,<Rt>,c4,c5,1 (DLR)

In addition, ERET is executed as DRPS in Debug state.

For more information see *Debug state instructions, DCPS, DRPS, MRS, MSR* on page H2-4421.

T32 instructions that are unchanged in Debug state

The following list shows the instructions that are unchanged in Debug state. Any T32 instruction that uses the PC or APSR.{N, Z, C, V} as the source or destination register is not included in the list. Moreover, the list only includes the 32-bit T32 encodings.

Any instruction that is UNDEFINED in Non-debug state

The list of instructions:

- Excludes any instruction listed in *T32 instructions that are changed in Debug state*.
- Excludes any instruction listed in *T32 instructions that are UNPREDICTABLE in Debug state* on page H2-4414 that is UNDEFINED because an enable or disable bit is not RES0 or RES1

Instructions that move System or Special registers to or from a general-purpose register

The list of instructions:

- Includes the instructions to transfer a general-purpose register to or from the DTR, which can be executed at any Exception level.
- Excludes APSR and CPSR access instructions.
- Excludes instructions for accessing banked registers for the current mode.

These instructions are:

- `MRS <spec_reg> <mode>`, `MSR <spec_reg> <mode>`.

  Note

  This does not apply to cases which are UNPREDICTABLE in Non-debug state in the current mode.

- `MRC <system_reg>`, `MCR <system_reg>`

  Note

  This includes all allocated CP15 and CP14 System registers, other than an `MRC` move to APSR_nzcv.

- `MRS SPSR`, `MSR SPSR`
- `VMRS <vfp_system_reg>`, `VMSR <vfp_system_reg>`

  Note

  This includes all allocated Advanced SIMD and floating-point system registers, other than an a `VMRS` move to APSR_nzcv.

Floating-point moves between a SIMD&FP register and a general-purpose register

These instructions are:

- `VMOV` (between a general-purpose register and a single-precision register).
- `VMOV` (between a general-purpose register and a doubleword floating-point register).

SIMD moves between a SIMD&FP register and a general-purpose register

These instructions are:

- `VMOV` (between a general-purpose register and a scalar).

Barriers

These instructions are:

- `ISB`.
- `DSB`.
- `DMB`.

Memory access instructions at various access sizes

The following constraints apply:

- General purpose-registers only.
- One of the following addressing modes:
  - Immediate (8-bit or 12-bit) offset.
  - Immediate (8-bit) post-indexed.
  - Immediate (8-bit) pre-indexed.
  - Unprivileged (8-bit).
- Not literal.

- One of the following types:
  - (Single) register.
  - Dual.
  - Exclusive.
  - Exclusive doubleword.
  - Acquire/Release.
  - Acquire/Release Exclusive.
  - Acquire/Release Exclusive doubleword.

These instructions are:

- `LDR.W`, `LDRB.W`, `LDRH.W`, `LDRD`, `LDRSB.W`, `LDRSH.W` (immediate, not literal).
- `LDRT`, `LDRBT`, `LDRHT`, `LDRSBT`, `LDRSHT` (immediate).
- `LDREX`, `LDREXB`, `LDREXH`, `LDA`, `LDAB`, `LDAH`, `LDAEX`, `LDAEXB`, `LDAEXH`.
- `LDREXD`, `LDAEXD`.
- `STR.W`, `STRB.W`, `STRH.W`, `STRD` (immediate).
- `STRT`, `STRBT`, `STRHT` (immediate).
- `STREX`, `STREXB`, `STREXH`, `STL`, `STLB`, `STLH`, `STLEX`, `STLEXB`, `STLEXH`.
- `STREXD`, `STLEXD`.

Move immediate to general-purpose register

These instructions are:

- `MOVW`, `MOVT` (immediate)

Cache maintenance, Send Event, `NOP`, and Clear Exclusive

These instructions are:

- `ICIALLU`, `ICIALLUIS`, `ICIMVAU` (CP15 operations).
- `DCCIMVAC`, `DCCISW`, `DCCMVAC`, `DCCMVAU`, `DCCSW`, `DCIMVAC`, `DCISW` (CP15 operations).
- `TLBIALL`, `TLBIALLH`, `TLBIALLHIS`, `TLBIALLIS`, `TLBIALLNSNH`, `TLBIALLNSNHIS`, `TLBIASID`, `TLBIASIDIS`, `TLBIIPAS2`, `TLBIIPAS2IS`, `TLBIIPAS2L`, `TLBIIPAS2LIS`, `TLBIMVA`, `TLBIMVAA`, `TLBIMVAAIS`, `TLBIMVAAL`, `TLBIMVAALIS`, `TLBIMVAH`, `TLBIMVAHIS`, `TLBIMVAIS`, `TLBIMVAL`, `TLBIMVALH`, `TLBIMVALHIS`, `TALBIMVALIS` (CP15 operations).
- `ATS12NSOPR`, `ATS12NSOPW`, `ATS12NSOUR`, `ATS12NSOUW`, `ATS1CPR`, `ATS1CPW`, `ATS1CUR`, `ATS1CUW`, `ATS1HR`, `ATS1HW` (CP15 operations).
- `BPIALL`, `BPIALLIS`, `BPIMVA` (CP15 operations).
- `SEV.W`, `SEVL.W`.
- `NOP.W` (no operation hint).
- `CLREX`.

T32 instructions that are UNPREDICTABLE in Debug state

This subsection describes all instruction not listed in either:

- *T32 instructions that are changed in Debug state* on page H2-4412.
- *T32 instructions that are unchanged in Debug state* on page H2-4412.

These instructions are CONSTRAINED UNPREDICTABLE in Debug state. In general, the permissible behaviors are:

- The instruction generates an Undefined Instruction exception.
- The instruction executes as a `NOP`.
- If the instruction reads the PC or PSTATE, it uses an UNKNOWN value.

- If the instruction modifies the PC or PSTATE, other than by advancing the PC to the sequentially next instruction, it sets DLR and DSPSR to UNKNOWN values.
- If the instruction is similar to a Debug state instruction, it executes as that Debug state instruction.
- The instruction has the same behavior as in Non-debug state.

The following list shows the permissible behaviors for T32 instruction in Debug state. An instruction might appear multiple times in the list, in which case the choice of permissible behaviors is any of those listed.

T32 instructions with a 16-bit encoding

These instructions behave in one of the following ways:

- They are UNDEFINED.
- The executes as a `NOP`.
- They do either or both of the following:
  - Have the alternative behavior listed for the equivalent 32-bit instruction in this table.
  - Set DLR and DSPSR to UNKNOWN values.

Exception-generating instructions

These instructions are:

- `SVC`.
- `HVC`.
- `SMC`.
- `UDF`.
- `BKPT`.
- `HLT`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- `SVC` behaves as `DCPS1`.
- `HVC` behaves as `DCPS2`.
- `SMC` behaves as `DCPS3`.
- They generate the exception the instruction would generate in Non-debug state. The exception is taken as described in *Exceptions in Debug state* on page H2-4425

Note

`SMC` must not generate a Secure Monitor Call exception from Non-secure state if EDSCR.SDD is set to 1.

Exception return and related instructions

These instructions are:

- `SRS, RFE, SUBS pc, lr`, and related instructions.

Note

The T32 `ERET` instruction is decoded as `DRPS` and is not included in this list.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They execute as `DRPS` instead of performing an exception return, using UNKNOWN link and SPSR values.

- They set DSPSR and DLR to UNKNOWN values.

Instructions that explicitly write to the PC (branches)

These instructions are:

- `B, B` (conditional), `CBZ, CBNZ BL`.
- `BX, BLX` (register or immediate).
- `BXJ, TBB, TBH`.
- `MOV pc` and related instructions.
- `LDR pc, LDM` (with a register list includes the PC), `POP` (with a register list that includes the PC).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They set DSPSR and DLR to UNKNOWN values.

Instructions that read the PC

These instructions are:

- `LDR` (literal), `LDRB` (literal), `LDRH` (literal), `LDRSB` (literal), `LDRSH` (literal).
- `ADR, ADRL, ADRH`.
- `PLD` (literal), `PLI` (literal).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They read an UNKNOWN value for the PC operand.

Instructions that explicitly modify PSTATE (other than `DCPS` and `DRPS`)

These instructions are:

- `CPS, SETEND, IT`.
- `MSR CPSR` (register or immediate).

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They set DSPSR and DLR to UNKNOWN values.

Instruction that read the NZCV condition flags or other PSTATE fields

These instructions are:

- `<opc><cond>`.

  Note

  `<opc>` is any instruction and `<cond>` is not AL or NV.

- `ADC, SBC, RCS`, all instructions with an `RRX` shift.
- `MRS CPSR`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- For the conditional operations and those using the PSTATE.C flag, they use an UNKNOWN value for the flag.
- For the `MRS` operations, they return an UNKNOWN value.

Instructions that explicitly modify the NZCV condition flags

These instructions are:

- `CMP, TST, TEO, CMN`.
- `<opc>S`
- `MRC p14,0,APSR_nzcv,c0,c1,0 (DBGDSCRint)`.
- `MSR CPSR`.
- `VMRS APSR nzcv,FPSCR`.

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They set DSPSR and DLR to UNKNOWN values.
- They generate an exception if the instruction would generate an exception Non-debug state.

Instructions that suspend execution

These instructions are:

- `WFE, WFI`

These instructions behave in one of the following ways:

- Are UNDEFINED.
- Execute as a `NOP`.
- Generate an exception if the corresponding instruction would be trapped in Non-debug state.

Note

This means that these instructions must not suspend execution.

All other instructions

These instructions behave in one of the following ways:

- They are UNDEFINED.
- They execute as a `NOP`.
- They have the same behavior as in Non-debug state.

Note

This includes instructions defined as UNPREDICTABLE in Non-debug state. These instructions are UNPREDICTABLE in Debug state. This includes some T32 instructions that specify R15 as a destination or source register, such as:

```
MOV.W R15, #<uimm16>
LDREX R15, [Rn]
```

Appendix A *Architectural Constraints on UNPREDICTABLE behaviors* describes the CONSTRAINED UNPREDICTABLE behavior for these instructions. In Debug state these CONSTRAINED UNPREDICTABLE choices are further restricted:

- Instructions that specify R15 as a destination register:
  - Are not permitted to branch, because the architecture does not define a branch operation in Debug state.
  - Might set DLR and DSPSR to UNKNOWN values.
  - Might have any of the other permitted behaviors.
- Instructions that specify R15 as a source operand:
  - Cannot use PC + offset, because there is no architecturally-defined PC in Debug state.

— Might have any of the other permitted behaviors, including using an UNKNOWN value.

H2.4.3 Decode tables

The syntax in the tables is defined as follows:

1 The bit has a fixed value of 1.

0 The bit has a fixed value of 0.

!= The field has any value other than the value or values specified. The field might be an encoding field in the instruction whose value is supplied by the debugger.

Note

The instruction encodings in Chapter C6 *A64 Base Instruction Descriptions* and Chapter F7 *T32 and A32 Base Instruction Set Instruction Descriptions* might show these bits as (0) or (1). A debugger must set these bits to 0 or 1, as appropriate.

Some values might be reserved or UNDEFINED, in which case the instruction is UNDEFINED or UNPREDICTABLE in Debug state, as it is in Non-debug state. Any other value indicates an encoding field in the instruction whose value is supplied by the debugger.

For more information about the instruction encodings, see:

- Chapter C6 *A64 Base Instruction Descriptions*.
- Chapter F7 *T32 and A32 Base Instruction Set Instruction Descriptions*.

For information about the syntax used in Table H2-2, Table H2-3, Table H2-4 on page H2-4419, and Table H2-5 on page H2-4420, see:

- *Common syntax terms* on page C1-111.
- *Assembler syntax* on page F2-2327.

Table H2-2 shows the A64 instructions that are modified in Debug state. For details of how these are packed in EDITR, see *EDITR, External Debug Instruction Transfer Register* on page H9-4580.

H2.4.4 Security in Debug state

If EL3 is implemented or the PE is Secure, security in Debug state is governed by the Secure debug disabled flag, EDSCR.SDD.

On entry to Debug state

If entering in Secure state, EDSCR.SDD is set to 0. Otherwise EDSCR.SDD is set to the inverse of `ExternalSecureInvasiveDebugEnabled()`. That is:

- If `ExternalSecureInvasiveDebugEnabled()` == TRUE, EDSCR.SDD is set to 0.
- If `ExternalSecureInvasiveDebugEnabled()` == FALSE, EDSCR.SDD is set to 1.

Note

Normally, if `ExternalSecureInvasiveDebugEnabled()` == FALSE then halting is prohibited and it is not possible to enter Debug state from Secure state. However, because changes to the authentication signals require a *Context synchronization operation* to guarantee their effect, there is a period during which the PE might halt even though the authentication signals prohibit halting.

In Debug state

The value of EDSCR.SDD does not change, even if `ExternalSecureInvasiveDebugEnabled()` changes.

Note

- DBGAUTHSTATUS_EL1.{SNID, SID, NSNID, NSID} are not frozen in Debug state.
- If EDSCR.SDD set to 1 in Debug state, then there is no means no enter Secure state from Non-secure state. In this case it is impossible for the PE to be in Secure state. This is a general principle of behavior in Debug state.

In Non-debug state

EDSCR.SDD returns the inverse of `ExternalSecureInvasiveDebugEnabled()`. If the authentication signals that control `ExternalSecureInvasiveDebugEnabled()` change, a *Context synchronization operation* is required to guarantee their effect.

Note

- In Non-debug state, EDSCR.SDD is unaffected by the Security state of the PE.
- A *Context synchronization operation* is also required to guarantee that changes in the authentication signals are visible in DBGAUTHSTATUS_EL1.{SNID, SID, NSNID, NSID}.

If EL3 is not implemented and the PE is Non-secure, EDSCR.SDD is RES1.

H2.4.5 Privilege in Debug state

The only additional privileges offered to Debug state are:

- The privilege to execute *Debug state instructions, DCPS, DRPS, MRS, MSR*.
- The privilege to execute DTR access instructions regardless of the Exception level and traps.

In Non-debug state, the Debug state instructions are UNDEFINED, except for the T32 `DRPS` instruction. The T32 `DRPS` instruction uses the encoding of the Non-debug T32 `ERET` instruction.

In Debug state, the Debug state instructions can be executed at any Exception level. However, there are some cases where the instructions are UNDEFINED. For more information, see *Debug state instructions, DCPS, DRPS, MRS, MSR*. These instructions generate an Undefined Instruction exception when they are UNDEFINED. If this Undefined Instruction exception is taken to an Exception level using AArch64, it is reported using ESR_ELx.EC, with the code `0x00`, and if taken to AArch32 Hyp mode, reported using HSR.EC `of 0x00`.

The DTR access instructions can be executed at any Exception level, including EL0, regardless of any control register settings that might force these instructions to be UNDEFINED or trapped in Non-debug state. These instruction are:

- The `MRS` and `MSR` instructions that access DBGDTR_EL0, DBGDTRTX_EL0, and DBGDTRRX_EL0 in AArch64 state.
- The `MRC` and `MCR` instructions that access DBGDTRTXint and DBGDTRRXint in AArch32 state.

All other instructions operate with the privilege determined by the current Exception level and security state. This applies to all special and system registers accesses, memory accesses, and UNDEFINED instructions, and includes generating exceptions when the system registers trap or disable an instruction.

H2.4.6 Debug state instructions, DCPS, DRPS, MRS, MSR

ARMv8 defines instructions to change between Exception levels in Debug state. These instructions can also change the mode at the current Exception level.

DCPS

DCPS allows the debugger to move the PE to a higher Exception level or to a specific mode at the current Exception level.

If the DCPS instruction is executed in AArch32 state and the target Exception level is using AArch64:

- The current instruction set switches from T32 to A64.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for system calls in Non-debug state. See *Execution state* on page D1-1403.

Otherwise, the instruction set state does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE can change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- In AArch64, the current endianness is set according to SCTLR_ELx.EE for the target Exception level.
- In AArch32, the current endianness is set according to SCTLR.EE or HSCTLR.EE for the target Exception level.

The assembler syntax for the DCPS instructions is:

```
DCPS1     {#<uimm16>}
DCPS2     {#<uimm16>}
DCPS3     {#<uimm16>}
```

<uimm16> is only available in the A64 encoding and is ignored by hardware.

The decode can be found in the instruction descriptions for DCPS1, DCPS2, and DCPS3 for A64, and DCPS1, DCPS2, DCPS3 for T32.

DCPS is UNDEFINED in Non-debug state.

Table H2-6 shows the target of the instruction. In Table H2-6 the column entries have the following meaning:

EL1h/Svc This means that the target mode is EL1 handler mode, if EL1 is using AArch64. Otherwise this is Svc mode.

EL2h/Hyp This means that the target mode is EL2 handler mode, if EL2 is using AArch64. Otherwise this is Hyp mode.

EL3h/Monitor This means that the target mode is EL3 handler mode, if EL3 is using AArch64. Otherwise this is Monitor mode.

Table H2-6 Target for DCPS instructions in Debug state

Instruction	Target modes when taken from Exception level				
	EL0	EL1	EL2	EL3 (AArch64)	EL3 (AArch32)
DCPS1	EL1h/Svc	EL1h/Svc	EL2h/Hyp	EL3h	Svc, clears NS to 0
DCPS2	EL2h/Hyp	EL2h/Hyp	EL2h/Hyp	EL3h	UNDEFINED
DCPS3	EL3h/Monitor	EL3h/Monitor	EL3h/Monitor	EL3h	Monitor, clears NS to 0

Note

- In AArch32 Monitor mode, DCPS1 and DCPS3 clear SCR.NS to 0.
- In AArch64, at EL3, DCPS does not change SCR_EL3.NS.

However:

- DCPS1 is UNDEFINED at EL0 in Non-secure state if both:
  - EL2 is implemented.
  - HCR_EL2.TGE == 1.
- DCPS2 is UNDEFINED at all Exception levels if EL2 is not implemented.
- DCPS2 is UNDEFINED at the following Exception levels if EL2 is implemented:
  - At EL0 and EL1 in Secure state.
  - At EL3 if EL3 is using AArch32.
- DCPS3 is UNDEFINED at all Exception levels if either:
  - EDSCR.SDD == 1.
  - EL3 is not implemented.

DCPS is also defined in T32, see *DCPS1, DCPS2, DCPS3 on page F7-2519*. There is no A32 encoding.

On executing a DCPS instruction:

- If the target Exception level is using AArch64:
  - ELR_ELx of the target Exception level becomes UNKNOWN.
  - SPSR_ELx of the target Exception level becomes UNKNOWN.
  - ESR_ELx of the target Exception level becomes UNKNOWN.
  - DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- If the target Exception level is using AArch32 DLR and DSPSR become UNKNOWN and:
  - If the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become UNKNOWN.
  - If the target Exception level is EL2, then ELR_hyp, SPSR_hyp, and HSR become UNKNOWN.

If the target Exception level is using AArch32, and the target Exception level is EL1 or EL3, the LR and SPSR of the target mode become UNKNOWN.

The pseudocode for DCPSInstruction() is as follows:

```
// DCPSInstruction()
// =================
// Operation of the DCPS instruction in Debug state

DCPSInstruction(bits(2) target_el)

    SynchronizeContext();

    case target_el of
        when EL1
            if PSTATE.EL == EL2 || (PSTATE.EL == EL3 && !UsingAArch32()) then handle_el = PSTATE.EL;
            elsif HaveEL(EL2) && !IsSecure() && HCR_EL2.TGE == '1' then UndefinedFault();
            else handle_el = EL1;

        when EL2
            if !HaveEL(EL2) then UndefinedFault();
            elsif PSTATE.EL == EL3 && !UsingAArch32() then handle_el = EL3;
            elsif IsSecure() then UndefinedFault();
            else handle_el = EL2;

        when EL3
            if EDSCR.SDD == '1' || !HaveEL(EL3) then UndefinedFault();
            handle_el = EL3;

    if ELUsingAArch32(handle_el) then
```

```
        if PSTATE.M == M32_Monitor then SCR.NS = '0';
        assert UsingAArch32();                  // Cannot move from AArch64 to AArch32
        case handle_el of
            when EL1  AArch32.WriteMode(M32_Svc);
            when EL2  AArch32.WriteMode(M32_Hyp);
            when EL3  AArch32.WriteMode(M32_Monitor);
        if handle_el == EL2 then
            ELR_hyp = bits(32) UNKNOWN;  HSR = bits(32) UNKNOWN;
        else
            LR = bits(32) UNKNOWN;
        SPSR[] = bits(32) UNKNOWN;
        PSTATE.E = SCTLR[].EE;
    else                                        // Targetting AArch64
        if UsingAArch32() then MaybeZeroRegisterUppers(handle_el);
        ELR[] = bits(64) UNKNOWN;  SPSR[] = bits(32) UNKNOWN;  ESR[] = bits(32) UNKNOWN;
        PSTATE.nRW = '0';  PSTATE.SP = '1';  PSTATE.EL = handle_el;

    DLR_EL0 = bits(64) UNKNOWN;  DSPSR_EL0 = bits(32) UNKNOWN;
    UpdateEDSCRFields();                        // Update EDSCR processor state flags.

    return;
```

DRPS

DRPS allows the debugger to move the PE to a lower Exception level or to another mode at the current Exception level by copying the current SPSR to PSTATE.

If DRPS is executed in AArch64 state and the target Exception level is using AArch32:

- The current instruction set switches from A64 to T32.
- The effect on registers that are not visible or only partially visible in AArch32 state is the same as for exception returns in Non-debug state. See *Execution state* on page D1-1403.

Otherwise the instruction set state does not change.

If the target Exception level is the same as the current Exception level, then the PE does not change Exception level. However, the PE can change mode.

The effect on endianness is the same as for exceptions and exception returns in Non-debug state:

- If targeting an Exception level using AArch64, current endianness is set according to SCTLR_ELx.EE, or SCTLR_EL1.E0E for the target Exception level.
- If targeting an Exception level using AArch32, current endianness is set by SPSR.E as appropriate.

The assembler syntax for the DRPS instruction is:

```
DRPS
```

The decode can be found in the instruction description for DRPS.

If the SPSR specifies an illegal exception return, then PSTATE.{M, nRW, EL, SP} are unchanged and PSTATE.IL is set to 1. For further information on illegal exception returns, see *Illegal return events* on page D1-1438.

PSTATE.{N, Z, C, V, Q, GE, IT, J, T, SS, D, A, I, F} are ignored in Debug state. This means that the effect of DRPS on these fields is to set them to an UNKNOWN value that might be the value from the SPSR. For more information see *Process state (PSTATE) in Debug state* on page H2-4407.

All other PSTATE fields are copied from SPSR.

DRPS is UNDEFINED at EL0 and in Non-debug state. In Debug state, the T32 encoding for ERET is decoded as DRPS. There is no A32 encoding for DRPS.

Note

Unlike an exception return, DRPS has no architecturally-defined effect on the Event Register and exclusive monitors. DRPS might set the Event Register or clear the exclusive monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

On executing a DRPS instruction:

- If the target Exception level is using AArch64:
  - DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- If the target Exception level is using AArch32:
  - DLR and DSPSR become UNKNOWN.

The pseudocode for DRPSInstruction() is as follows:

```
// DRPSInstruction()
// =================
// Operation of the A64 DRPS and T32 ERET instructions in Debug state

DRPSInstruction()

    SynchronizeContext();

    SetPSTATEFromPSR(SPSR[]);

    // PSTATE.{N,Z,C,V,Q,GE,SS,D,A,I,F} are not observable and ignored in Debug state, so
    // behave as if UNKNOWN.
    if UsingAArch32() then
        PSTATE.<N,Z,C,V,Q,GE,SS,A,I,F> = bits(13) UNKNOWN;
        //  In AArch32, all instructions are T32 and unconditional.
        PSTATE.IT = '00000000';  PSTATE.<J,T> = '01';
    else
        PSTATE.<N,Z,C,V,SS,D,A,I,F> = bits(9) UNKNOWN;
    DLR_EL0 = bits(64) UNKNOWN;  DSPSR_EL0 = bits(32) UNKNOWN;

    UpdateEDSCRFields();                                // Update EDSCR processor state flags.

    return;
```

MRS and MSR instructions to access DLR_EL0 and DSPSR_EL0

The other Debug state instructions are MRS and MSR (register) instructions to read or write DLR_EL0 and DSPSR_EL0, and the equivalent MRC and MCR operations in AArch32 state.

```
MRS <Xt>, DLR_EL0      ; Copy DLR_EL0 to <Xt>
MRS <Xt>, DSPSR_EL0    ; Copy DSPSR_EL0 to <Xt>
MSR DLR_EL0, <Xt>      ; Copy <Xt> to DLR_EL0
MSR DSPSR_EL0, <Xt>    ; Copy <Xt> to DSPSR_EL0
```

These instructions can be executed at any Exception level when in Debug state, including EL0. They are UNDEFINED in Non-debug state.

H2.4.7 Exceptions in Debug state

The following sections describe how exceptions are handled in Debug state:

- *Generating exceptions in Debug state* on page H2-4426.
- *Taking exceptions in Debug state* on page H2-4426.
- *Reset in Debug state* on page H2-4429.

Generating exceptions in Debug state

In Debug state:

- Instruction Abort exceptions cannot happen because instructions are not fetched from memory.
- Interrupts, including SError and virtual interrupts are ignored and remain pending:
  - The pending interrupt remains visible in ISR.
- Debug exceptions are ignored.
- SCR.EA is treated as if it were set to 0, regardless of its actual state, other than for the purpose of reading the bit.
- All instruction bit patterns that are an allocated instruction at the current Exception level, but listed in *Executing instructions in Debug state* on page H2-4407 as UNDEFINED in Debug state, generate Undefined Instruction exceptions, which are taken to the current Exception level, or to EL1 if executing at EL0. This includes `SVC`, `HVC`, `SMC`, `BRK`, and `HLT`. The priority and syndrome for these exceptions is the same as for executing an encoding that does not have an allocated instruction.
- Instructions executed at EL2, EL1 and EL0 that are configured by EL3 control registers to trap to EL3:
  - Generate the appropriate trap exception taken to EL3 if EDSCR.SDD == 0.
  - Generate an Undefined Instruction exception taken to the current Exception level, or to EL1 if executing at EL0, if EDSCR.SDD == 1. If the exception is taken to an Exception level using AArch64 or to AArch32 Hyp mode, this is reported with an exception class of `0x00`.

  Otherwise configurable traps, enables, and disables, for instructions are unaffected by Debug state, and executing the affected instructions generates the appropriate exceptions.

Otherwise, synchronous exceptions, including Data Aborts, are generated as they would be in Non-debug state and taken to the appropriate Exception level in Debug state.

Note

If EDSCR.SDD == 1 then an exception from Non-secure state is never taken to Secure state. See *Security in Debug state* on page H2-4420.

Taking exceptions in Debug state

Once generated, exceptions, all of which are synchronous, are taken in Debug state. This means that:

- The target Exception level and mode are as defined for the exception in Non-debug state. That is:
  - For exceptions taken to an Exception level using AArch64, the mode is the handler mode for that Exception level.
  - For exceptions taken to an Exception level using AArch32, the mode is the exception mode appropriate for the exception.
- The exception is reported as defined for the exception in Non-debug state, using the syndrome register or registers for the target Exception level. In AArch64, these are ESR_ELx, and FAR_ELx. In AArch32, these are DFSR, DFAR, HSR, HDFAR, and HPFAR. For example:
  - If a Data Abort exception is taken to Abort mode at EL1 or EL3 and the exception is taken from AArch32 state and using the Short-descriptor translation table format, the DFSR reports the exception using the Short-descriptor format fault encoding. For exceptions other than Data Abort exceptions taken in Abort mode, DFSR is not updated.
  - If an instruction is trapped to an Exception level using AArch64 due to a configurable trap, disable, or enable, the exception code reported is the same as it would be in Non-debug state.

  The effect on auxiliary syndrome registers, such as AFSR, is IMPLEMENTATION DEFINED.
- The PE remains in Debug state and changes to the target mode.

- If EL3 is using AArch32 and the exception is taken from Monitor mode, SCR.NS is cleared to 0.
- If the exception is taken to an Exception level using AArch32, the PE continues to execute T32 instructions, regardless of the TE bit in the system control register for the target Exception level.
- The endianness switches to that indicated by the EE bit of the system control register for the target Exception level.
- The SPSR for the target Exception level or mode is corrupted and becomes UNKNOWN.
- If the target Exception level is using AArch64, ELR_ELx for the target Exception level becomes UNKNOWN.
- If the target Exception level is EL2 using AArch32, ELR_hyp becomes UNKNOWN.
- If the target Exception level is EL1 or EL3 using AArch32, LR_<mode> for the target mode becomes UNKNOWN.
- DLR and DSPSR become UNKNOWN.
- The cumulative error flag, EDSCR.ERR, is set to 1. See *Cumulative error flag* on page H4-4469.
- PSTATE.IL is cleared to 0.
- PSTATE.{IT, J, T, SS, D, A, I, F} are set to UNKNOWN values, and PSTATE.{N, Z, C, V, Q, GE} are unchanged. However, these fields are ignored and are not observable in Debug state. For more information see *Process state (PSTATE) in Debug state* on page H2-4407.

The debugger must save any state that can be corrupted by an exception before executing an instruction that might generate another exception.

Pseudocode details for taking exceptions in Debug state

The pseudocode function `TakeException()` in *Pseudocode description of exception entry to AArch64 state* on page D1-1424 shows the behavior when the PE takes an exception to an Exception level using AArch64 in Non-debug state. In Debug state, this is replaced with the function `TakeExceptionInDebugState()`.

```
// AArch64.TakeExceptionInDebugState()
// ===================================
// Take an exception in Debug state to an Exception Level using AArch64.

AArch64.TakeExceptionInDebugState(bits(2) target_el, ExceptionRecord exception)
    assert HaveEL(target_el) && !ELUsingAArch32(target_el) && UInt(target_el) >= UInt(PSTATE.EL);

    // If coming from AArch32 state, the top parts of the X[] registers might be set to zero
    from_32 = UsingAArch32();
    if from_32 then MaybeZeroRegisterUppers(target_el);

    AArch64.ReportException(exception, target_el);

    PSTATE.EL = target_el;  PSTATE.nRW = '0';  PSTATE.SP = '1';

    SPSR[] = bits(32) UNKNOWN;
    ELR[] = bits(64) UNKNOWN;

    // PSTATE.{SS,D,A,I,F} are not observable and ignored in Debug state, so behave as if UNKNOWN.
    PSTATE.<SS,D,A,I,F> = bits(5) UNKNOWN;
    DLR_EL0 = bits(64) UNKNOWN;
    DSPSR_EL0 = bits(32) UNKNOWN;
    PSTATE.IL = '0';
    if from_32 then                             // Coming from AArch32
        PSTATE.IT = '00000000';  PSTATE.<J,T> = '00';

    EDSCR.ERR = '1';
    UpdateEDSCRFields();                        // Update EDSCR processor state flags.
    EndOfInstruction();
```

The pseudocode functions EnterMode(), EnterHypMode(), and EnterMonitorMode() in *Additional pseudocode functions for exception handling* on page G1-3452 show the behavior when the PE takes an exception to an Exception level using AArch32 in Non-debug state. In Debug state, EnterMode() is replaced with the function EnterModeInDebugState().

```
// AArch32.EnterModeInDebugState()
// ===============================
// Take an exception in Debug state to a mode other than Monitor and Hyp mode.

AArch32.EnterModeInDebugState(bits(5) target_mode)
    assert ELUsingAArch32(EL1) && PSTATE.EL != EL2;

    if PSTATE.M == M32_Monitor then SCR.NS = '0';
    AArch32.WriteMode(target_mode);
    SPSR[] = bits(32) UNKNOWN;
    // In Debug state, the PE always execute T32 instructions when in AArch32 state, and
    // PSTATE.{SS,A,I,F} are not observable so behave as UNKNOWN.
    PSTATE.<J,T> = '01';
    PSTATE.<SS,A,I,F> = bits(4) UNKNOWN;
    DLR = bits(32) UNKNOWN;
    DSPSR = bits(32) UNKNOWN;
    PSTATE.E = SCTLR.EE;
    PSTATE.IL = '0';
    PSTATE.IT = '00000000';
    EDSCR.ERR = '1';
    UpdateEDSCRFields();                        // Update EDSCR processor state flags.
    EndOfInstruction();
```

In Debug state, EnterHypMode() is replaced with the function EnterHypModeInDebugState().

```
// AArch32.EnterHypModeInDebugState()
// ==================================
// Take an exception in Debug state to Hyp mode.

AArch32.EnterHypModeInDebugState(ExceptionRecord exception)
    assert HaveEL(EL2) && !IsSecure() && ELUsingAArch32(EL2);

    AArch32.WriteMode(M32_Hyp);
    AArch32.ReportHypEntry(exception);
    SPSR[] = bits(32) UNKNOWN;
    R[14] = bits(32) UNKNOWN;
    // In Debug state, the PE always execute T32 instructions when in AArch32 state, and
    // PSTATE.{SS,A,I,F} are not observable so behave as UNKNOWN.
    PSTATE.<J,T> = '01';
    PSTATE.<SS,A,I,F> = bits(4) UNKNOWN;
    DLR = bits(32) UNKNOWN;
    DSPSR = bits(32) UNKNOWN;
    PSTATE.E = HSCTLR.EE;
    PSTATE.IL = '0';
    PSTATE.IT = '00000000';
    EDSCR.ERR = '1';
    UpdateEDSCRFields();
    EndOfInstruction();
```

In Debug state, EnterMonitorMode() is replaced with EnterMonitorModeInDebugState().

```
// AArch32.EnterHypModeInDebugState()
// ==================================
// Take an exception in Debug state to Hyp mode.

AArch32.EnterHypModeInDebugState(ExceptionRecord exception)
    assert HaveEL(EL2) && !IsSecure() && ELUsingAArch32(EL2);

    AArch32.WriteMode(M32_Hyp);
    AArch32.ReportHypEntry(exception);
    SPSR[] = bits(32) UNKNOWN;
    R[14] = bits(32) UNKNOWN;
```

```
// In Debug state, the PE always execute T32 instructions when in AArch32 state, and
// PSTATE.{SS,A,I,F} are not observable so behave as UNKNOWN.
PSTATE.<J,T> = '01';
PSTATE.<SS,A,I,F> = bits(4) UNKNOWN;
DLR = bits(32) UNKNOWN;
DSPSR = bits(32) UNKNOWN;
PSTATE.E = HSCTLR.EE;
PSTATE.IL = '0';
PSTATE.IT = '00000000';
EDSCR.ERR = '1';
UpdateEDSCRFields();
EndOfInstruction();
```

Reset in Debug state

If the PE is reset when in Debug state, it exits Debug state and enters Non-debug reset state. When the PE is in reset state, EDSCR.STATUS == `0b000010` and writes to EDITR are ignored.

Note

If EDECR.RCE == 1, meaning that a Reset Catch debug event is programmed, and if halting is allowed on exiting reset state, then on exiting reset state the PE halts and re-enters Debug state. See *Reset Catch debug event* on page H3-4454. All PE registers have taken their reset values, which might be UNKNOWN.

H2.4.8 Accessing registers in Debug state

Register accesses are unchanged in Debug state. The view of each register is determined by either the current Exception level or the mode, or both, and accesses might be disabled or trapped by controls at a higher Exception level.

General-purpose register access, other than SP access in AArch64 state

A single general-purpose register can be read by issuing an `MSR` instruction through the ITR to write DBGDTR_EL0 in AArch64 state, or an `MCR` instruction through the ITR to write DBGDTRTXint in AArch32 state. The debugger can then read the DTR register or registers through the external debug interface. The reverse sequence writes to a general-purpose register.

Figure H2-1 on page H2-4430 shows the reading and writing of general-purpose registers, other than SP, in Debug state in AArch64 state.

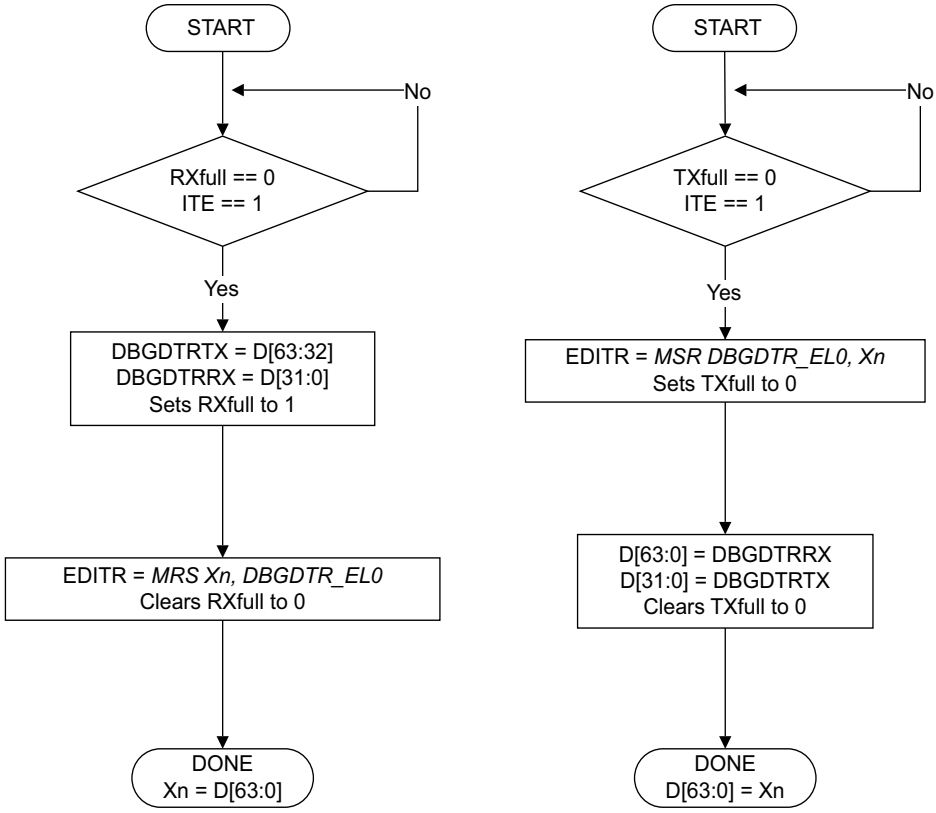

Figure H2-1 Reading and writing general-purpose registers, other than SP, in Debug state in AArch64 state

Figure H2-2 shows the reading and writing of general-purpose registers in Debug state in AArch32 state.

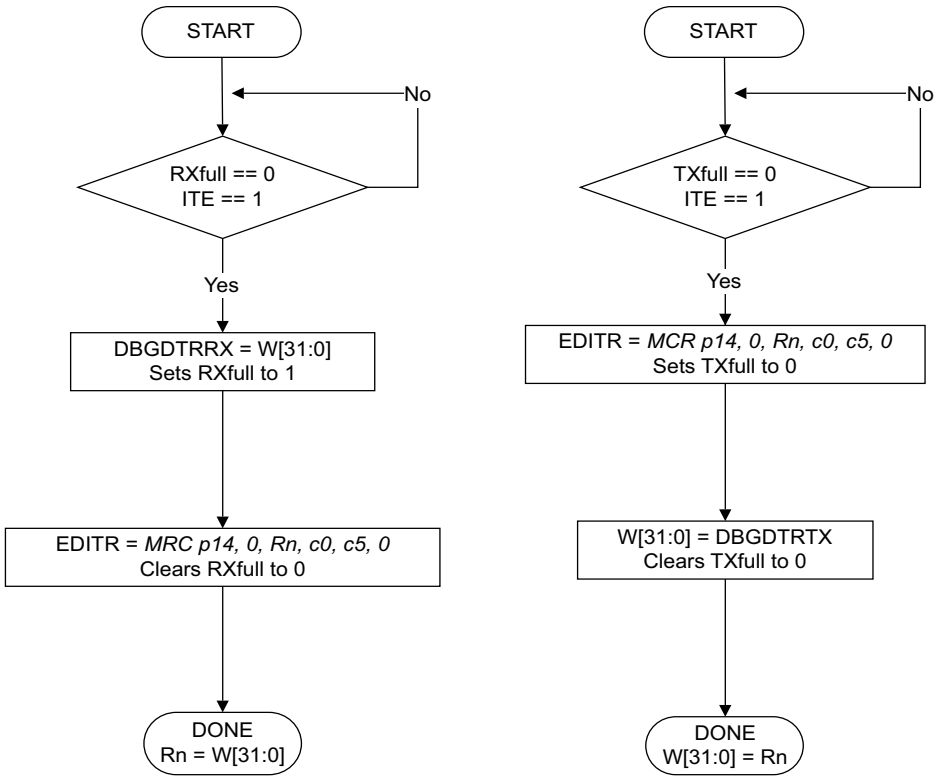

Figure H2-2 Reading and writing general-purpose registers in Debug state in AArch32 state

SIMD and floating-point, and system register accesses, and SP access in AArch64 state

To read a SIMD and floating-point register or a system register, the debugger must first copy the value into a general-purpose register using:

- An `FMOV` instruction in AArch64 or a `VMOV` instruction in AArch32 for floating-point transfers to SIMD and FP registers.
- A `UMOV` instruction in AArch64 or a `VMOV` instruction in AArch32 for SIMD transfers to SIMD and FP registers.
- An `MRS` instruction in AArch64 or an `MRC` instruction in AArch32 for system registers.
- A `MOV Xd,SP` instruction for the SP register in AArch64 state.

The debugger can then read out the particular general-purpose register. The reverse sequence writes a register.

PC and PSTATE access

The debugger reads the program counter and PSTATE of the process being debugged through the DLR_EL0 and DSPSR_EL0 system registers. The actual values of PC and PSTATE cannot be directly observed in Debug state:

- Instructions that are used for direct reads and writes of PC and PSTATE in Non-debug state are UNDEFINED in Debug state.
- On taking an exception, ELR_ELx and SPSR_ELx at the target exception level are UNKNOWN. They do not record the PC and PSTATE.

PSTATE.{IL, E, M, nRW, EL, SP} are indirectly read by instructions executed in Debug state, but all other PSTATE fields are ignored and cannot be observed. See also:

- *Process state (PSTATE) in Debug state* on page H2-4407.
- *Executing instructions in Debug state* on page H2-4407.
- *Exceptions in Debug state* on page H2-4425.

H2.4.9 Accessing memory in Debug state

How the PE accesses memory is unchanged in Debug state. This includes:

- The operation of the MMU, including address translation, tagged address handling, access permissions, memory attribute determination, and the operation of any TLBs.
- The operation of any caches and coherency mechanisms.
- Alignment support.
- Endianness support.
- The Memory order model.

Simple memory transfers

Simple memory accesses can be performed in Debug state by issuing memory access instructions through the ITR and passing data through the DTR registers. *Executing instructions in Debug state* on page H2-4407 lists the memory access instructions that are supported in Debug state.

Bulk memory transfers

Memory access mode can accelerate bulk memory transfers in Debug state. See *DCC and ITR access modes* on page H4-4463.

H2.5 Exiting Debug state

The PE exits Debug state when it receives a Restart request trigger event. If EDSCR.ITE == 0 the behavior of any instruction issued through the ITR in normal mode or an operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the PE executes the restart sequence.
- It must complete execution in Non-debug state after the PE executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Note

- Implementations can set EDSCR.ITE to 1 to indicate that further instructions can be accepted by ITR before the previous instructions have completed. If any previous instruction has not completed and EDSCR.ITE == 1, then the PE must complete these instructions in Debug state before executing the restart sequence. EDSCR.ITE == 0 indicates that the PE is not ready to restart.
- A debugger must observe that any instructions issued through EDITR that might generate a synchronous exception, as complete, before issuing a restart request. It can do this by observing the completion of a later instruction, as synchronous exceptions must occur in program order. For example, a debugger can observe that an instruction that reads or writes a DTR register is complete because of its effect on the EDSCR.{TXfull, RXfull} flags.

On exiting Debug state, the PE sets the program counter to the address in DLR, where:

- If exiting to AArch32 state:
  - Bits[63:32] of DLR are ignored.
  - Bits[31:1] of the PC are set to the value of bits[31:1] of DLR.
  - Bit[0] of the PC is set to a CONSTRAINED UNPREDICTABLE choice of 0 or the value of bit[0] in DLR.
- If exiting to AArch64 state:
  - Bits[63:56] of DLR_EL0[31:0] might be ignored as part of tagged address handling. See *Address tagging in AArch64 state* on page D4-1634.
  - Otherwise the PC is set from DLR_EL0[31:0].

Exit from Debug state can give rise to a misaligned PC exception when the program counter is used. Unlike an exception return, this might also happen when returning to AArch32 state. For more information, see *PC alignment checking* on page D1-1415.

PSTATE is set from DSPSR in the same way that an exception return sets PSTATE from SPSR_ELx:

- The same illegal exception return checks that apply to an exception return also apply to exiting Debug state. If the return from Debug state is an illegal exception return then the effect on PSTATE and the PC is the same as for any other illegal exception return. See *Exception return* on page D1-1437.
- The checks on the PSTATE.IT bits that apply to exiting Debug state into AArch32 state are the same as those that apply to an exception return. See Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.
- PSTATE.SS is copied from DSPSR.SS if all of the following hold:
  - MDSCR_EL1.SS == 1.
  - The debug target Exception level is using AArch64.
  - Software step exceptions from the restart Exception level are enabled.

  However, if OSDLR.DLK == 1 and DBGPRCR.CORENPDRQ == 0 (that is, the OS Double Lock is locked in Non-debug state and thereby disabling Software Step exceptions) but otherwise Software Step exceptions would be enabled from the restart Exception level, it is CONSTRAINED UNPREDICTABLE whether PSTATE.SS is copied from DSPSR.SS.

Note

- One important difference between Debug state exit and an exception return is that the PE can exit Debug state at EL0. Despite this, the behavior of an exit from Debug state is similar to an exception return. For example, PSTATE.{D, A, I, F} is updated regardless of the value of SCTLR_EL1.UMA.
- Exit from Debug state has no architecturally-defined effect on the Event Register and exclusive monitors. An exit from Debug state might set the Event Register or clear the exclusive monitors, or both, but this is not a requirement and debuggers must not rely on any implementation specific behavior.

The pseudocode for `ExitDebugState()` is as follows.

```
// ExitDebugState()
// ================

ExitDebugState()
    assert Halted();
    SynchronizeContext();

    // Although EDSCR.STATUS signals that the processor is restarting, debuggers must use EDPRSR.SDR
    // to detect that the processor has restarted.
    EDSCR.STATUS = '000001';                          // Signal restarting
    // Return to saved processing state
    EDESR<2:0> = '000';                               // Clear any pending Halting debug events

    from_32 = (PSTATE.nRW == '1');

    new_pc = DLR_EL0;
    spsr = DSPSR;

    // If this is an illegal return, SetPSTATEFromPSR() will set PSTATE.IL.
    SetPSTATEFromPSR(spsr);                           // Can update privileged bits, even at EL0.

    if spsr<4> == '1' then
        // Align PC[1:0] according to the target instruction set state. If coming from AArch64 and
        // PSTATE.IL==1 then the state did not change, but the PC alignment might have occurred.
        if from_32 || PSTATE.IL == '0' || ConstrainUnpredictableBool() then
            if spsr<5> == '1' then                    // T32
                new_pc<0> = '0';
            else                                      // A32
                new_pc<1:0> = '00';

        // Zero the 32 most significant bits of the target PC
        if from_32 || PSTATE.IL == '0' || ConstrainUnpredictableBool() then
            new_pc<63:32> = Zeros();

    if PSTATE.nRW == '1' then
        BranchTo(new_pc<31:0>, BranchType_UNKNOWN);   // AArch32 branch
    else
        BranchTo(new_pc, BranchType_DBGEXIT);         // A type of branch that is never predicted

    (EDSCR.STATUS,EDPRSR.SDR) = ('000010','1');       // Atomically signal restarted
    UpdateEDSCRFields();                              // Stop signalling processor state.
    DisableITRAndResumeInstructionPrefetch();

    return;
```

Chapter H3
Halting Debug Events

This chapter describes a particular class of debug events. It contains the following sections:

Note

Table J-1 on page AppxJ-5170 disambiguates the general register references used in this chapter.

H3.1 Introduction to Halting debug events

External debug defines Halting debug events. The following Halting debug events are available in ARMv8:

- *Halting Step debug event* on page H3-4438.
- *Halt Instruction debug event* on page H3-4448.
- *Exception Catch debug event* on page H3-4449.
- *External Debug Request debug event* on page H3-4452.
- *OS Unlock Catch debug event* on page H3-4453.
- *Reset Catch debug event* on page H3-4454.
- *Software Access debug event* on page H3-4455.

If halting is allowed, a Halting debug event halts the PE. The PE enters Debug state.

In addition, breakpoints and watchpoints might halt the PE if halting is allowed. See *Breakpoint and Watchpoint debug events* on page H2-4396. Because breakpoints and watchpoints can generate an exception or halt the PE, Breakpoint and Watchpoint debug events are not classified as Halting debug events.

For a definition of Debug state, see Chapter H2 *Debug State*. For a definition of halting allowed, see *Halting allowed and halting prohibited* on page H2-4395.

Debug state entry and debug event prioritization on page H2-4397 describes the behavior when multiple debug events are generated by an instruction.

See also *Synchronization and Halting debug events* on page H3-4456.

Table H3-1 shows the behavior of Breakpoint, Watchpoint, and Halting debug events.

Table H3-1 Summary of debug events and possible outcomes

Debug event type	PE behavior when halting is:	
	Allowed	Prohibited
Breakpoint and Watchpoint debug events on page H2-4396	Halt	See Table D2-1 on page D2-1532 and Table G2-1 on page G2-3512
Halt Instruction debug event on page H3-4448	Halt	UNDEFINED
Software Access debug event on page H3-4455	Halt	Ignored
Exception Catch debug event on page H3-4449	Halt	Ignored
Halting Step debug event on page H3-4438	Halt	Pended
External Debug Request debug event on page H3-4452	Halt	Pended
Reset Catch debug event on page H3-4454	Halt	Pended
OS Unlock Catch debug event on page H3-4453	Pended	Pended

Table H3-2 shows where the pseudocode details for each Halting debug event type is located.

Table H3-2 Pseudocode details for Halting debug events

Halting debug event type	Pseudocode details
Halt Instruction debug event on page H3-4448	*HLT* on page C6-479 for AArch64 and *HLT* on page F7-2531 for AArch32
Software Access debug event on page H3-4455	*Pseudocode details for Software Access debug event* on page H3-4455
Exception Catch debug event on page H3-4449	*Pseudocode details for Exception Catch debug events* on page H3-4451
Halting Step debug event on page H3-4438	*Pseudocode details for Halting Step debug events* on page H3-4447

Table H3-2 Pseudocode details for Halting debug events (continued)

Halting debug event type	Pseudocode details
External Debug Request debug event on page H3-4452	*Pseudocode details for External Debug Request debug events* on page H3-4452
Reset Catch debug event on page H3-4454	*Pseudocode details for Reset Catch debug event* on page H3-4454
OS Unlock Catch debug event on page H3-4453	*Pseudocode details for OS Unlock Catch debug event* on page H3-4453

H3.2 Halting Step debug event

Halting Step is a debug resource that a debugger can use to make the PE step through code one instruction at a time. This section describes the Halting Step debug events. It is divided into the following sections:

- *Overview of a Halting Step debug event*.
- *The Halting Step state machine*.
- *Using Halting Step* on page H3-4441.
- *Detailed Halting Step state machine behavior* on page H3-4441.
- *Synchronization and the Halting Step state machine* on page H3-4444.
- *Stepping T32 IT instructions* on page H3-4445.
- *Disabling interrupts while stepping* on page H3-4446.
- *Syndrome information on Halting Step* on page H3-4446.
- *Pseudocode details for Halting Step debug events* on page H3-4447.

The architecture describes the behavior as a simple Halting Step state machine. See *The Halting Step state machine*.

H3.2.1 Overview of a Halting Step debug event

The behavior of Halting Step is defined by a state machine, shown in Figure H3-1 on page H3-4440. A Halting Step debug event executes a single instruction and then return control to the debugger. When debugger software wants to execute a Halting Step:

1. With the PE in Debug state, the debugger activates Halting Step.
2. The debugger signals the PE to exit Debug state and return to the instruction that is to be stepped.
3. The PE executes that single instruction.
4. The PE enters Debug state before executing the next instruction.

However, an exception might be generated while the instruction is being stepped. That is either:

- A synchronous exception generated by the instruction being stepped.
- An asynchronous exception taken before or after the instruction being stepped.

Halting Step has its own enable control bit, EDECR.SS and EDESR.SS.

Note

Because the Halting Step state machine states occur as a result of normal PE operation, the states can be described as both:

- PE states.
- Halting Step states.

H3.2.2 The Halting Step state machine

The state machine states are:

Inactive Halting Step is inactive. No Halting Step debug events can be generated, therefore execution is not affected by Halting Step. The PE is in this state whenever either of the following is true:

- Halting Step is disabled. That is, EDECR.SS is set to 0 and EDESR.SS is set to 0.
- Halting is prohibited. See *Halting the PE on debug events* on page H2-4395.

In Figure H3-1 on page H3-4440 this state is shown in red.

Active-not-pending

Halting Step is enabled and active. This is the state in which the PE steps an instruction. EDECR.SS == 1 and EDESR.SS == 0. A debugger must only set EDECR.SS to 1 when the PE is in Debug state.

In Figure H3-1 on page H3-4440 this state is shown in green.

Active-pending

Halting Step is enabled and active. The step has completed, and the PE enters Debug state. EDESR.SS == 1.

In Figure H3-1 on page H3-4440 this state is shown in green.

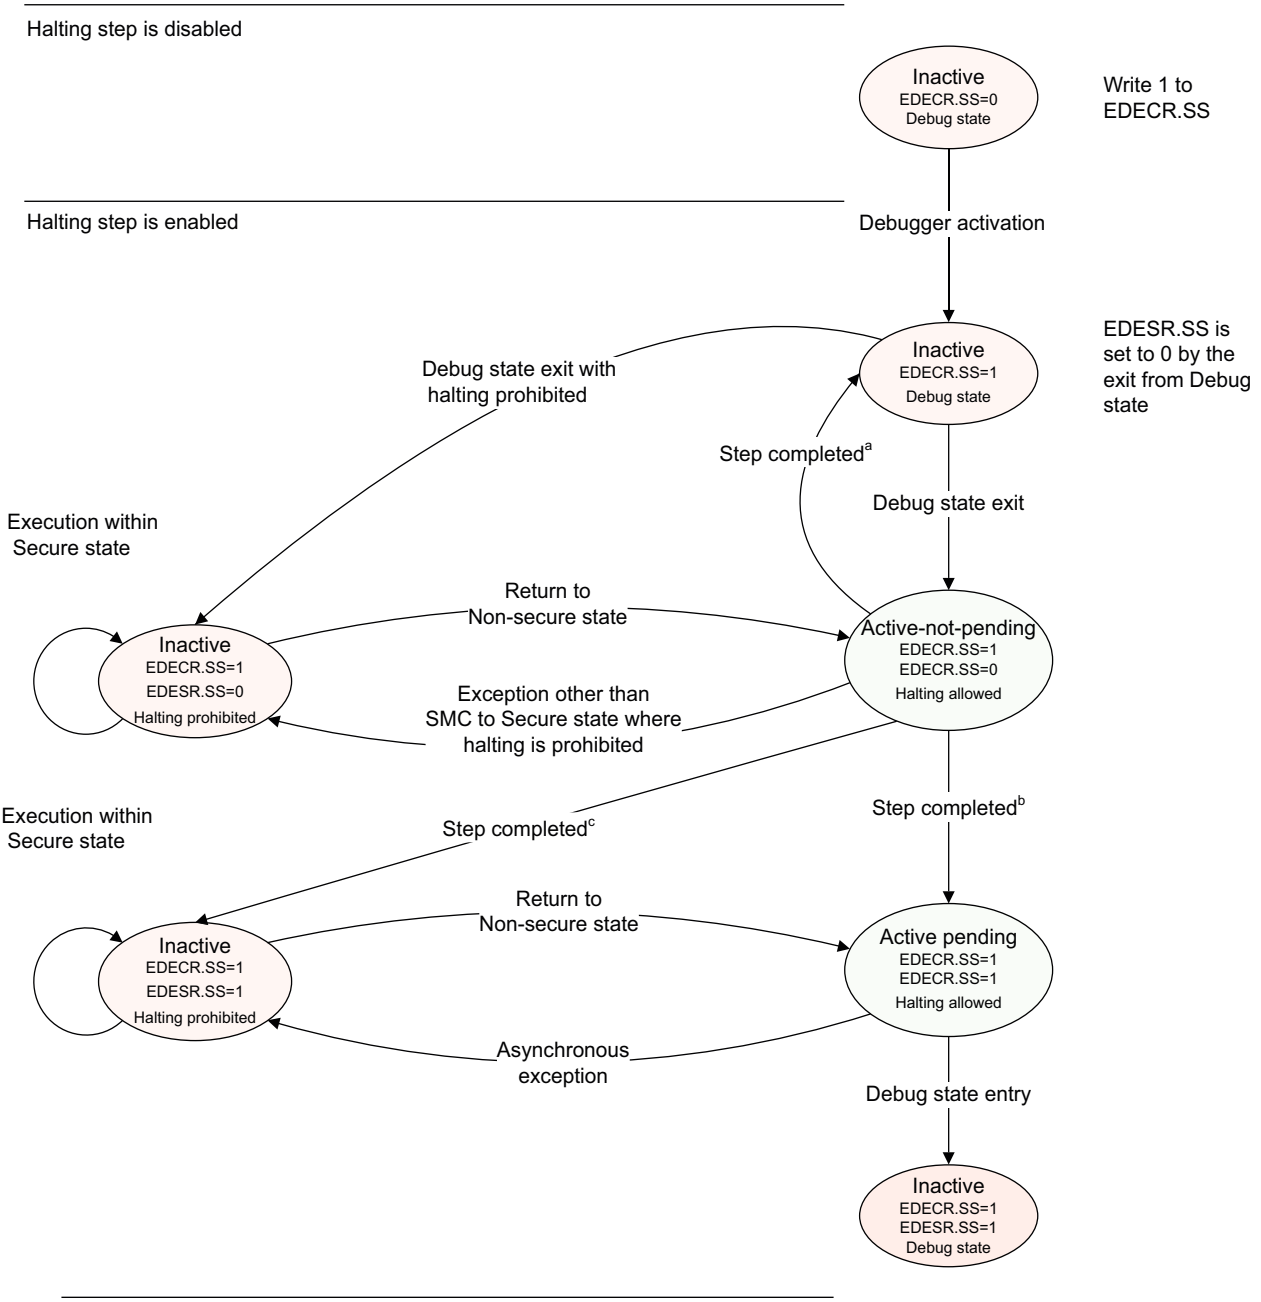
Whenever Halting Step is enabled and active, whether the state machine is in the active-not-pending state or in the active-pending state depends on EDESR.SS. *Halting Step state machine states* on page H3-4441 shows this.

In the simple sequential execution of the program the PE executes the Halting Step state machine, as follows:

1. Initially, Halting Step is inactive.
2. After exiting Debug state, Halting Step is active-not-pending.
3. The PE executes an instruction and Halting Step is active-pending.
4. The pending Debug state entry is taken on the next instruction and the step is complete.

Exceptions and other changes to the PE context can interrupt this sequence.

Figure H3-1 on page H3-4440 shows a Halting Step state machine.



a. Step completed occurs when:
   - A debug event, other than a Halting Step debug event, causes entry into Debug state.

b. Step completed occurs when:
   - An instruction is executed without taking an exception.
   - An exception is taken to a state where halting is allowed.
   - A reset.

c. Step completed occurs when:
   - An SMC exception is taken to Secure state where halting is prohibited.

Figure H3-1 Halting Step state machine

Note

Figure H3-1 on page H3-4440 only describes state transitions to and from the inactive state by exit from Debug state, executing an exception return, or taking an exception. Other changes to the PE context, including writes to registers such as EDECR and OSDLR and changes to the authentication interface can also cause changes to the Halting Step state machine. These can lead to UNPREDICTABLE behavior. See *Synchronization and the Halting Step state machine* on page H3-4444.

The following bits control the state machine, as shown in Table H3-3:

- EDECR.SS. This is the Halting Step enable bit.

  Note

  — The EDECR value is preserved over powerdown, meaning that the step active state is maintained over a powerdown event.

  — A debugger must only set EDECR.SS to 1 when the PE is in Debug state.

- EDESR.SS.

Table H3-3 shows the Halting Step state machine states. The letter X in a register column means that the relevant bit can be set to either zero or one.

Table H3-3 Halting Step state machine states

Halting	EDECR.SS	EDESR.SS	Halting Step state
Prohibited	X	X	Inactive
Allowed	0	0	Inactive
Allowed	1	0	Active-not-pending
Allowed	X	1	Active-pending

H3.2.3 Using Halting Step

To step a single instruction the PE must be in Debug state:

1. The debugger sets EDECR.SS to 1 to enable Halting step.
2. The debugger signals the PE to exit Debug state with DLR set to the address of the instruction being stepped. The PE clears EDESR.SS to 0 and the Halting Step state machine enter the active-not-pending state.
3. The PE executes the instruction being stepped.

   If an exception is taken to a state where halting is prohibited, then EDESR.SS is always correct for the preferred return address of the exception.
4. The PE enters Debug state before executing the next instruction and the step is complete.

H3.2.4 Detailed Halting Step state machine behavior

The behavior of the Halting Step state machine is described in the following sections:

- *Entering the active-not-pending state* on page H3-4442.
- *PE behavior in the active-not-pending state* on page H3-4442.
- *Entering the active-pending state* on page H3-4443.
- *PE behavior in the inactive state when in Non-debug state* on page H3-4444.
- *PE behavior in Debug state* on page H3-4444.

Entering the active-not-pending state

The PE enters the active-not-pending state:

- By exiting Debug state with EDECR.SS == 1.
- By an exception return from a state where halting is prohibited to a state where halting is allowed with EDECR.SS == 1 and EDESR.SS == 0.
- As described in *Synchronization and the Halting Step state machine* on page H3-4444.

PE behavior in the active-not-pending state

When the PE is in the active-not-pending state it does one of the following:

- It executes one instruction and does one of the following:
  - Completes it without generating a synchronous exception.
  - Generates a synchronous exception.
  - Generates a debug event that causes entry to Debug state.
- It takes an asynchronous exception without executing any instruction.
- It takes an asynchronous debug event into Debug state.

If no exception or debug event is generated

If no exception or debug event is generated the PE sets EDESR.SS to 1. This means that the Halting Step state machine advances to the active-pending state.

If an exception or debug event is generated

The PE sets EDESR.SS according to all of the following:

- The type of exception.
- The target Exception level of the exception.
- If the exception is taken to Secure state, whether halting is prohibited in Secure state.
  - This is determined by the result of `ExternalSecureInvasiveDebugEnabled()`.

If an exception or debug event is generated, the PE sets EDESR.SS to 1 if one of the following applies:

- A synchronous exception is generated by the instruction and one of the following applies:
  - The exception is taken to EL1 or EL2.
  - The exception is not an SMC exception and `ExternalSecureInvasiveDebugEnabled()` == TRUE.
  - The exception is an SMC exception.
- An asynchronous exception is generated before executing an instruction and this is either:
  - Taken to EL1 or EL2.
  - Taken to EL3 and `ExternalSecureInvasiveDebugEnabled()` == TRUE.
- A PE reset occurs.

Otherwise EDESR.SS is unchanged. This happens when:

- No instruction is executed because either:
  - An asynchronous exception is taken to EL3 and `ExternalSecureInvasiveDebugEnabled()` == FALSE.
  - An asynchronous debug event causes entry to Debug state.
- An instruction is executed and either:
  - Generates a synchronous exception other than an SMC exception which is taken to EL3, and `ExternalSecureInvasiveDebugEnabled()` == FALSE.
  - Generates a synchronous debug event and causes entry to Debug state.

If halting is prohibited after taking the exception or debug event, then the Halting Step state machine advances to the inactive state. Otherwise the Halting Step state machine advances to the active-pending state.

Note

The underlying criteria for the value of EDESR.SS on an exception are:

- Whether halting is allowed at the target of the exception. If halting is allowed, the PE must step into the exception. If halting is prohibited, the PE must step over the exception.
- Whether the preferred return address of the exception is the instruction itself or the next instruction, if the PE steps over the exception.

Table H3-4 shows the behavior of the active-not-pending state. The letter X indicates that `ExternalSecureInvasiveDebugEnabled()` can be either TRUE or FALSE.

Table H3-4 Summary of active-not-pending state behavior

Event	Target EL	`ExternalSecureInvasiveDebugEnabled()`	Value written to EDESR.SS
No exception or debug event	Not applicable	X	1
SMC exception	EL3	X	1
Reset	Highest	X	1
Exception, other than SMC exception	EL1	X	1
	EL2	X	1
	EL3	TRUE	1
		FALSE	0
Debug event	Debug state	X	0

Entering the active-pending state

The PE enters the active-pending state by one of the following:

- From the active-not-pending state by:
  - Executing an instruction without taking an exception.
  - Taking an exception so that the PE remains in a state where halting is allowed.
- An exception return from a state where halting is prohibited when EDESR.SS == 1.

  Note

  That is, an exception return from Secure state with `ExternalSecureInvasiveDebugEnabled()` == FALSE to Non-secure state with `ExternalInvasiveDebugEnabled()` == TRUE.
- A reset when the value of EDECR.SS == 1, regardless of the state the PE was in before the reset occurred.
- Following the description in *Synchronization and the Halting Step state machine* on page H3-4444.

When the PE is in the active-pending state, it enters Debug state before executing an instruction. However, if `ExternalSecureInvasiveDebugEnabled()` == FALSE, the architecture does not define the prioritization of this Debug state entry with respect to any pending asynchronous exception that is taken from Non-secure state to EL3.

If an exception is prioritized over the halt, then EDESR.SS is unchanged. On return from the exception the Halting Step state machine re-enters the active-pending state.

The entry into Debug state has higher priority than all other types of exception, including all other asynchronous exceptions.

Note

This means that it is possible to step a reentrant exception in the exception vector table.

PE behavior in the inactive state when in Non-debug state

EDESR.SS is not updated by the execution of an instruction or the taking of an exception when Halting Step is inactive. This means that EDESR.SS is not changed by an exception handled in a state where halting is prohibited.

On return to a state where halting is allowed, the Halting Step state machine is restored either to the active-pending state or the active-not-pending state, depending on the value of EDESR.SS. The return to a state where halting is allowed is normally by an exception return, which is a *Context synchronization operation*.

See also *Synchronization and the Halting Step state machine*.

PE behavior in Debug state

Entry to Debug state, the execution of an instruction in Debug state, or the taking of an exception when in Debug state, does not change EDESR.SS.

EDESR.SS is cleared to 0 on exiting Debug state as the result of a restart request. This forces the Halting Step state machine to active-not-pending if EDECR.SS == 1.

Note

Using Halting Step to step over an A32 instruction that generates a misaligned PC value does not suppress the resulting misaligned PC exception. On exiting Debug state, the misaligned PC value is written from DLR and a misaligned PC exception is generated.

However, if the PE exits Debug state as the result of a PE reset and EDECR.SS == 1, then the PE immediately enters the active-pending state, as EDESR.SS is set to the value of EDECR.SS.

H3.2.5 Synchronization and the Halting Step state machine

The Halting Step state machine also changes state if:

- Halting becomes allowed or prohibited other than by exit from Debug state, an exception return, or taking an exception. This means that halting becomes allowed or prohibited because:
  - The security state changes without an exception return. See *State and mode changes without explicit context synchronization operations* on page G2-3572.
  - The external authentication interface changes.
  - The OS Double Lock status, `DoubleLockStatus()`, changes.
- A write to EDECR when the PE is in Non-debug state changes the value of EDECR.SS.
- A write to EDESR when the PE is in Non-debug state clears EDESR.SS to 0.

These operations are guaranteed to take effect only after a *Context synchronization operation*.

The PE must perform the required behavior of the new state before or immediately following the next *Context synchronization operation*, but it is not required to do so immediately. This means that the PE can perform the required behavior of the old state before the next *Context synchronization operation*. This is illustrated in Example H3-1 on page H3-4445 and Example H3-2 on page H3-4445.

Example H3-1 Synchronization requirements 1

EDECR.SS is set to 1 in Debug state, requesting the active-not-pending state on exit from Debug state. On exit from Debug state the PE immediately takes an exception to Secure state. `ExternalSecureInvasiveDebugEnabled() ==` FALSE, meaning that halting is prohibited in Secure state. The PE does not step any instructions but executes the software in Secure state as normal. EDESR.SS remains set to 0. If `ExternalSecureInvasiveDebugEnabled()` subsequently becomes TRUE, meaning that halting is now allowed, the PE must perform the required behavior of the active-not-pending state before or immediately following the next *Context synchronization operation*, but it is not required to do so immediately.

Example H3-2 Synchronization requirements 2

EDECR.SS is set to 1 in Debug state. On exit from Debug the PE executes an `MSR` instruction that sets OSDLR_EL1.DLK to 1 and `DoubleLockStatus()` becomes TRUE. This change requires a *Context synchronization operation* to guarantee its effect, meaning it is CONSTRAINED UNPREDICTABLE whether:

- Halting is allowed:
  - The PE enters Debug state on the next instruction.
- Halting is prohibited:
  - The PE does not enter Debug state.

The value in EDESR.SS depends on whether halting was allowed or prohibited when the write to OSDLR_EL1.DLK completed, and so it might be 0 or 1. If a second `MSR` instruction clears OSDLR_EL1.DLK to 0, the PE must perform the required behavior of the state indicated by EDESR.SS before or immediately following the next *Context synchronization operation*, but it is not required to do so immediately.

See also *Synchronization and Halting debug events* on page H3-4456.

H3.2.6 Stepping T32 `IT` instructions

The ARMv8 architecture permits a combination of one T32 `IT` instruction and another 16-bit T32 instruction to be treated as one 32-bit instruction when the value of SCTLR.ITD, SCTLR_EL1.ITD or HSCTLR.ITD as applicable, is 1.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:

- The PE considers such a pair of instructions to be one instruction.
- The PE considers such a pair of instructions be two instructions.

It is IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable ITD bit. For example:

- The debug logic might consider such a pair of instructions to be one instruction, regardless of the state of SCTLR.ITD, SCTLR_EL1.ITD, or HSCTLR.ITD.
- The debug logic might consider such a pair of instructions to be two instructions, regardless of the state of SCTLR.ITD, SCTLR_EL1.ITD, or HSCTLR.ITD.
- The debug logic might consider such a pair of instructions to be one instruction when SCTLR.ITD, SCTLR_EL1.ITD, or HSCTLR.ITD is set to 1, and two instructions when the ITD bit is set to 0.

H3.2.7 Disabling interrupts while stepping

When using Halting Step, the sequence of entering Debug state, interacting with the debugger, and then exiting Debug state for each instruction reduces the rate at which the PE executes instructions. However, the rate at which certain interrupts, such as timer interrupts, are generated might be fixed by the system. This means it might be necessary to disable interrupts while using Halting Step by setting EDSCR.INTdis, to allow the code being debugged to make forward progress.

H3.2.8 Syndrome information on Halting Step

Three EDSCR.STATUS encodings record different scenarios for entering Debug state on a Halting Step debug event:

Halting Step, normal

An instruction other than a Load-Exclusive instruction was stepped.

Halting Step, exclusive

A Load-Exclusive instruction was stepped.

Halting Step, no syndrome

The syndrome data is not available.

If the PE enters Debug state due to a Halting Step debug event immediately after stepping an instruction in the active-not-pending state, EDSCR.STATUS is set to either:

- Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.
- Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.

If the stepped instruction was a conditional Load-Exclusive instruction that failed its condition code test, EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, normal, or Halting Step, exclusive.

Otherwise the PE enters Debug state without stepping an instruction. This means that the Halting Step state machine enters the active-pending state directly from the inactive state, without going through active-not-pending state. In this case, EDSCR.STATUS is set to Halting Step, no syndrome. This happens when:

- The PE enters directly into the active-pending state on an exception return to Non-secure state from EL3 when Halting is prohibited in Secure state.
- A pending asynchronous exception is taken before the instruction is executed.
- The active-pending state is entered for other reasons. See *Synchronization and the Halting Step state machine on page H3-4444*

In these cases the debugger cannot determine whether the instruction that was stepped was a Load-Exclusive instruction.

In addition, EDSCR.STATUS is set to one of a CONSTRAINED UNPREDICTABLE choice if:

- The instruction being stepped generated a synchronous exception, meaning that it was not completed.

  In this case EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of:

  — Halting Step, no syndrome, or Halting Step, normal, if the stepped instruction was not a Load-Exclusive instruction.

  — Halting Step, no syndrome, or Halting Step, exclusive, if the stepped instruction was a Load-Exclusive instruction.

- The instruction that was stepped was an exception return instruction or an `ISB`. As these instructions are not in the Load-Exclusive instructions, EDSCR.STATUS is set to a CONSTRAINED UNPREDICTABLE choice of Halting Step, no syndrome or Halting Step, normal.

In all cases, if EDSCR.STATUS is not set to Halting Step, no syndrome, then it must indicate whether the stepped instruction was a Load-Exclusive instruction by setting EDSCR.STATUS to Halting Step, normal or Halting Step, exclusive.

Note

An implementation that always sets EDSCR.STATUS to Halting Step, no syndrome is not compliant.

H3.2.9 Pseudocode details for Halting Step debug events

There are two pseudocode functions for Halting Step debug events:

- `RunHaltingStep()`. This is called after an instruction has executed and any exception generated by the instruction is taken. It is also called after taking a reset before executing any instructions. That is, reset is treated like an asynchronous exception, even if EDECR.RCE == 1. `RunHaltingStep()` affects the next instruction.
- `CheckHaltingDebugStep()`. This is called before the next instruction is executed. If a step is pending, it generates the debug event.

```
// RunHaltingStep()
// ================

RunHaltingStep(boolean exception_generated, bits(2) exception_target, boolean syscall,
               boolean reset)
    // “exception_generated” is TRUE if the previous instruction generated a synchronous exception
    // or was cancelled by an asynchronous exception.
    // if “exception_generated” == TRUE then “exception_target” is the target of the exception, and
    // “syscall” is TRUE if the exception is a synchronous exception where the preferred return
    // address is the instruction following that which generated the exeception.
    // “reset” = TRUE if exiting reset state into the highest EL.
    if reset then assert !Halted();             // Cannot come out of reset halted

    active = EDECR.SS == ‘1’ && !Halted();

    if active && reset then                     // Coming out of reset with EDECR.SS set.
        EDESR.SS = ‘1’;
    elsif active && HaltingAllowed() then
        if exception_generated && exception_target == EL3 then
            advance = syscall || ExternalSecureInvasiveDebugEnabled();
        else
            advance = TRUE;
        if advance then EDESR.SS = ‘1’;

    return;

// CheckHaltingStep()
// ==================
// Check whether EDESR.SS has been set by Halting Step

CheckHaltingStep()
    if HaltingAllowed() && EDESR.SS == ‘1’ then
        // The STATUS code depends on how we arrived at the state where EDESR.SS == 1.
        if HaltingStep_DidNotStep() then
            Halt(DebugHalt_Step_NoSyndrome);
        elsif HaltingStep_SteppedEX() then
            Halt(DebugHalt_Step_Exclusive);
        else
            Halt(DebugHalt_Step_Normal);
```

H3.3 Halt Instruction debug event

A Halt Instruction debug event is generated when EDSCR.HDE == 1, halting is allowed, and software executes the Halting software breakpoint instruction, HLT.

The pseudocode for Halt Instruction Debug events is described in *HLT* on page C6-479 for A64 and *HLT* on page F7-2531 for A32 and T32.

HLT never generates a debug exception. It is treated as UNDEFINED if EDSCR.HDE == 0, or if halting is prohibited.

Note

A debugger can replace a program instruction with a Halt instruction to generate a Halting Software Breakpoint. Debuggers that use the HLT instruction must be aware of the ARMv8-A rules for concurrent modification of executable code, CMODX. The rules for concurrent modification and execution of instructions do not allow one thread of execution or an external debugger to replace an instruction with an HLT instruction when these same instructions are being executed by a different thread of execution. See *Concurrent modification and execution of instructions* on page B2-80.

The T32 HLT instruction is unconditionally executed inside an IT block, even when it is treated as UNDEFINED. The A32 HLT instruction is CONSTRAINED UNPREDICTABLE if the condition code field is not 0b1110, with the set of behaviors the same as for BKPT. See Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Note

The HLT instruction is part of the external debug solution for ARMv8-A. As such, the presence of the HLT instruction is not indicated in the ID registers. In particular, the AArch32 CP15 register ID_ISAR0.Debug does not indicate the presence of the HLT instruction.

H3.3.1 HLT instructions as the first instruction in a T32 IT block

The ARMv8 architecture defines combinations of IT and a single 16-bit T32 instruction that can be treated as a 32-bit instruction when SCTLR.ITD, SCTLR_EL1.ITD or HSCTLR.ITD, as applicable, is set to 1.

The T32 HLT instruction is not such an instruction. If the first instruction in an IT block is an HLT instruction, then the behavior of the instruction depends on the value of SCTLR.ITD, SCTLR_EL1.ITD or HSCTLR.ITD, as applicable:

- If the ITD bit is set to 1, then the combination is treated as UNDEFINED and an Undefined Instruction exception is generated either by the IT instruction or by the HLT instruction.
- If the ITD bit is set to 0, then the HLT instruction either:
  - Is treated as UNDEFINED and generates an Undefined Instruction exception.
  - Generates an HLT Instruction debug event.

To set an HLT Instruction debug event on the first instruction of an IT block, debuggers must replace the IT instruction with an HLT instruction to ensure consistent behavior.

Note

An HLT instruction is always unconditional, even within an IT block.

H3.4 Exception Catch debug event

Exception Catch debug events:

- Are generated when the corresponding bit in the Exception Catch Control Register, EDECCR, is set to 1 on all entries to a given Exception level. This means:
  - Exceptions taken to the Exception level.
  - Exception returns to the Exception level.
  - Entry to the Exception level due to reset. This is an overlap with a Reset Catch debug event. See *Reset Catch debug event* on page H3-4454.
  - Exit from Debug state to the Exception level.
- Are taken synchronously, after entry to the Exception level.
- Ignore the Execution state of the target Exception level.
- Are ignored if halting is prohibited.

The EDECCR contains two fields:

- One field for Non-secure state.
- One field for Secure state.

Each field contains one bit for each Exception level in that state. Bits corresponding to Exception levels that are not implemented are RES0. See *EDECCR, External Debug Exception Catch Control Register* on page H9-4572.

Note

- EDECCR does not replace DBGVCR:
  - DBGVCR is retained in AArch32 state for backwards compatibility.
  - DBGVCR is ignored in AArch64 state and never generates entries to Debug state.
  - DBGVCR cannot be accessed by the external debug interface.
- EDECCR is only visible as OSECCR_EL1 by System Register instructions in AArch64 state, and as DBGOSECCR by CP14 register access instructions in AArch32 state, when the OS Lock is locked to allow software to save and restore it over a powerdown.
- Exception Catch debug events are not disabled when the OS Lock is locked.

For an Exception Catch debug event generated after taking an exception to a trapped Exception level:

- The PE must not fetch instructions from the vector address before entering Debug state, if the translation regime MMU at the target Exception level is disabled.
- On entering Debug state:
  - The current Exception level is the target Exception level of the exception.
  - The ELR, SPSR, ESR, and other syndrome registers contain information about the exception.
  - DLR contains the exception vector address.

H3.4.1 Prioritization of Exception Catch debug events

Exception Catch debug events have a higher priority than all synchronous exceptions other than *Software Step exceptions* on page D2-1579 and a lower priority than *Reset Catch debug event* on page H3-4454. It is IMPLEMENTATION DEFINED whether Exception Catch debug events are higher or lower priority than both:

- *Software Step exceptions* on page D2-1579.
- *Halting Step debug event* on page H3-4438.

Note

As described in *Synchronous exception prioritization* on page D1-1448, an exception trapping form of a Vector Catch debug event might generate a second debug exception as part of the exception entry, before the Exception Catch debug event is taken. See *Vector Catch exceptions* on page D2-1578 or *Vector Catch exceptions* on page G2-3564.

A second unmasked asynchronous exception can be taken before the PE enters Debug state. If this second exception does not generate an Exception Catch debug event, the exception handler executed at the higher Exception level later returns to the trapped Exception level, causing the Exception Catch debug event to be generated again.

See also *Debug state entry and debug event prioritization* on page H2-4397.

H3.4.2 UNPREDICTABLE generation of Exception Catch debug events

When the PE is executing code at a given Exception level and the corresponding EDECCR bit is 1, it is CONSTRAINED UNPREDICTABLE whether an Exception Catch debug event is generated.

Note

It is possible to generate Exception Catch debug events:

- As a trap on all instruction fetches from the trapped Exception level as part of an instruction fetch.
- On entry to the Exception level, as described in *Detailed Halting Step state machine behavior* on page H3-4441.

This is similar to the implementation options allowed for Vector Catch debug events. The architecture does not require that the event is generated following an `ISB` operation executed at the Exception level.

Examples of this are:

- If the debugger writes to EDECCR so that the current Exception level is trapped.
- If the OS restore code writes to OSECCR so that the current Exception level is trapped.
- If the code executing in AArch32 state changes the Exception level or security state other than by an exception return, and the target Exception level is trapped. See *State and mode changes without explicit context synchronization operations* on page G2-3572.

H3.4.3 Examples of Exception Catch debug events

If EDECCR == `0x20`, meaning that the Exception Catch debug event is enabled for Non-secure EL1, then the following exceptions generate Exception Catch debug events:

- An exception taken from Non-secure EL0 to Non-secure EL1.
- An exception return from EL2 to Non-secure EL1.
- An exception return from EL3 to Non-secure EL1.

For example, on taking a Data Abort exception from Non-secure EL0 to Non-secure EL1, using AArch64:

- ELR_EL1 and SPSR_EL1 are written with the preferred return address and PE state for a return to EL0.
- ESR_EL1 and FAR_EL1 are written with the syndrome information for the exception.
- DLR_EL0 is set to VBAR_EL1 + `0x400`, the synchronous exception vector.
- DSPSR_EL0 is written with the PE state for an exit to EL1.

The following do not generate Exception Catch debug events:

- An exception taken from Non-secure EL0 to EL2 or EL3.
- An exception return from EL2 to Non-secure EL0.
- An exception taken from Secure EL0 to Secure EL1.
- An exception return from EL3 to Secure EL1.

H3.4.4 Pseudocode details for Exception Catch debug events

The pseudocode for the CheckExceptionCatch() function is as follows:

```
// CheckExceptionCatch()
// =====================
// Check whether an Exception Catch debug event is set on the current Exception level

CheckExceptionCatch()
    // Called after taking an exception, that is, such that IsSecure() and PSTATE.EL are correct
    // for the exception target.
    base = if IsSecure() then 0 else 4;
    if HaltingAllowed() && EDECCR<UInt(PSTATE.EL) + base> == '1' then
        Halt(DebugHalt_ExceptionCatch);
```

H3.5 External Debug Request debug event

An External Debug Request debug event is generated when signaled by the embedded cross-trigger. See Chapter H5 *The Embedded Cross Trigger Interface*.

Note

ARMv8-A requires the implementation of an embedded cross-trigger.

External Debug Request debug events are asynchronous debug events.

An implementation might also support IMPLEMENTATION DEFINED ways of generating an External Debug Request debug event.

H3.5.1 Pseudocode details for External Debug Request debug events

The pseudocode details for the `ExternalDebugRequest()` function is as follows:

```
// ExternalDebugRequest()
// ======================

ExternalDebugRequest()
    if HaltingAllowed() then
        Halt(DebugHalt_EDBGRQ);
    // Otherwise the CTI continues to assert the debug request until it is taken.
```

H3.6 OS Unlock Catch debug event

An OS Unlock Catch debug event is generated when EDECR.OSUCE == 1 and the state of the OS Lock changes from locked to unlocked.

When the OS Unlock Catch debug event is generated, it is recorded by setting EDESR.OSUC to 1, meaning it immediately becomes pending and is not guaranteed to be taken immediately. Clearing the OS Lock is not a self-synchronizing operation. See *Synchronization and Halting debug events* on page H3-4456.

OS Unlock Catch debug events are not generated if the OS Lock is unlocked when the PE is in Debug state. See also:

- *Debug behavior when the OS Lock is unlocked* on page H6-4504.
- *EDECR, External Debug Execution Control Register* on page H9-4574.
- *EDESR, External Debug Event Status Register* on page H9-4576.

EDESR.OSUC is cleared to 0 on a Warm reset and on exiting Debug state.

H3.6.1 Using the OS Unlock Catch debug event

If the debugger attempts to access a debug register when the Core power down domain is completely off or in a low-power state in which the core power domain registers cannot be accessed, and that access returns an error, then the debugger must retry the access. However, if the Core power domain is regularly powered down, this can lead to unreliable debugger behavior.

The debugger can program a Reset Catch debug event to halt the PE when it has powered-up, and can program the debug registers from Debug state. However, if the PE boot software restores the debug registers, as described in *Debug OS Save and Restore sequences* on page H6-4502, then newly written values are overwritten by the restore sequence.

The debugger can program an OS Unlock Catch debug event to halt the PE after the restore sequence has completed, and program the debug registers from Debug state.

H3.6.2 Pseudocode details for OS Unlock Catch debug event

The `CheckOSUnlockCatch()` function is called when the OS Lock is unlocked.

```
// CheckOSUnlockCatch()
// ====================
// Called on unlocking the OS Lock to pend an OS Unlock Catch debug event

CheckOSUnlockCatch()
    if EDECR.OSUCE == '1' && !Halted() then EDESR.OSUC = '1';
```

The `CheckPendingOSUnlockCatch()` function is called before an instruction is executed. If an OS Unlock Catch is pending, it generates the debug event.

```
// CheckPendingOSUnlockCatch()
// ===========================
// Check whether EDESR.OSUC has been set by an OS Unlock Catch debug event

CheckPendingOSUnlockCatch()
    if HaltingAllowed() && EDESR.OSUC == '1' then
        Halt(DebugHalt_OSUnlockCatch);
```

H3.7 Reset Catch debug event

A Reset Catch debug event is generated when EDECR.RCE == 1 and the PE exits reset state. When the Reset Catch debug event is generated, it is recorded by setting EDESR.RC to 1.

If halting is allowed when the event is generated, the Reset Catch debug event is taken immediately and synchronously. On entering Debug state, DLR has the address of the reset vector. The PE must not fetch any instructions from memory.

Otherwise, the Reset Catch debug event is pended and taken when halting is allowed. See also:

- *Synchronization and Halting debug events* on page H3-4456.
- *EDECR, External Debug Execution Control Register* on page H9-4574.
- *EDESR, External Debug Event Status Register* on page H9-4576.

This means that EDESR.RC is set to the value of EDECR.RCE on a Warm reset. EDESR.RC is cleared to 0 on exiting Debug state.

H3.7.1 Pseudocode details for Reset Catch debug event

The `CheckResetCatch()` function is called after reset before executing any instruction.

```
// CheckResetCatch()
// =================
// Called after reset

CheckResetCatch()
    if EDECR.RCE == '1' then
        EDESR.RC = '1';
        // If halting is allowed then halt immediately
        if HaltingAllowed() then Halt(DebugHalt_ResetCatch);
```

The `CheckPendingResetCatch()` function is called before an instruction is executed. If a Reset Catch is pending, it generates the Reset Catch debug event.

```
// CheckPendingResetCatch()
// ========================
// Check whether EDESR.RC has been set by a Reset Catch debug event

CheckPendingResetCatch()
    if HaltingAllowed() && EDESR.RC == '1' then
        Halt(DebugHalt_ResetCatch);
```

H3.8 Software Access debug event

When the value of EDSCR.TDA == 1, software access to the following debug registers cause a trap to Debug state:

- The Breakpoint Value Registers, DBGBVR.
- The Breakpoint Control Registers, DBGBCR.
- The Watchpoint Value Registers, DBGWVR.
- The Watchpoint Control Registers, DBGWCR.

However, EDSCR.TDA is ignored if either:

- The value of OSLSR.OSLK == 1, meaning that the OS Lock is locked.
- Halting is prohibited. See *Halting allowed and halting prohibited* on page H2-4395.

Note

- The accesses are only trapped into Debug state if they do not generate an exception. For more information see the relevant register description in Chapter D7 *AArch64 System Register Descriptions*, Chapter G5 *AArch32 System Register Descriptions*, or Chapter I3 *Memory-Mapped System Register Descriptions*.
- DBGPRCR.CORENPDRQ (Core No-powerdown Request), DCC registers, and CLAIM tag bits are also shared, but are deliberately excluded from this list.

H3.8.1 Pseudocode details for Software Access debug event

The pseudocode details for `CheckSoftwareAccessToDebugRegisters()` are as follows:

```
// CheckSoftwareAccessToDebugRegisters()
// =====================================
// Check for access to Breakpoint and Watchpoint registers.

CheckSoftwareAccessToDebugRegisters()

    os_lock = (if ELUsingAArch32(EL1) then DBGOSLSR.OSLK else OSLSR_EL1.OSLK);
    if HaltingAllowed() && EDSCR.TDA == '1' && os_lock == '0' then
        Halt(DebugHalt_SoftwareAccess);
```

H3.9 Synchronization and Halting debug events

The behavior of external debug depends on:

- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special purpose registers.
- The state of the external authentication interface.

This means that any change to these registers or the external authentication interface requires explicit synchronization by a *Context synchronization operation* before the change takes effect. This ensures that for instructions appearing in program order after the change, the change affects the following:

- The generation and behavior of Software debug events. See *Synchronization and debug exceptions* on page D2-1593 for exceptions taken from AArch64 state, or *Synchronization and debug exceptions* on page G2-3572 for exceptions taken from AArch32 state.
- The generation of all Halting debug events.
- Taking a pending Halting debug event or other asynchronous Debug event. See:
  - *Pending Halting debug events*.
  - *Taking Halting debug events asynchronously* on page H3-4457.
- The behavior of the Halting Step state machine. See *Synchronization and the Halting Step state machine* on page H3-4444.

If there is an instruction between the write and the *Context synchronization operation*, it is CONSTRAINED UNPREDICTABLE whether the PE uses the old state or the new state.

Some register updates are self-synchronizing, but others require an explicit *Context synchronization operation*. For more information on the synchronization of register updates see:

- *Synchronization requirements for System registers* on page D7-1794.
- *Synchronization of changes to the external debug registers* on page H8-4517.
- *State and mode changes without explicit context synchronization operations* on page G2-3572.

A change on the external authentication interface is typically asynchronous to software and can happen without a *Context synchronization operation*.

External Debug Request debug events must be taken in finite time, without requiring the synchronization of any necessary change to the external authentication interface.

Example H3-3 shows an example of the synchronization requirements.

Example H3-3 Synchronization requirements

Secure software locks up in a tight loop, so it executes indefinitely without any synchronization operations. An External debug request must be able to break the PE out of that loop. This is a requirement even if **DBGEN** or **SPIDEN** or both are LOW on entry to the loop, meaning that halting is prohibited, and are only asserted HIGH later.

H3.9.1 Pending Halting debug events

A pending Halting debug event is taken when halting becomes allowed. This can happen without a *Context synchronization operation* if:

- The PE enters Non-secure state with `ExternalInvasiveDebugEnabled()` == TRUE, and this is not the result of an exception return. See *State and mode changes without explicit context synchronization operations* on page G2-3572.
- A change on the external authentication interface means halting becomes allowed in the current state.

- The OS Double Lock status, `DoubleLockStatus()` becomes FALSE. For example, this can happen when software clears OSDLR.DLK to 0 or sets DBGPRCR.COREPDRQ to 1.
- The debug event is an OS Unlock Catch debug event. OS Unlock Catch debug events are generated in a pending state, rather than taken synchronously.

In these cases a pending Halting debug event is taken asynchronously.

H3.9.2 Taking Halting debug events asynchronously

The ARM architecture does not define when Halting debug events that are taken asynchronously are taken.

Any Halting debug event that is observed as pending in the EDESR before a *Context synchronization operation*, or an External Debug Request debug event that is asserted before a *Context synchronization operation*, is taken and the PE enters Debug state before the first instruction following the *Context synchronization operation* completes its execution. This is only possible if halting is allowed after completion of the *Context synchronization operation*.

If the first instruction after the *Context synchronization operation* generates a synchronous exception, or an asynchronous exception is also pending, then the architecture does not define the order in which the debug event and the exception or exceptions are taken, unless both:

- A Halting Step debug event is pending. EDESR.SS == 1.
- The *Context synchronization operation* is an exception return from a state where halting is prohibited to a state where halting is allowed.

Note

This applies to an exception return from Secure state with `ExternalSecureInvasiveDebugEnabled()` == FALSE to Non-secure state with `ExternalInvasiveDebugEnabled()` == TRUE.

In this case the order in which the debug events are handled is specified to avoid a double-step. See *Entering the active-pending state* on page H3-4443.

Note

These rules are based on the rules that apply to taking asynchronous exceptions. See *Asynchronous exception types, routing, masking and priorities* on page D1-1453.

Chapter H4
The Debug Communication Channel and Instruction Transfer Register

This chapter describes communication between a debugger and the implemented debug logic, using the *Debug Communications Channel* (DCC) and the I*nstruction Transfer Registe*r (ITR), and associated control flags. It contains the following sections:

Note

Where necessary Table J-1 on page AppxJ-5170 disambiguates the general register references used in this chapter.

H4.1 Introduction

The *Debug Communications Channe*l, DCC, is a channel for passing data between the PE and an external agent, such as a debugger. The DCC provides a communications channel between:

- An external debugger, described as the *debug host*.
- The debug implementation on the PE, described as the *debug target*.

The DCC can be used:

- As a 32-bit full-duplex channel.
- As a 64-bit half-duplex channel.

The DCC is an essential part of Debug state operation and can also be used in Non-debug state.

The *Instruction Transfer Register*, ITR, passes instructions to the PE to execute in Debug state.

The PE includes flow-control mechanisms for both the DCC and ITR.

H4.2 DCC and ITR registers

The DCC comprises *data transfer registers*, the DTRs, and associated flow-control flags. The data transfer registers are DTRRX and DTRTX.

The ITR comprises a single register, EDITR, and associated flow-control flags.

In AArch64 state, software can access the data transfer registers as:

- A receive and transmit pair for 32-bit full duplex operation:
  - The write-only DBGDTRTX_EL0 register to transmit data.
  - The read-only DBGDTRRX_EL0 register to receive data.
- A single 64-bit read/write register, DBGDTR_EL0, for 64-bit half-duplex operation.
- The read/write OSDTRTX_EL1 and OSDTRRX_EL1 registers for save and restore.

In AArch32 state, software can only access the data transfer registers as:

- A receive and transmit pair, for 32-bit full duplex operation:
  - The write-only DBGDTRTXint register to transmit data.
  - The read-only DBGDTRRXint register to receive data.
- The read/write DBGDTRTXext and DBGDTRRXext registers for save and restore.

The data transfer registers are also accessible by the external debug interface as a pair of 32-bit registers, DBGDTRRX_EL0 and DBGDTRTX_EL0. Both registers are read/write, allowing both 32-bit full-duplex and 64-bit half-duplex operation.

The DCC flow-control flags are EDSCR.{RXfull, TXfull, RXO, TXU}:

- The RXfull and TXfull ready flags are used for flow-control and are visible to software in the debug system registers in DCCSR.
- The RX overrun flag, RXO, and the TX underrun flag, TXU, report flow-control errors.
- The flow-control flags are also accessible by software as simple read/write bits for saving and restoring over a powerdown when the OS Lock is locked in DSCR.
- The flow-control flags are accessible from the external debug interface in EDSCR.

Figure H4-1 on page H4-4462 shows the system register and external debug interface views of the EDSCR and DTR registers in both AArch64 state and AArch32 state. These figures do not include the save and restore views.

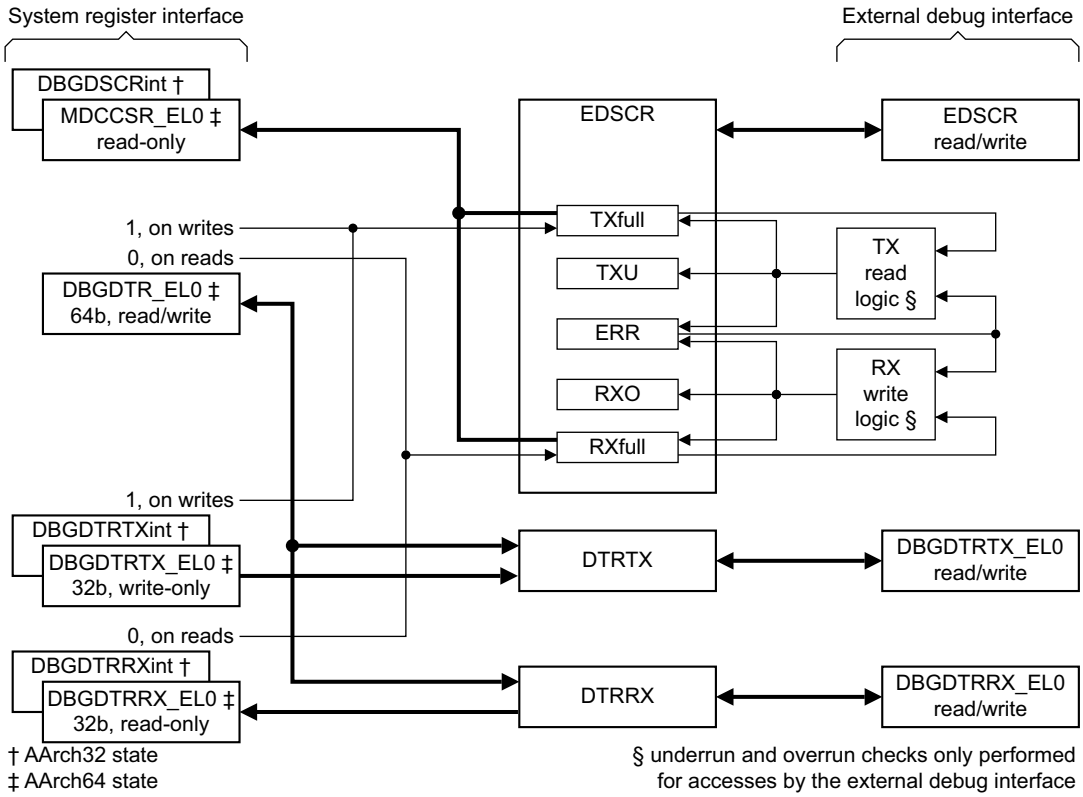


Figure H4-1 System register and external debug interface views of EDSCR and DTR registers, Normal access mode

EDITR and the ITR flow-control flags, EDSCR.{ITE, ITO} are accessible only by the external debug interface:

- The EDITR specifies an instruction to execute in Debug state.
- The ITR empty flag, ITE, is used for flow-control.
- The ITR overrun flag, ITO, reports flow-control errors.

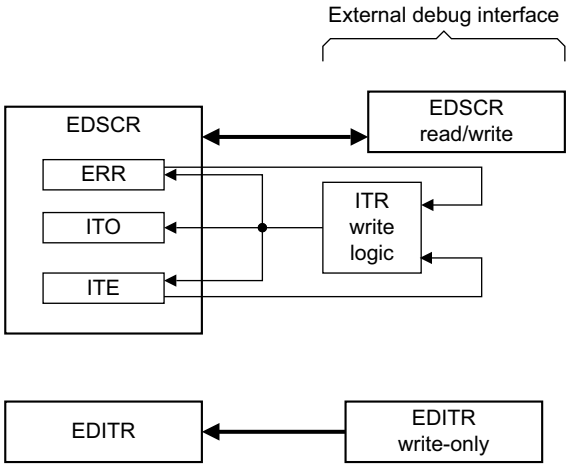

Figure H4-2 External debug interface views of EDSCR and EDITR registers, Normal access mode

The sticky overflow flag, EDSCR.ERR, is used by both the DCC and ITR to report flow-control errors.

H4.3 DCC and ITR access modes

The DCC and ITR support two access modes:

- *Normal access mode*, when EDSCR.MA == 0 or the PE is in Non-debug state.
- *Memory access mode* on page H4-4464, when EDSCR.MA == 1 and the PE is in Debug state.

H4.3.1 Normal access mode

The Normal access mode allows use of the DCC as a communications channel between target and host. It also allows the use of the ITR for issuing instructions to the PE in Debug state.

In Normal access mode, if there is no overrun or underrun, the following occurs:

For accesses by software:

- Direct writes to DBGDTRTX update the value in DTRTX and indirectly write 1 to TXfull.
- Direct reads from DBGDTRRX return the value in DTRRX and indirectly write 0 to RXfull.
- In AArch64 state, direct writes to DBGDTR_EL0 update both DTRTX and DTRRX, indirectly write 1 to TXfull, and do not change RXfull:
  - DTRTX is set from bits[31:0] of the transfer register.
  - DTRRX is set from bits[63:32] of the transfer register.
- In AArch64 state, direct reads from DBGDTR_EL0 return the concatenation of DTRRX and DTRTX, indirectly write 0 to RXfull, and do not change TXfull:
  - Bits[31:0] of the transfer register are set from DTRRX.
  - Bits[63:32] of the transfer register are set from DTRTX.

Note

For DBGDTR_EL0, the word order is reversed for reads with respect to writes.

Software reads TXfull and RXfull using DCCSR.

For accesses by the external debug interface:

- Writes to EDITR trigger the instruction to be executed if the PE is in Debug state:
  - If the PE is in AArch64 state, this is an A64 instruction.
  - If the PE is in AArch32 state, this is a T32 instruction. The T32 instruction is a pair of halfwords where the first halfword is taken from the lower 16-bits, and the second halfword is taken from the upper 16-bits.
- Reads of DBGDTRTX_EL0 return the value in DTRTX and indirectly write 0 to TXfull.
- Writes to DBGDTRTX_EL0 update the value in DTRTX and do not change TXfull.
- Reads of DBGDTRRX_EL0 return the value in DTRRX and do not change RXfull.
- Writes to DBGDTRRX_EL0 update the value in DTRRX and indirectly write 1 to RXfull.

TXfull and RXfull are visible to the external debug interface in EDSCR.

The PE detects overrun and underrun by the external debug interface, and records errors in EDSCR.{TXU, RXO, ITO, ERR}. See *Flow-control of the DCC and ITR registers* on page H4-4467.

See also *Synchronization of DCC and ITR accesses* on page H4-4470.

H4.3.2 Memory access mode

When the PE is in Debug state, a special Memory access mode can be selected to accelerate word-aligned block reads or writes of memory by an external debugger. Memory access mode can only be enabled in Debug state, and no instructions can be issued directly by the debugger when in Memory access mode.

If there is no overrun or underrun when in Memory access mode, an access by the external debug interface results in the following:

- External reads from DBGDTRTX_EL0 cause:
  1. The existing value in DTRTX to be returned. This clears EDSCR.TXfull to 0.
  2. The equivalent of `LDR W1,[X0],#4`, if in AArch64 state, or `LDR R1,[R0],#4`, if in AArch32 state, to be executed.
  3. The equivalent of the `MSR DBGDTRTX_EL0,X1` instruction, if in AArch64 state, or the `MCR p14,0,R1,c0,c5,0` instruction, if in AArch32 state, to be executed.
  4. EDSCR.{TXfull, ITE} to be set to {1,1}, and X1 or R1 to be set to an UNKNOWN value.
- External writes to DBGDTRRX_EL0 cause:
  1. The value in DTRRX to be updated. This sets EDSCR.RXfull to 1.
  2. The equivalent of the instruction `MRS X1,DBGDTRRX_EL0`, if in AArch64 state, or `MRC p14,0,R1,c0,c5,0` if in AArch32 state, to be executed.
  3. The equivalent of the instruction `STR W1,[X0],#4`, if in AArch64 state, or `STR R1,[R0],#4`, if in AArch32 state, to be executed.
  4. EDSCR.{RXfull, ITE} to be set to {0,1}, and X1 or R1 to be set to an UNKNOWN value.
- External reads from DBGDTRRX_EL0 return the last value written to DTRRX.
- External writes to EDITR generate an overrun error.

During these accesses, EDSCR.{TXfull, RXfull, ITE} are used for flow control.

The architecture does not require precisely when these flags are set or cleared by the sequence of operations outlined in this section. For example, in the case of an external write to DBGDTRRX_EL0, in AArch64 state, RXfull might be cleared after step 2, or it might not be cleared until after step 3, as an implementation is free to fuse these steps into a single operation. The architecture does require that the flags are set as at step 4 when the PE is ready to accept a further read or write without causing an overrun error or an underrun error.

The process outlined in this section represents a simple sequential execution model of Memory access mode. An implementation is free to pipeline, buffer, and re-order instructions and transactions, as long as the following remain true:

- Data items are transferred into and out of the DTR in order and without loss of data, other than as a result of an overrun or an underrun.
- Data Aborts occur in order.
- The constraints of the memory type are met.
- In the list describing *External reads from DBGDTRTX_EL0*:
  - The `MSR` equivalent operation at step 3 of the sequence reads the value loaded by step 2.
  - If the list is performed in a loop, for all but the first iteration of this list, the value read by step 1 returns the values written by the `MSR` equivalent operation at the previous iteration of step 3.
- In the list describing *External writes to DBGDTRRX_EL0*:
  - The `MRS` equivalent operation at step 2 of the sequence returns the value written at step 1.
  - The `STR` equivalent at step 3 of the sequence writes the value read at step 2.
- If the PE cannot accept a read or write, as applicable, during the sequence, then the flags are updated to indicate an overrun or underrun

See *Flow-control of the DCC and ITR registers* on page H4-4467 for more information on overrun and underrun.

Ordering, access sizes and effect on exclusive monitors

For the purposes of memory ordering, access sizes, and effect on the exclusive monitor, accesses in Memory access mode are consistent with Load/Store word instructions executed by the PE.

Data aborts

If the memory access generates a Data Abort, then:

- The Data Abort exception is taken. See *Exceptions in Debug state* on page H2-4425. In particular, EDSCR.ERR is set to 1. See *Cumulative error flag* on page H4-4469.
- Register R0 retains the address that generated the abort.
- Register R1 is set to an UNKNOWN value.
- EDSCR.TXfull, for a load, or EDSCR.RXfull, for a store, is set to an UNKNOWN value.
- DTRTX, for a load, or DTRRX, for a store, is set to an UNKNOWN value.
- EDSCR.ITE is set to 1.

Illegal Execution State exception

If PSTATE.IL is set to 1 when EDSCR.MA == 1, then on an external write access to DBGDTRRX_EL0 or an external read from DBGDTRTX_EL0, it is CONSTRAINED UNPREDICTABLE whether the PE:

- Takes an Illegal Execution State exception without performing any operations. In this case:
  - EDSCR.ERR is set to 1, see *Cumulative error flag* on page H4-4469.
  - Register R0 is unchanged.
  - Register R1 is set to an UNKNOWN value.
  - EDSCR.TXfull or EDSCR.RXfull, as applicable, is set to an UNKNOWN value.
  - DTRTX or DTRRX, as applicable, is set an UNKNOWN value.
  - EDSCR.ITE is set to 1.

  See also *Exceptions in Debug state* on page H2-4425.
- Ignores PSTATE.IL.

Note

The typical usage model for Memory access mode involves executing instructions in Normal mode to set up X0 before setting EDSCR.MA to 1. These instructions generate an Illegal State exception if PSTATE.IL is set to 1.

Alignment constraints

If the address in R0 is not aligned to a multiple of four, the behavior is as follows:

- For each external DTR access a CONSTRAINED UNPREDICTABLE choice of:
  1. The PE makes an unaligned memory access to R0. If alignment checking is enabled for the memory access, this generates an Alignment fault.
  2. The PE makes a memory access to `Align(X[0],4)` in AArch64 state, or `Align(R[0],4)` in AArch32 state.
  3. The PE generates an Alignment fault, regardless of whether alignment checking is enabled.
  4. The PE does nothing.
- Following each memory access, if there is no Data Abort, R0 is updated with an UNKNOWN value.
- For external writes to DBGDTRRX_EL0, if the PE writes to memory, an UNKNOWN value is written.

- For external reads of DBGDTRTX_EL0 an UNKNOWN value is returned.
- The RXfull and TXfull flags are left in an UNKNOWN state, meaning that a DBGDTRTX_EL0 read can trigger a TX underrun, and a DBGDTRTX_EL0 write can trigger an RX overrun.

H4.3.3 Memory-mapped accesses to the DCC and ITR

Writes to the flags in EDSCR by external debug interface accesses to the DCC and the ITR registers are indirect writes, because they are a side-effect of the access. The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see *Register access permissions for memory-mapped accesses* on page H8-4521.

H4.4 Flow-control of the DCC and ITR registers

This sub-section describes the flow-control of the DCC and ITR registers:

- *Ready flags*.
- *Buffering writes to EDITR*.
- *Overrun and underrun flags*.
- *Cumulative error flag* on page H4-4469.

H4.4.1 Ready flags

In Normal mode:

- For the DTR registers there are two ready flags:
  - EDSCR.RXfull == 1 indicates that DBGDTRRX_EL0 contains a valid value that has been written by the external debugger and not yet read by software running on the target.
  - EDSCR.TXfull == 1 indicates that DBGDTRTX_EL0 contains a valid value that has been written by software running on the target and not yet read by an external debugger.
- For the ITR register there is a single ready flag:
  - EDSCR.ITE == 1 indicates that the PE is ready to accept an instruction to the ITR.

    Note

    The architecture permits a PE to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, as long as those instructions are discarded if EDSCR.ERR is set, either by an underrun or overrun or by any of the other error conditions described in this architecture, such as an instruction generating an abort.

In Memory access mode:

- EDSCR.{RXfull, ITE} == {0,1} indicates that DBGDTRRX_EL0 is empty and the PE is ready to accept a word external write to DBGDTRRX_EL0.
- EDSCR.{TXfull, ITE} == {1,1} indicates that DBGDTRTX_EL0 is full and the PE is ready to accept a word external read from DBGDTRTX_EL0.

All other values indicate that the PE is not ready, and result in a DTR overrun or underrun error, an ITR overrun error, or both, as defined in *Overrun and underrun flags*.

H4.4.2 Buffering writes to EDITR

The architecture permits a PE to continue to accept and buffer instructions when previous instructions have not completed their architecturally defined behavior, provided that:

- Those instructions are discarded if EDSCR.ERR is set to 1, either by an underrun or an overrun, or by any of the other error conditions described in this architecture, such as an instruction generating an abort.
- The PE maintains the simple sequential execution model with the order of instructions determined by the order in which the PE accepts the EDITR writes. In particular, the buffered instructions must be executed in the execution state consistent with a simple sequential execution of the instructions, even if one of the previous instructions is a state changing operation, such as `DCPS` or `DRPS`.

H4.4.3 Overrun and underrun flags

Each of the ready flags has a corresponding overrun or a corresponding underrun flag. These are sticky status flags that are set if the register is accessed using the external debug interface when the corresponding ready flag is not in the ready state.

If the PE is in Debug state and Memory access mode, the corresponding error flag is also set if the PE is not ready to accept an operation because a previous load or store is still in progress. The sticky status flag remains set until cleared by writing 1 to EDRCR.CSE.

Note

The architecture permits a PE to continue to accept and buffer data to write to memory in Memory access mode.

Table H4-1 shows DCC and ITR ready flags and the overrun and underrun flags associated with them.

Table H4-1 DCC and ITR ready flags and the associated overrun/underrun flags

External debug interface access	Overrun/Underrun condition	EDSCR flag
Write DBGDTRRX_EL0	`EDSCR.RXfull == '1' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0')`	RXO
Read DBGDTRTX_EL0	`EDSCR.TXfull == '0' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0')`	TXU
Write EDITR	`Halted() && (EDSCR.ITE == '0' || EDSCR.MA == '1')`	ITO

When an overrun or underrun flag is set to 1, the cumulative error flag, EDSCR.ERR, described in *Cumulative error flag* on page H4-4469, is also set to 1. This has the effect that all subsequent external debug interface accesses to the EDITR or DTR registers are ignored.

In the event of an external write to DBGDTRRX_EL0 or EDITR generating an overrun, or an external read from DBGDTRTX_EL0 generating an underrun:

- For a write, the written value is ignored.
- For a read, an UNKNOWN value is returned.
- EDSCR.TXfull, EDSCR.RXfull or EDSCR.ITE, as applicable, are not updated.

There is no overrun or underrun detection on external reads of DBGDTRRX_EL0 or external writes of DBGDTRTX_EL0.

There is no overrun or underrun detection of direct reads and direct writes of the DTR system registers by software:

- If RXfull == 0, a direct read of DBGDTRRX or DBGDTR_EL0 returns UNKNOWN.
- If TXfull == 1, a direct write of:
  - DBGDTRTX sets DTRTX to UNKNOWN.
  - DBGDTR_EL0 sets DTRRX and DTRTX to UNKNOWN.

See *DCC accesses in Non-debug state* on page H4-4471 for more information.

Accessing 64-bit data

In AArch64 state, a software access to the DBGDTR_EL0 register and an external debugger access to both DBGDTRRX_EL0 and DBGDTRTX_EL0 can perform a 64-bit half-duplex operation.

However, there is only overrun and underrun detection on one of the external debug registers. That is:

- If software directly writes a 64-bit value to DBGDTR_EL0, only TXfull is set to 1, meaning:
  - A subsequent external write to DBGDTRRX_EL0 would not be detected as an overrun.
  - If the external debugger reads DBGDTRTX_EL0 first, software might observe MDCCSR_EL0.TXfull == 0 and send a second value before the external debugger reads DBGDTRRX_EL0, leading to an undetected overrun.
- On external writes to both DBGDTRRX_EL0 and DBGDTRTX_EL0 only RXfull is set to 1, meaning:
  - A subsequent direct write of DBGDTRTX_EL0 would not be detected as an overrun.

— If the external debugger writes to DBGDTRRX_EL0 first, software might observe MDCCSR_EL0.RXfull == 1 and read a full 64-bit value, before the external debugger writes to DBGDTRTX_EL0, leading to an undetected underrun.

To avoid this, debuggers need to be aware of the data size used by software for transfers and ensure that 64-bit data is read or written in the correct order. If the PE is in Non-debug state, this order is as follows:

- The external debugger must check EDSCR.{RXfull, TXfull} before each transfer.
- To receive a 64-bit value from the target, the external debugger must read DBGDTRRX_EL0 before reading DBGDTRTX_EL0.
- To send a 64-bit value to the target, the external debugger must write to DBGDTRTX_EL0 before writing DBGDTRRX_EL0.

Because three accesses are required to transfer 64 bits of data, 64-bit transfers are not recommended for regular communication between host and target. The use of underrun and overrun detection means that only one access is required for 32 bits of data when using 32-bit transfers.

In Debug state, the debugger controls the instructions executed by the PE, so these limitations do not apply. 64-bit transfers provide a means to transfer a 64-bit general register between the host and the target in Debug state.

H4.4.4 Cumulative error flag

The cumulative error flag, EDSCR.ERR, is set to 1 on taking exceptions taken in Debug state and on any signaled overrun or underrun in the DCC or ITR.

When EDSCR.ERR == 1:

- External reads of DBGDTRTX_EL0 do not have any side-effects.
- External writes to DBGDTRRX_EL0 are ignored.
- External writes to EDITR are ignored.
- No further instructions can be issued in Debug state. This includes any instructions previously accepted as external writes to EDITR that occur in program order after the instruction or access that caused the error.

This allows a debugger to stream data, or, in Debug state, instructions, to the target without having to:

- Check EDSCR.{RXfull, TXfull, ITE} before each access.
- Check EDSCR.{ITO, RXO, TXU} following each access, for overrun or underrun.
- Check PSTATE or other syndrome registers, or both, for an exception following each instruction executed in Debug state that might generate a synchronous exception.

The cumulative error flag remains set until cleared by writing 1 to EDRCR.CSE. See *EDRCR, External Debug Reserve Control Register* on page H9-4601.

For overruns and underruns, EDSCR.{ITO, RXO, TXU} record the error type.

Pseudocode details for clearing the error flag

The pseudocode details for the `ClearStickyError()` function is as follows:

```
// ClearStickyErrors()
// ===================

ClearStickyErrors()
    EDSCR.TXU = '0';            // Clear TX underrun flag
    EDSCR.RXO = '0';            // Clear RX overrun flag
    if Halted() then            // in Debug state
        EDSCR.ITO = '0';        // Clear ITR overrun flag
    EDSCR.ERR = '0';            // Clear cumulative error flag
    return;
```

H4.5 Synchronization of DCC and ITR accesses

In addition to the standard synchronization requirements for register accesses, the following subsections describe additional requirements that apply for the DCC and ITR registers:

- *Summary of system register accesses to the DCC*.
- *DCC accesses in Non-debug state* on page H4-4471.

In these sections, accesses by the external debug interface are referred to as external reads and external writes. Accesses to system registers are referred to as direct reads, direct writes, indirect reads, and indirect writes.

Note

In *Synchronization requirements for System registers* on page D7-1794 external reads and external writes are described as forms of indirect access. This whole section uses more explicit terminology.

The DTR registers and the DCC flags, TXfull and RXfull, form a communication channel, with one end operating asynchronously to the other. Implementations must respect the ordering of accesses to these registers in order to maintain the correct behavior of the channel.

External reads of, and external writes to DBGDTRRX_EL0 and DBGDTRTX_EL0 are asynchronous to direct reads of, and direct writes to,DBGDTRRX, DBGDTRTX, and in AArch64 state DBGDTR_EL0, made by software using system register access instructions. The direct reads and direct writes indirectly write to the DCC flags. The external reads and external writes indirectly read the DCC flags to check for underrun and overrun.

H4.5.1 Summary of system register accesses to the DCC

System register accesses to the DTR registers are direct reads and writes of those registers, as shown in Table H4-2. Several of these instructions access the same registers using different encodings.

With the exception of the read and write bits, DBGDTRRX and DBGDTRTX are the same encoding, but use different registers. The ARMv8 architecture governs the order of these instructions, as described in *Synchronization requirements for System registers* on page D7-1794. For more details, see the description of the individual register in the relevant chapter, Chapter D7 *AArch64 System Register Descriptions* or Chapter G5 *AArch32 System Register Descriptions*.

Table H4-2 shows a summary of system register accesses to the DCC.

Table H4-2 Summary of system register accesses to the DCC

Operation	OS Lock	AArch64 (MRS/MSR)	AArch32 (MRC/MCR)	Description
Read	-	DBGDTRRX_EL0	DBGDTRRXint	Direct read of DTRRX
Write	-	DBGDTRTX_EL0	DBGDTRTXint	Direct read of DTRTX
Read/write	-	DBGDTR_EL0	-	Direct read/write of both DTRRX and DTRTX
All of the above				Indirect write to the DCC flags
Read	-	MDCCSR_EL0	DBGDSCRint	Direct read of the DCC flags
Read/write	-	OSDTRRX_EL1	DBGDTRRXext	Direct read/write of DTRRX
Read/write	-	OSDTRTX_EL1	DBGDTRTXext	Direct read/write of DTRTX
Read	Unlocked	MDSCR_EL1	DBGDSCRext	Direct read of DCC flags
Read/write	Locked	MDSCR_EL1	DBGDSCRext	Direct read/write of DCC flags

H4.5.2 DCC accesses in Non-debug state

In Non-debug state DCC accesses are as described in *Normal access mode* on page H4-4463:

- If a direct read of DCCSR returns RXfull == 1, then a following direct read of DBGDTRRX or in AArch64 state of DBGDTR_EL0, returns valid data and indirectly writes 0 to DCCSR.RXfull as a side-effect.
- If a direct read of DCCSR returns TXfull == 0, then a following direct write to DBGDTRTX, or in AArch64 state to DBGDTR_EL0, writes the intended value, and indirectly writes 1 to DCCSR.TXfull as a side-effect.

No context synchronization operation is required between these two instructions. Overrun and underrun detection prevents intervening external reads and external writes affecting the outcome of the second instruction.

The indirect write to the DCC flags as part of the DTR access instruction is made atomically with the DTR access.

Because a direct read of DBGDTRRX is an indirect write to DCCSR.RXfull, it must occur in program order with respect to the direct read of DCCSR, meaning it must not return a speculative value for DTTRX that predates the RXfull flag returned by the read of DCCSR. The direct write to DBGDTRTX must not be executed speculatively.

Direct reads of DBGDTRRX, or in AArch64 state DBGDTR_EL0, and DCCSR, must occur in program order with respect to other direct reads of the same register using the same encoding.

All observers must observe the same order for accesses.

Note

These requirements do not create order where order does not otherwise exist. It applies only for ordered accesses.

The following accesses have an implied order within the atomic access:

- In the simple sequential execution of the program the indirect write of the DCC flags occurs immediately after the direct DTR access.
- In the simple sequential execution model, for an external read of DBGDTRTX_EL0 or an external write of DBGDTRRX_EL0:
  - The check of the DCC flags for overrun or underrun occurs immediately before the access.
  - If there is no underrun or overrun, the update of the DCC flags occurs immediately after the access.
  - If there is underrun or overrun, the update of the DCC underrun or overrun flags occurs immediately after the access.

This means that:

- Following a direct read of DBGDTRRX, or in AArch64 state DBGDTR_EL0, made when the value of RXfull is 1, if an external write to DBGDTRRX_EL0 checks the RXfull flag for overrun and observes that the value of RXfull is 0, the value returned by the previous direct read must not be affected by the external write.
- Following a direct write to DBGDTRTX, or in AArch64 state DBGDTR_EL0, made when the value of TXfull is 0, if an external read of DBGDTRTX_EL0 checks the TXfull flag for underrun and observes that the value of TXfull is 1, the value returned by the external read must be the value written by the previous direct write.
- Following an external read of DBGDTRTX_EL0 that does not underrun, if a direct read of DCCSR returns a TXfull value of 0, then the value returned by the external read must not be affected by a following direct write to DBGDTRTX, or in AArch64 state DBGDTR_EL0.
- Following an external write to DBGDTRRX_EL0 that does not overrun, if a direct read of DCCSR returns the RXfull value of 1, then the value returned by a following direct read of DBGDTRRX must be the value written by the previous external write.

Without explicit synchronization following external writes and external reads:

- The value written by the external write to DBGDTRRX_EL0 must be observable to direct reads of DBGDTRRX in finite time.

- The DCC flags that are updated as a side-effect of the external write or external read must be observable:
  - To direct reads of DCCSR in finite time.
  - To subsequent external reads of EDSCR.
  - To subsequent external reads of DBGDTRRX_EL0 and external writes to DBGDTRTX_EL0 when checking for overrun and underrun.

However, explicit synchronization is required to guarantee that a direct read of DCCSR returns up-to-date DCC flags. This means that if a signal is received from another agent that indicates that DCCSR must be read, an `ISB` is required to ensure that the read of DCCSR occurs after the signal has been received. This also synchronizes the value in DBGDTRRX, if applicable. However, if that signal is an interrupt exception triggered by **COMMIRQ**, **COMMTX**, or **COMMRX**, the exception entry is sufficient synchronization. See *Synchronization of DCC interrupt request signals*.

Explicit synchronization is required following a direct read or direct write:

- To ensure that a value directly written to DBGDTRTX is observable to external reads of DBGDTRTX_EL0.
- To ensure that a value directly written to DBGDTR_EL0 is observable to external reads of DBGDTRTX_EL0 and DBGDTRRX_EL0.
- To guarantee that the indirect writes to the DCC flags that were a side-effect of the direct read or direct write have occurred, and therefore that the updated values are:
  - Observable to external reads of EDSCR.
  - Observable to external reads of DBGDTRRX_EL0.
  - Observable to external writes of DBGDTRTX_EL0 when checking for overrun and underrun
  - Returned by a following direct read of DCCSR.

See also *Memory-mapped accesses to the DCC and ITR* on page H4-4466 and *Synchronization of changes to the external debug registers* on page H8-4517.

Note

These ordering rules mean that software:

- Must not read DBGDTRRX without first checking DCCSR.RXfull or if the previously-read value of DCCSR.RXfull is 0.

  It is not sufficient to read both registers and then later decide whether to discard the read value, as there might be an intervening write from the external debug interface.
- Must not write DBGDTRTX without first checking DCCSR.TXfull or if the previously-read value of DCCSR.TXfull is 1.

  The write to DBGDTRTX overwrites the value in DTRTX, and the external debugger might or might not have read this value.
- Must ensure there is an explicit context synchronization operation following a DTR access, even if not immediately returning to read DCCSR again. This synchronization operation can be an exception return.

H4.5.3 Synchronization of DCC interrupt request signals

Following an external read or external write access to the DTR registers, the interrupt request signals, **COMMIRQ**, **COMMTX**, and **COMMRX**, must be updated in finite time without explicit synchronization.

The updated values must be observable to a direct read of DCCSR or DBGDTRRX, or a direct write of DBGDTRTX executed after taking an interrupt exception generated by the interrupt request. The updated values must also be observable to a direct write of DBGDTRTX executed after taking an interrupt exception generated by the interrupt request.

Following a direct read of DBGDTRRX or a direct write to DBGDTRRX, software must execute a context synchronization operation to guarantee the interrupt request signals have been updated in finite time. This synchronization operation can be an exception return.

H4.5.4 DCC and ITR access in Debug state

In Debug state, stricter observability rules apply for instructions issued through the ITR, to maintain communication between a debugger and the PE, without requiring excessive explicit synchronization.

In Normal mode, without explicit synchronization:

- A direct read or direct write of the DTR registers by an instruction written to EDITR must be observable to an external write or an external read in finite time:
  - A direct read of DBGDTRRX must be observable to an external write of DBGDTRRX_EL0.
  - A direct write of DBGDTRTX must be observable to an external read of DBGDTRTX_EL0.

  This includes the indirect write to the DCC flags that occurs atomically with the access as described in *DCC accesses in Non-debug state* on page H4-4471.

  The subsequent external write or external read must observe either the old or the new values of both the DTR contents and DCC flags. If the old values are observed, this typically results in overrun or underrun, assuming the old DCC flag values indicate an overrun or underrun condition, as would normally be the case.

  This means the debugger can observe the direct read or direct write without explicit synchronization and without explicitly testing the DCC flags in EDSCR, because it can rely on overrun and underrun tests.
- External reads of DBGDTRTX_EL0 that do not underrun and external writes to DBGDTRRX_EL0 that do not overrun must be observable to an instruction subsequently written to EDITR on completion of the first external access. This includes the indirect write to the DCC flags.

  This means that without explicit synchronization and without the need to first check the DCC flags in DCCSR:
  - If the instruction is a direct read of DBGDTRRX, it observes the external write.
  - If the instruction is a direct write of DBGDTRTX, it observes the external read.
- Writes to EDITR that do not overrun commit an instruction for execution immediately. The instruction must complete execution in finite time without requiring any further operation by the debugger.

In Memory access mode, these requirements shift to the instructions implicitly executed by external reads and external writes of the DTR registers, as described in *Memory access mode* on page H4-4464.

H4.6 Interrupt-driven use of the DCC

ARM recommends implementations provide a level-sensitive DCC interrupt request through the IMPLEMENTATION DEFINED interrupt controller as a private peripheral interrupt for the originating PE.

Note

In addition to connection to the interrupt controller ARM also recommends **COMMIRQ**, **COMMTX**, and **COMMRX** signals that might be implemented for use by any legacy system peripherals.

The DCCINT register provides a first level of interrupt masking within the PE, meaning only a single interrupt source, **COMMIRQ**, is needed at the interrupt controller.

See also *Synchronization of DCC interrupt request signals* on page H4-4472.

H4.7 Pseudocode details for the operation of the DCC and ITR registers

The basic operation of the DCC and ITR registers is shown by the following pseudocode functions. These functions do not cover the behavior when OSLSR.OSLK == 1, meaning that the OS lock is locked.

The definition of the DTR Registers is:

```
bits(32) DTRRX;
bits(32) DTRTX;
```

The pseudocode for the DBGDTR_EL0() function is as follows:

```
// DBGDTR_EL0[] (write)
// ===================
// System register writes to DBGDTR_EL0, DBGDTRTX_EL0 (AArch64) and DBGDTRTXint (AArch32)

DBGDTR_EL0[] = bits(N) value
    // For MSR DBGDTRTX_EL0,<Rt>  N=32, value=X[t]<31:0>, X[t]<63:32> is ignored
    // For MSR DBGDTR_EL0,<Xt>    N=64, value=X[t]<63:0>
    assert N IN {32,64};
    if EDSCR.TXfull == '1' then
        value = bits(N) UNKNOWN;
    // On a 64-bit write, implement a half-duplex channel
    if N == 64 then DTRRX = value<63:32>;
    DTRTX = value<31:0>;        // 32-bit or 64-bit write
    EDSCR.TXfull = '1';
    return;

// DBGDTR_EL0[] (read)
// ===================
// System register reads of DBGDTR_EL0, DBGDTRRX_EL0 (AArch64) and DBGDTRRXint (AArch32)

bits(N) DBGDTR_EL0[]
    // For MRS <Rt>,DBGDTRTX_EL0  N=32, X[t]=Zeros(32):result
    // For MRS <Xt>,DBGDTR_EL0    N=64, X[t]=result
    assert N IN {32,64};
    bits(N) result;
    if EDSCR.RXfull == '0' then
        result = bits(N) UNKNOWN;
    else
        // On a 64-bit read, implement a half-duplex channel
        // NOTE: the word order is reversed on reads with regards to writes
        if N == 64 then result<63:32> = DTRTX;
        result<31:0> = DTRRX;
    EDSCR.RXfull = '0';
    return result;
```

The pseudocode for the DBGDTRRX_EL0() function is as follows:

```
// DBGDTRRX_EL0[] (external write)
// ===============================
// Called on writes to debug register 0x08C.

DBGDTRRX_EL0[boolean memory_mapped] = bits(32) value

    if EDPRSR<6:5,0> != '001' then                      // Check DLK, OSLK and PU bits
        IMPLEMENTATION_DEFINED "signal slave-generated error";
        return;

    if EDSCR.ERR == '1' then return;                    // Error flag set: ignore write

    // The Software lock is OPTIONAL.
    if memory_mapped && EDLSR.SLK == '1' then return;   // Software lock locked: ignore write

    if EDSCR.RXfull == '1' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0') then
        EDSCR.RXO = '1';  EDSCR.ERR = '1';              // Overrun condition: ignore write
        return;
```

```
    EDSCR.RXfull = '1';
    DTRRX = value;

    if Halted() && EDSCR.MA == '1' then
        EDSCR.ITE = '0';                                // See comments in EDITR[] (external write)

        if !UsingAArch32() then
            ExecuteA64(0xD5330501<31:0>);               // A64 "MRS X1,DBGDTRRX_EL0"
            ExecuteA64(0xB8004401<31:0>);               // A64 "STR W1,[X0],#4"
            X[1] = bits(64) UNKNOWN;
        else
            ExecuteT32(0xEE10<15:0> /*hw1*/, 0x1E15<15:0> /*hw2*/);  // T32 "MRS R1,DBGDTRRXint"
            ExecuteT32(0xF840<15:0> /*hw1*/, 0x1B04<15:0> /*hw2*/);  // T32 "STR R1,[R0],#4"
            R[1] = bits(32) UNKNOWN;

        // If the store aborts, the Data Abort exception is taken and EDSCR.ERR is set to 1
        if EDSCR.ERR == '1' then
            EDSCR.RXfull = bit UNKNOWN;
            DBGDTRRX_EL0 = bits(32) UNKNOWN;
        else
            // "MRS X1,DBGDTRRX_EL0" calls DBGDTR_EL0[] (read) which clears RXfull.
            assert EDSCR.RXfull == '0';

        EDSCR.ITE = '1';                                // See comments in EDITR[] (external write)
    return;

// DBGDTRRX_EL0[] (external read)
// ==============================

bits(32) DBGDTRRX_EL0[boolean memory_mapped]
    return DTRRX;
```

The pseudocode for the DBGDTRTX_EL0() function is as follows:

```
// DBGDTRTX_EL0[] (external read)
// ==============================
// Called on reads of debug register 0x080.

bits(32) DBGDTRTX_EL0[boolean memory_mapped]

    if EDPRSR<6:5,0> != '001' then                      // Check DLK, OSLK and PU bits
        IMPLEMENTATION_DEFINED "signal slave-generated error";
        return bits(32) UNKNOWN;

    if EDSCR.ERR == '1' then return DTRTX;              // Error flag set: no side-effects

    // The Software lock is OPTIONAL.
    if memory_mapped && EDLSR.SLK == '1' then           // Software lock locked: no side-effects
        return DTRTX;

    if EDSCR.TXfull == '0' || (Halted() && EDSCR.MA == '1' && EDSCR.ITE == '0') then
        EDSCR.TXU = '1';  EDSCR.ERR = '1';              // Underrun condition: block side-effects
        return bits(32) UNKNOWN;                        // Return UNKNOWN

    EDSCR.TXfull = '0';
    value = DTRTX;                                      // Return previous value of DTRTX

    if Halted() && EDSCR.MA == '1' then
        EDSCR.ITE = '0';                                // See comments in EDITR[] (external write)

        if !UsingAArch32() then
            ExecuteA64(0xB8404401<31:0>);               // A64 "LDR W1,[X0],#4"
        else
            ExecuteT32(0xF850<15:0> /*hw1*/, 0x1B04<15:0> /*hw2*/);      // T32 "LDR R1,[R0],#4"

        // If the load aborts, the Data Abort exception is taken and EDSCR.ERR is set to 1
        if EDSCR.ERR == '1' then
```

```
            EDSCR.TXfull = bit UNKNOWN;
            DBGDTRTX_EL0 = bits(32) UNKNOWN;
        else
            if !UsingAArch32() then
                ExecuteA64(0xD5130501<31:0>);           // A64 “MSR DBGDTRTX_EL0,X1”
            else
                ExecuteT32(0xEE00<15:0> /*hw1*/, 0x1E15<15:0> /*hw2*/);  // T32 “MSR DBGDTRTXint,R1”
            // “MSR DBGDTRTX_EL0,X1” calls DBGDTR_EL0[] (write) which sets TXfull.
            assert EDSCR.TXfull == ‘1’;

        if !UsingAArch32() then
            X[1] = bits(64) UNKNOWN;
        else
            R[1] = bits(32) UNKNOWN;

        EDSCR.ITE = ‘1’;                                // See comments in EDITR[] (external write)

    return value;

// DBGDTRTX_EL0[] (external write)
// ===============================

DBGDTRTX_EL0[boolean memory_mapped] = bits(32) value
    // The Software lock is OPTIONAL.
    if memory_mapped && EDLSR.SLK == ‘1’ then return;   // Software lock locked: ignore write
    DTRTX = value;
    return;
```

The pseudocode for the EDITR() function is as follows:

```
// EDITR[] (external write)
// ========================
// Called on writes to debug register 0x088.

EDITR[boolean memory_mapped] = bits(32) value
    if EDPRSR<6:5,0> != ‘001’ then                      // Check DLK, OSLK and PU bits
        IMPLEMENTATION_DEFINED “signal slave-generated error”;
        return;

    if EDSCR.ERR == ‘1’ then return;                    // Error flag set: ignore write

    // The Software lock is OPTIONAL.
    if memory_mapped && EDLSR.SLK == ‘1’ then return;   // Software lock locked: ignore write

    if !Halted() then return;                           // Non-debug state: ignore write

    if EDSCR.ITE == ‘0’ || EDSCR.MA == ‘1’ then
        EDSCR.ITO = ‘1’;  EDSCR.ERR = ‘1’;              // Overrun condition: block write
        return;

    // ITE indicates whether the processor is ready to accept another instruction; the processor
    // may support multiple outstanding instructions. Unlike the “InstrCompl” flag in [v7A] there
    // is no indication that the pipeline is empty (all instructions have completed). In this
    // pseudocode, the assumption is that only one instruction can be executed at a time,
    // meaning ITE acts like “InstrCompl”.
    EDSCR.ITE = ‘0’;

    if !UsingAArch32() then
        ExecuteA64(value);
    else
        ExecuteT32(value<15:0>/*hw1*/, value<31:16> /*hw2*/);

    EDSCR.ITE = ‘1’;

    return;
```

The pseudocode for the `CheckForDCCInterrupts()` function is as follows:

```
// CheckForDCCInterrupts()
// =======================

CheckForDCCInterrupts()
    commrx = (EDSCR.RXfull == '1');
    commtx = (EDSCR.TXfull == '0');

    // COMMRX and COMMTX support is optional and not recommended for new designs.
    // SetInterruptRequestLevel(InterruptID_COMMRX, if commrx then HIGH else LOW);
    // SetInterruptRequestLevel(InterruptID_COMMTX, if commtx then HIGH else LOW);

    // The value to be driven onto the common COMMIRQ signal.
    commirq = ((commrx && MDCCINT_EL1.RX == '1') ||
               (commtx && MDCCINT_EL1.TX == '1'));
    SetInterruptRequestLevel(InterruptID_COMMIRQ, if commirq then HIGH else LOW);

    return;
```

Chapter H5
The Embedded Cross Trigger Interface

This chapter describes the embedded cross-trigger interface. It contains the following sections:

H5.1 About the Embedded Cross Trigger (ECT)

The *Embedded Cross Trigger*, ECT, allows a debugger to:

- Send trigger events to a PE. For example, this might be done to halt the PE.
- Send a trigger event to one or more PEs when a trigger event occurs on another PE. For example, this might be done to halt all PEs when one individual PE halts.

Figure H5-1 shows the logical structure of an ECT.

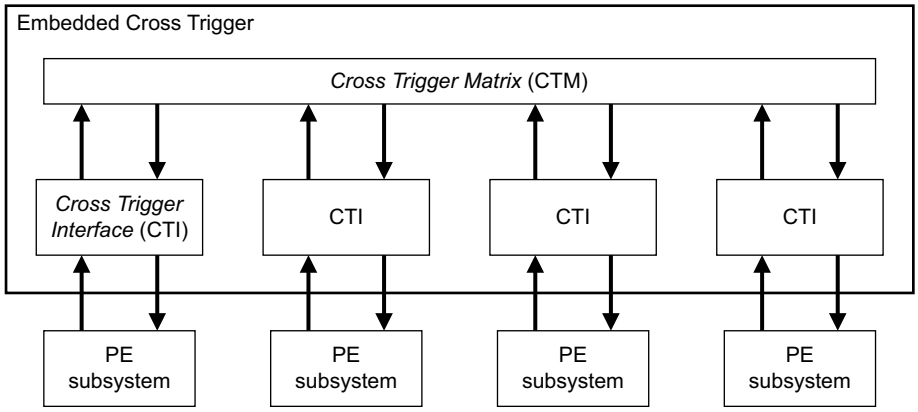

Figure H5-1 Structure of an embedded cross trigger

The ECT can deliver many types of trigger events, which are described in the following sections:

- *Debug request trigger event* on page H5-4487.
- *Restart request trigger event* on page H5-4488.
- *Cross-halt trigger event* on page H5-4488.
- *Performance Monitors overflow trigger event* on page H5-4488.
- *Generic trace external input trigger events* on page H5-4489.
- *Generic trace external output trigger events* on page H5-4489.
- *Generic CTI interrupt trigger event* on page H5-4489.

An ARMv8-A implementation must:

- Include a cross-trigger interface, CTI.
- Implement at least the input and output triggers defined in this architecture.

See *Cross-triggers on a PE in an ARMv8 implementation* on page H5-4486.

In addition, ARM recommends that the cross-trigger includes:

- The ability to route trigger events between Trace extensions:
  - These typically have advanced event triggering logic.
- An output trigger to the interrupt controller.

Note

The ECT and CTI must only signal trigger events for external debugging. They must not route software events, such as interrupts. For example, the Performance Monitors overflow input trigger is provided to allow entry to Debug state on a counter overflow, and the output trigger to the interrupt controller is provided to generally allow events from the external debug sub-system to be routed to a software agent. However, the combination of the two must not be used as a mechanism to route Performance Monitors overflows to an interrupt controller.

H5.1.1 Implementation with a CoreSight CTI

For details of the recommended connections in an ARMv8-A implementation, see Appendix B *Recommended External Debug Interface*. See also *CoreSight™ SoC Technical Reference Manual*.

H5.2 Basic operation on the ECT

The ECT comprises a Cross-Trigger Matrix, CTM, and one Cross-Trigger Interface, CTI, for each PE. The CTM passes events between the CTI blocks over channels. The CTM can have a maximum of 32 channels.

The main interfaces of the cross-trigger interface, CTI, are:

- The input triggers:
  - These are trigger event inputs from the PE to the CTI.
- The output triggers:
  - These are trigger event outputs from the CTI to the PE.
- The input channels:
  - These are channel event inputs from the cross-trigger matrix, CTM, to the CTI.
- The output channels:
  - These are channel event outputs from the CTI to the CTM.

Each CTI block has:

- Up to 32 input triggers that come from the PE:
  - The input triggers are numbered 0-31.
- Up to 32 output triggers that go to the PE:
  - The output triggers are numbered 0-31.

Figure H5-2 on page H5-4483 shows the logical internal structure of a CTI.

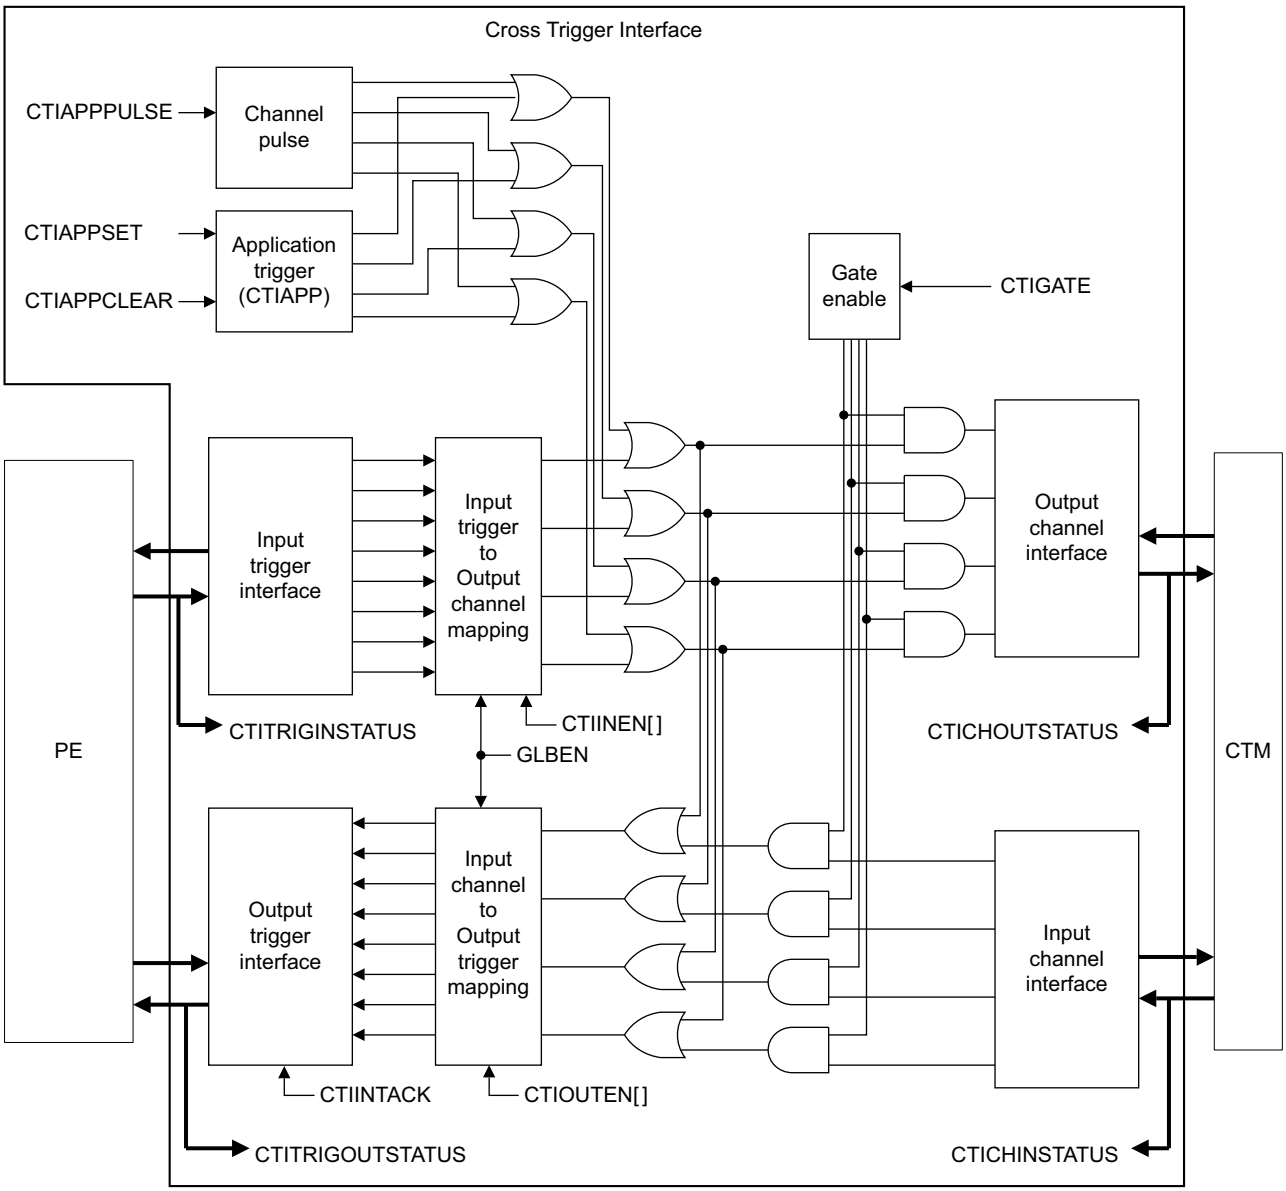

Figure H5-2 Structure of a cross-trigger interface

Note

- The number of triggers in IMPLEMENTATION DEFINED. Figure H5-2 shows eight input and eight output triggers.
- The number of channels is IMPLEMENTATION DEFINED. Figure H5-2 shows four channels.
- In Figure H5-2 the input channel gate function is a CTIv2 feature.

When the CTI receives an input trigger event, this generates channel events on one or more internal channels, according to the *mapping function* defined by the *Input trigger→output channel mapping registers*, CTIINEN<n>.

The CTI also contains an *application trigger* and *channel pulse* to allow a debugger to create channel events directly on internal channels by writing to the CTI control registers.

Channel events on each internal channel are passed to a corresponding output channel that is controlled by a *channel gate*. The channel gate can block propagation of channel events from an internal channel to an output channel.

The output channels from a CTI are combined, using a logical OR function, with the output channels from all other CTIs to form the input channels on other CTIs. The input channels of this CTI are the logical OR of the output channels on all other CTIs. This is the *cross-trigger matrix*, CTM. Therefore, the number of input channels must equal the number of output channels.

Note

The number of input triggers and output triggers is not required to be the same.

The internal channels form an internal cross-trigger matrix within the CTI. This delivers events directly from the input triggers to the output triggers. Therefore the number of internal channels is the same as the number of input and output channels on the external CTM, and there is a direct mapping between the two.

Channel events received on each input channel are passed to the corresponding internal channel. It is IMPLEMENTATION DEFINED whether the cross-trigger gate also blocks propagation of channel events from input channels to internal channels.

When the CTI receives a channel event on an internal channel this generates trigger events on one or more output triggers, according to the mapping function defined by the *Input channel → output trigger mapping registers*, CTIOUTEN<n>.

The CTI contains the input and output trigger interfaces to the PE and the interface of the cross-trigger matrix. The architecture does not define the signal protocol used on the trigger interfaces, and:

- It is IMPLEMENTATION DEFINED whether the CTI supports multicycle input trigger events.
- It is IMPLEMENTATION DEFINED whether the CTM supports multicycle channel events.

See *Multicycle events*.

However, an output trigger is asserted until acknowledged. The output trigger can be:

- Self-acknowledging. This means that no further action is required from the debugger.
- Acknowledged by the debugger writing 1 to the corresponding bit of CTIINTACK.

The time taken to propagate a trigger event from the first PE, through its CTI, across the CTM to another CTI, and thereby to a second PE is IMPLEMENTATION DEFINED.

Note

ARM recommends that this path is not longer than the shortest software communication path between those PEs. This is because if the first PE halts, the Cross-halt trigger event can propagate through the ECT and halt the second PE without causing software on the second PE to malfunction because the first PE is in Debug state and is not responding.

H5.2.1 Multicycle events

A multicycle event is one with a continuous state that might persist over many cycles, as opposed to a discrete event. A typical implementation of a multicycle event is a level-based signal interface, whereas a discrete event might be implemented as a pulse signal or message.

CTI support for multicycle trigger events is IMPLEMENTATION DEFINED. Use of multicycle trigger events is deprecated. Of the architecturally defined input trigger events, the Performance Monitors overflow trigger event and Generic trace external output trigger events can be multicycle input triggers.

CTM support for multicycle channel events is IMPLEMENTATION DEFINED. A CTM that does not support multicycle channel events cannot propagate a multicycle trigger event between CTIs.

Note

A full ECT might comprise a mix of CTIs, some of which can support multicycle trigger events. In bridging these components, multicycle channel events become single channel events at the boundary between the CTIs.

An ECT that supports multicycle trigger events

When an ECT supports multicycle trigger events, an input trigger event to the CTI continuously asserts channel events on all output channels mapped to it until either:

- The input trigger event is removed.
- The channel mapping function is disabled.

This means that an input trigger that is asserted for multiple cycles causes any channels that are mapped to it to become active for multiple cycles. Consequently, any output triggers mapped from that channel are asserted for multiple cycles.

Note

The output trigger remains asserted for at least as long as the channel remains active. This means that even if the output trigger is acknowledged, it remains asserted until the channel deactivates.

The CTI does not guarantee that these events have precisely the same duration, as the triggers and channels can cross between clock domains.

CTIAPPSET and CTIAPPCLEAR can set a channel active for multiple cycles. CTIAPPPULSE generates a single channel event. CTICHINSTATUS and CTICHOUTSTATUS can report whether a channel is active.

An ECT that does not support multicycle trigger events

When an ECT does not support multicycle trigger events, an input trigger event to the CTI generates a single channel event on all output channels mapped to it, regardless of how long the input trigger event is asserted.

This means that an input trigger event that is asserted for multiple cycles generates a single channel event on any channels mapped to it. Consequently any self-acknowledging output triggers mapped from those channels are single trigger events.

Note

A single event is typically a single cycle, but there is no guarantee that this is always the case.

CTIAPPSET and CTIAPPCLEAR can only generate a single channel event. CTIAPPPULSE generates a single channel event. If the ECT does not support multicycle channel events, use of CTIAPPSET and CTIAPPCLEAR is deprecated, and the debugger must only use CTIAPPPULSE. CTICHINSTATUS and CTICHOUTSTATUS must be treated as UNKNOWN.

H5.3 Cross-triggers on a PE in an ARMv8 implementation

An ARMv8 PE must include a cross-trigger interface, and the implementation must include at least the input and output triggers defined in this architecture. The number of channels in the cross-trigger matrix is IMPLEMENTATION DEFINED, but there must be a minimum of three. Software can read CTIDEVID.NUMCHAN to discover the number of implemented channels.

The CTM must connect to all PEs in the same Inner Shareability domain as the ARMv8-A PE, but can also connect to additional PEs. ARM strongly recommends that the CTM connects all PEs implementing a CTI in the system. This includes ARMv7-A PEs and other PEs that can be connected using a CoreSight CTI module.

Note

In a uniprocessor system the CTM is OPTIONAL. The CTM might be connected other CTI modules for non-PEs, such as triggers for system visibility components. ARM recommends that the CTM is implemented.

Any CTI connected to a PE that is not an ARMv8-A PE must implement at least:

- The Debug request trigger event.
- The Restart trigger event.
- The Cross-halt trigger event.

For more information about the CTI, see the *CoreSight ™ SoC Technical Reference Manual*. ARMv8-A refines the generic CTI by defining roles for each of the implemented input and output triggers.

H5.4 Description and allocation of CTI triggers

Table H5-1 shows the output trigger events defined by the architecture and the related trigger numbers.

Table H5-1 Allocation of CTI output trigger events

Number	Source	Destination	Event description
0	CTI	PE	*Debug request trigger event*
1	CTI	PE	*Restart request trigger event* on page H5-4488
2	CTI	IRQ controller	*Generic CTI interrupt trigger event* on page H5-4489
3	-	-	Reserved
4 - 7	CTI	Trace extension	OPTIONAL *Generic trace external input trigger events* on page H5-4489

Note

Output triggers from the CTI are inputs to other blocks.

Table H5-2 shows the input trigger events defined by the architecture and the related trigger numbers.

Table H5-2 Allocation of CTI input trigger events

Number	Source	Destination	Event description
0	PE	CTI	*Cross-halt trigger event* on page H5-4488
1	PE	CTI	*Performance Monitors overflow trigger event* on page H5-4488
2 - 3	-	-	Reserved
4 - 7	Trace extension	CTI	OPTIONAL *Generic trace external output trigger events* on page H5-4489

Note

Input triggers to the CTI are outputs from other blocks.

Table H5-1 and Table H5-2 show the minimum set of trigger events defined by the architecture. However:

- The Generic trace external input and output trigger events are only required if the OPTIONAL Trace extension is implemented. If the OPTIONAL Trace extension is not implemented, these trigger events are reserved.
- Support for the generic CTI interrupt trigger event is IMPLEMENTATION DEFINED because details of interrupt handling in the system, including any interrupt controllers, are IMPLEMENTATION DEFINED. Details regarding how the CTI interrupt is connected to an interrupt controller and its allocated interrupt number lie outside the scope of the architecture. ARM strongly recommends that implementations provide a means to generate interrupts based on external debug events.
- The other trigger events are required by the architecture.

An ARMv8-A implementation can extend the CTI with additional triggers. These start with the number eight.

H5.4.1 Debug request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to force the PE into Debug state. The trigger event is asserted until acknowledged by the debugger. The debugger acknowledges the assert by writing 1 to CTIINTACK[0].

If the PE is already in Debug state, the PE ignores the trigger event, but the CTI continues to assert it until it is removed by the debugger. See also *External Debug Request debug event* on page H3-4452.

H5.4.2 Restart request trigger event

This is an output trigger event from the CTI, and an input trigger event to the PE, asserted by the CTI to request the PE to exit Debug state. If the PE is not in Debug state, the request is ignored and dropped by the CTI.

If a Restart request trigger event is received at or about the same time as the PE enters Debug state, it is CONSTRAINED UNPREDICTABLE whether:

- The restart is ignored. In this case the PE enters Debug state and remains in Debug state.
- The PE enters Debug state and then immediately restarts.

Debuggers must program the CTI to send Restart request trigger events only to PEs that are halted. To enable the PE to disambiguate discrete Restart request trigger events, after sending a Restart request trigger event, the debugger must confirm that the PE has restarted and halted before sending another Restart request trigger event.

Debuggers can use EDPRSR.{SDR, HALTED} to determine the Execution state of the PE.

The trigger event is self-acknowledging, meaning that the debugger requires no further action to remove the trigger event. See also *Exiting Debug state* on page H2-4433.

H5.4.3 Cross-halt trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted by a PE when it is entering Debug state.

Note

To reduce the latency of halting, ARM recommends that an implementation issues the Cross-halt trigger event early in the committed process of entering Debug state. This means that there is no requirement to wait until all aspects of entry to Debug state have completed before issuing the trigger event. Speculative emission of Cross-halt trigger events is not allowed. The Cross-halt trigger event must not be issued early enough for a subsequent Debug request trigger event, that might be derived from the Cross-halt trigger event, to be recorded in the EDSCR.STATUS field. This applies to Debug request trigger events that are acting as inputs to the PE.

H5.4.4 Performance Monitors overflow trigger event

This is an input trigger event to the CTI, and an output trigger event from the PE, asserted each time the PE asserts a new Performance Monitors counter overflow interrupt request. See Chapter D5 *The Performance Monitors Extension*.

If the CTI supports multicycle trigger events, then the trigger event remains asserted until the overflow is cleared by a write to PMOVSCLR_EL0. Otherwise, the trigger event is not asserted again until the overflow is cleared by a write to PMOVSCLR_EL0.

Note

- This does not replace the recommended connection of Performance Monitors overflow trigger event to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI.
- Events can be counted when `ExternalNoninvasiveDebugEnabled()` == FALSE, and, in Secure state, when `ExternalSecureNoninvasiveDebugEnabled()` == FALSE. Secure software must be aware that overflow trigger events are nevertheless visible to the CTI.

H5.4.5 Generic trace external input trigger events

These are output trigger events from the CTI, and input trigger events to the OPTIONAL Trace extension, that are used in conjunction with the Generic trace external output trigger events to pass trigger events between:

- The PE and the OPTIONAL Trace extension.
- The OPTIONAL Trace extension and any other component attached to the CTM, including other Trace extensions.

There are four Generic trace external input trigger events.

The trigger events are self-acknowledging. This means that the debugger does not have to take any further action to to remove the events.

H5.4.6 Generic trace external output trigger events

These are input trigger events to the CTI, and output trigger events from the OPTIONAL Trace extension, used in conjunction with the Generic trace external input trigger events to pass trigger events between:

- The PE and the OPTIONAL Trace extension.
- The OPTIONAL Trace extension and any other component attached to the CTM, including other Trace extensions.

There are four Generic trace external output trigger events.

H5.4.7 Generic CTI interrupt trigger event

This is an output trigger event from the CTI, and an input to an IMPLEMENTATION DEFINED interrupt controller, and can transfer trigger events from the PE, Trace extension, or any other component attached to the CTI and CTM to software as an interrupt. The Generic CTI interrupt trigger event must be connected to the interrupt controller as an interrupt that can target the originating PE.

Note

ARM recommends that the Generic CTI interrupt trigger event is a private peripheral interrupt, but implementations might instead make this trigger event available as a shared peripheral interrupt or a local peripheral interrupt.

It is IMPLEMENTATION DEFINED whether this trigger event is:

- Self-acknowledging. This means that the debugger is not required to take any further action, and that the interrupt controller must treat the trigger event as a pulse or edge-sensitive interrupt.
- Acknowledged by the debugger. The debugger acknowledges the trigger event by writing 1 to CTIINTACK[2]. This means that the interrupt controller must treat the trigger event as a level-sensitive interrupt.

ARM recommends that the Generic CTI interrupt trigger event is a self-acknowledging trigger event.

H5.5 CTI registers programmers' model

The CTI registers programmers' model is described in Chapter H8 *About the External Debug Registers*. The following sections contain information specific to the CTI:

- *External debug register resets* on page H8-4537.
- *External debug interface register access permissions* on page H8-4523.
- *Cross-trigger interface registers* on page H8-4533.
- The individual register descriptions in *Cross-Trigger Interface registers* on page H9-4626.

See also *Memory-mapped accesses to the external debug interface* on page H8-4521.

H5.5.1 CTI reset

An External Debug reset resets the CTI. See *External debug register resets* on page H8-4537 for details of CTI register resets. All CTI output triggers and output channels are deasserted on an External Debug reset.

H5.5.2 CTI authentication

The CTI ignores the state of the IMPLEMENTATION DEFINED authentication interface. This means that:

- CTITRIGINSTATUS shows the status of the input triggers and CTICHINSTATUS shows the status of the input channels, regardless of the value of `ExternalNoninvasiveDebugEnabled()`.

  Note

  The PE does not generate the Cross-halt trigger event and the Trace extension does not generate Generic trace external output trigger events when `ExternalNoninvasiveDebugEnabled()` == FALSE. However, the PE can generate Performance Monitors overflow trigger events.

- The CTI can generate external triggers regardless of the value of `ExternalInvasiveDebugEnabled()`.

  Note

  The PE ignores Debug request and Restart request trigger events when `ExternalInvasiveDebugEnabled()` == FALSE. The Trace extension ignores Generic trace external input trigger events when `ExternalNoninvasiveDebugEnabled()` == FALSE. The behavior of Generic CTI interrupt requests is part of the IMPLEMENTATION DEFINED handling of these interrupts, but it is permissible for an interrupt controller to receive these requests even when `ExternalInvasiveDebugEnabled()` == FALSE.

H5.6 Examples

The CTI is fully programmable and allows for flexible cross-triggering of events within a PE and between PEs in a multiprocessor system. For example:

- The Cross-halt trigger event and the Debug request trigger event can be used for cross-triggering in a multiprocessor system.
- The Cross-halt trigger event and the Generic interrupt trigger event can be used for event-driven debugging in a multiprocessor system.
- The Performance Monitors overflow trigger event and the Debug request trigger event can force entry to Debug state on overflow of a Performance Monitors event counter, for event-driven profiling.

  Note

  This does not replace the recommended connection of Performance Monitors overflow trigger events to an interrupt controller. Software must be able to program an interrupt on Performance Monitors overflow without programming the CTI. ARM recommends that the Performance Monitors overflow signal is directly available as a local interrupt source.

- The Generic trace external input and Generic trace external output trigger events can pass trace events into and out of the event logic of the Trace extension. They can do this:
  - To pass trace events between Trace extensions.
  - In conjunction with the Performance Monitors overflow trigger event, to couple the Performance Monitors to the Trace extension.
  - In conjunction with the Debug request trigger event, to trigger entry to Debug state on a trace event.
  - In conjunction with other CTIs, to signal a trace trigger event onto a CoreSight trace interconnect.

The following sections describe some examples in more detail:

- *Halting a single PE*.
- *Halting all PEs in a group when any one PE halts* on page H5-4492.
- *Synchronously restarting a group of PEs* on page H5-4492.
- *Halting a single PE on Performance Monitors overflow* on page H5-4492.

Example H5-1 Halting a single PE

To halt a single PE, set:

1. CTIGATE[0] = 0, so that the CTI does not pass channel events on internal channel 0 to the CTM.
2. CTIOUTEN<n>[0] = 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 0.

   Note

   In this example, *n* is 0.

3. CTIAPPPULSE[0] = 1, to generate a channel event on channel 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to CTIINTACK[0], before restarting the PE.

Example H5-2 Halting all PEs in a group when any one PE halts

To program a group of PEs so that when one PE in the group halts, all of the PEs in that group halt, set the following registers for each PE in the group:

1. CTIGATE[2] = 1, so that each CTI passes channel events on internal channel 2 to the CTM.
2. CTIINEN<n>[2] = 1,so that each CTI generates a channel event on channel 2 in response to a Cross-halt trigger event.

   Note

   In this example, *n* is 0.

3. CTIOUTEN<n>[2] = 1, so that each CTI generates a Debug request trigger event in response to an channel event on channel 2.

   Note

   In this example, *n* is 0.

When a PE has halted, clear the Debug request trigger event by writing a value of 1to CTIINTACK[0], before restarting the PE.

Example H5-3 Synchronously restarting a group of PEs

To restart a group of PEs, for each PE in the group set:

1. CTIGATE[1] = 1, so that each CTI passes channel events on internal channel 1 to the CTM.
2. CTIOUTEN<n>[1] = 1, so that each CTI generates a Restart request trigger event in response to a channel event on channel 1.

   Note

   In this example, *n* is 1.

3. CTIAPPPULSE[1] = 1 on any one PE in the group, to generate a channel event on channel 1.

Example H5-4 Halting a single PE on Performance Monitors overflow

To halt a single PE on a Performance Monitors overflow set:

1. CTIGATE[3] = 0, so that the CTI does not pass channel events on internal channel 3 to the CTM.
2. CTIINEN<n>[3] = 1, so that the CTI generates a channel event on channel 3 in response to a Performance Monitors overflow trigger event.

   Note

   In this example, *n* is 1.

3. CTIOUTEN<n>[3] = 1, so that the CTI generates a Debug request trigger event in response to a channel event on channel 3.

Note

. In this example, *n* is 0.

When the PE has entered Debug state, clear the Debug request trigger event by writing 1 to CTIINTACK[0], before restarting the PE. Clear the overflow status by writing to PMOVSCLR_EL0.

Chapter H6
Debug Reset and Powerdown Support

This chapter describes the reset and powerdown support in the Debug architecture. It contains the following sections:

- *About Debug over powerdown* on page H6-4496.
- *Power domains and debug* on page H6-4497.
- *Core power domain power states* on page H6-4498.
- *Emulating low-power states* on page H6-4500.
- *Debug OS Save and Restore sequences* on page H6-4502.

Note

Where necessary, Table J-1 on page AppxJ-5170 disambiguates the general register references used in this chapter.

H6.1 About Debug over powerdown

Debug over powerdown is a facility for an operating system to save and restore the PE state on behalf of a self-hosted or external debugger or both.

For external debug over powerdown, the architecture defines the OS Lock, OS Double Lock, and the logical split of the hardware on which a PE executes into the *Core power domain* and the *Debug power domain*. See:

- *Power domains and debug* on page H6-4497.
- *Core power domain power states* on page H6-4498.

H6.2 Power domains and debug

The external debug component of ARMv8-A has two logical power domains, each with its own reset:

- The debug power domain contains the interface between the PE and the external debugger, and is powered up whenever an external debugger is connected to the SoC. It remains powered up while the external debugger is connected. Registers in this domain are reset by an external debug reset.
- The core power domain contains the rest of the PE, and is allowed to power up and power down independently of the Debug power domain.

The core power domain contains several types of registers:

- Non-debug logic refers to all registers and logic that are not associated with debug.
- Self-hosted debug logic refers to registers and logic associated solely with the self-hosted debug aspects of the architecture.
- Shared debug logic refers to registers and logic associated with both the self-hosted and external debug aspects of the architecture.
- External debug logic refers to registers and logic associated solely with the external debug aspects of the architecture.

Note

- The model of two logical power domains has an impact on the reset and access permission requirements of the debug programmers' model.
- The power domains are described as logical because the architecture defines the requirements but does not require two physical power domains. Any power domain split that meets the requirements of the programmers' model is a valid implementation.

Figure H6-1 shows the recommended power domain split. The signals **DBGPWRUPREQ**, **DBGNOPWRDWN**, and **DBGPWRDUP** shown in Figure H6-1 provide an interface between the power controller and the PE debug logic that is in the debug power domain. They are part of the recommended interface. See Appendix B *Recommended External Debug Interface*.

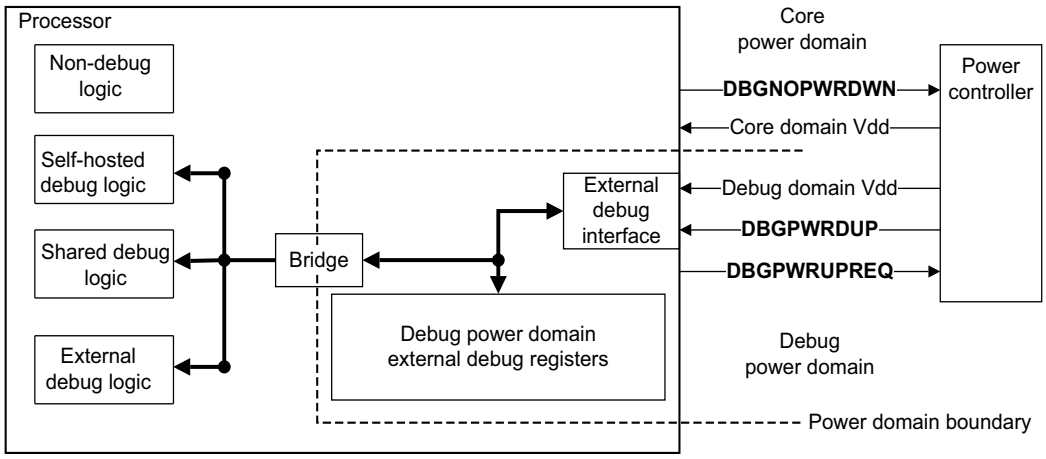

Figure H6-1 Recommended power domain split between core and debug power domains

H6.3 Core power domain power states

The ARM architecture does not define the power states of the PE as these are not normally visible to software. However, they are visible to the external debugger. The Debug architecture uses a four logical power states model for the core power domain. The four logical power states are as follows:

Normal The core power domain is fully powered on and the debug registers are accessible.

Standby The core power domain is on, but there are measures to reduce energy consumption. In a typical implementation, the PE enters standby by executing a `WFI` or `WFE` instruction, and exits on a wake-up event. There can be other IMPLEMENTATION DEFINED measures the OS can take to enter standby.

The PE preserves the PE state, including the debug logic state. Changing from standby to normal operation does not involve a reset of the PE.

Standby is the least invasive OS energy saving state. Standby implies only that the PE is unavailable and does not clear any debug settings. For standby, the debug architecture requires only the following:

- An External Debug Request debug event is a wake-up event when halting is allowed. This means that the PE must exit standby to handle the debug event. If the PE executed a `WFE` or a `WFI` instruction to enter standby, then it retires that instruction,
- If the external debug interface is accessed, the PE must respond to that access. ARM recommends that, if the PE executed a `WFI` or `WFE` instruction to enter standby, then it does not retire that instruction.

Standby is transparent, meaning that to software and to an external debugger it is indistinguishable from normal operation.

Retention The OS takes some measures, including IMPLEMENTATION DEFINED measures, to reduce energy consumption. The PE state, including debug settings, is preserved in low-power structures, allowing the core power domain to be at least partially turned off.

Changing from low-power retention to normal operation does not involve a reset of the PE. The saved PE state is restored on changing from low-power retention state to normal operation.

External Debug Request debug events stay pending and debug registers in the core power domain cannot be accessed.

Note

- This model of retention does not include implementations where the PE exits the state in response to a debug register access. From the Debug architecture perspective, implementations like this are forms of standby.

Powerdown The OS takes some measures to reduce energy consumption by turning the core power domain off. These measures must include the OS saving any PE state, including the debug settings, that must be preserved over powerdown. Changing from powerdown to normal operation must include:

- A Cold reset of the PE after the power level has been restored.
- The OS restoring the saved PE state.

External Debug Request debug events stay pending and debug registers in the core power domain cannot be accessed.

The Debug architecture uses a simpler two states model for the Debug power domain. The two states are:

Off The debug power domain is turned off.

On The debug power domain is turned on.

The available power states, including the cross-product of core power domain and debug power domain power states is IMPLEMENTATION DEFINED. Implementations are not required to implement all of these states and might include additional states. These additional states must appear to the debugger as one of the logical power states defined by this model. The control of power states is IMPLEMENTATION DEFINED.

Note

As a result, it is IMPLEMENTATION DEFINED whether it is possible for the debug power domain to be on when the core power domain is off.

H6.4 Emulating low-power states

The control registers DBGPRCR.CORENPDRQ and EDPRCR.COREPURQ provide an interface between the power controller and the PE. They typically map directly to signals in the recommended external debug interface. With this interface the external debugger can request the power controller to:

- Emulate states where the core power domain is completely off or in a low-power state where the core power domain registers cannot be accessed. This simplifies the requirements on software by sacrificing entirely realistic behavior.
- Restore full power to the core power domain.

EDPRSR.{SPD, PU} indicates the core power domain power state. For more information see:

- *DBGPRCR_EL1, Debug Power Control Register* on page D7-2005 and *DBGPRCR, Debug Power Control Register* on page G5-4206.
- *EDPRCR, External Debug Power/Reset Control Register* on page H9-4592.
- *EDPRSR, External Debug Processor Status Register* on page H9-4595.
- Appendix B *Recommended External Debug Interface*.

The measures to emulate powerdown are IMPLEMENTATION DEFINED. The ability of the debugger to access the state of the PE and the system might be limited as a result of the measures adopted.

In an emulated powerdown state, the debugger must be able to access all debug registers in both the debug power domain and the core power domain as if the core power domain were on. That is, the debugger must be able to read and write to such registers without receiving errors. This allows an external debugger to debug the powerup sequence. To stop the OS Double Lock preventing access to debug registers when powerdown is being emulated, `DoubleLockStatus() == FALSE` when DBGPRCR.CORENPDRQ == 1.

Otherwise, the behavior of the PE in emulated powerdown must be similar to that in a real powerdown state. In particular, the PE must not respond to other system stimuli, such as interrupts.

Example H6-1 and Example H6-2 are examples of two approaches to emulating powerdown.

Example H6-1 An example of emulating powerdown

The PE is held in Standby state, isolated from any system stimuli. It is IMPLEMENTATION DEFINED whether the PE can respond to debug stimuli such as an External Debug Request debug event.

If the PE can enter Debug state, then the external debugger is able to use the ITR to execute instructions, such as loads and stores. This causes the external debugger to interact with the system. If the external debugger restarts the PE, the PE leaves Standby state and restarts fetching instructions from memory.

Example H6-2 Another example of emulating powerdown

The PE is held in Warm reset. This limits the ability of an external debugger to access the resources of the PE. For example, the PE cannot be put into Debug state.

On exit from emulated powerdown the PE is reset. However, the debug registers that are only reset by a Cold reset must not be reset. Typically this means that a Warm reset is substituted for the Cold reset.

Note

- Warm reset and Cold reset have different effects apart from resetting the debug registers. In particular, RMR_ELx is reset by a Cold reset and controls the reset state on a Warm reset. This means that if a Cold reset is substituted by a Warm reset, the behavior of the reset code might be different.
- The timing effects of powering down are typically not factored in the powerdown emulation. Examples of these timing effects are clock and voltage stabilization.

- Emulation does not model the state lost during powerdown, meaning that it might mask errors in the state storage and recovery routines.

H6.5 Debug OS Save and Restore sequences

In ARMv8-A, the following registers provide the OS Save and restore mechanism:

- The *OS Lock Access Register*, OSLAR, locks the OS Lock to restrict access to debug registers before starting an OS Save sequence, and unlocks the OS Lock after an OS Restore sequence.
- The *OS Lock Status Register*, OSLSR, shows the status of the OS Lock.
- The *External Debug Execution Control Register*, EDECR, can be configured to generate a debug event when the OS Lock is unlocked.
- The *OS Double Lock Register*, OSDLR, locks out an external debug interface entirely. This is only used immediately before a powerdown sequence.

See also:

- *Reset and debug* on page H8-4535
- Appendix D *Example OS Save and Restore sequences*

H6.5.1 Debug registers to save over powerdown

Table H6-1 shows the different requirements for self-hosted debug over powerdown and external debug over powerdown:

- The column labeled Self-hosted lists registers that software must preserve over powerdown so that it can support self-hosted debug over powerdown. This does not require use of the OS Save and Restore mechanism.
- The column labeled External lists registers that software must preserve over powerdown so that it can support external debug over powerdown. This requires use of the OS Save and Restore mechanism:
  - Some external debug registers are not normally accessible to software executing on the PE. Additional debug registers are provided that give software the required access to save and restore these external debug registers when OSLSR.OSLK is locked. These registers include OSECCR, OSDTRRX, and OSDTRTX.
- Some registers might only present in some implementations, or might not be accessible at all Exception levels or in Non-secure state. DBGVCR32_EL2 and SDER32_EL3 are only required to support AArch32.

Table H6-1 does not include registers for the OPTIONAL Trace and Performance Monitor extensions.

Table H6-1 Debug registers to save over powerdown

Register in AArch64	Register in AArch32	Self-hosted	External
MDSCR_EL1	DBGDSCRext	Yes	Yes[a]
DBGBVR<n>_EL1	DBGBVR<n>	Yes	Yes
DBGBCR<n>_EL1	DBGBCR<n>	Yes	Yes
DBGWVR<n>_EL1	DBGWVR<n>	Yes	Yes
DBGWCR<n>_EL1	DBGWCR<n>	Yes	Yes
DBGVCR32_EL2	DBGVCR	Yes	-
MDCR_EL2	HDCR	Yes	-
SDER32_EL3	SDER	Yes	-
MDCR_EL3	SDCR	Yes[b]	-
MDCCINT_EL1	DBGDCCINT	-	Yes[b]

Table H6-1 Debug registers to save over powerdown (continued)

Register in AArch64	Register in AArch32	Self-hosted	External
DBGCLAIMSET_EL1 DBGCLAIMCLR_EL1	DBGCLAIMSET, DBGCLAIMCLR	-	Yes[c]
OSECCR_EL1	DBGOSECCR	-	Yes[ab]
OSDTRRX_EL1 OSDTRTX_EL1	DBGDTRRXext DBGDTRTXext	-	Yes

a. The OS Lock must be locked to save and restore for external debug. When the OS Lock is locked, DSCR is part of the software save and restore mechanism for external debug. It provides a mechanism for an operating system to access some fields of EDSCR that are otherwise read-only or not visible to software. This allows the operating system to save and restore these settings over a powerdown for the external debugger.

b. This register is new in ARMv8-A. Sequences written for ARMv7 do not preserve the register over powerdown.

c. Read DBGCLAIMCLR to save, write DBGCLAIMSET to restore.

H6.5.2 OS Save sequence

To preserve the debug logic state over a powerdown, the state must be saved to nonvolatile storage. This means the OS Save sequence must:

1. Lock the OS Lock by:
   - Writing the key value `0xC5ACCE55` to the DBGOSLAR in AArch32 state.
   - Writing 1 to OSLAR_EL1.OSLK in AArch64 state.
2. Execute an `ISB` instruction.
3. Walk through the debug registers listed in *Debug registers to save over powerdown* on page H6-4502 and save the values to the nonvolatile storage.

Before removing power from the core power domain, software must:

1. Lock the OS Double Lock by writing 1 to OSDLR_EL1.DLK.
2. Execute a context synchronization operation.

H6.5.3 OS Restore sequence

After a powerdown, the OS Restore sequence must perform the following steps to restore the debug logic state from the non-volatile storage:

1. Lock the OS Lock, as described in *Debug registers to save over powerdown* on page H6-4502. The OS Lock is generally locked by the Cold reset, but this step ensures that it is locked.
2. Execute an `ISB` instruction.
3. Walk through the debug registers listed in *Debug registers to save over powerdown* on page H6-4502, and restore the values from the nonvolatile storage.
4. Execute an `ISB` instruction.
5. Unlock the OS Lock by:
   - Writing any non-key value to DBGOSLAR in AArch32 state.
   - Writing 0 to OSLAR_EL1.OSLK in AArch64 state.
6. Execute a context synchronization operation.

Note

The OS Restore sequence overwrites the debug registers with the values that were saved. If there are valid values in these registers immediately before the restore sequence, then those values are lost.

H6.5.4 Debug behavior when the OS Lock is locked

The main purpose of the OS Lock is to prevent updates to debug registers during an OS Save or OS Restore operation. The OS Lock is locked on a Cold reset.

When the OS Lock is locked:

- Access to debug registers through the system register interface is mainly unchanged except that:
  - Certain registers are read and written without side-effects.
  - Fields in DSCR and OSECCR that are normally read-only become read/write.

  This allows the state to be saved or restored. For more information, see the relevant register description in Chapter H9 *External Debug Register Descriptions*.
- Access to debug registers by the external debug interface is restricted to prevent an external debugger modifying the registers that are being saved or restored. For more information see *External debug interface register access permissions summary* on page H8-4525.
- Debug exceptions, other than Software Breakpoint Instruction exceptions are not generated.

The OS Lock has no effect on Software Breakpoint Instruction debug events and Halting debug events.

H6.5.5 Debug behavior when the OS Lock is unlocked

When the OS Lock is unlocked, an OS Unlock Catch debug event is generated if EDECR.OUCE is set to 1. See *OS Unlock Catch debug event* on page H3-4453.

H6.5.6 Debug behavior when the OS Double Lock is locked

The OS Double Lock is locked immediately before a powerdown sequence. The OS Double Lock ensures that it is safe to remove core power by forcing the debug interfaces to be quiescent.

When `DoubleLockStatus()` == TRUE:

- The external debug interface only has restricted access to the debug registers, so that it is quiescent before removing power. See *External debug interface register access permissions summary* on page H8-4525.
- Debug exceptions, other than Software Breakpoint Instruction exceptions, are not generated.
- Halting is prohibited. See *Halting allowed and halting prohibited* on page H2-4395.

  Note

  Pending Halting debug events might be lost when core power is removed.
- No asynchronous debug events are `WFI` or `WFE` wake-up events.

Software must synchronize the update to OSDLR before it indicates to the system that core power can be removed. The interface between the PE and its power controller is IMPLEMENTATION DEFINED.

Typically software indicates that core power can be removed by entering the Wait For Interrupt state. This means that software must explicitly synchronize the OSDLR update before issuing the `WFI` instruction.

OSDLR.DLK is ignored and `DoubleLockStatus()` == FALSE if either:

- The PE is in Debug state.
- DBGPRCR.CORENPDRQ is set to 1.

Note

It is possible to enter Debug state with OSDLR.DLK set to 1. This is because a context synchronization operation is required to ensure the OS Double Lock is locked, meaning that Debug state might be entered before the OSDLR update is synchronized.

As the purpose of the OS Double Lock is to ensure that it is safe to remove core power, it is important to avoid race conditions that defeat this purpose. ARM recommends that:

- Once the write to OSDLR.DLK has been synchronized by a *Context synchronization operation* and `DoubleLockStatus()` == TRUE, a PE must:
  - Not allow a debug event generated before the *Context synchronization operation* to cause an entry to Debug state or act as a wake-up event for a `WFI` or `WFE` instruction after the context synchronization operation has completed.
  - Complete any external debug access started before the *Context synchronization operation* by the time the context synchronization operation completes.

    Note

    A debug register access might be in progress when software sets OSDLR.DLK to 1. An implementation must not permit the synchronization of locking the OS Double Lock to stall indefinitely while waiting for that access to complete. This means that any debug register access that is in progress when software sets OSDLR.DLK to 1 must complete or return an error in finite time.

- If a write to DBGPRCR or EDPRCR made when OSDLR.DLK == 1 changes DBGPRCR.CORENPDRQ or EDPRCR.CORENPDRQ from 1 to 0, meaning `DoubleLockStatus()` changes from FALSE to TRUE, then before signaling to the system that the CORENPDRQ field has been cleared and emulation of powerdown is no longer requested, meaning the system can remove core power, the PE must ensure that all the requirements for `DoubleLockStatus()` == TRUE listed in this section are met.

In the standard OS Save sequence, the OS Lock is locked before the OS Double Lock is locked. This means that writes to CORENPDRQ are ignored by the time the OS Double Lock is locked. However, if `DoubleLockStatus()` == FALSE, an external debugger can clear the OS Lock at any time, and then write to EDPRCR.

The pseudocode for the `DoubleLockStatus()` function is as follows:

```
// DoubleLockStatus)()
// ===================
// Returns the value of EDPRSR.DLK.
//    FALSE if OSDLR_EL1.DLK == 0 or DBGPRCR_EL1.CORENPDRQ == 1 or the PE is in Debug state.
//    TRUE if OSDLR_EL1.DLK == 1 and DBGPRCR_EL1.CORENPDRQ == 0 and the PE is in Non-debug state.

boolean DoubleLockStatus()

    if ELUsingAArch32(EL1) then
        return DBGOSDLR.DLK == ‘1’ && DBGPRCR.CORENPDRQ == ‘0’ && !Halted();
    else
        return OSDLR_EL1.DLK == ‘1’ && DBGPRCR_EL1.CORENPDRQ == ‘0’ && !Halted();
```

Chapter H7
The Sample-based Profiling Extension

This chapter describes the Sample-based Profiling extension, that is an OPTIONAL extension to the ARMv8 architecture. The extension provides a non-invasive external debug component.

Note

This form of the Sample-based Profiling extension is OPTIONAL. ARM recommends that if extension EDPCSR is not implemented that an alternative IMPLEMENTATION DEFINED form of Sample-based Profiling is implemented.

It contains the following section:

H7.1 Sample-based profiling

Sample-based profiling is an OPTIONAL extension to the architecture. It provides a mechanism for coarse-grained profiling of software executing on the PE by an external debugger, without changing the behavior of that software. The following sections describe this extension:

- *The implemented Sample-based profiling registers*
- *Reads of the External Debug Program Counter Sampling Registers*
- *Reads of the External Debug Virtual Context Sample Register* on page H7-4509
- *Accuracy of sampling* on page H7-4509
- *Sample-based Profiling and security* on page H7-4510
- *Pseudocode details of Sample-based Profiling* on page H7-4510

H7.1.1 The implemented Sample-based profiling registers

An implementation that includes the Sample-based profiling extension implements the following external debug registers:

- EDPCSR is a 64-bit read-only register that contains a sampled program counter value. As external debug register accesses are atomic only at word granularity, EDPCSR is split into two registers: EDPCSRhi and EDPCSRlo. See *Reads of the External Debug Program Counter Sampling Registers*.
- EDCIDSR is a read-only register that contains the sampled value of CONTEXTIDR_EL1 captured on reading EDPCSRlo.

  Note

  If EL3 is implemented and using AArch32 then CONTEXTIDR is a Banked register and EDCIDSR samples the current Banked copy of CONTEXTIDR.

- EDVIDSR is a read-only register that contains sampled values captured on reading EDPSRlo. If neither EL3 nor EL2 are implemented, EDVIDSR is not implemented.

H7.1.2 Reads of the External Debug Program Counter Sampling Registers

A read of the EDPCSRlo normally has the side-effect of indirectly writing to EDCIDSR, EDVIDSR, and EDPCSRhi. When EDPCSRlo is read, the bottom 32 bits of a program counter sample are returned. The top 32 bits are captured in EDPCSRhi and can be read later. However:

- If the PE is in Debug state, or Sample-based Profiling is prohibited, EDPCSRlo reads as `0xFFFFFFFF` and EDCIDSR, EDVIDSR and EDPCSRhi become UNKNOWN. See *Sample-based Profiling and security* on page H7-4510.
- If the PE is in Reset state, the sampled value is UNKNOWN and EDCIDSR, EDVIDSR and EDPCSRhi become UNKNOWN.
- If no instruction has been retired since the PE left Reset state, Debug state, or a state where Sample-based Profiling is prohibited, the sampled value is UNKNOWN and EDCIDSR, EDVIDSR and EDPCSRhi become UNKNOWN.
- The indirect writes to EDCIDSR, EDVIDSR, and EDPCSRhi might not occur for a memory-mapped access to the external debug interface. For more information, see *Memory-mapped accesses to the external debug interface* on page H8-4521.

Note

In ARMv7 the Sample-based Profiling extension an offset was applied to the sampled program counter value and this offset and the instruction set state indicated in bits [1:0] of the sampled value. In the ARMv8 Sample-based Profiling extension, the sampled value is the address of an instruction that has executed, with no offset and no indication of the instruction set state.

H7.1.3 Reads of the External Debug Virtual Context Sample Register

A read of the EDVIDSR contains sampled values captured on reading EDPSRlo, where:

- EDVIDSR.NS indicates the security state associated with the most recent EDPCSR sample.
- EDVIDSR.E2 indicates whether the most recent EDPCSR sample was associated with EL2. If EDVIDSR.NS == 0, this bit is 0.
- EDVIDSR.E3 indicates whether the most recent EDPCSR sample was associated with EL3 using AArch64. If EDVIDSR.NS == 1 or the PE was in AArch32 state when EDPCSRlo was read, this bit is 0.
- EDVIDSR.HV indicates whether EDPCSRhi is valid, that is, bits [63:32] of the most recent program counter sample are non-zero.

  Note

  — EDVIDSR.HV == 1 does not mean that EDPCSRhi != 0. EDVIDSR.HV == 0 is a hint that EDPCSRhi does not need to be read.

  — Tools must take care to avoid skewing sampled data by over-sampling code for which EDVIDSR.HV == 0.

- EDVIDSR.VMID indicates the value of the VTTBR_EL2.VMID register associated with the most recent EDPCSRlo sample. If EDVIDSR.NS == 0 or EDVIDSR.E2 == 1, this field is RAZ.

If EL2 is not implemented, EDVIDSR.E2 and EDVIDSR.VMID are RES0.

If EL3 is not implemented, EDVIDSR.E3 is RES0, and EDVIDSR.NS has a fixed read-only value.

H7.1.4 Accuracy of sampling

Sample-based Profiling is provided as a mechanism for tools to populate a statistical model of the performance of software executing on the PE. The statistical data returned by random sampling of EDPCSR, EDCIDSR, and EDVIDSR must allow such statistical modeling.

It must be possible to sample references to branch targets. It is IMPLEMENTATION DEFINED whether references to other instructions can be sampled. The branch target for a conditional branch instruction that fails its condition check is the instruction that follows the conditional branch instruction. The branch target for an exception is the exception vector address.

To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the sampled data is acceptable. ARM does not define *a reasonable degree of inaccuracy* but recommends the following guidelines:

- Under normal operating conditions, the whole sample, EDPCSR, EDCIDSR, and EDVIDSR, must reference an instruction, including its context.
- In exceptional circumstances, such as a change in security state or other boundary condition, it is acceptable for the sample to represent an instruction that was not committed for execution.
- Under very unusual non-repeating pathological cases the sample can represent an instruction that was not committed for execution. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in sampling is very unlikely.

See also *Non-invasive behavior* on page D5-1750.

H7.1.5 Sample-based Profiling and security

Sample-based Profiling is a non-invasive external debug component, controlled by an IMPLEMENTATION DEFINED authentication interface. Sample-based Profiling is prohibited unless both:

- Allowed by the IMPLEMENTATION DEFINED authentication interface `ExternalNoninvasiveDebugEnabled()`
- Any one of:
  - Executing in Non-secure state.
  - EL3 is not implemented.
  - EL3 is implemented, executing in Secure state, and allowed by the IMPLEMENTATION DEFINED authentication interface `ExternalSecureNoninvasiveDebugEnabled()`.
  - EL3 is implemented, EL3 or EL1 is using AArch32, executing at EL0 in Secure state, and SDER32_EL3.SUNIDEN == 1.

The state of IMPLEMENTATION DEFINED authentication interface is visible through DBGAUTHSTATUS_EL1.

See also Appendix B *Recommended External Debug Interface*.

H7.1.6 Pseudocode details of Sample-based Profiling

`PCSample()` records a PC sample for the EDPCSR and associated registers.

```
type PCSample is (
    boolean valid,
    bits(64) pc,
    bits(2) el,
    bit rw,
    bit ns,
    bits(32) contextidr,
    bits(8) vmid
)

PCSample pc_sample;
// CreatePCSample()
// ================

CreatePCSample()
    // In a simple sequential execution of the program, CreatePCSample is executed each time the PE
    // executes an instruction that can be sampled. An implementation is not constrained such that
    // reads of EDPCSRlo return the current values of PC, etc.
    enabled = (if IsSecure() then ExternalSecureNoninvasiveDebugEnabled()
                             else ExternalNoninvasiveDebugEnabled());

    pc_sample.valid = enabled && !Halted();
    pc_sample.pc = ThisInstrAddr();
    pc_sample.el = PSTATE.EL;
    pc_sample.rw = if UsingAArch32() then '0' else '1';
    pc_sample.ns = if IsSecure() then '0' else '1';
    pc_sample.contextidr = if ELUsingAArch32(EL1) then CONTEXTIDR else CONTEXTIDR_EL1;
    if HaveEL(EL2) && !IsSecure() then
        pc_sample.vmid = if ELUsingAArch32(EL2) then VTTBR.VMID else VTTBR_EL2.VMID;

    return;

// EDPCSRlo[] (read)
// =================

bits(32) EDPCSRlo[]

    if pc_sample.valid then
        sample = pc_sample.pc<31:0>;
        EDPCSRhi = (if pc_sample.rw == '0' then Zeros(32) else pc_sample.pc<63:32>);
        EDCIDSR = pc_sample.contextidr;
```

```
    EDVIDSR.VMID = (if HaveEL(EL2) && pc_sample.ns == '1' && pc_sample.el IN {EL1,EL0}
                    then pc_sample.vmid else Zeros(8));
    EDVIDSR.NS = pc_sample.ns;
    EDVIDSR.E2 = (if pc_sample.el == EL2 then '1' else '0');
    EDVIDSR.E3 = (if pc_sample.el == EL3 then '1' else '0') AND pc_sample.rw;
    // The conditions for setting HV are not specified if PCSRhi is zero.
    // An example implementation may be "pc_sample.rw".
    EDVIDSR.HV = (if !IsZero(EDPCSRhi) then '1' else bit IMPLEMENTATION_DEFINED "0 or 1");
else
    sample = Ones(32);
    EDPCSRhi = bits(32) UNKNOWN;
    EDCIDSR = bits(32) UNKNOWN;
    EDVIDSR = (bits(4) UNKNOWN):Zeros(20):(bits(8) UNKNOWN);

return sample;
```

Chapter H8
About the External Debug Registers

This chapter provides some additional information about the external debug registers. It contains the following sections:

Note

Where necessary Table J-1 on page AppxJ-5170 disambiguates the general register references used in this chapter.

H8.1 Relationship between external debug and System registers

Table H8-1 shows the relationship between external debug registers and system registers. Where no relationship exists, the registers are not listed.

Table H8-1 Equivalence between external debug and System registers

EDDEVAFF0 EDDEVAFF1	MPIDR_EL1[31:0][a] MPIDR_EL1[63:32][a]	MPIDR	Read-only copies of system ID registers

a. This is a word of a 64-bit register.

In addition:

- EDSCR.{TXfull, RXfull} are read-only aliases for DCCSR.{TXfull, RXfull}.
- EDPRCR.CORENPDRQ is a read/write alias for DBGPRCR.CORENPDRQ.
- EDPRSR.OSLK is a read-only alias for OSLSR.OSLK.

- EDPRSR.DLK is a read-only function of OSLSR.DLK.

H8.2 Supported access sizes

The memory access sizes supported by any peripheral is IMPLEMENTATION DEFINED by the peripheral. For accesses to the debug registers, Performance Monitor registers, and CTI registers, implementations must support:

- Word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations.
- Doubleword-aligned 64-bit accesses to access 64-bit registers mapped to a doubleword-aligned pair of adjacent 32-bit locations.

Note

This means that a system implementing the debug registers using a 32-bit bus, such as a AMBA APB3, with a wider system interconnect must implement a bridge between the system and the debug bus that can split 64-bit accesses.

All registers are only single-copy atomic at word granularity. This means that for 64-bit accesses to a 64-bit register, the system might generate a pair of 32-bit accesses. The order in which the two halves are accessed is not specified.

The following accesses are not supported:

- Byte.
- Halfword.
- Unaligned word. These accesses are not word single-copy atomic.
- Unaligned doubleword. These accesses are not doubleword single-copy atomic.
- Doubleword accesses to a pair of 32-bit locations that are not a doubleword-aligned pair forming a 64-bit register.
- Quadword or higher.
- Exclusive accesses.

For each of these access types, it is CONSTRAINED UNPREDICTABLE whether:

- The access generates an external abort or not.
- The defined side-effects of a read occur or not. A read returns UNKNOWN data.
- A write is ignored or sets the accessed register or registers to UNKNOWN.

For accesses from the external debug interface, the size of an access is determined by the interface. For an access from an ADIv5-compliant Memory Access Port, MEM-AP, this is specified by the MEM-AP CSW register.

See *Access sizes for memory-mapped accesses* on page H8-4522.

H8.3 Synchronization of changes to the external debug registers

This section describes the synchronization requirements for the external debug interface.

For more information on how these requirements affect debug, see:

- *Synchronization and debug exceptions* on page D2-1593 for exceptions taken from AArch64 state, or *Synchronization and debug exceptions* on page G2-3572 for exceptions taken from AArch32 state.
- *Synchronization and Halting debug events* on page H3-4456.
- *Synchronization of DCC and ITR accesses* on page H4-4470.

This section refers to accesses from the external debug interface as external reads and external writes. It refers to accesses to system registers as direct reads, direct writes, indirect reads, and indirect writes.

Note

Synchronization requirements for System registers on page D7-1794 defines direct read, direct write, indirect read, and indirect write, and classifies external reads as indirect reads, and external writes as indirect writes.

Writes to the same register are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes. With the exception of DBGBCR<n>_EL1, DBGBVR<n>_EL1, DBGWCR<n>_EL1, and DBGWVR<n>_EL1, external writes to different registers are not necessarily observed in the same order by all observers as the order in which they complete.

Synchronization of DCC and ITR accesses on page H4-4470 describes the synchronization requirements for the DCC and ITR.

Changes to the IMPLEMENTATION DEFINED authentication interface are external writes to the authentication status registers by the master of the authentication interface. See *Synchronization and the authentication interface* on page H8-4518.

Explicit synchronization is not required for an external read or an external write by an external agent to be observable to a following external read or external write by that agent to the same register using the same address, and so is never required for registers that are accessible only in the external debug interface.

Some registers are guaranteed to be observable to all observers in finite time, without explicit synchronization. For more information, see *Synchronization requirements for System registers* on page D7-1794. Otherwise, explicit synchronization is normally required following an external write to any register for that write to be observable by:

- A direct access.
- An indirect read by an instruction.
- An external read of the register using a different address.

This means that an external write by an external agent is guaranteed to have an effect on subsequent instructions executed by the PE only if all of the following are true:

- The write has completed.
- The PE has executed a context synchronization operation.
- The context synchronization operation was executed after the write completed.

The order and synchronization of direct reads and direct writes of system registers is defined by *Synchronization requirements for System registers* on page D7-1794.

The external agent must be able to guarantee completion of a write. For example by:

- Marking the memory as Device-nGnRnE and executing a `DSB` barrier, if the system supports this property.
- Reading back the value written.
- Some guaranteed property of the connection between the PE and the external agent.

Note

For an external Debug Access Port, this is an IMPLEMENTATION DEFINED property. For a CoreSight system using APB-AP to access a debug APB, a write is guaranteed to complete before the APB-AP allows a second APB transaction to complete.

The external agent and PE can guarantee ordering by, for example, passing messages in an ordered way with respect to the external write and the context synchronization operation, and relying on the memory ordering rules provided by the memory model.

External reads and external writes complete in the order in which they arrive at the PE. For accesses to different register locations the external agent must create this order by:

- Marking the memory as Device-nGnRnE or Device-nGnRE.
- Using the appropriate memory barriers.
- Some guaranteed property of the connection between the PE and the external agent.

Note

For an external Debug Access Port, this is an IMPLEMENTATION DEFINED property. For a CoreSight system using APB-AP to access a debug APB, accesses complete in order.

However, the external agent cannot force synchronization of completed writes without halting the PE. Executing an `ISB` instruction, either in Debug state or in Non-debug state, and exiting from Debug state forces synchronization. If the PE is in Debug state, executing an `ISB` instruction is guaranteed to explicitly synchronize any external reads, external writes, and changes to the authentication interface that are ordered before the external write to EDITR.

For any given observer, external writes to the following register groups are guaranteed to be observable in the same order in which they complete:

- The breakpoint registers, DBGBCR<n>_EL1 and DBGBVR<n>_EL1.
- The watchpoint registers, DBGWCR<n>_EL1 and DBGWVR<n>_EL1.

This guarantee only applies to external writes to registers within one of these groups. There is no guarantee regarding the ordering of the observability of external writes within these groups with respect to external writes to registers, for example EDSCR, or between breakpoints and watchpoints, including watchpoints linked to context matching breakpoints.

Note

This means that a debugger can rely on the external writes to be observed in the same order in which they complete. It does not mean that a debugger can rely on the external writes being observed in finite time.

In a simple sequential execution an indirect write that occurs as a side-effect of an access happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

If two or more interfaces simultaneously access a register, the behavior must be as if the accesses occurred atomically and in any order. This is described in *Examples of the synchronization of changes to the external debug registers* on page H8-4519.

Some registers have the property that for certain bits a write of 0 is ignored and a write of 1 has an effect. This means that simultaneous writes must be merged. Registers that have this property and support both external debug and system register access include DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, PMCR_EL0.{C,P}, PMOVSSET_EL0, PMOVSCLR_EL0, PMCNTENSET_EL0, PMCNTENCLR_EL0, PMINTENSET_EL1, PMINTENCLR_EL1, and PMSWINC_EL0. This last register is OPTIONAL and deprecated in the external debug interface.

H8.3.1 Synchronization and the authentication interface

Changes to the authentication interface are indirect writes to the Authentication Status registers by the master of the authentication interface. For each of these Authentication Status registers, it is IMPLEMENTATION DEFINED whether a change on the authentication interface is guaranteed to be observable to an external debug interface read of the register only after a context synchronization operation or in finite time.

For DBGAUTHSTATUS_EL1, a change on the authentication interface is guaranteed to be observable to a system register read of DBGAUTHSTATUS_EL1 only after a context synchronization operation.

H8.3.2 Examples of the synchronization of changes to the external debug registers

Example H8-1, Example H8-2, and Example H8-3 show the synchronization of changes to the external debug registers.

Example H8-1 Order of synchronization of Breakpoint and Watchpoint register writes

Initially DBGBVR<n>_EL1 is `0x8000` and DBGBCR<n>_EL1 is `0x0181`. This means that a breakpoint is enabled on the halfword T32 instruction at address `0x8000`.

A sequence of external writes occurs in the following order:

1. `0x0000` is written to DBGBCR<n>_EL1, disabling the breakpoint.
2. `0x9000` is written to DBGBVR<n>_EL1[31:0].
3. `0x0061` is written to DBGBCR<n>_EL1, enabling a breakpoint on the halfword at address `0x9002`.

The external writes must be observable to indirect reads in the same order as the external writes complete. This means that at no point is there a breakpoint enabled on either of the halfwords at address `0x8002` and `0x9000`.

Similarly a breakpoint or watchpoint must be disabled:

- If both halves of a 64-bit address have to be updated.
- If any of the DBGBCR<n>_EL1 or DBGWCR<n>_EL1 fields are modified at the same time as updating the address.

Example H8-2 Simultaneous accesses to DTR registers

Initially EDSCR.{TXfull, TXU, ERR} are 0. Then:

- `0x0DCCDA7A` is directly written to DBGDTRTX_EL0 by an `MSR` instruction.
- DBGDTRTX_EL0 is indirectly read by the external debug interface.

These accesses might happen at the same time and in any order.

If the direct write of `0x0DCCDA7A` to DBGDTRTX_EL0 is handled first, then:

- The external debug interface read of DBGDTRTX_EL0 clears EDSCR.TXfull to 0.
- EDSCR.{TXU, ERR} are unchanged.
- The external debug interface read returns `0x0DCCDA7A`.

If the indirect read of DBGDTRTX_EL0 by the external debug interface is handled first, then:

- The external debug interface read of DBGDTRTX_EL0 causes an underrun and as a result EDSCR.{TXU, ERR} are both set to 1.
- The external debug interface returns an UNKNOWN value.
- Writing `0x0DCCDA7A` to DBGDTRTX_EL0 sets DTRTX to `0x0DCCDA7A` and EDSCR.TXfull to 1.

Example H8-3 Simultaneous writes to CLAIM registers

Initially all CLAIM tag bits are 0. Then:

- `0x01` is written to DBGCLAIMSET_EL1 by a direct write, followed by an explicit context synchronization operation.
- `0x02` is written to DBGCLAIMSET_EL1 by an external write.

These events might happen at the same time and in either order.

After this:

- DBGCLAIMCLR_EL1 is read by a direct read.
- DBGCLAIMCLR_EL1 is read by an external read.

In this case, a direct read can return either `0x01` or `0x03`, and the external read can return either `0x02` or `0x03`.

The only permitted final result for the CLAIM tags is the value `0x03`, because this would be the result regardless of whether `0x01` or `0x02` is written first. This is because the external write is guaranteed to be observable to a direct read in finite time. See *Synchronization requirements for System registers* on page D7-1794.

It is not possible for a direct read to return `0x01` and the external read to return `0x02`, because the writes to DBGCLAIMCLR_EL1 are serialized.

In the following scenario, there is only one permitted result. Both observers observe the value `0x03`, and then, at the same time, two writes occur:

- `0x04` is written to DBGCLAIMSET_EL1 by a direct write, followed by an explicit context synchronization operation.
- `0x01` is written to DBGCLAIMCLR_EL1 by an external write.

In this case only permitted final result for the CLAIM tags is the value `0x06`.

H8.4 Memory-mapped accesses to the external debug interface

Support for memory-mapped access to the external debug interface is OPTIONAL.

If the external debug interface is CoreSight compliant, then an OPTIONAL Software Lock can be implemented for memory-mapped accesses to each component. The Software Locks are controlled by EDLSR and EDLAR, PMLSR and PMLAR, and CTILSR and CTILAR. See *Management registers and CoreSight compliance* on page AppxB-4878.

With the exception of these registers and the effect of the Software Lock, the behavior of the memory-mapped accesses is the same as for other accesses to the external debug interface.

Note

The recommended memory-mapped accesses to the external debug interface are not compatible with the memory-mapped interface defined in ARMv7. In particular:

- The memory map is different.
- Memory-mapped accesses do not behave differently to Debug Access Port accesses when OSLSR.OSLK == 1, meaning that the OS Lock is locked.

H8.4.1 Register access permissions for memory-mapped accesses

It is IMPLEMENTATION DEFINED whether unprivileged memory-mapped accesses are allowed. Privileged software is responsible for controlling memory-mapped accesses using the MMU.

If memory-mapped accesses are made through an ADIv5 interface, the Debug Access Port can block the access using **DBGSWENABLE**. This is outside the scope of the ARMv8-A architecture. See *ARM® Debug Interface Architecture Specification ADIv5.0 to ADIv5.2*.

Effect of the OPTIONAL Software Lock on memory-mapped access

For memory-mapped accesses, if other controls permit access to a register, the OPTIONAL Software Lock is implemented, and EDLSR.SLK, PMLSR.SLK, or CTILSR.SLK is set to 1, meaning the Software Lock is locked, then with the exception of the LAR itself:

- If other controls permit access to a register, then writes are ignored. That is:
  - Read/write (RW) registers become read-only (RO).
  - Write-only (WO) registers become write-ignored (WI).
- Reads and writes have no side-effects. A side-effect is where a direct read or a direct write of a register creates an indirect write of the same or another register. When the Software Lock is locked, the indirect write does not occur.
- Writes to EDLAR, PMLAR, and CTILAR are unaffected.

This behavior must also apply to all IMPLEMENTATION DEFINED registers.

For example, if EDLSR.SLK is set to 1:

- EDSCR.{TXfull, TXU, ERR} are unchanged by a memory-mapped read from DBGDTRTX_EL0.
- EDSCR.{RXfull, RXO, ERR} are unchanged by a memory-mapped write to DBGDTRRX_EL0 that is ignored.
- EDSCR.{ITE, ITO, ERR} are unchanged by a memory-mapped write to EDITR that is ignored.
- OSLSR.OSLK is unchanged by a memory-mapped write to OSLAR_EL1 that is ignored.
- EDPCSR[63:32], EDCIDSR, and EDVIDSR are unchanged by a memory-mapped read from EDPCSR[31:0].

- EDPRSR.{SDR, SPMAD, SDAD, SR, SPD} are unchanged by a memory-mapped read from EDPRSR.
- EDPRSR.SDAD is not set if an error response is returned due to a memory-mapped read or write of any debug register as the result of the value of the EDAD field.
- The CLAIM tags are unchanged by memory-mapped writes to DBGCLAIMSET_EL1 and DBGCLAIMCLR_EL1 which are ignored.

Similarly, if PMLSR.SLK is set to 1, then EDPRSR.SPMAD is not set if an error response is returned to a memory-mapped read or write of any Performance Monitors register due to the value of the EPMAD field.

Behavior of a not permitted memory-mapped access

Where the architecture requires that an external debug interface access generates an error response, a memory-mapped access must also generate an error response. However, it is IMPLEMENTATION DEFINED how the error response is handled, as this depends on the system.

ARM recommends that the error is returned as either:

- A synchronous external Data Abort.
- A System Error interrupt.

H8.4.2 Synchronization of memory-mapped accesses to external debug registers

The synchronization requirements for memory-mapped accesses to the external debug interface is described in *Synchronization of changes to the external debug registers* on page H8-4517.

The synchronization requirements between different routes to the external debug interface, that is, between Debug Access Port accesses and memory-mapped accesses are IMPLEMENTATION DEFINED.

H8.4.3 Access sizes for memory-mapped accesses

For memory-mapped accesses from a PE that complies with an ARM architecture, the single-copy atomicity rules for the instruction, the type of instruction, and the type of memory accessed, determine the size of the access made by an instruction. Example H8-4 shows this.

Example H8-4 Access sizes for memory-mapped accesses

Two Load Doubleword instructions made to consecutive doubleword-aligned locations generate a pair of single-copy atomic doubleword reads. However, if the accesses are made to Normal memory or Device-GRE memory they might appear as a single quadword access that is not supported by the peripheral.

ARMv8 does not require the size of each element accessed by a multi-register load or store instruction to be identifiable by the memory system beyond the PE. Any memory-mapped access to a debug register is defined to be beyond the PE.

Software must use a Device-nGRE or stronger memory-type and use only single register load and store instructions to create memory accesses that are supported by the peripheral. For more information, see *Memory types and attributes* on page B2-89.

H8.5 External debug interface register access permissions

Some external accesses to debug registers and Performance Monitor registers are not permitted and return an error response if:

- The Core power domain is powered-down or is in low-power state where the registers cannot be accessed.
- OSLSR.OSLK == 1. The OS Lock is locked.
- `DoubleLockStatus()` == TRUE. The OS Double Lock is locked, that is, EDPRSR.DLK == 1.
- Access by the external debug interface is disabled by the authentication interface or secure monitor.

Not all registers are affected in all of these cases. For details, see *External debug interface register access permissions summary* on page H8-4525.

Note

OSLSR.OSLK is visible through EDPRSR.

H8.5.1 External debug over powerdown and locks

Accessing registers using the external debug interface is not possible when the Debug power domain is off. In this case all accesses return an error.

External accesses to debug and Performance Monitors registers in the Core power domain are not permitted and return an error response if:

- The Core power domain is off or in low-power state where the registers cannot be accessed.
- OSLSR.OSLK == 1, meaning that the OS Lock is locked. This allows software to prevent external debugger modification of the registers while it saves and restores them over powerdown.

  Note

  In this case OSLAR_EL1 can be accessed, meaning an external debugger can override this lock.

- `DoubleLockStatus()` == TRUE. This means that the OS Double Lock is locked and EDPRSR.DLK == 1. The OS Double Lock ensures that it is safe to remove Core power by forcing the debug interface to be quiescent.

See also *Debug registers to save over powerdown* on page H6-4502.

The following pseudocode outlines the `AllowExternalAccess()` function.

```
// AllowExternalAccess()
// =====================

boolean AllowExternalAccess()
    return !DoubleLockStatus() && OSLSR_EL1.OSLK == '0' && EDPRSR.PU == '1';
```

H8.5.2 External access disabled

Accesses are further controlled by the external authentication interface. An untrusted external debugger cannot program the breakpoint and watchpoint registers to generate spurious debug exceptions. If external invasive debugging is not enabled, these external accesses to the registers are disabled. If EL3 is implemented, then SDCR provides additional external access disable controls for those registers if Secure external invasive debugging is disabled.

The disable applies to:

- *DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15* on page H9-4545.
- *DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15* on page H9-4542.
- *DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15* on page H9-4555.
- *DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15* on page H9-4552.

The external debug interface cannot access these registers if either:

- External debugging is not enabled. `ExternalInvasiveDebugEnabled()` == FALSE.
- Secure external debugging is not enabled, meaning `ExternalSecureInvasiveDebugEnabled()` == FALSE, and any of the following:
  - EL3 is not implemented and the PE is Secure.
  - EL3 is implemented and SDCR.EDAD == 1.

The following pseudocode outlines the `AllowExternalDebugAccess()` function.

```
// AllowExternalDebugAccess()
// ==========================
// Returns the status of EDPRSR.EDAD.

boolean AllowExternalDebugAccess()
    // The access may also be subject to OS lock, power-down, etc.
    if AllowExternalAccess() && ExternalInvasiveDebugEnabled() then
        if ExternalSecureInvasiveDebugEnabled() then
            return TRUE;
        elsif HaveEL(EL3) then
            return (if ELUsingAArch32(EL3) then SDCR.EDAD else MDCR_EL3.EDAD) == '0';
        else
            return !IsSecure();
    else
        return FALSE;
```

PEs might also provide an OPTIONAL external debug interface to the Performance Monitor registers. The authentication interface and SDCR provide similar external access disable controls for those registers.

The external debug interface cannot access the Performance Monitor registers if either:

- External non-invasive debug is not enabled. `ExternalNoninvasiveDebugEnabled()` == FALSE.
- Secure external non-invasive debugging is not enabled, `ExternalSecureNoninvasiveDebugEnabled()` == FALSE, and any of:
  - EL3 is not implemented and the PE is Secure.
  - EL3 is implemented and SDCR.EPMAD == 1.

The following pseudocode outlines the `AllowExternalPMUAccess()` function.

```
// AllowExternalPMUAccess()
// ========================
// Returns the status of EDPRSR.EPMAD.

boolean AllowExternalPMUAccess()
    // The access may also be subject to OS lock, power-down, etc.
    if AllowExternalAccess() && ExternalNoninvasiveDebugEnabled() then
        if ExternalSecureNoninvasiveDebugEnabled() then
            return TRUE;
        elsif HaveEL(EL3) then
            return (if ELUsingAArch32(EL3) then SDCR.EPMAD else MDCR_EL3.EPMAD) == '0';
        else
            return !IsSecure();
    else
        return FALSE;
```

Note

- ARM recommends that secure software that is not making use of debug hardware does not lock out the external debug interface.
- ARMv8-A does not provide the equivalent control over access to Trace extension registers.

H8.5.3 Behavior of a not permitted access

For an external debug interface access by a Debug Access Port, the Debug Access Port receives the error response and must signal this to the external debugger. For an ADIv5 implementation of a Debug Access Port, the error sets a sticky error flag in the Debug Access Port that the debugger can poll, and that suppresses further accesses until it is explicitly cleared.

When an error is returned because external access is disabled, and this is the highest priority error condition, a sticky error flag in EDPRSR is indirectly written to 1 as a side-effect of the access:

- For a debug register access when `AllowExternalDebugAccess()` == FALSE, EDPRSR.SDAD is indirectly written to 1.
- For Performance Monitor register access when `AllowExternalPMUAccess()` == FALSE, EDPRSR.SPMAD is indirectly written to 1.

The indirect write might not occur for a memory-mapped access to the external debug interface. For more information, see *Register access permissions for memory-mapped accesses* on page H8-4521.

If no error is returned, or the error is returned because of a higher priority error condition, the flag in EDPRSR is unchanged.

See also *Behavior of a not permitted memory-mapped access* on page H8-4522.

For more information, see *ARM® Debug Interface Architecture Specification*.

H8.5.4 Trapping software access to debug registers

When EDSCR.TDA == 1, software access to the breakpoint and watchpoint registers generate a Halting debug event and entry to Debug state. For more information see *Software Access debug event* on page H3-4455.

H8.5.5 External debug interface register access permissions summary

For accesses to:

- IMPLEMENTATION DEFINED registers, see *IMPLEMENTATION DEFINED registers*.
- OPTIONAL registers for CoreSight compliance, see *OPTIONAL CoreSight management registers*.
- Reserved, unallocated, or unimplemented registers, writes to read-only registers, and reads of write-only registers, see *Reserved and unallocated registers* on page H8-4526.

For all other external debug interface, CTI, and Performance Monitor registers, Table H8-3 on page H8-4531, Table H8-4 on page H8-4533 and Table I2-1 on page I2-4685, show the response of the PE to accesses by the external debug interface.

H8.5.6 IMPLEMENTATION DEFINED registers

For debug registers, Performance Monitors registers, CTI registers, IMPLEMENTATION DEFINED register access permissions are IMPLEMENTATION DEFINED. The power domain in which these registers are implemented is also IMPLEMENTATION DEFINED.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses to registers. These constraints must also apply to IMPLEMENTATION DEFINED registers. In particular, if the OPTIONAL Software Lock is locked, writes are ignored and accesses have no side-effects. For more information see *Register access permissions for memory-mapped accesses* on page H8-4521.

H8.5.7 OPTIONAL CoreSight management registers

Compliance with CoreSight architecture requires additional registers in the range `0xF00 - 0xFFC` that are always accessible. See *Management registers and CoreSight compliance* on page AppxB-4878.

H8.5.8 Reserved and unallocated registers

The following information relates to certain types of reserved accesses:

- Reads and writes of unallocated locations. These accesses are reserved for the architecture.
- Reads and writes of locations for features that are not implemented, including:
  - OPTIONAL features that are not implemented.
  - Breakpoints and watchpoints that are not implemented.
  - Performance Monitors counters that are not implemented.
  - CTI triggers that are not implemented.

  These accesses are reserved.
- Reads of WO locations. These accesses are reserved for the architecture.
- Writes to RO locations. These accesses are reserved for the architecture.

Reserved accesses are normally RES0. That is, they must return zero on reads and ignore writes.

Note

Reads of WO and writes to RO refers to the default access permissions for a register. For example, when the SLK field is set, meaning that the relevant registers become RO, a memory-mapped write to a RW register is ignored, and not treated as a reserved access.

The following reserved registers are RES0 in all conditions, other than when debug power is off:

- If the implementation is CoreSight architecture compliant, all reserved registers in the range `0xF00 - 0xFFC`. See *Management register access permissions* on page AppxB-4879.
- All unallocated Processor ID Registers. That is, unallocated debug registers in the range `0xD00-0xDFC`.
- All reserved CTI registers.

Otherwise, the architecture defines that:

1. If debug power is off, all register accesses, including reserved accesses, return an error.
2. For reserved debug registers and Performance Monitors registers, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0, when any of the following hold:

   Off The Core power domain is either completely off or in a low-power state in which the Core power domain registers cannot be accessed.

   DLK `DoubleLockStatus()` == TRUE. The OS Double Lock is locked, that is, EDPRSR.DLK == 1.

   OSLK OSLSR.OSLK == 1. The OS Lock is locked.
3. In addition, for reserved debug registers in the address ranges `0x400 - 0x4FC` and `0x800 - 0x8FC`, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:

   EDAD `AllowExternalDebugAccess()` == FALSE. External debug is disabled.

   Note

   See also *Behavior of a not permitted access* on page H8-4525.
4. In addition, for reserved Performance Monitors registers in the address ranges `0x000 - 0x0FC` and `0x400 - 0x47C`, the response is a CONSTRAINED UNPREDICTABLE choice of error or RES0 when conditions 1 or 2 do not apply and:

   EPMAD `AllowExternalPMUAccess()` == FALSE. External Performance Monitor access is disabled.

Note

See also *Behavior of a not permitted access* on page H8-4525.

H8.6 External debug interface registers

The external debug interface register map is described by:

- *Performance Monitors memory-mapped register view* on page I3-4691.
- *Cross-trigger interface registers* on page H8-4533.
- Table H8-2.

Table H8-2 External debug interface register map

a. Only if the OPTIONAL Sample-based Profiling extension is implemented.

b. A 64-bit register mapped to a pair of 32-bit locations. Doubleword accesses to this register are not guaranteed to be 64-bit single copy atomic. See *Supported access sizes* on page H8-4516. Software must ensure a breakpoint or watchpoint is disabled before altering the value register.
c. Implemented breakpoints and watchpoints only. *n* is the breakpoint or the watchpoint number.

Note

All other locations are reserved.

H8.6.1 Access permissions for the External debug interface registers

Table H8-3 on page H8-4531 shows the access permissions for the external debug interface registers in an ARMv8-A Debug implementation. The terms are defined as follows:

Domain This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

Conditions This lists the conditions under which the access is attempted.

To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true.

The conditions are:

Off EDPRSR.PU == 0. The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed.

Note

If debug power is off, then all external debug interface accesses return an error.

DLK `DoubleLockStatus()` == TRUE. The OS Double Lock is locked, that is, EDPRSR.DLK == 1.

OSLK OSLSR.OSLK == 1. The OS Lock is locked.

EDAD `AllowExternalDebugAccess()` == FALSE. External debug access is disabled. See also *Behavior of a not permitted access* on page H8-4525.

EPMAD `AllowExternalPMUAccess()` == FALSE. Access to the external Performance Monitors is disabled. See also *Behavior of a not permitted access* on page H8-4525.

Default This provides the default access permissions, if there are no conditions that prevent access to the register.

SLK This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See *Register access permissions for memory-mapped accesses* on page H8-4521. For all other accesses, this column is ignored.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.

RO This means that the register or field is read-only.

RW This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details.

RC This means that the bit clears to 0 after a read.

(SE) This means that accesses to this register have indirect write side-effects. A side-effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register.

WO This means that the register or field is write-only.

WI This means that the register or field ignores writes.

IMP DEF This means that the access permissions are IMPLEMENTATION DEFINED.

If OPTIONAL memory-mapped access to the external debug interface is supported, there might be additional constraints on memory-mapped accesses. See *Register access permissions for memory-mapped accesses* on page H8-4521.

0xFC8	EDDEVID	Debug	-	-	-	-	RO	RO

a. Only if the Sample-based profiling extension is implemented.
b. Some control bits are in the Core power domain. These bits ignore writes when Core power domain registers cannot be accessed as shown.
c. Some status bits are fetched from the Core power domain. These bits read UNKNOWN when Core power domain registers cannot be accessed as shown.
d. Implemented breakpoints and watchpoints only. *n* is the breakpoint or watchpoint number.

For the reset values for the external debug interface registers, see Table H8-6 on page H8-4537.

H8.7 Cross-trigger interface registers

The embedded Cross-trigger Interface, CTI, is located within its own block of the external debug memory map. There must be one such block per PE or cluster of virtual PEs.

If the CTI of a PE does not implement the CTIDEVAFF0 or CTIDEVAFF1 registers it must be located 64KB above the debug registers in the external debug interface.

Table H8-4 shows the CTI register map.

0xFC8	CTIDEVID	Debug	-	-	-	-	RO	RO

a. Implemented triggers only (including triggers that are not connected). *n* is the trigger number.

For the reset values of the CTI registers, see Table H8-7 on page H8-4538.

H8.8 Reset and debug

All registers in the Core power domain are reset either by a Warm reset or a Cold reset, as described in *Reset* on page D1-1417, including external debug logic registers.

All registers in the Debug power domain are reset by an External Debug reset.

Figure H8-1 shows this reset scheme. The following three reset signals are an example implementation of the reset scheme:

- **CORERESET**, which must be asserted for a Warm reset.
- **CPUPORESET**, which must be asserted for a Cold reset.
- **PRESETDBG**, which must be asserted for an External Debug reset.

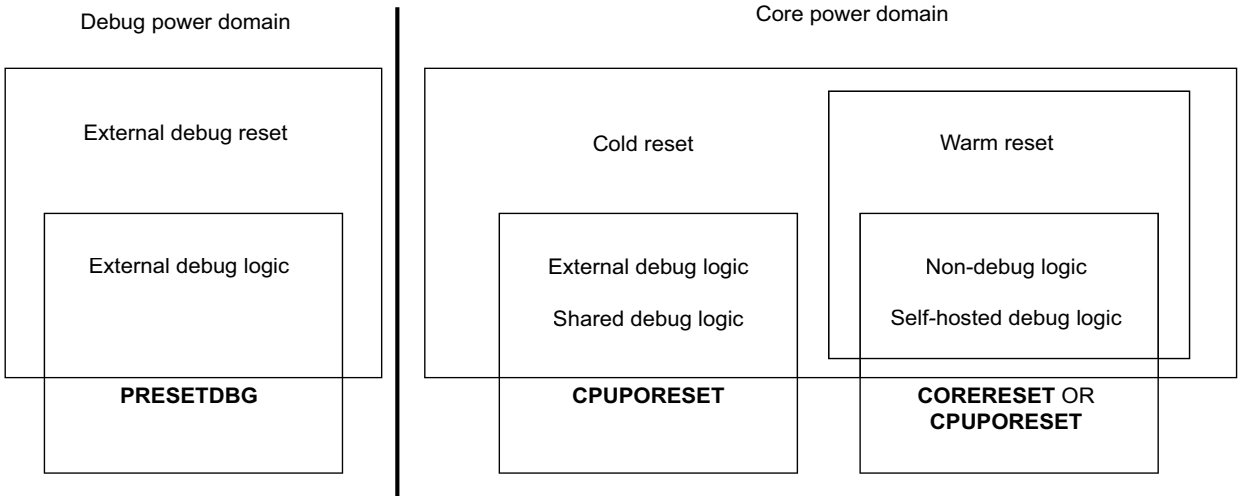

Figure H8-1 Power and reset domains

For more information about power domains and power states, see *Power domains and debug* on page H6-4497.

When power is first applied to the Debug power domain, **PRESETDBG** must be asserted.

When power is first applied to the Core power domain, **CPUPORESET** must be asserted.

Note

In this scheme, logic in the Warm reset domain is reset by asserting either **CORERESET** or **CPUPORESET**. This implies a particular implementation style that permits these approaches.

CPUPORESET is not normally asserted on moving from a low-power state, where power has not been removed, to a full-power state. This can occur, for example, on exiting a low-power retention state. See also *Emulating low-power states* on page H6-4500 and *EDPRSR, External Debug Processor Status Register* on page H9-4595.

H8.8.1 External debug interface accesses to registers in reset

If a reset signal is asserted and the external debug interface:

- Writes a register, or indirectly writes a register or register field as a side-effect of an access:
  - Then, if the register or register field is reset by that reset signal, it is CONSTRAINED UNPREDICTABLE whether the register or register field takes the reset value or the value written. The reset value might be UNKNOWN.
  - Otherwise the register or register field takes the value that is written.
- Reads a register, or indirectly reads a register or register field, as part of an access:
  - Then, if the register or register field is reset by that reset signal, the value returned in UNKNOWN.

— Otherwise, the value of the register or register field is returned.

It is IMPLEMENTATION DEFINED whether any register can be accessed when External Debug reset is being asserted. The result of these accesses is IMPLEMENTATION DEFINED.

H8.9 External debug register resets

Each register or field has a defined reset domain:

- Registers and fields in the Warm reset domain are also reset by a Cold reset and unchanged by an External Debug reset that is not coincident with a Cold reset or a Warm reset.
- Registers and fields in the Cold reset domain are unchanged by a Warm reset or an External Debug reset that is not coincident with a Cold reset.
- Registers and fields in the External Debug reset domain are unchanged by a Cold reset or a Warm reset that is not coincident with an External Debug reset.

Table H8-6 and Table H8-7 on page H8-4538 show the external debug register and CTI register resets. For other debug registers and Performance Monitors registers, see *Management register resets* on page AppxB-4883 and *Power domains and Performance Monitors registers reset* on page I2-4686.

Note

By reference to Figure H8-1 on page H8-4535 the power domain can be deduced from the reset domain. Table B-7 on page AppxB-4883 also shows reset power domains.

Table H8-6 and Table H8-7 on page H8-4538 do not include:

- Read-only identification registers, such as Processor ID Registers and PMCFGR, that have a fixed value from reset.
- Read-only status registers, such as EDSCR.RW, that are evaluated each time the register is read and that have no meaningful reset value.
- Write-only registers, such as EDRCR, that only have an effect on writes, and have no meaningful reset value.
- Read/write registers, such as breakpoint and watchpoint registers, and EDPRCR.CORENPDRQ, that alias other registers. The reset values are described by the descriptions of those other registers.
- IMPLEMENTATION DEFINED registers. The reset values and reset domains of these registers are also IMPLEMENTATION DEFINED and might be UNKNOWN.

All other fields in the registers are set to an IMPLEMENTATION DEFINED value, that can be UNKNOWN. The register is in the specified reset domain.

Table H8-6 Summary of external debug register resets, debug registers

Register	Reset domain	Field	Value	Description
EDESR	Warm	SS	EDECR.SS	Halting Step debug event pending
		RC	EDECR.RCE	Reset Catch debug event pending
		OSUC	0	OS Unlock Catch debug event pending
EDECR	External debug	SS	0	Halting Step debug event enable
		RCE	0	Reset Catch debug event enable
		OSUCE	0	OS Unlock Catch debug event enable
EDWAR	Cold	-	-	All fields

Table H8-6 Summary of external debug register resets, debug registers (continued)

Register	Reset domain	Field	Value	Description
EDSCR	Cold	RXfull	0	DTRRX register full
		TXfull	0	DTRTX register full
		RXO	0	DTRRX overrun
		TXU	0	DTRTX underrun
		INTdis	0	Interrupt disable
		TDA	0	Trap debug register accesses to Debug state
		MA	0	Memory access mode in Debug state
		HDE	0	Halting debug mode enable
		ERR	0	Cumulative error flag
EDECCR	Cold	NSE[2:1]	0b00	Coarse-grained Non-secure exception catch
		SE[3,1]	0b00	Coarse-grained Secure exception catch
EDPCSR	Cold	-	-	All fields
EDCIDSR	Cold	-	-	All fields
EDVIDSR	Cold	-	-	All fields
EDPRCR	External debug	COREPURQ	0	Core powerup request
EDPRSR	Warm	SDR	-	Sticky debug restart
	Cold	SPMAD	0	Sticky EPMAD error
		SDAD	0	Sticky EDAD error
	Warm	SR	1	Sticky reset status
	Cold	SPD	1	Sticky powerdown status

Table H8-7 shows the reset values for the CTI registers

Table H8-7 Summary of external debug register resets, CTI registers

Register	Reset domain	Field	Value	Description
CTICONTROL	External debug	GLBEN	0	CTI global enable
CTIAPPSET	External debug	-	-	All fields
CTIINEN<n>	External debug	-	-	All fields
CTIOUTEN<n>	External debug	-	-	All fields
CTIGATE	External debug	-	-	All fields

Chapter H9
External Debug Register Descriptions

This chapter provides a description of the external debug registers.

It contains the following items:

H9.1 Debug registers

This section describes each of the external Debug registers.

H9.1.1 DBGAUTHSTATUS_EL1, Debug Authentication Status register

The DBGAUTHSTATUS_EL1 characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

DBGAUTHSTATUS_EL1 is architecturally mapped to AArch64 register DBGAUTHSTATUS_EL1.

DBGAUTHSTATUS_EL1 is architecturally mapped to AArch32 register DBGAUTHSTATUS.

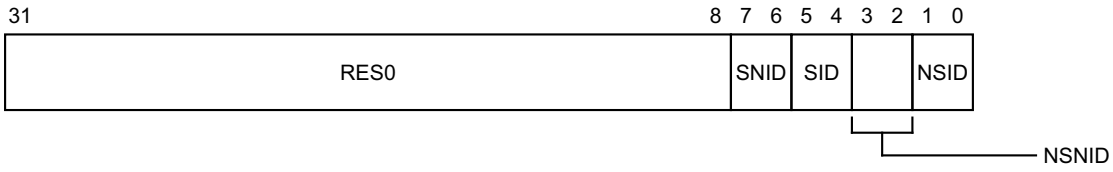
DBGAUTHSTATUS_EL1 is in the Debug power domain.

Attributes

DBGAUTHSTATUS_EL1 is a 32-bit register.

Field descriptions

The DBGAUTHSTATUS_EL1 bit assignments are:



Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Secure non-invasive debug. Possible values of this field are:

`00` Not implemented. EL3 is not implemented and the processor is Non-secure.

`10` Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.

`11` Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

`00` Not implemented. EL3 is not implemented and the processor is Non-secure.

10 Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSNID, bits [3:2]

Non-secure non-invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the processor is Secure.

10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the processor is Secure.

10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

Other values are reserved.

Accessing the DBGAUTHSTATUS_EL1

DBGAUTHSTATUS_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFB8

H9.1.2 DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n>_EL1 characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>_EL1, where n is 0 to 15.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

When the E field is zero, all the other fields in the register are ignored.

Configurations

DBGBCR<n>_EL1 is architecturally mapped to AArch64 register DBGBCR<n>_EL1.

DBGBCR<n>_EL1 is architecturally mapped to AArch32 register DBGBCR<n>.

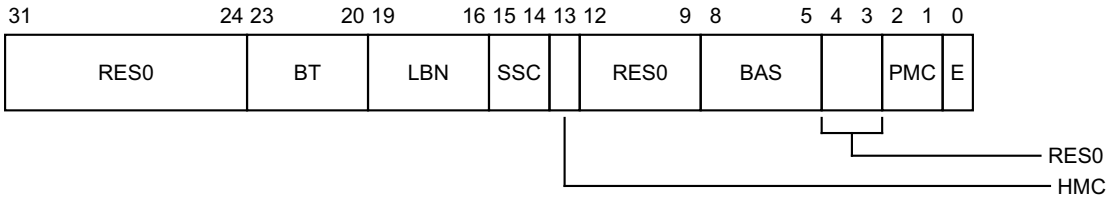
DBGBCR<n>_EL1 is in the Core power domain.

Attributes

DBGBCR<n>_EL1 is a 32-bit register.

Field descriptions

The DBGBCR<n>_EL1 bit assignments are:



Bits [31:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type. Possible values are:

`0000` Unlinked instruction address match.

`0001` Linked instruction address match.

`0010` Unlinked context ID match.

`0011` Linked context ID match

`0100` Unlinked instruction address mismatch.

`0101` Linked instruction address mismatch.

`1000` Unlinked VMID match.

`1001` Linked VMID match.

`1010` Unlinked VMID and context ID match.

1011 Linked VMID and context ID match.

The field breaks down as follows:

- BT[3:1]: Base type.
  - 000 Match address. DBGBVR<n>_EL1 is the address of an instruction.
  - 010 Mismatch address. Behaves as type 000 if in an AArch64 translation, or if Halting debug is enabled and halting is allowed. Otherwise, DBGBVR<n>_EL1 is the address of an instruction to be stepped.
  - 001 Match context ID. DBGBVR<n>_EL1[31:0] is a context ID.
  - 100 Match VMID. DBGBVR<n>_EL1[39:32] is a VMID.
  - 101 Match VMID and context ID. DBGBVR<n>_EL1[31:0] is a context ID, and DBGBVR<n>_EL1[39:32] is a VMID.
- BT[0]: Enable linking.

If the breakpoint is not context-aware, BT[3] and BT[1] are RES0. If EL2 is not implemented, BT[3] is RES0. If EL1 using AArch32 is not implemented, BT[2] is RES0.

The values 011x and 11xx are reserved, but must behave as if the breakpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

LBN, bits [19:16]

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

SSC, bits [15:14]

Security state control. Determines the security states under which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields.

Bits [12:9]

Reserved, RES0.

BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state. In an AArch64-only implementation, this field is reserved, RES1. Otherwise:

- BAS[2] and BAS[0] are read/write.
- BAS[3] and BAS[1] are read-only copies of BAS[2] and BAS[0] respectively.

The values 0011 and 1100 are only supported if AArch32 is supported at any exception level.

The permitted values depend on the breakpoint type.

For Address match breakpoints in either AArch32 or AArch64 state:

BAS	Match instruction at	Constraint for debuggers
0011	DBGBVR<n>_EL1	Use for T32 instructions.
1100	DBGBVR<n>_EL1+2	Use for T32 instructions.
1111	DBGBVR<n>_EL1	Use for A64 and A32 instructions.

0000 is reserved and must behave as if the breakpoint is disabled or map to a permitted value.

For Address mismatch breakpoints in an AArch32 stage 1 translation regime:

BAS	Step instruction at	Constraint for debuggers
0000	-	Use for a match anywhere breakpoint.
0011	DBGBVR<n>_EL1	Use for stepping T32 instructions.
1100	DBGBVR<n>_EL1+2	Use for stepping T32 instructions.
1111	DBGBVR<n>_EL1	Use for stepping A64 and A32 instructions.

For Context matching breakpoints, this field is RES1 and ignored.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the exception level or levels at which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

E, bit [0]

Enable breakpoint DBGBVR<n>_EL1. Possible values are:

0 Breakpoint disabled.

1 Breakpoint enabled.

Accessing the DBGBCR<n>_EL1

DBGBCR<n>_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x408 + 16n

H9.1.3 DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n>_EL1 characteristics are:

Purpose

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint n together with control register DBGBCR<n>_EL1, where n is 0 to 15.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

DBGBVR<n>_EL1 is architecturally mapped to AArch64 register DBGBVR<n>_EL1.

DBGBVR<n>_EL1[31:0] is architecturally mapped to AArch32 register DBGBVR<n>.

DBGBVR<n>_EL1[63:32] is architecturally mapped to AArch32 register DBGBXVR<n>.

DBGBVR<n>_EL1 is in the Core power domain.

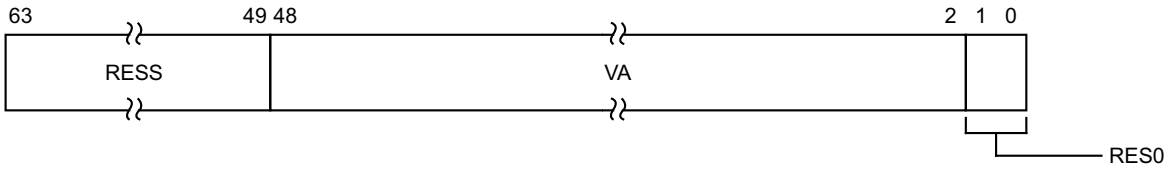
Attributes

DBGBVR<n>_EL1 is a 64-bit register.

Field descriptions

The DBGBVR<n>_EL1 bit assignments are:

When DBGBCR<n>_EL1.BT==0b0x0x:



RESS, bits [63:49]

Reserved, Sign extended. Hardwired to the value of the sign bit, bit [48]. Hardware and software must treat this field as RES0 if bit[48] is 0, and as RES1 if bit[48] is 1.

VA, bits [48:2]

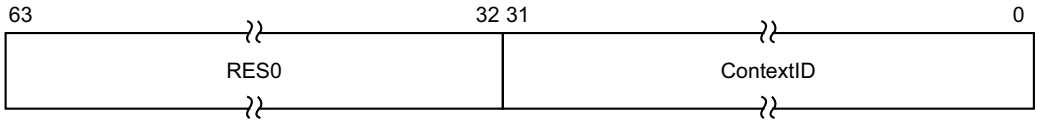
If the address is being matched in an AArch64 stage 1 translation regime, this field contains bits[48:2] of the address for comparison.

If the address is being matched in an AArch32 stage 1 translation regime, the first 16 bits of this field are RES0, and the rest of the field contains bits[31:2] of the address for comparison.

Bits [1:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT==0b0x1x:



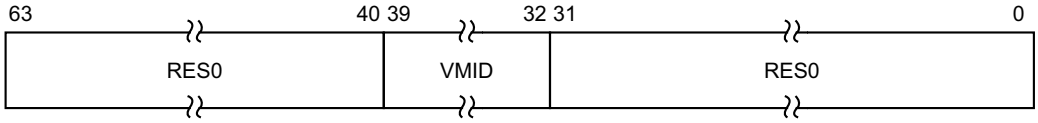
Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison.

When DBGBCR<n>_EL1.BT==0b1x0x and EL2 implemented:



Bits [63:40]

Reserved, RES0.

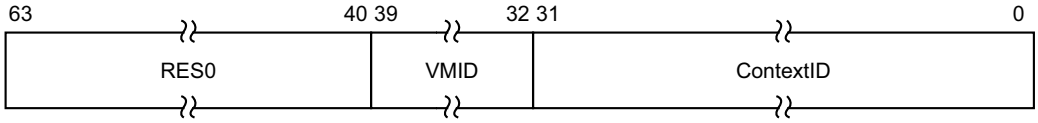
VMID, bits [39:32]

VMID value for comparison.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT==0x1x1x and EL2 implemented:



Bits [63:40]

Reserved, RES0.

VMID, bits [39:32]

VMID value for comparison.

ContextID, bits [31:0]

Context ID value for comparison.

Accessing the DBGBVR<n>_EL1

DBGBVR<n>_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x400` + 16n

DBGBVR<n>_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x404` + 16n

H9.1.4 DBGCLAIMCLR_EL1, Debug Claim Tag Clear register

The DBGCLAIMCLR_EL1 characteristics are:

Purpose

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

Configurations

DBGCLAIMCLR_EL1 is architecturally mapped to AArch64 register DBGCLAIMCLR_EL1.

DBGCLAIMCLR_EL1 is architecturally mapped to AArch32 register DBGCLAIMCLR.

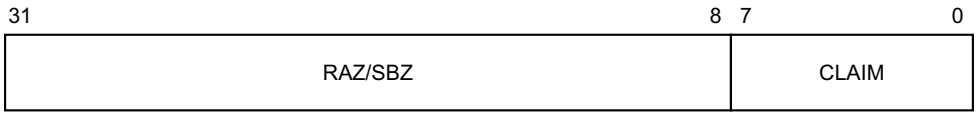
DBGCLAIMCLR_EL1 is in the Core power domain.

Attributes

DBGCLAIMCLR_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMCLR_EL1 bit assignments are:



Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Claim clear bits. Reading this field returns the current value of the CLAIM bits.

Writing a 1 to one of these bits clears the corresponding CLAIM bit to 0. This is an indirect write to the CLAIM bits.

A single write operation can clear multiple bits to 0. Writing 0 to one of these bits has no effect.

Accessing the DBGCLAIMCLR_EL1

DBGCLAIMCLR_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFA4

H9.1.5 DBGCLAIMSET_EL1, Debug Claim Tag Set register

The DBGCLAIMSET_EL1 characteristics are:

Purpose

Used by software to set CLAIM bits to 1.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

Configurations

DBGCLAIMSET_EL1 is architecturally mapped to AArch64 register DBGCLAIMSET_EL1.

DBGCLAIMSET_EL1 is architecturally mapped to AArch32 register DBGCLAIMSET.

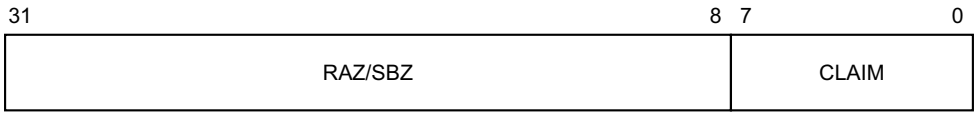
DBGCLAIMSET_EL1 is in the Core power domain.

Attributes

DBGCLAIMSET_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMSET_EL1 bit assignments are:



Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Claim set bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM bit to 1. This is an indirect write to the CLAIM bits.

A single write operation can set multiple bits to 1. Writing 0 to one of these bits has no effect.

Accessing the DBGCLAIMSET_EL1

DBGCLAIMSET_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFA0`

H9.1.6 DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

Purpose

Transfers 32 bits of data from an external host to the processor.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

Configurations

DBGDTRRX_EL0 is architecturally mapped to AArch64 register DBGDTRRX_EL0.

DBGDTRRX_EL0 is architecturally mapped to AArch32 register DBGDTRRXint.

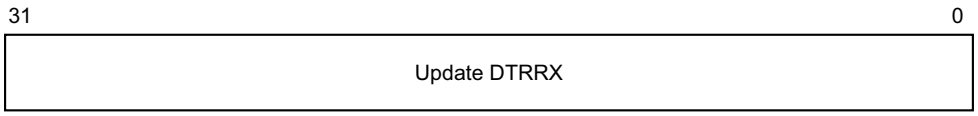
DBGDTRRX_EL0 is in the Core power domain.

Attributes

DBGDTRRX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRRX_EL0 bit assignments are:



Bits [31:0]

Update DTRRX. Writes to this register update the value in DTRRX and set RXfull to 1.

Reads of this register return the last value written to DTRRX and do not change RXfull.

Accessing the DBGDTRRX_EL0

DBGDTRRX_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x080

H9.1.7 DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers 32 bits of data from the processor to an external host.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

Configurations

DBGDTRTX_EL0 is architecturally mapped to AArch64 register DBGDTRTX_EL0.

DBGDTRTX_EL0 is architecturally mapped to AArch32 register DBGDTRTXint.

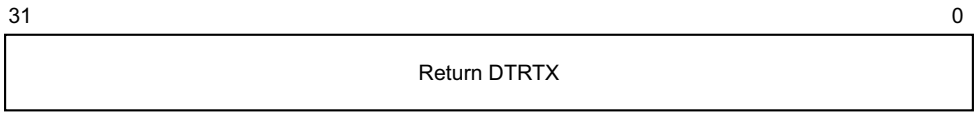
DBGDTRTX_EL0 is in the Core power domain.

Attributes

DBGDTRTX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRTX_EL0 bit assignments are:



Bits [31:0]

Return DTRTX. Reads of this register return the value in DTRTX and clear TXfull to 0.

Writes of this register update the value in DTRTX and do not change TXfull.

Accessing the DBGDTRTX_EL0

DBGDTRTX_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x08C

H9.1.8 DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n>_EL1 characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>_EL1, where n is 0 to 15.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

When the E field is zero, all the other fields in the register are ignored.

Configurations

DBGWCR<n>_EL1 is architecturally mapped to AArch64 register DBGWCR<n>_EL1.

DBGWCR<n>_EL1 is architecturally mapped to AArch32 register DBGWCR<n>.

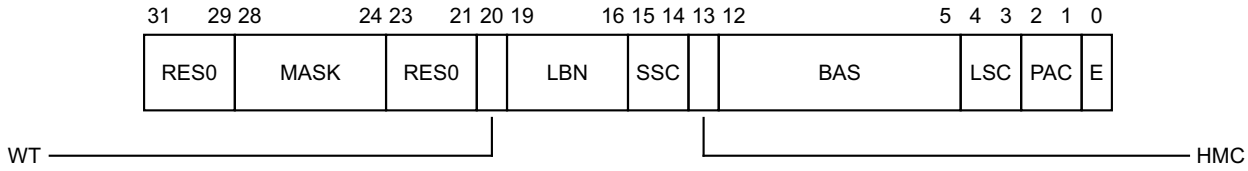
DBGWCR<n>_EL1 is in the Core power domain.

Attributes

DBGWCR<n>_EL1 is a 32-bit register.

Field descriptions

The DBGWCR<n>_EL1 bit assignments are:



Bits [31:29]

Reserved, RES0.

MASK, bits [28:24]

Address mask. Only objects up to 2GB can be watched using a single mask.

`00000` No mask.

`00001` Reserved.

`00010` Reserved.

Other values mask the corresponding number of address bits, from `0b00011` masking 3 address bits (`0x00000007` mask for address) to `0b11111` masking 31 address bits (`0x7FFFFFFF` mask for address).

Bits [23:21]

Reserved, RES0.

WT, bit [20]

Watchpoint type. Possible values are:

`0` Unlinked data address match.

`1` Linked data address match.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

SSC, bits [15:14]

Security state control. Determines the security states under which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n>_EL1 is being watched.

BAS	Description
xxxxxxx1	Match byte at DBGWVR<n>_EL1
xxxxxx1x	Match byte at DBGWVR<n>_EL1+1
xxxxx1xx	Match byte at DBGWVR<n>_EL1+2
xxxx1xxx	Match byte at DBGWVR<n>_EL1+3

In cases where DBGWVR<n>_EL1 addresses a double-word:

BAS	Description, if DBGWVR<n>_EL1[2] == 0
xxx1xxxx	Match byte at DBGWVR<n>_EL1+4
xx1xxxxx	Match byte at DBGWVR<n>_EL1+5
x1xxxxxx	Match byte at DBGWVR<n>_EL1+6
1xxxxxxx	Match byte at DBGWVR<n>_EL1+7

If DBGWVR<n>_EL1[2] == 1, only BAS[3:0] is used. ARM deprecates setting DBGWVR<n>_EL1 == 1.

The valid values for BAS are `0b0000000`, or a binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software.

If BAS is zero, no bytes are watched by this watchpoint.

Ignored if E is 0.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

`01` . Match instructions that load from a watchpointed address.

`10` . Match instructions that store to a watchpointed address.

`11` . Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

Ignored if E is 0.

PAC, bits [2:1]

Privilege of access control. Determines the exception level or levels at which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

E, bit [0]

Enable watchpoint n. Possible values are:

`0` Watchpoint disabled.

`1` Watchpoint enabled.

Accessing the DBGWCR<n>_EL1

DBGWCR<n>_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x808` + 16n

H9.1.9 DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n>_EL1 characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>_EL1, where n is 0 to 15.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EDAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

DBGWVR<n>_EL1 is architecturally mapped to AArch64 register DBGWVR<n>_EL1.

DBGWVR<n>_EL1[31:0] is architecturally mapped to AArch32 register DBGWVR<n>.

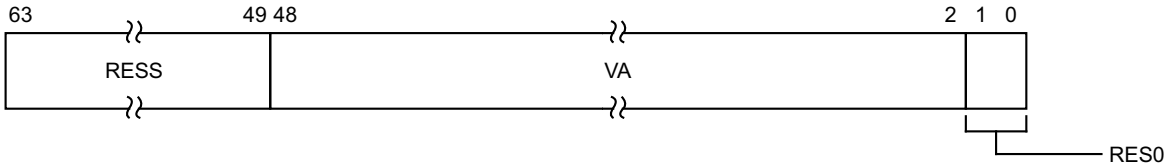
DBGWVR<n>_EL1 is in the Core power domain.

Attributes

DBGWVR<n>_EL1 is a 64-bit register.

Field descriptions

The DBGWVR<n>_EL1 bit assignments are:



RESS, bits [63:49]

Reserved, Sign extended. Hardwired to the value of the sign bit, bit [48]. Hardware and software must treat this field as RES0 if bit[48] is 0, and as RES1 if bit[48] is 1.

VA, bits [48:2]

Bits[48:2] of the address value for comparison.

ARM deprecates setting DBGWVR<n>_EL1[2] == 1.

Bits [1:0]

Reserved, RES0.

Accessing the DBGWVR<n>_EL1

DBGWVR<n>_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x800 + 16n

DBGWVR<n>_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x804 + 16n

H9.1.10 EDACR, External Debug Auxiliary Control Register

The EDACR characteristics are:

Purpose

Allows implementations to support IMPLEMENTATION DEFINED controls.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
IMP DEF	IMP DEF	IMP DEF	RO	RW

Configurations

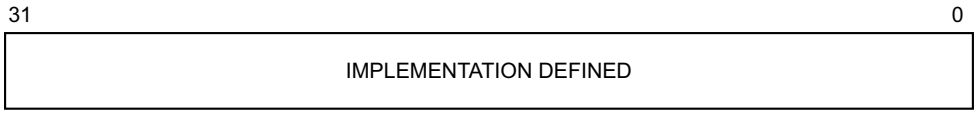
It is IMPLEMENTATION DEFINED whether EDACR is in the Core power domain or in the Debug power domain.

Attributes

EDACR is a 32-bit register.

Field descriptions

The EDACR bit assignments are:



Accessing the EDACR

EDACR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x094

H9.1.11 EDCIDR0, External Debug Component Identification Register 0

The EDCIDR0 characteristics are:

Purpose

Provides information to identify an external debug component.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDCIDR0 is in the Debug power domain.

EDCIDR0 is optional to implement in the external register interface.

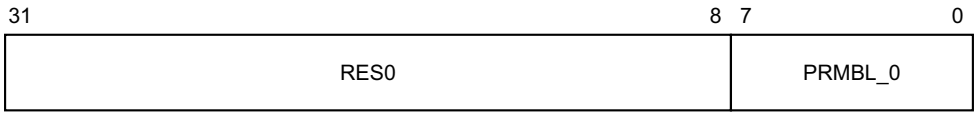
This register is required for CoreSight compliance.

Attributes

EDCIDR0 is a 32-bit register.

Field descriptions

The EDCIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as `0x0D`.

Accessing the EDCIDR0

EDCIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFF0`

H9.1.12 EDCIDR1, External Debug Component Identification Register 1

The EDCIDR1 characteristics are:

Purpose

Provides information to identify an external debug component.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDCIDR1 is in the Debug power domain.

EDCIDR1 is optional to implement in the external register interface.

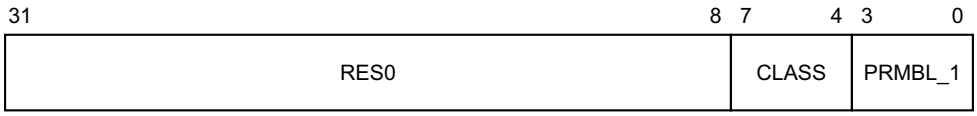
This register is required for CoreSight compliance.

Attributes

EDCIDR1 is a 32-bit register.

Field descriptions

The EDCIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as `0x9`, debug component.

PRMBL_1, bits [3:0]

Preamble. RAZ.

Accessing the EDCIDR1

EDCIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFF4`

H9.1.13 EDCIDR2, External Debug Component Identification Register 2

The EDCIDR2 characteristics are:

Purpose

Provides information to identify an external debug component.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDCIDR2 is in the Debug power domain.

EDCIDR2 is optional to implement in the external register interface.

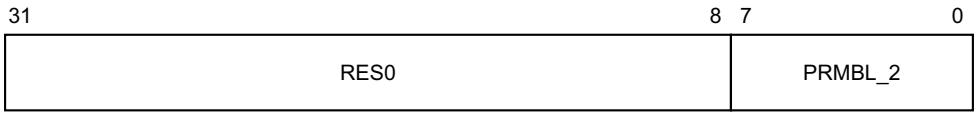
This register is required for CoreSight compliance.

Attributes

EDCIDR2 is a 32-bit register.

Field descriptions

The EDCIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Must read as `0x05`.

Accessing the EDCIDR2

EDCIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFF8`

H9.1.14 EDCIDR3, External Debug Component Identification Register 3

The EDCIDR3 characteristics are:

Purpose

Provides information to identify an external debug component.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDCIDR3 is in the Debug power domain.

EDCIDR3 is optional to implement in the external register interface.

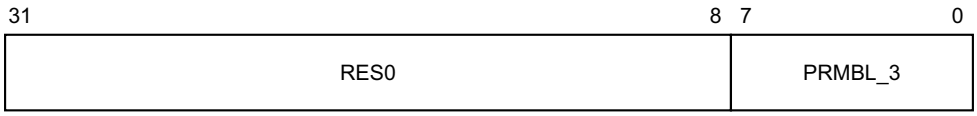
This register is required for CoreSight compliance.

Attributes

EDCIDR3 is a 32-bit register.

Field descriptions

The EDCIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Must read as `0xB1`.

Accessing the EDCIDR3

EDCIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFFC`

H9.1.15 EDCIDSR, External Debug Context ID Sample Register

The EDCIDSR characteristics are:

Purpose

Contains the sampled value of CONTEXTIDR_EL1, captured on reading the low half of EDPCSR.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	Default
Error	Error	Error	RO

Configurations

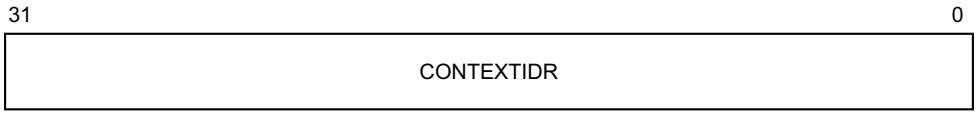
EDCIDSR is in the Core power domain.

Attributes

EDCIDSR is a 32-bit register.

Field descriptions

The EDCIDSR bit assignments are:



CONTEXTIDR, bits [31:0]

The sampled value of CONTEXTIDR_EL1, captured on reading the low half of EDPCSR.

If EL3 is implemented and using AArch32 then CONTEXTIDR is a Banked register, and EDCIDSR samples the current Banked copy of CONTEXTIDR.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the EDCIDSR

EDCIDSR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x0A4

H9.1.16 EDDEVAFF0, External Debug Device Affinity register 0

The EDDEVAFF0 characteristics are:

Purpose

Copy of the low half of the processor MPIDR_EL1 register that allows a debugger to determine which processor in a multiprocessor system the external debug component relates to.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDDEVAFF0 is in the Debug power domain.

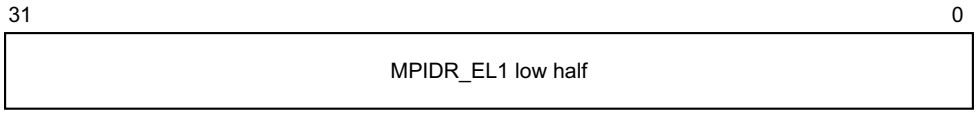
EDDEVAFF0 is optional to implement in the external register interface.

Attributes

EDDEVAFF0 is a 32-bit register.

Field descriptions

The EDDEVAFF0 bit assignments are:



Bits [31:0]

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented exception level.

Accessing the EDDEVAFF0

EDDEVAFF0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFA8

H9.1.17 EDDEVAFF1, External Debug Device Affinity register 1

The EDDEVAFF1 characteristics are:

Purpose

Copy of the high half of the processor MPIDR_EL1 register that allows a debugger to determine which processor in a multiprocessor system the external debug component relates to.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDDEVAFF1 is in the Debug power domain.

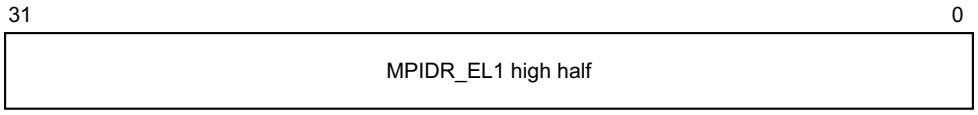
EDDEVAFF1 is optional to implement in the external register interface.

Attributes

EDDEVAFF1 is a 32-bit register.

Field descriptions

The EDDEVAFF1 bit assignments are:



Bits [31:0]

MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented exception level.

Accessing the EDDEVAFF1

EDDEVAFF1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFAC

H9.1.18 EDDEVARCH, External Debug Device Architecture register

The EDDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the external debug component.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDDEVARCH is in the Debug power domain.

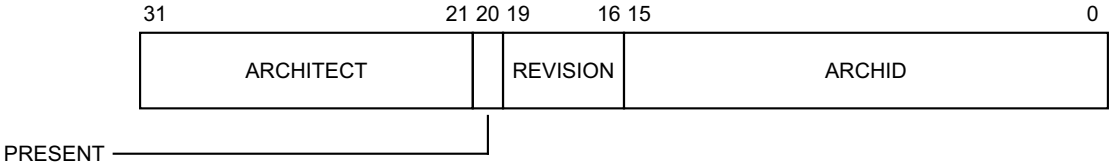
EDDEVARCH is optional to implement in the external register interface.

Attributes

EDDEVARCH is a 32-bit register.

Field descriptions

The EDDEVARCH bit assignments are:



ARCHITECT, bits [31:21]

Defines the architecture of the component. For debug, this is ARM Limited.

Bits [31:28] are the JEP 106 continuation code, `0x4`.

Bits [27:21] are the JEP 106 ID code, `0x3B`.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in v8-A.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by ARM this is the minor revision.

For debug, the revision defined by v8-A is `0x0`.

All other values are reserved.

ARCHID, bits [15:0]

Defines this part to be a v8-A debug component. For architectures defined by ARM this is further subdivided.

For debug:

- Bits [15:12] are the architecture version, `0x6`.
- Bits [11:0] are the architecture part number, `0xA15`.

This corresponds to debug architecture version v8-A.

Accessing the EDDEVARCH

EDDEVARCH can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFBC`

H9.1.19 EDDEVID, External Debug Device ID register 0

The EDDEVID characteristics are:

Purpose

Provides extra information for external debuggers about features of the debug implementation.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

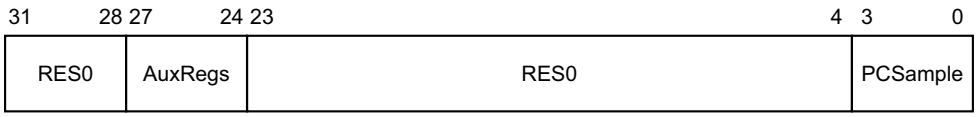
EDDEVID is in the Debug power domain.

Attributes

EDDEVID is a 32-bit register.

Field descriptions

The EDDEVID bit assignments are:



Bits [31:28]

Reserved, RES0.

AuxRegs, bits [27:24]

Indicates support for Auxiliary registers. Permitted values for this field are:

`0000` None supported.

`0001` Support for External Debug Auxiliary Control Register, EDACR.

All other values are reserved.

Bits [23:4]

Reserved, RES0.

PCSample, bits [3:0]

Indicates the level of Sample-based profiling support using external debug registers 40 through 43. Permitted values of this field in v8-A are:

`0000` Architecture-defined form of Sample-based profiling not implemented.

`0010` EDPCSR and EDCIDSR are implemented (only permitted if EL3 and EL2 are not implemented).

`0011` EDPCSR, EDCIDSR, and EDVIDSR are implemented.

All other values are reserved.

Accessing the EDDEVID

EDDEVID can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFC8

H9.1.20 EDDEVID1, External Debug Device ID register 1

The EDDEVID1 characteristics are:

Purpose

Provides extra information for external debuggers about features of the debug implementation.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

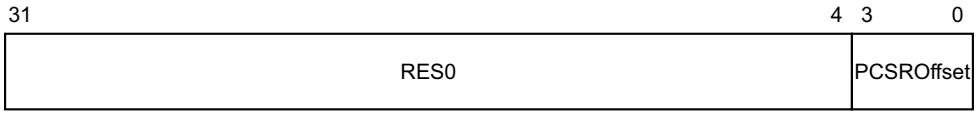
EDDEVID1 is in the Debug power domain.

Attributes

EDDEVID1 is a 32-bit register.

Field descriptions

The EDDEVID1 bit assignments are:



Bits [31:4]

Reserved, RES0.

PCSROffset, bits [3:0]

This field indicates the offset applied to PC samples returned by reads of EDPCSR. Permitted values of this field in v8-A are:

`0000` EDPCSR not implemented.

`0010` EDPCSR implemented, and samples have no offset applied and do not sample the instruction set state in AArch32 state.

Accessing the EDDEVID1

EDDEVID1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFC4`

H9.1.21 EDDEVID2, External Debug Device ID register 2

The EDDEVID2 characteristics are:

Purpose

Reserved for future descriptions of features of the debug implementation.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

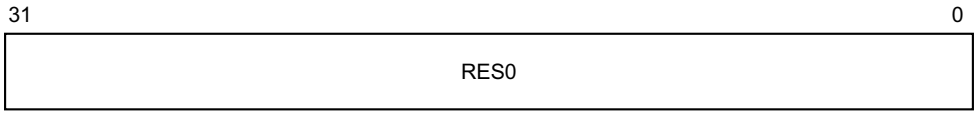
EDDEVID2 is in the Debug power domain.

Attributes

EDDEVID2 is a 32-bit register.

Field descriptions

The EDDEVID2 bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the EDDEVID2

EDDEVID2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFC0

H9.1.22 EDDEVTYPE, External Debug Device Type register

The EDDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a processor's debug logic.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDDEVTYPE is in the Debug power domain.

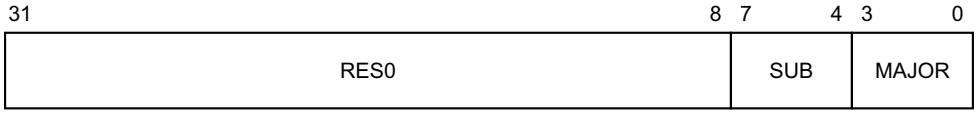
EDDEVTYPE is optional to implement in the external register interface.

Attributes

EDDEVTYPE is a 32-bit register.

Field descriptions

The EDDEVTYPE bit assignments are:



Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Must read as `0x1` to indicate this is a processor component.

MAJOR, bits [3:0]

Major type. Must read as `0x5` to indicate this is a debug logic component.

Accessing the EDDEVTYPE

EDDEVTYPE can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFCC`

H9.1.23 EDECCR, External Debug Exception Catch Control Register

The EDECCR characteristics are:

Purpose

Controls exception catch debug events.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

Configurations

EDECCR is architecturally mapped to AArch64 register OSECCR_EL1.

EDECCR is architecturally mapped to AArch32 register DBGOSECCR.

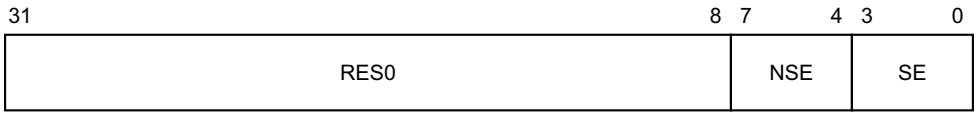
EDECCR is in the Core power domain.

Attributes

EDECCR is a 32-bit register.

Field descriptions

The EDECCR bit assignments are:



Bits [31:8]

Reserved, RES0.

NSE, bits [7:4]

Coarse-grained Non-secure exception catch. Possible values of this field are:

`0000` Exception catch debug event disabled for Non-secure exception levels.

`0010` Exception catch debug event enabled for Non-secure EL1.

`0100` Exception catch debug event enabled for Non-secure EL2.

`0110` Exception catch debug event enabled for Non-secure EL1 and EL2.

All other values are reserved. Bits [7,4] are reserved, RES0.

On Cold reset, the field resets to 0.

SE, bits [3:0]

Coarse-grained Secure exception catch. Possible values of this field are:

`0000` Exception catch debug event disabled for Secure exception levels.

`0010` Exception catch debug event enabled for Secure EL1.

`1000` Exception catch debug event enabled for Secure EL3.

`1010` Exception catch debug event enabled for Secure EL1 and EL3.

All other values are reserved. Bits [2,0] are reserved. RES0. Ignored if ExternalSecureInvasiveDebugEnabled() == FALSE.

On Cold reset, the field resets to 0.

Accessing the EDECCR

EDECCR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x098

H9.1.24 EDECR, External Debug Execution Control Register

The EDECR characteristics are:

Purpose

Controls Halting debug events.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

Configurations

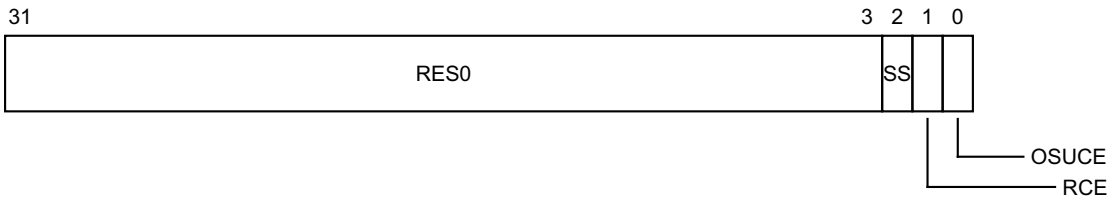
EDECR is in the Debug power domain.

Attributes

EDECR is a 32-bit register.

Field descriptions

The EDECR bit assignments are:



Bits [31:3]

Reserved, RES0.

SS, bit [2]

Halting step enable. Possible values of this field are:

`0` Halting step debug event disabled.

`1` Halting step debug event enabled.

If the value of EDECR.SS is changed when the processor is in Non-debug state, the resulting value of EDECR.SS is UNKNOWN.

On External debug reset, the field resets to 0.

RCE, bit [1]

Reset catch enable. Possible values of this field are:

`0` Reset catch debug event disabled.

`1` Reset catch debug event enabled.

On External debug reset, the field resets to 0.

OSUCE, bit [0]

OS unlock catch enabled. Possible values of this field are:

`0` OS unlock catch debug event disabled.

`1` OS unlock catch debug event enabled.

On External debug reset, the field resets to 0.

Accessing the EDECR

EDECR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x024`

H9.1.25 EDESR, External Debug Event Status Register

The EDESR characteristics are:

Purpose

Indicates the status of internally pending Halting debug events.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	SLK	Default
Error	Error	RO	RW

If a request to clear a pending Halting debug event is received at or about the time when halting becomes allowed, it is CONSTRAINED UNPREDICTABLE whether the event is taken.

If Core power is removed while a Halting debug event is pending, it is lost. However, it may become pending again when the Core is powered back on and Cold reset.

Configurations

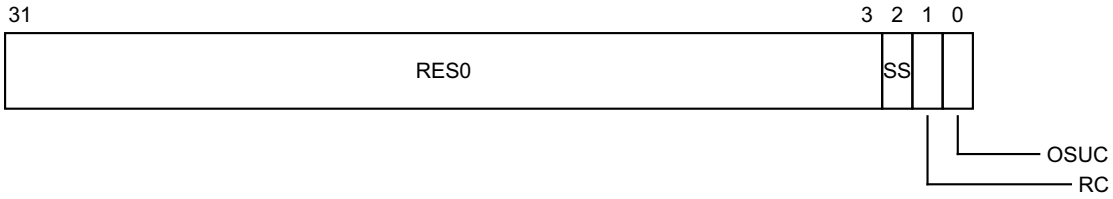
EDESR is in the Core power domain.

Attributes

EDESR is a 32-bit register.

Field descriptions

The EDESR bit assignments are:



Bits [31:3]

Reserved, RES0.

SS, bit [2]

Halting step debug event pending. Possible values of this field are:

`0` Reading this means that a Halting step debug event is not pending. Writing this means no action.

`1` Reading this means that a Halting step debug event is pending. Writing this clears the pending Halting step debug event.

On Warm reset, the field resets to 0.

RC, bit [1]

Reset catch debug event pending. Possible values of this field are:

`0` Reading this means that a Reset catch debug event is not pending. Writing this means no action.

`1` Reading this means that a Reset catch debug event is pending. Writing this clears the pending Reset catch debug event.

On Warm reset, the field resets to 0.

OSUC, bit [0]

OS unlock debug event pending. Possible values of this field are:

`0` Reading this means that an OS unlock catch debug event is not pending. Writing this means no action.

`1` Reading this means that an OS unlock catch debug event is pending. Writing this clears the pending OS unlock catch debug event.

On Warm reset, the field resets to 0.

Accessing the EDESR

EDESR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x020`

H9.1.26 EDITCTRL, External Debug Integration mode Control register

The EDITCTRL characteristics are:

Purpose

Enables the external debug to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the processor, for integration testing or topology detection.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	Default
IMP DEF	IMP DEF	IMP DEF	RW

Configurations

It is IMPLEMENTATION DEFINED whether EDITCTRL is in the Core power domain or in the Debug power domain.

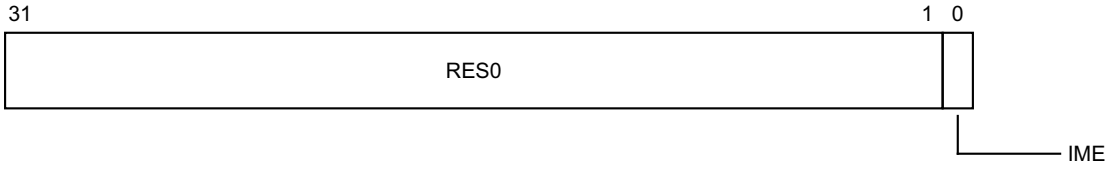
EDITCTRL is optional to implement in the external register interface.

Attributes

EDITCTRL is a 32-bit register.

Field descriptions

The EDITCTRL bit assignments are:



Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

`0` Normal operation.

`1` Integration mode enabled.

On IMPLEMENTATION DEFINED reset, the field resets to 0.

Accessing the EDITCTRL

EDITCTRL can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xF00

H9.1.27 EDITR, External Debug Instruction Transfer Register

The EDITR characteristics are:

Purpose

Used in Debug state for passing instructions to the processor for execution.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	WI	WO

If EDSCR.ITE == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any instruction issued through the ITR in normal mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Configurations

EDITR is in the Core power domain.

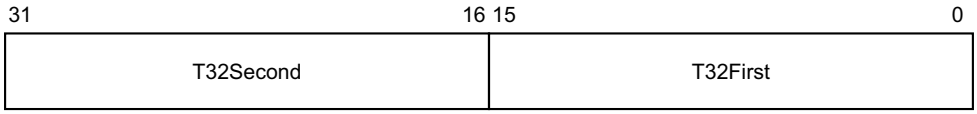
Attributes

EDITR is a 32-bit register.

Field descriptions

The EDITR bit assignments are:

When in AArch32 state:



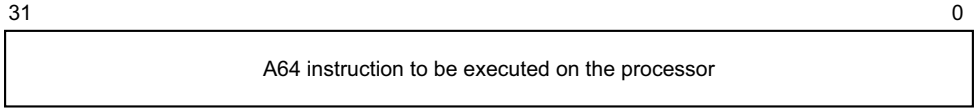
T32Second, bits [31:16]

Second halfword of the T32 instruction to be executed on the processor.

T32First, bits [15:0]

First halfword of the T32 instruction to be executed on the processor.

When in AArch64 state:



Bits [31:0]

A64 instruction to be executed on the processor.

Accessing the EDITR

EDITR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x084

H9.1.28 EDLAR, External Debug Lock Access Register

The EDLAR characteristics are:

Purpose

Allows or disallows access to the external debug registers through a memory-mapped interface.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
WO

Configurations

EDLAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

EDLAR ignores writes if the Software lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

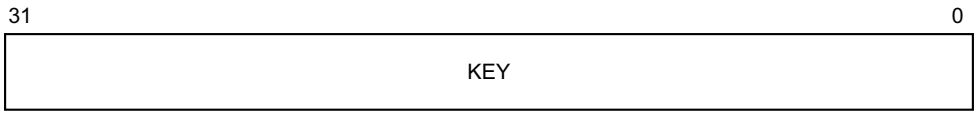
Software uses EDLAR to set or clear the lock, and EDLSR to check the current status of the lock.

Attributes

EDLAR is a 32-bit register.

Field descriptions

The EDLAR bit assignments are:



KEY, bits [31:0]

Lock Access control. Writing the key value `0xC5ACCE55` to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Accessing the EDLAR

EDLAR can be accessed through the internal memory-mapped interface:

Component	Offset
Debug	`0xFB0`

H9.1.29 EDLSR, External Debug Lock Status Register

The EDLSR characteristics are:

Purpose

Indicates the current status of the software lock for external debug registers.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDLSR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

EDLSR is RAZ if the Software lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the debug registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the debug registers. It does not, and cannot, prevent all accidental or malicious damage.

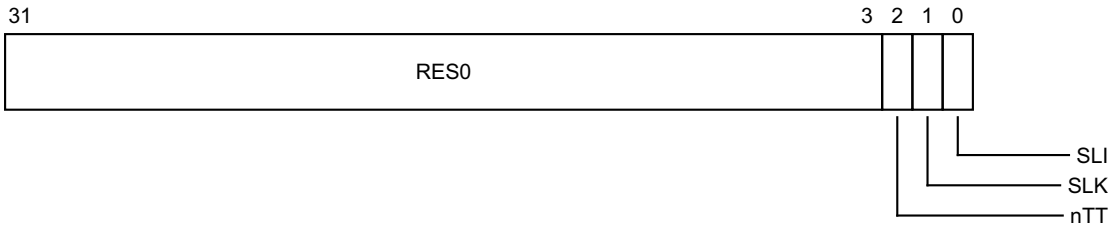
Software uses EDLAR to set or clear the lock, and EDLSR to check the current status of the lock.

Attributes

EDLSR is a 32-bit register.

Field descriptions

The EDLSR bit assignments are:



Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

SLK, bit [1]

Software lock status for this component. For an access to LSR that is not a memory-mapped access, or when the software lock is not implemented, this field is RES0.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:

`0` Lock clear. Writes are permitted to this component's registers.

`1` Lock set. Writes to this component's registers are ignored, and reads have no side effects.

On External debug reset, the field resets to 1.

SLI, bit [0]

Software lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

`0` Software lock not implemented or not memory-mapped access.

`1` Software lock implemented and memory-mapped access.

Accessing the EDLSR

EDLSR can be accessed through the internal memory-mapped interface:

Component	Offset
Debug	`0xFB4`

H9.1.30 EDPCSR, External Debug Program Counter Sample Register

The EDPCSR characteristics are:

Purpose

Holds a sampled instruction address value.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RO

Configurations

EDPCSR is in the Core power domain.

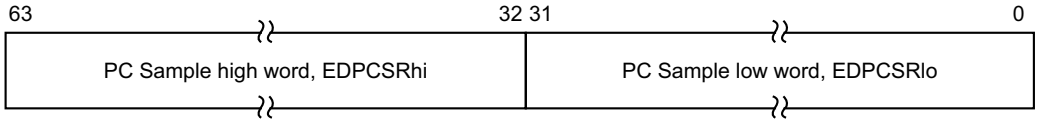
EDPCSR is optional to implement in the external register interface.

Attributes

EDPCSR is a 64-bit register.

Field descriptions

The EDPCSR bit assignments are:



Bits [63:32]

PC Sample high word, EDPCSRhi. If EDVIDSR.HV == 0 then this field is RAZ, otherwise bits [63:32] of the sampled PC.

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [31:0]

PC Sample low word, EDPCSRlo. Bits [31:0] of the sampled instruction address value. Reading EDPCSRlo has the side-effect of updating EDCIDSR, EDVIDSR, and EDPCSRhi. However:

- If the processor is in Debug state, or Sample-based profiling is prohibited, EDPCSRlo reads as `0xFFFFFFFF` and EDCIDSR, EDVIDSR, and EDPCSRhi become UNKNOWN.
- If the processor is in Reset state, the sampled value is unknown and EDCIDSR, EDVIDSR and EDPCSRhi become UNKNOWN.
- If no instruction has been retired since the processor left Reset state, Debug state, or a state where Non-invasive debug is not permitted, the sampled value is UNKNOWN and EDCIDSR, EDVIDSR, and EDPCSRhi become UNKNOWN.
- For a read of EDPCSRlo from the memory-mapped interface, if EDLSR.SLK == 1, meaning the Software Lock is locked, then the access has no side-effects. That is, EDCIDSR, EDVIDSR, and EDPCSRhi are unchanged.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the EDPCSR

EDPCSR[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x0A0

EDPCSR[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x0AC

H9.1.31 EDPIDR0, External Debug Peripheral Identification Register 0

The EDPIDR0 characteristics are:

Purpose

Provides information to identify an external debug component.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDPIDR0 is in the Debug power domain.

EDPIDR0 is optional to implement in the external register interface.

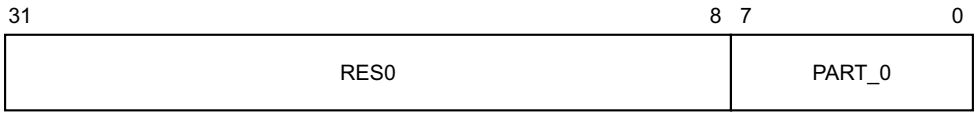
This register is required for CoreSight compliance.

Attributes

EDPIDR0 is a 32-bit register.

Field descriptions

The EDPIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

Accessing the EDPIDR0

EDPIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFE0

H9.1.32 EDPIDR1, External Debug Peripheral Identification Register 1

The EDPIDR1 characteristics are:

Purpose

Provides information to identify an external debug component.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDPIDR1 is in the Debug power domain.

EDPIDR1 is optional to implement in the external register interface.

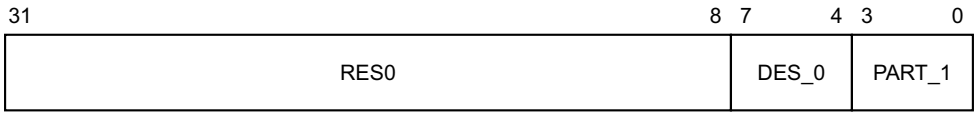
This register is required for CoreSight compliance.

Attributes

EDPIDR1 is a 32-bit register.

Field descriptions

The EDPIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is `0b1011`.

PART_1, bits [3:0]

Part number, most significant nibble.

Accessing the EDPIDR1

EDPIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFE4`

H9.1.33 EDPIDR2, External Debug Peripheral Identification Register 2

The EDPIDR2 characteristics are:

Purpose

Provides information to identify an external debug component.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDPIDR2 is in the Debug power domain.

EDPIDR2 is optional to implement in the external register interface.

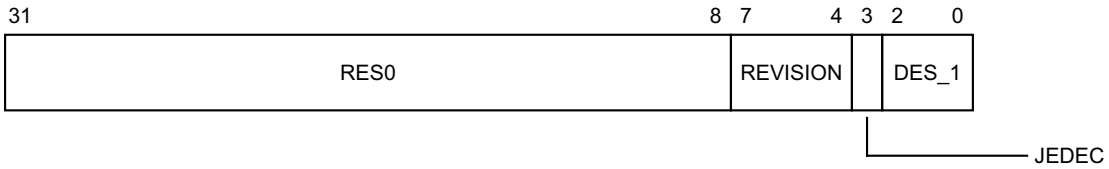
This register is required for CoreSight compliance.

Attributes

EDPIDR2 is a 32-bit register.

Field descriptions

The EDPIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is `0b011`.

Accessing the EDPIDR2

EDPIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFE8`

H9.1.34 EDPIDR3, External Debug Peripheral Identification Register 3

The EDPIDR3 characteristics are:

Purpose

Provides information to identify an external debug component.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDPIDR3 is in the Debug power domain.

EDPIDR3 is optional to implement in the external register interface.

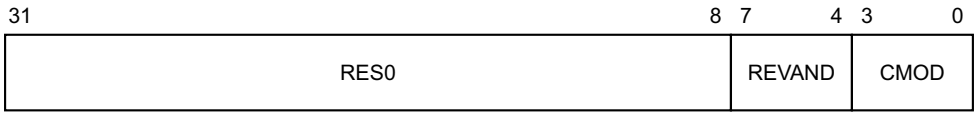
This register is required for CoreSight compliance.

Attributes

EDPIDR3 is a 32-bit register.

Field descriptions

The EDPIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using EDPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

Accessing the EDPIDR3

EDPIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xFEC

H9.1.35 EDPIDR4, External Debug Peripheral Identification Register 4

The EDPIDR4 characteristics are:

Purpose

Provides information to identify an external debug component.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

EDPIDR4 is in the Debug power domain.

EDPIDR4 is optional to implement in the external register interface.

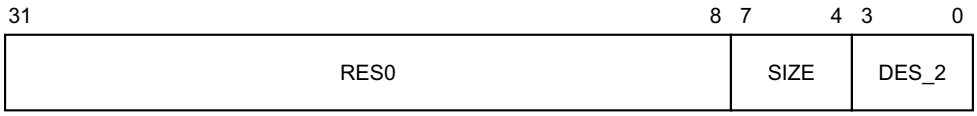
This register is required for CoreSight compliance.

Attributes

EDPIDR4 is a 32-bit register.

Field descriptions

The EDPIDR4 bit assignments are:



Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. Log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is `0b0100`.

Accessing the EDPIDR4

EDPIDR4 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xFD0`

H9.1.36 EDPRCR, External Debug Power/Reset Control Register

The EDPRCR characteristics are:

Purpose

Controls processor functionality related to powerup, reset, and powerdown.

This register is part of the Debug registers functional group.

Usage constraints

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

Configurations

EDPRCR contains fields that are in the Core power domain and fields that are in the Debug power domain.

Bit [0] of this register is mapped to DBGPRCR.CORENPDRQ, bit [0] of the AArch32 view of this register.

Bit [0] of this register is mapped to DBGPRCR_EL1.CORENPDRQ, bit [0] of the AArch64 view of this register.

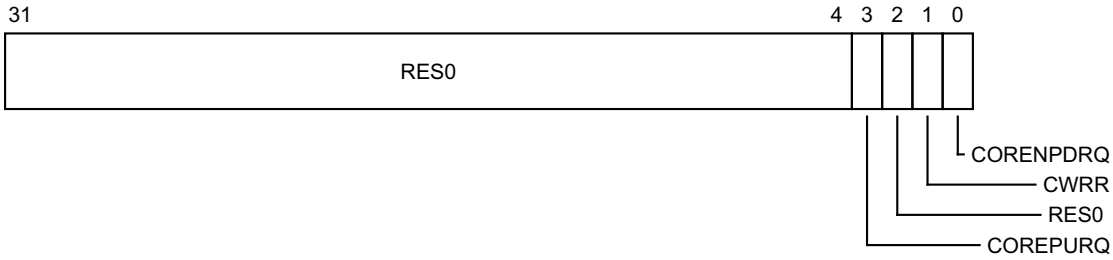
The other bits in these registers are not mapped to each other.

Attributes

EDPRCR is a 32-bit register.

Field descriptions

The EDPRCR bit assignments are:



Bits [31:4]

Reserved, RES0.

COREPURQ, bit [3]

Core powerup request. Allows a debugger to request that the power controller power up the core, enabling access to the debug register in the Core power domain. The actions on writing to this bit are:

`0` No effect.

`1` Request the power controller to powerup the core.

In an implementation that includes the recommended external debug interface, this bit drives the DBGPWRUPREQ signal.

This bit can be read and written when the Core power domain is powered off.

The power controller must not allow the Core power domain to switch off while this bit is one.

On External debug reset, the field resets to 0.

This field is accessible as shown below:

SLK	Default
RO	RW

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

Bit [2]

Reserved, RES0.

CWRR, bit [1]

Warm reset request. Write only bit that reads as zero. The actions on writing to this bit are:

`0` No action.

`1` Request Warm reset.

The processor ignores writes to this bit if any of the following are the case:

- ExternalInvasiveDebugEnabled() == FALSE, EL3 is not implemented, and the processor is Non-secure.
- ExternalSecureInvasiveDebugEnabled() == FALSE and one of the following is true:
  - EL3 is implemented.
  - The processor is Secure.
- The Core power domain is either completely off or in a low-power state where the Core power domain registers cannot be accessed.
- DoubleLockStatus() == TRUE (OS Double Lock is set).
- OSLSR.OSLK == 1 (OS lock is locked).

In an implementation that includes the recommended external debug interface, this bit drives the DBGRSTREQ signal.

On Warm reset, the field resets to 0.

This field is accessible as shown below:

Off	DLK	OSLK	SLK	Default
WI	WI	WI	WI	WO

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:

`0` On a powerdown request, the system powers down the Core power domain.

`1` On a powerdown request, the system emulates powerdown of the Core power domain. In this emulation mode the Core power domain is not actually powered down.

On Cold reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	OSLK	SLK	Default
WI	WI	WI	RO	RW

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

Accessing the EDPRCR

EDPRCR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x310`

H9.1.37 EDPRSR, External Debug Processor Status Register

The EDPRSR characteristics are:

Purpose

Holds information about the reset and powerdown state of the processor.

This register is part of the Debug registers functional group.

Usage constraints

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

If the Core power domain is on (EDPRSR.PU == 1), then following a read of EDPRSR:

- If EDPRSR.DLK == 0, then:
  - EDPRSR.{SDR, SPMAD, SDAD, SPD} are cleared to 0.
  - EDPRSR.SR is cleared to 0 if the non-debug logic of the processor is not in reset state (EDPRSR.R == 0).
- Otherwise it is CONSTRAINED UNPREDICTABLE whether or not this clearing occurs.

Configurations

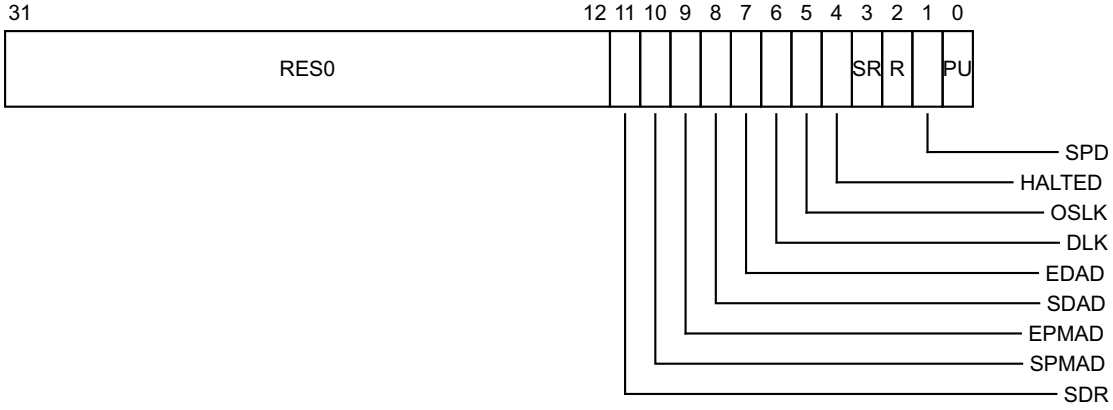
EDPRSR contains fields that are in the Core power domain and fields that are in the Debug power domain.

Attributes

EDPRSR is a 32-bit register.

Field descriptions

The EDPRSR bit assignments are:



Bits [31:12]

Reserved, RES0.

SDR, bit [11]

Sticky debug restart. Set to 1 when the processor exits Debug state and cleared to 0 following reads of EDPRSR.

0 The processor has not restarted since EDPRSR was last read.

1 The processor has restarted since EDPRSR was last read.

This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

This bit clears to 0 when following a read of EDPRSR.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

SPMAD, bit [10]

Sticky EPMAD error. Set to 1 if an access returns an error because AllowExternalPMUAccess() == FALSE.

`0` No accesses to the external performance monitors registers have failed since EDPRSR was last read.

`1` At least one access to the external performance monitors registers has failed since EDPRSR was last read.

This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

This bit clears to 0 when following a read of EDPRSR.

On Cold reset, the field resets to 0.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

EPMAD, bit [9]

External performance monitors access disable status.

`0` External performance monitors access enabled.

`1` External performance monitors access disabled.

If external performance monitors access is not implemented, EPMAD is RAO. This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	Default
UNK	UNK	RO

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

SDAD, bit [8]

Sticky EDAD error. Set to 1 if an access returns an error because AllowExternalDebugAccess() == FALSE.

0 No accesses to the external debug registers have failed since EDPRSR was last read.

1 At least one access to the external debug registers has failed since EDPRSR was last read.

This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

This bit clears to 0 following a read of EDPRSR.

On Cold reset, the field resets to 0.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

EDAD, bit [7]

External debug access disable status.

0 External debug access enabled.

1 External debug access disabled.

This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1, or EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	EDAD	Default
UNK	UNK	RAO	RAZ

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

DLK, bit [6]

OS Double Lock status bit.

0 OSDLR_EL1.DLK == 0 or EDPRCR.CORENPDRQ == 1 or the processor is in Debug state.

1 OSDLR_EL1.DLK == 1 and EDPRCR.CORENPDRQ == 0 and the processor is in Non-debug state.

This bit is UNKNOWN on reads if EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	Default
UNK	RAO	RAZ

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

OSLK, bit [5]

OS lock status bit. A read of this bit returns the value of OSLSR_EL1.OSLK.

This bit is UNKNOWN on reads if either of EDPRSR.{DLK, R} is 1 or EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	OSLK	Default
UNK	UNK	RAO	RAZ

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

HALTED, bit [4]

Halted status bit. Possible values are:

`0` EDSCR.STATUS is `0b000010` (processor in Non-debug state).

`1` EDSCR.STATUS is not `0b000010`.

This bit is UNKNOWN on reads if EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	Default
UNK	RAZ	RO

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

SR, bit [3]

Sticky core reset status bit. Possible values are:

`0` The non-debug logic of the processor is not in reset state and has not been reset since the last time EDPRSR was read.

`1` The non-debug logic of the processor is in reset state or has been reset since the last time EDPRSR was read.

This bit is UNKNOWN on reads if EDPRSR.DLK is 1 or EDPRSR.PU is 0.

This bit clears to 0 following a read of EDPRSR if the non-debug logic of the processor is not in reset state.

On Warm reset, the field resets to 1.

This field is accessible as shown below:

Off	DLK	SLK	Default
UNK	UNK	RO	RC

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

R, bit [2]

Core reset status bit. Possible values are:

`0` The non-debug logic of the processor is not in reset state.

`1` The non-debug logic of the processor is in reset state.

This bit is UNKNOWN on reads if either EDPRSR.DLK is 1 or EDPRSR.PU is 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	DLK	Default
UNK	UNK	RO

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

SPD, bit [1]

Sticky core power-down status bit.

This bit is set to 1 on Cold reset to indicate the state of the debug registers has been lost. Since a Cold reset is required on powering up the processor, this usually indicates the Core power domain has been completely powered off.

Possible values are:

`0` If the Core power domain is off (EDPRSR.PU is 0), it is not known whether the state of the debug registers in the Core power domain is lost. Otherwise, the Core power domain is on, and the state of the debug registers in the Core power domain has not been lost.

`1` The state of the debug registers in the Core power domain is lost.

This bit is UNKNOWN on reads if both EDPRSR.DLK and EDPRSR.PU are 1.

This bit clears to 0 following a read of EDPRSR if the processor is not in the powered down state.

There are two logical power off states for the Core power domain:

`Retention` The states of the debug registers, including EDPRSR.SPD, in the Core power domain is preserved, and restored on leaving retention state.

`Power-down` The states of the debug registers in the Core power domain is lost, and a Cold reset is asserted on leaving power-down state.

In these states, it is IMPLEMENTATION DEFINED whether:

- EDPRSR.SPD shows whether the state of the debug registers in the Core power domain has been lost since the last time EDPRSR was read when the Core power domain was on.
- EDPRSR.SPD reads-as-zero.

EDPRSR.SPD is not cleared following a read of EDPRSR in these states.

This means it is IMPLEMENTATION DEFINED whether a processor implements EDPRSR.SPD as:

- Fixed RAZ when in one or both of the retention and power-down states.
- Retaining its previous value when in the retention state.
- Fixed RAO in the power-down state.

Note that this definition does not allow EDPRSR.SPD to be fixed RAO in the low-power retention state, as the state of the debug registers in the Core power domain is not lost by entering this state. However, the bit can be read as 1 in this state if the state of the registers was lost before entering this state (i.e. EDPRSR has not been read since the last Cold reset).

ARM recommends that an implementation make EDPRSR.SPD fixed RAO when in the power-down state, particularly if it does not support a low-power retention state.

On Cold reset, the field resets to 1.

This field is accessible as shown below:

Off	DLK	SLK	Default
RO	UNK	RO	RC

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

PU, bit [0]

Core power-up status bit. Indicates whether the Core power domain debug registers can be accessed:

`0` Core is in a low-power or power-down state where the debug registers cannot be accessed.

`1` Core is in a power-up state where the debug registers can be accessed.

On Warm reset, the field reset value is architecturally UNKNOWN.

This field is accessible as shown below:

Off	Default
RAZ	RAO

The meanings of the conditions in the table above are summarized in *Access permissions for the External debug interface registers* on page H8-4530. The priority at which each condition applies is from highest priority on the left to lowest on the right.

Accessing the EDPRSR

EDPRSR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x314`

H9.1.38 EDRCR, External Debug Reserve Control Register

The EDRCR characteristics are:

Purpose

This register is used to allow imprecise entry to Debug state and clear sticky bits in EDSCR.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	WI	WO

Configurations

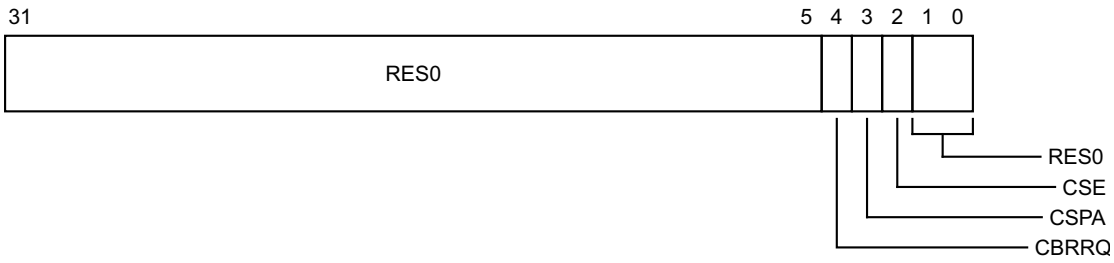
EDRCR is in the Core power domain.

Attributes

EDRCR is a 32-bit register.

Field descriptions

The EDRCR bit assignments are:



Bits [31:5]

Reserved, RES0.

CBRRQ, bit [4]

Allow imprecise entry to Debug state. The actions on writing to this bit are:

0 No action.

1 Allow imprecise entry to Debug state, for example by canceling pending bus accesses.

Setting this bit to 1 allows a debugger to request imprecise entry to Debug state. An External Debug Request debug event must be pending before the debugger sets this bit to 1.

This feature is optional. If this feature is not implemented, writes to this bit are ignored.

CSPA, bit [3]

Clear Sticky Pipeline Advance. This bit is used to clear the EDSCR.PipeAdv bit to 0. The actions on writing to this bit are:

0 No action.

1 Clear the EDSCR.PipeAdv bit to 0.

CSE, bit [2]

Clear Sticky Error. Used to clear the EDSCR cumulative error bits to 0. The actions on writing to this bit are:

0	No action.
1	Clear the EDSCR.{TXU, RXO, ERR} bits, and, if the processor is in Debug state, the EDSCR.ITO bit, to 0.

Bits [1:0]

Reserved, RES0.

Accessing the EDRCR

EDRCR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x090

H9.1.39 EDSCR, External Debug Status and Control Register

The EDSCR characteristics are:

Purpose

Main control register for the debug implementation.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	SLK	Default
Error	Error	Error	RO	RW

Configurations

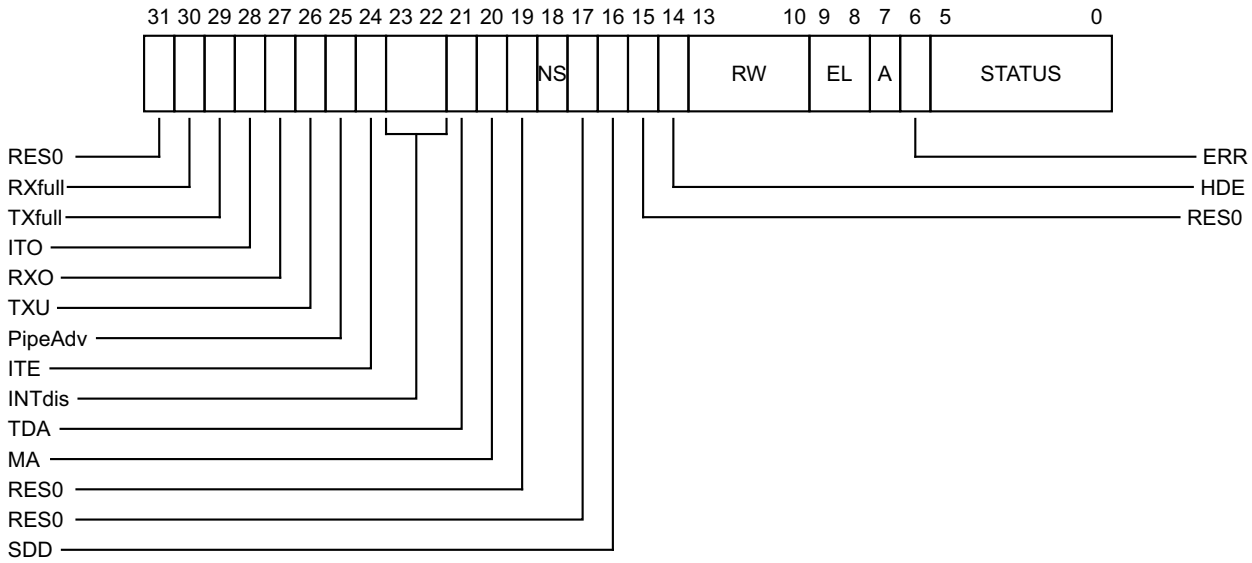
EDSCR is in the Core power domain.

Attributes

EDSCR is a 32-bit register.

Field descriptions

The EDSCR bit assignments are:



Bit [31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. This bit is RO.

On Cold reset, the field resets to 0.

TXfull, bit [29]

DTRTX full. This bit is RO.

On Cold reset, the field resets to 0.

ITO, bit [28]

EDITR overrun. This bit is RO.

If the processor is not in Debug state, this bit is UNKNOWN. ITO is set to 0 on entry to Debug state.

RXO, bit [27]

DTRRX overrun. This bit is RO.

On Cold reset, the field resets to 0.

TXU, bit [26]

DTRTX underrun. This bit is RO.

On Cold reset, the field resets to 0.

PipeAdv, bit [25]

Pipeline advance. Read-only. Set to 1 every time the processor pipeline retires one or more instructions. Cleared to 0 by a write to EDRCR.CSPA.

The architecture does not define precisely when this bit is set to 1. It requires only that this happen periodically in Non-debug state to indicate that software execution is progressing.

ITE, bit [24]

ITR empty. This bit is RO.

If the processor is not in Debug state, this bit is UNKNOWN. It is always valid in Debug state.

INTdis, bits [23:22]

Interrupt disable. Disables taking interrupts (including virtual interrupts and System Error interrupts) in Non-Debug state.

If external invasive debug is disabled, the value of this field is ignored.

If external invasive debug is enabled, the possible values of this field are:

`00` Do not disable interrupts

`01` Disable interrupts targeting Non-secure EL1.

`10` Disable interrupts targeting only Non-secure EL1 and Non-secure EL2. If external secure invasive debug is enabled, also disable interrupts targeting Secure EL1.

`11` Disable interrupts targeting only Non-secure EL1 and Non-secure EL2. If external secure invasive debug is enabled, also disable all other interrupts.

The value of INTdis does not affect whether an interrupt is a WFI wake-up event, but can mask an interrupt as a WFE wake-up event.

If EL3 and EL2 are not implemented, INTdis[0] is RO and reads the same value as INTdis[1], meaning only the values `00` and `11` can be selected.

On Cold reset, the field resets to 0.

TDA, bit [21]

Trap debug registers accesses.

On Cold reset, the field resets to 0.

MA, bit [20]

Memory access mode. Controls use of memory-access mode for accessing EDITR and the DCC. This bit is ignored if in Non-debug state and set to zero on entry to Debug state.

Possible values of this field are:

`0` Normal access mode.

`1` Memory access mode.

On Cold reset, the field resets to 0.

Bit [19]

Reserved, RES0.

NS, bit [18]

Non-secure status. Read-only. When in Debug state, gives the current security state:

0 Secure state, IsSecure() == TRUE.

1 Non-secure state, IsSecure() == FALSE.

In Non-debug state, this bit is UNKNOWN.

Bit [17]

Reserved, RES0.

SDD, bit [16]

Secure debug disabled. This bit is RO.

On entry to Debug state:

- If entering in Secure state, SDD is set to 0.
- If entering in Non-secure state, SDD is set to the inverse of ExternalSecureInvasiveDebugEnabled().

In Debug state, the value of the SDD bit does not change, even if ExternalSecureInvasiveDebugEnabled() changes.

In Non-debug state:

- SDD returns the inverse of ExternalSecureInvasiveDebugEnabled(). If the authentication signals that control ExternalSecureInvasiveDebugEnabled() change, a context synchronization operation is required to guarantee their effect.
- This bit is unaffected by the Security state of the processor.

If EL3 is not implemented and the implementation is Non-secure, this bit is RES1.

Bit [15]

Reserved, RES0.

HDE, bit [14]

Halting debug enable.

On Cold reset, the field resets to 0.

RW, bits [13:10]

Exception level Execution state status. Read-only. In Debug state, each bit gives the current Execution state of each EL:

1111 All exception levels are AArch64 state.

1110 EL0 is AArch32 state. All other exception levels are AArch64 state.

1100 EL0 and EL1 are AArch32 state. All other exception levels are AArch64 state. Never seen if EL2 is not implemented in the current security state.

1000 EL0, EL1, and, if implemented in the current security state, EL2 are AArch32 state. All other exception levels are AArch64 state.

0000 All exception levels are set to AArch32 state (32-bit configuration).

However:

- If not at EL0: RW[0] == RW[1].
- If EL2 is not implemented in the current security state: RW[2] == RW[1].
- If EL3 is not implemented: RW[3] == RW[2].

In Non-debug state, this field is RAO.

EL, bits [9:8]

Exception level. Read-only. In Debug state, this gives the current EL of the processor.

In Non-debug state, this field is RAZ.

A, bit [7]

System Error interrupt pending. Read-only. In Debug state, indicates whether a SError interrupt is pending:

- If HCR_EL2.{AMO, TGE} = {1, 0} and in Non-secure EL0 or EL1, a virtual SError interrupt.
- Otherwise, a physical SError interrupt.

`0` No SError interrupt pending.

`1` SError interrupt pending.

A debugger can read EDSCR to check whether a SError interrupt is pending without having to execute further instructions. A pending SError might indicate data from target memory is corrupted.

UNKNOWN in Non-debug state.

ERR, bit [6]

Cumulative error flag. This field is RO. It is set to 1 following exceptions in Debug state and on any signaled overrun or underrun on the DTR or EDITR.

On Cold reset, the field resets to 0.

STATUS, bits [5:0]

Debug status flags. This field is RO.

The possible values of this field are:

`000010` Processor is in Non-debug state.

`000001` Processor is restarting (exiting Debug state).

`000111` Breakpoint.

`010011` External debug request.

`011011` Halting step, normal.

`011111` Halting step, exclusive.

`100011` OS unlock catch.

`100111` Reset catch.

`101011` Watchpoint.

`101111` HLT instruction.

`110011` Software access to debug register.

`110111` Exception catch.

`111011` Halting step, no syndrome.

All other values of STATUS are reserved.

Accessing the EDSCR

EDSCR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0x088`

H9.1.40 EDVIDSR, External Debug Virtual Context Sample Register

The EDVIDSR characteristics are:

Purpose

Contains sampled values captured on reading EDPCSR.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	Default
Error	Error	Error	RO

Configurations

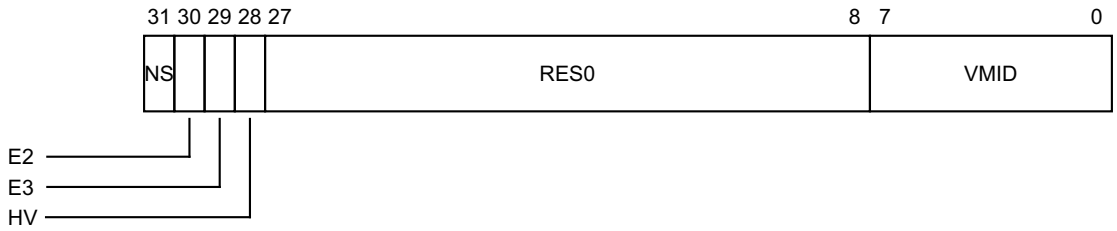
EDVIDSR is in the Core power domain.

Attributes

EDVIDSR is a 32-bit register.

Field descriptions

The EDVIDSR bit assignments are:



NS, bit [31]

Non-secure state sample. Indicates the security state associated with the most recent EDPCSR sample.

On Cold reset, the field reset value is architecturally UNKNOWN.

E2, bit [30]

Exception level 2 status sample. Indicates whether the most recent EDPCSR sample was associated with EL2. If EDVIDSR.NS == 0, this bit is 0.

On Cold reset, the field reset value is architecturally UNKNOWN.

E3, bit [29]

Exception level 3 status sample. Indicates whether the most recent EDPCSR sample was associated with AArch64 EL3. If EDVIDSR.NS == 1 or the processor was in AArch32 state when EDPCSR was read, this bit is 0.

On Cold reset, the field reset value is architecturally UNKNOWN.

HV, bit [28]

EDPCSR high half valid. Indicates whether bits [63:32] of the most recent EDPCSR sample are valid. If EDVIDSR.HV == 0, the value of EDPCSR[63:32] is RAZ.

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [27:8]

Reserved, RES0.

VMID, bits [7:0]

VMID sample. The value of VTTBR_EL2.VMID associated with the most recent EDPCSR sample. If EDVIDSR.NS == 0 or EDVIDSR.E2 == 1, this field is RAZ.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the EDVIDSR

EDVIDSR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x0A8

H9.1.41 EDWAR, External Debug Watchpoint Address Register

The EDWAR characteristics are:

Purpose

Contains the virtual data address being accessed when a watchpoint debug event was triggered.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	Default
Error	Error	Error	RO

Configurations

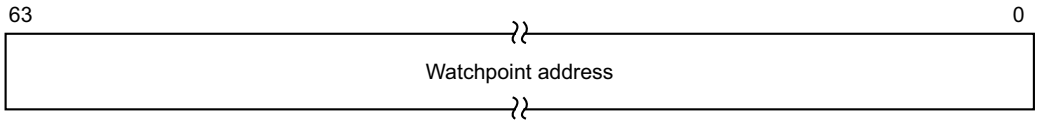
EDWAR is in the Core power domain.

Attributes

EDWAR is a 64-bit register.

Field descriptions

The EDWAR bit assignments are:



Bits [63:0]

Watchpoint address. The virtual data address being accessed when a watchpoint debug event was triggered and caused entry to Debug state.

UNKNOWN if the processor is not in Debug state, or if Debug state was entered other than for a watchpoint debug event.

The address must be within a naturally-aligned block of memory of power-of-two size no larger than the DC ZVA block size.

Accessing the EDWAR

EDWAR[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x030

EDWAR[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x034

H9.1.42 ID_AA64DFR0_EL1, Debug Feature Register 0

The ID_AA64DFR0_EL1 characteristics are:

Purpose

Provides top level information about the debug system in AArch64.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

ID_AA64DFR0_EL1 is architecturally mapped to AArch64 register ID_AA64DFR0_EL1.

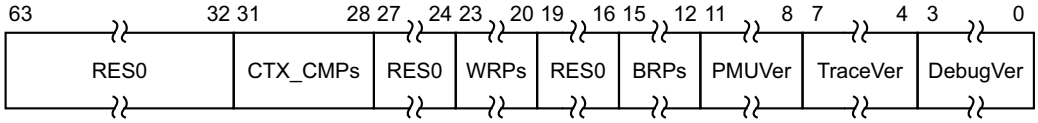
ID_AA64DFR0_EL1 is in the Debug power domain.

Attributes

ID_AA64DFR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64DFR0_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

CTX_CMPs, bits [31:28]

Number of breakpoints that are context-aware, minus 1. These are the highest numbered breakpoints.

Bits [27:24]

Reserved, RES0.

WRPs, bits [23:20]

Number of watchpoints, minus 1. The value of `0b0000` is reserved.

Bits [19:16]

Reserved, RES0.

BRPs, bits [15:12]

Number of breakpoints, minus 1. The value of `0b0000` is reserved.

PMUVer, bits [11:8]

Performance Monitors extension version. Indicates whether system register interface to Performance Monitors extension is implemented. Permitted values are:

`0000` Performance Monitors extension system registers not implemented.

0001 Performance Monitors extension system registers implemented, PMUv3.

1111 IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported.

All other values are reserved.

TraceVer, bits [7:4]

Trace extension. Indicates whether system register interface to Trace extension is implemented. Permitted values are:

0000 Trace extension system registers not implemented.

0001 Trace extension system registers implemented.

All other values are reserved.

A value of 0000 only indicates that no system register interface to the trace extension is implemented. A trace extension may nevertheless be implemented without a system register interface.

DebugVer, bits [3:0]

Debug architecture version. Indicates presence of v8-A debug architecture.

0110 v8-A debug architecture.

All other values are reserved.

Accessing the ID_AA64DFR0_EL1

ID_AA64DFR0_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD28

ID_AA64DFR0_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD2C

H9.1.43 ID_AA64DFR1_EL1, Debug Feature Register 1

The ID_AA64DFR1_EL1 characteristics are:

Purpose

Reserved for future expansion of top level information about the debug system in AArch64.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

ID_AA64DFR1_EL1 is architecturally mapped to AArch64 register ID_AA64DFR1_EL1.

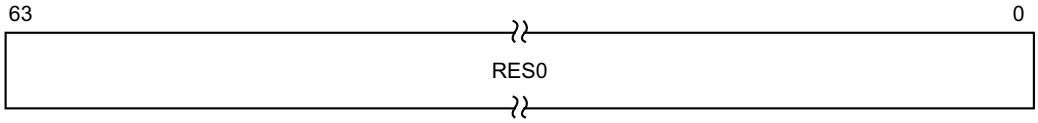
ID_AA64DFR1_EL1 is in the Debug power domain.

Attributes

ID_AA64DFR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64DFR1_EL1 bit assignments are:



Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64DFR1_EL1

ID_AA64DFR1_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD48

ID_AA64DFR1_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD4C

H9.1.44 ID_AA64ISAR0_EL1, Instruction Set Attribute Register 0

The ID_AA64ISAR0_EL1 characteristics are:

Purpose

Provides information about the instructions implemented by the processor in AArch64.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

ID_AA64ISAR0_EL1 is architecturally mapped to AArch64 register ID_AA64ISAR0_EL1.

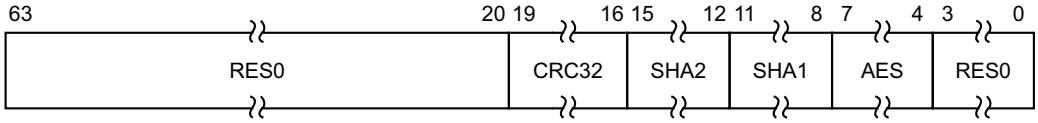
ID_AA64ISAR0_EL1 is in the Debug power domain.

Attributes

ID_AA64ISAR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64ISAR0_EL1 bit assignments are:



Bits [63:20]

Reserved, RES0.

CRC32, bits [19:16]

CRC32 instructions in AArch64. Possible values of this field are:

`0000` No CRC32 instructions implemented.

`0001` CRC32B, CRC32H, CRC32W, CRC32X, CRC32CB, CRC32CH, CRC32CW, and CRC32CX instructions implemented.

All other values are reserved.

This field must have the same value as ID_ISAR5.CRC32. The architecture requires that if CRC32 is supported in one Execution state, it must be supported in both Execution states.

SHA2, bits [15:12]

SHA2 instructions in AArch64. Possible values of this field are:

`0000` No SHA2 instructions implemented.

`0001` SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 instructions implemented.

All other values are reserved.

SHA1, bits [11:8]

SHA1 instructions in AArch64. Possible values of this field are:

`0000` No SHA1 instructions implemented.

`0001` SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 instructions implemented.

All other values are reserved.

AES, bits [7:4]

AES instructions in AArch64. Possible values of this field are:

`0000` No AES instructions implemented.

`0001` AESE, AESD, AESMC, and AESIMC instructions implemented.

`0010` As for `0001`, plus PMULL/PMULL2 instructions operating on 64-bit data quantities.

Bits [3:0]

Reserved, RES0.

Accessing the ID_AA64ISAR0_EL1

ID_AA64ISAR0_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xD30`

ID_AA64ISAR0_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	`0xD34`

H9.1.45 ID_AA64ISAR1_EL1, Instruction Set Attribute Register 1

The ID_AA64ISAR1_EL1 characteristics are:

Purpose

Reserved for future expansion of the information about the instruction sets implemented by the processor in AArch64.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

ID_AA64ISAR1_EL1 is architecturally mapped to AArch64 register ID_AA64ISAR1_EL1.

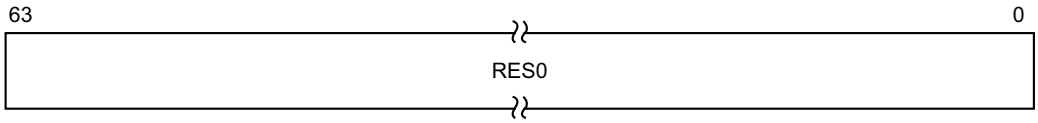
ID_AA64ISAR1_EL1 is in the Debug power domain.

Attributes

ID_AA64ISAR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64ISAR1_EL1 bit assignments are:



Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64ISAR1_EL1

ID_AA64ISAR1_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD50

ID_AA64ISAR1_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD54

H9.1.46 ID_AA64MMFR0_EL1, Memory Model Feature Register 0

The ID_AA64MMFR0_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

ID_AA64MMFR0_EL1 is architecturally mapped to AArch64 register ID_AA64MMFR0_EL1.

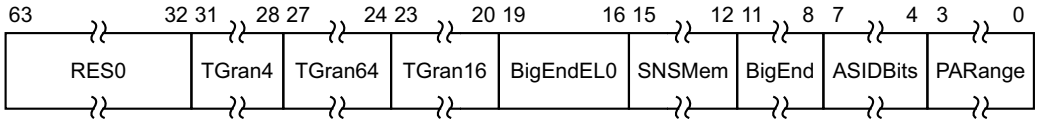
ID_AA64MMFR0_EL1 is in the Debug power domain.

Attributes

ID_AA64MMFR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64MMFR0_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

TGran4, bits [31:28]

Support for 4 KB memory translation granule size. Permitted values are:

0000 4 KB granule supported.

1111 4 KB granule not supported.

All other values are reserved.

TGran64, bits [27:24]

Support for 64 KB memory translation granule size. Permitted values are:

0000 64 KB granule supported.

1111 64 KB granule not supported.

All other values are reserved.

TGran16, bits [23:20]

Support for 16 KB memory translation granule size. Permitted values are:

0000 16 KB granule not supported.

0001 16 KB granule supported.

All other values are reserved.

BigEndEL0, bits [19:16]

Mixed-endian support at EL0 only. Permitted values are:

`0000` No mixed-endian support at EL0. The SCTLR_EL1.E0E bit has a fixed value.

`0001` Mixed-endian support at EL0. The SCTLR_EL1.E0E bit can be configured.

All other values are reserved.

This field is invalid and is RES0 if the BigEnd field, bits [11:8], is not `0000`.

SNSMem, bits [15:12]

Secure versus Non-secure Memory distinction. Permitted values are:

`0000` Does not support a distinction between Secure and Non-secure Memory.

`0001` Does support a distinction between Secure and Non-secure Memory.

All other values are reserved.

BigEnd, bits [11:8]

Mixed-endian configuration support. Permitted values are:

`0000` No mixed-endian support. The SCTLR_ELx.EE bits have a fixed value. See the BigEndEL0 field, bits[19:16], for whether EL0 supports mixed-endian.

`0001` Mixed-endian support. The SCTLR_ELx.EE and SCTLR_EL1.E0E bits can be configured.

All other values are reserved.

ASIDBits, bits [7:4]

Number of ASID bits. Permitted values are:

`0000` 8 bits.

`0010` 16 bits.

All other values are reserved.

PARange, bits [3:0]

Physical Address range supported. Permitted values are:

`0000` 32 bits, 4 GB.

`0001` 36 bits, 64 GB.

`0010` 40 bits, 1 TB.

`0011` 42 bits, 4 TB.

`0100` 44 bits, 16 TB.

`0101` 48 bits, 256 TB.

All other values are reserved.

Accessing the ID_AA64MMFR0_EL1

ID_AA64MMFR0_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD38

ID_AA64MMFR0_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD3C

H9.1.47 ID_AA64MMFR1_EL1, Memory Model Feature Register 1

The ID_AA64MMFR1_EL1 characteristics are:

Purpose

Reserved for future expansion of the information about the implemented memory model and memory management support in AArch64.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

ID_AA64MMFR1_EL1 is architecturally mapped to AArch64 register ID_AA64MMFR1_EL1.

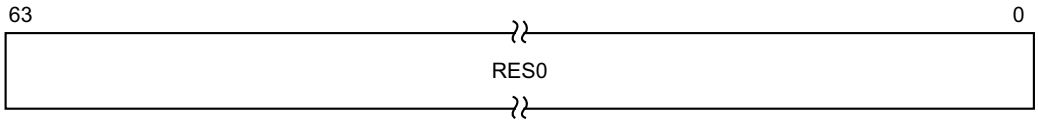
ID_AA64MMFR1_EL1 is in the Debug power domain.

Attributes

ID_AA64MMFR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64MMFR1_EL1 bit assignments are:



Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64MMFR1_EL1

ID_AA64MMFR1_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD58

ID_AA64MMFR1_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD5C

H9.1.48 ID_AA64PFR0_EL1, Processor Feature Register 0

The ID_AA64PFR0_EL1 characteristics are:

Purpose

Provides additional information about implemented processor features in AArch64.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

ID_AA64PFR0_EL1 is architecturally mapped to AArch64 register ID_AA64PFR0_EL1.

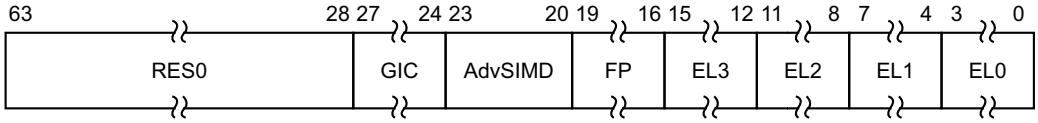
ID_AA64PFR0_EL1 is in the Debug power domain.

Attributes

ID_AA64PFR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64PFR0_EL1 bit assignments are:



Bits [63:28]

Reserved, RES0.

GIC, bits [27:24]

GIC system register interface. Permitted values are:

0000 No GIC system registers are supported.

0001 GICv3 system registers are supported.

All other values are reserved.

AdvSIMD, bits [23:20]

Advanced SIMD. Permitted values are:

0000 Advanced SIMD is implemented.

1111 Advanced SIMD is not implemented.

All other values are reserved.

FP, bits [19:16]

Floating-point. Permitted values are:

0000 Floating-point is implemented.

1111 Floating-point is not implemented.

All other values are reserved.

EL3, bits [15:12]

EL3 exception level handling. Permitted values are:

0000 EL3 is not implemented.

0001 EL3 can be executed in AArch64 state only.

0010 EL3 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

EL2, bits [11:8]

EL2 exception level handling. Permitted values are:

0000 EL2 is not implemented.

0001 EL2 can be executed in AArch64 state only.

0010 EL2 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

EL1, bits [7:4]

EL1 exception level handling. Permitted values are:

0000 EL1 is not implemented.

0001 EL1 can be executed in AArch64 state only.

0010 EL1 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

EL0, bits [3:0]

EL0 exception level handling. Permitted values are:

0000 EL0 is not implemented.

0001 EL0 can be executed in AArch64 state only.

0010 EL0 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

Accessing the ID_AA64PFR0_EL1

ID_AA64PFR0_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD20

ID_AA64PFR0_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD24

H9.1.49 ID_AA64PFR1_EL1, Processor Feature Register 1

The ID_AA64PFR1_EL1 characteristics are:

Purpose

Reserved for future expansion of information about implemented processor features in AArch64.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

ID_AA64PFR1_EL1 is architecturally mapped to AArch64 register ID_AA64PFR1_EL1.

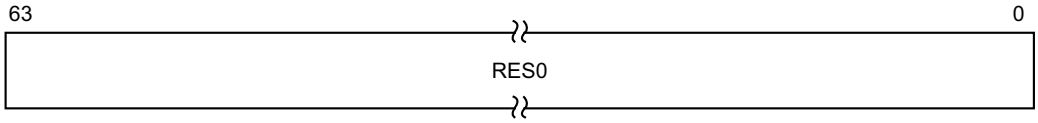
ID_AA64PFR1_EL1 is in the Debug power domain.

Attributes

ID_AA64PFR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64PFR1_EL1 bit assignments are:



Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64PFR1_EL1

ID_AA64PFR1_EL1[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD40

ID_AA64PFR1_EL1[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD44

H9.1.50 MIDR_EL1, Main ID Register

The MIDR_EL1 characteristics are:

Purpose

Provides identification information for the processor, including an implementer code for the device and a device ID number.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

MIDR_EL1 is architecturally mapped to AArch64 register MIDR_EL1.

MIDR_EL1 is architecturally mapped to AArch32 register MIDR.

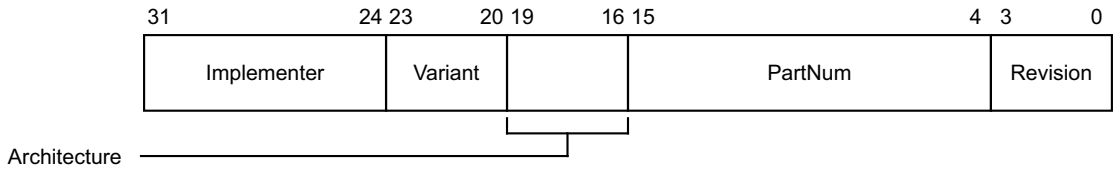
MIDR_EL1 is in the Debug power domain.

Attributes

MIDR_EL1 is a 32-bit register.

Field descriptions

The MIDR_EL1 bit assignments are:



Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

Hex representation	ASCII representation	Implementer
0x41	A	ARM Limited
0x42	B	Broadcom Corporation
0x43	C	Cavium Inc.
0x44	D	Digital Equipment Corporation
0x49	I	Infineon Technologies AG
0x4D	M	Motorola or Freescale Semiconductor Inc.
0x4E	N	NVIDIA Corporation

Hex representation	ASCII representation	Implementer
0x50	P	Applied Micro Circuits Corporation
0x51	Q	Qualcomm Inc.
0x56	V	Marvell International Ltd.
0x69	i	Intel Corporation

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

Architecture, bits [19:16]

The permitted values of this field are:

0001 ARMv4

0010 ARMv4T

0011 ARMv5 (obsolete)

0100 ARMv5T

0101 ARMv5TE

0110 ARMv5TEJ

0111 ARMv6

1111 Defined by CPUID scheme

All other values are reserved.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

Accessing the MIDR_EL1

MIDR_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0xD00

H9.1.51 OSLAR_EL1, OS Lock Access Register

The OSLAR_EL1 characteristics are:

Purpose

Used to lock or unlock the OS lock.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	SLK	Default
Error	Error	WI	WO

Configurations

OSLAR_EL1 is architecturally mapped to AArch64 register OSLAR_EL1.

OSLAR_EL1 is architecturally mapped to AArch32 register DBGOSLAR.

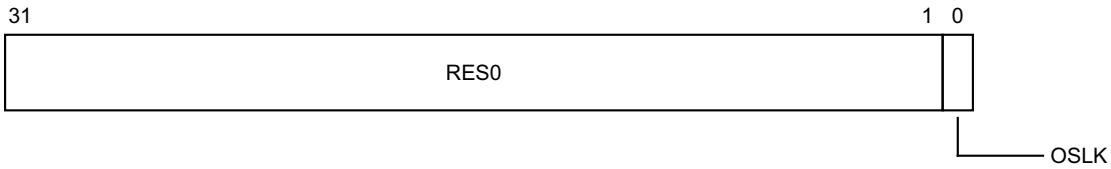
OSLAR_EL1 is in the Core power domain.

Attributes

OSLAR_EL1 is a 32-bit register.

Field descriptions

The OSLAR_EL1 bit assignments are:



Bits [31:1]

Reserved, RES0.

OSLK, bit [0]

On writes to OSLAR_EL1, bit[0] is copied to the OS lock.

Use EDPRSR.OSLK to check the current status of the lock.

Accessing the OSLAR_EL1

OSLAR_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
Debug	0x300

H9.2 Cross-Trigger Interface registers

This section describes each of the Cross-Trigger Interface registers.

H9.2.1 ASICCTL, CTI External Multiplexer Control register

The ASICCTL characteristics are:

Purpose

Provides a control for external multiplexing of additional triggers into the CTI.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

Configurations

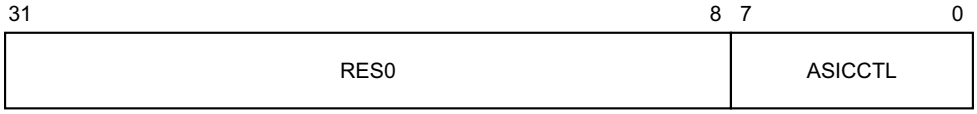
ASICCTL is in the Debug power domain.

Attributes

ASICCTL is a 32-bit register.

Field descriptions

The ASICCTL bit assignments are:



Bits [31:8]

Reserved, RES0.

ASICCTL, bits [7:0]

IMPLEMENTATION DEFINED ASIC control. Provides a control for external multiplexing of additional triggers into the CTI.

If external multiplexing of trigger signals is implemented then the number of multiplexed signals on each trigger must be reflected in CTIDEVID.EXTMUXNUM.

If CTIDEVID.EXTMUXNUM is zero, this field is RAZ.

On IMPLEMENTATION DEFINED reset, the field resets to an IMPLEMENTATION DEFINED value.

Accessing the ASICCTL

ASICCTL can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0x144

H9.2.2 CTIAPPCLEAR, CTI Application Trigger Clear register

The CTIAPPCLEAR characteristics are:

Purpose

Clears bits of the Application Trigger register.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	WO

Configurations

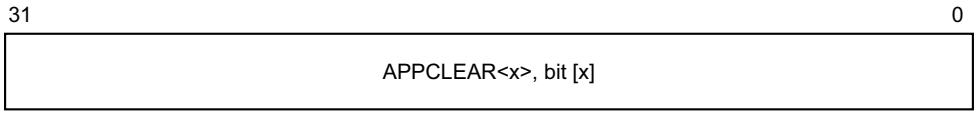
CTIAPPCLEAR is in the Debug power domain.

Attributes

CTIAPPCLEAR is a 32-bit register.

Field descriptions

The CTIAPPCLEAR bit assignments are:



APPCLEAR<x>, bit [x], for x = 0 to 31

Application trigger <x> disable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Writing to this bit has the following effect:

`0` No effect.

`1` Clear corresponding bit in CTIAPPTRIG to 0 and clear the corresponding channel event.

If the ECT does not support multicycle channel events, use of CTIAPPCLEAR is deprecated and the debugger must only use CTIAPPPULSE.

Accessing the CTIAPPCLEAR

CTIAPPCLEAR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x018`

H9.2.3 CTIAPPPULSE, CTI Application Pulse register

The CTIAPPPULSE characteristics are:

Purpose

Causes event pulses to be generated on ECT channels.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	WO

Configurations

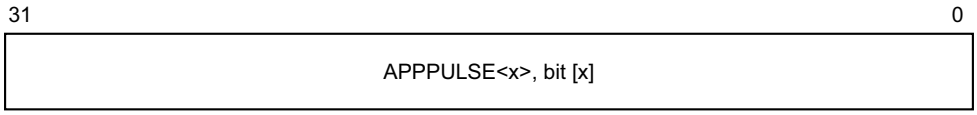
CTIAPPPULSE is in the Debug power domain.

Attributes

CTIAPPPULSE is a 32-bit register.

Field descriptions

The CTIAPPPULSE bit assignments are:



APPPULSE<x>, bit [x], for x = 0 to 31

Generate event pulse on ECT channel <x>.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Writing to this bit has the following effect:

`0` No effect.

`1` Channel <x> event pulse generated for one clock period.

Accessing the CTIAPPPULSE

CTIAPPPULSE can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x01C`

H9.2.4 CTIAPPSET, CTI Application Trigger Set register

The CTIAPPSET characteristics are:

Purpose

Sets bits of the Application Trigger register.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

Configurations

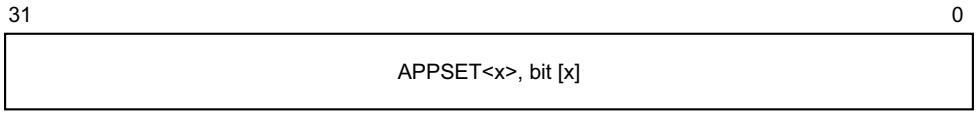
CTIAPPSET is in the Debug power domain.

Attributes

CTIAPPSET is a 32-bit register.

Field descriptions

The CTIAPPSET bit assignments are:



APPSET<x>, bit [x], for x = 0 to 31

Application trigger <x> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0` Reading this means the application trigger is inactive. Writing this has no effect.

`1` Reading this means the application trigger is active. Writing this sets the corresponding bit in CTIAPPTRIG to 1 and generates a channel event.

If the ECT does not support multicycle channel events, use of CTIAPPSET is deprecated and the debugger must only use CTIAPPPULSE.

On External debug reset, the field reset value is architecturally UNKNOWN.

Accessing the CTIAPPSET

CTIAPPSET can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x014`

H9.2.5 CTIAUTHSTATUS, CTI Authentication Status register

The CTIAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for CTI.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTIAUTHSTATUS is in the Debug power domain.

This register is OPTIONAL, and is required for CoreSight compliance. ARM recommends that this register is implemented.

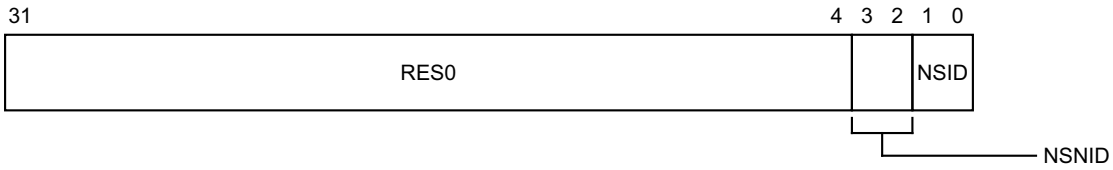
CTIAUTHSTATUS.{SNID,SID} are RAZ, because the CTI does not itself provide Secure authentication.

Attributes

CTIAUTHSTATUS is a 32-bit register.

Field descriptions

The CTIAUTHSTATUS bit assignments are:



Bits [31:4]

Reserved, RES0.

NSNID, bits [3:2]

If EL3 is not implemented and the processor is Secure, holds the same value as DBGAUTHSTATUS_EL1.SNID.

Otherwise, holds the same value as DBGAUTHSTATUS_EL1.NSNID.

NSID, bits [1:0]

If EL3 is not implemented and the processor is Secure, holds the same value as DBGAUTHSTATUS_EL1.SID.

Otherwise, holds the same value as DBGAUTHSTATUS_EL1.NSID.

Accessing the CTIAUTHSTATUS

CTIAUTHSTATUS can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFB8

H9.2.6 CTICHINSTATUS, CTI Channel In Status register

The CTICHINSTATUS characteristics are:

Purpose

Provides the raw status of the ECT channel inputs to the CTI.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

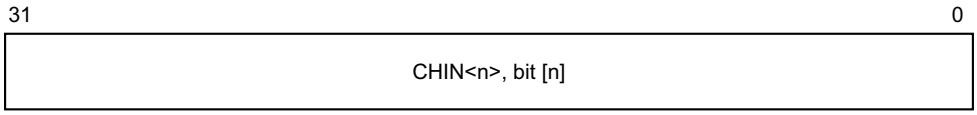
CTICHINSTATUS is in the Debug power domain.

Attributes

CTICHINSTATUS is a 32-bit register.

Field descriptions

The CTICHINSTATUS bit assignments are:



CHIN<n>, bit [n], for n = 0 to 31

Input channel <n> status.

Bits [31:N] are RAZ. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0` Input channel <n> is inactive.

`1` Input channel <n> is active.

Accessing the CTICHINSTATUS

CTICHINSTATUS can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x138`

H9.2.7 CTICHOUTSTATUS, CTI Channel Out Status register

The CTICHOUTSTATUS characteristics are:

Purpose

Provides the status of the ECT channel outputs from the CTI.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

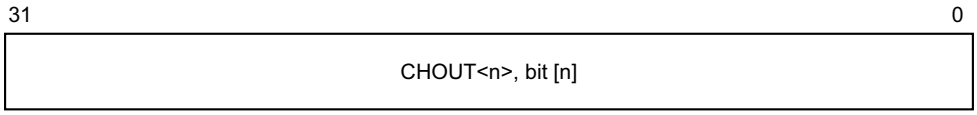
CTICHOUTSTATUS is in the Debug power domain.

Attributes

CTICHOUTSTATUS is a 32-bit register.

Field descriptions

The CTICHOUTSTATUS bit assignments are:



CHOUT<n>, bit [n], for n = 0 to 31

Output channel <n> status.

Bits [31:N] are RAZ. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0` Output channel <n> is inactive.

`1` Output channel <n> is active.

Accessing the CTICHOUTSTATUS

CTICHOUTSTATUS can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x13C`

H9.2.8 CTICIDR0, CTI Component Identification Register 0

The CTICIDR0 characteristics are:

Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTICIDR0 is in the Debug power domain.

CTICIDR0 is optional to implement in the external register interface.

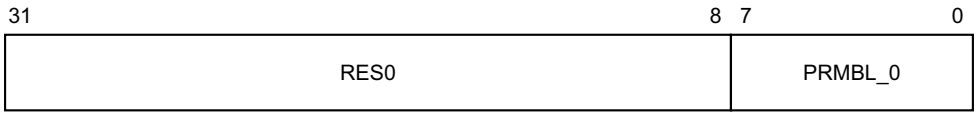
This register is required for CoreSight compliance.

Attributes

CTICIDR0 is a 32-bit register.

Field descriptions

The CTICIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as `0x0D`.

Accessing the CTICIDR0

CTICIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFF0`

H9.2.9 CTICIDR1, CTI Component Identification Register 1

The CTICIDR1 characteristics are:

Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTICIDR1 is in the Debug power domain.

CTICIDR1 is optional to implement in the external register interface.

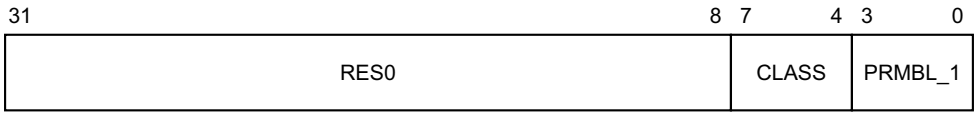
This register is required for CoreSight compliance.

Attributes

CTICIDR1 is a 32-bit register.

Field descriptions

The CTICIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as `0x9`, debug component.

PRMBL_1, bits [3:0]

Preamble. RAZ.

Accessing the CTICIDR1

CTICIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFF4`

H9.2.10 CTICIDR2, CTI Component Identification Register 2

The CTICIDR2 characteristics are:

Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTICIDR2 is in the Debug power domain.

CTICIDR2 is optional to implement in the external register interface.

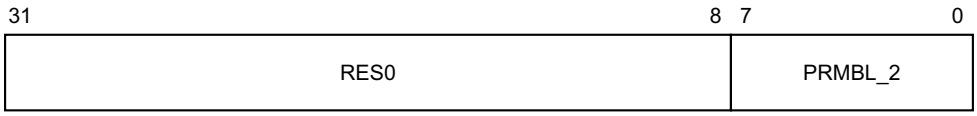
This register is required for CoreSight compliance.

Attributes

CTICIDR2 is a 32-bit register.

Field descriptions

The CTICIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Must read as `0x05`.

Accessing the CTICIDR2

CTICIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFF8`

H9.2.11 CTICIDR3, CTI Component Identification Register 3

The CTICIDR3 characteristics are:

Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTICIDR3 is in the Debug power domain.

CTICIDR3 is optional to implement in the external register interface.

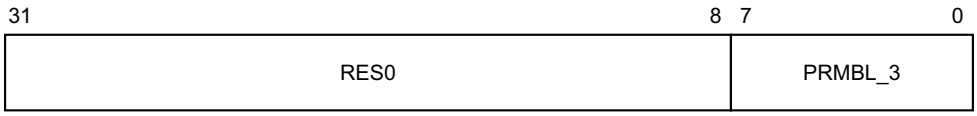
This register is required for CoreSight compliance.

Attributes

CTICIDR3 is a 32-bit register.

Field descriptions

The CTICIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Must read as `0xB1`.

Accessing the CTICIDR3

CTICIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFFC`

H9.2.12 CTICLAIMCLR, CTI Claim Tag Clear register

The CTICLAIMCLR characteristics are:

Purpose

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

Configurations

CTICLAIMCLR is in the Debug power domain.

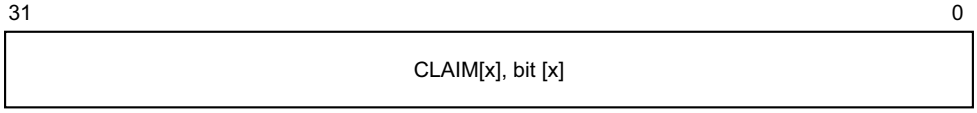
CTICLAIMCLR is optional to implement in the external register interface.

Attributes

CTICLAIMCLR is a 32-bit register.

Field descriptions

The CTICLAIMCLR bit assignments are:



CLAIM[x], bit [x], for x = 0 to 31

Clear CLAIM tag. If x is greater than or equal to the IMPLEMENTATION DEFINED number of CLAIM tags, this bit is RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

Otherwise, reads return the value of CLAIM[x] and the behavior on writes is:

`0` No action.

`1` Indirectly clear CLAIM[x] to 0.

A single write to CTICLAIMCLR can clear multiple tags to 0.

Accessing the CTICLAIMCLR

CTICLAIMCLR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFA4`

H9.2.13 CTICLAIMSET, CTI Claim Tag Set register

The CTICLAIMSET characteristics are:

Purpose

Used by software to set CLAIM bits to 1.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

Configurations

CTICLAIMSET is in the Debug power domain.

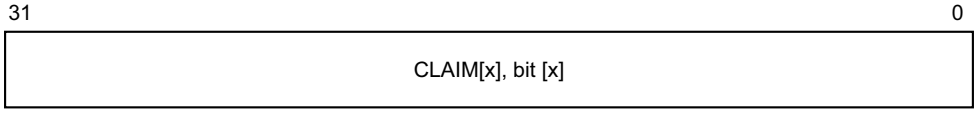
CTICLAIMSET is optional to implement in the external register interface.

Attributes

CTICLAIMSET is a 32-bit register.

Field descriptions

The CTICLAIMSET bit assignments are:



CLAIM[x], bit [x], for x = 0 to 31

CLAIM tag set bit. If x is greater than or equal to the IMPLEMENTATION DEFINED number of CLAIM tags, this bit is RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

Otherwise, the bit is RAO and the behavior on writes is:

`0` No action.

`1` Indirectly set CLAIM[x] tag to 1.

A single write to CTICLAIMSET can set multiple tags to 1.

Accessing the CTICLAIMSET

CTICLAIMSET can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFA0`

H9.2.14 CTICONTROL, CTI Control register

The CTICONTROL characteristics are:

Purpose

Controls whether the CTI is enabled.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

Configurations

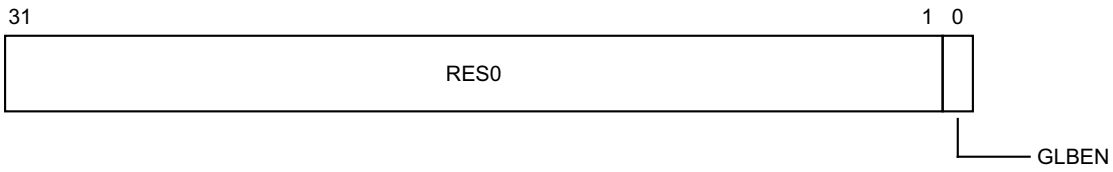
CTICONTROL is in the Debug power domain.

Attributes

CTICONTROL is a 32-bit register.

Field descriptions

The CTICONTROL bit assignments are:



Bits [31:1]

Reserved, RES0.

GLBEN, bit [0]

Enables or disables the CTI mapping functions. Possible values of this field are:

`0` CTI mapping functions disabled.

`1` CTI mapping functions enabled.

When the mapping functions are disabled, no new events are signaled on either output triggers or output channels. If a previously asserted output trigger has not been acknowledged, it remains asserted after the mapping functions are disabled. All output triggers are disabled by CTI reset.

On External debug reset, the field resets to 0.

Accessing the CTICONTROL

CTICONTROL can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x000`

H9.2.15 CTIDEVAFF0, CTI Device Affinity register 0

The CTIDEVAFF0 characteristics are:

Purpose

Copy of the low half of the processor MPIDR_EL1 register that allows a debugger to determine which processor in a multiprocessor system the CTI component relates to.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTIDEVAFF0 is in the Debug power domain.

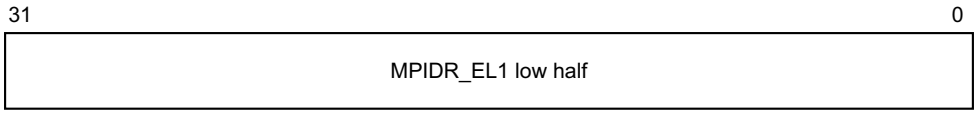
CTIDEVAFF0 is optional to implement in the external register interface.

Attributes

CTIDEVAFF0 is a 32-bit register.

Field descriptions

The CTIDEVAFF0 bit assignments are:



Bits [31:0]

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented exception level.

Accessing the CTIDEVAFF0

CTIDEVAFF0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFA8

H9.2.16 CTIDEVAFF1, CTI Device Affinity register 1

The CTIDEVAFF1 characteristics are:

Purpose

Copy of the high half of the processor MPIDR_EL1 register that allows a debugger to determine which processor in a multiprocessor system the CTI component relates to.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTIDEVAFF1 is in the Debug power domain.

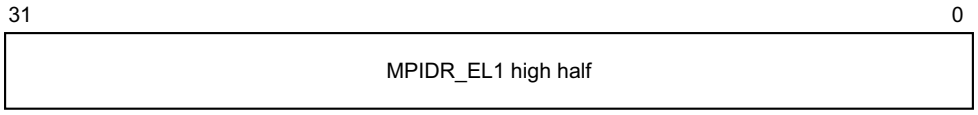
CTIDEVAFF1 is optional to implement in the external register interface.

Attributes

CTIDEVAFF1 is a 32-bit register.

Field descriptions

The CTIDEVAFF1 bit assignments are:



Bits [31:0]

MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented exception level.

Accessing the CTIDEVAFF1

CTIDEVAFF1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFAC

H9.2.17 CTIDEVARCH, CTI Device Architecture register

The CTIDEVARCH characteristics are:

Purpose

Identifies the programmers' model architecture of the CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTIDEVARCH is in the Debug power domain.

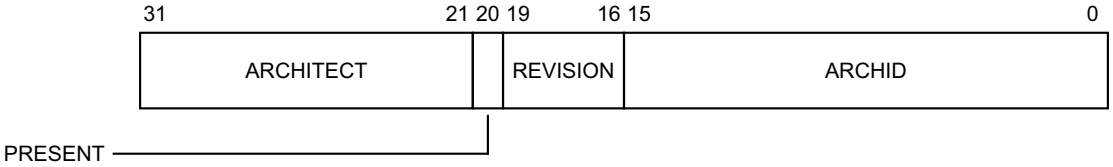
CTIDEVARCH is optional to implement in the external register interface.

Attributes

CTIDEVARCH is a 32-bit register.

Field descriptions

The CTIDEVARCH bit assignments are:



ARCHITECT, bits [31:21]

Defines the architecture of the component. For CTI, this is ARM Limited.

Bits [31:28] are the JEP 106 continuation code, `0x4`.

Bits [27:21] are the JEP 106 ID code, `0x3B`.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in v8-A.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by ARM this is the minor revision.

For CTI, the revision defined by v8-A is `0x0`.

All other values are reserved.

ARCHID, bits [15:0]

Defines this part to be a v8-A debug component. For architectures defined by ARM this is further subdivided.

For CTI:

- Bits [15:12] are the architecture version, `0x1`.
- Bits [11:0] are the architecture part number, `0xA14`.

This corresponds to CTI architecture version CTIv2.

Accessing the CTIDEVARCH

CTIDEVARCH can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFBC`

H9.2.18 CTIDEVID, CTI Device ID register 0

The CTIDEVID characteristics are:

Purpose

Describes the CTI component to the debugger.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

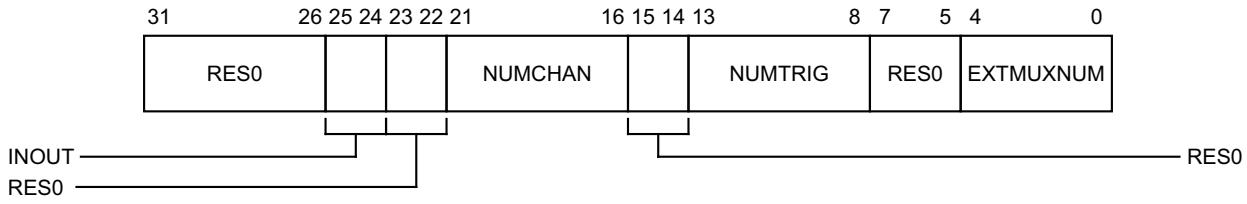
CTIDEVID is in the Debug power domain.

Attributes

CTIDEVID is a 32-bit register.

Field descriptions

The CTIDEVID bit assignments are:



Bits [31:26]

Reserved, RES0.

INOUT, bits [25:24]

Input/output options. Indicates presence of the input gate. If the CTM is not implemented, this field is RAZ.

`00` CTIGATE does not mask propagation of input events from external channels.

`01` CTIGATE masks propagation of input events from external channels.

All other values are reserved.

Bits [23:22]

Reserved, RES0.

NUMCHAN, bits [21:16]

Number of ECT channels implemented. IMPLEMENTATION DEFINED. For v8-A, valid values are:

`000011` 3 channels (0-2) implemented.

`000100` 4 channels (0-3) implemented.

`000101` 5 channels (0-4) implemented.

`000110` 6 channels (0-5) implemented.

and so on up to:

`100000` 32 channels (0-31) implemented.

All other values are reserved.

Bits [15:14]

Reserved, RES0.

NUMTRIG, bits [13:8]

Number of triggers implemented. IMPLEMENTATION DEFINED. This is one more than the index of the largest trigger, rather than the actual number of triggers.

For v8-A, valid values are:

`000011` Up to 3 triggers (0-2) implemented.

`001000` Up to 8 triggers (0-7) implemented.

`001001` Up to 9 triggers (0-.8) implemented.

`001010` Up to 10 triggers (0-9) implemented.

and so on up to:

`100000` 32 triggers (0-31) implemented.

All other values are reserved. If the Trace Extension is implemented, this field must be at least 001000. There is no guarantee that any of the implemented triggers, including the highest numbered, are connected to any components.

Bits [7:5]

Reserved, RES0.

EXTMUXNUM, bits [4:0]

Maximum number of external triggers available for multiplexing into the CTI. This relates only to additional external triggers outside those defined for v8-A.

Accessing the CTIDEVID

CTIDEVID can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFC8`

H9.2.19 CTIDEVID1, CTI Device ID register 1

The CTIDEVID1 characteristics are:

Purpose

Reserved for future information about the CTI component to the debugger.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

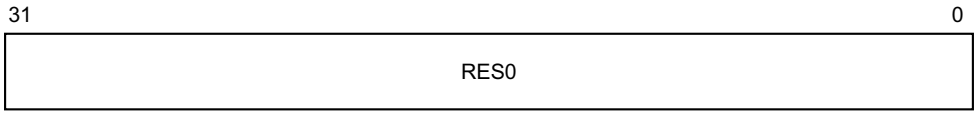
CTIDEVID1 is in the Debug power domain.

Attributes

CTIDEVID1 is a 32-bit register.

Field descriptions

The CTIDEVID1 bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the CTIDEVID1

CTIDEVID1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFC4

H9.2.20 CTIDEVID2, CTI Device ID register 2

The CTIDEVID2 characteristics are:

Purpose

Reserved for future information about the CTI component to the debugger.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

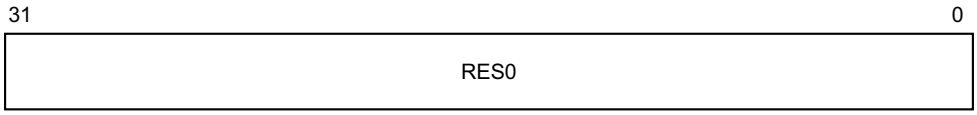
CTIDEVID2 is in the Debug power domain.

Attributes

CTIDEVID2 is a 32-bit register.

Field descriptions

The CTIDEVID2 bit assignments are:



Bits [31:0]

Reserved, RES0.

Accessing the CTIDEVID2

CTIDEVID2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFC0

H9.2.21 CTIDEVTYPE, CTI Device Type register

The CTIDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a processor's cross-trigger interface.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTIDEVTYPE is in the Debug power domain.

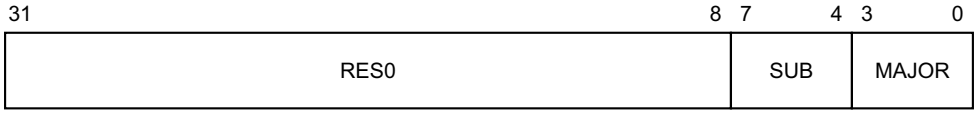
CTIDEVTYPE is optional to implement in the external register interface.

Attributes

CTIDEVTYPE is a 32-bit register.

Field descriptions

The CTIDEVTYPE bit assignments are:



Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Must read as `0x1` to indicate this is a processor component.

MAJOR, bits [3:0]

Major type. Must read as `0x4` to indicate this is a cross-trigger component.

Accessing the CTIDEVTYPE

CTIDEVTYPE can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFCC`

H9.2.22 CTIGATE, CTI Channel Gate Enable register

The CTIGATE characteristics are:

Purpose

Determines whether events on channels propagate through the CTM to other ECT components, or from the CTM into the CTI.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

Configurations

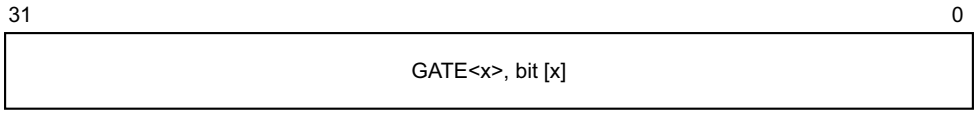
CTIGATE is in the Debug power domain.

Attributes

CTIGATE is a 32-bit register.

Field descriptions

The CTIGATE bit assignments are:



GATE<x>, bit [x], for x = 0 to 31

Channel <x> gate enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0` Disable output and, if CTIDEVID.INOUT == `0b01`, input channel <x> propagation.

`1` Enable output and, if CTIDEVID.INOUT == `0b01`, input channel <x> propagation.

On External debug reset, the field reset value is architecturally UNKNOWN.

Accessing the CTIGATE

CTIGATE can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x140`

H9.2.23 CTIINEN<n>, CTI Input Trigger to Output Channel Enable registers, n = 0 - 31

The CTIINEN<n> characteristics are:

Purpose

Enables the signaling of an event on output channels when input trigger event n is received by the CTI.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

Configurations

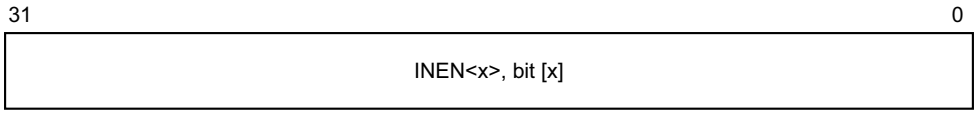
CTIINEN<n> is in the Debug power domain.

Attributes

CTIINEN<n> is a 32-bit register.

Field descriptions

The CTIINEN<n> bit assignments are:



INEN<x>, bit [x], for x = 0 to 31

Input trigger <n> to output channel <x> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0` Input trigger <n> will not generate an event on output channel <x>.

`1` Input trigger <n> will generate an event on output channel <x>.

On External debug reset, the field reset value is architecturally UNKNOWN.

Accessing the CTIINEN<n>

CTIINEN<n> can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x020` + 4n

H9.2.24 CTIINTACK, CTI Output Trigger Acknowledge register

The CTIINTACK characteristics are:

Purpose

Can be used to create soft acknowledges for output triggers.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	WO

Configurations

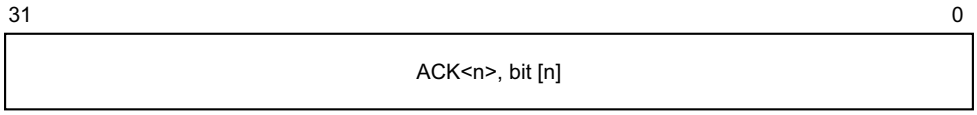
CTIINTACK is in the Debug power domain.

Attributes

CTIINTACK is a 32-bit register.

Field descriptions

The CTIINTACK bit assignments are:



ACK<n>, bit [n], for n = 0 to 31

Acknowledge for output trigger <n>.

Bits [31:N] are RAZ/WI. N is the number of CTI triggers implemented as defined by the CTIDEVID.NUMTRIG field.

If any of the following is true, writes to ACK<n> are ignored:

- n >= CTIDEVID.NUMTRIG, the number of implemented triggers.
- Output trigger n is not active.
- The channel mapping function output, as controlled by CTIOUTEN<n>, is still active.

Otherwise, if any of the following are true, it is IMPLEMENTATION DEFINED whether writes to ACK<n> are ignored:

- Output trigger n is not implemented.
- Output trigger n is not connected.
- Output trigger n is self-acknowledging and does not require software acknowledge.

Otherwise, the behavior on writes to ACK<n> is as follows:

`0` No effect

`1` Deactivate the trigger.

Accessing the CTIINTACK

CTIINTACK can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x010`

H9.2.25 CTIITCTRL, CTI Integration mode Control register

The CTIITCTRL characteristics are:

Purpose

Enables the CTI to switch from its default mode into integration mode, where test software can control directly the inputs and outputs of the processor, for integration testing or topology detection.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RW

Configurations

CTIITCTRL is in the Debug power domain.

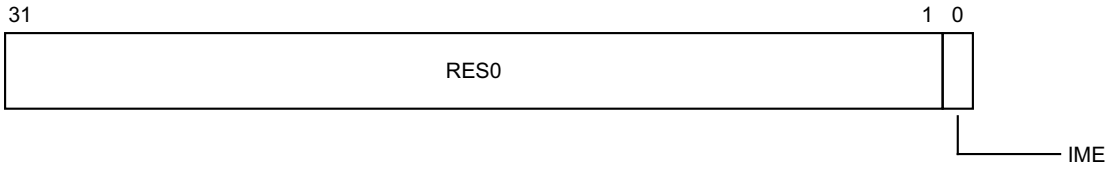
CTIITCTRL is optional to implement in the external register interface.

Attributes

CTIITCTRL is a 32-bit register.

Field descriptions

The CTIITCTRL bit assignments are:



Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

`0` Normal operation.

`1` Integration mode enabled.

On IMPLEMENTATION DEFINED reset, the field resets to 0.

Accessing the CTIITCTRL

CTIITCTRL can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xF00`

H9.2.26 CTILAR, CTI Lock Access Register

The CTILAR characteristics are:

Purpose

Allows or disallows access to the CTI registers through a memory-mapped interface.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

Default
WO

Configurations

CTILAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

CTILAR ignores writes if the Software lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

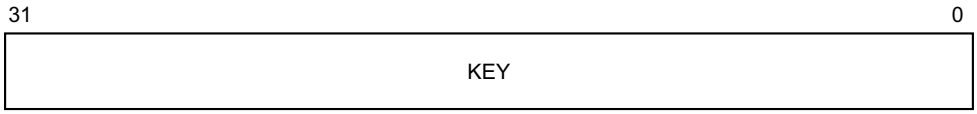
Software uses CTILAR to set or clear the lock, and CTILSR to check the current status of the lock.

Attributes

CTILAR is a 32-bit register.

Field descriptions

The CTILAR bit assignments are:



KEY, bits [31:0]

Lock Access control. Writing the key value `0xC5ACCE55` to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Accessing the CTILAR

CTILAR can be accessed through the internal memory-mapped interface:

Component	Offset
CTI	`0xFB0`

H9.2.27 CTILSR, CTI Lock Status Register

The CTILSR characteristics are:

Purpose

Indicates the current status of the software lock for CTI registers.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

CTILSR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

CTILSR is RAZ if the Software lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the Cross-Trigger Interface registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Cross-Trigger Interface registers. It does not, and cannot, prevent all accidental or malicious damage.

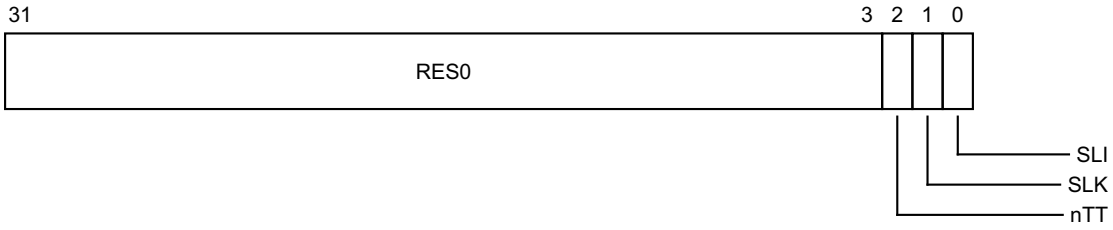
Software uses CTILAR to set or clear the lock, and CTILSR to check the current status of the lock.

Attributes

CTILSR is a 32-bit register.

Field descriptions

The CTILSR bit assignments are:



Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

SLK, bit [1]

Software lock status for this component. For an access to LSR that is not a memory-mapped access, or when the software lock is not implemented, this field is RES0.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:

`0` Lock clear. Writes are permitted to this component's registers.

`1` Lock set. Writes to this component's registers are ignored, and reads have no side effects.

On External debug reset, the field resets to 1.

SLI, bit [0]

Software lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

`0` Software lock not implemented or not memory-mapped access.

`1` Software lock implemented and memory-mapped access.

Accessing the CTILSR

CTILSR can be accessed through the internal memory-mapped interface:

Component	Offset
CTI	`0xFB4`

H9.2.28 CTIOUTEN<n>, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31

The CTIOUTEN<n> characteristics are:

Purpose

Defines which input channels generate output trigger n.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RW

Configurations

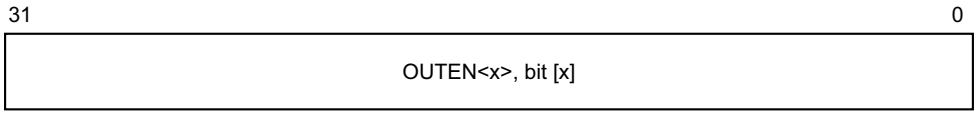
CTIOUTEN<n> is in the Debug power domain.

Attributes

CTIOUTEN<n> is a 32-bit register.

Field descriptions

The CTIOUTEN<n> bit assignments are:



OUTEN<x>, bit [x], for x = 0 to 31

Input channel <x> to output trigger <n> enable.

Bits [31:N] are RAZ/WI. N is the number of ECT channels implemented as defined by the CTIDEVID.NUMCHAN field.

Possible values of this bit are:

`0` An event on input channel <x> will not cause output trigger <n> to be asserted.

`1` An event on input channel <x> will cause output trigger <n> to be asserted.

On External debug reset, the field reset value is architecturally UNKNOWN.

Accessing the CTIOUTEN<n>

CTIOUTEN<n> can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x0A0` + 4n

H9.2.29 CTIPIDR0, CTI Peripheral Identification Register 0

The CTIPIDR0 characteristics are:

Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTIPIDR0 is in the Debug power domain.

CTIPIDR0 is optional to implement in the external register interface.

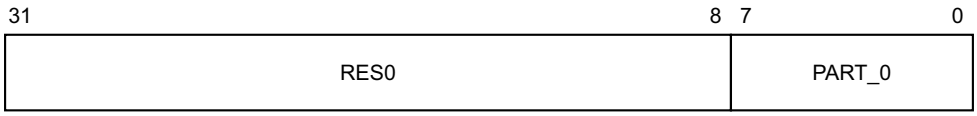
This register is required for CoreSight compliance.

Attributes

CTIPIDR0 is a 32-bit register.

Field descriptions

The CTIPIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

Accessing the CTIPIDR0

CTIPIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFE0

H9.2.30 CTIPIDR1, CTI Peripheral Identification Register 1

The CTIPIDR1 characteristics are:

Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTIPIDR1 is in the Debug power domain.

CTIPIDR1 is optional to implement in the external register interface.

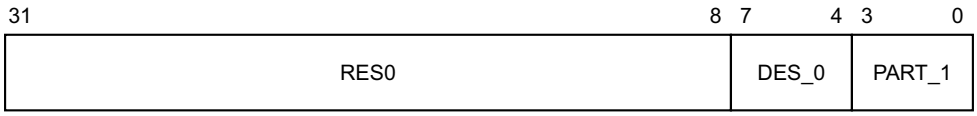
This register is required for CoreSight compliance.

Attributes

CTIPIDR1 is a 32-bit register.

Field descriptions

The CTIPIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is `0b1011`.

PART_1, bits [3:0]

Part number, most significant nibble.

Accessing the CTIPIDR1

CTIPIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFE4`

H9.2.31 CTIPIDR2, CTI Peripheral Identification Register 2

The CTIPIDR2 characteristics are:

Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTIPIDR2 is in the Debug power domain.

CTIPIDR2 is optional to implement in the external register interface.

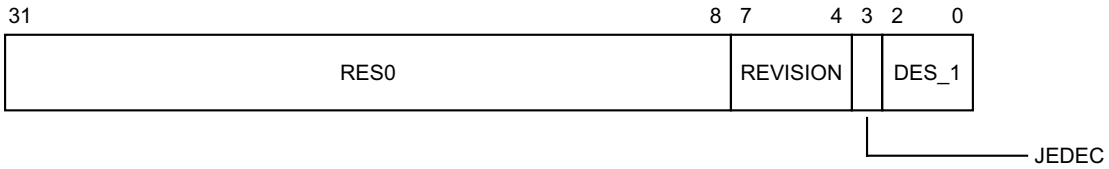
This register is required for CoreSight compliance.

Attributes

CTIPIDR2 is a 32-bit register.

Field descriptions

The CTIPIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is `0b011`.

Accessing the CTIPIDR2

CTIPIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFE8`

H9.2.32 CTIPIDR3, CTI Peripheral Identification Register 3

The CTIPIDR3 characteristics are:

Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTIPIDR3 is in the Debug power domain.

CTIPIDR3 is optional to implement in the external register interface.

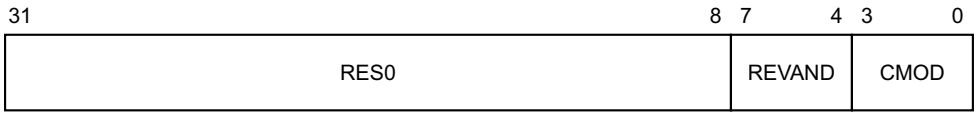
This register is required for CoreSight compliance.

Attributes

CTIPIDR3 is a 32-bit register.

Field descriptions

The CTIPIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using CTIPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

Accessing the CTIPIDR3

CTIPIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	0xFEC

H9.2.33 CTIPIDR4, CTI Peripheral Identification Register 4

The CTIPIDR4 characteristics are:

Purpose

Provides information to identify a CTI component.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

CTIPIDR4 is in the Debug power domain.

CTIPIDR4 is optional to implement in the external register interface.

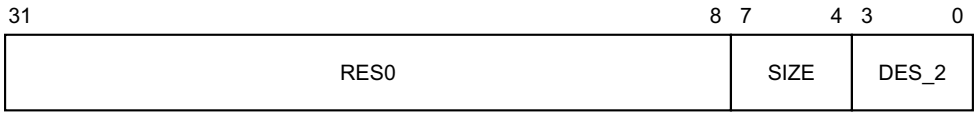
This register is required for CoreSight compliance.

Attributes

CTIPIDR4 is a 32-bit register.

Field descriptions

The CTIPIDR4 bit assignments are:



Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. Log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is `0b0100`.

Accessing the CTIPIDR4

CTIPIDR4 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0xFD0`

H9.2.34 CTITRIGINSTATUS, CTI Trigger In Status register

The CTITRIGINSTATUS characteristics are:

Purpose

Provides the status of the trigger inputs.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

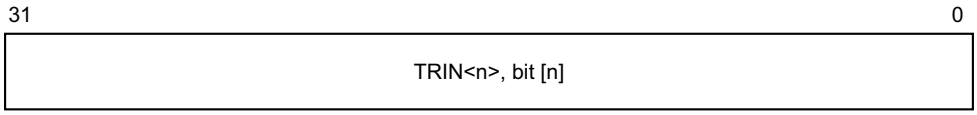
CTITRIGINSTATUS is in the Debug power domain.

Attributes

CTITRIGINSTATUS is a 32-bit register.

Field descriptions

The CTITRIGINSTATUS bit assignments are:



TRIN<n>, bit [n], for n = 0 to 31

Trigger input <n> status.

Bits [31:N] are RAZ. N is the number of CTI triggers implemented as defined by the CTIDEVID.NUMTRIG field.

Possible values of this bit are:

`0` Input trigger n is inactive.

`1` Input trigger n is active.

Not implemented and not-connected input triggers are always inactive.

Accessing the CTITRIGINSTATUS

CTITRIGINSTATUS can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x130`

H9.2.35 CTITRIGOUTSTATUS, CTI Trigger Out Status register

The CTITRIGOUTSTATUS characteristics are:

Purpose

Provides the status of the trigger outputs.

This register is part of the Cross-Trigger Interface registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

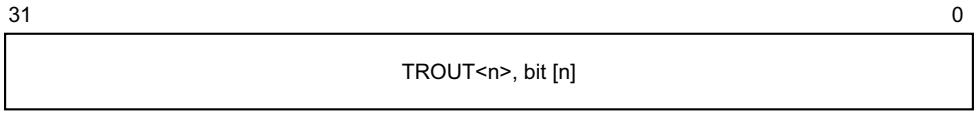
CTITRIGOUTSTATUS is in the Debug power domain.

Attributes

CTITRIGOUTSTATUS is a 32-bit register.

Field descriptions

The CTITRIGOUTSTATUS bit assignments are:



TROUT<n>, bit [n], for n = 0 to 31

Trigger output <n> status.

Bits [31:N] are RAZ. N is the number of CTI triggers implemented as defined by the CTIDEVID.NUMTRIG field.

If output trigger <n> is implemented and connected, possible values of this bit are:

`0` Output trigger n is inactive.

`1` Output trigger n is active.

Otherwise it is IMPLEMENTATION DEFINED whether TROUT<n> is RAZ or behaves as above.

Accessing the CTITRIGOUTSTATUS

CTITRIGOUTSTATUS can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
CTI	`0x134`

Part I

Memory-mapped Components of the ARMv8 Architecture

Chapter I1
System Level Implementation of the Generic Timer

This chapter defines the system level implementation of the optional Generic Timer. It contains the following sections:

Note

- *Generic Timer memory-mapped register descriptions* on page I3-4745 describes the System level Generic Timer registers. These registers are memory-mapped.
- Chapter D6 *The Generic Timer* gives a general description of the Generic Timer, and describes the system control register interface to the Generic Timer.

I1.1 About the Generic Timer specification

Chapter D6 *The Generic Timer* describes the ARM Generic Timer, and its implementation as an optional extension to an ARMv8 processor implementation. Chapter D6 includes the definition of the low-latency System register interface to the Generic Timer Extension. However, the ARM Generic Timer architecture requires the implementation of some parts of the timer at the system level. This system level implementation includes a memory-mapped interface to the timer that:

- Provides some top-level management of the Generic Timer, that is not available from the System register interface from any PE in the system.
- Provides memory-mapped access to Generic Timer features, for system components that cannot implement a System register interface to the timer. The latency of this memory-mapped access can be significantly higher than the latency of System register accesses.

The Generic Timer architecture defines both a counter and a timer. The counter and timer work in combination, but each has a distinct purpose:

- The counter counts the passing of time.
- The timer schedules the triggering of events.

See *About the Generic Timer* on page D6-1784 for more information about the timer and the counter. *Generic Timer example* on page D6-1784 shows a system-wide implementation of the Generic Timer.

Most of this chapter describes the system level implementation of the Generic Timer. *Gray-count scheme for timer distribution scheme* on page I1-4682 describes a possible scheme for distributing the counter value across this system.

I1.1.1 The memory-mapped view of the Generic Timer

The memory-mapped view of the Generic Timer provides:

- Access to the system level features of the Generic Timer:
  - *Memory-mapped counter module* on page I1-4671 describes these features.
  - *Counter module control and status register summary* on page I1-4674 describes the memory-mapped interface to those features.
- Memory-mapped access to the Generic Timer features defined in Chapter D6 *The Generic Timer*. This provides memory-mapped access to different views of the system control registers described in that chapter. *About the memory-mapped view of the counter and timer* on page I1-4676 describes this access.

I1.2 Memory-mapped counter module

The memory-mapped counter module provides top-level control of the system counter. It provides:

- A RW control register CNTCR, that provides:
  - An enable bit for the system counter.
  - An enable bit for Halt-on-Debug. When this is enabled, if the debug halt signal into the system counter is asserted, it halts the system counter. Otherwise, the system counter ignores the state of this halt signal. For more information about Halt-on-Debug, contact ARM.
  - A field that can be written to request a change to the update frequency of the system counter, with a corresponding change to the increment made at each update. For more information see *Control of counter operating frequency and increment* on page I1-4672.

  Writes to this register are rare. In a system that uses security, this register is writable only by Secure writes.
- A RO status register, CNTSR, that provides:
  - A bit that indicates whether the system counter is halted because of an asserted Halt-on-Debug signal.
  - A field that indicates the current update frequency of the system counter. This field can be polled to determine when a requested change to the update frequency has been made.
- Two contiguous RW registers that hold the current system counter value, CNTCV. If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

  The system counter must be disabled before writing to these registers, otherwise the effect of the write is UNPREDICTABLE.

  Writes to these registers are rare. In a system that uses security, these registers are writable only by Secure writes.
- A table of one or more 32-bit entries, where:
  - The first entry defines the *base frequency* of the system counter. This is the maximum frequency at which the counter updates.
  - Each subsequent entry defines an alternative frequency of the system counter, and must be an exact divisor of the base frequency.

  A 32-bit zero entry immediately follows the last table entry.

  This table can be WO or RW. For more information, see *The frequency modes table* on page I1-4672.
- Two contiguous RO registers that hold the current system counter value, CNTCV. If the system supports 64-bit atomic accesses, these two registers must be accessible by such accesses.

These registers are located in two memory *frames*, identified by different base addresses:

- The locations of the RO copies of CNTCV are defined relative to the CNTReadBase base address.
- The locations of all the other registers are defined relative to the CNTControlBase base address.

Note

The final twelve words of the first or only 4KB block of a register memory frame is an ID block.

Counter module control and status register summary on page I1-4674 describes CNTReadBase and CNTControlBase memory maps, and the registers in each frame.

I1.2.1 Control of counter operating frequency and increment

The system counter has a fixed *base frequency*, and must maintain the required counter accuracy, meaning ARM recommends that it does not gain or lose more than ten seconds in a 24-hour period, see *System counter* on page D6-1785. However, the counter can increment at a lower frequency than the base frequency, using a correspondingly larger increment. For example, it can increment by four at a quarter of the base frequency. Any lower-frequency operation, and any switching between operating frequencies, must not reduce the accuracy of the counter.

Control of the system counter frequency and increment is provided only through the memory-mapped counter module. The following sections describe this control:

- *The frequency modes table*
- *Changing the system counter and increment*.

The frequency modes table

The frequency modes table starts at offset `0x20` from CNTControlBase.

Table entries are 32-bits, and each entry specifies a system counter update frequency, in Hz.

The first entry in the table specifies the base frequency of the system counter.

To ensure overall counter accuracy is maintained, any subsequent entries in the table must be exact divisors of the base frequency. That is, ARM strongly recommends that all frequency values in the table are integer power-of-two divisors of the base frequency.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

increment = (base_frequency) / (selected_frequency)

A 32-bit word of zero value marks the end of the table. That is, the word of memory immediately after the last entry in the table must be zero.

The only required entry in the table is the entry for the base frequency.

Typically, the frequency modes table are in RO memory. However, a system implementation might use RW memory for the table, and initialize the table entries as part of its startup sequence. Therefore, the CNTControlBase memory map shows the table region as RO or RW.

ARM strongly recommends that the frequency modes table is not updated once the system is running.

The architecture can support up to 1004 entries in the frequency modes table, and the maximum number of entries is IMPLEMENTATION DEFINED, up to this limit.

Note

ARM considers it unlikely that implementations will require significantly fewer entries than the architectural limit.

Changing the system counter and increment

The value of the CNTCR.FREQ field specifies which frequency modes table entry specifies the system counter update frequency.

Changing the value of CNTCR.FREQ requests a change to the system counter update frequency. To ensure the frequency change does not affect the overall accuracy of the counter, it is made as follows:

- When changing from a higher frequency to a lower frequency, the counter:
  1. Continues running at the higher frequency until the count reaches an integer multiple of the required lower frequency.
  2. Switches to operating at the lower frequency.

- When changing from a lower frequency to a higher frequency, the counter:
  1. Waits until the end of the current lower-frequency cycle.
  2. Makes the counter increment required for operation at that lower frequency.
  3. Switches to operating at the higher frequency.

When the frequency has changed, CNTSR is updated to indicate the new frequency. Therefore, a system component that is waiting for a frequency change can poll CNTSR to detect the change.

I1.3 Counter module control and status register summary

The Counter module control and status registers are memory-mapped registers in the following register memory *frames*:

- A control frame, with base address CNTControlBase.
- A status frame, with base address CNTReadBase.

Each of these register memory frames is at least 4KB in size, or is at least the size of the memory protection granule if this granule size is larger than 4KB. Similarly, each base address must be aligned to 4KB, or to the memory protection granule if that is larger than 4KB.

Note

The memory protection granule is either 4KB or 64KB.

In each register memory frame, the memory at offset `0xFD0-0xFFF` is reserved for twelve 32-bit IMPLEMENTATION DEFINED ID registers, see the CounterID<n> register descriptions for more information.

The counter is assumed to be little-endian.

In an implementation that supports Secure and Non-secure memory spaces, CNTControlBase is implemented only in the Secure memory space.

Table I1-1 shows the CNTControlBase control registers, in order of their offsets from CNTControlBase. *Generic Timer memory-mapped register descriptions* on page I3-4745 describes each of these registers.

Table I1-1 CNTControlBase memory map

Offset	Name	Type	Description
`0x000`	CNTCR	RW	Counter Control Register.
`0x004`	CNTSR	RO	Counter Status Register.
`0x008`	CNTCV[31:0]	RW	Counter Count Value register.
`0x00C`	CNTCV[63:32]	RW	
`0x010-0x01C`	-	RES0	Reserved.
`0x020`	CNTFID0	RO or RW	Frequency modes table, and end marker. CNTFID0 is the base frequency, and each CNTFID*n* is an alternative frequency. For more information see *The frequency modes table* on page I1-4672.
`0x020+4`*n*	CNTFID*n*	RO or RW	
`(0x024+4`*n*`)-0x0BC`	-	RES0	Reserved.
`0x0C0-0x0FC`	-	IMPLEMENTATION DEFINED	Reserved for IMPLEMENTATION DEFINED registers.
`0x100-0xFCC`	-	RES0	Reserved.
`0xFD0-0xFFC`	CounterID<n>	RO	Counter ID registers 0-11.

Table I1-2 shows the CNTReadBase control registers, in order of their offsets from CNTReadBase. *Generic Timer memory-mapped register descriptions* on page I3-4745 describes each of these registers.

Table I1-2 CNTReadBase memory map

Offset	Name	Type	Description
0x000	CNTCV[31:0]	RO	Counter Count Value register
0x004	CNTCV[63:32]	RO	
0x008-0xFCC	-	RES0	Reserved
0xFD0-0xFFC	CounterID<n>	RO	Counter ID registers 0-11

I1.4 About the memory-mapped view of the counter and timer

To provide the Generic Timer functionality to any programmable system components that cannot implement a coprocessor interface to the Generic Timer, the Generic Timer specification defines a memory-mapped component that can be placed close to such a component. ARM recommends that the system implementation includes an instance of this memory-mapped structure for each system component requiring memory-mapped access to the Generic Timer.

The memory map consists of up to 8 timer *frames*. Each timer frame:

- Provides its own set of timers and associated interrupts.
- Is in its own memory protection region that is:
  - In its own memory protection region, with a system-defined size of 4KB or 64KB.
  - At a start address that is aligned to 4KB.

  Note

  The 4KB alignment requirement applies regardless of the memory protection region size.

The base address of a frame is CNTBase*N*, where *N* numbers from 0 up to a maximum permitted value of 7.

The system provides a second view of each implemented CNTBase*N* frame. The base address of the second view of the CNTBase*N* frame is CNTEL0Base*N*, and in this view:

- All registers visible in CNTBase*N* are visible, except for CNTVOFF and CNTEL0ACR.
- The offsets of all visible registers are the same as their offsets in the CNTBase*N* frame.

In addition, the system provides a control frame at base address CNTCTLBase.

The memory protection region and alignment requirements for the CNTEL0Base*N* and CNTCTLBase frames are the same as the requirements for the CNTBase*N* frames.

The system defines the position of each frame in the memory map. This means the values of each of the CNTBase*N*, CNTEL0Base*N*, and CNTCTLBase base addresses is IMPLEMENTATION DEFINED.

The memory-mapped timers are assumed to be little-endian.

The following sections describe the implementation of a memory-mapped view of the counter and timer:

- *The CNTBaseN and CNTEL0BaseN frames* on page I1-4677.
- *The CNTCTLBase frame* on page I1-4679.
- *Providing a complete set of counter and timer features* on page I1-4680.

I1.5 The CNTBase*N* and CNTEL0Base*N* frames

Table I1-3 shows the CNTBase*N* registers, in order of their offsets from CNTBase*N*. Whether a frame includes a virtual timer is IMPLEMENTATION DEFINED. If it does not then memory at offsets `0x030-0x03C` is RAZ/WI. Except for CNTEL0ACR and the CounterID<n> registers, these registers are also implemented in the system control register interface to the Generic Timer.

Generic Timer memory-mapped register descriptions on page I3-4745 describes each of these registers.

Table I1-3 CNTBase*N* memory map

Offset	Register, VMSA	Type	Description
`0x000`	CNTPCT[31:0][a]	RO	Physical Count register
`0x004`	CNTPCT[63:32][a]	RO	
`0x008`	CNTVCT[31:0][a]	RO	Virtual Count register
`0x00C`	CNTVCT[63:32][a]	RO	
`0x010`	CNTFRQ[a]	RO[b]	Counter Frequency register
`0x014`	CNTEL0ACR	RW[c]	Counter EL0 Access Control Register, optional in the CNTBase*N* memory map
`0x018`	CNTVOFF[31:0][a]	RO[d]	Virtual Offset register, if implementation includes EL2
`0x01C`	CNTVOFF[63:32][a]	RO[d]	
`0x020`	CNTP_CVAL[31:0][a]	RW	EL1 Physical Timer CompareValue register
`0x024`	CNTP_CVAL[63:32][a]	RW	
`0x028`	CNTP_TVAL[a]	RW	EL1 Physical TimerValue register
`0x02C`	CNTP_CTL[a]	RW	EL1 Physical Timer Control register
`0x030`	CNTV_CVAL[31:0][a]	RW[c]	Virtual Timer CompareValue register, optional in the CNTBase*N* memory map
`0x034`	CNTV_CVAL[63:32][a]	RW[c]	
`0x038`	CNTV_TVAL[a]	RW[c]	Virtual TimerValue register, optional in the CNTBase*N* memory map
`0x03C`	CNTV_CTL[a]	RW[c]	Virtual Timer Control register, optional in the CNTBase*N* memory map
`0x040-0xFCF`	-	RES0	Reserved
`0xFD0-0xFFC`	CounterID<n>	RO	Counter ID registers 0-11

a. These registers are also defined in the System register interface to the Generic Timer, and therefore are also described in *Generic Timer registers* on page D7-2082 and *Generic Timer registers* on page G5-4271. The bit assignments of the registers are identical in the System register interface and in the memory-mapped system level interface.

b. But must be writable for initial configuration.

c. Address is reserved, RAZ/WI if register not implemented

d. The CNTCTLBase frame includes a RW view of this register.

For any value of N, the layout of the registers in the frame at CNTEL0Base*N* is identical to that at CNTBase*N*, except that:

- CNTVOFF is not visible, and the memory at `0x018-0x01C` is RAZ/WI.
- CNTEL0ACR is never visible, and the memory at `0x014` is always RAZ/WI.

- If implemented in the frame at CNTBase*N*, CNTEL0ACR controls whether CNTPCT, CNTVCT, CNTFRQ, the EL1 Physical Timer, and the Virtual Timer registers are visible in the frame at CNTEL0Base*N*.

  If CNTEL0ACR is not implemented then these registers are not visible in the frame at CNTEL0Base*N*, and their addresses are RAZ/WI.

- If CNTFRQ is visible it is always RO. That is, it is not RW for initial configuration.

If an implementation supports 64-bit atomic accesses, then CNTPCT, CNTVCT, CNTVOFF, CNTP_CVAL, and CNTV_CVAL must be accessible as atomic 64-bit values.

I1.6 The CNTCTLBase frame

The CNTCTLBase frame contains an identification register for the features of the memory-mapped counter and timer implementation, access controls for each CNTBase*N* frame, and a virtual offset register for frames that implement a virtual timer. Table I1-4 shows the CNTCTLBase registers, in order of their offsets from CNTCTLBase. The CNTFRQ and CNTVOFF registers are also implemented in the Secure system control register interface to the Generic Timer.

Generic Timer memory-mapped register descriptions on page I3-4745 describes each of these registers.

Table I1-4 CNTCTLBase memory map

Offset	Register	Type	Security	Description
0x000	CNTFRQ[a]	RW	Secure	Counter Frequency register.
0x004	CNTNSAR	RW	Secure	Counter Non-Secure Access Register.
0x008	CNTTIDR	RO	Both	Counter Timer ID Register.
0x00C- 0x03F	-	RES0	-	Reserved.
0x040+4*N*[b]	CNTACR<n>	RW	Configurable[c]	Counter Access Control Register *N*.
0x060- 0x07F	-	RES0	-	Reserved.
0x080+8*N*[b]	CNTVOFF<n>[31:0][a]	RW[d]	Configurable[c]	Virtual Offset register, if implementation includes EL2. Optional in the CNTCTLBase memory map
0x084+8*N*[b]	CNTVOFF<n>[63:32][a]	RW[d]		
0x0C0- 0xFCF	-	RES0	-	Reserved.
0xFD0- 0xFFC	CounterID<n>	RO	Both	Counter ID registers 0-11.

a. These registers are also defined in the Secure System registers interface to the Generic Timer, and therefore are also described in *Generic Timer registers* on page D7-2082 and *Generic Timer registers* on page G5-4271. The bit assignments of the registers are identical in the System registers interface and in the memory-mapped system level interface.

b. Implemented for each value of *N* from 0 to 7.

c. The CNTNSAR determines the Non-secure accessibility of the CNTACR<n>s and the CNTVOFF<n>s in the CNTCTLBase frame. For more information, see the register descriptions.

d. Address is reserved, RAZ/WI if register not implemented.

I1.7 Providing a complete set of counter and timer features

Using the general model for implementing a memory-mapped interface to the Generic Timer described in this section, the feature set of a System registers counter and timer, in an implementation that includes EL2 and EL3, can be implemented using the following set of timer frames:

- A CNTCTLBase control frame.
- The following CNTBase*N* timer frames:

  Frame 0 Accessible from Non-secure state, with second view and virtual capability. This provides the Non-secure EL1&0 timers.

  Frame 1 Accessible from Non-secure state, with no second view and no virtual capability. This provides the Non-secure EL2 timers.

  Frame 2 Accessible only Secure state, with a second view but no virtual capability. This provides the Secure EL1&0 timers.

In this implementation, the full set of implemented frames, and their configuration in the memory map, is as follows:

CNTCTLBase

The control frame. This frame is located in both Secure and Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

CNTBase0 The first view of the Non-secure EL1&0 timers. This frame is located only in Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible only at EL1.

CNTEL0Base0

The second view of CNTBase0, meaning it is the EL0 view of the Non-secure EL1&0 timers. This frame is located only in Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame can be accessible at EL1, or at EL1 and EL0, but this is not required.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.

CNTBase1 The first and only view of the Non-secure EL2 timers. This frame is located only in Non-secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- In the Non-secure EL2 translation regime, this frame is accessible.
- In the Non-secure EL1&0 translation regime, this frame is not accessible.

CNTBase2 The first view of the Secure EL1&0 timers. This frame is located only in Secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible only at EL1.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

CNTEL0Base2

The second view of CNTBase2, meaning it is the EL0 view of the Secure EL1&0 timers. This frame is located only in Secure physical memory, and:

- In the Secure EL1&0 translation regime, this frame is accessible at EL1 and EL0.
- Because the frame is in Secure memory, it is not accessible in any Non-secure translation regime.

Note

About VMSAv8-32 on page G4-3618 describes the translation regimes.

I1.8 Gray-count scheme for timer distribution scheme

The distribution of the Counter value using a Gray-code provides a relatively simple mechanism to avoid any danger of the count being sampled with an intermediate value even if the clocking is asynchronous. It has a further advantage that the distribution is relatively low power, since only one bit changes on the main distribution wires for each clock tick.

A suitable Gray-coding scheme can be achieved with the following logic:

Gray[N] = Count[N]

Gray[i] = (XOR(Gray[N:i+1])) XOR Count[i] for N–1 >= i >= 0

Count[i] = XOR(Gray[N:i]) for N >= i >= 0

This is for an N+1 bit counter, where Count is a conventional binary count value, and Gray is the corresponding Gray count value.

Note

This scheme has the advantage of being relatively simple to switch, in either direction, between operating with low-frequency and low-precision, and operating with high-frequency and high-precision. To achieve this, the ratio of the frequencies must be 2^n, where n is an integer. A switch-over can occur only on the 2n+1 boundary to avoid losing the Gray-coding property on a switch-over.

Chapter I2
Recommended Memory-mapped Interfaces to the Performance Monitors

This chapter describes the recommended memory-mapped and external debug interfaces to the Performance Monitors. It contains the following section:

- *About the memory-mapped views of the Performance Monitors registers* on page I2-4684.

Note

Performance Monitors memory-mapped register descriptions on page I3-4693 describes the memory-mapped registers for the Performance Monitors.

I2.1 About the memory-mapped views of the Performance Monitors registers

An implementation can provide:

- Memory-mapped access to the Performance Monitors registers. Software running on any processor in a system can use this interface to access counters in the Performance Monitors.
- Access to the Performance Monitors registers through an external debug interface. A debugger can use this interface to access counters in the Performance Monitors.

  ARM recommends that any external debug interface is implemented as defined in the *ARM Debug Interface v5 Architecture Specification*.

  An external debug interface provides a memory-mapped view of the Performance Monitors registers.

Performance Monitors memory-mapped registers summary on page I3-4691 gives the memory map of these registers.

The following sections describe the memory-mapped views of the Performance Monitors registers:

- *Differences in the memory-mapped views of the Performance Monitors registers*.
- *Synchronization of changes to the memory-mapped views*.
- *Access permissions for memory-mapped views of the Performance Monitors*.

In this section, unless the context explicitly indicates otherwise, any reference to *a memory-mapped view* applies equally to a register view using:

- A access through an external debug interface.
- A memory-mapped access.

I2.1.1 Differences in the memory-mapped views of the Performance Monitors registers

A memory-mapped view of the Performance Monitors registers accesses the same registers as the System registers interface described in *Performance Monitors Extension registers* on page D5-1777, except that:

1. The PMSELR is accessible only in the System registers interface.
2. The PMCFGR, PMLAR, PMLSR, PMAUTHSTATUS, PMDEVARCH, PMDEVTYPE, PMPIDR0, PMPIDR1, PMPIDR2, PMPIDR3, PMPIDR4, PMCIDR0, PMCIDR1, PMCIDR2 and PMCIDR3 registers are accessible only in memory-mapped views. *Performance Monitors memory-mapped register descriptions* on page I3-4693 describes these registers.
3. The following controls do not affect the memory-mapped view:
   - PMSELR.
   - PMUSERENR.
   - HDCR.{TPM, TPMCR, HPMN}.

   Instead, see the register descriptions in Chapter I3 *Memory-Mapped System Register Descriptions*.

I2.1.2 Synchronization of changes to the memory-mapped views

If a Performance Monitor is visible in both system register and a memory-mapped views, and is accessed simultaneously through these two mechanisms, the behavior must be as if the access occurred atomically in any order. For more information, see *Synchronization of changes to the external debug registers* on page H8-4517.

I2.1.3 Access permissions for memory-mapped views of the Performance Monitors

For more information, see *External debug interface register access permissions* on page H8-4523.

Table I2-1 on page I2-4685 shows the access permissions for the Performance Monitors registers in a v8 Debug implementation. This table uses the following terms:

DLK When the OS Double Lock is locked, EDPRSR.DLK == 1, accesses to some registers produce an error. Applies to both interfaces.

EPMAD When `AllowExternalPMUAccess()` == FALSE, external debug access is disabled. See also *Behavior of a not permitted memory-mapped access* on page H8-4522.

Error Indicates that the access gives an error response.

Default This shows the default access permissions, if none of the conditions in this list prevent access to the register.

Off When EDPRSR.PU == 0, the Core power domain is completely off, or in a low-power state where the Core power domain registers cannot be accessed.

Note

If debug power is off, then all external debug interface accesses return an error.

OSLK When the OS Lock is locked, OSLAR_EL1.OSLK == 1, accesses to some registers produces an error. This column shows the effect of this control on accesses using the external debug interface.

SLK This indicates the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software lock is locked. See *Register access permissions for memory-mapped accesses* on page H8-4521.

For all other accesses, this column is ignored.

- Indicates that the control has no effect on the behavior of the access:
  - If no other control affects the behavior, the Default access behavior applies.
  - However, another control might determine the behavior.

Table I2-1 Access permissions for the Performance Monitors registers

Offset	Register	Domain	Off	DLK	OSLK	EPMAD	Default	SLK
0x000+8xn	PMEVCNTR<n>_EL0[a]	Core	Error	Error	Error	Error	RW	RO
0x0F8	PMCCNTR_EL0[31:0]	Core	Error	Error	Error	Error	RW	RO
0x0FC	PMCCNTR_EL0[63:32]	Core	Error	Error	Error	Error	RW	RO
0x400+4xn	PMEVTYPER<n>_EL0[a]	Core	Error	Error	Error	Error	RW	RO
0x47C	PMCCFILTR_EL0	Core	Error	Error	Error	Error	RW	RO
0x600-0x6FC	-	-	Access is IMPLEMENTATION DEFINED					
0xA00-0xBFC	-	-	Access is IMPLEMENTATION DEFINED					
0xC00	PMCNTENSET_EL0	Core	Error	Error	Error	Error	RW	RO
0xC20	PMCNTENCLR_EL0	Core	Error	Error	Error	Error	RW	RO
0xC40	PMINTENSET_EL1	Core	Error	Error	Error	Error	RW	RO
0xC60	PMINTENCLR_EL1	Core	Error	Error	Error	Error	RW	RO
0xC80	PMOVSCLR_EL0	Core	Error	Error	Error	Error	RW	RO
0xCA0	PMSWINC_EL0[b]	Core	Error	Error	Error	Error	WO	WI
0xCC0	PMOVSSET_EL0	Core	Error	Error	Error	Error	RW	RO
0xD80-0xDFC	-	-	Access is IMPLEMENTATION DEFINED					
0xE00	PMCFGR	Core	Error	Error	Error	Error	RO	RO
0xE04	PMCR_EL0	Core	Error	Error	Error	Error	RW	RO

Table I2-1 Access permissions for the Performance Monitors registers (continued)

Offset	Register	Domain	Off	DLK	OSLK	EPMAD	Default	SLK
0xE20	PMCEID0_EL0	Core	Error	Error	Error	Error	RO	RO
0xE24	PMCEID1_EL0	Core	Error	Error	Error	Error	RO	RO
0xE80-0xEFC	Integration registers	-	Access is IMPLEMENTATION DEFINED					
0xF00-0xFFC	*Management registers and CoreSight compliance* on page AppxB-4878							

a. Implemented counters only. *n* is the counter number.
b. Only if the OPTIONAL PMSWINC_EL0 register is implemented in the external debug interface.

I2.1.4 Power domains and Performance Monitors registers reset

For ARMv8-A implementations, ARM recommends that Performance Monitors are implemented as part of the core power domain, not as part of a separate debug power domain. There is no interface to access the Performance Monitors registers when the core power domain is powered down.

A Warm or Cold reset sets the Performance Monitors registers to their reset values. An External Debug reset does not change the values of the Performance Monitors registers.

For more information about the reset scheme recommended for a v8 Debug implementation see Chapter H6 *Debug Reset and Powerdown Support*.

Table I2-2 shows the Performance Monitors register resets for writable register fields. The column headings use the following terms:

64 This is the architectural reset value when resetting into AArch64 state.

32 This is the architectural reset value when resetting into AArch32 state.

- This indicates an IMPLEMENTATION DEFINED reset value on the specified reset. This might be UNKNOWN.

Note

This table does not include:

- Read-only identification registers and fields that have a fixed value. In this case, the reset value is that fixed value. An example of this is PMCR_EL0.N.
- Write-only registers and fields that only have an effect on writes. These do not have a reset value. An example of this is PMSWINC_EL0.
- IMPLEMENTATION DEFINED registers, In this case, the reset domains are IMPLEMENTATION DEFINED. The reset values are IMPLEMENTATION DEFINED and might be UNKNOWN.

Table I2-2 Performance Monitors system register resets

Register	Domain	Field	64	32	Description
PMCR_EL0	Warm	DP	-	0	Disable PMCCNTR_EL0 when prohibited
		X	-	0	Export enable
		D	-	0	Clock divider
		E	0	0	Performance Monitors enable

Table I2-2 Performance Monitors system register resets (continued)

Register	Domain	Field	64	32	Description
PMCNTENSET_EL0 PMCNTENCLR_EL0	Warm	-	-	-	All fields in register
PMOVSSET_EL0 PMOVSCLR_EL0	Warm	-	-	-	All fields in register
PMSELR_EL0	Warm	SEL	-	-	Selected event counter
PMCCNTR_EL0	Warm	-	-	-	All fields in register
PMEVTYPER<n>_EL0	Warm	-	-	-	All fields in register
PMCCFILTR_EL0	Warm	[31:26]	-	0x00	PMCCNTR_EL0 filtering controls
PMEVCNTR<n>_EL0	Warm	-	-	-	All fields in register
PMUSERENR_EL0	Warm	ER	-	0	Enable counter read access in EL0
		CR	-	0	Enable PMCCNTR_EL0 read access in EL0
		SW	-	0	Enable PMSWINC_EL0 write access in EL0
		EN	-	0	Enable Performance Monitors access in EL0
PMINTENSET_EL1 PMINTENCLR_EL1	Warm	-	-	-	All fields in register

Chapter I3
Memory-Mapped System Register Descriptions

This chapter describes the memory-mapped system control registers.

It contains the following items:

I3.1 About the memory-mapped system register descriptions

This chapter describes the memory-mapped system control registers other than the memory-mapped debug registers. That is, it describes:

The memory-mapped view of the Performance Monitors registers

- *Performance Monitors memory-mapped registers summary* on page I3-4691 lists these registers and describes their memory map.
- *Performance Monitors memory-mapped register descriptions* on page I3-4693 describes each of the memory-mapped registers.

Chapter I2 *Recommended Memory-mapped Interfaces to the Performance Monitors* describes the recommended interface to these registers.

Note

Chapter D5 *The Performance Monitors Extension* describes the Performance Monitors. Chapter D7 *AArch64 System Register Descriptions* and Chapter G5 *AArch32 System Register Descriptions* describe the System register interfaces to the Performance Monitor.

The registers for the system-level Generic Timer component

Any implementation that includes the Generic Timer must include the memory-mapped system-level component described in Chapter I1 *System Level Implementation of the Generic Timer*. In this chapter:

- *Generic Timer memory-mapped registers overview* on page I3-4744 gives an overview of the registers, referring to Chapter I1 for more information.
- *Generic Timer memory-mapped register descriptions* on page I3-4745 describes each of the memory-mapped registers.

Note

Chapter D6 *The Generic Timer* describes the Generic Timer component that is accessible using the System registers.

Note

Chapter H9 *External Debug Register Descriptions* describes the memory-mapped debug registers.

I3.2 Performance Monitors memory-mapped registers summary

The locations of the registers in the memory-mapped view of the Performance Monitors are defined as offsets from a system-defined base address. *Performance Monitors memory-mapped register view* defines this memory map.

I3.2.1 Performance Monitors memory-mapped register view

Table I3-1 shows the memory-mapped view of the Performance Monitors registers. All other entries in this memory map are reserved.

Note

- Counters that are reserved because HDCR.HPMN has been changed from its reset value remain visible in any memory-mapped view.
- The registers that relate to an implemented event counter, PMN*x*, are PMEVCNTR<n> and PMEVTYPER<n>.

Each entry in the *Name* column links to the register description in *Performance Monitors memory-mapped register descriptions* on page I3-4693, and:

- If the *System register?* column of the table shows that the register is a System register, the memory-mapped interface provides a view of the System register described in:
  - *Performance Monitors registers* on page D7-2046, for the AArch64 System register.
  - *Performance Monitors registers* on page G5-4232, for the AArch32 System register.
- Otherwise, the register is accessible only using the memory-mapped interface.

Table I3-1 Performance Monitors memory-mapped register views

Offset	Type	Name	Description	System register?
0x000+ 8xn	RW	PMEVCNTR<n>_EL0	Performance Monitors Event Counter Register.	Yes
0x0F8-0x0FC	RW	PMCCNTR_EL0[31:0] PMCCNTR_EL0[63:32]	Performance Monitors Cycle Counter Register[a]	Yes
0x400+ 4xn	RW	PMEVTYPER<n>_EL0	Performance Monitors Event Type and Filter Register.	Yes
0x47C	RW	PMCCFILTR_EL0	Performance Monitors Cycle Counter Filter Register	Yes
0x600-0x6FC	-	-	IMPLEMENTATION DEFINED	-

a. The interface must support at least single-copy atomic 32-bit accesses. If single-copy atomic 64-bit access to the registers is not possible, software must use a high-low-high read access to read the counter value if the counter is enabled.

b. CoreSight interface registers, see *Management registers and CoreSight compliance* on page AppxB-4878.

c. The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.

I3.3 Performance Monitors memory-mapped register descriptions

This section describes the Performance Monitoring registers. *Performance Monitors memory-mapped registers summary* on page I3-4691 lists these registers in their memory map.

I3.3.1 PMAUTHSTATUS, Performance Monitors Authentication Status register

The PMAUTHSTATUS characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for Performance Monitors.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMAUTHSTATUS is in the Debug power domain.

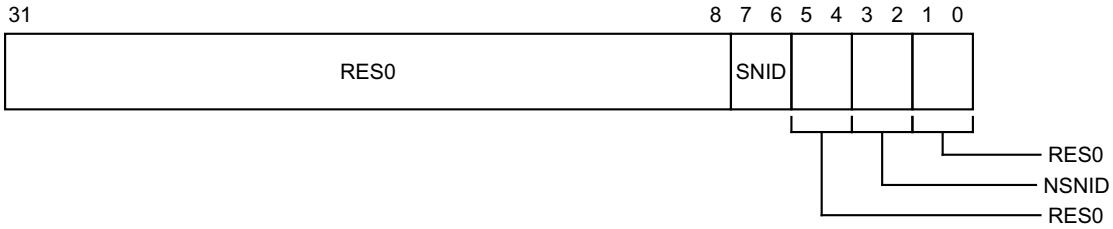
This register is OPTIONAL, and is required for CoreSight compliance. ARM recommends that this register is implemented.

Attributes

PMAUTHSTATUS is a 32-bit register.

Field descriptions

The PMAUTHSTATUS bit assignments are:



Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Holds the same value as DBGAUTHSTATUS_EL1.SNID.

Bits [5:4]

Reserved, RES0.

NSNID, bits [3:2]

Holds the same value as DBGAUTHSTATUS_EL1.NSNID.

Bits [1:0]

Reserved, RES0.

Accessing the PMAUTHSTATUS

PMAUTHSTATUS can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFB8

I3.3.2 PMCCFILTR_EL0, Performance Monitors Cycle Counter Filter Register

The PMCCFILTR_EL0 characteristics are:

Purpose

Determines the modes in which the Cycle Counter, PMCCNTR_EL0, increments.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

PMCCFILTR_EL0 is architecturally mapped to AArch64 register PMCCFILTR_EL0.

PMCCFILTR_EL0 is architecturally mapped to AArch32 register PMCCFILTR.

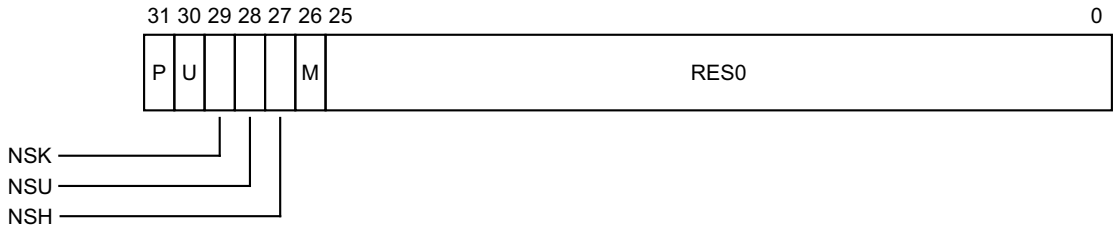
PMCCFILTR_EL0 is in the Core power domain.

Attributes

PMCCFILTR_EL0 is a 32-bit register.

Field descriptions

The PMCCFILTR_EL0 bit assignments are:



P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

`0` Count cycles in EL1.

`1` Do not count cycles in EL1.

U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

`0` Count cycles in EL0.

`1` Do not count cycles in EL0.

NSK, bit [29]

Non-secure kernel modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

NSU, bit [28]

Non-secure user modes filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

NSH, bit [27]

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

`0` Do not count cycles in EL2.

`1` Count cycles in EL2.

M, bit [26]

Secure EL3 filtering bit. Most applications can ignore this bit and set the value to zero. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

Bits [25:0]

Reserved, RES0.

Accessing the PMCCFILTR_EL0

PMCCFILTR_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0x47C`

I3.3.3 PMCCNTR_EL0, Performance Monitors Cycle Counter

The PMCCNTR_EL0 characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

PMCCNTR_EL0 is architecturally mapped to AArch64 register PMCCNTR_EL0.

PMCCNTR_EL0 is architecturally mapped to AArch32 register PMCCNTR.

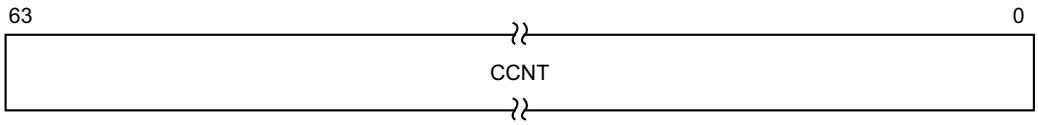
PMCCNTR_EL0 is in the Core power domain.

Attributes

PMCCNTR_EL0 is a 64-bit register.

Field descriptions

The PMCCNTR_EL0 bit assignments are:



CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR_EL0.{LC,D}, the cycle count increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

The cycle count can be reset to zero by writing 1 to PMCR_EL0.C.

Accessing the PMCCNTR_EL0

PMCCNTR_EL0[31:0] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0x0F8

PMCCNTR_EL0[63:32] can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0x0FC

I3.3.4 PMCEID0_EL0, Performance Monitors Common Event Identification register 0

The PMCEID0_EL0 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

Configurations

PMCEID0_EL0 is architecturally mapped to AArch64 register PMCEID0_EL0.

PMCEID0_EL0 is architecturally mapped to AArch32 register PMCEID0.

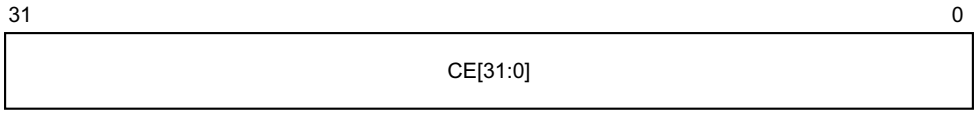
PMCEID0_EL0 is in the Core power domain.

Attributes

PMCEID0_EL0 is a 32-bit register.

Field descriptions

The PMCEID0_EL0 bit assignments are:



CE[31:0], bits [31:0]

Common architectural and microarchitectural feature events that can be counted by the PMU event counters.

For each bit described in the following table, the event is implemented if the bit is set to 1, or not implemented if the bit is set to 0.

Bit	Event number	Event mnemonic
31	0x01F	L1D_CACHE_ALLOCATE
30	0x01E	CHAIN
29	0x01D	BUS_CYCLES
28	0x01C	TTBR_WRITE_RETIRED
27	0x01B	INST_SPEC
26	0x01A	MEMORY_ERROR
25	0x019	BUS_ACCESS

Bit	Event number	Event mnemonic
24	0x018	L2D_CACHE_WB
23	0x017	L2D_CACHE_REFILL
22	0x016	L2D_CACHE
21	0x015	L1D_CACHE_WB
20	0x014	L1I_CACHE
19	0x013	MEM_ACCESS
18	0x012	BR_PRED
17	0x011	CPU_CYCLES
16	0x010	BR_MIS_PRED
15	0x00F	UNALIGNED_LDST_RETIRED
14	0x00E	BR_RETURN_RETIRED
13	0x00D	BR_IMMED_RETIRED
12	0x00C	PC_WRITE_RETIRED
11	0x00B	CID_WRITE_RETIRED
10	0x00A	EXC_RETURN
9	0x009	EXC_TAKEN
8	0x008	INST_RETIRED
7	0x007	ST_RETIRED
6	0x006	LD_RETIRED
5	0x005	L1D_TLB_REFILL
4	0x004	L1D_CACHE
3	0x003	L1D_CACHE_REFILL
2	0x002	L1I_TLB_REFILL
1	0x001	L1I_CACHE_REFILL
0	0x000	SW_INCR

Accessing the PMCEID0_EL0

PMCEID0_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xE20

I3.3.5 PMCEID1_EL0, Performance Monitors Common Event Identification register 1

The PMCEID1_EL0 characteristics are:

Purpose

Reserved for future indication of which common architectural and common microarchitectural feature events are implemented.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

Configurations

PMCEID1_EL0 is architecturally mapped to AArch64 register PMCEID1_EL0.

PMCEID1_EL0 is architecturally mapped to AArch32 register PMCEID1.

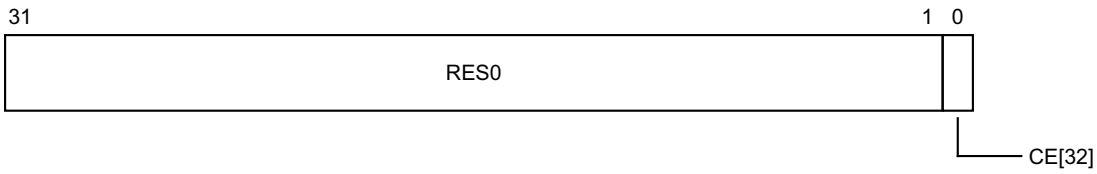
PMCEID1_EL0 is in the Core power domain.

Attributes

PMCEID1_EL0 is a 32-bit register.

Field descriptions

The PMCEID1_EL0 bit assignments are:



Bits [31:1]

Reserved, RES0.

CE[32], bit [0]

Common architectural and microarchitectural feature events that can be counted by the PMU event counters.

For the bit described in the following table, the event is implemented if the bit is set to 1, or not implemented if the bit is set to 0.

Bit	Event number	Event mnemonic
0	0x020	L2D_CACHE_ALLOCATE

Accessing the PMCEID1_EL0

PMCEID1_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xE24

I3.3.6 PMCFGR, Performance Monitors Configuration Register

The PMCFGR characteristics are:

Purpose

Contains PMU-specific configuration data.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RO

Configurations

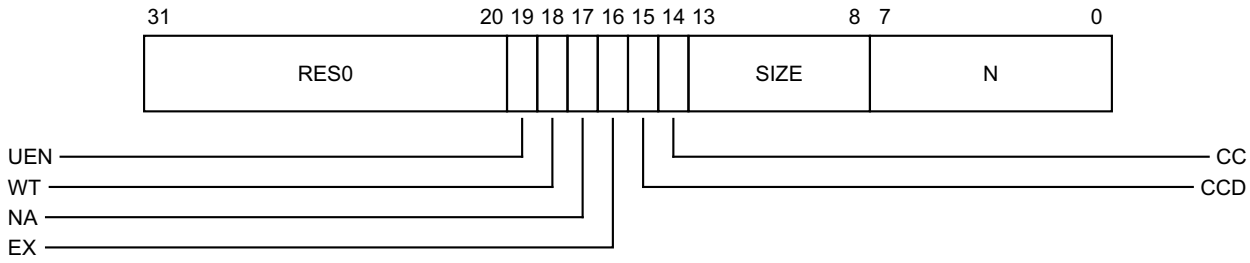
PMCFGR is in the Core power domain.

Attributes

PMCFGR is a 32-bit register.

Field descriptions

The PMCFGR bit assignments are:



Bits [31:20]

Reserved, RES0.

UEN, bit [19]

User-mode Enable Register supported. PMUSERENR_EL0 is not visible in the external debug interface, so this bit is RES0.

WT, bit [18]

This feature is not supported, so this bit is RES0.

NA, bit [17]

This feature is not supported, so this bit is RES0.

EX, bit [16]

Export supported. Value is IMPLEMENTATION DEFINED.

`0` PMCR_EL0.X is RES0.

1 PMCR_EL0.X is read/write.

CCD, bit [15]

Cycle counter has prescaler. This is RES1 if AArch32 is supported at any EL, and RES0 otherwise.

`0` PMCR_EL0.D is RES0.

`1` PMCR_EL0.D is read/write.

CC, bit [14]

Dedicated cycle counter (counter 31) supported. This bit is RES1.

SIZE, bits [13:8]

Size of counters. This field determines the spacing of counters in the memory-map.

In v8-A the counters are at doubleword-aligned addresses, and the largest counter is 64-bits, so this field is `0b111111`.

N, bits [7:0]

Number of counters implemented in addition to the cycle counter, PMCCNTR_EL0. The maximum number of event counters is 31, so bits[7:5] are always RES0.

`00000000` Only PMCCNTR_EL0 implemented.

`00000001` PMCCNTR_EL0 plus one event counter implemented.

and so on up to `00011111`, which indicates PMCCNTR_EL0 and 31 event counters implemented.

Accessing the PMCFGR

PMCFGR can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xE00`

I3.3.7 PMCIDR0, Performance Monitors Component Identification Register 0

The PMCIDR0 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMCIDR0 is in the Debug power domain.

PMCIDR0 is optional to implement in the external register interface.

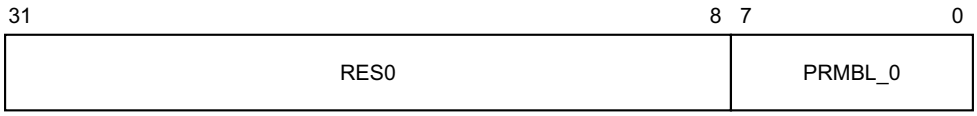
This register is required for CoreSight compliance.

Attributes

PMCIDR0 is a 32-bit register.

Field descriptions

The PMCIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_0, bits [7:0]

Preamble. Must read as `0x0D`.

Accessing the PMCIDR0

PMCIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFF0`

I3.3.8 PMCIDR1, Performance Monitors Component Identification Register 1

The PMCIDR1 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMCIDR1 is in the Debug power domain.

PMCIDR1 is optional to implement in the external register interface.

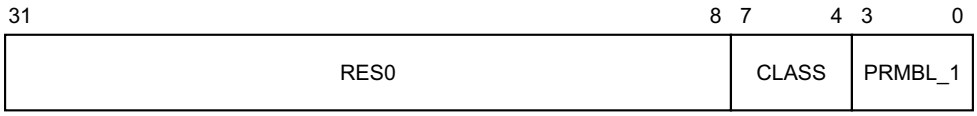
This register is required for CoreSight compliance.

Attributes

PMCIDR1 is a 32-bit register.

Field descriptions

The PMCIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

CLASS, bits [7:4]

Component class. Reads as `0x9`, debug component.

PRMBL_1, bits [3:0]

Preamble. RAZ.

Accessing the PMCIDR1

PMCIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFF4`

I3.3.9 PMCIDR2, Performance Monitors Component Identification Register 2

The PMCIDR2 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMCIDR2 is in the Debug power domain.

PMCIDR2 is optional to implement in the external register interface.

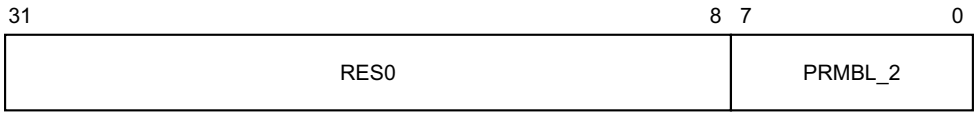
This register is required for CoreSight compliance.

Attributes

PMCIDR2 is a 32-bit register.

Field descriptions

The PMCIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_2, bits [7:0]

Preamble. Must read as `0x05`.

Accessing the PMCIDR2

PMCIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFF8`

I3.3.10 PMCIDR3, Performance Monitors Component Identification Register 3

The PMCIDR3 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMCIDR3 is in the Debug power domain.

PMCIDR3 is optional to implement in the external register interface.

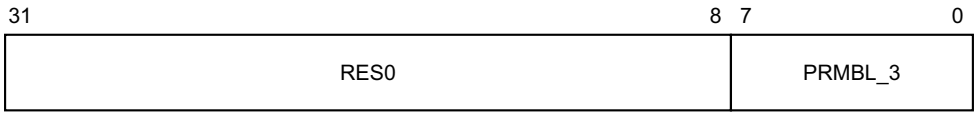
This register is required for CoreSight compliance.

Attributes

PMCIDR3 is a 32-bit register.

Field descriptions

The PMCIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

PRMBL_3, bits [7:0]

Preamble. Must read as `0xB1`.

Accessing the PMCIDR3

PMCIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFFC`

I3.3.11 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register

The PMCNTENCLR_EL0 characteristics are:

Purpose

Disables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<x>. Reading this register shows which counters are enabled.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

PMCNTENCLR_EL0 is architecturally mapped to AArch64 register PMCNTENCLR_EL0.

PMCNTENCLR_EL0 is architecturally mapped to AArch32 register PMCNTENCLR.

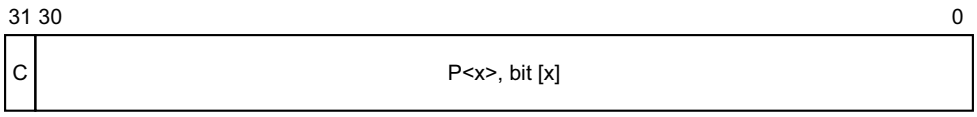
PMCNTENCLR_EL0 is in the Core power domain.

Attributes

PMCNTENCLR_EL0 is a 32-bit register.

Field descriptions

The PMCNTENCLR_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 disable bit. Disables the cycle counter register. Possible values are:

`0` When read, means the cycle counter is disabled. When written, has no effect.

`1` When read, means the cycle counter is enabled. When written, disables the cycle counter.

P<x>, bit [x], for x = 0 to 30

Event counter disable bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI. N is the value in PMCR_EL0.N.

Possible values of each bit are:

`0` When read, means that PMEVCNTR<x> is disabled. When written, has no effect.

`1` When read, means that PMEVCNTR<x> is enabled. When written, disables PMEVCNTR<x>.

Accessing the PMCNTENCLR_EL0

PMCNTENCLR_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xC20

I3.3.12 PMCNTENSET_EL0, Performance Monitors Count Enable Set register

The PMCNTENSET_EL0 characteristics are:

Purpose

Enables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<x>. Reading this register shows which counters are enabled.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

PMCNTENSET_EL0 is architecturally mapped to AArch64 register PMCNTENSET_EL0.

PMCNTENSET_EL0 is architecturally mapped to AArch32 register PMCNTENSET.

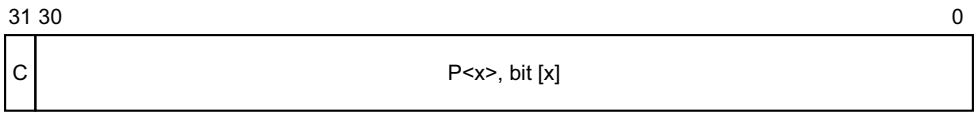
PMCNTENSET_EL0 is in the Core power domain.

Attributes

PMCNTENSET_EL0 is a 32-bit register.

Field descriptions

The PMCNTENSET_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 enable bit. Enables the cycle counter register. Possible values are:

`0` When read, means the cycle counter is disabled. When written, has no effect.

`1` When read, means the cycle counter is enabled. When written, enables the cycle counter.

P<x>, bit [x], for x = 0 to 30

Event counter enable bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI. N is the value in PMCR_EL0.N.

Possible values of each bit are:

`0` When read, means that PMEVCNTR<x> is disabled. When written, has no effect.

`1` When read, means that PMEVCNTR<x> event counter is enabled. When written, enables PMEVCNTR<x>.

Accessing the PMCNTENSET_EL0

PMCNTENSET_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xC00

I3.3.13 PMCR_EL0, Performance Monitors Control Register

The PMCR_EL0 characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

PMCR_EL0 is architecturally mapped to AArch64 register PMCR_EL0.

PMCR_EL0 is architecturally mapped to AArch32 register PMCR.

PMCR_EL0 is in the Core power domain.

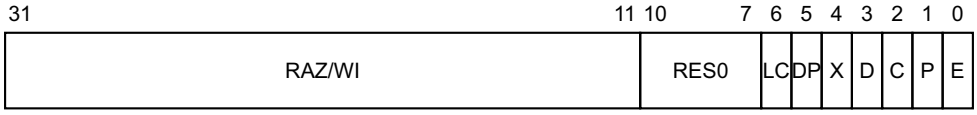
Bits [31:11] of this register must be implemented as RAZ/WI despite the mapping to the internal PMCR system register. An external agent must use other means to discover this information, such as PMCFGR and the ID registers.

Attributes

PMCR_EL0 is a 32-bit register.

Field descriptions

The PMCR_EL0 bit assignments are:



Bits [31:11]

Reserved, RAZ/WI.

Bits [10:7]

Reserved, RES0.

LC, bit [6]

Long cycle counter enable. Determines which PMCCNTR_EL0 bit generates an overflow recorded by PMOVSR[31].

0 Cycle counter overflow on increment that changes PMCCNTR_EL0[31] from 1 to 0.

1 Cycle counter overflow on increment that changes PMCCNTR_EL0[63] from 1 to 0.

ARM deprecates use of PMCR_EL0.LC = 0.

DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

0 PMCCNTR_EL0, if enabled, counts when event counting is prohibited.

1 PMCCNTR_EL0 does not count when event counting is prohibited.

Event counting is prohibited when ProfilingProhibited(IsSecure(),PSTATE.EL) == TRUE.

This bit is RW.

X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

0 Do not export events.

1 Export events where not prohibited.

This bit is used to permit events to be exported to another debug device, such as an OPTIONAL trace extension, over an event bus. If the implementation does not include such an event bus, this bit is RAZ/WI.

This bit does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the processor.

If the implementation does not include an exported event stream, this bit is RAZ/WI. Otherwise this bit is RW.

D, bit [3]

Clock divider. The possible values of this bit are:

0 When enabled, PMCCNTR_EL0 counts every clock cycle.

1 When enabled, PMCCNTR_EL0 counts once every 64 clock cycles.

This bit is RW.

If PMCR_EL0.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.

ARM deprecates use of PMCR.D = 1.

C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

0 No action.

1 Reset PMCCNTR_EL0 to zero.

This bit is always RAZ.

Resetting PMCCNTR_EL0 does not clear the PMCCNTR_EL0 overflow bit to 0.

P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

0 No action.

1 Reset all event counters, not including PMCCNTR_EL0, to zero.

This bit is always RAZ.

Resetting the event counters does not clear any overflow bits to 0.

E, bit [0]

Enable. The possible values of this bit are:

0 All counters, including PMCCNTR_EL0, are disabled.

1 All counters are enabled by PMCNTENSET_EL0.

This bit is RW.

Accessing the PMCR_EL0

PMCR_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xE04

I3.3.14 PMDEVAFF0, Performance Monitors Device Affinity register 0

The PMDEVAFF0 characteristics are:

Purpose

Copy of the low half of the processor MPIDR_EL1 register that allows a debugger to determine which processor in a multiprocessor system the Performance Monitor component relates to.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMDEVAFF0 is in the Debug power domain.

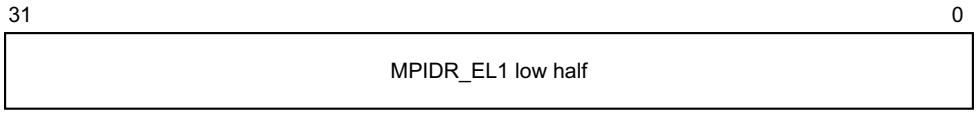
PMDEVAFF0 is optional to implement in the external register interface.

Attributes

PMDEVAFF0 is a 32-bit register.

Field descriptions

The PMDEVAFF0 bit assignments are:



Bits [31:0]

MPIDR_EL1 low half. Read-only copy of the low half of MPIDR_EL1, as seen from the highest implemented exception level.

Accessing the PMDEVAFF0

PMDEVAFF0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFA8

I3.3.15 PMDEVAFF1, Performance Monitors Device Affinity register 1

The PMDEVAFF1 characteristics are:

Purpose

Copy of the high half of the processor MPIDR_EL1 register that allows a debugger to determine which processor in a multiprocessor system the Performance Monitor component relates to.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMDEVAFF1 is in the Debug power domain.

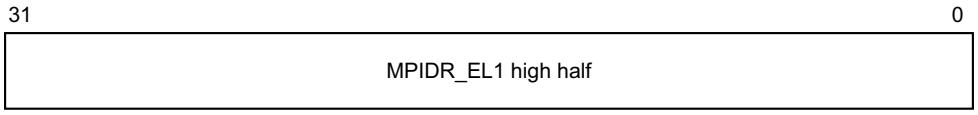
PMDEVAFF1 is optional to implement in the external register interface.

Attributes

PMDEVAFF1 is a 32-bit register.

Field descriptions

The PMDEVAFF1 bit assignments are:



Bits [31:0]

MPIDR_EL1 high half. Read-only copy of the high half of MPIDR_EL1, as seen from the highest implemented exception level.

Accessing the PMDEVAFF1

PMDEVAFF1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFAC

I3.3.16 PMDEVARCH, Performance Monitors Device Architecture register

The PMDEVARCH characteristics are:

Purpose

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMDEVARCH is in the Debug power domain.

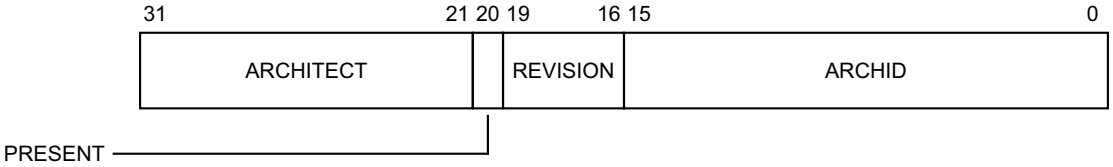
PMDEVARCH is optional to implement in the external register interface.

Attributes

PMDEVARCH is a 32-bit register.

Field descriptions

The PMDEVARCH bit assignments are:



ARCHITECT, bits [31:21]

Defines the architecture of the component. For Performance Monitors, this is ARM Limited.

Bits [31:28] are the JEP 106 continuation code, `0x4`.

Bits [27:21] are the JEP 106 ID code, `0x3B`.

PRESENT, bit [20]

When set to 1, indicates that the DEVARCH is present.

This field is 1 in v8-A.

REVISION, bits [19:16]

Defines the architecture revision. For architectures defined by ARM this is the minor revision.

For Performance Monitors, the revision defined by v8-A is `0x0`.

All other values are reserved.

ARCHID, bits [15:0]

Defines this part to be a v8-A debug component. For architectures defined by ARM this is further subdivided.

For Performance Monitors:

- Bits [15:12] are the architecture version, `0x2`.
- Bits [11:0] are the architecture part number, `0xA16`.

This corresponds to Performance Monitors architecture version PMUv3.

Accessing the PMDEVARCH

PMDEVARCH can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFBC`

I3.3.17 PMDEVTYPE, Performance Monitors Device Type register

The PMDEVTYPE characteristics are:

Purpose

Indicates to a debugger that this component is part of a processor's performance monitor interface.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMDEVTYPE is in the Debug power domain.

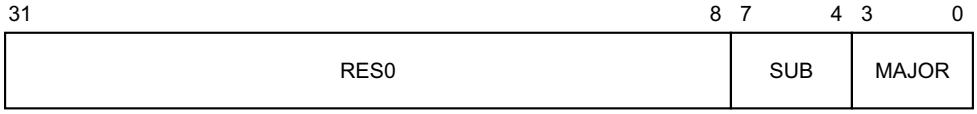
PMDEVTYPE is optional to implement in the external register interface.

Attributes

PMDEVTYPE is a 32-bit register.

Field descriptions

The PMDEVTYPE bit assignments are:



Bits [31:8]

Reserved, RES0.

SUB, bits [7:4]

Subtype. Must read as `0x1` to indicate this is a processor component.

MAJOR, bits [3:0]

Major type. Must read as `0x6` to indicate this is a performance monitor component.

Accessing the PMDEVTYPE

PMDEVTYPE can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFCC`

I3.3.18 PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>_EL0 characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

External accesses to the performance monitors ignore PMUSERENR_EL0 and, if implemented, MDCR_EL2.{TPM, TPMCR, HPMN} and MDCR_EL3.TPM. This means that all counters are accessible regardless of the current EL or privilege of the access.

Configurations

PMEVCNTR<n>_EL0 is architecturally mapped to AArch64 register PMEVCNTR<n>_EL0.

PMEVCNTR<n>_EL0 is architecturally mapped to AArch32 register PMEVCNTR<n>.

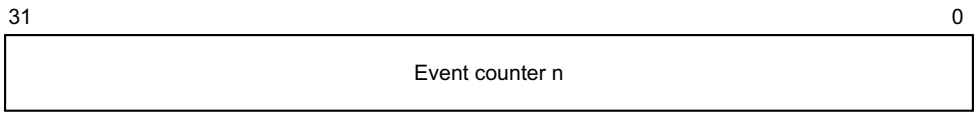
PMEVCNTR<n>_EL0 is in the Core power domain.

Attributes

PMEVCNTR<n>_EL0 is a 32-bit register.

Field descriptions

The PMEVCNTR<n>_EL0 bit assignments are:



Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

Accessing the PMEVCNTR<n>_EL0

PMEVCNTR<n>_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0x000 + 8n

I3.3.19 PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n>_EL0 characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

PMEVTYPER<n>_EL0 is architecturally mapped to AArch64 register PMEVTYPER<n>_EL0.

PMEVTYPER<n>_EL0 is architecturally mapped to AArch32 register PMEVTYPER<n>.

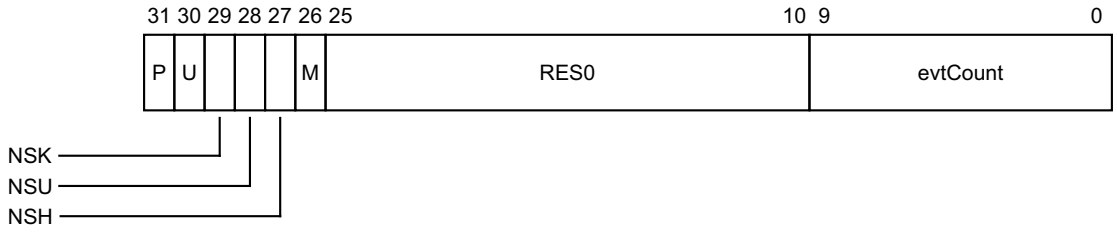
PMEVTYPER<n>_EL0 is in the Core power domain.

Attributes

PMEVTYPER<n>_EL0 is a 32-bit register.

Field descriptions

The PMEVTYPER<n>_EL0 bit assignments are:



P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

`0` Count events in EL1.

`1` Do not count events in EL1.

U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

`0` Count events in EL0.

`1` Do not count events in EL0.

NSK, bit [29]

Non-secure kernel modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

NSU, bit [28]

Non-secure user modes filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted.

Otherwise, events in Non-secure EL0 are not counted.

NSH, bit [27]

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

`0` Do not count events in EL2.

`1` Count events in EL2.

M, bit [26]

Secure EL3 filtering bit. Most applications can ignore this bit and set the value to zero. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Secure EL3 are counted.

Otherwise, events in Secure EL3 are not counted.

Bits [25:10]

Reserved, RES0.

evtCount, bits [9:0]

Event to count. The event number of the event that is counted by event counter PMEVCNTR<n>_EL0.

Software must program this field with an event defined by the processor or a common event defined by the architecture.

If evtCount is programmed to an event that is reserved or not implemented, the behavior depends on the event type.

For common architectural and microarchitectural events:

- No events are counted.
- The value read back on evtCount is the value written.

For IMPLEMENTATION DEFINED events:

- It is UNPREDICTABLE what event, if any, is counted. UNPREDICTABLE in this case means the event must not expose privileged information.
- The value read back on evtCount is an UNKNOWN value with the same effect.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

Accessing the PMEVTYPER<n>_EL0

PMEVTYPER<n>_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0x400` + 4n

I3.3.20 PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR_EL1 characteristics are:

Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

PMINTENCLR_EL1 is architecturally mapped to AArch64 register PMINTENCLR_EL1.

PMINTENCLR_EL1 is architecturally mapped to AArch32 register PMINTENCLR.

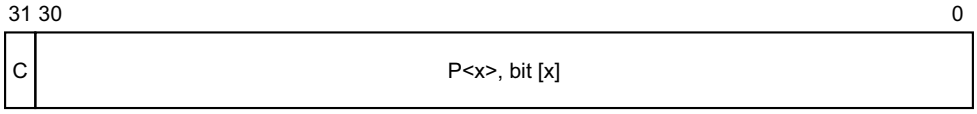
PMINTENCLR_EL1 is in the Core power domain.

Attributes

PMINTENCLR_EL1 is a 32-bit register.

Field descriptions

The PMINTENCLR_EL1 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow interrupt request disable bit. Possible values are:

`0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`1` When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

P<x>, bit [x], for x = 0 to 30

Event counter overflow interrupt request disable bit for PMEVCNTR<x>_EL0.

N is the value in PMCR_EL0.N. Bits [30:N] are RAZ/WI.

Possible values are:

`0` When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is disabled. When written, has no effect.

`1` When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is enabled. When written, disables the PMEVCNTR<x>_EL0 interrupt request.

Accessing the PMINTENCLR_EL1

PMINTENCLR_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xC60

I3.3.21 PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register

The PMINTENSET_EL1 characteristics are:

Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

PMINTENSET_EL1 is architecturally mapped to AArch64 register PMINTENSET_EL1.

PMINTENSET_EL1 is architecturally mapped to AArch32 register PMINTENSET.

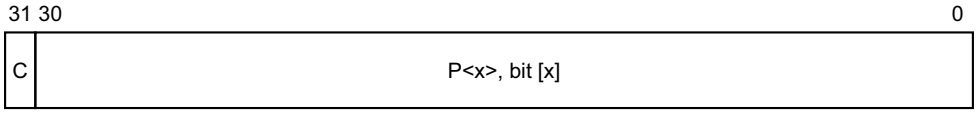
PMINTENSET_EL1 is in the Core power domain.

Attributes

PMINTENSET_EL1 is a 32-bit register.

Field descriptions

The PMINTENSET_EL1 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow interrupt request enable bit. Possible values are:

`0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`1` When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

P<x>, bit [x], for x = 0 to 30

Event counter overflow interrupt request enable bit for PMEVCNTR<x>_EL0.

N is the value in PMCR_EL0.N. Bits [30:N] are RAZ/WI.

Possible values are:

`0` When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is disabled. When written, has no effect.

`1` When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is enabled. When written, enables the PMEVCNTR<x>_EL0 interrupt request.

Accessing the PMINTENSET_EL1

PMINTENSET_EL1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xC40

I3.3.22 PMITCTRL, Performance Monitors Integration mode Control register

The PMITCTRL characteristics are:

Purpose

Enables the Performance Monitors to switch from default mode into integration mode, where test software can control directly the inputs and outputs of the processor, for integration testing or topology detection.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	Default
IMP DEF	IMP DEF	IMP DEF	RW

Configurations

It is IMPLEMENTATION DEFINED whether PMITCTRL is in the Core power domain or in the Debug power domain.

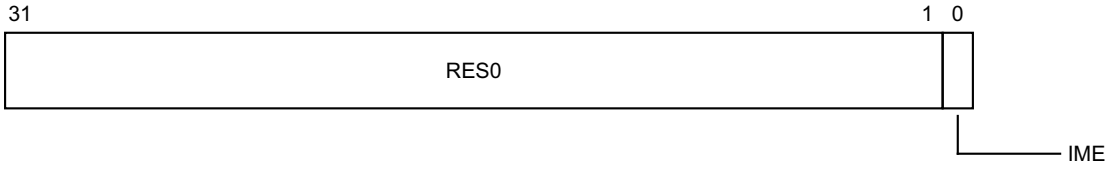
PMITCTRL is optional to implement in the external register interface.

Attributes

PMITCTRL is a 32-bit register.

Field descriptions

The PMITCTRL bit assignments are:



Bits [31:1]

Reserved, RES0.

IME, bit [0]

Integration mode enable. When IME == 1, the device reverts to an integration mode to enable integration testing or topology detection. The integration mode behavior is IMPLEMENTATION DEFINED.

`0` Normal operation.

`1` Integration mode enabled.

On IMPLEMENTATION DEFINED reset, the field resets to 0.

Accessing the PMITCTRL

PMITCTRL can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xF00

I3.3.23 PMLAR, Performance Monitors Lock Access Register

The PMLAR characteristics are:

Purpose

Allows or disallows access to the Performance Monitors registers through a memory-mapped interface.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Default
WO

Configurations

PMLAR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

PMLAR ignores writes if the Software lock is not implemented and ignores writes for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

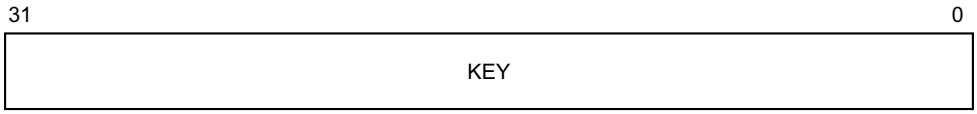
Software uses PMLAR to set or clear the lock, and PMLSR to check the current status of the lock.

Attributes

PMLAR is a 32-bit register.

Field descriptions

The PMLAR bit assignments are:



KEY, bits [31:0]

Lock Access control. Writing the key value `0xC5ACCE55` to this field unlocks the lock, enabling write accesses to this component's registers through a memory-mapped interface.

Writing any other value to this register locks the lock, disabling write accesses to this component's registers through a memory mapped interface.

Accessing the PMLAR

PMLAR can be accessed through the internal memory-mapped interface:

Component	Offset
PMU	`0xFB0`

I3.3.24 PMLSR, Performance Monitors Lock Status Register

The PMLSR characteristics are:

Purpose

Indicates the current status of the software lock for Performance Monitors registers.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

PMLSR is in the Debug power domain.

If OPTIONAL memory-mapped access to the external debug interface is supported then an OPTIONAL Software lock can be implemented as part of CoreSight compliance.

PMLSR is RAZ if the Software lock is not implemented and is RAZ for other accesses to the external debug interface.

The Software lock provides a lock to prevent memory-mapped writes to the Performance Monitors registers. Use of this lock mechanism reduces the risk of accidental damage to the contents of the Performance Monitors registers. It does not, and cannot, prevent all accidental or malicious damage.

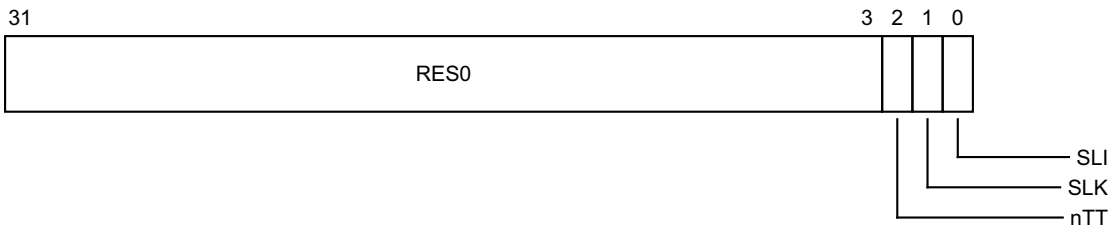
Software uses PMLAR to set or clear the lock, and PMLSR to check the current status of the lock.

Attributes

PMLSR is a 32-bit register.

Field descriptions

The PMLSR bit assignments are:



Bits [31:3]

Reserved, RES0.

nTT, bit [2]

Not thirty-two bit access required. RAZ.

SLK, bit [1]

Software lock status for this component. For an access to LSR that is not a memory-mapped access, or when the software lock is not implemented, this field is RES0.

For memory-mapped accesses when the software lock is implemented, possible values of this field are:

`0` Lock clear. Writes are permitted to this component's registers.

`1` Lock set. Writes to this component's registers are ignored, and reads have no side effects.

On External debug reset, the field resets to 1.

SLI, bit [0]

Software lock implemented. For an access to LSR that is not a memory-mapped access, this field is RAZ. For memory-mapped accesses, the value of this field is IMPLEMENTATION DEFINED. Permitted values are:

`0` Software lock not implemented or not memory-mapped access.

`1` Software lock implemented and memory-mapped access.

Accessing the PMLSR

PMLSR can be accessed through the internal memory-mapped interface:

Component	Offset
PMU	`0xFB4`

I3.3.25 PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear register

The PMOVSCLR_EL0 characteristics are:

Purpose

Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<x>. Writing to this register clears these bits.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

PMOVSCLR_EL0 is architecturally mapped to AArch64 register PMOVSCLR_EL0.

PMOVSCLR_EL0 is architecturally mapped to AArch32 register PMOVSR.

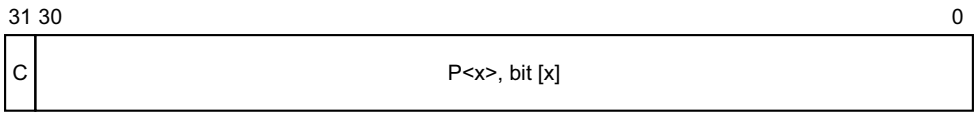
PMOVSCLR_EL0 is in the Core power domain.

Attributes

PMOVSCLR_EL0 is a 32-bit register.

Field descriptions

The PMOVSCLR_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow bit. Possible values are:

`0` When read, means the cycle counter has not overflowed. When written, has no effect.

`1` When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.

PMCR_EL0.LC is used to control from which bit of PMCCNTR_EL0 (bit 31 or bit 63) an overflow is detected.

P<x>, bit [x], for x = 0 to 30

Event counter overflow clear bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI. N is the value in PMCR_EL0.N.

Possible values of each bit are:

`0` When read, means that PMEVCNTR<x> has not overflowed. When written, has no effect.

`1` When read, means that PMEVCNTR<x> has overflowed. When written, clears the PMEVCNTR<x> overflow bit to 0.

Accessing the PMOVSCLR_EL0

PMOVSCLR_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xC80

I3.3.26 PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register

The PMOVSSET_EL0 characteristics are:

Purpose

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<x>.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	RO	RW

Configurations

PMOVSSET_EL0 is architecturally mapped to AArch64 register PMOVSSET_EL0.

PMOVSSET_EL0 is architecturally mapped to AArch32 register PMOVSSET.

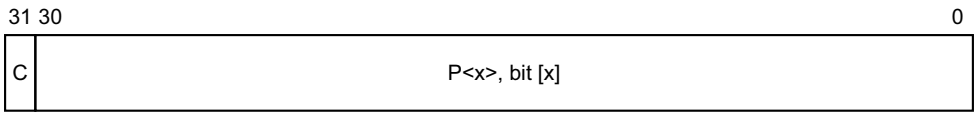
PMOVSSET_EL0 is in the Core power domain.

Attributes

PMOVSSET_EL0 is a 32-bit register.

Field descriptions

The PMOVSSET_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow bit. Possible values are:

`0` When read, means the cycle counter has not overflowed. When written, has no effect.

`1` When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.

P<x>, bit [x], for x = 0 to 30

Event counter overflow set bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI. N is the value in PMCR_EL0.N.

Possible values are:

`0` When read, means that PMEVCNTR<x> has not overflowed. When written, has no effect.

`1` When read, means that PMEVCNTR<x> has overflowed. When written, sets the PMEVCNTR<x> overflow bit to 1.

Accessing the PMOVSSET_EL0

PMOVSSET_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xCC0

I3.3.27 PMPIDR0, Performance Monitors Peripheral Identification Register 0

The PMPIDR0 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMPIDR0 is in the Debug power domain.

PMPIDR0 is optional to implement in the external register interface.

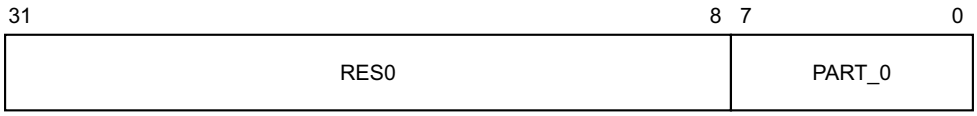
This register is required for CoreSight compliance.

Attributes

PMPIDR0 is a 32-bit register.

Field descriptions

The PMPIDR0 bit assignments are:



Bits [31:8]

Reserved, RES0.

PART_0, bits [7:0]

Part number, least significant byte.

Accessing the PMPIDR0

PMPIDR0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFE0

I3.3.28 PMPIDR1, Performance Monitors Peripheral Identification Register 1

The PMPIDR1 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMPIDR1 is in the Debug power domain.

PMPIDR1 is optional to implement in the external register interface.

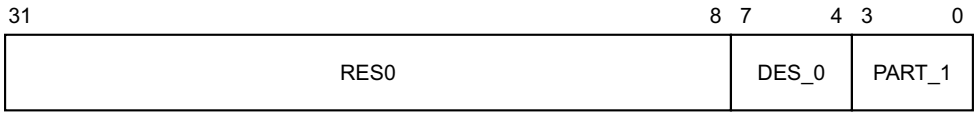
This register is required for CoreSight compliance.

Attributes

PMPIDR1 is a 32-bit register.

Field descriptions

The PMPIDR1 bit assignments are:



Bits [31:8]

Reserved, RES0.

DES_0, bits [7:4]

Designer, least significant nibble of JEP106 ID code. For ARM Limited, this field is `0b1011`.

PART_1, bits [3:0]

Part number, most significant nibble.

Accessing the PMPIDR1

PMPIDR1 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFE4`

I3.3.29 PMPIDR2, Performance Monitors Peripheral Identification Register 2

The PMPIDR2 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMPIDR2 is in the Debug power domain.

PMPIDR2 is optional to implement in the external register interface.

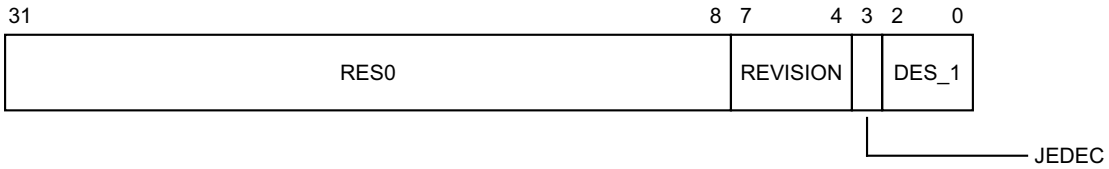
This register is required for CoreSight compliance.

Attributes

PMPIDR2 is a 32-bit register.

Field descriptions

The PMPIDR2 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVISION, bits [7:4]

Part major revision. Parts can also use this field to extend Part number to 16-bits.

JEDEC, bit [3]

RAO. Indicates a JEP106 identity code is used.

DES_1, bits [2:0]

Designer, most significant bits of JEP106 ID code. For ARM Limited, this field is `0b011`.

Accessing the PMPIDR2

PMPIDR2 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFE8`

I3.3.30 PMPIDR3, Performance Monitors Peripheral Identification Register 3

The PMPIDR3 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMPIDR3 is in the Debug power domain.

PMPIDR3 is optional to implement in the external register interface.

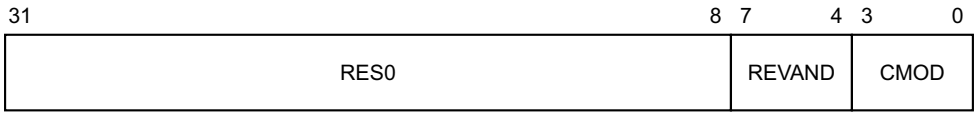
This register is required for CoreSight compliance.

Attributes

PMPIDR3 is a 32-bit register.

Field descriptions

The PMPIDR3 bit assignments are:



Bits [31:8]

Reserved, RES0.

REVAND, bits [7:4]

Part minor revision. Parts using PMPIDR2.REVISION as an extension to the Part number must use this field as a major revision number.

CMOD, bits [3:0]

Customer modified. Indicates someone other than the Designer has modified the component.

Accessing the PMPIDR3

PMPIDR3 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xFEC

I3.3.31 PMPIDR4, Performance Monitors Peripheral Identification Register 4

The PMPIDR4 characteristics are:

Purpose

Provides information to identify a Performance Monitor component.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

SLK	Default
RO	RO

Configurations

PMPIDR4 is in the Debug power domain.

PMPIDR4 is optional to implement in the external register interface.

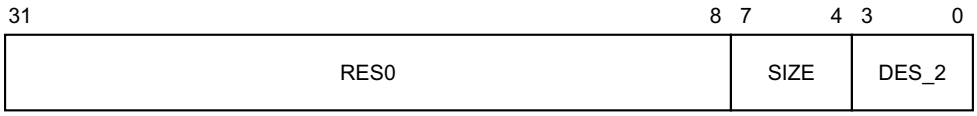
This register is required for CoreSight compliance.

Attributes

PMPIDR4 is a 32-bit register.

Field descriptions

The PMPIDR4 bit assignments are:



Bits [31:8]

Reserved, RES0.

SIZE, bits [7:4]

Size of the component. RAZ. Log_2 of the number of 4KB pages from the start of the component to the end of the component ID registers.

DES_2, bits [3:0]

Designer, JEP106 continuation code, least significant nibble. For ARM Limited, this field is `0b0100`.

Accessing the PMPIDR4

PMPIDR4 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	`0xFD0`

I3.3.32 PMSWINC_EL0, Performance Monitors Software Increment register

The PMSWINC_EL0 characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event `0x00`.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

Off	DLK	OSLK	EPMAD	SLK	Default
Error	Error	Error	Error	WI	WO

Configurations

PMSWINC_EL0 is architecturally mapped to AArch64 register PMSWINC_EL0.

PMSWINC_EL0 is architecturally mapped to AArch32 register PMSWINC.

PMSWINC_EL0 is in the Core power domain.

PMSWINC_EL0 is optional to implement in the external register interface.

If this register is implemented, use of it is deprecated.

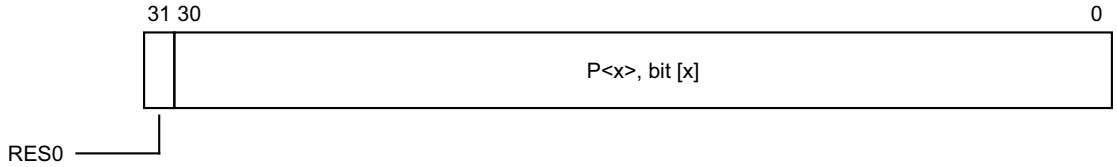
If 1 is written to bit [x] from the external debug interface, it is CONSTRAINED UNPREDICTABLE whether or not a SW_INCR event is created for counter x. This is consistent with not implementing the register in the external debug interface.

Attributes

PMSWINC_EL0 is a 32-bit register.

Field descriptions

The PMSWINC_EL0 bit assignments are:



Bit [31]

Reserved, RES0.

P<x>, bit [x], for x = 0 to 30

Event counter software increment bit for PMEVCNTR<x>.

P<x> is WI if x >= PMCR_EL0.N, the number of implemented counters.

Otherwise, the effects of writing to this bit are:

`0` No action. The write to this bit is ignored.

`1` It is CONSTRAINED UNPREDICTABLE whether a SW_INCR event is generated for event counter x.

Accessing the PMSWINC_EL0

PMSWINC_EL0 can be accessed through the internal memory-mapped interface and the external debug interface:

Component	Offset
PMU	0xCA0

I3.4 Generic Timer memory-mapped registers overview

The Generic Timer memory-mapped registers are implemented as multiple register frames, with each register frame having its own base address, as follows:

- A single CNTCTLBase register frame, at base address CNTCTLBase.
- Between one and seven CNTBase*N* register frames, each with its own base address CNTBase*N*.
- For each CNTBase*N* register frame, if required, a CNTEL0Base*N* register frame, at base address CNTEL0Base*N*, that provides an EL0 view of the CNTBase*N* register frame.

For more information, see:

- *About the memory-mapped view of the counter and timer* on page I1-4676.
- *The CNTBaseN and CNTEL0BaseN frames* on page I1-4677. This section includes the memory map of the CNTBase*N* and CNTBase*N* register frames.
- *The CNTCTLBase frame* on page I1-4679. This section includes the memory map of the CNTCTLBase register frame.
- *Providing a complete set of counter and timer features* on page I1-4680.

I3.5 Generic Timer memory-mapped register descriptions

This section describes the Generic Timer registers. *Generic Timer memory-mapped registers overview* on page I3-4744 gives an overview of these registers, and includes links to their memory maps.

I3.5.1 CNTACR<n>, Counter-timer Access Control Registers, n = 0 - 7

The CNTACR<n> characteristics are:

Purpose

Provides top-level access controls for the elements of a timer frame. CNTACR<n> provides the controls for frame CNTBaseN.

In addition to the CNTACR<n> control:

- CNTNSAR controls whether CNTACR<n> is accessible from Non-secure state.
- If frame CNTEL0BaseN is implemented, the CNTEL0ACR in frame CNTBaseN provides additional control of accesses to frame CNTEL0BaseN.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RW

In a system that implements both Secure and Non-secure states:

- This register is always accessible in Secure state.
- CNTNSAR.NS<n> determines whether CNTACR<n> is accessible in Non-secure state.

Configurations

Implemented only if CNTTIDR.FI<n> is RAO.

An implementation of the counters might not provide configurable access to some or all of the features. In this case, the associated field in the CNTACR<n> register is:

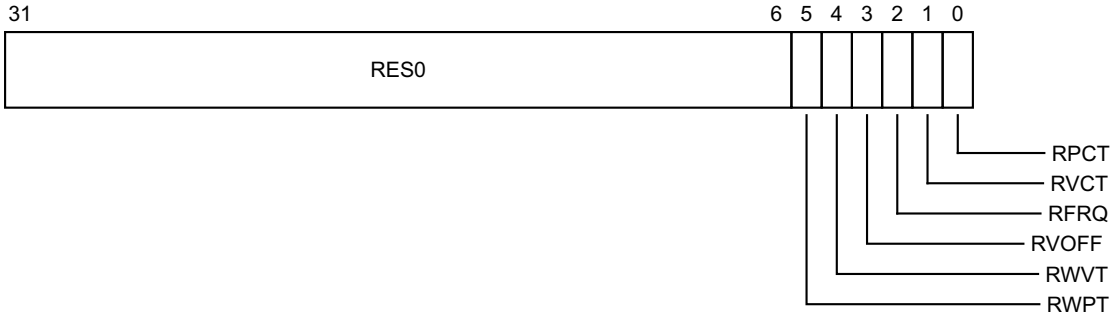
- RAZ/WI if access is always denied.
- RAO/WI if access is always permitted.

Attributes

CNTACR<n> is a 32-bit register.

Field descriptions

The CNTACR<n> bit assignments are:



Bits [31:6]

Reserved, RES0.

RWPT, bit [5]

Read/write access to the EL1 Physical Timer registers CNTP_CVAL, CNTP_TVAL, and CNTP_CTL, in frame <n>. The possible values of this bit are:

0 No access to the EL1 Physical Timer registers in frame <n>. The registers are RES0.

1 Read/write access to the EL1 Physical Timer registers in frame <n>.

RWVT, bit [4]

Read/write access to the Virtual Timer register CNTV_CVAL, CNTV_TVAL, and CNTV_CTL, in frame <n>. The possible values of this bit are:

0 No access to the Virtual Timer registers in frame <n>. The registers are RES0.

1 Read/write access to the Virtual Timer registers in frame <n>.

RVOFF, bit [3]

Read-only access to CNTVOFF, in frame <n>. The possible values of this bit are:

0 No access to CNTVOFF in frame <n>. The register is RES0.

1 Read-only access to CNTVOFF in frame <n>.

RFRQ, bit [2]

Read-only access to CNTFRQ, in frame <n>. The possible values of this bit are:

0 No access to CNTFRQ in frame <n>. The register is RES0.

1 Read-only access to CNTFRQ in frame <n>.

RVCT, bit [1]

Read-only access to CNTVCT, in frame <n>. The possible values of this bit are:

0 No access to CNTVCT in frame <n>. The register is RES0.

1 Read-only access to CNTVCT in frame <n>.

RPCT, bit [0]

Read-only access to CNTPCT, in frame <n>. The possible values of this bit are:

0 No access to CNTPCT in frame <n>. The register is RES0.

1 Read-only access to CNTPCT in frame <n>.

Accessing the CNTACR<n>

CNTACR<n> can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	`0x040` + 4n

I3.5.2 CNTCR, Counter Control Register

The CNTCR characteristics are:

Purpose

Enables the counter, controls the counter frequency setting, and controls counter behavior during debug.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RW

In a system that implements both Secure and Non-secure states, this register is only writable in Secure state.

Configurations

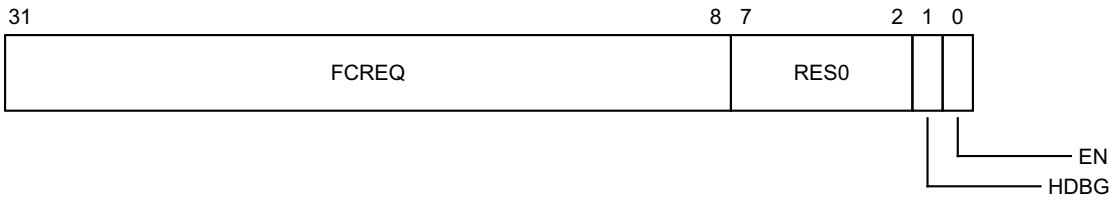
There are no configuration notes.

Attributes

CNTCR is a 32-bit register.

Field descriptions

The CNTCR bit assignments are:



FCREQ, bits [31:8]

Frequency change request. Indicates the number of the entry in the frequency table to select.

Selecting an unimplemented entry, or an entry that contains 0, has no effect on the counter.

Resets to 0.

Bits [7:2]

Reserved, RES0.

HDBG, bit [1]

Halt-on-debug. Controls whether a Halt-on-debug signal halts the system counter:

`0` System counter ignores Halt-on-debug.

`1` Asserted Halt-on-debug signal halts system counter update.

Reset value is architecturally UNKNOWN.

EN, bit [0]

Enables the counter:

`0` System counter disabled.

`1` System counter enabled.

Resets to 0.

Accessing the CNTCR

CNTCR can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	`0x000`

I3.5.3 CNTCV, Counter Count Value register

The CNTCV characteristics are:

Purpose

Indicates the current count value.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RW in CNTControlBase, RO in CNTReadBase

Configurations

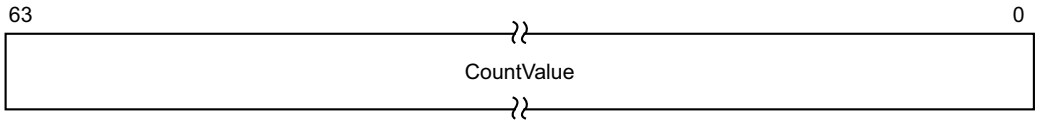
There are no configuration notes.

Attributes

CNTCV is a 64-bit register.

Field descriptions

The CNTCV bit assignments are:



CountValue, bits [63:0]

Indicates the counter value.

Accessing the CNTCV

CNTCV[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x008
Timer	CNTReadBase	0x000

CNTCV[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x00C
Timer	CNTReadBase	0x004

I3.5.4 CNTEL0ACR, Counter-timer EL0 Access Control Register

The CNTEL0ACR characteristics are:

Purpose

An implementation of CNTEL0ACR in the frame at CNTBaseN controls whether the CNTPCT, CNTVCT, CNTFRQ, EL1 Physical Timer, and Virtual Timer registers are visible in the frame at CNTEL0BaseN.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RW

Configurations

CNTEL0ACR is optional to implement in the external register interface.

In each implemented CNTBaseN frame, CNTEL0ACR is optional. If it is not implemented:

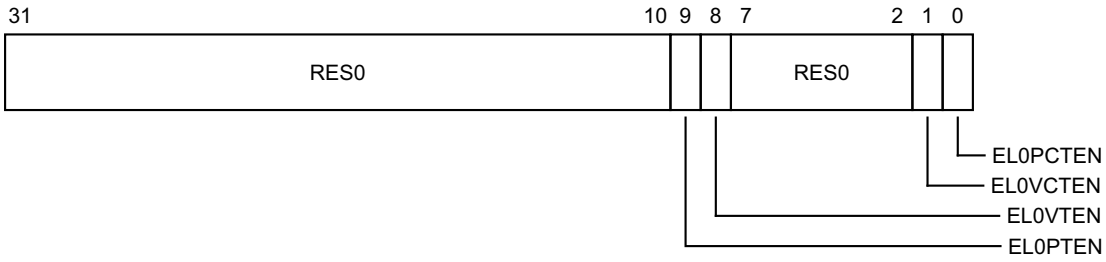
- Its location is RAZ/WI.
- The registers it controls are not visible in the corresponding CNTEL0BaseN frame.

Attributes

CNTEL0ACR is a 32-bit register.

Field descriptions

The CNTEL0ACR bit assignments are:



Bits [31:10]

Reserved, RES0.

EL0PTEN, bit [9]

Second view read/write access control for the EL1 Physical Timer registers. This bit controls whether the CNTP_CVAL, CNTP_TVAL, and CNTP_CTL registers in the current CNTBaseN frame are also accessible in the corresponding CNTEL0BaseN frame. The possible values of this bit are:

`0` No access. Registers are RES0 in the second view.

`1` Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.

EL0VTEN, bit [8]

Second view read/write access control for the Virtual Timer registers. This bit controls whether the CNTV_CVAL, CNTV_TVAL, and CNTV_CTL registers in the current CNTBaseN frame are also accessible in the corresponding CNTEL0BaseN frame. The possible values of this bit are:

`0` No access. Registers are RES0 in the second view.

`1` Access permitted. If the registers are accessible in the current frame then they are accessible in the second view.

The definition of this bit means that, if the Virtual Timer registers are not implemented in the current CNTBaseN frame, then the Virtual Timer register addresses are RES0 in the corresponding CNTEL0BaseN frame, regardless of the value of this bit.

Bits [7:2]

Reserved, RES0.

EL0VCTEN, bit [1]

Second view read access control for CNTVCT and CNTFRQ. The possible values of this bit are:

`0` CNTVCT is not visible in the second view.
If EL0PCTEN is set to 0, CNTFRQ is not visible in the second view.

`1` Access permitted. If CNTVCT and CNTFRQ are visible in the current frame then they are visible in the second view.

EL0PCTEN, bit [0]

Second view read access control for CNTPCT and CNTFRQ. The possible values of this bit are:

`0` CNTPCT is not visible in the second view.
If EL0VCTEN is set to 0, CNTFRQ is not visible in the second view.

`1` Access permitted. If CNTPCT and CNTFRQ are visible in the current frame then they are visible in the second view.

Accessing the CNTEL0ACR

CNTEL0ACR can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	`0x014`

I3.5.5 CNTFID0, Counter Frequency ID

The CNTFID0 characteristics are:

Purpose

Indicates the base frequency of the system counter.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO or RW

Configurations

The possible frequencies for the system counter are stored as 32-bit words starting with the base frequency, CNTFID0.

A 32-bit word of zero value after the final frequency mode entry marks the end of the frequency modes table.

Typically, the frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialise the table entries as part of its start-up sequence.

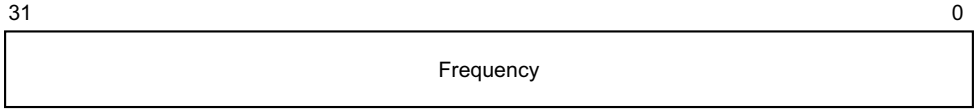
If the frequency modes table is in read/write memory, ARM strongly recommends that the frequency modes table is not updated once the system is running.

Attributes

CNTFID0 is a 32-bit register.

Field descriptions

The CNTFID0 bit assignments are:



Frequency, bits [31:0]

The base frequency of the system counter, in Hz.

Accessing the CNTFID0

CNTFID0 can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x020

I3.5.6 CNTFID<n>, Counter Frequency IDs, n = 1 - 23

The CNTFID<n> characteristics are:

Purpose

Indicates alternative system counter update frequencies.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO or RW

Configurations

CNTFID<n> is optional to implement in the external register interface.

The possible frequencies for the system counter are stored as 32-bit words starting with the base frequency, CNTFID0.

A 32-bit word of zero value after the final frequency mode entry marks the end of the frequency modes table. The only required entry in the table is the entry for CNTFID0.

Typically, the frequency modes table will be in read-only memory. However, a system implementation might use read/write memory for the table, and initialise the table entries as part of its start-up sequence.

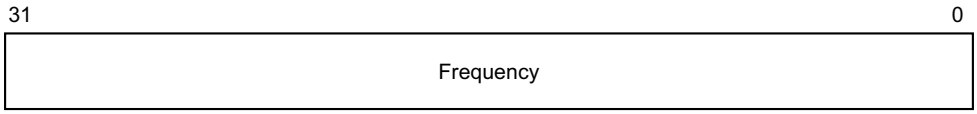
If the frequency modes table is in read/write memory, ARM strongly recommends that the frequency modes table is not updated once the system is running.

Attributes

CNTFID<n> is a 32-bit register.

Field descriptions

The CNTFID<n> bit assignments are:



Frequency, bits [31:0]

A system counter update frequency, in Hz. Must be an exact divisor of the base frequency. ARM strongly recommends that all frequency values in the table are integer power-of-two divisors of the base frequency.

When the system timer is operating at a lower frequency than the base frequency, the increment applied at each counter update is given by:

increment = (base frequency) / selected frequency)

Accessing the CNTFID<n>

CNTFID<n> can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	`0x020` + 4n

I3.5.7 CNTFRQ, Counter-timer Frequency

The CNTFRQ characteristics are:

Purpose

Holds the clock frequency of the system counter.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

In a system that implements both Secure and Non-secure states, this register is only accessible in Secure state.

Configurations

CNTFRQ is architecturally mapped to AArch64 register CNTFRQ_EL0.

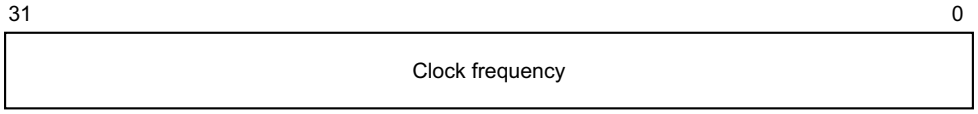
CNTFRQ is architecturally mapped to AArch32 register CNTFRQ.

Attributes

CNTFRQ is a 32-bit register.

Field descriptions

The CNTFRQ bit assignments are:



Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

Accessing the CNTFRQ

CNTFRQ can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x010
Timer	CNTEL0BaseN	0x010
Timer	CNTCTLBase	0x000

I3.5.8 CNTNSAR, Counter-timer Non-secure Access Register

The CNTNSAR characteristics are:

Purpose

Provides the highest-level control of whether frames CNTBaseN and CNTEL0BaseN are accessible by Non-secure accesses.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RW

In a system that implements both Secure and Non-secure states, this register is only accessible in Secure state.

Configurations

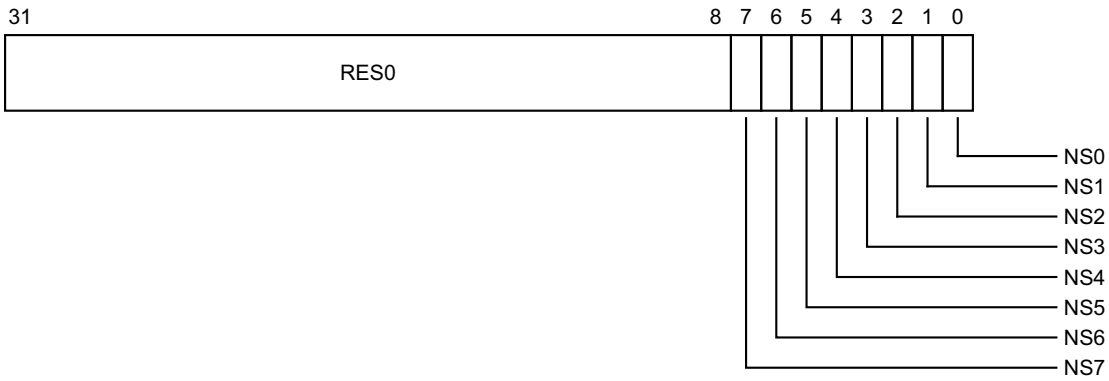
There are no configuration notes.

Attributes

CNTNSAR is a 32-bit register.

Field descriptions

The CNTNSAR bit assignments are:



Bits [31:8]

Reserved, RES0.

NS<n>, bit [n], for n = 0 to 7

Non-secure access to frame n. The possible values of this bit are:

`0` Secure access only. Behaves as RES0 to Non-secure accesses.

`1` Secure and Non-secure accesses permitted.

If frame CNTBase<n>:

- Is not implemented, then NS<n> is RES0.
- Is not Configurable access, and is accessible only by Secure accesses, then NS<n> is RES0.
- Is not Configurable access, and is accessible only by Non-secure accesses, then NS<n> is RES1.

Accessing the CNTNSAR

CNTNSAR can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x004

I3.5.9 CNTP_CTL, Counter-timer Physical Timer Control

The CNTP_CTL characteristics are:

Purpose

Control register for the physical timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RW

CNTACR<n>.RWPT enables access to this register in frame <n>.

Configurations

CNTP_CTL is architecturally mapped to AArch64 register CNTP_CTL_EL0.

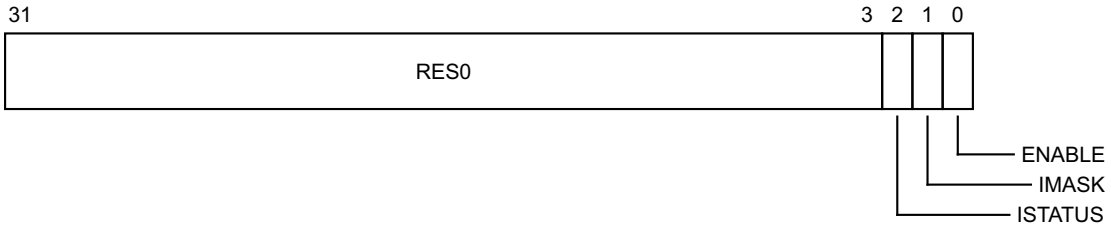
CNTP_CTL is architecturally mapped to AArch32 register CNTP_CTL.

Attributes

CNTP_CTL is a 32-bit register.

Field descriptions

The CNTP_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer interrupt:

0 Interrupt not asserted.

1 Interrupt asserted.

This bit is read-only.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

0 Timer interrupt is not masked.

1 Timer interrupt is masked.

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0` Timer disabled.

`1` Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

Accessing the CNTP_CTL

CNTP_CTL can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	`0x02C`
Timer	CNTEL0BaseN	`0x02C`

I3.5.10 CNTP_CVAL, Counter-timer Physical Timer CompareValue

The CNTP_CVAL characteristics are:

Purpose

Holds the 64-bit compare value for the EL1 physical timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RW

CNTACR<n>.RWPT enables access to this register in frame <n>.

If the implementation supports 64-bit atomic accesses, then the CNTP_CVAL register must be accessible as an atomic 64-bit value.

Configurations

CNTP_CVAL is architecturally mapped to AArch64 register CNTP_CVAL_EL0.

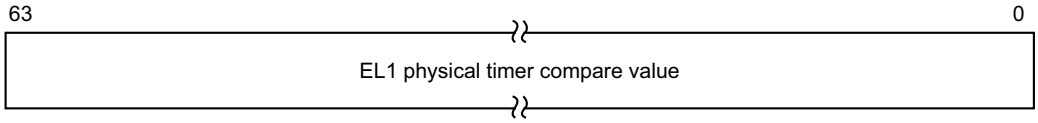
CNTP_CVAL is architecturally mapped to AArch32 register CNTP_CVAL.

Attributes

CNTP_CVAL is a 64-bit register.

Field descriptions

The CNTP_CVAL bit assignments are:



Bits [63:0]

EL1 physical timer compare value.

Accessing the CNTP_CVAL

CNTP_CVAL[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x020
Timer	CNTEL0BaseN	0x020

CNTP_CVAL[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x024
Timer	CNTEL0BaseN	0x024

I3.5.11 CNTP_TVAL, Counter-timer Physical Timer TimerValue

The CNTP_TVAL characteristics are:

Purpose

Holds the timer value for the EL1 physical timer. This provides a 32-bit downcounter.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RW

CNTACR<n>.RWPT enables access to this register in frame <n>.

Configurations

CNTP_TVAL is architecturally mapped to AArch64 register CNTP_TVAL_EL0.

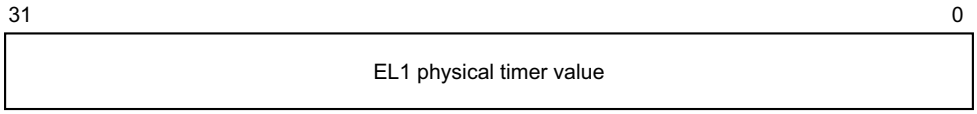
CNTP_TVAL is architecturally mapped to AArch32 register CNTP_TVAL.

Attributes

CNTP_TVAL is a 32-bit register.

Field descriptions

The CNTP_TVAL bit assignments are:



Bits [31:0]

EL1 physical timer value.

Accessing the CNTP_TVAL

CNTP_TVAL can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x028
Timer	CNTEL0BaseN	0x028

I3.5.12 CNTPCT, Counter-timer Physical Count

The CNTPCT characteristics are:

Purpose

Holds the 64-bit physical count value.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

CNTACR<n>.RPCT enables access to this register in frame <n>.

If the implementation supports 64-bit atomic accesses, then the CNTPCT register must be accessible as an atomic 64-bit value.

Configurations

CNTPCT is architecturally mapped to AArch64 register CNTPCT_EL0.

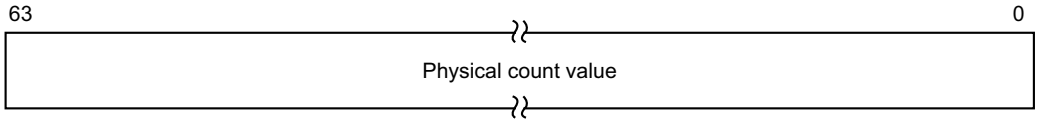
CNTPCT is architecturally mapped to AArch32 register CNTPCT.

Attributes

CNTPCT is a 64-bit register.

Field descriptions

The CNTPCT bit assignments are:



Bits [63:0]

Physical count value.

Accessing the CNTPCT

CNTPCT[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x000
Timer	CNTEL0BaseN	0x000

CNTPCT[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x004
Timer	CNTEL0BaseN	0x004

I3.5.13 CNTSR, Counter Status Register

The CNTSR characteristics are:

Purpose

Provides counter frequency status information.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

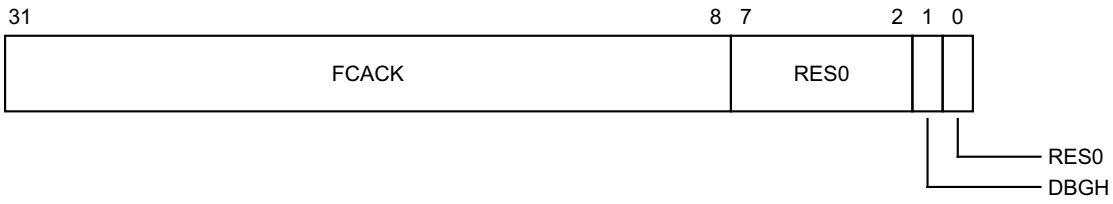
There are no configuration notes.

Attributes

CNTSR is a 32-bit register.

Field descriptions

The CNTSR bit assignments are:



FCACK, bits [31:8]

Frequency change acknowledge. Indicates the currently selected entry in the frequency table.

Resets to 0.

Bits [7:2]

Reserved, RES0.

DBGH, bit [1]

Indicates whether the counter is halted because the Halt-on-Debug signal is asserted:

0 Counter is not halted.

1 Counter is halted.

Reset value is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

Accessing the CNTSR

CNTSR can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	0x004

I3.5.14 CNTTIDR, Counter-timer Timer ID Register

The CNTTIDR characteristics are:

Purpose

Indicates the implemented timers in the memory map, and their features. For each value of N from 0 to 7 it indicates whether:

- Frame CNTBaseN is a view of an implemented timer.
- Frame CNTBaseN has a second view, CNTEL0BaseN.
- Frame CNTBaseN has a virtual timer capability.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

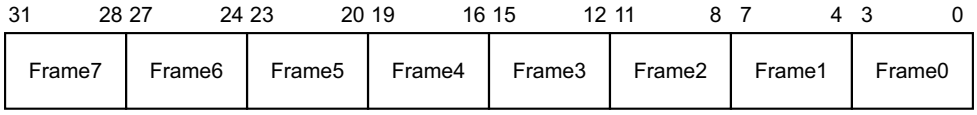
There are no configuration notes.

Attributes

CNTTIDR is a 32-bit register.

Field descriptions

The CNTTIDR bit assignments are:



Frame<n>, bits [4n+3:4n], for 4n+3:4n = 0 to 7

A 4-bit field indicating the features of frame CNTBase<n>.

Bit[3] of the field is RES0.

Bit[2] indicates whether frame CNTBase<n> has a second view, CNTEL0Base<n>. The possible values of this bit are:

Bit[2]	Meaning
0	Frame <n> does not have a second view. CNTEL0Base<n> is RES0.
1	Frame <n> has a second view, CNTEL0Base<n>.

If bit[0] is 0, bit[2] is RES0.

Bit[1] indicates whether both:

- Frame CNTBase<n> implements the virtual timer registers CNTV_CVAL, CNTV_TVAL, and CNTV_CTL.
- This CNTCTLBase frame implements the virtual timer offset register CNTVOFF<n>.

The possible values of bit[1] are:

Bit[1]	Meaning
0	Frame <n> does not have virtual capability. The virtual time and offset registers are RES0.
1	Frame <n> has virtual capability. The virtual time and offset registers are implemented.

If bit[0] is 0, bit[1] is RES0.

Bit[0] indicates whether frame <n> is implemented. The possible values of bit[0] are:

Bit[0]	Meaning
0	Frame <n> not implemented. All registers associated with the frame are RES0.
1	Frame <n> is implemented.

Accessing the CNTTIDR

CNTTIDR can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x008

I3.5.15 CNTV_CTL, Counter-timer Virtual Timer Control

The CNTV_CTL characteristics are:

Purpose

Control register for the virtual timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RW

Bit [1] of CNTTIDR.Frame<n> indicates whether CNTV_CTL is implemented for frame <n>.

If CNTV_CTL is implemented, CNTACR<n>.RWVT enables access to the register in frame <n>.

If CNTV_CTL is not implemented, the register location is RAZ/WI.

Configurations

CNTV_CTL is architecturally mapped to AArch64 register CNTV_CTL_EL0.

CNTV_CTL is architecturally mapped to AArch32 register CNTV_CTL.

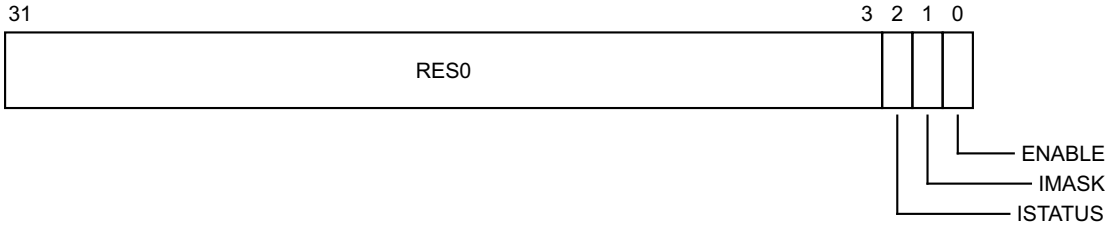
CNTV_CTL is optional to implement in the external register interface.

Attributes

CNTV_CTL is a 32-bit register.

Field descriptions

The CNTV_CTL bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer interrupt:

0 Interrupt not asserted.

1 Interrupt asserted.

This bit is read-only.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0` Timer interrupt is not masked.

`1` Timer interrupt is masked.

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0` Timer disabled.

`1` Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

Accessing the CNTV_CTL

CNTV_CTL can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	`0x03C`
Timer	CNTEL0BaseN	`0x03C`

I3.5.16 CNTV_CVAL, Counter-timer Virtual Timer CompareValue

The CNTV_CVAL characteristics are:

Purpose

Holds the 64-bit compare value for the virtual timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RW

Bit [1] of CNTTIDR.Frame<n> indicates whether CNTV_CVAL is implemented for frame <n>.

If CNTV_CVAL is implemented, CNTACR<n>.RWVT enables access to the register in frame <n>.

If CNTV_CVAL is not implemented, the register location is RAZ/WI.

If the implementation supports 64-bit atomic accesses, then the CNTV_CVAL register must be accessible as an atomic 64-bit value.

Configurations

CNTV_CVAL is architecturally mapped to AArch64 register CNTV_CVAL_EL0.

CNTV_CVAL is architecturally mapped to AArch32 register CNTV_CVAL.

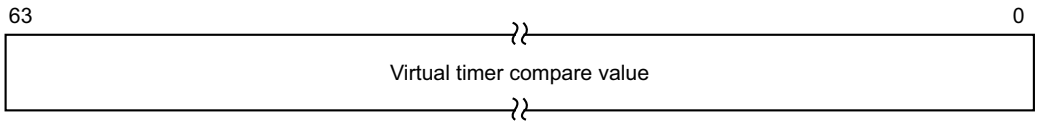
CNTV_CVAL is optional to implement in the external register interface.

Attributes

CNTV_CVAL is a 64-bit register.

Field descriptions

The CNTV_CVAL bit assignments are:



Bits [63:0]

Virtual timer compare value.

Accessing the CNTV_CVAL

CNTV_CVAL[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x030
Timer	CNTEL0BaseN	0x030

CNTV_CVAL[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x034
Timer	CNTEL0BaseN	0x034

I3.5.17 CNTV_TVAL, Counter-timer Virtual Timer TimerValue

The CNTV_TVAL characteristics are:

Purpose

Holds the timer value for the virtual timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RW

Bit [1] of CNTTIDR.Frame<n> indicates whether CNTV_TVAL is implemented for frame <n>.

If CNTV_TVAL is implemented, CNTACR<n>.RWVT enables access to the register in frame <n>.

If CNTV_TVAL is not implemented, the register location is RAZ/WI.

Configurations

CNTV_TVAL is architecturally mapped to AArch64 register CNTV_TVAL_EL0.

CNTV_TVAL is architecturally mapped to AArch32 register CNTV_TVAL.

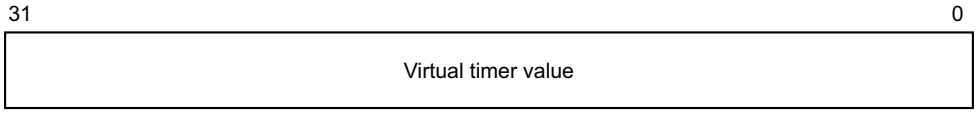
CNTV_TVAL is optional to implement in the external register interface.

Attributes

CNTV_TVAL is a 32-bit register.

Field descriptions

The CNTV_TVAL bit assignments are:



Bits [31:0]

Virtual timer value.

Accessing the CNTV_TVAL

CNTV_TVAL can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x038
Timer	CNTEL0BaseN	0x038

I3.5.18 CNTVCT, Counter-timer Virtual Count

The CNTVCT characteristics are:

Purpose

Holds the 64-bit virtual count value.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

CNTACR<n>.RVCT enables access to this register in frame <n>.

If the implementation supports 64-bit atomic accesses, then the CNTPCT register must be accessible as an atomic 64-bit value.

Configurations

CNTVCT is architecturally mapped to AArch64 register CNTVCT_EL0.

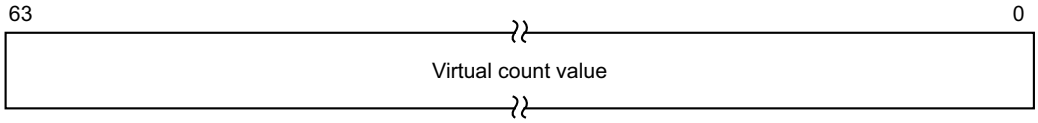
CNTVCT is architecturally mapped to AArch32 register CNTVCT.

Attributes

CNTVCT is a 64-bit register.

Field descriptions

The CNTVCT bit assignments are:



Bits [63:0]

Virtual count value.

Accessing the CNTVCT

CNTVCT[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x008
Timer	CNTEL0BaseN	0x008

CNTVCT[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x00C
Timer	CNTEL0BaseN	0x00C

I3.5.19 CNTVOFF, Counter-timer Virtual Offset

The CNTVOFF characteristics are:

Purpose

Holds the 64-bit virtual offset.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

If the implementation supports 64-bit atomic accesses, then the CNTVOFF register must be accessible as an atomic 64-bit value.

Configurations

CNTVOFF is architecturally mapped to AArch64 register CNTVOFF_EL2.

CNTVOFF is architecturally mapped to AArch32 register CNTVOFF.

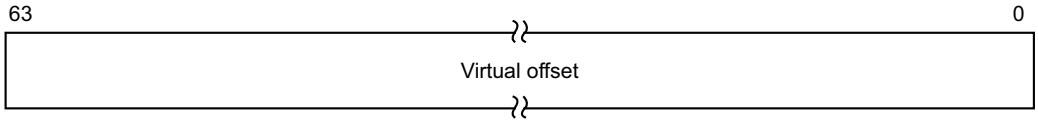
CNTACR<n>.RVOFF enables access to this register for frame CNTBase<n>.

Attributes

CNTVOFF is a 64-bit register.

Field descriptions

The CNTVOFF bit assignments are:



Bits [63:0]

Virtual offset.

Accessing the CNTVOFF

CNTVOFF[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x018

CNTVOFF[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTBaseN	0x01C

I3.5.20 CNTVOFF<n>, Counter-timer Virtual Offsets, n = 0 - 7

The CNTVOFF<n> characteristics are:

Purpose

Holds the 64-bit virtual offset for frame CNTBase<n>.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RW

If the implementation supports 64-bit atomic accesses, then the CNTVOFF<n> registers must be accessible as atomic 64-bit values.

Configurations

CNTVOFF<n> is architecturally mapped to AArch64 register CNTVOFF_EL2.

CNTVOFF<n> is architecturally mapped to AArch32 register CNTVOFF.

CNTVOFF<n> is optional to implement in the external register interface.

CNTVOFF<n> is accessible in the CNTCTLBase register map if CNTACR<n>.RVOFF is 1 and bit [1] of CNTTIDR.Frame<n> is 1.

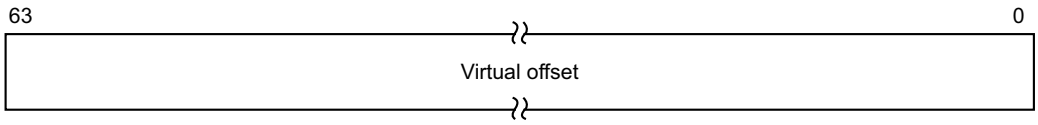
If bit [1] of CNTTIDR.Frame<n> is 0, or CNTACR<n>.RVOFF is 1, CNTVOFF<n> is RAZ/WI.

Attributes

CNTVOFF<n> is a 64-bit register.

Field descriptions

The CNTVOFF<n> bit assignments are:



Bits [63:0]

Virtual offset.

Accessing the CNTVOFF<n>

CNTVOFF<n>[31:0] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x080 + 8n

CNTVOFF<n>[63:32] can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTCTLBase	0x084 + 8n

I3.5.21 CounterID<n>, Counter ID registers, n = 0 - 11

The CounterID<n> characteristics are:

Purpose

IMPLEMENTATION DEFINED identification registers 0 to 11 for the memory-mapped Generic Timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

Default
RO

Configurations

These registers are implemented independently in each of the frames accessed through the different memory maps.

If the implementation of the Counter ID registers requires an architecture version, the value for this version of the ARM Generic Timer is version 0.

The Counter ID registers can be implemented as a set of CoreSight ID registers, comprising Peripheral ID Registers and Component ID Registers. An implementation of these registers for the Generic Timer must use a Component class value of `0xF`.

Attributes

CounterID<n> is a 32-bit register.

Field descriptions

The CounterID<n> bit assignments are:

Accessing the CounterID<n>

CounterID<n> can be accessed through the internal memory-mapped interface:

Component	Frame	Offset
Timer	CNTControlBase	`0xFD0` + 4n
Timer	CNTReadBase	`0xFD0` + 4n
Timer	CNTBaseN	`0xFD0` + 4n
Timer	CNTEL0BaseN	`0xFD0` + 4n
Timer	CNTCTLBase	`0xFD0` + 4n

Architectural Constraints on UNPREDICTABLE behaviors

This chapter describes the architectural constraints on UNPREDICTABLE behaviors in the ARMv8 architecture. It contains the following sections:

- *AArch32 CONSTRAINED UNPREDICTABLE behaviors* on page AppxA-4784.
- *Constraints on AArch64 state UNPREDICTABLE behaviors* on page AppxA-4856.

A.1 AArch32 CONSTRAINED UNPREDICTABLE behaviors

ARMv8 defines architecturally-required constraints on many behaviors that are UNPREDICTABLE in ARMv7. The following sections define those constraints:

A.1.1 Overview of the constraints on UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch32 state, where previous versions of the architecture define behavior as UNPREDICTABLE, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Note

Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases.

A.1.2 Using R13

In prior versions of the architecture, the use of R13 as a named register specifier was described as UNPREDICTABLE in the pseudocode. In the ARMv8-A architecture, the use of R13 as a named register specifier is not UNPREDICTABLE, unless this is specifically stated, and R13 can be used in the regular form. Bits[1:0] of R13 are not treated as RES0, but can hold any values programmed into them.

A.1.3 Using R15

All uses of R15 as a named register specifier for a source register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual can do one of the following:

- Cause the instruction to be treated as an UNDEFINED instruction.
- Cause the instruction to execute as a `NOP`.
- Read the PC with the standard offset that applies for the current instruction set.
- Read the PC with the standard offset that applies for the current instruction set with alignment to a word boundary.
- Read 0.
- Read an UNKNOWN value.

All uses of R15 as a named register specifier for a destination register that are described as CONSTRAINED UNPREDICTABLE in the pseudocode or in other places in this reference manual can do one of the following:

- Cause the instruction to be treated as UNDEFINED.
- Cause the instruction to execute as a `NOP`.
- Ignore the write.
- Branch to an UNKNOWN location in either A32 or T32 state.

The choice between these behaviors might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Instructions that are CONSTRAINED UNPREDICTABLE when the base register is R15 and the instruction specifies a writeback of the base register, are treated as having R15 as both a source register and a destination register.

For instructions that have two destination registers, for example `LDRD`, `MRRC`, and many of the multiply instructions, if Rt, Rt2, RdLo, or RdHi is R15, then the other destination register of the pair is UNKNOWN, if the CONSTRAINED UNPREDICTABLE behavior for the write to R15 is either to ignore the write or to branch to an UNKNOWN location.

For instructions that affect any or all of CPSR.NZCV, CPSR.Q, and CPSR.GE when the register specifier is not R15, any flags affected by an instruction that is CONSTRAINED UNPREDICTABLE when the register specifier is R15 become UNKNOWN,

In addition, for `MRC` instructions for CP14 and CP15 that use R15 as the destination register descriptor, and thereby target APSR.NZCV, where these are described as being CONSTRAINED UNPREDICTABLE, ASPR.NZCV becomes UNKNOWN.

A.1.4 Branching into an IT block

Branching into an IT block leads to CONSTRAINED UNPREDICTABLE behavior. Execution starts from the address determined by the branch, but each instruction in the IT block is:

- Executed as if it were not in an IT block. This means that it is executed unconditionally.
- Executed as if it had passed its Condition code check within an IT block.
- Executed as a NOP. That is, it behaves as if it had failed the Condition code check.

A.1.5 Branching to an unaligned PC

In A32 state, when branching to an address that is not word aligned and is defined to be CONSTRAINED UNPREDICTABLE, one of the following behaviors can occur:

- The unaligned location is forced to be aligned.
- The unaligned address generates a Prefetch Abort exception on the first instruction using the unaligned PC value. If this is executed in EL0 when EL2 is using AArch32 and HCR.TGE == 1, or EL2 is using AArch64 and HCR_EL2.TGE == 1, then the exception is taken to EL2.

  Where the exception is taken to EL1 or EL3 using AArch32:

  — If TTBCR.EAE == 0, IFSR[10, 3:0] takes the value '00001'.

  — If TTBCR.EAE== 1, IFSR[5:0] takes the value '100001'.

  If the exception is taken to EL2 using AArch32, then all of the following are true:

  — The HCR.EC code of 0x22 is used.

  — HSR.IL is UNKNOWN

  — HCR.ISS [24:0] is RES0.

  The IFAR or HIFAR takes the value of the address that faulted, including the misaligned low order bit[1].

  The R14_abt/ELR holds the address that faulted, including the misaligned low order bit[1] with the standard offset associated with that exception.

  Note

  Because bit[0] is used for interworking, it is impossible to specify a branch to A32 state when the bottom bit of the target address is 1. Therefore the bottom bit of IFAR or HIFAR is 0 for all these cases.

A.1.6 Loads and Stores to unaligned locations

Some unaligned loads and stores in the ARMv7 architecture are described as UNPREDICTABLE. These are defined in the ARMv8-A architecture to do one of the following:

- Take an alignment fault.
- Perform the specified load or store to the unaligned memory location.

A.1.7 CONSTRAINED UNPREDICTABLE instructions in an IT block

A number of instructions in the architecture are described as being CONSTRAINED UNPREDICTABLE either:

- Anywhere within an IT block.
- As an instruction within an IT block, other than the last instruction within an IT block.

Unless otherwise stated in this manual, when these instructions are committed for execution, one of the following occurs:

- An UNDEFINED exception results.
- The instructions are executed as if they had passed the Condition code check.
- The instructions execute as NOPs. This means that they behave as if they had failed the Condition code check.

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

Many instructions that are CONSTRAINED UNPREDICTABLE in an IT block are branch instructions or other non-sequential instructions that change the PC. Where these instructions are not treated as UNDEFINED within an IT block, the remaining iterations of the ITSTATE state machine can be treated as follows:

- ITSTATE can be cleared.
- ITSTATE can advance for either a sequential or a nonsequential change of the PC in the same way as it does for instructions that are not CONSTRAINED UNPREDICTABLE that cause a sequential change of the PC.

Note

This does not apply to an instruction that is the last instruction in an IT block.

The instructions addressed by the updated PC can:

- Execute as if they had passed the Condition code check for the remaining iterations of the ITSTATE state machine.
- Execute as NOPs. That is, they behave as if they had failed the Condition code check for the remaining iterations of the CPSR.ITSTATE state machine.
- Execute as if they were unconditional, or, if the instructions are part of another IT block, in accordance with the behavior described in *Branching into an IT block* on page AppxA-4786.

The behavior might in some implementations vary from instruction to instruction, or between different instances of the same instruction.

For exception returns or Debug state exits that cause ITSTATE to be set to a reserved value in T32 state or that return to A32 state with a nonzero value in ITSTATE, the ITSTATE bits are forced to '00000000'.

The reserved values are:

```
ITState[7:4] != '0000' && ITState[3:0] = '0000'
ITState[2:0] != '000' when SCTLR/SCTLR_EL_1.ITD == '1'
```

Exception returns or Debug state exits that set CPSR.ITSTATE to a non-reserved value in T32 state can occur when the flow of execution returns to a point:

- Outside an IT block, but with the ITSTATE bits set to a value other than '00000000'.
- Inside an IT block, but with a different value of the ITSTATE bits than if the IT block had been executed without an exception return or Debug state exit.

In this case the instructions at the target of the exception return or Debug state exit can:

- Execute as if they passed the Condition code check for the remaining iterations of the ITSTATE state machine.
- Execute as NOPs. That is, they behave as if they failed the Condition code check for the remaining iterations of the ITSTATE state machine.
- Execute as if they were unconditional, or as if the instruction were part of another IT block, in accordance with the behavior in *Branching into an IT block* on page AppxA-4786.

The remaining iterations of the CPSR.ITSTATE state machine can behaves as follows:

- The ITSTATE state machine advances as if it were in an IT block.
- The ITSTATE bits are ignored.
- The ITSTATE bits are forced to '00000000'.

A.1.8 Unallocated CP14 and CP15 instructions

In ARMv8-A, accesses to unallocated CP14 and CP15 register encodings are UNDEFINED.

A.1.9 SBZ or SBO fields in instructions

|Many of the A32 and T32 instructions have (0) or (1) in the instruction decode to indicate *should-be-zero*, SBZ, or *should-be-one*, SBO. Except for the specific cases called out in *CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instructions in the base instruction set* on page AppxA-4793, if the instruction bit pattern of an instruction is executed with these fields not having the *should be* values, one of the following can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction operates as if the bit had the *should-be* value.

The exceptions to this rule are:

- *LDM/LDMIA/LDMFD (T32)* on page AppxA-4795.
- *LDMDB/LDMEA* on page AppxA-4797.
- *LDR (literal)* on page AppxA-4803.
- *LDRB (literal)* on page AppxA-4804.
- *LDRH (literal)* on page AppxA-4804.
- *LDRSB (literal)* on page AppxA-4805.
- *LDRSH (literal)* on page AppxA-4805.
- *LDRD (immediate)* on page AppxA-4806.
- *LDRD (register)* on page AppxA-4806.
- *LDRD (literal)* on page AppxA-4807.
- *POP (T32)* on page AppxA-4811.
- *POP (A32)* on page AppxA-4812.
- *PUSH* on page AppxA-4812.
- *SDIV* on page AppxA-4814.
- *UDIV* on page AppxA-4815.
- *STM (STMIA, STMEA)* on page AppxA-4818.
- *STMDB (STMFD)* on page AppxA-4820.

A.1.10 Immediate constants in T32 data processing instructions

The immediate constants in the T32 data processing instructions describe immediate values generated by hw2[7:0] == 0000000 as being UNPREDICTABLE when

- Hw1[10] == 0 and hw2[14:12] == 001.
- Hw1[10] == 0 and hw2[14:12] == 010.
- Hw1[10] == 0 and hw2[14:12] == 011.

For the ARM architecture, these encodings produce the value `0b0000000`.

A.1.11 Unallocated values in register fields of CP14 and CP 15 registers and translation table entries

Unless otherwise stated, all unallocated or reserved values of fields with allocated values within CP15 registers and translation table entries behave in one of the following ways:

- The encoding maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.
- The encoding causes the field to have no functional effect.

A.1.12 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The ARM architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to CONSTRAINED UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with:

- The old data or control value.
- The new data or control value.
- An amalgamation of the old and new data or control values.

Note

This rules applies where inadequate invalidation of the TLB might cause multiple hits within the TLB. In this situation, a failure to invalidate the TLB by code running at a given Privilege level must not make access to regions of memory with permissions or attributes that could not be accessed at that Privilege level possible.

Alternatively, an implementation might generate a Data Abort exception when detecting multiple hits within a TLB, using the TLB Conflict fault code.

The choice between these behaviors might, in some implementations, vary for each use of a control or data value.

A.1.13 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The ARM architecture requires that changes to system registers must be synchronized before they take effect. This can lead to CONSTRAINED UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the processor is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

A.1.14 Translation Table Base Address alignment

A misaligned Translation Table Base Address can occur if:

- The VMSAv8-32 Short-descriptor translation table format is enabled and TTBR0[13-N:7], which is defined to be RES0, contains one or more nonzero values.
- The VMSAv8-32 Long-descriptor translation table format is enabled, and TTBR0[x-1:3], TTBR1[x-1:3], HTTBR[x-1:3], or VTTBR[x-1:3], which are defined to be RES0, contain one or more nonzero values.

In the event of a misaligned Translation Table Base Address, one of the following behaviors can occur:

- The field that is defined to be RES0 is treated as if all bits were zero:
  - The value that is read back might be the value written or it might be zero.
- The calculation of an address for a translation table walk using that register can be corrupted in those bits that are nonzero.

A.1.15 Handling of CP10 and CP11

As the VFP instruction set covers both CP10 and CP11, CPACR, HCPTR, and NSACR all have control bits associated with CP10 and CP11. If these control bits differ, then the behavior is the same as if the control bit for CP11 were equal to the control bit for CP10 in all respects, other than the value read back by an explicit read of the CP11 control bit.

CONSTRAINED UNPREDICTABLE CPACR and NSACR settings

If CPACR.cp<n> contains the encoding '10', then one of the following behaviors can occur:

- The encoding maps onto any of the allocated values, but otherwise does not cause UNPREDICTABLE behavior.
- The encoding causes effects that could be achieved by a combination of more than one of the allocated encodings.

Note

In ARMv7, CPACR had a D32DIS bit, and NSACR had an NSD32DIS bit. There is no CPACR.D32DIS or NSACR.NSD32DIS in ARMv8-A, and the corresponding bits in the two registers are RES0.

A.1.16 Performance Counters

The following cases can cause CONSTRAINED UNPREDICTABLE behavior:

- If PMSELR.SEL is not equal to 31, and PMSELR.SEL is greater than or equal to PMCR.N, and the PE is executing in Secure state or in Non-secure Hyp mode.
- If PMSELR.SEL is not 31, and PMSELR.SEL is greater than or equal to HDCR.HPMN, and the PE is executing in a Non-secure mode other than Hyp mode.

In these cases, one of the following behaviors can occur:

- Any access to PMXEVTYPER or PMXEVCNTR from that mode is UNDEFINED.
- Any access to PMXEVTYPER or PMXEVCNTR from that mode executes as a NOP.
- Any access to PMXEVTYPER or PMXEVCNTR from that mode either:
  - Ignores writes and returns 0 on reads.
  - Behaves as if PMSELR.SEL contains an UNKNOWN value that is less than PMCR.N and the PE is executing in Secure state or in Non-secure Hyp mode, or behaves as if PMSELR.SEL contains an UNKNOWN value that is less than HDCR.HPMN if the PE executing in a Non-secure mode other than Hyp mode.

If PMSELR.SEL is equal to 31, then one of the following behaviors can occur:

- Any access to PMXEVCNTR is UNDEFINED.
- Any access to PMXEVCNTR executes as a NOP.
- Any access to PMXEVCNTR either:
  - Ignores writes and returns 0 on reads.
  - Behaves as if PMSELR.SEL contains an UNKNOWN value that is less than PMCR.N and the PE is executing in Secure state or in Non-secure Hyp mode, or behaves as if PMSELR.SEL contains an UNKNOWN value that is less than HDCR.HPMN if the PE is executing in a Non-secure mode other than Hyp mode.

If HDCR.HPMN is greater than PMCR.N, then the behavior is as if HDCR.HPMN contains an UNKNOWN value less than or equal to the value of PMCR.N, in all respects other than the value read back from HDCR.HPMN.

If HDCR.HPMN is 0, then the behavior is either:

- As if HDCR.HPMN contains an UNKNOWN value less than or equal to PMCR.N, in all respects other than the value read back from HDCR.HPMN.
- As if it were not UNPREDICTABLE.

A.1.17 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as unallocated

When a CONSTRAINED UNPREDICTABLE instruction is treated as unallocated, this generates an exception:

- If this exception is taken in AArch64, then ESR_ELx is UNKNOWN.
- If this exception is taken at EL2 in AArch32, then HSR is UNKNOWN.

Note

The value written to ESR or HSR must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but resulted from a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

A.1.18 Out of range virtual address

If the PE executes an instruction for which the instruction address, size, and alignment mean it contains the bytes `0xFFFF FFFF` and `0x0000 0000`, then the bytes that wrap around and appear to be from `0x0000 0000` onwards come from an UNKNOWN address.

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean it accesses bytes `0xFFFF FFFF` and `0x0000 0000`, then the bytes that wrap around and appear to be from `0x0000 0000` onwards come from an UNKNOWN address.

A.1.19 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location when the MMU is enabled.

If a branch causes the program counter to point to a location in memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation can perform one of the following behaviors:

- It can treat the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It can take a Permission fault.

A.1.20 Multi-access instructions that load the PC from Device memory

Multi-access instructions that load the PC from Device memory when the MMU is enabled are UNPREDICTABLE in AArch32 state. In the ARMv8-A architecture in AArch32, an implementation can perform one of the following behaviors:

- It can load the PC from the memory location as if the memory location had the Normal Non-cacheable attribute.
- It can take a permission fault.

A.1.21 Programming CSSELR.Level for a cache level that is not implemented

If CSSELR.Level is programmed to a cache level that is not implemented, then a read of CSSELR returns an UNKNOWN value in CSSELR.Level.

If the CSSELR.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR an implementation can perform one of the following behaviors:

- The CCSIDR read executes as a `NOP`.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.

A.1.22 Crossing a page boundary with different memory types or shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different type or shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation can perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and shareability attribute associated with its own address.
- The instruction generates an Alignment fault.
- The instruction executes as a `NOP`.

A.1.23 Crossing a 4KB boundary with a Device access

A memory access from a load or store instruction to Device memory that crosses a 4KB boundary results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation can perform one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses, except that there is no guarantee of ordering between memory accesses.
- The instruction generates an Alignment fault.
- The instruction executes as a `NOP`.

A.1.24 CONSTRAINED UNPREDICTABLE behavior for memory hints, Advanced SIMD instructions, and miscellaneous A32 instructions

A number of memory hints, Advanced SIMD instructions, and miscellaneous A32 instructions can result in CONSTRAINED UNPREDICTABLE behavior.

If an instructions listed in *Memory hints, Advanced SIMD instructions, and miscellaneous instructions* on page F4-2404 is CONSTRAINED UNPREDICTABLE but does not have an encoding of `Op1= 101x001`, `Op2 = -`, and `Rn = 1111`, then an implementation can treat these encodings in one of the following ways:

- The encoding is UNDEFINED.
- The instruction executes as a `NOP`.

When `Op1= 101x001`, `Op2 = -`, and `Rn = 1111`, *PLD (literal)* on page F7-2681 describes the behavior. This encoding is subject to the rules outlined in *SBZ or SBO fields in instructions* on page AppxA-4788.

A.1.25 CONSTRAINED UNPREDICTABLE behavior for A32 and T32 instructions in the base instruction set

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 instructions listed in *Alphabetical list of T32 and A32 base instruction set instructions* on page F7-2450.

Note

- The pseudocode used in this section to describe cases that can result in CONSTRAINED UNPREDICTABLE behavior does not necessarily match the encoding specific pseudocode for a specific instruction.
- If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

BFC

For a description of these instructions and the encodings, see *BFC* on page F7-2486.

CONSTRAINED UNPREDICTABLE behavior

If `msbit < lsbit`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The output value is the registers in UNKNOWN.

BFI

For a description of these instructions and the encodings, see *BFI* on page F7-2487.

CONSTRAINED UNPREDICTABLE behavior

If `msbit < lsbit`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The output value in the registers is UNKNOWN.

BKPT

For a description of this instruction and the encoding, see *BKPT* on page F7-2493.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `cond !='1110'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction executes unconditionally.
  - The instruction executes conditionally.

CLZ

For a description of this instruction and the encoding, see *CLZ* on page F7-2503.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `!consistent(Rm)`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The register specified by hw1[3:0] is used as the source register.
  - The register specified by hw2[3:0] is used a the source register.
  - The value in the destination register is UNKNOWN.

CMP (register)

For a description of this instruction and the encoding, see *CMP (register)* on page F7-2512.

CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If `n < 8 && m < 8`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the comparison between Rn and Rm.
  - The condition flags become UNKNOWN.

CRC32, CRC32C

For a description of this instruction and the encoding, see *CRC32, CRC32C* on page F7-2516.

CONSTRAINED UNPREDICTABLE behavior

If `size == 64`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction behaves as if `sz == '10'`.

For the A1 encoding:

- If `cond! = '1110'`, then one of the following behaviors can occur:
- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction is executed unconditionally.
- The instruction is executed conditionally.

HLT

For a description of this instruction and the encoding, see *HLT* on page F7-2531.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `cond !='1110'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction is executed unconditionally.

— The instruction is executed conditionally.

IT

For a description of this instruction and the encoding, see *IT* on page F7-2533.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `firstcond == '1111'||(firstcond == '1110' && BitCount(mask)!= 1)` then one of the following behaviors occurs:
  - — The instruction is undefined.
  - — The instruction executes as a `NOP`.
  - — `firstcond == '1111'` is treated the same as `firstcond == '1110'`, meaning the always condition, and the ITSTATE state machine is progressed in the same way as for any other `cond_base` value.

LDC/LDC2 (literal)

For a description of this instruction and the encoding, see *LDC, LDC2 (literal)* on page F7-2549.

CONSTRAINED UNPREDICTABLE behavior

If `W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_ARM)`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The load instruction operates without writeback.

  Note

  This is consistent with ignoring writes to the PC.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, see *Using R15* on page AppxA-4785.

LDM/LDMIA/LDMFD (T32)

For a description of this instruction and the encoding, see *LDM (LDMIA, LDMFD), T32* on page F7-2551.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors can occur:
  - — The instruction is UNDEFINED.
  - — The instruction executes as a `NOP`.
  - — The instruction operates as an `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For the T2 encoding:

- If `BitCount(registers) < 2`, then one of the following behaviors can occur:
  - — The instruction is UNDEFINED.
  - — The instruction executes as a `NOP`.
  - — The instruction loads a single register using the specified addressing modes.
  - — The instruction operates as an `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

- If hw2[13] is set to 1, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

  Note

  This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788.

- If `P == '1' && M == '1'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.
- If `wback && registers<n> == '1'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode, and the content of the register being written back in UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

LDM/LDMIA/LDMFD (A32)

For a description of this instruction and the encoding, see *LDM (LDMIA, LDMFD), A32* on page F7-2553.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
- If `wback && registers<n> == '1'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode, and the content of the register being written back in UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

LDMDA/LDMFA

For a description of this instruction and the encoding, see *LDMDA (LDMFA)* on page F7-2555.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors can occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

  - The instruction operates as an LDM with the same addressing mode, but targeting an unspecified set of registers. These registers might include R15.

- If wback && registers<n> == '1', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back in UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

LDMIB/LDMED

For a description of this instruction and the encoding, see *LDMIB (LDMED)* on page F7-2559.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If BitCount(registers) < 1, then one of the following behaviors can occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as an LDM with the same addressing mode, but targeting an unspecified set of registers. These registers might include R15.
- If wback && registers<n> == '1', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back in UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

LDMDB/LDMEA

For a description of this instruction and the encoding, see *LDMDB (LDMEA)* on page F7-2557.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If wback && registers<n> == '1', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

For the A1 encoding:

- If BitCount(registers) < 1, then one of the following behaviors can occur:
  - The instruction is UNDEFINED
  - The instruction executes as a NOP.
  - The instruction operates as an LDM with the same addressing mode, but targeting an unspecified set of registers. These registers might include R15.

For the T1 encoding:

- If `BitCount(registers) < 2`, one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction loads a single register using the specified addressing modes.
  - The instruction operates as an `LDM` with the same addressing mode, but targeting an unspecified set of registers. These registers might include R15.
- If hw2[13] is set to 1, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

  Note

  This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788.
- If `P == '1' && M == '1'`, then one of the following behaviors can occur:
  - The instruction is undefined.
  - The instruction executes as a `NOP`.
  - The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

LDR (immediate, T32)

For a description of this instruction and the encoding, see *LDR (immediate), T32* on page F7-2561.

CONSTRAINED UNPREDICTABLE behavior

For the T4 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDR (immediate, A32)

For a description of this instruction and the encoding, see *LDR (immediate), A32* on page F7-2563.

CONSTRAINED UNPREDICTABLE behavior

For the A1encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDR (register, A32)

For a description of this instruction and the encoding, see *LDR (register), A32* on page F7-2569.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRB (immediate, T32)

For a description of this instruction and the encoding, see *LDRB (immediate), T32* on page F7-2571.

CONSTRAINED UNPREDICTABLE behavior

For the T3 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRB (immediate, A32)

For a description of this instruction and the encoding, see *LDRB (immediate), A32* on page F7-2573.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRB (register)

For a description of this instruction and the encoding, see *LDRB (register)* on page F7-2577.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.

— The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRBT

For a description of this instruction and the encoding, see *LDRBT* on page F7-2579.

CONSTRAINED UNPREDICTABLE behavior

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - — The instruction is UNDEFINED.
  - — The instruction executes as a `NOP`.
  - — The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed and post-indexed addressing implies writeback.

- When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in *LDRB (literal)* on page AppxA-4804.

LDRH (immediate, T32)

For a description of this instruction and the encoding, see *LDRH (immediate), T32* on page F7-2595.

CONSTRAINED UNPREDICTABLE behavior

For the T3 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - — The instruction is UNDEFINED.
  - — The instruction executes as a `NOP`.
  - — The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRH (immediate, A32)

For a description of this instruction and the encoding, see *LDRH (immediate), A32* on page F7-2597.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - — The instruction is UNDEFINED.
  - — The instruction executes as a `NOP`.
  - — The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRH (register)

For a description of this instruction and the encoding, see *LDRH (register)* on page F7-2601.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRHT

For a description of this instruction and the encoding, see *LDRHT* on page F7-2603.

CONSTRAINED UNPREDICTABLE behavior

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed and post-indexed addressing implies writeback.

- When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in *LDRH (literal)* on page AppxA-4804.

LDRSB (immediate)

For a description of this instruction and the encoding, see *LDRSB (immediate)* on page F7-2605.

CONSTRAINED UNPREDICTABLE behavior

For the A1 and T2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRSB (register)

For a description of this instruction and the encoding, see *LDRSB (register)* on page F7-2609.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && (n == t)`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRSBT

For a description of this instruction and the encoding, see *LDRSBT* on page F7-2611.

CONSTRAINED UNPREDICTABLE behavior

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed and post-indexed addressing implies writeback.

- When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in *LDRSB (literal)* on page AppxA-4805.

LDRSH (immediate)

For a description of this instruction and the encoding, see *LDRSH (immediate)* on page F7-2613.

CONSTRAINED UNPREDICTABLE behavior

For the T2 and A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRSH (register)

For a description of this instruction and the encoding, see *LDRSH (register)* on page F7-2617.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

LDRSHT

For a description of this instruction and the encoding, see *LDRSHT* on page F7-2619.

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed and post-indexed addressing implies writeback.

- When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in *LDRSB (literal)* on page AppxA-4805.

LDRT

For a description of this instruction and the encoding, see *LDRT* on page F7-2621.

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed and post-indexed addressing implies writeback.

- When the Rn field specifies R15, then this instruction can be treated either as described in this section or as described in *LDRSB (literal)* on page AppxA-4805.

LDR (literal)

For a description of this instruction and the encoding, see *LDR (literal)* on page F7-2565.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.
  - The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

    Note

    This is an exception to the principle in *SBZ or SBO fields in instructions* on page AppxA-4788.

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788 or the requirements described in *LDR (immediate, T32)* on page AppxA-4798.

LDRB (literal)

For a description of this instruction and the encoding, see *LDRB (literal)* on page F7-2575.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.
  - The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

    Note

    This is an exception to the principle in *SBZ or SBO fields in instructions* on page AppxA-4788.

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788 or the requirements described in *LDRB (immediate, T32)* on page AppxA-4799.

LDRH (literal)

For a description of this instruction and the encoding, see *LDRH (literal)* on page F7-2599.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  - The instruction is UNDEFINED.
  - The instruction is treated as a NOP.
  - The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.

— The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

Note

This is an exception to the principle in *SBZ or SBO fields in instructions* on page AppxA-4788.

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788 or the requirements described in *LDRH (immediate, T32)* on page AppxA-4800.

LDRSB (literal)

For a description of this instruction and the encoding, see *LDRSB (literal)* on page F7-2607.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  — The instruction is UNDEFINED.
  — The instruction is treated as a `NOP`.
  — The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.
  — The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

  Note

  This is an exception to the principle in *SBZ or SBO fields in instructions* on page AppxA-4788.

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788 or the requirements described in *LDRSB (immediate)* on page AppxA-4801.

LDRSH (literal)

For a description of this instruction and the encoding, see *LDRSH (literal)* on page F7-2615.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] has the same value as bit[21]:
  — The instruction is UNDEFINED.
  — The instruction is treated as a `NOP`.
  — The instruction is treated as if bit[24] had value of 1 and bit[21] had a value of 0.
  — The instruction treats bit[24] as the P bit, and bit[21] as the writeback bit, and uses the same addressing mode as described in the immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

  Note

  This is an exception to the principle in *SBZ or SBO fields in instructions* on page AppxA-4788.

- If bit[24] == 0 and bit[21] == 1, then the instruction can be handled according to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788 or the requirements described in *LDRSH (immediate)* on page AppxA-4802.

LDRD (immediate)

For a description of this instruction and the encoding, see *LDRD (immediate)* on page F7-2581.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `wback && (n == t || n == t2)`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For the T1 encoding:

- If `t == t2`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

For the A1 encoding:

- If `P=='0' && W=='1'` then one of the following behaviors can occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction behaves as if the values of P and W were as follows:

    `P == '1' && W == '0'`

    `P == '1' && W == '1'`

    `P == '0' && W == '0'`

- If `Rt<0>=='1'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The behavior is the same as if `Rt<0> =='0'`.
  - The register accessed are both specified by Rt. This means that Rt and Rt+1 are the same, and both have bit[0] == 1.
  - The registers accessed are specified by Rt and Rt+1.

    Note

    This does not apply if `Rt=='1111'`.

LDRD (register)

For a description of this instruction and the encoding, see *LDRD (register)* on page F7-2585.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `wback && (n == t || n == t2)`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.

  - The instruction performs all the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

- If `P == '0' && W == '1'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction behaves as if the values of P and W were as follows:

    `P == '1' && W == '0'`

    `P == '1' && W == '1'`

    `P == '0' && W == '0'`

- If `m == t || m ==t2`, then one of the following behaviors can occur;
  - The instruction is UNDEFINED.
  - The instruction is treated as a `NOP`.
  - The instruction loads register Rm with an UNKNOWN value.

- If `Rt<0>=='1'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The behavior is the same as if `Rt<0> == '0'`.
  - The registers accessed are both specified by Rt. This means that Rt and Rt+1 are the same, and in both cases bit[0] == 1.
  - The registers accessed are specified by Rt and Rt+1.

    Note

    This does not apply if `Rt=='1111'`.

LDRD (literal)

For a description of this instruction and the encoding, see *LDRD (literal)* on page F7-2583.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[24] and bit[21] do not have their *should be* values, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction is treated as if the bits had their *should be* values.

- If `Rt<0>=='1'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The behavior is the same as if `Rt<0> =='0'`.
  - The registers accessed are both specified by Rt. This means that Rt and Rt+1 are the same, and both have bit[0] equal to 1.
  - The registers accessed are specified by Rt and Rt+1.

    Note

    This does not apply if `Rt=='1111'`.

For the T1 encoding:

- If `t == t2`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.
- If `W == '1'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction is treated as if `W == '0'`.
  - The instruction uses the P and W bits as described for *LDRD (immediate)* on page AppxA-4806.

LDREX

For a description of this instruction and the encoding, see *LDREX* on page F7-2587.

CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

LDREXH

For a description of this instruction and the encoding, see *LDREXH* on page F7-2593.

CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

LDREXB

For a description of this instruction and the encoding, see *LDREXB* on page F7-2589.

CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

LDAEX

For a description of this instruction and the encoding, see *LDAEX* on page F7-2537.

CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

LDAEXH

For a description of this instruction and the encoding, see *LDAEXH* on page F7-2543.

CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

LDAEXB

For a description of this instruction and the encoding, see *LDAEXB* on page F7-2539.

CONSTRAINED UNPREDICTABLE behavior

If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

LDREXD

For a description of this instruction and the encoding, see *LDREXD* on page F7-2591.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

For the T1 encoding:

- If `t == t2`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

For the A1 encoding:

- If `Rt<0>=='1'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The behavior is the same as if the `Rt<0>=='0'`.
  - The registers accessed are both specified by Rt. This means that Rt and Rt+1 are the same, and both have bit[0] == 1.
  - The registers accessed are specified by Rt and Rt+1.

Note

If `t2 == 15`, then the requirements described in *Using R15* on page AppxA-4785 apply.

LDAEXD

For a description of this instruction and the encoding, see *LDAEXD* on page F7-2541.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the Load-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.

For the T1 encoding:

- If `t == t2`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.

— The instruction performs all of the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

For the A1 encoding:

- If `Rt<0>=='1'`, then one of the following behaviors can occur:
  - — The instruction is UNDEFINED.
  - — The instruction executes as a `NOP`.
  - — The behavior is the same as if the `Rt<0>=='0'`.
  - — The registers accessed are both specified by Rt. This means that Rt and Rt+1 are the same, and both have bit[0] == 1.
  - — The registers accessed are specified by Rt and Rt+1.

Note

If `t2 == 15`, then the requirements described in *Using R15* on page AppxA-4785 apply.

MOV (register, T32)

For a description of this instruction and the encoding, see *MOV (register), T32* on page F7-2641.

CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If `InITBlock()` , then one of the following behaviors can occur:
  - — The instruction generates an UNDEFINED exception.
  - — The instruction is executed as if it passed its condition code check.
  - — The instruction executes as a `NOP`. That is, it behaves as if it failed its condition code check.
  - — The instruction is treated as MOV Rd, Rm.

Note

This is an exception to the general behavior described in *CONSTRAINED UNPREDICTABLE instructions in an IT block* on page AppxA-4786.

MRRC, MRRC2

For a description of this instruction and the encoding, see *MRRC, MRRC2* on page F7-2649.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `t == t2`, then one of the following behaviors can occur:
  - — The instruction is UNDEFINED.
  - — The instruction executes as a `NOP`.
  - — The register that is transferred takes an UNKNOWN value.

MSR (register)

For a description of this instruction and the encoding, see *MSR (register)* on page F7-2655.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `mask == '00'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.

POP (T32)

For a description of this instruction and the encoding, see *POP, T32* on page F7-2689.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as a `POP` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For the T2 encoding:

- If `BitCount(registers) < 2`, one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction loads a single register using the specified addressing modes.
  - The instruction operates as an `LDM` with the same addressing mode but targeting an unspecified set of registers. These might include R15.
- If hw2 bit[13] is set to 1, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode but R13 in UNKNOWN.

    Note

    This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788.
- If `P == '1' && M == '1'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

For the T3 encoding:

- If `t == 13`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the load using the specified addressing mode but R15 is UNKNOWN.

    Note

    This is an exception to the requirements described in *Using R13* on page AppxA-4785.

POP (A32)

For a description of this instruction and the encoding, see *POP, A32* on page F7-2691.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If bit[13] is set to 1, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the loads using the specified addressing mode but R13 is UNKNOWN.

For the A2 encoding:

- If `t == 13`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the load using the specified addressing mode but R13 is UNKNOWN.

  Note

  This is an exception to the requirements described in *Using R13* on page AppxA-4785.

PUSH

For a description of this instruction and the encoding, see *PUSH* on page F7-2693.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as a `PUSH` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For the T2 encoding:

- If `BitCount(registers) < 2`, one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction stores a single register using the specified addressing modes.
  - The instruction operates as a `PUSH` with the same addressing mode but targeting an unspecified set of registers. These might include R15.
- If hw2 bit[13] is set, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the stores using the specified addressing mode but R13 in UNKNOWN.

    Note

    This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788.

- If hw2 bit[15] is set to 1, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the stores using the specified addressing mode, but R15 is UNKNOWN.

  Note

  This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788.

RBIT

For a description of this instruction and the encoding, see *RBIT* on page F7-2715.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `! Consistent(Rm)`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The register specified by Rm in halfword 1 is used as the source register.
  - The register specified by Rm in halfword 2] is used as the source register.
  - The value in the destination register is UNKNOWN.

REV

For a description of this instruction and the encoding, see *REV* on page F7-2717.

CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If `! Consistent(Rm)`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The register specified by Rm in halfword 1 is used as the source register.
  - The register specified by Rm in halfword 2 is used as the source register.
  - The value in the destination register is UNKNOWN.

REV16

For a description of this instruction and the encoding, see *REV16* on page F7-2719.

CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If `! Consistent(Rm)`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The register specified by Rm in halfword 1 is used as the source register.
  - The register specified by Rm in halfword 2 is used as the source register.
  - The value in the destination register is UNKNOWN.

REVSH

For a description of this instruction and the encoding, see *REVSH* on page F7-2721.

CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If `! Consistent(Rm)`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The register specified by Rm in halfword 1 is used as the source register.
  - The register specified by Rm in halfword 2 is used as the source register.
  - The value in the destination register is UNKNOWN.

SBFX

For a description of this instruction and the encoding, see *SBFX* on page F7-2753.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `msbit > 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The output value in the register is UNKNOWN.

UBFX

For a description of this instruction and the encoding, see *UBFX* on page F7-2925.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `msbit > 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The output value in the register is UNKNOWN.

SDIV

For a description of this instruction and the encoding, see *SDIV* on page F7-2755.

CONSTRAINED UNPREDICTABLE behavior

For the T1encoding:

- If hw2 bits[15:12] !='1111', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs a divide with no side-effects on other registers.
  - The instruction performs a divide and the register specified by bits[15:12] becomes UNKNOWN.

Note

This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788.

For the A1 encoding:

- If bits[15:12] !='1111', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs a divide with no side-effects on other registers.
  - The instruction performs a divide and the register specified by bits[15:12] becomes UNKNOWN.

Note

This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788.

UDIV

For a description of this instruction and the encoding, see *UDIV* on page F7-2929.

CONSTRAINED UNPREDICTABLE behavior

For the T1encoding:

- If hw2 bits[15:12] !='1111', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs a divide with no side-effects on other registers.
  - The instruction performs a divide and the register specified by bits[15:12] becomes UNKNOWN.

Note

This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788.

For the A1 encoding:

- If bits[15:12] !='1111', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs a divide with no side-effects on other registers.
  - The instruction performs a divide and the register specified by bits[15:12] becomes UNKNOWN.

Note

This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788.

SMULL

For a description of this instruction and the encoding, see *SMULL* on page F7-2803.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register takes an UNKNOWN value.

SMLAL

For a description of this instruction and the encoding, see *SMLAL* on page F7-2781.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register takes an UNKNOWN value.

SMLALBB, SMLALBT, SMLALTB, SMLALTT

For a description of this instruction and the encoding, see *SMLALBB, SMLALBT, SMLALTB, SMLALTT* on page F7-2783.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register takes an UNKNOWN value.

SMLALD

For a description of this instruction and the encoding, see *SMLALD* on page F7-2785.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register takes an UNKNOWN value.

SMLSLD

For a description of this instruction and the encoding, see *SMLSLD* on page F7-2791.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.

— The instruction executes as a NOP.
— The destination register takes an UNKNOWN value.

UMULL

For a description of this instruction and the encoding, see *UMULL* on page F7-2947.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.
  — The destination register takes an UNKNOWN value.

UMAAL

For a description of this instruction and the encoding, see *UMAAL* on page F7-2943.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.
  — The destination register takes an UNKNOWN value.

UMLAL

For a description of this instruction and the encoding, see *UMLAL* on page F7-2945.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `dHi == dLo`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.
  — The destination register takes an UNKNOWN value.

STC, STC2

For a description of this instruction and the encoding, see *STC, STC2* on page F7-2819.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `n == 15 && (wback || CurrentInstrSet() != InstrSet_A32)`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.
  — The store instruction operates without writeback.

  Note

  This is consistent with ignoring writes to the PC.

— The instruction set uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

Note

Use of R15 by the T32 `STC` instruction is also covered by *Using R15* on page AppxA-4785.

STM (STMIA, STMEA)

For a description of this instruction and the encoding, see *STM (STMIA, STMEA)* on page F7-2835.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

For the T1 and A1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a `NOP`.
  — The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For the T2 encoding:

- If `BitCount(registers) < 2`, then one of the following behaviors occurs:
  — The instruction is UNDEFINED.
  — The instruction executes as a `NOP`.
  — The instruction stores a single register using the specified addressing modes.
  — The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These might include R15.
- If hw2 bit[13] is set, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a `NOP`.
  — The instruction performs all the stores using the specified addressing mode but the value of R13 is UNKNOWN.

  Note

  This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788.
- If hw2 bit[15] is set to 1, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a `NOP`.
  — The instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

  Note

  This is an exception to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788.

- If `wback && registers<n> == '1'`, and that case is defined to be UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the stores using the specified addressing mode and the value stored for the base register is UNKNOWN.

STMDA (STMED)

For a description of this instruction and the encoding, see *STMDA (STMED)* on page F7-2837.

CONSTRAINED UNPREDICTABLE behavior

For the A1encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
- If the instruction uses R15 as a base register and specifies writeback, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction is performed without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

STMIB (STMFA)

For a description of this instruction and the encoding, see *STMIB (STMFA)* on page F7-2841.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
- If the instruction uses R15 as a base register and specifies writeback, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction is performed without writeback.

Note

This is consistent with ignoring writes to the PC.

— The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

STMDB (STMFD)

For a description of this instruction and the encoding, see *STMDB (STMFD)* on page F7-2839.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

For the A1 encoding:

- If `BitCount(registers) < 1`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For the T1 encoding:

- If `BitCount(register) < 2`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction stores a single register using the specified addressing mode.
  - The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These might include R15.
- If `wback && registers<n> == '1'`, and that case is defined to be UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the stores using the specified addressing mode and the value stored for the base register is UNKNOWN.
- If hw2 bit[13] is set to 1, then one of the following behaviors occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the stores using the specified addressing mode but the value of R13 is UNKNOWN.

    Note

    This an exception to the requirements described in *SBZ or SBO fields in instructions* on page AppxA-4788.

- If hw2 bit[15] is set to 1, then one of the following behaviors occurs:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

    Note

    This is an exception to the requirement described in *SBZ or SBO fields in instructions* on page AppxA-4788.

STR (immediate, T32)

For a description of this instruction and the encoding, see *STR (immediate), T32* on page F7-2843.

CONSTRAINED UNPREDICTABLE behavior

For the T3 encoding:

- If `t == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

For the T4 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

  Note

  Pre-indexed and post-indexed addressing implies writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

STR (immediate, A32)

For a description of this instruction and the encoding, see *STR (immediate), A32* on page F7-2845.

CONSTRAINED UNPREDICTABLE behavior

For the A1encoding:

- If `t == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

    Note

    Pre-indexed and post-indexed addressing implies writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

STR (register)

For a description of this instruction and the encoding, see *STR (register)* on page F7-2847.

CONSTRAINED UNPREDICTABLE behavior

For the T2 encoding:

- If `t == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

For the A1encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

Note

Pre-indexed and post-indexed addressing implies writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

STRB (immediate), T32

For a description of this instruction and the encoding, see *STRB (immediate), T32* on page F7-2849.

CONSTRAINED UNPREDICTABLE behavior

For the T3 encoding:

- If `t == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

Note

Pre-indexed and post-indexed addressing implies writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

STRB (immediate, A32)

For a description of this instruction and the encoding, see *STRB (immediate), A32* on page F7-2851.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `t == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

Note

Pre-indexed and post-indexed addressing implies writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

STRB (register)

For a description of this instruction and the encoding, see *STRB (register)* on page F7-2853.

CONSTRAINED UNPREDICTABLE behavior

For the A1 and T2 encoding:

- If `t == 15` is UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.

— The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a `NOP`.
  — The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a `NOP`.
  — The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  — The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

  Note

  Pre-indexed and post-indexed addressing implies writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

STRBT

For a description of this instruction and the encoding, see *STRBT* on page F7-2855.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `t == 15`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a `NOP`.
  — The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a `NOP`.
  — The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a `NOP`.

— The store instruction operates without writeback.

Note

This is consistent with ignoring writes to the PC.

— The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

Note

Pre-indexed and post-indexed addressing implies writeback.

STRH (immediate, T32)

For a description of this instruction and the encoding, see *STRH (immediate), T32* on page F7-2869.

CONSTRAINED UNPREDICTABLE behavior

For T2 and T3 encodings:

- If `t == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

For the T3 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

Note

Pre-indexed and post-indexed addressing implies writeback.

STRH (immediate, A32)

For a description of this instruction and the encoding, see *STRH (immediate), A32* on page F7-2871.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `t == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

    Note

    Pre-indexed and post-indexed addressing implies writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

STRH (register)

For a description of this instruction and the encoding, see *STRH (register)* on page F7-2873.

CONSTRAINED UNPREDICTABLE behavior

For the T2 and A1 encoding:

- If `t == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

For the A1 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.

- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

Note

Pre-indexed and post-indexed addressing implies writeback.

STRHT

For a description of this instruction and the encoding, see *STRHT* on page F7-2875.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `t == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

Note

Pre-indexed and post-indexed addressing implies writeback.

STRT

For a description of this instruction and the encoding, see *STRT* on page F7-2877.

CONSTRAINED UNPREDICTABLE behavior

For the T1 encoding:

- If `t == 15` is UNPREDICTABLE, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For the A1 and A2 encoding:

- If `wback && n == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store using the specified addressing mode but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

    Note

    Pre-indexed and post-indexed addressing implies writeback.
- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

STRD (immediate)

For a description of this instruction and the encoding, see *STRD (immediate)* on page F7-2857.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `t == 15` or `t2 == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If `wback && (n == t || n == t2)`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.

— The instruction performs the store of the registers specified using the specified addressing mode but the value of the registers stored is UNKNOWN.

- If `wback && n == 15`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a `NOP`.
  — The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  — The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

  Note

  Pre-indexed and post-indexed addressing implies writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

For the A1 encoding:

- If `Rt<0>=='1'`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a `NOP`.
  — The behavior is the same as if `Rt<0>=='0'`.
  — The registers accessed are both specified by Rt. For example, Rt and Rt+1 are the same, and both have bit[0] equal to 1.
  — The registers accessed are specified by Rt and Rt+1.

    Note

    This does not apply if `Rt=='1111'`.

- If `P == '0' && W == '1'`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction is treated as a `NOP`.
  — The instruction behaves as if the values of P and W were one of:
    `P == '1' && W == '0'`
    `P == '1' && W == '1'`
    `P == '0' && W == '0'`

STRD (register)

For a description of this instruction and the encoding, see *STRD (register)* on page F7-2859.

CONSTRAINED UNPREDICTABLE behavior

For the A1 encoding:

- If `t2 == 15`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a `NOP`.

  - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

- If `wback && (n == t || n == t2)`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store of the registers specified using the specified addressing mode but the value of the registers stored is UNKNOWN.

- If `wback && n == 15`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction operates without writeback.

    Note

    This is consistent with ignoring writes to the PC.

  - The instruction uses the addressing mode described in the equivalent immediate offset instruction. If this results in writeback to the PC, then the requirements described in *Using R15* on page AppxA-4785 apply.

Note

Pre-indexed and post-indexed addressing implies writeback.

- The value used by stores using R15 as a base register follow the requirements described in *Using R15* on page AppxA-4785.

- If `Rt<0>=='1'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The behavior is the same as if `Rt<0>=='0'`.
  - The registers accessed are both specified by Rt. For example, Rt and Rt+1 are the same, and both have bit[0] equal to 1.
  - The registers accessed are specified by Rt and Rt+1.

    Note

    This does not apply if `Rt=='1111'`.

- If `P == '0' && W == '1'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction is treated as a `NOP`.
  - The instruction behaves as if the values of P and W were one of:

    ```
    P == '1' && W == '0'
    P == '1' && W == '1'
    P == '0' && W == '0'
    ```

STREX

For a description of this instruction and the encoding, see *STREX* on page F7-2861.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction executes, but the value stored is UNKNOWN.
- If `d == n`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that `t2==15`, then the requirements described in *Using R15* on page AppxA-4785 apply.

STREXB

For a description of this instruction and the encoding, see *STREXB* on page F7-2863.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction executes, but the value stored is UNKNOWN.
- If `d == n`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that `t2==15`, then the requirements described in *Using R15* on page AppxA-4785 apply.

STREXD

For a description of this instruction and the encoding, see *STREXD* on page F7-2865.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction executes, but the value stored is UNKNOWN.
- If `d == n`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.

  - The instruction executes as a NOP.
  - The instruction performs the store to an UNKNOWN address.

- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that t2==15, then the requirements described in *Using R15* on page AppxA-4785 apply.

For the A1 encoding:

- If Rt<0>=='1', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The behavior is the same as if Rt<0>=='0'.
  - The register accessed are both specified by Rt. For example, Rt and Rt+1 are the same, and both have bit[0] == 1.
  - The registers accessed are specified by Rt and R+1.

STREXH

For a description of this instruction and the encoding, see *STREXH* on page F7-2867.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If d == t, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction executes, but the value stored is UNKNOWN.
- If d == n, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that t2==15, then the requirements described in *Using R15* on page AppxA-4785 apply.

STLEX

For a description of this instruction and the encoding, see *STLEX* on page F7-2825.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If d == t, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The store instruction executes, but the value stored is UNKNOWN.
- If d == n, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

  - The instruction performs the store to an UNKNOWN address.

- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that `t2==15`, then the requirements described in *Using R15* on page AppxA-4785 apply.

STLEXB

For a description of this instruction and the encoding, see *STLEXB* on page F7-2827.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction executes, but the value stored is UNKNOWN.
- If `d == n`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that `t2==15`, then the requirements described in *Using R15* on page AppxA-4785 apply.

STLEXD

For a description of this instruction and the encoding, see *STLEXD* on page F7-2829.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d == t`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The store instruction executes, but the value stored is UNKNOWN.
- If `d == n`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that `t2==15`, then the requirements described in *Using R15* on page AppxA-4785 apply.

For the A1 encoding:

- If `Rt<0>=='1'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.

— The instruction executes as a NOP.
— The behavior is the same as if Rt<0>=='0'.
— The register accessed are both specified by Rt. For example, Rt and Rt+1 are the same, and both have bit[0] == 1.
— The registers accessed are specified by Rt and R+1.

STLEXH

For a description of this instruction and the encoding, see *STLEXH* on page F7-2831.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If d == t, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.
  — The store instruction executes, but the value stored is UNKNOWN.
- If d == n, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.
  — The instruction performs the store to an UNKNOWN address.
- If the Store-Exclusive is to any type of Device memory, then the instruction operates as if the access were to Normal memory.
- If the instruction specifies that t2==15, then the requirements described in *Using R15* on page AppxA-4785 apply.

A.1.26 CONSTRAINED UNPREDICTABLE behavior, A32 and T32 system instructions in the base instruction set

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 system instructions listed in *Alphabetical list of system instructions* on page F7-2998.

Note

If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

CPS (A32)

For a description of this instruction and the encoding, see *CPS, A32* on page F7-3000.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the instruction transfers an illegal mode encoding to the CPSR mode field, then this invokes an illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

  Note

  — An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.
  — CPS executed from User mode acts as a NOP.

For the A1 encoding:

- If (imod == '00 && M =='0') || imod == '01', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
- If mode != '00000' && M == '0', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as if M == '1'.
  - The instruction operates as if mode == '0000'.
- If (imod<1> == '1' && A:I:F == '000'), then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction behaves as if imod<1> == '0'.
  - The instruction behaves as if A:I:F had an UNKNOWN nonzero value.
- If (imod<1> == '0' && A:I:F != 000) then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction behaves as if imod<1> == '1'.
  - The instruction behaves as if A:I:F == 000.

CPS (T32)

For a description of this instruction and the encoding, see *CPS, T32* on page F7-2998.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the instruction transfers an illegal mode encoding to the CPSR mode field, then this invokes the illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

  Note

  - An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.
  - CPS executed from User mode acts as a NOP.

For the T1 encoding:

- If A:I:F == '000', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.

For the T2 encoding:

- If imod == '01', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
- If mode != '00000' && M == '0', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as if M =='1'.
  - The instruction behaves as if mode == '0000'.

- If (imod<1> == '1' && A:I:F == '000'), then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction behaves as if imod<1> == '0'.
  - The instruction behaves as if A:I:F had an UNKNOWN nonzero value.
- If (imod<1> == '0' && A:I:F != '000') then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction behaves as if imod<1> == '1'.
  - The instruction behaves as if A:I:F == '000'.

LDM (exception return)

For a description of this instruction and the encoding, see *LDM (exception return)* on page F7-3006.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
- If wback && registers<n> == '1', then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction performs all the loads using the specified addressing mode and the content of the register being written back is UNKNOWN. In addition, if an exception occurs during the execution of this instruction, the base address might be corrupted so that the instruction cannot be repeated.
- If the instruction transfers an illegal mode encoding to the CPSR mode field, then this invokes the illegal exception return.

  Note

  An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

LDM (User registers)

For a description of this instruction and the encoding, see *LDM (User registers)* on page F7-3008.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If BitCount(registers) < 1, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
- If this instruction is executed in User mode or in System mode, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.

— The instruction executes as a NOP.

— The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

MRS

For a description of this instruction and the encoding, see *MRS* on page F7-3010.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode and is accessing the SPSR, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.

MSR (immediate)

For a description of this instruction and the encoding, see *MSR (immediate)* on page F7-3016.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If the instruction is executed in User mode or in System mode and is accessing the SPSR, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.
- If `mask == '0000' && R == '1'`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.

  If the instruction transfers an illegal mode encoding to the CPSR mode field, then this invokes the illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

  Note

  An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

MSR (register)

For a description of this instruction and the encoding, see *MSR (register)* on page F7-3018.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode and is accessing the SPSR, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.
- If `mask == '0000'`, then one of the following behaviors can occur:
  — The instruction is UNDEFINED.
  — The instruction executes as a NOP.

If the instruction transfers an illegal mode encoding to the CPSR mode field, then this invokes the illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

Note

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

RFE

For a description of this instruction and the encoding, see *RFE* on page F7-3020.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
- If the instruction transfers an illegal mode encoding to the CPSR mode field, then this invokes the illegal exception return.

Note

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

SRS (T32)

For a description of this instruction and the encoding, see *SRS, T32* on page F7-3024.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
- If the instruction specifies an illegal mode field, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - R13 of the current mode is used.
  - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

SRS (A32)

For a description of this instruction and the encoding, see *SRS, A32* on page F7-3026.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.

  - The instruction executes as a NOP.

- If the instruction specifies an illegal mode field, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - R13 of the current mode is used.
  - The store occurs to an UNKNOWN address, and if the instruction specifies writeback, any general-purpose register that can be accessed without privilege violation from the current Exception level become UNKNOWN.

STM (User registers)

For a description of this instruction and the encoding, see *STM (User registers)* on page F7-3028.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `BitCount(registers) < 1`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.
- If the instruction is executed from User mode or System mode, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
  - The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

SUBS PC, LR and related instructions (T32)

For a description of this instruction and the encoding, see *SUBS PC, LR and related instructions, T32* on page F7-3030.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a NOP.
- If the instruction transfers an illegal mode encoding to the CPSR mode field, then this invokes the illegal exception return.

  Note

  An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

SUBS PC. LR and related instructions (A32)

For a description of this instruction and the encoding, see *SUBS PC, LR and related instructions, A32* on page F7-3032.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If this instruction is executed in User mode or in System mode, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
- If the instruction transfers an illegal mode encoding to the CPSR mode field, then this invokes the illegal exception return.

Note

An illegal mode encoding is either an unallocated mode encoding or one that is not accessible at the current Exception level.

A.1.27 CONSTRAINED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 Advanced SIMD and floating-point instructions listed in *Alphabetical list of floating-point and Advanced SIMD instructions* on page F8-3036.

Note

- The pseudocode used in this section to describe cases that can result in CONSTRAINED UNPREDICTABLE behavior does not necessarily match the encoding specific pseudocode for a specific instruction.
- If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

VCVT (between floating-point and fixed-point)

For a description of this instruction and the encoding, see *VCVT (between floating-point and fixed-point, floating-point)* on page F8-3108.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `frac_bits < 0`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The result of the conversion is UNKNOWN.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD1 (multiple single elements)

For a description of this instruction and the encoding, see *VLD1 (multiple single elements)* on page F8-3136.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d+regs > 32`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD1 (single element to all lanes)

For a description of this instruction and the encoding, see *VLD1 (single element to all lanes)* on page F8-3140.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d+regs > 32`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (multiple 2-element structures)

For a description of this instruction and the encoding, see *VLD2 (multiple 2-element structures)* on page F8-3142.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d2+regs > 32`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (single 2-element structure to one lane)

For a description of this instruction and the encoding, see *VLD2 (single 2-element structure to one lane)* on page F8-3144.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d2 > 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD2 (single 2-element structure to all lanes)

For a description of this instruction and the encoding, see *VLD2 (single 2-element structure to all lanes)* on page F8-3146.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d2 > 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD3 (multiple 3-element structures)

For a description of this instruction and the encoding, see *VLD3 (multiple 3-element structures)* on page F8-3148.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d3 > 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD3 (single 3-element structure to one lane)

For a description of this instruction and the encoding, see *VLD3 (single 3-element structure to one lane)* on page F8-3150.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d3 > 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD3 (single 3-element structure to all lanes)

For a description of this instruction and the encoding, see *VLD3 (single 3-element structure to all lanes)* on page F8-3152.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d+regs > 32`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD4 (multiple 4-element structures)

For a description of this instruction and the encoding, see *VLD4 (multiple 4-element structures)* on page F8-3154.

CONSTRAINED UNPREDICTABLE behavior

If `d3 > 31`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD4 (single 4-element structure to one lane)

For a description of this instruction and the encoding, see *VLD4 (single 4-element structure to one lane)* on page F8-3156.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d4 > 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLD4 (single 4-element structure to all lanes)

For a description of this instruction and the encoding, see *VLD4 (single 4-element structure to all lanes)* on page F8-3158.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d4 > 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VLDM

For a description of this instruction and the encoding, see *VLDM* on page F8-3160.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `regs == 0`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as a `VLDM` or a `VPOP` with the same addressing mode but loads no registers.
- If the register list includes a register that is out of range, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD&FP registers become UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Note

Out of range means that the register list includes:

- A register with a number greater than the number of registers implemented.
- More than 16 double word registers.
- A double word register specified as D16-D31 with an odd value of `imm8`.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VPOP

For a description of this instruction and the encoding, see *VPOP* on page F8-3230.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `regs == 0`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as a `VLDM` or a `VPOP` with the same addressing mode but loads no registers.
- If the register list includes a register that is out of range, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD&FP registers become UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Note

Out of range means that the register list includes:

- A register with a number greater than the number of registers implemented.
- More than 16 double word registers.
- A double word register specified as D16-D31 with an odd value of `imm8`.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VMOV (between two general-purpose registers and two single-precision registers)

For a description of this instruction and the encoding, see *VMOV (between two general-purpose registers and two single-precision registers)* on page F8-3186.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `to_arm_registers && t == t2`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register becomes UNKNOWN.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

- If `m == 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD&FP single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

VMOV (between two general-purpose registers and a doubleword floating-point register)

For a description of this instruction and the encoding, see *VMOV (between two general-purpose registers and a doubleword floating-point register)* on page F8-3188.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `to_arm_registers && t == t2`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The destination register becomes UNKNOWN.

  If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST1 (multiple single elements)

For a description of this instruction and the encoding, see *VST1 (multiple single elements)* on page F8-3318.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d+regs > 32`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST2 (multiple 2-element structures)

For a description of this instruction and the encoding, see *VST2 (multiple 2-element structures)* on page F8-3322.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d2+regs > 32`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST2 (single 2-element structure from one lane)

For a description of this instruction and the encoding, see *VST2 (single 2-element structure from one lane)* on page F8-3324.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d2 > 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST3 (multiple 3-element structures)

For a description of this instruction and the encoding, see *VST3 (multiple 3-element structures)* on page F8-3326.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d3 > 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST3 (single 3-element structure from one lane)

For a description of this instruction and the encoding, see *VST3 (single 3-element structure from one lane)* on page F8-3328.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d3 > 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST4 (multiple 4-element structures)

For a description of this instruction and the encoding, see *VST4 (multiple 4-element structures)* on page F8-3330.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d4 > 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VST4 (single 4-element structure from one lane)

For a description of this instruction and the encoding, see *VST4 (single 4-element structure from one lane)* on page F8-3332.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `d4 > 31`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VSTM

For a description of this instruction and the encoding, see *VSTM* on page F8-3334.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `regs == 0`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as a `VSTM` or `VPUSH` with the same addressing mode but loads no registers.
- If the register list includes a register that is out of range, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

Note

Out of range means that the register list includes:

- A register with a number greater than the number of registers implemented.
- More than 16 double word registers.
- A double word register specified as D16-D31 with an odd value of `imm8`.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VPUSH

For a description of this instruction and the encoding, see *VPUSH* on page F8-3232.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `regs == 0`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction operates as a `VSTM` or `VPUSH` with the same addressing mode but loads no registers.
- If the register list includes a register that is out of range, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register become unknown. This behavior does not affect any other memory locations.

Note

Out of range means that the register list includes:

- A register with a number greater than the number of registers implemented.
- More than 16 double word registers.
- A double word register specified as D16-D31 with an odd value of `imm8`.

If this instruction is not UNDEFINED, then whether it is affected by traps or enables relating to the use of the SIMD&FP registers when it is CONSTRAINED UNPREDICTABLE, is IMPLEMENTATION DEFINED. The implementation must ensure that the CONSTRAINED UNPREDICTABLE behavior does not corrupt registers that are not accessible at the current Exception level by instructions that are not CONSTRAINED UNPREDICTABLE.

VTBL, VTBX

For a description of this instruction and the encoding, see *VTBL, VTBX* on page F8-3348.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `n + length > 32`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - One or more of the SIMD&FP registers become UNKNOWN. This behavior does not affect any general-purpose registers.

A.1.28 CONSTRAINED UNPREDICTABLE behavior, A32 and T32 Advanced SIMD and floating-point system instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A32 and T32 system instructions listed in *Advanced SIMD and floating-point system instructions* on page F8-3358.

Note

If an instruction can result in CONSTRAINED UNPREDICTABLE behavior that is not specific to that particular instruction, see the relevant section in this appendix for a description of the CONSTRAINED UNPREDICTABLE behavior.

VMRS

For a description of this instruction and the encoding, see *VMRS* on page F8-3358.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `t == 15 && reg !='0001'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction transfers an UNKNOWN value to the specified general-purpose register.

In addition, `CheckVFPEnabled(FALSE)` can be called by this instruction for the CONSTRAINED UNPREDICTABLE cases.

VMSR

For a description of this instruction and the encoding, see *VMSR* on page F8-3360.

CONSTRAINED UNPREDICTABLE behavior

For all encodings:

- If `reg!= '000x' && reg!='1000'`, then one of the following behaviors can occur:
  - The instruction is UNDEFINED.
  - The instruction executes as a `NOP`.
  - The instruction transfers the value in the general-purpose register to one of the allocated registers accessible using `VMSR` at the same Exception level.

In addition, `CheckVFPEnabled(FALSE)` can be called by this instruction for the CONSTRAINED UNPREDICTABLE cases.

A.1.29 CONSTRAINED UNPREDICTABLE behaviors associated with the VTCR

The following subsections describe the CONSTRAINED UNPREDICTABLE behavior associated with VTCR.S:

- *VTCR.S*.
- *CONSTRAINED UNPREDICTABLE combinations of the starting level and size fields*.

VTCR.S

VTCR.S must be programmed to T0SZ[3], or the effect is CONSTRAINED UNPREDICTABLE. For the ARMv8-A architecture, if VTCR.S is not programmed correctly, then the stage 2 T0SZ value is treated as an UNKNOWN value within the legal range that can be programmed.

CONSTRAINED UNPREDICTABLE combinations of the starting level and size fields

If the stage 2 input address size, as programmed in VTCR.T0SZ, is out of range with respect to the starting level, as programmed in the VTCR.SL0 field at the time of a translation walk that uses the stage 2 translation, then a stage 2 First level Translation Fault is generated.

A.1.30 CONSTRAINED UNPREDICTABLE behavior in Debug state

Behavior in Debug state on page H2-4407 of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.

A.1.31 CONSTRAINED UNPREDICTABLE behavior within virtualization

The following sections describe CONSTRAINED UNPREDICTABLE behavior that can occur when using virtualization:

- *ERET in User mode or System mode* on page AppxA-4853.
- *Accessing Hyp mode from outside Hyp mode* on page AppxA-4853.
- *Modifying CPSR.M when in Hyp mode* on page AppxA-4853
- *Use of Hyp mode in Secure state* on page AppxA-4853.
- *Instructions which are UNDEFINED or CONSTRAINED UNPREDICTABLE in Hyp mode* on page AppxA-4853.
- *Exception return to Hyp mode* on page AppxA-4853.
- *Accessing registers that cannot be accessed using MSR/MRS instructions* on page AppxA-4853.
- *Memory type handling* on page AppxA-4854.
- *TLB instructions defined by virtualization* on page AppxA-4854.
- *VA to PA operations* on page AppxA-4854.
- *Stage 1 default memory type* on page AppxA-4854.
- *Trapping of general exceptions to Hyp mode* on page AppxA-4854.
- *Prevention of rootkits using Hyp mode or Secure state* on page AppxA-4855.
- *HVC* on page AppxA-4855.
- *MSR/MRS banked registers* on page AppxA-4855.

ERET in User mode or System mode

If ERET is executed in User mode or System mode, it behaves as described in *SUBS PC, LR and related instructions (T32)* on page AppxA-4840.

Accessing Hyp mode from outside Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in *SRS (T32)* on page AppxA-4839 and *SRS (A32)* on page AppxA-4839.

Modifying CPSR.M when in Hyp mode

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in *SRS (T32)* on page AppxA-4839 and *SRS (A32)* on page AppxA-4839.

Use of Hyp mode in Secure state

Attempting to change into Hyp mode or out of Hyp mode using the MSR or CPS instruction invokes the ARMv8 illegal exception return by not changing the mode, and setting PSTATE.IL to 1.

SRS using the Hyp mode SP from Non-secure modes other than Hyp mode, or from Secure state, is handled as described in *SRS (T32)* on page AppxA-4839 and *SRS (A32)* on page AppxA-4839.

Instructions which are UNDEFINED or CONSTRAINED UNPREDICTABLE in Hyp mode

If LDRT, LDRSHT, LDRHT, LDRSBT, LDRBT, STRT, STRHT or STRBT are executed in Hyp mode, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction performs the equivalent, corresponding LDR, LDRSH, LDRH, LDRSB, LDRB, STR, STRH or STRB instruction in Hyp mode.

Exception return to Hyp mode

Exception returns to Hyp mode when SCR.NS == 0 or from a Non-secure kernel mode invokes the ARMv8 illegal exception return.

Exception returns to Hyp mode when SPSR.J == 1 and SPSR.T == 1 invokes the ARMv8 illegal exception return.

Accessing registers that cannot be accessed using MSR/MRS instructions

The following MSR and MRS instructions can lead to CONSTRAINED UNPREDICTABLE behavior:

```
MSR <Rm>_<mode>, <Rn>

MSR <SPSR>_<mode>, <Rn>

MSR <ELR_<mode>, <Rn>

MRS <Rn>, <Rm>_<mode>

MRS <Rn>, SPSR_<mode>

MRS <Rn>, ELR_<mode>
```

If these instructions are executed in either Secure or Non-secure User mode, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.

If the MSR and MRS instructions attempt to access a register that cannot be legally accessed, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- For MRS instructions, the destination general-purpose register becomes UNKNOWN.
- For MSR instructions, if the register specified could be accessed from the current mode by other mechanisms, then this register is UNKNOWN. Otherwise the instruction executes as a NOP.

Memory type handling

If the attributes for a memory location after combining stage 1 and stage 2 of a translation regime is Normal Inner Non-cacheable, Outer Non-cacheable, then the shareability attributes after combining the two stages of translation is Outer Shareable.

TLB instructions defined by virtualization

If a TLBIMVAH, TLBIMVALH, TLBIMVAHIS, TLBIMVALHIS, TLBIALLNSNH, TLBIALLNSNHIS, TLBIALLH, or a TLBIALLHIS instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction is executed as if had been executed in Monitor mode.

VA to PA operations

If an ATS12NSOPR, ATS12NSOPW, ATS12NSOUR, ATS12NSOUW, ATS1CPR, ATS1CPW, ATS1CUR, ATS1CUW, ATS1HR or ATS1HW instruction is executed in a Secure Privileged mode other than Monitor mode, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a NOP.
- The instruction is executed as if had been executed in Monitor mode.

Stage 1 default memory type

If HCR.DC == 1, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with:

- SCTLR.M == 0, regardless of the actual value of SCTLR.M, other than for the value returned by an explicit read of SCTLR.M.
- HCR.VM == 1, regardless of the actual value of HCR.VM, other than for an explicit read of this bit.

Trapping of general exceptions to Hyp mode

Attempting to perform an exception return to a Non-secure kernel mode when HCR.TGE == 1 invokes an illegal exception return.

Attempting to change from Monitor mode to a Non-secure kernel mode when HCR.TGE == 1 by executing a CPS or MSR instruction invokes the illegal exception return, by not changing the mode, and setting PSTATE.IL to 1.

When EL3 is using AArch32, attempting to change from a Secure kernel mode to a Non-secure kernel mode when HCR.TGE is set, by changing SCR.NS from 0 to 1, results in no change of SCR.NS

Because taking an exception into Non-secure kernel modes leads to a CONSTRAINED UNPREDICTABLE situation, the following additional properties apply when HCR.TGE == 1:

- All exceptions that would be routed to EL1 are routed to EL2.
- Non-secure SCTLR.M is treated as being 0, regardless of its actual value, other than for an explicit read of of this bit.
- HCR.FMO, HCR.IMO, and HCR.AMO are treated as being 1, regardless of their actual value, other than for an explicit read of these bits.
- All virtual interrupts are disabled.
- Any IMPLEMENTATION DEFINED mechanisms for signalling virtual interrupts are disabled.

Prevention of rootkits using Hyp mode or Secure state

If an HVC instruction is executed in Hyp mode when SCR.HCE == 0, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.

If an SMC instruction is executed in a Secure privileged mode when SCR.SCD == 1, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.

HVC

For a description of this instruction and the encoding, see *HVC* on page F7-3004.

For the A1 encoding, if `cond field !=1110`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction executes unconditionally.
- The instruction executes conditionally.

MSR/MRS banked registers

Some unallocated encodings for the `MSR/MRS` banked register instructions can cause CONSTRAINED UNPREDICTABLE behavior. If an unallocated encoding for the `MSR/MRS` banked register instructions is executed, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- An allocated `MSR/MRS` banked register instruction is executed.

A.2 Constraints on AArch64 state UNPREDICTABLE behaviors

It contains the following sections:

A.2.1 Overview of the constraints on AArch64 UNPREDICTABLE behaviors

The term UNPREDICTABLE describes a number of cases where the architecture has a feature that software must not use. For execution in AArch64 state, the ARMv8-A architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

Note

Software designed to be compatible with the ARMv8-A architecture must not rely on these CONSTRAINED UNPREDICTABLE cases being handled in any way other than those listed under the heading CONSTRAINED UNPREDICTABLE.

A.2.2 Reserved values in system registers and translation table entries

Unless otherwise stated in this manual, all unallocated or reserved values of fields with allocated values within system registers and translation table entries behave in one of the following ways:

- The unallocated value maps onto any of the allocated values, but otherwise does not cause CONSTRAINED UNPREDICTABLE behavior.
- The unallocated value causes effects that could be achieved by a combination of more than one of the allocated values.
- The unallocated value causes the field to have no functional effect.

A.2.3 CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values

The ARM architecture allows copies of control values or data values to be cached in a cache or TLB. This can lead to UNPREDICTABLE behavior if the cache or TLB has not been correctly invalidated following a change of the control or data values.

Unless explicitly stated otherwise, the behavior of the PE is consistent with:

- The old data or control value.
- The new data or control value.
- An amalgamation of the control or data values.

Note

This rules applies where inadequate invalidation of the TLB might cause multiple hits within the TLB. In this situation, a failure to invalidate the TLB by code running at a given Privilege level must not make access to regions of memory with permissions or attributes that could not be accessed at that Privilege level possible.

Alternatively, an implementation might generate a Data Abort exception when detecting multiple hits within a TLB, using the TLB Conflict fault code.

The choice between these behaviors might, in some implementations, vary for each use of a control or data value.

A.2.4 CONSTRAINED UNPREDICTABLE behavior due to inadequate context synchronization

The ARM architecture requires that changes to system registers must be synchronized before they take effect. This can lead to UNPREDICTABLE behavior if the synchronization has not been performed.

In these cases, the behavior of the processor is consistent with the unsynchronized control value being either the old value or the new value.

Where multiple control values are updated but not yet synchronized, each control value might independently be the old value or the new value.

In addition, where the unsynchronized control value applies to different areas of functionality, or what an implementation has constructed as different areas of functionality, those areas might independently treat the control value as being either the old value or the new value.

The choice between these behaviors might, in some implementations, vary for each use of a control value.

A.2.5 Translation table base address alignment

Field [x-1:0] in TTBR0_EL1, TTBR1_EL1, TTBR0_EL2, VTTBR_EL2 or TTBR0_EL3 is RES0. If this field does not have a value of 0, this might result in a misaligned translation table base address. In this case, one of the following behaviors can occur:

- The field that is defined to be RES0 is treated as if all the bits had a value of 0:
  - The value read back might be the value written or it might be 0.
- The calculation of an address for a translation table walk using those registers can be corrupted in those bits that are non-zero.

A.2.6 Performance Counters

The following cases can cause CONSTRAINED UNPREDICTABLE behavior:

- If PMSELR_EL0.SEL is not equal to 31, and PMSELR_EL0.SEL is greater than or equal to PMCR_EL0.N, and the PE is executing in an Exception level in Secure state or in EL2.
- If PMSELR_EL0.SEL is not 31, and PMSELR_EL0.SEL is greater than or equal to MDCR_EL2.HPMN, and the PE is executing in an Exception level in Non-secure state other than in EL2.

In these cases, one of the following behaviors can occur:

- Any access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from that state is UNDEFINED.
- Any access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from that state executes as a `NOP`.
- Any access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 from that state either:
  - Ignores writes and returns 0 on reads.
  - Behaves as if PMSELR_EL0.SEL contains an UNKNOWN value that is less than PMCR_EL0.N and the PE is executing in an Exception level in Secure state or in EL2, or behaves as if PMSELR_EL0.SEL contains an UNKNOWN value that is less than MDCR_EL2.HPMN if the PE executing in an Exception level in Non-secure state other than in EL2.

If PMSELR_EL0.SEL is equal to 31, then one of the following behaviors can occur:

- Any access to PMXEVCNTR_EL0 is UNDEFINED.
- Any access to PMXEVCNTR_EL0 executes as a NOP.
- Any access to PMXEVCNTR_EL0 either:
  - Ignores writes and returns 0 on reads.
  - Behaves as if PMSELR_EL0.SEL contains an UNKNOWN value that is less than PMCR_EL0.N and the PE is executing in an Exception level in Secure state or in EL2, or behaves as if PMSELR_EL0.SEL contains an UNKNOWN value that is less than MDCR_EL2.HPMN if the PE is executing in an Exception level in Non-secure state other than in EL2.

If MDCR_EL2.HPMN is greater than PMCR_EL0.N, then the behavior is as if MDCR_EL2.HPMN contains an UNKNOWN value less than or equal to the value of PMCR_EL0.N. However, the value read back from MDCR_EL2.HPMN is the actual value.

If MDCR_EL2.HPMN is 0, then the behavior is either:

- As if MDCR_EL2.HPMN contains an UNKNOWN value less than or equal to PMCR_EL0.N. However, the value read back from MDCR_EL2.HPMN is the actual value.
- As if it were not UNPREDICTABLE.

A.2.7 Syndrome register handling for CONSTRAINED UNPREDICTABLE instructions treated as unallocated

When a CONSTRAINED UNPREDICTABLE instruction is treated as unallocated, ESR_ELx is UNKNOWN.

Note

The value written to ESR_ELx must be consistent with a value that could be created as the result of an exception from the same Exception level that generated the exception, but was the result of a situation that is not CONSTRAINED UNPREDICTABLE at that Exception level. This is to avoid a possible privilege violation.

A.2.8 Out of range virtual address

Because of program counter alignment constraints, it is impossible for a PE to fetch an A64 instruction that includes the bytes at virtual address `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`.

If the PE executes a load or store instruction with tagged addressing disabled in the current translation regime, and where the computed virtual address, total access size, and alignment mean that it accesses the bytes at `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`, then the bytes that appear to be from `0x0000 0000 0000 0000` onwards are accessed at an UNKNOWN address.

If the PE executes a load or store instruction with tagged addressing enabled in the current translation regime, and where the computed address, total access size, and alignment mean that it accesses the bytes at `0xFFFF FFFF FFFF FFFF` and `0x0000 0000 0000 0000`, then the bytes that appear to be from `0x0000 0000 0000 0000` onwards are accessed at an UNKNOWN address and the tags associated with address also become UNKNOWN.

A.2.9 Instruction fetches from Device memory

Instruction fetches from Device memory are CONSTRAINED UNPREDICTABLE.

If a location in memory has the Device attribute and is not marked as execute-never, then an implementation might perform speculative instruction accesses to this memory location at times when the MMU is enabled.

If a branch causes the program counter to point to an area of memory with the Device attribute that is not marked as execute-never for the current Exception level for instruction fetches, then an implementation can perform one of the following behaviors:

- It can treat the instruction fetch as if it were to a memory location with the Normal, Non-cacheable attribute.
- It can take a Permission fault.

A.2.10 Programming the CSSELR_EL1.Level for a cache level that is not implemented

If the CSSELR_EL1.Level is programmed to a cache level that is not implemented, then a read of CSSELR_EL1 returns an UNKNOWN value in CSSELR_EL1.Level.

If the CSSELR_EL1.Level is programmed to a cache level that is not implemented, then on a read of CCSIDR_EL1 an implementation can perform one of the following behaviors:

- The CCSIDR_EL1 read executes as a `NOP`.
- The CCSIDR_EL1 read is UNDEFINED.
- The CCSIDR_EL1 read returns an UNKNOWN value.

A.2.11 Crossing a page boundary with different memory types or shareability attributes

A memory access from a load or store instruction that crosses a page boundary to a memory location that has a different type or shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation can perform one of the following behaviors:

- All memory accesses generated by the instruction use the memory type and shareability attributes associated with the first address accessed by the instruction.
- All memory accesses generated by the instruction use the memory type and shareability attributes associated with the last address accessed by the instruction.
- Each memory access generated by the instruction uses the memory type and shareability attribute associated with its own address.
- The instruction generates an Alignment fault.
- The instruction executes as a `NOP`.

A.2.12 Crossing a peripheral boundary with a Device access

A memory access from a load or store instruction to Device memory that crosses an IMPLEMENTATION DEFINED boundary results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation can perform one of the following behaviors:

- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses.
- All memory accesses generated by the instruction are performed as if the presence of the boundary had no effect on the memory accesses, except that there is no guarantee of ordering between memory accesses.
- The instruction generates an Alignment fault.
- The instruction executes as a `NOP`.

A.2.13 CONSTRAINED UNPREDICTABLE behavior in Debug state

Behavior in Debug state on page H2-4407 of this manual describes the CONSTRAINED UNPREDICTABLE behaviors that are specifically associated with Debug state.

A.2.14 CONSTRAINED UNPREDICTABLE behavior for A64 instructions

This section lists the CONSTRAINED UNPREDICTABLE behavior for the different A64 instructions listed in Chapter C6 *A64 Base Instruction Descriptions* and Chapter C7 *A64 Advanced SIMD and Floating-point Instruction Descriptions*.

LDR (immediate)

For a description of this instruction and the encoding, see *LDR (immediate)* on page C6-512.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed and post-indexed addressing implies writeback.

LDRB (immediate)

For a description of this instruction and the encoding, see *LDRB (immediate)* on page C6-519.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed and post-indexed addressing implies writeback.

LDRH (immediate)

For a description of this instruction and the encoding, see *LDRH (immediate)* on page C6-525.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.

- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed and post-indexed addressing implies writeback.

LDRSB (immediate)

For a description of this instruction and the encoding, see *LDRSB (immediate)* on page C6-531.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed and post-indexed addressing implies writeback.

LDRSH (immediate)

For a description of this instruction and the encoding, see *LDRSH (immediate)* on page C6-537.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed and post-indexed addressing implies writeback.

LDRSW (immediate)

For a description of this instruction and the encoding, see *LDRSW (immediate)* on page C6-543.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

Note

Pre-indexed and post-indexed addressing implies writeback.

LDP

For a description of this instruction and the encoding, see *LDP* on page C6-506.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `(t == n || t2 == n) && n != 31`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If t == t2, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

Note

Pre-indexed and post-indexed addressing implies writeback.

LDPSW

For a description of this instruction and the encoding, see *LDPSW* on page C6-509.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `(t == n || t2 == n) && n != 31`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value. In addition, if an exception occurs during such an instruction, the base register might be corrupted so that the instruction cannot be repeated.

If `t == t2`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs all of the loads using the specified addressing mode, and the register loaded is set to an UNKNOWN value.

Note

Pre-indexed and post-indexed addressing implies writeback.

LDNP (SIMD&FP)

For a description of this instruction and the encoding, see *LDNP (SIMD&FP)* on page C7-1045.

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDP (SIMD&FP)

For a description of this instruction and the encoding, see *LDP (SIMD&FP)* on page C7-1047.

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDAXP

For a description of this instruction and the encoding, see *LDAXP* on page C6-492*LDP* on page C6-506.

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

LDXP

For a description of this instruction and the encoding, see *LDXP* on page C6-574.

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a load using the specified addressing mode, and the base register is set to an UNKNOWN value.

STR (immediate)

For a description of this instruction and the encoding, see *STR (immediate)* on page C6-689.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

Note

Pre-indexed and post-indexed addressing implies writeback.

STRB (immediate)

For a description of this instruction and the encoding, see *STRB (immediate)* on page C6-695.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

Note

Pre-indexed and post-indexed addressing implies writeback.

STRH (immediate)

For a description of this instruction and the encoding, see *STRH (immediate)* on page C6-701.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `n == t && n != 31`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

Note

Pre-indexed and post-indexed addressing implies writeback.

STP

For a description of this instruction and the encoding, see *STP* on page C6-686.

CONSTRAINED UNPREDICTABLE behavior

If the instruction encoding specifies pre-indexed addressing or post-indexed addressing, and `(t == n || t2 == n) && n != 31`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs a store using the specified addressing mode but the value stored is UNKNOWN.

Note

Pre-indexed and post-indexed addressing implies writeback.

STLXR

For a description of this instruction and the encoding, see *STLXR* on page C6-675.

CONSTRAINED UNPREDICTABLE behavior

If `s == t || (pair && s == t2)`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored in UNKNOWN.

If `s == n && n != 31` then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STLXRB

For a description of this instruction and the encoding, see *STLXRB* on page C6-678.

CONSTRAINED UNPREDICTABLE behavior

If `s == t || (pair && s == t2)`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored in UNKNOWN.

If `s == n && n != 31` then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STLXRH

For a description of this instruction and the encoding, see *STLXRH* on page C6-681.

CONSTRAINED UNPREDICTABLE behavior

If `s == t || (pair && s == t2)`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored in UNKNOWN.

If `s == n && n != 31` then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STXR

For a description of this instruction and the encoding, see *STXR* on page C6-722.

CONSTRAINED UNPREDICTABLE behavior

If `s == t || (pair && s == t2)`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored in UNKNOWN.

If `s == n && n != 31` then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.

- The instruction performs the store to an UNKNOWN address.

STXRB

For a description of this instruction and the encoding, see *STXRB* on page C6-725.

CONSTRAINED UNPREDICTABLE behavior

If `s == t || (pair && s == t2)`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored in UNKNOWN.

If `s == n && n != 31` then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STXRH

For a description of this instruction and the encoding, see *STXRH* on page C6-728.

CONSTRAINED UNPREDICTABLE behavior

If `s == t || (pair && s == t2)`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored in UNKNOWN.

If `s == n && n != 31` then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STLXP

For a description of this instruction and the encoding, see *STLXP* on page C6-672.

CONSTRAINED UNPREDICTABLE behavior

If `s == t || (pair && s == t2)`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored in UNKNOWN.

If `s == n && n != 31` then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

STXP

For a description of this instruction and the encoding, see *STXP* on page C6-719.

CONSTRAINED UNPREDICTABLE behavior

If `s == t || (pair && s == t2)`, then one of the following behaviors can occur:

- The instruction is UNDEFINED.

- The instruction executes as a `NOP`.
- The instruction performs the store to the specified address, but the value stored in UNKNOWN.

If `s == n && n != 31` then one of the following behaviors can occur:

- The instruction is UNDEFINED.
- The instruction executes as a `NOP`.
- The instruction performs the store to an UNKNOWN address.

Appendix B
Recommended External Debug Interface

This appendix describes the recommended external debug interface. It contains the following sections:

Note

This recommended external debug interface specification is not part of the ARM architecture specification. Implementers and users of the ARMv8 architecture must not consider this appendix as a requirement of the architecture. It is included as an appendix to this manual only:

- As reference material for users of ARM products that implement this interface.
- As an example of how an external debug interface might be implemented.

The inclusion of this appendix is no indication of whether any ARM products might, or might not, implement this external debug interface. For details of the implemented external debug interface you must always see the appropriate product documentation.

B.1 About the recommended external debug interface

See the *Note* on the first page of this appendix for information about the architectural status of this recommended debug interface.

This specification provides a recommended external debug interface for ARMv8 to define a standard set of connections for validation environments. The connection between components, such as between the PE and Trace extension or between the PE and the CTI, is not described here. Table B-1 shows the signals in the recommended interface.

Table B-1 Recommended debug interface signals

Name	Direction	Description	Notes
DBGEN	In	External debug enable	-
SPIDEN	In	Secure privileged external debug enable	-
		Secure privileged self-hosted debug enable	Only in Secure AArch32 modes when enabled by MDCR_EL3.SPD32
NIDEN	In	External profiling and trace enable	-
SPNIDEN	In	Secure external profiling and trace enable	-
DBGRESTART	In	External debug restart	Provided for legacy connections only.
DBGRESTARTED	Out	External debug restart acknowledge	
EDBGRQ	In	External halt request	
DBGACK	Out	External halt request acknowledge	
DBGTRIGGER	Out	External trigger notification	
DBGTRIGGERACK	In	External trigger notification acknowledge	
DBGCPUDONE	Out	PE is in Debug state	See *DBGCPUDONE* on page AppxB-4874
COMMIRQ	Out	DCC interrupt	Interface to an interrupt controller. See *Interrupt-driven use of the DCC* on page H4-4474 and the pseudocode for function `CheckForDCCInterrupts()` in *Pseudocode details for the operation of the DCC and ITR registers* on page H4-4475.
PMUIRQ	Out	Performance Monitor overflow	Interface to an interrupt controller. See *Behavior on overflow* on page D5-1752.
COMMRX	Out	DTRRX is full	Provided for legacy connection to an interrupt controller only. See *Interrupt-driven use of the DCC* on page H4-4474 and the pseudocode for function `CheckForDCCInterrupts()` in *Pseudocode details for the operation of the DCC and ITR registers* on page H4-4475.
COMMTX	Out	DTRTX is empty	
PMUEVENT[n:0]	Out	Performance Monitors event bus	See *PMUEVENT bus* on page AppxB-4873

Table B-1 Recommended debug interface signals (continued)

Name	Direction	Description	Notes
DBGNOPWRDWN	Out	Core no powerdown request	Interface to a power controller. See DBGPRCR_EL1.CORENPDRQ.
DBGPWRUPREQ	Out	Core powerup request	Interface to a power controller. See EDPRCR.COREPURQ.
DBGRSTREQ	Out	Warm reset request	Interface to a power controller. See EDPRCR.CWRR.
DBGBUSCANCELREQ	Out	All asynchronous entry to Debug state	Extension to the bus interface. See EDPRCR.CBRRQ.
DBGPWRDUP	In	Core powerup status	Interface to a power controller. See EDPRSR.PU.
DBGROMADDR[n:12]	In	MDRAR_EL1.ROMADDR	*n* depends on the size of the physical address space.
DBGROMADDRV	In	MDRAR_EL1.Valid	-
PRESETDBG	In	External debug reset	-
CPUPORESET	In	Cold reset	-
CORERESET	In	Warm reset	-
PSELDBG	In	Debug APB slave port	For details see *AMBA APB3*. ARM recommends a single slave port for all integrated debug components. **PADDRDBG31** distinguishes memory-mapped and DAP accesses: **0** Memory-mapped access; **1** DAP access
PENABLEDBG	In		
PWRITEDBG	In		
PRDATADBG[31:0]	Out		
PWDATADBG[31:0]	In		
PADDRDBG[n:2][a]	In		
PREADYDBG	Out		
PSLVERRDBG	Out		
PCLKDBG	In		
PCLKENDBG	In		

a. The value of *n* depends on the size of the address space occupied by the Debug port.

Figure B-1 on page AppxB-4872 shows the recommended debug interface.

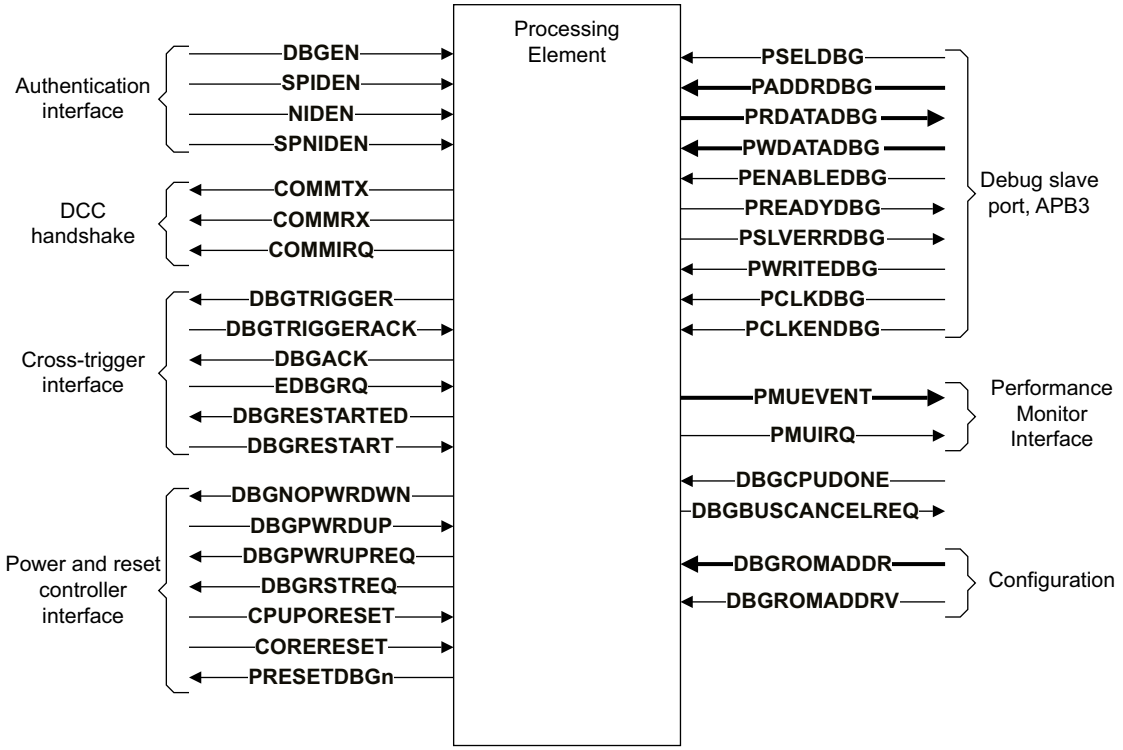

Figure B-1 Recommended external debug interface, including the APB3 slave port

In Figure B-1, signals with a lower-case n suffix are active LOW and all other signals are active HIGH.

B.2 PMUEVENT bus

The **PMUEVENT** bus exports Performance Monitor events from the PE to an on-chip agent. ARM recommends that it has the following characteristics:

- The bus is synchronous.
- The width of the bus is IMPLEMENTATION DEFINED.
- It is IMPLEMENTATION DEFINED which events are exported on the bus.
- Each exported event occupies a contiguous sub-field of the bus. ARM recommends that the sub-fields of the bus are occupied in the same order as the event numbers.
- If the event can only occur once per cycle, it occupies a single bit. If the event can occur more than once per cycle, it is IMPLEMENTATION DEFINED how the event is encoded. The encoding depends on constraints such as the designated use of the event bus and the number of pins available. For example, the event can be encoded:
  - As a count, using a plain binary number. This is the most useful encoding when exporting to an external counter. It is not a useful encoding for exporting to a Trace extension external input.
  - As a count, using thermometer encoding. This is the most useful encoding when exporting to a Trace extension.
  - Using a single bit encoding to indicate whether the event count is zero or non-zero. This is useful for exporting to an activity monitor where the number of pins is constrained.

If a Trace extension is implemented, the **PMUEVENT** bus is normally connected to the Trace extension using the external inputs. TRCEXTINSELR multiplexes a wide **PMUEVENT** bus to a narrow set of inputs. An external **PMUEVENT** bus might also be provided. For more information, contact ARM.

B.3 DBGCPUDONE

The PE asserts **DBGCPUDONE** only after it has completed all Non-debug state memory accesses. Therefore, the system can use **DBGCPUDONE** as an indicator that all memory accesses issued by the PE result from operations performed by a debugger.

B.4 Recommended authentication interface

The details of the debug authentication interface are IMPLEMENTATION DEFINED.

ARM recommends the use of the CoreSight interface, which has four signals for external debug authentication:

- **DBGEN**,
- **SPIDEN**.
- **NIDEN**.
- **SPNIDEN**.

CoreSight forbids asserting **SPIDEN** without also asserting **DBGEN**. CoreSight also forbids asserting **SPNIDEN** without also asserting **NIDEN**.

ARM recommends an interface in which **DBGEN** and **SPIDEN** are also used for self-hosted secure debug authentication if either:

- EL3 is using AArch32 and SDCR.SPD == `0b00`.
- Secure EL1 is using AArch32 and MDCR_EL3.SPD32 == `0b00`.

If EL3 is not implemented and the PE is in Non-secure state, **SPIDEN** and **SPNIDEN** are not implemented, and the PE behaves as if these signals were tied LOW.

If EL3 is not implemented and the PE is in Secure state, **SPIDEN** is usually connected to **DBGEN** and **SPNIDEN** is connected to **NIDEN**, but this is not required. The recommended interface is defined as if all four signals are implemented.

How the authentication signals are driven is IMPLEMENTATION DEFINED. For example, the signals might be hard-wired, connected to fuses, or to an authentication module. The architecture permits PEs within a cluster to have independent authentication interfaces, but this is not required. ARM recommends that any Trace extension has the same authentication interface as the PE it is connected to.

Table B-2 shows the debug authentication pseudocode functions and the recommended implementations.

Table B-2 Recommended implementation of debug enable pseudocode functions

Pseudocode function	Description	Implementation
`AArch32SelfHostedSecurePrivilegedInvasvieDebugEnabled()` See *Pseudocode details for AArch32 Self-Hosted Secure Privileged Invasive Debug Enabled* on page AppxB-4876	Secure invasive self-hosted debug enabled in AArch32 state (legacy)	(**DBGEN** AND **SPIDEN**)
`ExternalSecureNoninvasiveDebugEnabled()` See *Pseudocode details for External Invasive Debug Enabled* on page AppxB-4876	Secure non-invasive debug enabled	(**DBGEN** OR **NIDEN**) AND (**SPIDEN** OR **SPNIDEN**)
`ExternalSecureInvasiveDebugEnabled()` See *Pseudocode details for External Secure Invasive Debug Enabled* on page AppxB-4876	Secure invasive debug enabled	(**DBGEN** AND **SPIDEN**)
`ExternalNoninvasiveDebugEnabled()` See *Pseudocode details for External Non-invasive Debug Enabled* on page AppxB-4877	Non-secure non-invasive debug enabled	(**DBGEN** OR **NIDEN**)
`ExternalInvasiveDebugEnabled()` See *Pseudocode details for External Secure Non-invasive Debug Enabled* on page AppxB-4877	Non-secure invasive debug enabled	**DBGEN**

The following assertions must apply to all implementations:

if `!ExternalInvasiveDebugEnabled()` then assert `!ExternalSecureInvasiveDebugEnabled()`

if `!ExternalNoninvasiveDebugEnabled()` then assert `!ExternalSecureNoninvasiveDebugEnabled()`

if `ExternalInvasiveDebugEnabled()` then assert `ExternalNoninvasiveDebugEnabled()`

if `ExternalSecureInvasiveDebugEnabled()` then assert `ExternalSecureNoninvasiveDebugEnabled()`

The definition for the `Debug_authentication()` function is as follows:

```
signal DBGEN;

signal NIDEN;

signal SPIDEN;

signal SPNIDEN;
```

B.4.1 Pseudocode details for AArch32 Self-Hosted Secure Privileged Invasive Debug Enabled

The pseudocode for the `AArch32SelfHostedSecurePrivilegedInvasiveDebugEnabled()` function is as follows:

```
// AArch32SelfHostedSecurePrivilegedInvasiveDebugEnabled()
// =======================================================

boolean AArch32SelfHostedSecurePrivilegedInvasiveDebugEnabled()
    // In the recommended interface, AArch32SelfHostedSecurePrivilegedInvasiveDebugEnabled returns
    // the state of the (DBGEN AND SPIDEN) signal.
    if !HaveEL(EL3) && !IsSecure() then return FALSE;
    return DBGEN == HIGH && SPIDEN == HIGH;
```

B.4.2 Pseudocode details for External Invasive Debug Enabled

The pseudocode for the `ExternalInvasiveDebugEnabled()` function is as follows:

```
// ExternalInvasiveDebugEnabled()
// ==============================

boolean ExternalInvasiveDebugEnabled()
    // In the recommended interface, ExternalInvasiveDebugEnabled returns the state of the DBGEN
    // signal.
    return DBGEN == HIGH;
```

B.4.3 Pseudocode details for External Secure Invasive Debug Enabled

The pseudocode for the `ExternalSecureInvasiveDebugEnabled()` function is as follows:

```
// ExternalSecureInvasiveDebugEnabled()
// ====================================

boolean ExternalSecureInvasiveDebugEnabled()
    // In the recommended interface, ExternalSecureInvasiveDebugEnabled returns the state of the
    // (DBGEN AND SPIDEN) signal.
    // CoreSight allows asserting SPIDEN without also asserting DBGEN, but this is not recommended.
```

```
    if !HaveEL(EL3) && !IsSecure() then return FALSE;
    return ExternalInvasiveDebugEnabled() && SPIDEN == HIGH;
```

B.4.4 Pseudocode details for External Non-invasive Debug Enabled

The pseudocode for the `ExternalNoninvasiveDebugEnabled()` function is as follows:

```
// ExternalNoninvasiveDebugEnabled()
// =================================

boolean ExternalNoninvasiveDebugEnabled()
    // In the recommended interface, ExternalNoninvasiveDebugEnabled returns the state of the (DBGEN
    // OR NIDEN) signal.
    return ExternalInvasiveDebugEnabled() || NIDEN == HIGH;
```

B.4.5 Pseudocode details for External Secure Non-invasive Debug Enabled

The pseudocode for the `ExternalSecureNoninvasiveDebugEnabled()` function is as follows:

```
// ExternalSecureNoninvasiveDebugEnabled()
// =======================================

boolean ExternalSecureNoninvasiveDebugEnabled()
    // In the recommended interface, ExternalSecureNoninvasiveDebugEnabled returns the state of the
    // (DBGEN OR NIDEN) AND (SPIDEN OR SPNIDEN) signal.
    if !HaveEL(EL3) && !IsSecure() then return FALSE;
    return ExternalNoninvasiveDebugEnabled() && (SPIDEN == HIGH || SPNIDEN == HIGH);
```

B.5 Management registers and CoreSight compliance

The CoreSight architecture requires the implementation of a set of management registers that occupy the memory map from `0xF00` upwards in each of the debug components.

CoreSight compliance and complete implementation of the management registers is OPTIONAL, but ARM recommends that the registers are implemented.

The CoreSight architecture specification recommends that any integration test registers are implemented starting from `0xEFC` downwards. Each of the debug components has an IMPLEMENTATION DEFINED region from `0xE80` to `0xEFC` for this purpose.

B.5.1 Coresight interface register map

Table B-3 shows the external management register maps for the following registers:

ED These are the external debug register.

CTI These are the Cross-trigger interface registers.

PMU These are the Performance Monitors registers.

Table B-3 Coresight interface register map

Offset	Mnemonic			Name
	ED	CTI	PMU	
`0xF00`	EDITCTRL	CTIITCTRL	PMITCTRL	Integration Model Control registers
`0xF04-0xF8C`	-	-	-	Reserved, RES0
`0xFA0`	DBGCLAIMSET_EL1[a]	CTICLAIMSET[b]	-	Claim Tag Set registers
`0xFA4`	DBGCLAIMCLR_EL1[a]	CTICLAIMCLR[b]	-	Claim Tag Clear registers
`0xFA8`	EDDEVAFF0[a]	CTIDEVAFF0[c]	PMDEVAFF0	Device Affinity registers
`0xFAC`	EDDEVAFF1[a]	CTIDEVAFF1[c]	PMDEVAFF1	
`0xFB0`	EDLAR[d]	CTILAR[d]	PMLAR[d]	Lock Access register
`0xFB4`	EDLSR[d]	CTILSR[d]	PMLSR[d]	Lock Status register
`0XFB8`	DBGAUTHSTATUS_EL1[a]	CTIAUTHSTATUS	PMAUTHSTATUS	Authentication Status register
`0xFBC`	EDDEVARCH	CTIDEVARCH	PMDEVARCH	Device Architecture register
`0xFC0`	EDDEVID2[a]	CTIDEVID2[a]	-	Device ID register
`0xFC4`	EDDEVID1[a]	CTIDEVID1[a]	-	
`0xFC8`	EDDEVID[a]	CTIDEVID[a]	-	
`0xFCC`	EDDEVTYPE	CTIDEVTYPE	PMDEVTYPE	Device Type register
`0xFD0`	EDPIDR4	CTIPIDR4	PMPIDR4	Peripheral ID registers
`0xFD4-0xFDC`	-	-	-	Reserved, RES0
`0xFE0`	EDPIDR0	CTIPIDR0	PMPIDR0	Peripheral ID registers
`0xFE4`	EDPIDR1	CTIPIDR1	PMPIDR1	
`0xFE8`	EDPIDR2	CTIPIDR2	PMPIDR2	
`0xFEC`	EDPIDR3	CTIPIDR3	PMPIDR3	

Table B-3 Coresight interface register map (continued)

Offset	Mnemonic			Name
	ED	CTI	PMU	
0xFF0	EDCIDR0	CTICIDR0	PMCIDR0	Component ID registers
0xFF4	EDCIDR1	CTICIDR1	PMCIDR1	
0xFF8	EDCIDR2	CTICIDR2	PMCIDR2	
0xFFC	EDCIDR3	CTICIDR3	PMCIDR3	

a. This register must always be implemented, regardless of whether the component is CoreSight compliant.
b. If implemented, the number of CLAIM bits is IMPLEMENTATION DEFINED and can be discovered by reading CLAIMSET.
c. If the CTI implements CTIv1, this register is not implemented. See the register description for details.
d. The Software lock registers are defined as part of CoreSight compliance, but their contents depend on the type of access that is made and whether the OPTIONAL Software lock is implemented. See the register description for details.

B.5.2 Management register access permissions

Access to the OPTIONAL Integration Control register (ITCTRL) is IMPLEMENTATION DEFINED.

If the Debug power domain is off, all register accesses return an error.

Otherwise, Table B-4 on page AppxB-4880, Table B-5 on page AppxB-4881, and Table B-6 on page AppxB-4882 show the response to accesses by the external debug interface to the CoreSight management registers. For definitions of the terms used in the tables, see *External debug interface register access permissions summary* on page H8-4525.

Note

Access to the CoreSight management registers is not affected by the values of EDAD and EPMAD.

Table B-4 on page AppxB-4880, Table B-5 on page AppxB-4881, and Table B-6 on page AppxB-4882 include reserved management registers, because the CoreSight architecture requires that these registers are always RES0. The descriptions in *Reserved and unallocated registers* on page H8-4526 does not apply to reserved management registers if the implementation is CoreSight compliant.

If OPTIONAL memory-mapped access to the external debug interface is supported, there are additional constraints on memory-mapped accesses. See *Register access permissions for memory-mapped accesses* on page H8-4521.

The terms in Table B-4 on page AppxB-4880, Table B-5 on page AppxB-4881, and Table B-6 on page AppxB-4882 are defined as follows:

Domain This describes the power domain in which the register is logically implemented. Registers described as implemented in the Core power domain might be implemented in the Debug power domain, as long as they exhibit the required behavior.

Conditions This lists the conditions under which the access is attempted.

To determine the access permissions for a register, read these columns from left to right, and stop at first column which lists the condition as being true.

The conditions are:

Off EDPRSR.PU == 0. The Core power domain is completely off, or in low-power state. In these cases the Core power domain registers cannot be accessed.

Note

If debug power is off, then all external debug interface accesses return an error.

DLK `DoubleLockStatus()` == TRUE. The OS Double Lock is locked, that is, EDPRSR.DLK == 1.

OSLK OSLSR.OSLK == 1. The OS Lock is locked.

Default This provides the default access permissions, if there are no conditions that prevent access to the register.

SLK This provides the modified default access permissions for OPTIONAL memory-mapped accesses to the external debug interface if the OPTIONAL Software Lock is locked. See *Register access permissions for memory-mapped accesses* on page H8-4521. For all other accesses, this column is ignored.

The access permissions are:

- This means that the default access permission applies. See the Default column, or the SLK column, if applicable.

RO This means that the register or field is read-only.

RW This means that the register or field is read/write. Individual fields within the register might be RO. See the relevant register description for details.

RC This means that the bit clears to 0 after a read.

(SE) This means that accesses to this register have indirect write side-effects. A side-effect occurs when a direct read or a direct write of a register creates an indirect write to the same register or to another register.

WO This means that the register or field is write-only.

WI This means that the register or field ignores writes.

IMP DEF This means that the access permissions are IMPLEMENTATION DEFINED.

Table B-4 External debug interface access permissions, CoreSight registers (debug)

			Conditions (priority left to right)				
Offset	**Register**	**Domain**	**Off**	**DLK**	**OSLK**	**Default**	**SLK**

B.5.3 Management register resets

Table B-7 shows the management register resets. This table does not include:

- Read-only identification registers that have a fixed value from reset. These registers include those with the DEVAFFn, DEVARCH, DEVID{n}, DEVTYPE, PIDRn, and CIDRn mnemonics.
- Registers that have the AUTHSTATUS mnemonic. This is a read-only status register that reflects the status outside of the reset domain of the register.
- Registers that have the LAR mnemonic. These are write-only registers that only have an effect on writes.

All other fields in the management registers are reset to an IMPLEMENTATION DEFINED value which can be UNKNOWN. The registers are in the reset domain specified in the table.

Table B-7 shows a summary of the management register resets.

Table B-7 Management register resets

Register	Reset domain	Field	Value	Description
CTIITCTRL EDITCTRL PMITCTRL	IMPLEMENTATION DEFINED	IME	0	Integration mode enable
DBGCLAIMCLR_EL1 CTICLAIMCLR[a]	External debug	CLAIM	0x0	Claim tags
CTILSR[b] EDLSR[b] PMLSR[b]	External debug	SLK	1	Software Lock

a. CTICLAIMCLR only if implemented. For DBGCLAIMCLR_EL1, see *DBGCLAIMCLR_EL1, Debug Claim Tag Clear register* on page H9-4548.

b. Only if the OPTIONAL Software Lock is implemented

Appendix C
Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events

This appendix describes the ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers. It contains the following sections:

C.1 ARM recommendations for IMPLEMENTATION DEFINED event numbers

These are the ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers. ARM does not define these events as rigorously as those in the architectural and microarchitectural event lists, and an implementation might:

- Modify the definition of an event to better correspond to the implementation.
- Not use some, or many, of these event numbers.
- Include cumulative occupancy for resource queues such as data access queues, and entry/exit counts, so that average latencies can be determined and counts for key resources that might exist can be separated.
- Provide registers in the IMPLEMENTATION DEFINED space to further extend such counts by, for example, specifying a minimum latency for an event to be counted.
- Use cumulative occupancy for resource queues, such as data access queues, and entry/exit counts, so that average latencies can be determined, separating out counts for key resources that might exist:
  - An implementation might also provide registers in the IMPLEMENTATION DEFINED space to further extend such counts, by, for example specifying a minimum latency for an event to be counted.

Table C-1 lists the PMU IMPLEMENTATION DEFINED event numbers in event number order.

Table C-1 PMU IMPLEMENTATION DEFINED event numbers

Event number	Event mnemonic	Description
0x040	L1D_CACHE_LD	Level 1 data cache access, read
0x041	L1D_CACHE_ST	Level 1 data cache access, write
0x042	L1D_CACHE_REFILL_LD	Level 1 data cache refill, read
0x043	L1D_CACHE_REFILL_ST	Level 1 data cache refill, write
0x044	L1D_CACHE_REFILL_INNER	Level 1 data cache refill, inner
0x045	L1D_CACHE_REFILL_OUTER	Level 1 data cache refill, outer
0x046	L1D_CACHE_WB_VICTIM	Level 1 data cache write-back, victim
0x047	L1D_CACHE_WB_CLEAN	Level 1 data cache write-back, cleaning and coherency
0x048	L1D_CACHE_INVAL	Level 1 data cache invalidate
0x049-0x04B	-	Reserved
0x04C	L1D_TLB_REFILL_LD	Level 1 data TLB refill, read
0x04D	L1D_TLB_REFILL_ST	Level 1 data TLB refill, write
0x04E-0x04F	-	Reserved
0x050	L2D_CACHE_LD	Level 2 data cache access, read
0x051	L2D_CACHE_ST	Level 2 data cache access, write
0x052	L2D_CACHE_REFILL_LD	Level 2 data cache refill, read
0x053	L2D_CACHE_REFILL_ST	Level 2 data cache refill, write
0x054-0x055	-	Reserved
0x056	L2D_CACHE_WB_VICTIM	Level 2 data cache write-back, victim
0x057	L2D_CACHE_WB_CLEAN	Level 2 data cache write-back, cleaning and coherency

Table C-1 PMU IMPLEMENTATION DEFINED event numbers (continued)

Event number	Event mnemonic	Description
0x058	L2D_CACHE_INVAL	Level 2 data cache invalidate
0x059-0x05F	-	Reserved
0x060	BUS_ACCESS_LD	Bus access, read
0x061	BUS_ACCESS_ST	Bus access, write
0x062	BUS_ACCESS_SHARED	Bus access, Normal, Cacheable, Shareable
0x063	BUS_ACCESS_NOT_SHARED	Bus access, not Normal, Cacheable, Shareable
0x064	BUS_ACCESS_NORMAL	Bus access, normal
0x065	BUS_ACCESS_PERIPH	Bus access, peripheral
0x066	MEM_ACCESS_LD	Data memory access, read
0x067	MEM_ACCESS_ST	Data memory access, write
0x068	UNALIGNED_LD_SPEC	Unaligned access, read
0x069	UNALIGNED_ST_SPEC	Unaligned access, write
0x06A	UNALIGNED_LDST_SPEC	Unaligned access
0x06B	-	Reserved
0x06C	LDREX_SPEC	Exclusive operation speculatively executed, LDREX or LDX
0x06D	STREX_PASS_SPEC	Exclusive operation speculatively executed, STREX or STX pass
0x06E	STREX_FAIL_SPEC	Exclusive operation speculatively executed, STREX or STX pass
0x06F	STREX_SPEC	Exclusive operation speculatively executed, STREX or STX
0x070	LD_SPEC	Operation speculatively executed, load
0x071	ST_SPEC	Operation speculatively executed, store
0x072	LDST_SPEC	Operation speculatively executed, load or store
0x073	DP_SPEC	Operation speculatively executed, integer data-processing
0x074	ASE_SPEC	Operation speculatively executed, Advanced SIMD instruction
0x075	VFP_SPEC	Operation speculatively executed, floating-point instruction
0x076	PC_WRITE_SPEC	Operation speculatively executed, software change of the PC
0x077	CRYPTO_SPEC	Operation speculatively executed, Cryptographic instruction
0x078	BR_IMMED_SPEC	Branch speculatively executed, immediate branch
0x079	BR_RETURN_SPEC	Branch speculatively executed, procedure return
0x07A	BR_INDIRECT_SPEC	Branch speculatively executed, indirect branch
0x07B	-	Reserved
0x07C	ISB_SPEC	Barrier speculatively executed, ISB
0x07D	DSB_SPEC	Barrier speculatively executed, DSB

Table C-1 PMU IMPLEMENTATION DEFINED event numbers (continued)

Event number	Event mnemonic	Description
0x07E	DMB_SPEC	Barrier speculatively executed, DMB
0x07F-0x080	-	Reserved
0x081	EXC_UNDEF	Exception taken, Other synchronous
0x082	EXC_SVC	Exception taken, Supervisor Call
0x083	EXC_PABORT	Exception taken, Instruction Abort
0x084	EXC_DABORT	Exception taken, Data Abort and SError
0x085	-	Reserved
0x086	EXC_IRQ	Exception taken, IRQ
0x087	EXC_FIQ	Exception taken, FIQ
0x088	EXC_SMC	Exception taken, Secure Monitor Call
0x089	-	Reserved
0x08A	EXC_HVC	Exception taken, Hypervisor Call
0x08B	EXC_TRAP_PABORT	Exception taken, Instruction Abort not taken locally
0x08C	EXC_TRAP_DABORT	Exception taken, Data Abort or SError not taken locally
0x08D	EXC_TRAP_OTHER	Exception taken, Other traps not taken locally
0x08E	EXC_TRAP_IRQ	Exception taken, IRQ not taken locally
0x08F	EXC_TRAP_FIQ	Exception taken, FIQ not taken locally
0x090	RC_LD_SPEC	Release consistency operation speculatively executed, Load-Acquire
0x091	RC_ST_SPEC	Release consistency operation speculatively executed, Store-Release

0x040, Level 1 data cache access, read

This event is similar to Level 1 data cache access but the counter counts only memory-read operations that access at least the Level 1 data or unified cache.

0x041, Level 1 data cache access, write

This event is similar to Level 1 data cache access but the counter counts only memory-write operations that access at least the Level 1 data or unified cache.

The counter counts DC ZVA as a store instruction.

0x042, Level 1 data cache refill, read

This event is similar to Level 1 data cache refill but the counter counts only memory-read operations that cause a refill of at least the Level 1 data or unified cache.

0x043, Level 1 data cache refill, write

This event is similar to Level 1 data cache refill but the counter counts only memory-write operations that cause a refill of at least the Level 1 data or unified cache.

The counter counts DC ZVA as a store instruction.

0x044, Level 1 data cache refill, inner

This event is similar to Level 1 data cache refill but the counter counts only memory-read and memory-write operations that generate refills satisfied by transfer from another cache inside of the immediate cluster.

Note

The boundary between *inner* and *outer* is IMPLEMENTATION DEFINED, and it is not necessarily linked to other similar boundaries, such as the boundary between Inner Cacheable and Outer Cacheable or the boundary between Inner Shareable and Outer Shareable.

0x045, Level 1 data cache refill, outer

This event is similar to Level 1 data cache refill but the counter counts only memory-read and memory-write operations that generate refills satisfied from outside of the immediate cluster.

0x046, Level 1 data cache write-back, victim

This event is similar to Level 1 data cache write-back but the counter counts only write-backs that are a result of the line being allocated for an access made by the PE.

CP15 cache maintenance operations do not count as events.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x047, Level 1 data cache write-back, cleaning and coherency

This event is similar to Level 1 data cache write-back but the counter counts only write-backs that are a result of a coherency operation made by another PE or from a CP15 cache maintenance operation. Whether write-backs made as a result of CP15 cache maintenance operations are counted is IMPLEMENTATION DEFINED.

If a coherency request from a requestor outside the PE results in a write-back, it is an Unattributable event.

Note

The transfer of a dirty cache line from the Level 1 data cache of this PE to the Level 1 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 2 cache or memory.

0x048, Level 1 data cache invalidate

The counter counts each invalidation of a cache line in the Level 1 data or unified cache.

The counter does not count events:

- If a cache refill invalidates a line.
- For locally executed CP15 cache set/way maintenance operations.

If a coherency request from a requestor outside the PE results in a write-back, it is an Unattributable event.

0x04C, Level 1 data TLB refill, read

This event is similar to Level 1 data TLB refill but the counter counts only memory-read operations that cause a data TLB refill of a least the Level 1 data or unified TLB.

0x04D, Level 1 data TLB refill, write

This event is similar to Level 1 data TLB refill but the counter counts only memory-write operations that cause a data TLB refill of a least the Level 1 data or unified TLB.

The counter counts DC ZVA as a store instruction.

0x050, Level 2 data cache access, read

This event is similar to Level 2 data cache access but the counter counts only memory-read operations that access at least the Level 2 data or unified cache.

0x051, Level 2 data cache access, write

This event is similar to Level 2 data cache access but the counter counts only memory-write operations that access at least the Level 2 data or unified cache.

The counter counts DC ZVA as a store instruction.

0x052, Level 2 data cache refill, read

This event is similar to Level 2 data cache refill but the counter counts only memory-read operations that cause a refill of at least the Level 2 data or unified cache.

0x053, Level 2 data cache refill, write

This event is similar to Level 2 data cache refill but the counter counts only memory-write operations that cause a refill of at least the Level 2 data or unified cache.

The counter counts DC ZVA as a store instruction.

0x056, Level 2 data cache write-back, victim

This event is similar to Level 2 data cache write-back but the counter counts only write-backs that are a result of the line being allocated for an access made by the PE.

CP15 cache maintenance operations do not count as events.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache is counted. For example, this might occur if the PE detects streaming writes to memory and does not allocate lines to the cache, or as the result of a DC ZVA.

0x057, Level 2 data cache write-back, cleaning and coherency

This event is similar to Level 2 data cache write-back but the counter counts only write-backs that are a result of a coherency operation made by another PE or CP15 cache maintenance operation. Whether write-backs made as a result of CP15 cache maintenance operations are counted is IMPLEMENTATION DEFINED.

Note

The transfer of a dirty cache line from the Level 2 data cache of this PE to the Level 2 data cache of another PE due to a hardware coherency operation is not counted unless the dirty cache line is also written back to a Level 3 cache or memory.

If a coherency request from a requestor outside the PE results in a write-back, it is an Unattributable event.

0x058, Level 2 data cache invalidate

The counter counts each invalidation of a cache line in the Level 2 data or unified cache.

The counter does not count events:

- If a cache refill invalidates a line.
- For locally executed CP15 set/way cache maintenance operations.

Note

Software that uses this event must know whether the Level 2 data cache is shared with other PEs. This event does not follow the general rule of Level 2 data cache events of only counting events that directly affect this PE.

If a coherency request from a requestor outside the PE results in a write-back, it is an Unattributable event.

`0x060`**, Bus access, read**

This event is similar to bus access but the counter counts only memory-read operations that access outside the boundary of the PE and its closely-coupled caches.

`0x061`**, Bus access, write**

This event is similar to bus access but the counter counts only memory-write operations that access outside the boundary of the PE and its closely-coupled caches.

`0x062`**, Bus access, Normal, Cacheable, Shareable**

This event is similar to bus access but the counter counts only memory-read and memory-write operations that make Normal, Cacheable, Shareable accesses outside the boundary of the PE and its closely-coupled caches.

Note

It is IMPLEMENTATION DEFINED how the PE translates the attributes from the translation table entry for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either Shareable or Not Shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as Shareable for the purposes of defining this event.

`0x063`**, Bus access, not Normal, Cacheable, Shareable**

This event is similar to bus access but the counter counts only memory-read and memory-write operations that make accesses outside the boundary of the PE and its closely-coupled caches that are not Normal, Cacheable, Shareable. For example, the counter counts accesses marked as:

- Normal, Cacheable, Not Shareable.
- Normal, Not Cacheable.
- Device.

Note

It is IMPLEMENTATION DEFINED, how the PE translates the attributes from the translation table entries for a region to the attributes on the bus.

In particular, a region of memory designated as Normal, Cacheable, Inner Shareable, Not Outer Shareable by a translation table entry, might be marked as either Shareable or Not Shareable at the boundary of the PE and its closely-coupled caches. This depends on where the IMPLEMENTATION DEFINED boundary lies, between Inner and Outer Shareable.

If the Inner Shareable extends beyond the PE boundary, and the bus indicates the distinction between Inner and Outer Shareable, then either is counted as Shareable for the purposes of defining this event.

`0x064`**, Bus access, normal**

This event is similar to bus access but the counter counts only memory-read and memory-write operations that make Normal accesses outside the boundary of the PE and its closely-coupled caches. For example, the counter counts Normal, Cacheable and Normal, Not Cacheable accesses but does not count Device accesses.

`0x065`**, Bus access, peripheral**

This event is similar to bus access but the counter counts only memory-read and memory-write operations that make Device accesses outside the boundary of the PE and its closely-coupled caches.

`0x066`**, Data memory access, read**

This event is similar to data memory access but the counter counts only memory-read operations that the PE made.

`0x067`**, Data memory access, write**

This event is similar to data memory access but the counter counts only memory-write operations made by the PE.

`0x068`**, Unaligned access, read**

This event is similar to data memory access but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

`0x069`**, Unaligned access, write**

This event is similar to data memory access but the counter counts only unaligned memory-read operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

`0x06A`**, Unaligned access**

This event is similar to data memory access but the counter counts only unaligned memory-read operations and unaligned memory-write operations that the PE made. It also counts unaligned accesses if they are subsequently transposed into multiple aligned accesses.

`0x06C`**, Exclusive operation speculatively executed, Load-Exclusive**

The counter counts Load-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

`0x06D`**, Exclusive operation speculatively executed, Store-Exclusive pass**

The counter counts Store-Exclusive instructions speculatively executed that completed a write.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the exclusive operation speculatively executed, Load-Exclusive event.

`0x06E`**, Exclusive operation speculatively executed, Store-Exclusive fail**

The counter counts Store-Exclusive instructions speculatively executed that fail to complete a write. It is within the IMPLEMENTATION DEFINED definition of speculatively executed whether this includes conditional instructions that fail the condition code check.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the exclusive operation speculatively executed, Load-Exclusive event.

`0x06F`**, Exclusive operation speculatively executed, Store-Exclusive**

The counter counts Store-Exclusive instructions speculatively executed.

The definition of speculatively executed is IMPLEMENTATION DEFINED but it must be the same as for the exclusive operation speculatively executed, Load-Exclusive event.

ARM recommends that this event is implemented if it is not possible to implement the exclusive operation speculatively executed, Store-Exclusive pass, and exclusive operation speculatively executed, Store-Exclusive fail, events with the same degree of speculation as the exclusive operation speculatively executed, Load-Exclusive event.

`0x070`**, Operation speculatively executed, load**

This event is similar to the operation speculatively executed but the counter counts only memory-reading instructions. Defined by the instruction architecturally executed, condition code check pass, load event, see *Common event numbers* on page D5-1765.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the operation speculatively executed event.

0x071, Operation speculatively executed, store

This event is similar to the operation speculatively executed but the counter counts only memory-writing instructions. Defined by the instruction architecturally executed, condition code check pass, store event, see *Common event numbers* on page D5-1765.

The counter counts DC ZVA as a store operation.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the operation speculatively executed event.

0x072, Operation speculatively executed, load or store

This event is similar to the operation speculatively executed but the counter counts only memory-reading instructions and memory-writing instructions. Defined by the instruction architecturally executed, condition code check pass, load and instruction architecturally executed, condition code check pass, store events, see *Common event numbers* on page D5-1765.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the operation speculatively executed event.

0x073, Operation speculatively executed, integer data-processing

This event is similar to the operation speculatively executed but counts only integer data-processing instructions. It counts the following operations that operate on the general-purpose registers:

- In AArch64 state, *Data processing - immediate* on page C3-142 and *Data processing - register* on page C3-147.
- In AArch32 state, *Data-processing instructions* on page F1-2300.

This includes MOV and MVN operations.

This event also counts the following miscellaneous instructions:

- In AArch64 state, *System register instructions* on page C3-128, *System instructions* on page C3-128, and *Hint instructions* on page C3-129.
- In AArch32 state, *Status register access instructions* on page F1-2308, *Banked register access instructions* on page F1-2308, *Miscellaneous instructions* on page F1-2312, other than ISB and preloads, and *Coprocessor instructions* on page F1-2314, other than coprocessor load and store instructions.

If the preload instructions PRFM, PLD, PLDW, and PLI, do not count as memory-reading instructions then they must count as integer data-processing instructions.

If ISBs do not count as software change of the PC then they must count as integer data-processing instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the operation speculatively executed event.

It is IMPLEMENTATION DEFINED whether the following instructions are counted as integer data-processing operations, SIMD operations, or floating-point operations, but ARM recommends that the instructions are all counted as integer data-processing operations:

- For AArch64 state, from the A64 floating-point convert to integer class, operations that move a value between a general-purpose register and a SIMD and floating-point register without type conversion:
  - FMOV (general).
- For AArch64 state, from the SIMD Move group, operations that move a values between a general-purpose register and an element or elements in a SIMD and floating-point register:
  - DUP (general).
  - SMOV.
  - UMOV.
  - INS (general).
- In AArch32 state:
  - VDUP (general-purpose register) and all VMOV instructions that transfer data between a general-purpose register and a SIMD and floating-point register.

— VMRS.

— VMSR.

0x074, Operation speculatively executed, Advanced SIMD

This event is similar to the operation speculatively executed but the counter counts only Advanced SIMD data-processing instructions, see:

- For AArch64 state, the SIMD operations listed in *Data processing - SIMD and floating-point* on page C3-154
- For AArch32 state, *Advanced SIMD data-processing instructions* on page F1-2318

This includes all operations that operate on the SIMD and floating-point registers, except those that are counted as:

- Integer data-processing operations.
- Floating-point data-processing operations.
- Memory-reading operations.
- Memory-writing operations.
- Cryptographic operations other than PMULL, in AArch64 state.
- VMULL, in AArch32 state.

Advanced SIMD scalar operations are counted as Advanced SIMD operations, including those which operate on floating-point values. In AArch64 state, PMULL, and in AArch32 state, VMULL are counted as Advanced SIMD operations.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the operation speculatively executed event.

0x075, Operation speculatively executed, floating-point

This event is similar to the operation speculatively executed but the counter counts only floating-point data-processing instructions, see:

- In AArch64 state, the floating-point operations listed in *Data processing - SIMD and floating-point* on page C3-154.
- In AArch32 state, *Floating-point data-processing instructions* on page F1-2324.

This includes all operations that operate on the SIMD and floating-point registers as floating-point values, except for SIMD scalar operations and those that are counted as one of:

- Integer data-processing.
- Memory-reading operations.
- Memory-writing operations.

The following instructions that take both an integer register and a floating-point register argument and perform a type conversion (to/from integer or to/from fixed-point), are counted as floating-point data-processing operations:

- In AArch64 state, FCVT{<mode>}, UCVTF, and SCVTF.
- In AArch32, VCVT<mode>(floating-point), VCVT, VCVTT, and VCVTB.

The definition of speculatively executed is IMPLEMENTATION DEFINED, but must be the same as for the operation speculatively executed event.

0x076, Operation speculatively executed, software change of the PC

This event is similar to the operation speculatively executed but the counter counts only software changes of the PC. Defined by the instruction architecturally executed, condition code check pass, software change of the PC event, see *Common event numbers* on page D5-1765.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the operation speculatively executed event.

See also PC_WRITE_RETIRED in Table D5-6 on page D5-1765.

0x077, Operation speculatively executed, Cryptographic instruction

This event is similar to the operation speculatively executed but the counter counts only Cryptographic instructions, except PMULL and VMULL, see *The Cryptographic Extensions* on page C3-171.

The definition of speculatively executed is IMPLEMENTATION DEFINED but must be the same as for the operation speculatively executed event.

0x078, Branch speculatively executed, immediate branch

The counter counts immediate branch instructions speculatively executed. Defined by the instruction architecturally executed, immediate branch event, see *Common event numbers* on page D5-1765.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also BR_IMMED_RETIRED in Table D5-6 on page D5-1765.

0x079, Branch speculatively executed, procedure return

The counter counts procedure return instructions speculatively executed. Defined by the instruction architecturally executed, condition code check pass, procedure return event, see *Common event numbers* on page D5-1765.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

See also BR_RETURN_RETIRED in Table D5-6 on page D5-1765.

0x07A, Branch speculatively executed, indirect branch

The counter counts indirect branch instructions speculatively executed. This includes software change of the PC other than exception-generating instructions and immediate branch instructions.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x07C, Barrier speculatively executed, ISB

The counter counts instruction synchronization barrier instructions speculatively executed, including CP15ISB.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x07D, Barrier speculatively executed, DSB

The counter counts data synchronization barrier instructions speculatively executed, including CP15DSB.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x07E, Barrier speculatively executed, DMB

The counter counts data memory barrier instructions speculatively executed, including CP15DSB. It does not include the implied barrier operations of load/store operations with release consistency semantics.

The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x081, Exception taken, other synchronous

This event is similar to exception taken but the counter counts only synchronous exceptions that are not counted by the other Exception taken events. This event counts only exceptions taken locally.

0x082, Exception taken, Supervisor Call

This event is similar to exception taken but the counter counts only Supervisor Call exceptions. This event counts only exceptions taken locally.

0x083, Exception taken, Instruction Abort

This event is similar to exception taken but the counter counts only Instruction Abort exceptions. This event counts only exceptions taken locally.

`0x084`**, Exception taken, Data Abort or SError**

This event is similar to exception taken but the counter counts only Data Abort or SError interrupt exceptions. The counter counts only exceptions taken locally.

`0x086`**, Exception taken, IRQ**

This event is similar to exception taken but the counter counts only IRQ exceptions. The counter counts only exceptions taken locally, including Virtual IRQ exceptions.

`0x087`**, Exception taken, FIQ**

This event is similar to exception taken but the counter counts only FIQ exceptions. The counter counts only exceptions taken locally, including Virtual FIQ exceptions.

`0x088`**, Exception taken, Secure Monitor Call**

This event is similar to exception taken but the counter counts only Secure Monitor Call exceptions. The counter does not increment on `SMC` instructions trapped as a Hyp Trap exception.

`0x08A`**, Exception taken, Hypervisor Call**

This event is similar to exception taken but the counter counts only Hypervisor Call exceptions. The counter counts for both Hypervisor Call exceptions taken locally in the hypervisor and those taken as an exception from Non-secure EL1.

`0x08B`**, Exception taken, Instruction Abort not taken locally**

This event is similar to exception taken but the counter counts only Instruction Abort exceptions not taken locally.

`0x08C`**, Exception taken, Data Abort or SError not taken locally**

This event is similar to exception taken but the counter counts only Data Abort or SError interrupt exceptions not taken locally.

`0x08D`**, Exception taken, other traps not taken locally**

This event is similar to exception taken but the counter counts only those traps that are not counted as:

- Exception taken, Hypervisor Call.
- Exception taken, Instruction Abort not taken locally.
- Exception taken, Data Abort or SError not taken locally.
- Exception taken, IRQ not taken locally.
- Exception taken, FIQ not taken locally.

`0x08E`**, Exception taken, IRQ not taken locally**

This event is similar to exception taken but the counter counts only IRQ exceptions not taken locally.

`0x08F`**, Exception taken, FIQ not taken locally**

This event is similar to exception taken but the counter counts only FIQ exceptions not taken locally.

`0x090`**, Release consistency operation speculatively executed, Load-Acquire**

The counter counts Load-Acquire operations that are speculatively executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

`0x091`**, Release consistency operation speculatively executed, Store-Release**

The counter counts Store-Release operations that are speculatively executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

C.2 Summary of events taken to an Exception Level using AArch64

Table C-2 shows the events for exceptions taken to an Exception level using AArch64.

Table C-2 Events for exceptions taken to an EL using AArch64

ESR.EC	Description		Event number and classification for exception taken to	
			EL1, or the current EL	EL2 or EL3, from below
0x00	Unknown or uncategorized		0x081, Other synchronous	0x08D, Other traps not taken locally
0x01	WFE/WFI traps		0x081, Other synchronous	0x08D, Other traps not taken locally
0x03	AArch32 CP15 MCR/MRC traps		0x081, Other synchronous	0x08D, Other traps not taken locally
0x04	AArch32 CP15 MCRR/MRRC traps		0x081, Other synchronous	0x08D, Other traps not taken locally
0x05	AArch32 CP14 MCR/MRC traps		0x081, Other synchronous	0x08D, Other traps not taken locally
0x06	AArch32 CP14 LDC/STC traps		0x081, Other synchronous	0x08D, Other traps not taken locally
0x07	Advanced SIMD or FP traps		0x081, Other synchronous	0x08D, Other traps not taken locally
0x08	AArch32 MVFR* and FPSID traps		-	0x08D, Other traps not taken locally
0x0C	AArch32 CP14 MCRR/MRRC traps		0x081, Other synchronous	0x08D, Other traps not taken locally
0x0E	Illegal instruction set state		0x081, Other synchronous	0x08D, Other traps not taken locally
0x11	AArch32 SVC		0x082, Supervisor Call	0x08D, Other traps not taken locally
0x12	AArch32 HVC that is not disabled		-	0x08A, Hypervisor Call
0x13	AArch32 SMC that is not disabled	to EL2	-	0x08D, Other traps not taken locally
		to EL3	-	0x088, Secure Monitor Call
0x15	AArch64 SVC		0x082, Supervisor Call	0x08D, Other traps not taken locally
0x16	AArch64 HVC that is not disabled		0x08A, Hypervisor Call	0x08A, Hypervisor Call
0x17	AArch64 SMC that is not disabled	to EL2	-	0x08D, Other traps not taken locally
		to EL3	0x088, Secure Monitor Call	0x088, Secure Monitor Call
0x18	AArch64 MSR, MRS and system instruction traps		0x081, Other synchronous	0x08D, Other traps not taken locally
0x20	Instruction abort from below		0x083, Instruction Abort	0x08B, Instruction Abort not taken locally
0x21	Instruction abort from current EL		0x083, Instruction Abort	-
0x22	PC alignment		0x083, Instruction Abort	0x08B, Instruction Abort not taken locally
0x24	Data Abort from below		0x084, Data Abort or SError	0x08C, Data Abort or SError not taken locally
0x25	Data Abort from current EL		0x084, Data Abort or SError	-
0x26	Stack pointer alignment		0x084, Data Abort or SError	0x08C, Data Abort or SError not taken locally

Table C-2 Events for exceptions taken to an EL using AArch64 (continued)

ESR.EC	Description	Event number and classification for exception taken to	
		EL1, or the current EL	EL2 or EL3, from below
0x28	AArch32 FP exception	0x081, Other synchronous	0x08D, Other traps not taken locally
0x2C	AArch64 FP exception	0x081, Other synchronous	0x08D, Other traps not taken locally
0x2F	SError interrupt	0x084, Data Abort or SError	0x08C, Data Abort or SError not taken locally
0x30	Breakpoint from below	0x083, Instruction Abort	0x08B, Instruction Abort not taken locally
0x31	Breakpoint from current EL	0x083, Instruction Abort	-
0x32	Software step from below	0x083, Instruction Abort	0x08B, Instruction Abort not taken locally
0x33	Software step from current EL	0x083, Instruction Abort	-
0x34	Watchpoint from below	0x084, Data Abort or SError	0x08C, Data Abort or SError not taken locally
0x35	Watchpoint from current EL	0x084, Data Abort or SError	-
0x38	AArch32 BKPT instruction	0x083, Instruction Abort	0x08B, Instruction Abort not taken locally
0x3A	AArch32 Vector Catch debug event	0x083, Instruction Abort	0x08B, Instruction Abort not taken locally
0x3C	AArch64 BRK instruction	0x083, Instruction Abort	0x08B, Instruction Abort not taken locally
-	IRQ interrupt	0x086, IRQ	0x08E, IRQ not taken locally
-	FIQ interrupt	0x087, FIQ	0x08F, FIQ not taken locally

Note

In these definitions, an exception that is *taken locally* means an exception that is taken to the default Exception level, and is not routed to another Exception level. See *Exception levels* on page D1-1400 for more information.

Appendix D
Example OS Save and Restore sequences

This appendix provides possible OS Save and Restore sequences for a v8 Debug implementation. It contains the following sections:

- *Save Debug registers* on page AppxD-4900.
- *Restore Debug registers* on page AppxD-4902.

D.1 Save Debug registers

This section shows how to save the registers that are used by an external debugger.

```
; On entry, X0 points to a block to save the debug registers in.
; Returns the pointer beyond the block and corrupts X1-X3

SaveDebugRegisters
    ; (1) Set OS lock.
    MOV     X2,#1                       ; Set the OS lock. In AArch64 state, the OS lock
    MSR     OSLAR_EL1,X2                ; is writable via OSLAR.
    ISB                                 ; Context synchronization operation

    ; (2) Walk through the registers, saving them
    MRS     X1,OSDTRRX_EL1              ; Read DTRRX
    MRS     X2,OSDTRTX_EL1              ; Read DTRTX
    STP     W1,W2,[X0],#8               ; Save { DTRRX, DTRTX }
    MRS     X1,MDSCR_EL1                ; Read DSCR
    MRS     X2,OSECCR_EL1               ; Read ECCR
    STP     W1,W2,[X0],#8               ; Save { DSCR, ECCR }
    [ AARCH32_SUPPORTED
    MRS     X1,DBGVCR32_EL2             ; Read DBGVCR
    MRS     X2,DBGCLAIMCLR_EL1          ; Read CLAIM - note, have to read via CLAIMCLR
    STP     W1,W2,[X0],#8               ; Save { VCR, CLAIM }
    ]

    ;; Macros for saving off a “register pair”
    ;; $WB      is W for watchpoint, B for breakpoint
    ;; $num     is the pair’s number
    ;; X0 contains a pointer for the value words
    ;; X1 contains a pointer for the control words
    ;; W2 contains the max index
    MACRO
    SaveRP  $WB,$num, $exit
    MRS     X3,DBG$WB.VR$num._EL1       ; Read DBGxVRn
    STR     X3,[X0],#8                  ; Save { xVRn }
    MRS     X3,DBG$WB.CR$num._EL1       ; Read DBGxCRn
    STR     W3,[X0],#4                  ; Save { xCRn }.
    [ $num > 1 :LAND: $num < 15
    CMP     W1,#$num
    BEQ     $exit
    ]
    MEND

    ; (3) Breakpoints
    MRS     X1,ID_AA64DFR0_EL1
    UBFX    W1,W1,#12,#4                ; Extract BRPs field
    MACRO
    SaveBRP $num                        ; Save a Breakpoint Register Pair
    SaveRP  B,$num,SaveDebugRegisters_Watchpoints
    MEND
    SaveBRP 0
    SaveBRP 1
    SaveBRP 2
    ;; and so on to ...
    SaveBRP 15

SaveDebugRegisters_Watchpoints
    ; (4) Watchpoints
    MRS     X1,ID_AA64DFR0_EL1          ; Read DBGDIDR
    UBFX    W1,W1,#20,#4                ; Extract WRPs field
    MACRO
    SaveWRP $num                        ; Save a Watchpoint Register Pair
    SaveRP  W,$num,SaveDebugRegisters_Exit
    MEND
    SaveWRP 0
    SaveWRP 1
    SaveWRP 2
```

```
    ;; and so on to ...
    SaveWRP 15

SaveDebugRegisters_Exit
    ; (5) Return the pointer to first word not read. This pointer is already in X0, so
    ; all that is needed is to return from this function. The OS double-lock (OSDLR_EL1.DLK) is
    ; locked later, just before the final entry to WFI state.
    RET
```

D.2 Restore Debug registers

This section shows how to restore the registers that are used by an external debugger.

```
; On entry, X0 points to a block of saved debug registers.
; Returns the pointer beyond the block and corrupts R1-R3,R12.

RestoreDebugRegisters
    ; (1) Lock OS lock. The lock will already be set, but this write is included to ensure it
    ; is locked.
    MOV     X2,#1                       ; Lock the OS lock. In AArch64 state, the OS lock
    MSR     OSLAR_EL1,X2                ; is writable via OSLAR.
    ISB                         ; Context synchronization operation

    ; (2) Walk through the registers, restoring them
    LDP     W1,W2,[X0],#8               ; Read { DTRRX,DTRTX }
    MSR     OSDTRRX_EL1,X1              ; Restore DTRRX
    MSR     OSDTRTX_EL1,X2              ; Restore DTRTX
    LDP     W1,W2,[X0],#8               ; Read { DSCR, ECCR }
    MSR     MDSCR_EL1,X1                ; Restore DSCR
    MSR     OSECCR_EL1,X2               ; Restore ECCR
    [ AARCH32_SUPPORTED
    LDP     W1,W2,[X0],#8               ; Read { VCR,CLAIM }
    MSR     DBGVCR32_EL2,X1             ; Restore DBGVCR
    MSR     DBGCLAIMSET_EL1,X2          ; Restore CLAIM - note, writes CLAIMSET
    ]

    ;; Macro for restoring a “register pair”
    MACRO
    RestoreRP $WB,$num,$exit
    LDR     X3,[X0],#8                  ; Read { xVRn }
    MSR     DBG$WB.VR$num._EL1,X3       ; Restore DBGxVRn
    LDR     W3,[X0],#4                  ; Read { xCRn }
    MSR     DBG$WB.CR$num._EL1,X3       ; Restore DBGxCRn

    RestoreRP  W,$num,RestoreDebugRegisters_Exit
    MEND
    RestoreWRP 0
    RestoreWRP 1
    RestoreWRP 2
    ;; and so on until ...
    RestoreWRP 15

RestoreDebugRegisters_Exit
```

```
; (5) Clear the OS lock.
ISB
MOV     X2,#0                       ; Clear the OS lock. In AArch64 state, the OS lock
MSR     OSLAR_EL1,X2                ; is writable via OSLAR.

; (6) A final ISB guarantees the restored register values are visible to subsequent
; instructions.
ISB

; (7) Return the pointer to first word not read. This pointer is already in X0, so
; all that is needed is to return from this function.
RET
```

Appendix E
Recommended Upload and Download Processes for External Debug

This chapter provides information about implementing and using the ARM architecture. It contains the following section:

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might find this information useful.

E.1 Using memory access mode in AArch64 state

Figure E-1 and Figure E-2 on page AppxE-4907 show the processes for using memory access mode to implement a download (external host to target) and an upload (target to external host).

To transfer *n* words of data:

- The download sequence needs *n*+6 accesses by the external debug interface.
- The upload sequence needs *n*+8 accesses by the external debug interface.

In both cases, in the innermost loop the debugger can make an external access to a DTR without polling EDSCR after each write as underrun and overrun detection prevent failure. Normally external accesses from the debugger are outpaced by the memory accesses of the PE, making underruns and overruns unlikely. If this is not the case, the EDSCR.ERR flag is set to 1. This is checked once at the end of the sequence, although a debugger can check it more often, for example once for each page. If the EDSCR.ERR flag is set to 1 because of overrun or underrun, the debugger can restart. The address to restart from is frozen in X0. EDSCR.ERR might also be set because of a Data abort.

If underruns and overruns are common, the debugger can pace itself accordingly.

Note

- The base address must be a multiple of 4.
- The order of the writes that set up the address does not matter in Debug state.

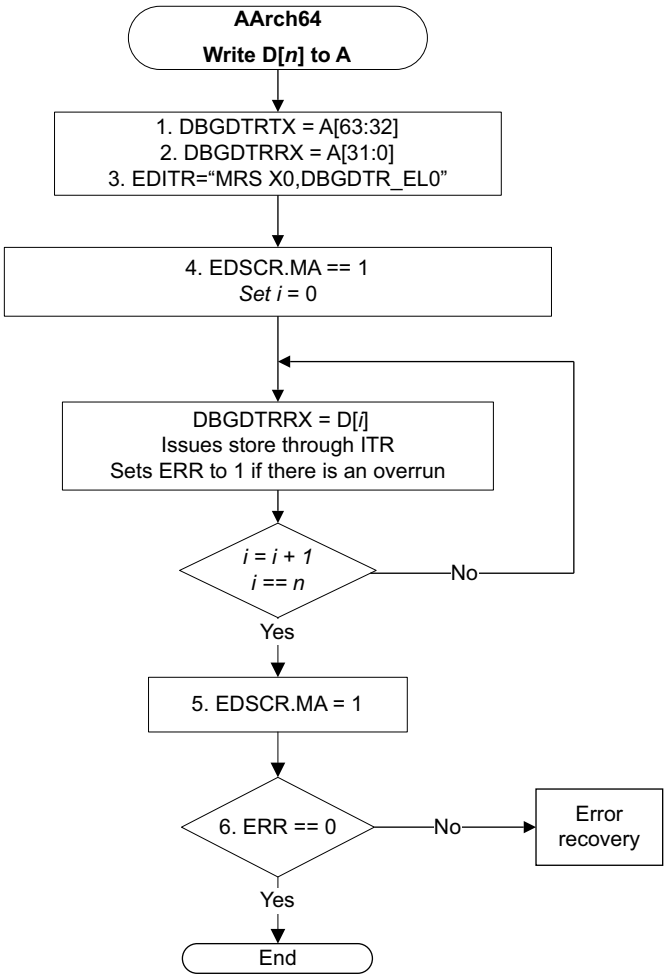

Figure E-1 Fast code download in AArch64 (external host to target)

In Figure E-1 on page AppxE-4906, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
   a. Write address [31:0] to DBGDTRRX_EL0.
   b. Write address [63:32] to DBGDTRTX_EL0.
   c. Write `MRS X0, DBGDTR_EL0` to EDITR. The PE executes this instruction.
   d. Set EDSCR.MA to 1.
2. Loop *n* times. From the external debug interface:
   a. Write to DBGDTRRX_EL0. The PE reads the word from DTRRX and stores it to memory. It increments X0 by 4.
3. Epilogue. From the external debug interface:
   a. Clear EDSCR.MA to 0.
   b. Read EDSCR to check for overruns or Data Aborts during download.

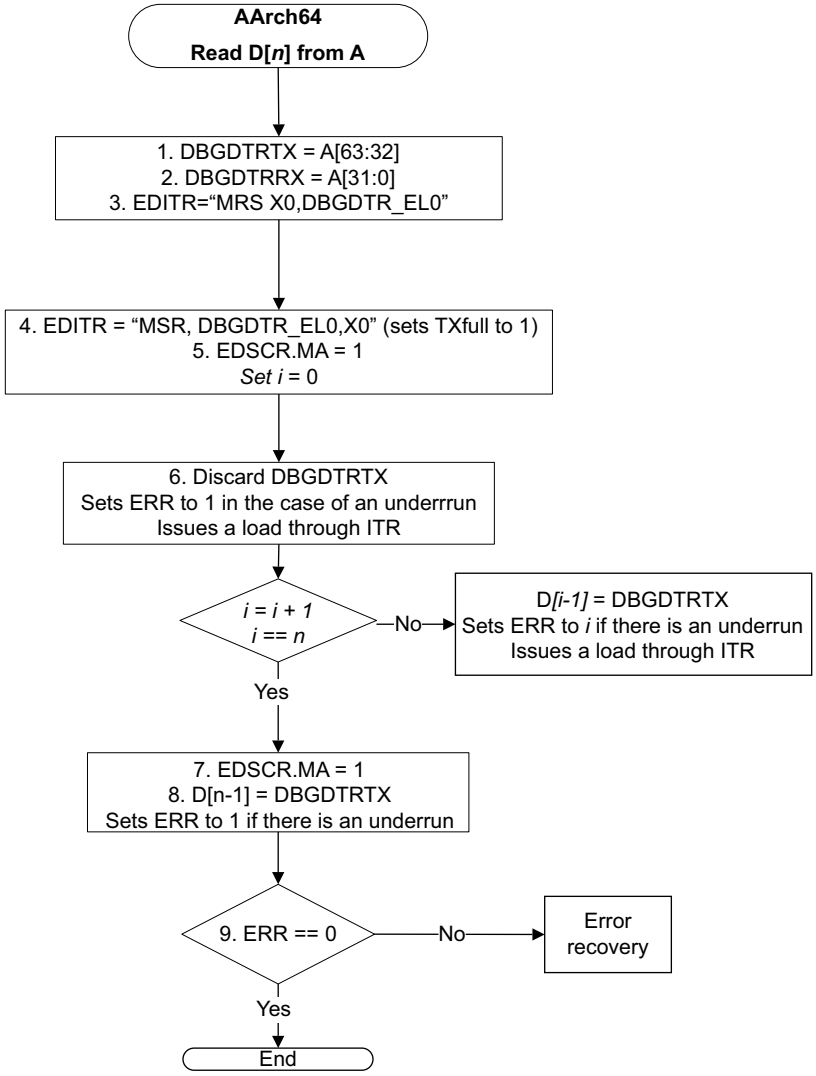

Figure E-2 Fast data upload in AArch64 (target to external host)

In Figure E-2, the sequence for the fast code download is as follows:

1. Setup. From the external debug interface:
   a. Write address [31:0] to DBGDTRRX_EL0.

   b. Write address [63:32] to DBGDTRTX_EL0.
   c. Write `MRS X0, DBGDTR_EL0` to EDITR.
   d. Write `MSR DBGDTR_EL0, X0` to EDITR. This dummy operation ensures EDSCR.TXfull == 1.
   e. Set EDSCR.MA to 1.
   f. Read DBGDTRTX_EL0 and discard the value. The PE returns the previous DTR value, loads the first word, and writes it to DTR. It increments X0 by 4.

2. Loop *n*-1 times. From the external debug interface:
   a. Read DBGDTRTX_EL0. The PE returns the previous DTRTX value, loads a new word, and writes it to DTRTX. It increments X0 by 4.

3. Epilogue. From the external debug interface:
   a. Clear EDSCR.MA to 0.
   b. Read DBGDTRTX_EL0 for the n^{th} value.
   c. Read EDSCR to check for underruns, overruns or Data Aborts during upload.

Appendix F
Barrier Litmus Tests

This appendix gives examples of the use of the barrier instructions provided by the ARMv8 architecture. It contains the following sections:

Note

This information is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

F.1 Introduction

The exact rules for the insertion of barriers into code sequences is a very complicated subject, and this appendix describes many of the corner cases and behaviors that are possible in an implementation of the ARMv8 architecture.

This appendix is to help programmers, hardware design engineers, and validation engineers understand the need for the different kinds of barriers.

F.1.1 Overview of memory consistency

Early generations of microprocessors were relatively simple processing engines that executed each instruction in program order. In such processors, the effective behavior was that each instruction was executed in its entirety before a subsequent instruction started to be executed. This behavior is sometimes referred to as the *Sequential Execution Model* (SEM).

In later processor generations, the needs to increase processor performance, both in terms of the frequency of operation and the number of instructions executed each cycle, mean that such a simple form of execution is abandoned. Many techniques, such as pipelining, write buffering, caching, speculation, and out-of-order execution, are introduced to provide improved performance.

For general purpose PEs, such as ARM, these microarchitectural innovations are largely hidden from the programmer by a number of microarchitectural techniques. These techniques ensure that, within an individual PE, the behavior of the PE largely remains the same as the SEM. There are some exceptions to this where explicit synchronization is required. In the ARM architecture, these are limited to cases such as:

- Synchronization of changes to the instruction stream.
- Synchronization of changes to system control registers.

In both these cases, the `ISB` instruction provides the necessary synchronization.

While the effect of ordering is largely hidden from the programmer within a single PE, the microarchitectural innovations have a profound impact on the ordering of memory accesses. Write buffering, speculation, and cache coherency protocols, in particular, can all mean that the order in which memory accesses occur, as seen by an external observer, differs significantly from the order of accesses that would appear in the SEM. This is usually invisible in a uniprocessor environment, but the effect becomes much more significant when multiple PEs are trying to communicate in memory. In reality, these effects are often only significant at particular synchronization boundaries between the different threads of execution.

The problems that arise from memory ordering considerations are sometimes described as the problem of *memory consistency*. Processor architectures have adopted one or more *memory consistency models*, or *memory models*, that describe the permitted limits of the memory re-ordering that can be performed by an implementation of the architecture. The comparison and categorization of these has generated significant research and comment in academic circles, and ARM recommends the *Memory Consistency Models for Shared Memory-Multiprocessors* paper as an excellent detailed treatment of this subject.

This appendix does not reproduce such a work, but instead concentrates on some cases that demonstrate the features of the weakly-ordered memory model of the ARM architecture from ARMv6. In particular, the examples show how the use of the `DMB` and `DSB` memory barrier instructions can provide the necessary safeguards to limit memory ordering effects at the required synchronization points.

F.1.2 Barrier operation definitions

The following reference, or provide, definitions of terms used in this appendix:

DMB See *Data Memory Barrier (DMB)* on page B2-85.

DSB See *Data Synchronization Barrier (DSB)* on page B2-86.

ISB See *Instruction Synchronization Barrier (ISB)* on page B2-85.

Observer, Completion

See *Observability and completion* on page B2-82.

Program order

The order of instructions as they appear in an assembly language program. This appendix does not attempt to describe or define the legal transformations from a program written in a higher level programming language, such as C or C++, into the machine language that can then be disassembled to give an equivalent assembly language program. Such transformations are a function of the semantics of the higher level language and the capabilities and options on the compiler.

F.1.3 Conventions

Many of the examples are written in a stylized extension to ARM assembler, to avoid confusing the examples with unnecessary code sequences.

AArch32

The construct `WAIT([Rx]==1)` describes the following sequence:

```
loop
    LDR R12, [Rx]
    CMP R12, #1
    BNE loop
```

Also, the construct `WAIT_ACQ([Rx]==1)` describes the following sequence:

```
   loop
    LDA R12, [Rx]       ; load acquire ensures it is ordered before subsequent loads/stores
    CMP R12, #1
    BNE loop
```

R12 is chosen as an arbitrary temporary register that is not in use. It is named to permit the generation of a false dependency to ensure ordering.

AArch64

The construct `WAIT([Xx]==1)` describes the following sequence:

```
loop
    LDR W12, [Xx]
    CMP W12, #1
    B.NE loop
```

Also, the construct `WAIT_ACQ([Xx]==1)` and describes the following sequence:

```
   loop
    LDAR W12, [Xx]       ; load acquire ensures it is ordered before subsequent loads/stores
    CMP W12, #1
    B.NE loop
```

For each example, a code sequence is preceded by an identifier of the observer running it:

- P0, P1…P*x* refer to caching coherent PEs that implement the ARMv8 architecture, and are in the same shareability domain.
- E0, E1…E*x* refer to non-caching observers, that do not participate in the coherency protocol, but execute ARM instructions and have a weakly-ordered memory model. This does not preclude these observers being different objects, such as DMA engines or other system masters.

These observers are unsynchronized other than as required by the documented code sequence.

Note

Throughout this appendix, *ARM instruction* and *instruction* refer to instructions from the A64, A32, or T32 instruction set, provided by ARMv8 implementations.

Results are expressed in terms of `<agent>:<register>`, such as `P0:R5`. The results can be described as:

Permissible This does not imply that the results expressed are required or are the only possible results. In most cases they are results that would not be possible under a sequentially consistent running of the code sequences on the agents involved. In general terms, this means that these results might be unexpected to anyone unfamiliar with memory consistency issues.

Not permissible Results that the architecture expressly forbids.

Required Results that the architecture expressly requires.

The examples omit the required shareability domain arguments of `DMB` and `DSB` instructions. The arguments are assumed to be selected appropriately for the shareability domains of the observers.

In AArch32 state, where the barrier function in the litmus test can be achieved by a `DMB ST`, that is a barrier to stores only, this is shown by the use of `DMB [ST]`. This indicates that the `ST` qualifier can be omitted without affecting the result of the test. In some implementations `DMB ST` is faster than `DMB`.

For AArch64 code, the shareability domain of the `DMB` or `DSB` must be included. This is shown in this manual using the notation `DMB <domain>` and `DSB <domain>` respectively.

Except where otherwise stated, other conventions are:

- All memory initializes to 0.
- R0 and W0 contain the value 1.
- R1 - R4 and W1 - W4 contain arbitrary independent addresses that initialize to the same value on all PEs. The addresses held in these registers are Shareable and:
  - The addresses held in R1 and R2 are in Write-Back Cacheable Normal memory.
  - The address held in R3 is in Write-Through Cacheable Normal memory.
  - The address held in R4 is in Non-cacheable Normal memory.
- R5 - R8 and W5 - W8 contain:
  - When used with an `STR` instruction, `0x55`, `0x66`, `0x77`, and `0x88` respectively.
  - When used with an `LDR` instruction, the value 0.
- R11 and W11 contain a new instruction or new translation table entry, as appropriate, and R10 contains the virtual address and the ASID, for use in this change of translation table entry.
- Memory locations are Normal memory locations unless otherwise stated.

The examples use mnemonics for the cache maintenance and TLB maintenance instructions. The following tables describe the mnemonics:

- *Cache maintenance instructions, functional group* on page G4-3794
- *TLB maintenance instructions, functional group* on page G4-3795.

Notes on timing effects

The ARMv8 architecture makes no statement about when an instruction will occur. In particular, stores may take an unbounded time to be observed by other observers. Therefore the `WAIT` loop waiting for the result of that store may take an unbounded time to move forward.

In cases that it is necessary to guarantee the completion of a store, a `DSB` instruction can be used to force this drain.

In general, the examples in this manual associated with ordering assume that stores will become observable over time and so a final `DSB` barrier to ensure the completion of stores is omitted.

F.2 Load-Acquire, Store-Release and barriers

The Load-Acquire and Store-Release instructions are described in *Load-Acquire, Store-Release* on page B2-87.

The following sections show that most of the examples in sections *Simple ordering and barrier cases* on page AppxF-4935 and *Load-Exclusive, Store-Exclusive and barriers* on page AppxF-4941 can be achieved using the Load-Acquire and Store-Release instructions without the need for additional barriers.

F.2.1 Message passing

The following sections describe:

- *Resolving weakly-ordered message passing by using Acquire and Release*.
- *Resolving message passing by the use of Store-Release and address dependency* on page AppxF-4914.

Resolving weakly-ordered message passing by using Acquire and Release

The message passing problem described in *Weakly-ordered message passing problem* on page AppxF-4935 can be solved by the use of Load-Acquire and Store-Release instructions when accessing the communications flag:

AArch32

P1

```
STR R5, [R1]          ; set new data
STL R0, [R2]          ; send flag indicating data ready, which is ordered after all
```

P2

```
WAIT_ACQ([R2]==1)     ; wait on flag
LDR R5, [R1]
```

AArch64

P1

```
STR W5, [X1]          ; set new data
STLR W0, [X2]         ; send flag indicating data ready, which is ordered after all
```

P2

```
WAIT_ACQ([X2]==1)     ; wait on flag
LDR W5, [X1]
```

This ensures the observed order of both the reads and the writes allows transfer of data such that the result P2:R5==0x55 is guaranteed.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

AArch32

P3

```
WAIT_ACQ([R2]==1)     ; wait on flag
LDR R5, [R1]
```

AArch64

P3

```
WAIT_ACQ([X2]==1)     ; wait on flag
LDR W5, [X1]
```

Resolving message passing by the use of Store-Release and address dependency

The lack of ordering of stores discussed in *Message passing with multiple observers* on page AppxF-4936 can be resolved by the use of Store-Release for the store of the valid flag by P1, even when the observers are using an address dependency:

AArch32

P1

```
STR R5, [R1]          ; set new data
STL R0, [R2]          ; send flag indicating data ready using a Store Release
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0      ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12]     ; Load is dependent and so is ordered after the flag has been seen
```

AArch64

P1

```
STR W5, [X1]          ; set new data
STLR W0, [X2]         ; send flag indicating data ready using a Store Release
```

P2

```
WAIT([X2]==1)
AND W12, W12, WZR     ; R12 is destination of LDR in WAIT macro
LDR W5, [X1, X12]     ; Load is dependent and so is ordered after the flag has been seen
```

This ensures the observed order of the writes allows transfer of data such that P2:R5 and P3:R5 contain the same value of `0x55`.

This approach also works with multiple observers, in a way that further observers use the same sequence as P2 uses:

AArch32

P3

```
WAIT([R2]==1)
AND R12, R12, #0      ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12]     ; Load is dependent and so is ordered after the flag has been seen
```

AArch64

P3

```
WAIT([X2]==1)
AND W12, W12, WZR     ; R12 is destination of LDR in WAIT macro
LDR W5, [X1, X12]     ; Load is dependent and so is ordered after the flag has been seen
```

F.2.2 Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object. A Store-Release can be used to ensure the order of the update of the base address:

AArch32

P1

```
STR R5, [R1, #offset] ; set new data in a field
```

```
    STL R1, [R2]          ; update base address
```

P2

```
    LDR R1, [R2]          ; read for base address
    CMP R1, #0            ; check if it is valid
    BEQ null_trap
    LDR R5, [R1, #offset] ; use base address to read field
```

AArch64

P1

```
    STR W5, [X1, #offset] ; set new data in a field
    STLR X1, [X2]         ; update base address
```

P2

```
    LDR X1, [X2]          ; read for base address
    CMP X1, #0            ; check if it is valid
    B.EQ null_trap
    LDR W5, [X1, #offset] ; use base address to read field
```

It is required that P2:R5==0x55 if the null_trap is not taken. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not need a barrier to ensure this behavior.

The read of the base address in P2 could be a Load-Acquire, but it is not necessary in this case.

F.2.3 Causal consistency issues with multiple observers

The cause consistent problem discussed in *Causal consistency issues with multiple observers* on page AppxF-4938 can be addressed by the use of a Store-Release, as this requires that the store is multicopy atomic in the case of a Load-Acquire. In addition, a Store-Release has an effect on the observation order of any stores observed by the observer executing the Store-Release.

The following sequences guarantee causal consistency:

- *Using multi-copy atomicity of the Store-Release when observed by Load-Acquire*.
- *Using ordering property of Store-Release on stores observed by the PE* on page AppxF-4916.

Using multi-copy atomicity of the Store-Release when observed by Load-Acquire

AArch32

P1

```
    STL R0, [R2]          ; set new data
                          ; this is made multi-copy atomic
```

P2

```
    WAIT_ACQ([R2]==1)     ; wait to see new data from P1
    STR R0, [R3]          ; send flag
                          ; must be after the new data has been by P2 as stores must not be speculative
                          ; this does not need to be a store release, though it could be a store
release
```

P3

```
    WAIT([R3]==1)         ; wait for P2 flag
                          ; this does not need to be a WAIT_ACQ, although
                          ; it could be a WAIT_ACQ (at which point the dependency is not needed)
    AND R12, R12, #0      ; dependency to ensure order (only needed for a WAIT, not WAIT_ACQ)
    LDA R0, [R2, R12]     ; read P1 data using a Load-Acquire
```

AArch64

P1

```
    STLR W0, [X2]         ; set new data
                          ; this is made multi-copy atomic
```

P2

```
    WAIT_ACQ([X2]==1)     ; wait to see new data from P1
    STR W0, [X3]          ; send flag
                          ; must be after the new data has been by P2 as stores
                          ; must not be speculative
                          ; this does not need to be a store release, though it could be a
                          ; store release
```

P3

```
    WAIT([X3]==1)         ; wait for P2 flag
                          ; this does not need to be a WAIT_ACQ, though
                          ; it could be a WAIT_ACQ (at which point the dependency is not needed
    AND W12, W12, WZR     ; dependency to ensure order (only needed for a WAIT, not WAIT_ACQ)
    LDAR W0, [X2, X12]    ; read P1 data using a Load-Acquire
```

In this case, P3:R0 == 0 is not permissible. P3 is guaranteed to see the store from P1 if P2 has seen the store from P1 using a Load-Acquire.

Using ordering property of Store-Release on stores observed by the PE

AArch32

P1

```
    STR R0, [R2]          ; set new data
                          ; this does not have to be a store release, though it
                          ; could be a store release
```

P2

```
    WAIT ([R2]==1)        ; wait to see new data from P1
                          ; this does not need to be a WAIT_ACQ, though it could be a WAIT_ACQ
    STL R0, [R3]          ; send flag
                          ; must be after the new data has been by P2 as stores must not be speculative
                          ; as a store release, this orders P1 store
```

P3

```
    WAIT([R3]==1)         ; wait for P2 flag
                          ; this does not need to be a WAIT_ACQ, although it could be a WAIT_ACQ
                          ; (at which point the dependency is not needed)
    AND R12, R12, #0      ; dependency to ensure order (only needed for a WAIT, not WAIT_ACQ)
    LDR R0, [R2, R12]     ; read P1 data
```

AArch64

P1

```
    STR W0, [X2]          ; set new data
                          ; this does not have to be a store release, though it
                          ; could be a store release
```

P2

```
    WAIT ([X2]==1)        ; wait to see new data from P1
                          ; this does not need to be a WAIT_ACQ, though it could be a WAIT_ACQ
    STLR W0, [X3]         ; send flag
                          ; must be after the new data has been by P2 as stores must not be speculative
                          ; as a store release, this orders P1 store
```

P3

```
WAIT([X3]==1)         ; wait for P2 flag
                      ; this does not need to be a WAIT_ACQ, though it could be a WAIT_ACQ
                      ; at which point the dependency is not needed
AND W12, W12, WZR     ; dependency to ensure order
                      ; only needed for a WAIT, not WAIT_ACQ
LDR W0, [X2, X12]     ; read P1 data
```

In this case, P3:R0 == 0 is not permissible. P3 is guaranteed to see the store from P1 if P2 has seen the store from P1 using a Load-Acquire.

Note

The use of dependency by P3 could be replaced by a Load-Acquire.

F.2.4 Multiple observers of writes to multiple locations

The ARM weakly consistent memory model means that different observers can observe writes to different locations in different orders as was shown in *Multiple observers of writes to multiple locations* on page AppxF-4938, but the use of Load-Acquire and Store-Release can resolve this. In this case, the loads by P3 and P4 must be Load-Acquire in order to ensure the perceived multi-copy atomicity of the stores:

AArch32

P1

```
STL R0, [R1]          ; set new data
```

P2

```
STL R0, [R2]          ; set new data
```

P3

```
LDA R10, [R2]         ; read P2 data before P1
LDA R9, [R1]          ;
BIC R9, R10, R9       ; R9  <- R10 & ~R9
                      ; R9 contains 1 if read from [R2] is observed to be 1 and
                      ; read from [R1] is observed to be 0
```

P4

```
LDA R9, [R1]
LDA R10, [R2]
BIC  R9, R9, R10      ; R9 <- R9 & ~R10
                      ; R9 contains 1 if read from [R2] is observed to be 0 and
                      ; read from [R1] is observed to be 1
```

AArch64

P1

```
STLR W0, [X1]         ; set new data
```

P2

```
STLR W0, [X2]         ; set new data
```

P3

```
LDAR W10, [X2]        ; read P2 data before P1
LDAR W9, [X1]         ;
BIC W9, W10, W9       ; W9  <- W10 & ~W9
                      ; W9 contains 1 if read from [X2] is observed to be 1 and
                      ; read from [X1] is observed to be 0
```

P4

```
LDAR W9, [X1]
```

```
    LDAR W10, [X2]
    BIC  W9, W9, W10      ; W9 <- W9 & ~W10
                          ; W9 contains 1 if read from [X2] is observed to be 0 and
                          ; read from [X1] is observed to be 1
```

In this case, the result P3:R9==1 and P4:R9==1 is not permissible, as the stores from P1 and P2 are multi-copy atomic when read by Load-Acquire.

Therefore, if P3 gets R10==1, then we know that the P3 load of R9 can only be observed after we know that P4 has also observed the P2 store to [R2]. Similarly, if the P4 load of R9 returns 1, and the P3 load of R9 returns 0, then the P3 load must have occurred before the P4 load.

Therefore, if the P3 load of R10 returns 1 and the P3 load of R9 returns 0, then we know that if the P4 load of R9 returns 1, it must have happened after P4 has observed the P2 store to [R2], so the P4 load of R10 must return 1.

This shows that, of the 4 possible values for {P3:R9, P4:R9}, the use of these instructions makes the result {1,1} impossible.

F.2.5 WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. An explicit `DSB` barrier instruction is required if it is necessary to ensure memory accesses made before the `WFI` or `WFE` are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the `DMB` described in *Posting a store before polling for acknowledgement* on page AppxF-4939, or a dependency on a load.

The following example requires the `DSB` to ensure that the store is visible:

AArch32

P1

```
    STR R0, [R2]
    DSB
Loop
    WFI
    B Loop
```

AArch64

P1

```
    STR W0, [X2]
    DSB <domain>
Loop
    WFI
    B Loop
```

This requirement is unchanged in ARMv8 by the presence of Load-Acquire or Store-Release.

F.3 Load-Acquire Exclusive, Store-Release Exclusive and barriers

The ARMv8 architecture adds the acquire and release semantics to Load-Exclusive and Store-Exclusive instructions, which allows them to gain ordering acquire and/or release semantics.

The Load-Exclusive instruction can be specified to have acquire semantics, and the Store-Exclusive instruction can be specified to have release semantics. These can be arbitrarily combined to allow the atomic update created by a successful Load-Exclusive and Store-Exclusive pair to have any of:

- No Ordering semantics (using `LDREX` and `STREX`).
- Acquire only semantics (using `LDAEX` and `STREX`).
- Release only semantics (using `LDREX` and `STLEX`).
- Sequentially consistent semantics (using `LDAEX` and `STLEX`).

In addition, the ARMv8 specification requires that the clearing of a global monitor will generate an event for the PE associated with the global monitor, which can simplify the use of `WFE`, by removing the need for a `DSB` barrier and `SEV` instruction.

F.3.1 Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

For a critical region, the requirement on taking a lock is usually for acquire semantics, while the clearing of a lock requires release semantics:

AArch32

Px

```
    PLDW[R1]              ; preload into cache in unique state
Loop
    LDAEX R5, [R1]        ; read lock with acquire
    CMP R5, #0            ; check if 0
    STREXEQ R5, R0, [R1]  ; attempt to store new value
    CMPEQ R5, #0          ; test if store suceeded
    BNE Loop              ; retry if not

    ; loads and stores in the critical region can now be performed
```

AArch64

Px

```
    PRFM PSTL1KEEP, [X1]  ; preload into cache in unique state
Loop
    LDAXR W5, [X1]        ; read lock with acquire
    CBNZ W5, Loop         ; check if 0
    STXR W5, W0, [X1]    ; attempt to store new value
    CBNZ W5, Loop         ; test if store succeeded and retry if not

    ; loads and stores in the critical region can now be performed
```

The acquire associated with the load is sufficient to ensure the required ordering in a lock situation. The Store-Exclusive will fail (and so be retried) if there is a store to the location being monitored between the Load-Exclusive and the Store-Exclusive.

F.3.2 Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, the lock release needs release semantics:

AArch32

Px

```
    ; loads and stores in the critical region
    MOV R0, #0
    STL R0, [R1]          ; clear the lock with release semantics
```

AArch64

Px

```
    ; loads and stores in the critical region
    STLR WZR, [X1]        ; clear the lock with release semantics
```

F.3.3 Ticket locks

When a lock is free, in order to avoid a rush to get the lock by many PEs, the use of ticket locks is common in more advanced systems. When the use is requested, the ticket locks determine the order of the users of the critical sections, in order to avoid starvation that can occur with a simple contention based spin lock.

A ticket lock allocates each thread a ticket number when it first requests the lock, and then compares that number with the current number for the lock. If they are the same, then the critical section can be entered. Otherwise the thread waits until the current number is equal to the ticket number for that thread.

The reading of the current number of the lock needs acquire semantics for the lock to be acquired.

Note

The code in this section is little-endian code, as it views the combined current and next values as a single combined quantity. The addresses of the current and next ticket values need to be adjusted for a big-endian system.

This is shown in the implementation below:

AArch32

Px

```
    ; R1 holds two 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PLDW[R1]              ; preload into cache in unique state
Loop1
    LDAEX R5, [R1]        ; read current and next
    ADD R5, R5, #0x10000  ; increment the next number
    STREX R6, R5, [R1]    ; and update the value
    CMP R6, #0            ; did the exclusive pass
    BNE Loop1             ; retry if not
    CMP R5, R5, ROR #16   ; is the current ticket ours
    BEQ block_start
Loop2
    LDAH R6, [R1]         ; read current value
    CMP R6, R5, LSR #16   ; compare it with our allocated ticket
    BNE Loop2             ; retry (spin) if it is not the same
block_start
```

AArch64

Px

```
     ; X1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number
```

```
    PRFM PSTL1KEEP, [X1]  ; preload into cache in unique state
Loop1
    LDAXR W5, [X1]        ; read current and next
    ADD W5, W5, #0x10000  ; increment the next number
    STXR W6, W5, [X1]    ; and update the value
    CBNZ W6, Loop1        ; did the exclusive pass - retry if not

    AND W6, W5, #0xFFFF
    CMP W6, W5, LSR #16   ; is the current ticket ours
    B.EQ block_start
Loop2
    LDARH W6, [X1]        ; read current value
    CMP W6, W5, LSR #16   ; compare it with the our allocated ticket
    B.NE Loop2            ; retry (spin) if it isn't the same
block_start
```

Releasing the ticket lock simply involves incrementing the current ticket number, that is still assumed to be in R3, and doing a Store-Release:

AArch32

```
    ADD R6, R6, #1
    STLH R6, [R1]
```

AArch64

```
    ADD W6, W6, #1
    STLRH W6, [X1]
```

F.3.4 Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture can use the Wait For Event mechanism to minimise the energy cost of polling variables by putting the PE into a low power state, suspending execution, until an asynchronous exception or an explicit event is seen by that PE. In ARMv8, the event can be generated as a result of clearing the global monitor, so removing the need for a `DSB` barrier or an explicit send event message.

This can be used with simple locks or with ticket locks.

Simple lock

The following is an example of lock acquire code using `WFE`:

AArch32

Px

```
    PLDW[R1]              ; preload into cache in unique state
Loop
    LDAEX R5, [R1]        ; read lock with acquire
    CMP R5, #0            ; check if 0
    WFENE                 ; sleep if the lock is held
    STREXEQ R5, R0, [R1]  ; attempt to store new value
    CMPEQ R5, #0          ; test if store succeeded
    BNE Loop              ; retry if not
```

AArch64

Px

```
    SEVL                  ; invalidates the WFE on the first loop iteration
    PRFM PSTL1KEEP, [X1]  ; allocate into cache in unique state
Loop
    WFE
    LDAXR W5, [X1]        ; read lock with acquire
    CBNZ W5, Loop         ; check if 0
    STXR W5, W0, [X1]    ; attempt to store new value
```

```
    CBNZ W5, Loop         ; test if store succeeded and retry if not

    ; loads and stores in the critical region can now be performed
```

And the following is an example of lock release code:

AArch32

Px

```
    ; loads and stores in the critical region
    MOV R0, #0
    STL R0, [R1]          ; clear the lock
```

AArch64

Px

```
    ; loads and stores in the critical region
    STLR WZR, [X1]        ; clear the lock
```

Ticket lock

In the Ticket lock case, the Load-Exclusive instruction can be used to move the monitor into the exclusive state for the express purpose of creating an event when the monitor changes state:

AArch32

Px

```
    ; R1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PLDW[R1]              ; preload into cache in unique state
Loop1
    LDAEX R5, [R1]        ; read current and next
    ADD R5, R5, #0x10000  ; increment the next number
    STREX R6, R5, [R1]    ; and update the value
    CMP R6, #0            ; did the exclusive pass
    BNE Loop              ; retry if not
    CMP R5, R5, ROR #16   ; is the current ticket ours
    BEQ block_start
    SEVL
Loop2
    WFE                   ; wait if there has not been a change to the count since last
                          ; read
    LDAEXH R6, [R1]       ; check the current count
    CMP R6, R5, LSR #16   ; check if it is equal
    BNE Loop2
block_start
```

AArch64

Px

```
     ; X1 holds 2 16 bit quantities
    ; the lower halfword holds the current ticket number
    ; the higher halfword holds the next ticket number

    PRFM PSTL1KEEP, [X1]  ; preload into cache in unique state
Loop1
    LDAXR W5, [X1]        ; read current and next
    ADD W5, W5, #0x10000  ; increment the next number
    STXR W6, W5, [X1]    ; and update the value
```

```
    CBNZ W6, Loop1        ; did the exclusive pass - retry if not

    AND W6, W5, 0xFFFF
    CMP W6, W5, LSR #16   ; is the current ticket ours
    B.EQ block_start
    SEVL
Loop2
    WFE
    LDAXRH W6, [X1]       ; read current value
    CMP W6, W5, LSR #16   ; compare it with our allocated ticket
    B.NE Loop2            ; retry (spin) if it is not the same
block_start
```

F.4 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a `DSB` instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

AArch32

P1

```
STR R5, [R1]          ; message stored to shared memory location
DSB ST
STR R0, [R4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

AArch64

P1

```
STR W5, [X1]          ; message stored to shared memory location
DSB ST
STR W0, [X4]          ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR W5, [X1]
```

These rules are required in connection to the ARM Generic Interrupt Controller (GIC).

F.5 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- *Data cache maintenance instructions*
- *Instruction cache maintenance instructions* on page AppxF-4929
- *TLB maintenance instructions and barriers* on page AppxF-4931.

F.5.1 Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- *Message passing to non-caching observers*
- *Multiprocessing message passing to non-caching observers*
- *Invalidating DMA buffers, non-functional example* on page AppxF-4926
- *Invalidating DMA buffers, functional example with single PE* on page AppxF-4927
- *Invalidating DMA buffers, functional example with multiple coherent PEs* on page AppxF-4928.

Message passing to non-caching observers

The ARMv8 architecture requires the use of `DMB` instructions to ensure the ordering of data cache maintenance instructions and their effects. The Load-Acquire and Store-Release instructions have no effect on cache maintenance instruction. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

AArch32

P1

```
STR R5, [R1]          ; update data (assumed to be in P1 cache)
DCCMVAC R1            ; clean cache to point of coherency
DMB                   ; ensure effects of the clean will be observed before the
                      ; flag is set
STR R0, [R4]          ; send flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([R4] == 1)  ; wait for the flag (with order)
LDR R5, [R1]          ; read the data
```

AArch64

P1

```
STR W5, [X1]          ; update data (assumed to be in P1 cache)
DC CVAC, X1           ; clean cache to point of coherency
DMB ISH               ; ensure effects of the clean will be observed before the
                      ; flag is set
STR W0, [X4]          ; send flag to external agent (Non-cacheable location)
```

E1

```
WAIT_ACQ ([X4] == 1)  ; wait for the flag (with order)
LDR W5, [X1]          ; read the data
```

In this example, it is required that E1:R5==`0x55`.

Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions combined with properties of barriers, means that the message passing principle for non-caching observers is:

AArch32

P1

```
    STR R5, [R1]          ; update data (assumed to be in P1 cache)
    STL R0, [R2]          ; send a flag for P2 (ordered by the store release)
```

P2

```
    WAIT ([R2] == 1)      ; wait for P1 flag
    DMB                   ; ensure cache clean is observed after P1 flag is observed
    DCCMVAC R1            ; clean cache to point of coherency - will clean P1 cache
    DMB                   ; ensure effects of the clean will be observed before the
                          ; flag to E1 is set
    STR R0, [R4]          ; send flag to E1
```

E1

```
    WAIT_ACQ ([R4] == 1)      ; wait for P2 flag (ordered)
    LDR R5, [R1]              ; read data
```

AArch64

P1

```
    STR W5, [X1]          ; update data (assumed to be in P1 cache)
    STLR W0, [X2]         ; send a flag for P2 (ordered)
```

P2

```
    WAIT ([X2] == 1)      ; wait for P1 flag
    DMB SY                ; ensure cache clean is observed after P1 flag is observed
    DC CVAC, X1           ; clean cache to point of coherency, will clean P1 cache
    DMB SY                ; ensure effects of the clean will be observed before the
                          ; flag to E1 is set
    STR W0, [X4]          ; send flag to E1
```

E1

```
    WAIT_ACQ ([X4] == 1)      ; wait for P2 flag
    LDR W5, [X1]              ; read data
```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

Note

The cache maintenance instructions are not ordered by the Load-Acquire and Store-Release instructions.

Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions marked as Cacheable can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

AArch32

P1

```
    DCIMVAC R1            ; ensure cache clean wrt memory. A clean operation could be used
                          ; but as the DMA will subsequently overwrite this region an
                          ; invalidate operation is sufficient and usually more efficient
    DMB                   ; ensures cache invalidation is observed before the next store
                          ; is observed
    STR R0, [R3]          ; send flag to external agent
    WAIT_ACQ ([R4]==1)    ; wait for a different flag from an external agent
    LDR R5, [R1]
```

E1

```
WAIT ([R3] == 1)      ; wait for flag
STR R5, [R1]          ; store new data
STL R0, [R4]          ; send a flag
```

AArch64

P1

```
DC IVAC, X1           ; ensure cache clean wrt memory. A clean operation could be used
                      ; but as the DMA will subsequently overwrite this region an
                      ; invalidate operation is sufficient and usually more efficient
DMB SY                ; ensures cache invalidation is observed before the next store
                      ; is observed
STR W0, [X3]          ; send flag to external agent
WAIT_ACQ ([X4]==1)    ; wait for a different flag from an external agent
LDR W5, [X1]
```

E1

```
WAIT ([X3] == 1)      ; wait for flag
STR W5, [X1]          ; store new data
STLR W0, [X4]         ; send a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

Invalidating DMA buffers, functional example with single PE

AArch32

P1

```
DCIMVAC R1            ; ensure cache clean wrt memory. A clean operation could be used
                      ; but as the DMA will subsequently overwrite this region an
                      ; invalidate operation is sufficient and usually more efficient
DMB                   ; ensures cache invalidation is observed before the next store
                      ; is observed
STR R0, [R3]          ; send flag to external agent
WAIT ([R4]==1)        ; wait for a different flag from an external agent
DMB                   ; ensure that cache invalidate is observed after the flag
                      ; from external agent is observed
DCIMVAC R1            ; ensure cache discards stale copies before use
LDR R5, [R1]
```

E1

```
WAIT ([R3] == 1)      ; wait for flag
STR R5, [R1]          ; store new data
STL R0, [R4]          ; send a flag
```

AArch64

P1

```
DC IVAC, X1           ; ensure cache clean wrt memory. A clean operation could be used
                      ; but as the DMA will subsequently overwrite this region an
                      ; invalidate operation is sufficient and usually more efficient
DMB SY                ; ensures cache invalidation is observed before the next store
                      ; is observed
STR W0, [X3]          ; send flag to external agent
WAIT ([X4]==1)        ; wait for a different flag from an external agent
DMB SY                ; ensure that cache invalidate is observed after the flag
                      ; from external agent is observed
DC IVAC, X1           ; ensure cache discards stale copies before use
LDR W5, [X1]
```

E1

```
WAIT ([X3] == 1)      ; wait for flag
STR W5, [X1]          ; store new data
STLR W0, [X4]         ; send a flag
```

In this example, the result P1:R5 == `0x55` is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of `DMB` instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

AArch32

P0

```
(Use data from [R1], potentially using [R1] as scratch space)
STL R0, [R2]          ; signal release of [R1]
WAIT_ACQ ([R2] == 0)  ; wait for new value from DMA
LDR R5, [R1]
```

P1

```
WAIT ([R2] == 1)      ; wait for release of [R1] by P0
DCIMVAC R1            ; ensure caches are clean wrt memory, invalidate is sufficient
DMB
STR R0, [R3]          ; request new data for [R1]
WAIT ([R4] == 1)      ; wait for new data
DMB
DCIMVAC R1            ; ensure caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2]          ; signal availability of new [R1]
```

E1

```
WAIT ([R3] == 1)      ; wait for new data request
STR R5, [R1]          ; send new [R1]
DMB [ST]
STR R0, [R4]          ; indicate new data available to P1
```

AArch64

P0

```
(Use data from [X1], potentially using [X1] as scratch space)
STLR W0, [X2]         ; signal release of [X1]
WAIT_ACQ ([X2] == 0)  ; wait for new value from DMA
LDR W5, [X1]
```

P1

```
WAIT ([X2] == 1)      ; wait for release of [R1] by P0
DC IVAC, X1           ; ensure caches are clean wrt memory, invalidate is sufficient
DMB SY
STR W0, [X3]          ; request new data for [R1]
WAIT ([X4] == 1)      ; wait for new data
DMB SY
DCIMVAC X1            ; ensure caches discard stale copies before use
DMB SY
STR WZR, [X2]         ; signal availability of new [R1]
```

E1

```
WAIT ([X3] == 1)      ; wait for new data request
STR W5, [X1]          ; send new [R1]
STR W0, [X4]          ; indicate new data available to P1
```

In this example, the result P0:R5 == 0x55 is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

F.5.2 Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- *Ensuring the visibility of updates to instructions for a uniprocessor*
- *Ensuring the visibility of updates to instructions for a multiprocessor*.

Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

AArch32

P1

```
STR R11, [R1]          ; R11 contains a new instruction to stored in program memory
DCCMVAU R1             ; clean to PoU makes visible to instruction cache
DSB
ICIMVAU R1             ; ensure instruction cache/branch predictor discard stale data
BPIMVA R1
DSB                    ; ensure completion of the invalidation
ISB                    ; ensure instruction fetch path sees new I cache state
BX R1
```

In AArch64, the branch predictor maintenance is not required.

AArch64

P1

```
STR W11, [X1]          ; W11 contains a new instruction to stored in program memory
DC CVAU, X1            ; clean to PoU makes visible to instruction cache
DSB ISH
IC IVAU, X1            ; ensure instruction cache/branch predictor discard stale data
DSB ISH                ; ensure completion of the invalidation
ISB                    ; ensure instruction fetch path sees new I cache state
BR X1
```

Note

Where the changes to the instructions span multiple cache lines, then the data cache and instruction cache maintenance instructions can be duplicated to cover each of the lines to be cleaned and to be invalidated.

Ensuring the visibility of updates to instructions for a multiprocessor

The ARMv8 architecture requires a PE that executes an instruction cache maintenance instruction to execute a DSB instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An ISB is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own ISB synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

AArch32

P1

```
STR R11, [R1]          ; R11 contains a new instruction to stored in program memory
DCCMVAU R1             ; clean to PoU makes visible to instruction cache
DSB                    ; ensure completion of the clean on all processors
ICIMVAU R1             ; ensure instruction cache/branch predictor discard stale data
BPIMVA R1
DSB                    ; ensure completion of the ICache and branch predictor
                       ; invalidation on all processors
STR R0, [R2]           ; set flag to signal completion
ISB                    ; synchronize context on this processor
BX R1                  ; branch to new code
```

P2-P*x*

```
WAIT ([R2] == 1)       ; wait for flag signalling completion
ISB                    ; synchronize context on this processor
BX R1                  ; branch to new code
```

AArch64

P1

```
STR X11, [X1]          ; X11 contains a new instruction to stored in program memory
DC CVAU, X1            ; clean to PoU makes visible to instruction cache
DSB ISH                ; ensure completion of the clean on all processors
IC IVAU, X1            ; ensure instruction cache/branch predictor discard stale data
DSB ISH                ; ensure completion of the ICache and branch predictor
                       ; invalidation on all processors
STR W0, [X2]           ; set flag to signal completion
ISB                    ; synchronize context on this processor
BR R1                  ; branch to new code
```

P2-P*x*

```
WAIT ([X2] == 1)       ; wait for flag signalling completion
ISB                    ; synchronize context on this processor
BR X1                  ; branch to new code
```

Nonfunctional approach

The following sequence does not have the same effect, because a `DSB` is not required to complete the instruction cache maintenance instructions that other PEs issue:

AArch32

P1

```
STR R11, [R1]          ; R11 contains a new instruction to stored in program memory
DCCMVAU R1             ; clean to PoU makes visible to instruction cache
DSB                    ; ensure completion of the clean on all processors
ICIMVAU R1             ; ensure instruction cache/branch predictor discard stale data
BPIMVA R1
DMB                    ; ensure ordering of the store after the invalidation
                       ; DOES NOT guarantee completion of instruction cache/branch
                       ; predictor on other processors
STR R0, [R2]           ; set flag to signal completion
DSB                    ; ensure completion of the invalidation on all processors
ISB                    ; synchronize context on this processor
BX R1                  ; branch to new code
```

P2-P*x*

```
WAIT ([R2] == 1)       ; wait for flag signalling completion
DSB                    ; this DSB does not guarantee completion of P1
                       ; ICIMVAU/BPIMVA
ISB
BX R1
```

AArch64

P1

```
STR W11, [X1]          ; W11 contains a new instruction to stored in program memory
DC CVAU, X1            ; clean to PoU makes visible to instruction cache
DSB ISH                ; ensure completion of the clean on all processors
IC IVAU, X1            ; ensure instruction cache/branch predictor discard stale data
DMB ISH                ; ensure ordering of the store after the invalidation
                       ; DOES NOT guarantee completion of instruction cache/branch
                       ; predictor on other processors
STR W0, [X2]           ; set flag to signal completion
DSB ISH                ; ensure completion of the invalidation on all processors
ISB                    ; synchronize context on this processor
BR X1                  ; branch to new code
```

P2-P*x*

```
WAIT ([X2] == 1)       ; wait for flag signalling completion
DSB ISH                ; this DSB does not guarantee completion of P1
                       ; ICIMVAU/BPIMVA
ISB
BR X1
```

In this example, P2…P*x* might not see the updated region of code at R1.

F.5.3 TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- *Ensuring the visibility of updates to translation tables for a uniprocessor*
- *Ensuring the visibility of updates to translation tables for a multiprocessor* on page AppxF-4932
- *Paging memory in and out* on page AppxF-4932.

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a `DSB` instruction.

The ARMv8 architecture requires that translation table walks look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a `DSB` and an `ISB`. Therefore, the code for updating a translation table entry is:

AArch32

P1

```
STR R11, [R1]          ; update the translation table entry
DSB                    ; ensure visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB                    ; ensure completion of the BP and TLB invalidation
ISB                    ; synchronise context on this processor
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

AArch64

P1

```
STR X11, [X1]          ; update the translation table entry
DSB ISH                ; ensure visibility of the update to translation table walks
```

```
TLBI VAE1, X10        ; assumes we are in the EL1
DSB ISH               ; ensure completion of the TLB invalidation
ISB                   ; synchronise context on this processor
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using
; the old mapping have been completed
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. The ARMv8 architecture requires a PE that executes a TLB maintenance instruction to execute a `DSB` instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a `DSB` that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

AArch32

P1

```
STR R11, [R1]         ; update the translation table entry
DSB                   ; ensure visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB                   ; ensure completion of the BP and TLB invalidation
ISB                   ; Note ISB is not broadcast and must be executed locally
                      ; on other processors
;  new translation table entry can be relied upon at this point and all accesses
;  generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed
```

AArch64

P1

```
STR X11, [X1]         ; update the translation table entry
DSB ISH               ; ensure visibility of the update to translation table walks
TLBI VAE1IS,  X10
DSB ISH               ; ensure completion of the TLB invalidation
ISB                   ; Note ISB is not broadcast and must be executed locally
                      ; on other processors
;  new translation table entry can be relied upon at this point and all accesses
;  generated by any observers affected by the broadcast TLBIMVAIS operation using
; the old mapping have been completed
```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a `DSB` by the observer that performed the TLB maintenance instruction. The execution of a `DSB` by a different observer does not have this effect, even if the `DSB` is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

AArch32

P1

```
STR R11, [R1]          ; update the translation table for the region being paged out
DSB                    ; ensure visibility of the update to translation table walks
TLBIMVAIS R10          ; invalidate the old entry
DSB                    ; ensure completion of the invalidation on all processors
ISB                    ; ensure visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB                    ; ensure completion of the memory transfer (this could be part of
                       ; LoadMemoryFromBackingStore
ICIALLUIS              ; also invalidates the branch predictor
STR R9, [R1]           ; create a new translation table entry with a new mapping
DSB                    ; ensure completion of the I Cache & Branch Predictor invalidation
                       ; AND ensure visibility of the new translation table mapping
ISB                    ; ensure synchronisation of this instruction stream
```

AArch64

P1

```
STR X11, [X1]          ; update the translation table for the region being paged out
DSB ISH                ; ensure visibility of the update to translation table walks
TLBI VAE1IS, X10       ; invalidate the old entry
DSB ISH                ; ensure completion of the invalidation on all processors
ISB                    ; ensure visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB ISH                ; ensure completion of the memory transfer (this could be part of
                       ; LoadMemoryFromBackingStore
IC IALLUIS             ; also invalidates the branch predictor
STR X9, [X1]           ; create a new translation table entry with a new mapping
DSB ISH                ; ensure completion of the I Cache & Branch Predictor invalidation
                       ; AND ensure visibility of the new translation table mapping
ISB                    ; ensure synchronisation of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of SaveMemoryPageToBackingStore and LoadMemoryFromBackingStore. LoadMemoryFromBackingStore is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of ICIALLUIS in AArch32 and IC IALLUIS in AArch64 to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU and IC IVAU operations in AArch32 and AArch64 respectively. This invalidation must be done when the mapping used for the ICIMVAU and IC IVAU operations is valid but not executable.

F.5.4 Ordering of Memory-mapped device control with payloads

With a Memory-mapped peripheral, such as a DMA, which can also access memory for its own use, it is common to have control or status registers which are Memory-mapped. These registers need to be accessed in an ordered manner with respect to the data that the Memory-mapped peripheral is handling.

Two simple examples of this are:

- When a Processing Element is writing a buffer of data, and then writing to a control register in the DMA peripheral to start that peripheral to access the buffer of data.

- When a DMA peripheral has written to a buffer of data in memory, and the Processing Element is reading a status register to determine that the DMA transfer has completed, and then is reading the data.

For the case of the Processing Element writing a buffer of data, before starting the DMA peripheral, the ordering requirements between the stores to the data buffer and the stores to the Memory-mapped a to the DMA peripheral can be met by the insertion of a `DSB <domain>` instruction between these sets of accesses as this ensures the global observation of the stores before the DMA is started. this is shown by the following code:

AArch32

P1

```
STR R5, [R2]          ; data written to the data buffer
DSB
STR R0, [R4]          ; R4 contains the address of the DMA control register
```

AArch64

P1

```
STR W5, [X2]          ; data written to the data buffer
DSB <domain>
STR W0, [X4]          ; X4 contains the address of the DMA control register
```

For the case of DMA peripheral writing the data buffer and then setting a status register when those stores are complete (and so globally observed) and then having this status register polled by the Processing element before the processing element reads the data buffer, the processing element must insert a `DSB <domain>` between the load that reads the status register, and the read of the buffer. A DMB, or load-acquire, is not sufficient as this problem is not solely concerned with observation order, since the polling read is actually a read of a status register at a slave, not the polling a data value that has been written by an observer.

For this case, the code is therefore:

AArch32

P1

```
WAIT ([R4] == 1)      ; R4 contains the address of the status register,
                      ; and the value ‘1’ indicates completion of the DMA transfer
DSB
LDR R5, [R2]          ; read data from the data buffer
```

AArch64

P1

```
WAIT ([X4] == 1)      ; X4 contains the address of the status register,
                      ; and the value ‘1’ indicates completion of the DMA transfer
DSB <domain>
LDR W5, [X2]          ; read data from the data buffer
```

F.6 ARMv7 compatible approaches for ordering, using DMB and DSB barriers

The following sections describe the ARMv7 compatible approaches for ordering, using DMB and DSB barriers:

- *Simple ordering and barrier cases*.
- *Load-Exclusive, Store-Exclusive and barriers* on page AppxF-4941.
- *Using a mailbox to send an interrupt* on page AppxF-4942.
- *Cache and TLB maintenance instructions and barriers* on page AppxF-4943.

F.6.1 Simple ordering and barrier cases

ARM implements a weakly consistent memory model for Normal memory. In general terms, this means that the order of memory accesses observed by other observers might not be the order that appears in the program, for either loads or stores.

This section includes examples of this.

Simple weakly consistent ordering example

P1

```
STR R5, [R1]
LDR R6, [R2]
```

P2

```
STR R6, [R2]
LDR R5, [R1]
```

In the absence of barriers, the result of P1: R6=0, P2: R5=0 is permissible.

Message passing

The following sections describe:

- *Weakly-ordered message passing problem*
- *Message passing with multiple observers* on page AppxF-4936.

Weakly-ordered message passing problem

P1

```
STR R5, [R1]            ; set new data
STR R0, [R2]            ; send flag indicating data ready
```

P2

```
WAIT([R2]==1)           ; wait on flag
LDR R5, [R1]            ; read new data
```

In the absence of barriers, an end result of P2: R5=0 is permissible.

Resolving by the addition of barriers

The addition of barriers, to ensure the observed order of the reads and the writes, ensures that data is transferred so that the result P2:R5==0x55 is guaranteed, as follows:

P1

```
STR R5, [R1]            ; set new data
DMB [ST]                ; ensure all observers observe data before the flag
STR R0, [R2]            ; send flag indicating data ready
```

P2

```
WAIT([R2]==1)           ; wait on flag
```

```
DMB                     ; ensure that the load of data is after the flag has been observed
LDR R5, [R1]
```

Resolving by the use of barriers and address dependency

There is a rule within the ARM architecture that:

- Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, then these two memory accesses are observed in program order.

  Where the value returned by a read is used for computation of the virtual address of a subsequent read or write, this is called an *address dependency*. An address dependency exists even if the value returned by the first read has no effect on the virtual address. This might occur if the value returned is masked off before it is used, or if it confirms a predicted address value that it might have changed.

  This restriction applies only when the data value returned by a read is used as a data value to calculate the address of a subsequent read or write. It does not apply if the data value returned by a read determines the condition flags values, and the values of the flags are used for condition code evaluation to determine the address of a subsequent read, either through conditional execution or the evaluation of a branch. This is called a *control dependency*.

  Where both a control and address dependency exist, the ordering behavior is consistent with the address dependency.

Table F-1 shows examples of address dependencies, control dependencies, and an address and control dependency.

Table F-1 Dependency examples

Address dependency		Control dependency		Address and control dependency[a]
(a)	**(b)**	**(c)**	**(d)**	**(e)**
`LDR r1, [r0]`	`LDR r1, [r0]`	`LDR r1, [r0]`	`LDR r1, [r0]`	`LDR r1, [r0]`
`LDR r2, [r1]`	`AND r1, r1, #0`	`CMP r1, #55`	`CMP r1, #55`	`CMP r1, #0`
	`LDR r2, [r3, r1]`	`LDRNE r2, [r3]`	`MOVNE r4, #22`	`LDRNE r2, [r1]`
			`LDR r2, [r3, r4]`	

a. The address dependency takes priority.

This means that the data transfer example of *Weakly-ordered message passing problem* on page AppxF-4935 can also be satisfied as shown in the following example:

P1

```
STR R5, [R1]            ; set new data
DMB [ST]                ; ensure all observers observe data before the flag
STR R0, [R2]            ; send flag indicating data ready
```

P2

```
WAIT([R2]==1)
AND R12, R12, #0        ; R12 is destination of LDR in WAIT macro
LDR R5, [R1, R12]       ; Load is dependent and so is ordered after the flag has been seen
```

The load of R5 by P2 is ordered with respect to the load from [R2] because there is an address dependency using R12. P1 uses a `DMB` to ensure that P2 does not observe the write of [R2] before the write of [R1].

Message passing with multiple observers

Where the ordering of Normal memory accesses is not resolved by the use of barriers or dependencies, then different observers might observe the accesses in a different order, as shown in the following example:

P1

```
    STR R5, [R1]            ; set new data
    STR R0, [R2]            ; send flag indicating data ready
```

P2

```
    WAIT([R2]==1)
    AND R12, R12, #0        ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]       ; Load is dependent and so is ordered after the flag has been seen
```

P3

```
    WAIT([R2]==1)
    AND R12, R12, #0        ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]       ; Load is dependent and so is ordered after the flag has been seen
```

In this case, it is permissible for P2:R5 and P3:R5 to contain different values, because there is no order guaranteed between the two stores performed by P1.

Resolving by the addition of barriers

The addition of a barrier by P1, as shown in the following example, ensures the observed order of the writes, transferring data so that P2:R5 and P3:R5 both contain the value `0x55`:

P1

```
    STR R5, [R1]            ; set new data
    DMB [ST]                ; ensure all observers observe data before the flag
    STR R0, [R2]            ; send flag indicating data ready
```

P2

```
    WAIT([R2]==1)
    AND R12, R12, #0        ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]       ; Load is dependent and so is ordered after the flag has been seen
```

P3

```
    WAIT([R2]==1)
    AND R12, R12, #0        ; R12 is destination of LDR in WAIT macro
    LDR R5, [R1, R12]       ; Load is dependent and so is ordered after the flag has been seen
```

Address dependency with object construction

When accessing an object-oriented data structure, the address dependency rule means that barriers are not required, even when initializing the object:

P1

```
    STR R5, [R1, #offset]   ; set new data in a field
    DMB [ST]                ; ensure all observers observe data before base address is updated
    STR R1, [R2]            ; update base address
```

P2

```
    LDR R1, [R2]            ; read for base address
    CMP R1, #0              ; check if it is valid
    BEQ null_trap
    LDR R5, [R1, #offset]   ; use base address to read field
```

If the null_trap is not taken, it is required that P2:R5==`0x55`. This avoids P2 observing a partially constructed object from P1. Significantly, P2 does not require a barrier to ensure this behavior.

P1 requires a barrier to ensure the observed order of the writes by P1. In general, the impact of requiring a barrier during the construction phase is much less than the impact of requiring a barrier for every read access.

Causal consistency issues with multiple observers

The fact that different observers can observe memory accesses in different orders extends, in the absence of barriers, to behaviors that do not fit naturally expected causal properties, as the following example shows:

P1

```
    STR R0, [R2]            ; set new data
```

P2

```
    WAIT([R2]==1)           ; wait to see new data from P1
    STR R0, [R3]            ; send flag, must be after the new data has been by P2 as stores
                            ; must not be speculative
```

P3

```
    WAIT([R3]==1)           ; wait for P2's flag
    AND R12, R12, #0        ; dependency to ensure order
    LDR R0, [R2, R12]       ; read P1's data
```

In this example, P3:R0==0 is permissible. P3 is not guaranteed to seethe stores from P1 and P2 in any particular order. This applies despite the fact that the store from P2 can only happen after P2 has observed the store from P1.

This example shows that the ARM memory order model for Normal memory does not conform to c*ausal consistency*. This means that the apparently transitive causal relationship between two variables is not guaranteed to be transitive.

The following example shows the insertion of a barrier by P2 to create causal consistency:

P1

```
    STR R0, [R2]            ; set new data
```

P2

```
    WAIT([R2]==1)           ; wait to see new data from P1
    DMB                     ; ensure P1's data is observed by all observers before any following store
    STR R0, [R3]            ; send flag
```

P3

```
    WAIT([R3]==1)           ; wait for P2's flag
    AND R12, R12, #0        ; dependency to ensure order
    LDR R0, [R2, R12]       ; read P1's data
```

This creates causal consistency because a `DMB` is required to order all accesses that the executing PE observed before the `DMB`, not only those it issued, before any of the accesses that follow the `DMB`.

Multiple observers of writes to multiple locations

The ARM weakly consistent memory model means that different observers can observe writes to different locations in different orders, as the following example shows:

P1

```
    STR R0, [R1]            ; set new data
```

P2

```
    STR R0, [R2]            ; set new data
```

P3

```
    LDR R10, [R2]           ; read P2's data before P1's
    LDR R9, [R1]            ;
    BIC R9, R10, R9         ; R9 <- R10 && ~R9
                            ; R9 contains 1 iff read from [R2] is observed to be 1 and
                            ; read from [R1] is observed to be 0.
```

P4

```
LDR R9, [R1]
LDR R10, [R2]
BIC  R9, R9, R10         ; R9 <- R9 && ~R10
                         ; R9 contains 1 iff read from [R2] is observed to be 0 and
                         ; read from [R1] is observed to be 1.
```

In this example, the result P3:R9==1 and P4:R9==1 is permissible. This means that P3 and P4 observed the stores from P1 and P2 in different orders.

The following example shows the use of DMB instructions to ensure sequential consistency:

P1

```
STR R0, [R1]             ; set new data
```

P2

```
STR R0, [R2]             ; set new data
```

P3

```
LDR R10, [R2]            ; read P2's data before P1's
DMB
LDR R9, [R1]
BIC R9, R10, R9          ; R9 <- R10 && ~R9
                         ; R9 contains 1 iff read from [R2] is observed to be 1 and
                         ; read from [R1] is observed to be 0.
```

P4

```
LDR R9, [R1]             ; read P1's data before P2's
DMB
LDR R10, [R2]
BIC  R9, R9, R10         ; R9 <- R9 && ~R10
                         ; R9 contains 1 iff read from [R2] is observed to be 0 and
                         ; read from [R1] is observed to be 1.
```

In this example:

- The DMB executed by P3 ensures that, if the P3 load from [R2] observes the P2 store to [R2], then all observers observe the P2 store to [R2] before they observe the P3 load from [R1].
- The DMB executed by P4 ensures that, if the P4 load from [R1] observes the P1 store to [R1], then all observers observe the P1 store to [R1 before they observe the P4 load from [R2].

If the P3 load from [R1] returns 0, then it has not observed the P1 store to [R1]. Also, if the P3 load of [R2] returns 1, then all observers must have observed the P2 store to [R2] before they observed the P1 store to [R1]. This means that P4 cannot observe the P1 store to [R1] without also observing the P2 store to [R2].

Alternatively, if the P4 load from [R2] returns 0, then it has not observed the P2 store to [R2]. If, also, the P4 load of [R1] returns 1, then all observers must have observed the P1 store to [R1] before they observed the P2 store to [R2]. This means that P3 cannot observe the P2 store to [R2] without also observing the P1 store to [R1].

This shows that, of the four possible results for {P3:R9, P4:R9}, the insertion of these barriers makes the result {1, 1} impossible.

Posting a store before polling for acknowledgement

In the case where an observer stores to a location, and then polls for an acknowledge from a different observer, the weak ordering of the memory model can lead to a deadlock, as the following example shows:

P1

```
STR R0, [R2]
WAIT ([R3]==1)
```

P2

```
WAIT ([R2]==1)
STR R0, [R3]
```

In ARMv7 implementations that do not include the Multiprocessing Extensions, then this can deadlock because P2 might not observe the store by P1 in finite time. For ARMv7 implementations with the Multiprocessing Extensions and for ARMv8, this is not an issue as all stores must be observed by all observers within their shareability domain in finite time.

The addition of a `DMB` instruction prevents this deadlock in ARMv7 implementations that do not include the Multiprocessing Extensions:

P1

```
STR R0, [R2]
DMB
WAIT ([R3]==1)
```

P2

```
WAIT ([R2]==1)
STR R0, [R3]
```

The `DMB` executed by P1 ensures that P2 observes the store by P1 before it observes the load by P1. This ensures a timely completion.

The following example is a variant of the previous example, where the two observers poll the same memory location:

P1

```
STR R0, [R2]
WAIT ([R2]==2)
```

P2

```
WAIT ([R2]==1)
LDR R0, [R2]
ADD R0, R0, #1
STR R0, [R2]
```

In this example, the same deadlock can occur, because the architecture permits P1 to read the result of its own store to [R2] early, and continue doing so for an indefinite amount of time. The addition of a `DMB` instruction prevents this deadlock:

P1

```
STR R0, [R2]
DMB
WAIT ([R2]==2)
```

P2

```
WAIT ([R2]==1)
LDR R0, [R2]
ADD R0, R0, #1
STR R0, [R2]
```

WFE and WFI and barriers

The Wait For Event and Wait For Interrupt instructions permit the PE to suspend execution and enter a low-power state. A `DSB` barrier instruction is required if it is necessary to ensure that memory accesses made before the `WFI` or `WFE` are visible to other observers, unless some other mechanism has ensured this visibility. Examples of other mechanism that would guarantee the required visibility are the `DMB` described in *Posting a store before polling for acknowledgement* on page AppxF-4939, or a dependency on a load.

The following example requires the `DSB` to ensure that the store is visible:

P1

```
    STR R0, [R2]
    DSB
Loop
    WFI
    B Loop
```

However, if the example in *Posting a store before polling for acknowledgement* on page AppxF-4939 is extended to include a WFE, there is no risk of a deadlock. The extended example is:

P1

```
    STR R0, [R2]
    DMB
Loop
    LDR R12, [R3]
    CMP R12, #1
    WFENE
    BNE Loop
```

P2

```
    WAIT ([R2]==1)
    STR R0, [R3]
    DSB
    SEV
```

In this example:

- The DMB by P1 ensures that P2 observes the store by P1 before it observes the load by P1.
- The dependency of the WFE on the result of the load by P1 means that this load must complete before P1 executes the WFE.

For more information about SEV, see *Use of Wait For Event (WFE) and Send Event (SEV) with locks* on page AppxF-4942.

F.6.2 Load-Exclusive, Store-Exclusive and barriers

The Load-Exclusive and Store-Exclusive instructions, described in *Synchronization and semaphores* on page B2-99, are predictable only with Normal memory. These instructions do not have any implicit barrier functionality. Therefore, any use of these instructions to implement locks of any type requires the addition of explicit barriers.

Acquiring a lock

A common use of Load-Exclusive and Store-Exclusive instructions is to claim a lock to permit entry into a critical region. This is typically performed by testing a lock variable that indicates 0 for a free lock and some other value, commonly 1 or an identifier of the process holding the lock, for a taken lock.

The lack of implicit barriers in the Load-Exclusive and Store-Exclusive instructions means that the mechanism requires a DMB instruction between acquiring a lock and making the first access to the critical region, to ensure that all observers observe the successful claim of the lock before they observe any subsequent loads or stores to the region. This example shows Px acquiring a lock:

P*x*

```
Loop
    LDREX R5, [R1]          ; read lock
    CMP R5, #0              ; check if 0
    STREXEQ R5, R0, [R1]    ; attempt to store new value
    CMPEQ R5, #0            ; test if store succeeded
    BNE Loop                ; retry if not
    DMB                     ; ensures that all subsequent accesses are observed after the
                            ; gaining of the lock is observed
```

```
    ; loads and stores in the critical region can now be performed
```

Releasing a lock

The converse operation of releasing a lock does not require the use of Load-Exclusive and Store-Exclusive instructions, because only a single observer is able to write to the lock. However, often it is necessary for any observer to observe any memory updates, or any values that are loaded into memory, before they observe the release of the lock. Therefore, a `DMB` usually precedes the lock release, as the following example shows.

P*x*

```
    ; loads and stores in the critical region
    MOV R0, #0
    DMB                     ; ensure all previous accesses are observed before the lock is cleared
    STR R0, [R1]            ; clear the lock
```

Use of Wait For Event (WFE) and Send Event (SEV) with locks

The ARMv8 architecture includes Wait For Event and Send Event instructions, that can be executed to reduce the required number of iterations of a lock-acquire loop, or *spinlock*, to reduce power. The basic mechanism involves an observer that is in a spinlock executing a `WFE` instruction that suspends execution on that observer until an asynchronous exception or an explicit event, sent by some other observer using the `SEV` instruction, is seen by the suspended observer. An observer that holds the lock executes an `SEV` instruction to send an event after it has released the lock.

The Event signal is a non-memory communication, and therefore the memory update that releases the lock must be observable by all observers before the `SEV` instruction is executed and the event is sent. This requires the use of `DSB` instruction, rather than `DMB`.

Therefore, the following is an example of lock acquire code using `WFE`:

P*x*

```
   Loop
    LDREX R5, [R1]          ; read lock
    CMP R5, #0              ; check if 0
    WFENE                   ; sleep if the lock is held
    STREXEQ R5, R0, [R1]    ; attempt to store new value
    CMPEQ R5, #0            ; test if store succeeded
    BNE Loop                ; retry if not
    DMB                     ; ensures that all subsequent accesses are observed after the
                            ; gaining of the lock is observed
    ; loads and stores in the critical region can now be performed
```

And the following is an example of lock release code using `SEV`:

P*x*

```
    ; loads and stores in the critical region
    MOV R0, #0
    DMB                     ; ensure all previous accesses are observed before the lock is cleared
    STR R0, [R1]            ; clear the lock
    DSB                     ; ensure completion of the store that cleared the lock before
                            ; sending the event
    SEV
```

F.6.3 Using a mailbox to send an interrupt

In some message passing systems, it is common for one observer to update memory and then notify a second observer of the update by sending an interrupt, using a mailbox.

Although a memory access might be made to initiate the sending of the mailbox interrupt, a `DSB` instruction is required to ensure the completion of previous memory accesses.

Therefore, the following sequence is required to ensure that P2 observes the updated value:

P1

```
STR R5, [R1]            ; message stored to shared memory location
DSB [ST]
STR R1, [R4]            ; R4 contains the address of a mailbox
```

P2

```
; interrupt service routine
LDR R5, [R1]
```

Note

The DSB executed by P1 ensures global observation of the store to [R1].The interrupt timing ensures that the code executed by P2 is executed after the global observation of the update to [R1], and therefore must see this update. In some implementations, this might be implemented by requiring that interrupts flush non-coherent buffers that hold speculatively loaded data.

F.6.4 Cache and TLB maintenance instructions and barriers

The following sections describe the use of barriers with cache and TLB maintenance instructions:

- *Data cache maintenance instructions*
- *Instruction cache maintenance instructions* on page AppxF-4945
- *TLB maintenance instructions and barriers* on page AppxF-4947.

Data cache maintenance instructions

The following sections describe the use of barriers with data cache maintenance instructions:

- *Message passing to non-caching observers*
- *Multiprocessing message passing to non-caching observers*
- *Invalidating DMA buffers, non-functional example* on page AppxF-4944
- *Invalidating DMA buffers, functional example with single PE* on page AppxF-4944
- *Invalidating DMA buffers, functional example with multiple coherent PEs* on page AppxF-4945.

Message passing to non-caching observers

The ARMv8 architecture requires the use of DMB instructions to ensure the ordering of data cache maintenance instructions and their effects. This means the following message passing approaches can be used when communicating between caching observers and non-caching observers:

P1

```
STR R5, [R1]            ; update data (assumed to be in P1's cache)
DCCMVAC R1              ; clean cache to point of coherency
DMB                     ; ensure effects of the clean will be observed before the flag is set
STR R0, [R4]            ; send flag to external agent (Non-cacheable location)
```

E1

```
WAIT ([R4] == 1)        ; wait for the flag
DMB                     ; ensure that flag has been seen before reading data
LDR R5, [R1]            ; read the data
```

In this example, it is required that E1:R5==0x55.

Multiprocessing message passing to non-caching observers

The broadcast nature of the cache maintenance instructions in ARMv8, and in ARMv7 implementations that include the Multiprocessing Extensions, combined with properties of barriers, means that the message passing principle for non-caching observers is:

P1

```
    STR R5, [R1]            ; update data (assumed to be in P1's cache)
    DMB [ST]                ; ensure new data is observed before the flag to P2 is set
    STR R0, [R2]            ; send flag to P2
```

P2

```
    WAIT ([R2] == 1)        ; wait for flag from P1
    DMB                     ; ensure cache clean is observed after P1's flag is observed
    DCCMVAC R1              ; clean cache to point of coherency - this cleans the cache of P1
    DMB                     ; ensure effects of the clean are observed before the flag to E1 is set
    STR R0, [R4]            ; send flag to E1
```

E1

```
    WAIT ([R4] == 1)        ; wait for flag from P2
    DMB                     ; ensure that flag has been observed before reading the data
    LDR R5, [R1]            ; read the data
```

In this example, it is required that E1:R5==0x55. The clean operation executed by P2 affects the data location in the P1 cache. The cast-out from the P1 cache is guaranteed to be observed before P2 updates [R4].

Invalidating DMA buffers, non-functional example

The basic scheme for communicating with an external observer that is a process that passes data in to a Cacheable memory region must take account of the architectural requirement that regions marked as Cacheable can be allocated into a cache at any time, for example as a result of speculation. The following example shows this possibility:

P1

```
    DCIMVAC R1              ; ensure cache clean with respect to memory. A clean operation could be
                            ; used but the DMA overwrites this region so an invalidate operation
                            ; is sufficient and usually more efficient
    DMB                     ; ensures cache invalidation is observed before the next store is observed
    STR R0, [R3]            ; send flag to external agent
    WAIT ([R4]==1)          ; wait for a different flag from an external agent
    DMB                     ; observe flag from external agent before reading new data. However [R1]
                            ; could have been brought into cache earlier
    LDR R5, [R1]
```

E1

```
    WAIT ([R3] == 1)        ; wait for flag
    STR R5, [R1]            ; store new data
    DMB
    STR R0, [R4]            ; send a flag
```

If a speculative access occurs, there is no guarantee that the cache line containing [R1] is not brought back into the cache after the cache invalidation, but before [R1] is written by E1. Therefore, the result P1:R5=0 is permissible.

Invalidating DMA buffers, functional example with single PE

P1

```
    DCIMVAC R1              ; ensure cache clean with respect to memory. A clean operation could be
                            ; used but the DMA overwrites this region so an invalidate operation
                            ; is sufficient and usually more efficient
    DMB                     ; ensures cache invalidation is observed before the next store is observed
    STR R0, [R3]            ; send flag to external agent
    WAIT ([R4]==1)          ; wait for a different flag from an external agent
    DMB                     ; ensure that cache invalidate is observed after the flag
                            ; from external agent is observed
    DCIMVAC R1              ; ensure cache discards stale copies before use
    LDR R5, [R1]
```

E1

```
    WAIT ([R3] == 1)        ; wait for flag
    STR R5, [R1]            ; store new data
```

```
DMB [ST]
STR R0, [R4]            ; send a flag
```

In this example, the result P1:R5 == 0x55 is required. Including a cache invalidation after the store by E1 to [R1] is observed ensures that the line is fetched from external memory after it has been updated.

Invalidating DMA buffers, functional example with multiple coherent PEs

The broadcasting of cache maintenance instructions, and the use of DMB instructions to ensure their observability, means that the previous example extends naturally to a multiprocessor system. Typically this requires a transfer of ownership of the region that the external observer is updating.

P0

```
(Use data from [R1], potentially using [R1] as scratch space)
DMB
STR R0, [R2]            ; signal release of [R1]
WAIT ([R2] == 0)        ; wait for new value from DMA
DMB
LDR R5, [R1]
```

P1

```
WAIT ([R2] == 1)        ; wait for release of [R1] by P0
DCIMVAC R1              ; ensure caches are clean with respect to memory, invalidate is sufficient
DMB
STR R0, [R3]            ; request new data for [R1]
WAIT ([R4] == 1)        ; wait for new data
DMB
DCIMVAC R1              ; ensure caches discard stale copies before use
DMB
MOV R0, #0
STR R0, [R2]            ; signal availability of new [R1]
```

E1

```
WAIT ([R3] == 1)        ; wait for new data request
STR R5, [R1]            ; send new [R1]
DMB [ST]
STR R0, [R4]            ; indicate new data available to P1
```

In this example, the result P0:R5 == 0x55 is required. The DMB issued by P1 after the first data cache invalidation ensures that effect of the cache invalidation on P0 is seen by E1 before the store by E1 to [R1]. The DMB issued by P1 after the second data cache invalidation ensures that its effects are seen before the store of 0 to the semaphore location in [R2].

Instruction cache maintenance instructions

The following sections describe the use of barriers with instruction cache maintenance instructions:

- *Ensuring the visibility of updates to instructions for a uniprocessor*
- *Ensuring the visibility of updates to instructions for a multiprocessor* on page AppxF-4946.

Ensuring the visibility of updates to instructions for a uniprocessor

On a single PE, the agent that causes instruction fetches, or instruction cache linefills, is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the instruction cache can rely only on seeing updates to memory that are complete. This must be ensured by the use of a DSB instruction.

Also, instruction cache maintenance instructions are only guaranteed to complete after the execution of a DSB, and an ISB is required to discard any instructions that might have been prefetched before the instruction cache invalidation completed. Therefore, on a uniprocessor, to ensure the visibility of an update to code and to branch to it, the following sequence is required:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
```

```
DCCMVAU R1              ; clean to PoU makes visible to instruction cache
DSB
ICIMVAU R1              ; ensure instruction cache and branch predictor discards stale data
BPIMVA R1
DSB                     ; ensure completion of the invalidation
ISB                     ; ensure instruction fetch path observes new instruction cache state
BX R1
```

Ensuring the visibility of updates to instructions for a multiprocessor

ARMv8, and an ARMv7 implementation that includes the Multiprocessing Extensions, requires a PE that executes an instruction cache maintenance instruction to execute a `DSB` instruction to ensure completion of the maintenance operation. This ensures that the cache maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

An `ISB` is not broadcast, and so does not affect other PEs. This means that any other PE must perform its own `ISB` synchronization after it knows that the update is visible, if it is necessary to ensure its synchronization with the update. The following example shows how this might be done:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes visible to instruction cache
DSB                     ; ensure completion of the clean on all processors
ICIMVAU R1              ; ensure instruction cache/branch predictor discards stale data
BPIMVA R1
DSB                     ; ensure completion of the ICache and branch predictor
                        ; invalidation on all processors
STR R0, [R2]            ; set flag to signal completion
ISB                     ; synchronize context on this processor
BX R1                   ; branch to new code
```

P2-P*x*

```
WAIT ([R2] == 1)        ; wait for flag signaling completion
ISB                     ; synchronize context on this processor
BX R1                   ; branch to new code
```

Nonfunctional approach

The following sequence does not have the same effect, because a `DSB` is not required to complete the instruction cache maintenance instructions that other PEs issue:

P1

```
STR R11, [R1]           ; R11 contains a new instruction to store in program memory
DCCMVAU R1              ; clean to PoU makes visible to instruction cache
DSB                     ; ensure completion of the clean on all processors
ICIMVAU R1              ; ensure instruction cache/branch predictor discards stale data
BPIMVA R1
DMB                     ; ensure ordering of the store after the invalidation
                        ; DOES NOT guarantee completion of instruction cache/branch
                        ; predictor on other processors
STR R0, [R2]            ; set flag to signal completion
DSB                     ; ensure completion of the invalidation on all processors
ISB                     ; synchronize context on this processor
BX R1                   ; branch to new code
```

P2-P*x*

```
WAIT ([R2] == 1)        ; wait for flag signaling completion
DSB                     ; this DSB does not guarantee completion of P1's ICIMVAU/BPIMVA
ISB
BX R1
```

In this example, P2…P*x* might not see the updated region of code at R1.

TLB maintenance instructions and barriers

The following sections describe the use of barriers with TLB maintenance instructions:

- *Ensuring the visibility of updates to translation tables for a uniprocessor*
- *Ensuring the visibility of updates to translation tables for a multiprocessor*
- *Paging memory in and out* on page AppxF-4948.

Ensuring the visibility of updates to translation tables for a uniprocessor

On a single PE, the agent that causes translation table walks is a separate memory system observer from the agent that causes data accesses. Therefore, any operations to invalidate the TLB can only rely on seeing updates to memory that are complete. This must be ensured by the use of a `DSB` instruction.

In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, translation table walks must look in the data or unified caches at L1, so such systems do not require data cache cleaning.

After the translation tables update, any old copies of entries that might be held in the TLBs must be invalidated. This operation is only guaranteed to affect all instructions, including instruction fetches and data accesses, after the execution of a `DSB` and an `ISB`. Therefore, the code for updating a translation table entry is:

P1

```
STR R11, [R1]           ; update the translation table entry
DSB                     ; ensure visibility of the update to translation table walks
TLBIMVA R10
BPIALL
DSB                     ; ensure completion of the BP and TLB invalidation
ISB                     ; synchronize context on this processor
;
; new translation table entry can be relied upon at this point and all accesses
; generated by this observer using the old mapping have been completed
```

Importantly, by the end of this sequence, all accesses that used the old translation table mappings have been observed by all observers.

An example of this is where a translation table entry is marked as invalid. Such a system must provide a mechanism to ensure that any access to a region of memory being marked as invalid has completed before any action is taken as a result of the region being marked as invalid.

Ensuring the visibility of updates to translation tables for a multiprocessor

The same code sequence can be used in a multiprocessing system. In the ARMv8 architecture, and in an ARMv7 implementation that includes the Multiprocessing Extensions, a PE that executes a TLB maintenance instruction must execute a `DSB` instruction to ensure completion of the maintenance operation. This ensures that the TLB maintenance instruction is complete on all PEs in the Inner Shareable shareability domain.

The completion of a `DSB` that completes a TLB maintenance instruction ensures that all accesses that used the old mapping have completed.

P1

```
STR R11, [R1]           ; update the translation table entry
DSB                     ; ensure visibility of the update to translation table walks
TLBIMVAIS R10
BPIALLIS
DSB                     ; ensure completion of the BP and TLB invalidation
ISB                     ; Note ISB is not broadcast and must be executed locally on other processors
;
; new translation table entry can be relied upon at this point and all accesses generated by any
; observers affected by the broadcast TLBIMVAIS operation using the old mapping have completed
```

The completion of the TLB maintenance instruction is guaranteed only by the execution of a `DSB` by the observer that performed the TLB maintenance instruction. The execution of a `DSB` by a different observer does not have this effect, even if the `DSB` is known to be executed after the TLB maintenance instruction is observed by that different observer.

Paging memory in and out

In a multiprocessor system there is a requirement to ensure the visibility of translation table updates when paging regions of memory into RAM from a backing store. This might, or might not, also involve paging existing locations in memory from RAM to a backing store. In such situations, the operating system selects one or more pages of memory that might be in use but are suitable to discard, with or without copying to a backing store, depending on whether or not the region of memory is writable. Disabling the translation table mappings for a page, and ensuring the visibility of that update to the translation tables, prevents agents accessing the page.

For this reason, it is important that the DSB that is performed after the TLB invalidation ensures that no other updates to memory using those mappings are possible.

An example sequence for the paging out of an updated region of memory, and the subsequent paging in of memory, is as follows:

P1

```
STR R11, [R1]            ; update the translation table for the region being paged out
DSB                      ; ensure visibility of the update to translation table walks
TLBIMVAIS R10            ; invalidate the old entry
DSB                      ; ensure completion of the invalidation on all processors
ISB                      ; ensure visibility of the invalidation
BL SaveMemoryPageToBackingStore
BL LoadMemoryFromBackingStore
DSB                      ; ensure completion of the memory transfer (this could be part of
                         ; LoadMemoryFromBackingStore
ICIALLUIS                ; also invalidates the branch predictor
STR R9, [R1]             ; create a new translation table entry with a new mapping
DSB                      ; ensure completion of instruction cache and branch predictor invalidation
                         ; and ensure visibility of the new translation table mapping
ISB                      ; ensure synchronization of this instruction stream
```

This example assumes the memory copies are performed by an observer that is coherent with the caches of PE P1. This observer might be P1 itself, using a specific paging mapping. For clarity, the example omits the functional descriptions of SaveMemoryPageToBackingStore and LoadMemoryFromBackingStore. LoadMemoryFromBackingStore is required to ensure that the memory updates that it makes are visible to instruction fetches.

In this example, the use of ICIALLUIS to invalidate the entire instruction cache is a simplification, that might not be optimal for performance. An alternative approach involves invalidating all of the lines in the caches using ICIMVAU operations. This invalidation must be done when the mapping used for the ICIMVAU operations is valid but not executable.

Appendix G
ARMv8 Pseudocode Library

This appendix contains the ARMv8 pseudocode library. It contains the following sections:

Note

Status of this appendix in the beta release document

ARM is currently working to improve the organization and presentation of the pseudocode in this document, including providing improved linking within the pseudocode. Currently, this chapter contains the complete pseudocode library for ARMv8, split between:

- Functions, or versions of functions, that are specific to execution in AArch64 state.
- Functions, or versions of functions, that are specific to execution in AArch32state.
- Functions that apply to execution in either Execution state.

Many pseudocode functions are included elsewhere in the document, to accompany the description of the associated functionality. Currently, those functions are repeated in this appendix.

G.1 Library pseudocode for AArch64

This section holds the pseudocode for execution in AArch64 state. Functions listed in this section are identified as `AArch64.FunctionName`. Some of these functions have an equivalent AArch32 function, `AArch32.FunctionName`. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `aarch64/debug/breakpoint`. The sections for the top level functional groups are:

- *aarch64/debug*.
- *aarch64/exceptions* on page AppxG-4956.
- *aarch64/functions* on page AppxG-4969.
- *aarch64/instrs* on page AppxG-4981.
- *aarch64/translation* on page AppxG-4989.

G.1.1 aarch64/debug

This section shows the AArch64 pseudocode describing debug operation, in the following sections:

- *aarch64/debug/breakpoint*.
- *aarch64/debug/enables* on page AppxG-4952.
- *aarch64/debug/pmu* on page AppxG-4953.
- *aarch64/debug/takeexceptiondbg* on page AppxG-4954.
- *aarch64/debug/watchpoint* on page AppxG-4955.

G.2 Library pseudocode for AArch32

This section holds the pseudocode for execution in AArch32 state. Functions listed in this section are identified as `AArch32.FunctionName`. Some of these functions have an equivalent AArch64 function, `AArch64.FunctionName`. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `aarch32/debug/breakpoint`. The sections for the top level functional groups are:

- *aarch32/debug*.
- *aarch32/exceptions* on page AppxG-5011.
- *aarch32/functions* on page AppxG-5027.
- *aarch32/translation* on page AppxG-5048.

G.2.1 aarch32/debug

This section shows the AArch32 pseudocode that describes debug operation, in the following sections:

- *aarch32/debug/VCRMatch*.
- *aarch32/debug/breakpoint* on page AppxG-5005.
- *aarch32/debug/enables* on page AppxG-5007.
- *aarch32/debug/pmu* on page AppxG-5008.
- *aarch32/debug/takeexceptiondbg* on page AppxG-5009.
- *aarch32/debug/watchpoint* on page AppxG-5010.

G.3 Common library pseudocode

This section holds the pseudocode that is common to execution in AArch64 state and in AArch32 state. Functions listed in this section are identified only by a `FunctionName`, without an `AArch64.` or `AArch32.` prefix. This section is organized by functional groups, with the functional groups being indicated by hierarchical path names, for example `shared/debug/DebugTarget`. The sections for the top level functional groups are:

- *shared/debug*.
- *shared/exceptions* on page AppxG-5081.
- *shared/functions* on page AppxG-5085.
- *shared/translation* on page AppxG-5131.

G.3.1 shared/debug

This section shows the pseudocode that is common to AArch64 and AArch32 operation and describes debug operation, in the following sections:

- *shared/debug/ClearStickyErrors*.
- *shared/debug/DebugTarget*.
- *shared/debug/DoubleLockStatus* on page AppxG-5068.
- *shared/debug/FindWatchpoint* on page AppxG-5068.
- *shared/debug/authentication* on page AppxG-5068.
- *shared/debug/cti* on page AppxG-5070.
- *shared/debug/dccanditr* on page AppxG-5070.
- *shared/debug/halting* on page AppxG-5073.
- *shared/debug/haltingevents* on page AppxG-5077.
- *shared/debug/interrupts* on page AppxG-5079.
- *shared/debug/samplebasedprofiling* on page AppxG-5079.
- *shared/debug/softwarestep* on page AppxG-5080.

shared/debug/ClearStickyErrors

```
// ClearStickyErrors()
// ===================

ClearStickyErrors()

G.3.2 shared/exceptions

This section shows the pseudocode that is common to AArch64 and AArch32 operation and describes exception handling, in the following sections:

- *shared/exceptions/exceptions*.
- *shared/exceptions/traps* on page AppxG-5083.

shared/exceptions/exceptions

```
// ~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
// Shared Exception Model
// ~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~

// Typical flow through a translation for EL0 using AArch32 under EL1 using AArch64
// is as follows:
//
//
```

```
//   WFE instruction pseudocode (AArch32)
//   |
//   `-> AArch32.WFxTrap(EL2)
//       |
//       `-> AArch32.TakeHypTrapException()
//           |
//           `-> AArch32.EnterHypMode()
//               |
//               |-> AArch32.ReportHypEntry()
//               |
//               `-> AArch32.BranchTo(HVBAR + offset)
//
// However, as necessary the exception handlers are marshalled to the correct
// exception regime for the exception type:
//
//   WFE instruction pseudocode (AArch32)
//   |
//   `-> AArch32.WFxTrap(EL2)
//       |
//       `-> AArch64.WFxTrap(EL2)
//           |
//           `-> AArch64.TakeException(EL2)
//               |
//               |-> MaybeZeroRegisterUppers()
//               |
//               |-> AArch64.ReportException()
//               |
//               `-> AArch64.BranchTo(VBAR[EL2] + offset)
//
// Syndrome handling is different in the two worlds, and this is deliberate (though
// not necessarily fortunate). AArch64 passes the syndrome down to the exception
// entry which writes ESR and FAR; AArch32 does this for Hyp entries but otherwise
// writes these before calling the entry point. This is necessary in the AArch32
// case because of the variance due to descriptor format, eventual destination of
// the exception, etc.

// Exception
// =========
// Classes of exception

// ===============

// Signals the memory system that memory accesses of type HINT to or from the specified ADDRESS are
// likely in the near future. The memory system may take some action to speed up the memory accesses
// when they do occur, such as pre-loading the the specified address into one or more caches as
// indicated by the innermost cache level TARGET (0=L1, 1=L2, etc) and non-temporal hint STREAM.

// Any or all prefetch hints may be treated as a NOP. A prefetch hint must not cause a synchronous
// abort due to alignment or translation faults and the like. Its only effect on software visible
// state should be on caches and TLBs associated with ADDRESS, which must be accessable by reads,
// writes or execution as defined in the translation regime of the current exception level.
// It is guaranteed not to access Device memory.

// A Prefetch_EXEC hint must not result in any access that could not be performed by a speculative
// instruction fetch, therefore if all associated MMUs are disabled, then it cannot access any
// memory location that cannot be accessed by instruction fetches.

shared/translation/translation

```
// ~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
// Shared Translation System
// ~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
// Shared exception model and translation table walking code.
//
// Typical flow through a translation for EL0 using AArch32 under EL1 using AArch64
// is as follows:
//
// AArch32.TranslateAddress(bits(32) vaddress)
// |
// `->  AArch64.TranslateAddress(ZeroExtend(vaddress, 64))
//      |
//      |-> AArch64.FirstStageTranslate(vaddress)
//      |   |
//      |   `-> AArch64.TranslationTableWalkLD()
//      |       |
//      |       `-> AArch64.SecondStageWalk()
//      |           |
//      |           `-> AArch64.SecondStageTranslate()
//      |               |
```

```
//      |               `-> AArch64.TranslationTableWalkLD()
//      |
//      `-> AArch64.SecondStageTranslate(vaddress)
//          |
//          `-> AArch64.TranslationTableWalkLD()
//
// In ARMv7 SecondStageTranslate was used only for the recursive call from
// TranslationTableWalk{SD|LD}. For ARMv8 it is extended to deal with all
// second stage translations, so as to support EL0 and EL1 using AArch32
// under EL2 using AArch64:
//
// AArch32.TranslateAddress(bits(32) vaddress)
// |
// |-> AArch32.FirstStageTranslate(vaddress)
// |   |
// |   `-> AArch32.TranslationTableWalkLD()
// |       |
// |       `-> AArch32.SecondStageWalk()
// |           |
// |           `-> AArch32.SecondStageTranslate()
// |               |
// |                `-> AArch64.SecondStageTranslate()
// |                    |
// |                    `-> AArch64.TranslationTableWalkLD()
// |
// `-> AArch32.SecondStageTranslate(vaddress)
//     |
//     `-> AArch64.SecondStageTranslate(vaddress)
//         |
//         `-> AArch64.TranslationTableWalkLD()
//
// Should translation fail then it calls DataAbort, but importantly it stays in
// the right translation regime so calls the correct exception handler.

// PAMax()
// =======
// Returns the IMPLEMENTATION DEFINED upper limit on the physical address
// size for this processor, as log2().

Appendix H
ARM Pseudocode Definition

This appendix provides a definition of the pseudocode used in this manual, and defines some *helper* procedures and functions used by pseudocode. It contains the following sections:

Note

Status of this appendix in this beta release document

ARM is currently working to improve the organization and presentation of the pseudocode in this document. Currently, this chapter contains the ARMv7 definition, and needs updating to incorporate changes and extensions to the pseudocode made for ARMv8. These updates will appear in the next issue of this manual.

The pseudocode in this manual describes ARMv8 execution in both AArch32 state and AArch64 state. It does not describe differences in earlier versions of the architecture.

H.1 About the ARM pseudocode

See the *Note* on the front page of this appendix, *Status of this appendix in this beta release document* on page AppxH-5137.

The ARM pseudocode provides precise descriptions of some areas of the ARM architecture. This includes description of the decoding and operation of all valid instructions. *Pseudocode for instruction descriptions* on page AppxH-5139 gives general information about this instruction pseudocode, including its limitations.

The following sections describe the ARM pseudocode in detail:

- *Data types* on page AppxH-5141.
- *Expressions* on page AppxH-5145.
- *Operators and built-in functions* on page AppxH-5147.
- *Statements and program structure* on page AppxH-5152.

H.1.1 General limitations of ARM pseudocode

The pseudocode statements `IMPLEMENTATION_DEFINED`, `SEE`, `SUBARCHITECTURE_DEFINED`, `UNDEFINED`, and `UNPREDICTABLE` indicate behavior that differs from that indicated by the pseudocode being executed. If one of them is encountered:

- Earlier behavior indicated by the pseudocode is only specified as occurring to the extent required to determine that the statement is executed.
- No subsequent behavior indicated by the pseudocode occurs. This means that these statements terminate pseudocode execution.

For more information, see *Simple statements* on page AppxH-5152.

H.2 Pseudocode for instruction descriptions

Each instruction description includes pseudocode that provides a precise description of what the instruction does, subject to the limitations described in *General limitations of ARM pseudocode* on page AppxH-5138 and *Limitations of the instruction pseudocode* on page AppxH-5140.

In the instruction pseudocode, instruction fields are referred to by the names shown in the encoding diagram for the instruction. *Instruction encoding diagrams and instruction pseudocode for T32 and A32 instructions* gives more information about the pseudocode provided for each instruction.

H.2.1 Instruction encoding diagrams and instruction pseudocode for T32 and A32 instructions

Note

Currently this appendix only describes A32/T32 instruction pseudocode.

Instruction descriptions in this manual contain:

- An Encoding section, containing one or more encoding diagrams, each followed by some encoding-specific pseudocode that translates the fields of the encoding into inputs for the common pseudocode of the instruction, and picks out any encoding-specific special cases.
- An Operation section, containing common pseudocode that applies to all of the encodings being described. The Operation section pseudocode contains a call to the `EncodingSpecificOperations()` function, either at its start or only after a condition code check performed by `if ConditionPassed() then`.

An encoding diagram specifies each bit of the instruction as one of the following:

- An obligatory 0 or 1, represented in the diagram as 0 or 1. If this bit does not have this value, the encoding corresponds to a different instruction.
- A *should be* 0 or 1, represented in the diagram as (0) or (1). If this bit does not have this value, the instruction is UNPREDICTABLE. For more information, see *SBZ or SBO fields in instructions* on page AppxA-4788.
- A named single bit or a bit in a named multi-bit field. The `cond` field in bits[31:28] of many A32/T32 instructions has some special rules associated with it.

An encoding diagram matches an instruction if all obligatory bits are identical in the encoding diagram and the instruction, and one of the following is true:

- The encoding diagram is not for an A32/T32 instruction.
- The encoding diagram is for an A32/T32 instruction that does not have a `cond` field in bits[31:28].
- The encoding diagram is for an A32/T32 instruction that has a `cond` field in bits[31:28], and bits[31:28] of the instruction are not `0b1111`.

In the context of the instruction pseudocode, the execution model for an instruction is:

1. Find all encoding diagrams that match the instruction. It is possible that no encoding diagram matches. In that case, abandon this execution model and consult the relevant instruction set chapter instead to find out how the instruction is to be treated. The bit pattern of such an instruction is usually reserved and UNDEFINED, though there are some other possibilities. For example, unallocated hint instructions are documented as being reserved and executed as NOPs.
2. If the operation pseudocode for the matching encoding diagrams starts with a condition code check, perform that check. If the condition code check fails, abandon this execution model and treat the instruction as a NOP. If there are multiple matching encoding diagrams, either all or none of their corresponding pieces of common pseudocode start with a condition code check.
3. Perform the encoding-specific pseudocode for each of the matching encoding diagrams independently and in parallel. Each such piece of encoding-specific pseudocode starts with a bitstring variable for each named bit or multi-bit field in its corresponding encoding diagram, named the same as the bit or multi-bit field and initialized with the values of the corresponding bit or bits from the bit pattern of the instruction.

In a few cases, the encoding diagram contains more than one bit or field with same name. In these cases, the values of the different instances of those bits or fields must be identical. The encoding-specific pseudocode contains a special case using the `Consistent()` function to specify what happens if they are not identical. `Consistent()` returns `TRUE` if all instruction bits or fields with the same name as its argument have the same value, and `FALSE` otherwise.

If there are multiple matching encoding diagrams, all but one of the corresponding pieces of pseudocode must contain a special case that indicates that it does not apply. Discard the results of all such pieces of pseudocode and their corresponding encoding diagrams.

There is now one remaining piece of pseudocode and its corresponding encoding diagram left to consider. This pseudocode might also contain a special case, most commonly one indicating that it is UNPREDICTABLE. If so, abandon this execution model and treat the instruction according to the special case.

4. Check the *should be* bits of the encoding diagram against the corresponding bits of the bit pattern of the instruction. If any of them do not match, abandon this execution model and treat the instruction as UNPREDICTABLE.

5. Perform the rest of the operation pseudocode for the instruction description that contains the encoding diagram. That pseudocode starts with all variables set to the values they were left with by the encoding-specific pseudocode.

The `ConditionPassed()` call in the common pseudocode, if present, performs step 2, and the `EncodingSpecificOperations()` call performs steps 3 and 4.

H.2.2 Limitations of the instruction pseudocode

The pseudocode descriptions of instruction functionality have a number of limitations. These are mainly due to the fact that, for clarity and brevity, the pseudocode is a sequential and mostly deterministic language.

These limitations include:

- Pseudocode does not describe the ordering requirements when an instruction generates multiple memory accesses. For a description of the ordering requirements on memory accesses see *Ordering requirements* on page E2-2267.
- Pseudocode does not describe the exact rules when an UNDEFINED instruction fails its condition code check. In such cases, the `UNDEFINED` pseudocode statement lies inside the `if ConditionPassed() then …` structure, either directly or in the `EncodingSpecificOperations()` function call, and so the pseudocode indicates that the instruction executes as a NOP. *Conditional execution of undefined instructions* on page G1-3430 describes the exact rules.
- Pseudocode does not describe the exact ordering requirements when a single floating-point instruction generates more than one floating-point exception and one or more of those floating-point exceptions is trapped. *Combinations of exceptions* on page E1-2222 describes the exact rules.

  Note

  There is no limitation in the case where all the floating-point exceptions are untrapped, because the pseudocode specifies the same behavior as the cross-referenced section.

- An exception can be taken during execution of the pseudocode for an instruction, either explicitly as a result of the execution of a pseudocode function such as `Abort()`, or implicitly, for example if an interrupt is taken during execution of an `LDM` instruction. If this happens, the pseudocode does not describe the extent to which the normal behavior of the instruction occurs. To determine that, see the descriptions of the exceptions in *Handling exceptions that are taken to an Exception level using AArch32* on page G1-3396.

H.3 Data types

This section describes:

- *General data type rules*.
- *Bitstrings*.
- *Integers* on page AppxH-5142.
- *Reals* on page AppxH-5142.
- *Booleans* on page AppxH-5142.
- *Enumerations* on page AppxH-5142.
- *Lists* on page AppxH-5143.
- *Arrays* on page AppxH-5144.

H.3.1 General data type rules

ARM architecture pseudocode is a strongly-typed language. Every constant and variable is of one of the following types:

- Bitstring.
- Integer.
- Boolean.
- Real.
- Enumeration.
- List.
- Array.

The type of a constant is determined by its syntax. The type of a variable is normally determined by assignment to the variable, with the variable being implicitly declared to be of the same type as whatever is assigned to it. For example, the assignments `x = 1`, `y = '1'`, and `z = TRUE` implicitly declare the variables `x`, `y` and `z` to have types integer, bitstring of length 1, and Boolean, respectively.

Variables can also have their types declared explicitly by preceding the variable name with the name of the type. This is most often done in function definitions for the arguments and the result of the function.

The remaining subsections describe each data type in more detail.

H.3.2 Bitstrings

A bitstring is a finite-length string of 0s and 1s. Each length of bitstring is a different type. The minimum permitted length of a bitstring is 1.

The type name for bitstrings of length `N` is `bits(N)`. A synonym of `bits(1)` is `bit`.

Bitstring constants are written as a single quotation mark, followed by the string of 0s and 1s, followed by another single quotation mark. For example, the two constants of type `bit` are `'0'` and `'1'`. Spaces can be included in bitstrings for clarity.

A special form of bitstring constant with `'x'` bits is permitted in bitstring comparisons, see *Equality and non-equality testing* on page AppxH-5147.

Every bitstring value has a left-to-right order, with the bits being numbered in standard *little-endian* order. That is, the leftmost bit of a bitstring of length *N* is bit (*N*–1) and its right-most bit is bit 0. This order is used as the most-significant-to-least-significant bit order in conversions to and from integers. For bitstring constants and bitstrings derived from encoding diagrams, this order matches the way they are printed.

Bitstrings are the only concrete data type in pseudocode, in the sense that they correspond directly to the contents of registers, memory locations, instructions, and so on. All of the remaining data types are abstract.

H.3.3 Integers

Pseudocode integers are unbounded in size and can be either positive or negative. That is, they are mathematical integers rather than what computer languages and architectures commonly call integers. Computer integers are represented in pseudocode as bitstrings of the appropriate length, associated with suitable functions to interpret those bitstrings as integers.

The type name for integers is `integer`.

Integer constants are normally written in decimal, such as `0`, `15`, `-1234`. They can also be written in C-style hexadecimal, such as `0x55` or `0x80000000`. Hexadecimal integer constants are treated as positive unless they have a preceding minus sign. For example, `0x80000000` is the integer $+2^{31}$. If -2^{31} needs to be written in hexadecimal, it must be written as `-0x80000000`.

H.3.4 Reals

Pseudocode reals are unbounded in size and precision. That is, they are mathematical real numbers, not computer floating-point numbers. Computer floating-point numbers are represented in pseudocode as bitstrings of the appropriate length, associated with suitable functions to interpret those bitstrings as reals.

The type name for reals is `real`.

Real constants are written in decimal with a decimal point. This means `0` is an integer constant, but `0.0` is a real constant.

H.3.5 Booleans

A Boolean is a logical `TRUE` or `FALSE` value.

The type name for Booleans is `boolean`. This is not the same type as `bit`, which is a length-1 bitstring. Boolean constants are `TRUE` and `FALSE`.

H.3.6 Enumerations

An enumeration is a defined set of symbolic constants, such as:

```
enumeration InstrSet {InstrSet_A32, InstrSet_T32};
```

An enumeration always contains at least one symbolic constant, and a symbolic constant must not be shared between enumerations.

Enumerations must be declared explicitly, although a variable of an enumeration type can be declared implicitly by assigning one of the symbolic constants to it. By convention, each of the symbolic constants starts with the name of the enumeration followed by an underscore. The name of the enumeration is its *type name*, or *type*, and the symbolic constants are its possible *constants*.

Note

A `boolean` is a pre-declared enumeration that does not follow the normal naming convention and that has a special role in some pseudocode constructs, such as `if` statements. This means the enumeration of a `boolean` is:

```
enumeration boolean {FALSE, TRUE};
```

H.3.7 Lists

A list is an ordered set of other data items, separated by commas and enclosed in parentheses, for example:

```
(bits(32) shifter_result, bit shifter_carry_out)
```

A list always contains at least one data item.

Lists are often used as the return type for a function that returns multiple results. For example, the list at the start of this section is the return type of the function `Shift_C()` that performs a standard A32/T32 shift or rotation, when its first operand is of type `bits(32)`.

Some specific pseudocode operators use lists surrounded by other forms of bracketing than the `(…)` parentheses. These are:

- Bitstring extraction operators, that use lists of bit numbers or ranges of bit numbers surrounded by angle brackets `<…>`.
- Array indexing, that uses lists of array indexes surrounded by square brackets `[…]`.
- Array-like function argument passing, that uses lists of function arguments surrounded by square brackets `[…]`.

Each combination of data types in a list is a separate type, with type name given by listing the data types. This means that the example list at the start of this section is of type `(bits(32), bit)`. The general principle that types can be declared by assignment extends to the types of the individual list items in a list. For example:

```
(shift_t, shift_n) = ('00', 0);
```

implicitly declares:

- `shift_t` to be of type `bits(2)`.
- `shift_n` to be of type `integer`.
- `(shift_t, shift_n)` to be of type `(bits(2), integer)`.

A list type can also be explicitly named, with explicitly named elements in the list. For example:

```
type ShiftSpec is (bits(2) shift, integer amount);
```

After this definition and the declaration:

```
ShiftSpec abc;
```

The elements of the resulting list can then be referred to as `abc.shift` and `abc.amount`. This qualified naming of list elements is only permitted for variables that have been explicitly declared, not for those that have been declared by assignment only.

Explicitly naming a type does not alter what type it is. For example, after the above definition of `ShiftSpec`, `ShiftSpec` and `(bits(2), integer)` are two different names for the same type, not the names of two different types. To avoid ambiguity in references to list elements, it is an error to declare a list variable multiple times using different names of its type or to qualify it with list element names not associated with the name by which it was declared.

An item in a list that is being assigned to can be written as "`-`" to indicate that the corresponding item of the assigned list value is discarded. For example:

```
(shifted, -) = LSL_C(operand, amount);
```

List constants are written as a list of constants of the appropriate types, for example the `('00', 0)` in the earlier example.

H.3.8 Arrays

Pseudocode arrays are indexed by either enumerations or integer ranges. An integer range is represented by the lower inclusive end of the range, then `..`, then the upper inclusive end of the range.

For example:

```
array bits(64) _R[0..30];
```

Arrays are always explicitly declared, and there is no notation for a constant array. Arrays always contain at least one element, because:

- Enumerations always contain at least one symbolic constant.
- Integer ranges always contain at least one integer.

Arrays do not usually appear directly in pseudocode. The items that syntactically look like arrays in pseudocode are usually array-like functions such as `R[i]`, `MemU[address, size]` or `Elem[vector, i, size]`. These functions package up and abstract additional operations normally performed on accesses to the underlying arrays, such as register banking, memory protection, endian-dependent byte ordering, exclusive-access housekeeping and Advanced SIMD element processing.

H.4 Expressions

This section describes:

- *General expression syntax*.
- *Operators and functions - polymorphism and prototypes* on page AppxH-5146.
- *Precedence rules* on page AppxH-5146.

H.4.1 General expression syntax

An expression is one of the following:

- A constant.
- A variable, optionally preceded by a data type name to declare its type.
- The word `UNKNOWN` preceded by a data type name to declare its type.
- The result of applying a language-defined operator to other expressions.
- The result of applying a function to other expressions.

Variable names normally consist of alphanumeric and underscore characters, starting with an alphabetic or underscore character.

Each register described in the text is to be regarded as declaring a correspondingly named bitstring variable, and that variable has the stated behavior of the register. For example, if a bit of a register is defined as RAZ/WI, then the corresponding bit of its variable reads as 0 and ignore writes.

An expression like `bits(32) UNKNOWN` indicates that the result of the expression is a value of the given type, but the architecture does not specify what value it is and software must not rely on such values. The value produced must not:

- Return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and do not return UNKNOWN values,
- Be promoted as providing any useful information to software.

Note

UNKNOWN values are similar to the definition of UNPREDICTABLE, but do not indicate that the entire architectural state becomes unspecified.

Only the following expressions are assignable. This means that these are the only expressions that can be placed on the left-hand side of an assignment.

- Variables.
- The results of applying some operators to other expressions.

  The description of each language-defined operator that can generate an assignable expression specifies the circumstances under which it does so. For example, those circumstances might require that one or more of the expressions the operator operates on is an assignable expression.
- The results of applying array-like functions to other expressions. The description of an array-like function specifies the circumstances under which it can generate an assignable expression.

Every expression has a data type.

- For a constant, this data type is determined by the syntax of the constant.
- For a variable, there are the following possible sources for the data type
  - An optional preceding data type name.
  - A data type the variable was given earlier in the pseudocode by recursive application of this rule.
  - A data type the variable is being given by assignment, either by direct assignment to the variable, or by assignment to a list of which the variable is a member.

It is a pseudocode error if none of these data type sources exists for a variable, or if more than one of them exists and they do not agree about the type.

- For a language-defined operator, the definition of the operator determines the data type.
- For a function, the definition of the function determines the data type.

H.4.2 Operators and functions - polymorphism and prototypes

Operators and functions in pseudocode can be polymorphic, producing different functionality when applied to different data types. Each resulting form of an operator or function has a different prototype definition. For example, the operator + has forms that act on various combinations of integers, reals and bitstrings.

One particularly common form of polymorphism is between bitstrings of different lengths. This is represented by using `bits(N)`, `bits(M)`, or similar, in the prototype definition.

H.4.3 Precedence rules

The precedence rules for expressions are:

1. Constants, variables and function invocations are evaluated with higher priority than any operators using their results, but see *Operations on Booleans* on page AppxH-5147.
2. Expressions on integers follow the normal operator precedence rules of *exponentiation before multiply/divide before add/subtract*, with sequences of multiply/divides or add/subtracts evaluated left-to-right.
3. Other expressions must be parenthesized to indicate operator precedence if ambiguity is possible, but need not be if all permitted precedence orders under the type rules necessarily lead to the same result. For example, if `i`, `j` and `k` are integer variables, `i > 0 && j > 0 && k > 0` is acceptable, but `i > 0 && j > 0 || k > 0` is not.

H.5 Operators and built-in functions

This section describes:

- *Operations on generic types*.
- *Operations on Booleans*.
- *Bitstring manipulation*.
- *Arithmetic* on page AppxH-5150.

H.5.1 Operations on generic types

The following operations are defined for all types.

Equality and non-equality testing

Any two values `x` and `y` of the same type can be tested for equality by the expression `x == y` and for non-equality by the expression `x != y`. In both cases, the result is of type `boolean`.

A special form of comparison is defined with a bitstring constant that includes `'x'` bits as well as `'0'` and `'1'` bits. The bits corresponding to the `'x'` bits are ignored in determining the result of the comparison. For example, if opcode is a 4-bit bitstring, `opcode == '1x0x'`, this matches the values ‘`1000`’, ‘`1100`’, ‘`1001`’ and ‘`1101`’.

Note

This special form is permitted in the implied equality comparisons in `when` parts of `case … of …` structures.

Conditional selection

If `x` and `y` are two values of the same type and `t` is a value of type `boolean`, then `if t then x else y` is an expression of the same type as `x` and `y` that produces `x` if `t` is `TRUE` and `y` if `t` is `FALSE`.

H.5.2 Operations on Booleans

If `x` is a `boolean`, then `!x` is its logical inverse.

If `x` and `y` are `booleans`, then `x && y` is the result of ANDing them together. As in the C language, if `x` is `FALSE`, the result is determined to be `FALSE` without evaluating `y`.

If `x` and `y` are `booleans`, then `x || y` is the result of ORing them together. As in the C language, if `x` is `TRUE`, the result is determined to be `TRUE` without evaluating `y`.

Note

If `x` and `y` are `booleans`, then the result of `x != y` is the same as the result of exclusive-ORing `x` and `y` together.

H.5.3 Bitstring manipulation

The following bitstring manipulation functions are defined:

Bitstring length and most significant bit

If `x` is a bitstring:

- The bitstring length function `Len(x)` returns the length of `x` as an integer.
- `TopBit(x)` is the leftmost bit of x. Using bitstring extraction, this means:

  `TopBit(x)= x<Len(x)-1>`.

Bitstring concatenation and replication

If x and y are bitstrings of lengths N and M respectively, then x:y is the bitstring of length N+M constructed by concatenating x and y in left-to-right order.

If x is a bitstring and n is an integer with n > 0:

- Replicate(x, n) is the bitstring of length n*Len(x) consisting of n copies of x concatenated together.
- Zeros(n) = Replicate('0', n), Ones(n) = Replicate('1', n).

Bitstring extraction

The bitstring extraction operator extracts a bitstring from either another bitstring or an integer. Its syntax is x<integer_list>, where x is the integer or bitstring being extracted from, and <integer_list> is a list of integers enclosed in angle brackets rather than the usual parentheses. The length of the resulting bitstring is equal to the number of integers in <integer_list>. In x<integer_list>, each of the integers in <integer_list> must be:

- >= 0.
- < Len(x) if x is a bitstring.

The definition of x<integer_list> depends on whether integer_list contains more than one integer:

- If integer_list contains more than one integer, x<i, j, k,…, n> is defined to be the concatenation:

  x<i> : x<j> : x<k> : … : x<n>.

- If integer_list consists of just one integer i, x<i> is defined to be:
  - If x is a bitstring, '0' if bit i of x is a zero and '1' if bit i of x is a one.
  - If x is an integer, let y be the unique integer in the range 0 to 2^(i+1)-1 that is congruent to x modulo 2^(i+1). Then x<i> is '0' if y < 2^i and '1' if y >= 2^i.

    Loosely, this definition treats an integer as equivalent to a sufficiently long two's complement representation of it as a bitstring.

In <integer_list>, the notation i:j with i >= j is shorthand for the integers in order from i down to j, with both end values included. For example, instr<31:28> is shorthand for instr<31, 30, 29, 28>.

The expression x<integer_list> is assignable provided x is an assignable bitstring and no integer appears more than once in <integer_list>. In particular, x<i> is assignable if x is an assignable bitstring and 0 <= i < Len(x).

Encoding diagrams for registers frequently show named bits or multi-bit fields. For example, the encoding diagram for the APSR shows its bit<31> as N. In such cases, the syntax APSR.N is used as a more readable synonym for APSR<31>.

Logical operations on bitstrings

If x is a bitstring, NOT(x) is the bitstring of the same length obtained by logically inverting every bit of x.

If x and y are bitstrings of the same length, x AND y, x OR y, and x EOR y are the bitstrings of that same length obtained by logically ANDing, ORing, and exclusive-ORing corresponding bits of x and y together.

Bitstring count

If x is a bitstring, BitCount(x) produces an integer result equal to the number of bits of x that are ones.

Testing a bitstring for being all zero or all ones

If x is a bitstring:

- `IsZero(x)` produces `TRUE` if all of the bits of x are zeros and `FALSE` if any of them are ones
- `IsZeroBit(x)` produces `'1'` if all of the bits of x are zeros and `'0'` if any of them are ones.

`IsOnes(x)` and `IsOnesBit(x)` work in the corresponding ways. This means:

```
IsZero(x)    = (BitCount(x) == 0)
IsOnes(x)    = (BitCount(x) == Len(x))
IsZeroBit(x) = if IsZero(x) then '1' else '0'
IsOnesBit(x) = if IsOnes(x) then '1' else '0'
```

Lowest and highest set bits of a bitstring

If x is a bitstring, and `N = Len(x)`:

- `LowestSetBit(x)` is the minimum bit number of any of its bits that are ones. If all of its bits are zeros, `LowestSetBit(x) = N`.
- `HighestSetBit(x)` is the maximum bit number of any of its bits that are ones. If all of its bits are zeros, `HighestSetBit(x) = -1`.
- `CountLeadingZeroBits(x)` is the number of zero bits at the left end of x, in the range 0 to N. This means:

  `CountLeadingZeroBits(x) = N - 1 - HighestSetBit(x)`.
- `CountLeadingSignBits(x)` is the number of copies of the sign bit of x at the left end of x, excluding the sign bit itself, and is in the range 0 to N-1. This means:

  `CountLeadingSignBits(x) = CountLeadingZeroBits(x<N-1:1> EOR x<N-2:0>)`.

Zero-extension and sign-extension of bitstrings

If x is a bitstring and i is an integer, then `ZeroExtend(x, i)` is x extended to a length of i bits, by adding sufficient zero bits to its left. That is, if `i == Len(x)`, then `ZeroExtend(x, i) = x`, and if `i > Len(x)`, then:

```
ZeroExtend(x, i) = Replicate('0', i-Len(x)) : x
```

If x is a bitstring and i is an integer, then `SignExtend(x, i)` is x extended to a length of i bits, by adding sufficient copies of its leftmost bit to its left. That is, if `i == Len(x)`, then `SignExtend(x, i) = x`, and if `i > Len(x)`, then:

```
SignExtend(x, i) = Replicate(TopBit(x), i-Len(x)) : x
```

It is a pseudocode error to use either `ZeroExtend(x, i)` or `SignExtend(x, i)` in a context where it is possible that `i < Len(x)`.

Converting bitstrings to integers

If x is a bitstring, `SInt(x)` is the integer whose two's complement representation is x:

```
// SInt()

// ======

integer SInt(bits(N) x)

    result = 0;

    for i = 0 to N-1

        if x<i> == '1' then result = result + 2^i;

    if x<N-1> == '1' then result = result - 2^N;
```

```
    return result;
```

`UInt(x)` is the integer whose unsigned representation is `x`:

```
// UInt()
// ======

integer UInt(bits(N) x)
    result = 0;
    for i = 0 to N-1
        if x<i> == '1' then result = result + 2^i;
    return result;
```

`Int(x, unsigned)` returns either `SInt(x)` or `UInt(x)` depending on the value of its second argument:

```
// Int()
// =====

integer Int(bits(N) x, boolean unsigned)
    result = if unsigned then UInt(x) else SInt(x);
    return result;
```

H.5.4 Arithmetic

Most pseudocode arithmetic is performed on integer or real values, with operands being obtained by conversions from bitstrings and results converted back to bitstrings afterwards. As these data types are the unbounded mathematical types, no issues arise about overflow or similar errors.

Unary plus, minus and absolute value

If `x` is an integer or real, then `+x` is `x` unchanged, `-x` is `x` with its sign reversed, and `Abs(x)` is the absolute value of `x`. All three are of the same type as `x`.

Addition and subtraction

If `x` and `y` are integers or reals, `x+y` and `x-y` are their sum and difference. Both are of type `integer` if `x` and `y` are both of type `integer`, and `real` otherwise.

Addition and subtraction are particularly common arithmetic operations in pseudocode, and so it is also convenient to have definitions of addition and subtraction acting directly on bitstring operands.

If `x` and `y` are bitstrings of the same length `N`, so that `N = Len(x) = Len(y)`, then `x+y` and `x-y` are the least significant `N` bits of the results of converting them to integers and adding or subtracting them. Signed and unsigned conversions produce the same result:

```
x+y = (SInt(x) + SInt(y))<N-1:0>
    = (UInt(x) + UInt(y))<N-1:0>
x-y = (SInt(x) - SInt(y))<N-1:0>
    = (UInt(x) - UInt(y))<N-1:0>
```

If `x` is a bitstring of length `N` and `y` is an integer, `x+y` and `x-y` are the bitstrings of length `N` defined by `x+y = x + y<N-1:0>` and `x-y = x - y<N-1:0>`. Similarly, if `x` is an integer and `y` is a bitstring of length `M`, `x+y` and `x-y` are the bitstrings of length `M` defined by `x+y = x<M-1:0> + y` and `x-y = x<M-1:0> - y`.

Comparisons

If `x` and `y` are integers or reals, then `x == y`, `x != y`, `x < y`, `x <= y`, `x > y`, and `x >= y` are equal, not equal, less than, less than or equal, greater than, and greater than or equal comparisons between them, producing Boolean results. In the case of `==` and `!=`, this extends the generic definition applying to any two values of the same type to also act between integers and reals.

Multiplication

If x and y are integers or reals, then `x * y` is the product of x and y. It is of type `integer` if x and y are both of type `integer`, and `real` otherwise.

Division and modulo

If x and y are integers or reals, then `x/y` is the result of dividing x by y, and is always of type `real`.

If x and y are integers, then `x DIV y` and `x MOD y` are defined by:

```
x DIV y = RoundDown(x/y)
x MOD y = x - y * (x DIV y)
```

It is a pseudocode error to use any of `x/y`, `x MOD y`, or `x DIV y` in any context where y can be zero.

Square root

If x is an integer or a real, `Sqrt(x)` is its square root, and is always of type `real`.

Rounding and aligning

If x is a real:

- `RoundDown(x)` produces the largest integer n such that `n <= x`.
- `RoundUp(x)` produces the smallest integer n such that `n >= x`.
- `RoundTowardsZero(x)` produces `RoundDown(x)` if `x > 0.0`, `0 if x == 0.0`, and `RoundUp(x) if x < 0.0`.

If x and y are both of type `integer`, `Align(x, y) = y * (x DIV y)` is of type `integer`.

If x is of type `bitstring` and y is of type `integer`, `Align(x, y) = (Align(UInt(x), y))<Len(x)-1:0>` is a `bitstring` of the same length as x.

It is a pseudocode error to use either form of `Align(x, y)` in any context where y can be 0. In practice, `Align(x, y)` is only used with y a constant power of two, and the bitstring form used with `y = 2^n` has the effect of producing its argument with its n low-order bits forced to zero.

Scaling

If x and n are of type `integer`, then:

- `x << n = RoundDown(x * 2^n)`.
- `x >> n = RoundDown(x * 2^(-n))`.

Maximum and minimum

If x and y are integers or reals, then `Max(x, y)` and `Min(x, y)` are their maximum and minimum respectively. Both are of type `integer` if x and y are both of type `integer`, and `real` otherwise.

Raising to a power

If x is an integer or a real and n is an integer then `x^n` is the result of raising x to the power of n, and:

- If x is of type `integer` then `x^n` is of type `integer`.
- If x is of type `real` then `x^n` is of type `real`.

H.6 Statements and program structure

This section describes the control statements used in the pseudocode.

H.6.1 Simple statements

Each of the following simple statements must be terminated with a semicolon, as shown.

Assignments

An assignment statement takes the form:

```
<assignable_expression> = <expression>;
```

Procedure calls

A procedure call takes the form:

```
<procedure_name>(<arguments>);
```

Return statements

A procedure return takes the form:

```
return;
```

And a function return takes the form:

```
return <expression>;
```

where `<expression>` is of the type declared in the function prototype line.

UNDEFINED

This subsection describes the statement:

```
UNDEFINED;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that the Undefined Instruction exception is taken.

UNPREDICTABLE

This subsection describes the statement:

```
UNPREDICTABLE;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is UNPREDICTABLE.

SEE…

This subsection describes the statement:

```
SEE <reference>;
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is that nothing occurs as a result of the current pseudocode because some other piece of pseudocode defines the required behavior. The `<reference>` indicates where that other pseudocode can be found.

It usually refers to another instruction, but can also refer to another encoding or note of the same instruction.

IMPLEMENTATION_DEFINED

This subsection describes the statement:

```
IMPLEMENTATION_DEFINED {<text>};
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is IMPLEMENTATION DEFINED. An optional `<text>` field can give more information.

SUBARCHITECTURE_DEFINED

This subsection describes the statement:

```
SUBARCHITECTURE_DEFINED {<text>};
```

This statement indicates a special case that replaces the behavior defined by the current pseudocode, apart from behavior required to determine that the special case applies. The replacement behavior is SUBARCHITECTURE DEFINED. An optional `<text>` field can give more information.

H.6.2 Compound statements

Indentation normally indicates the structure in compound statements. The statements contained in structures such as `if … then … else …` or procedure and function definitions are indented more deeply than the statement itself, and their end is indicated by returning to the original indentation level or less.

Indentation is normally done by four spaces for each level.

if … then … else …

A multi-line `if … then … else …` structure takes the form:

```
if <boolean_expression> then
    <statement 1>
    <statement 2>
    …
    <statement n>
elsif <boolean_expression> then
    <statement a>
    <statement b>
    …
    <statement z>
else
    <statement A>
    <statement B>
    …
    <statement Z>
```

The block of lines consisting of `elsif` and its indented statements is optional, and multiple `elseif` blocks can be used.

The block of lines consisting of `else` and its indented statements is optional.

Abbreviated one-line forms can be used when there are only simple statements in the `then` part and in the `else` part, if it is present, such as:

```
if <boolean_expression> then <statement 1>
if <boolean_expression> then <statement 1> else <statement A>
if <boolean_expression> then <statement 1> <statement 2> else <statement A>
```

Note

In these forms, `<statement 1>`, `<statement 2>` and `<statement A>` must be terminated by semicolons. This and the fact that the `else` part is optional are differences from the `if … then … else …` expression.

repeat … until …

A `repeat … until …` structure takes the form:

```
repeat
    <statement 1>
    <statement 2>
    …
    <statement n>
until <boolean_expression>;
```

while … do

A `while … do` structure takes the form:

```
while <boolean_expression> do
    <statement 1>
    <statement 2>
    …
    <statement n>
```

for …

A `for …` structure takes the form:

```
for <assignable_expression> = <integer_expr1> to <integer_expr2>
    <statement 1>
    <statement 2>
    …
    <statement n>
```

case … of …

A `case … of …` structure takes the form:

```
case <expression> of
    when <constant values>
        <statement 1>
        <statement 2>
        …
        <statement n>
        … more when groups …
    otherwise
        <statement A>
        <statement B>
        …
        <statement Z>
```

In this structure, `<constant values>` consists of one or more constant values of the same type as `<expression>`, separated by commas. Abbreviated one line forms of `when` and `otherwise` parts can be used when they contain only simple statements.

If `<expression>` has a bitstring type, `<constant values>` can also include bitstring constants containing `'x'` bits. For details see *Equality and non-equality testing* on page AppxH-5147.

Procedure and function definitions

A procedure definition takes the form:

```
<procedure name>(<argument prototypes>)
    <statement 1>
    <statement 2>
    …
    <statement n>
```

where <argument prototypes> consists of zero or more argument definitions, separated by commas. Each argument definition consists of a type name followed by the name of the argument.

Note

This first prototype line is not terminated by a semicolon. This helps to distinguish it from a procedure call.

A function definition is similar, but also declares the return type of the function:

```
<return type> <function name>(<argument prototypes>)
    <statement 1>
    <statement 2>
    …
    <statement n>
```

An array-like function is similar, but with square brackets:

```
<return type> <function name>[<argument prototypes>]
    <statement 1>
    <statement 2>
    …
    <statement n>
```

An array-like function also usually has an assignment prototype:

```
<function name>[<argument prototypes>] = <value prototypes>
    <statement 1>
    <statement 2>
    …
    <statement n>
```

H.6.3 Comments

Two styles of pseudocode comment exist:

- // starts a comment that is terminated by the end of the line.
- /* starts a comment that is terminated by */.

Appendix I
Pseudocode Index

This appendix provides indexes to pseudocode definitions and to the pseudocode functions. It contains the following:

Note

Status of this appendix in the beta release document

ARM is currently working to improve the organization of the pseudocode in this document, including providing improved linking within the pseudocode.

The pseudocode index in this chapter is work that is in progress, and it contains TBDs. TBD means work that is To Be Done.

I.1 Pseudocode operators and keywords

Table I-1 shows the pseudocode operators and keywords.

Table I-1 Pseudocode operators and keywords

Operator	Meaning
-	Unary minus on integers or reals
-	Subtraction of integers, reals and bitstrings
+	Unary plus on integers or reals
+	Addition of integers, reals and bitstrings
.	Extract named member from a list
.	Extract named bit or field from a register
:	Bitstring concatenation
:	Integer range in bitstring extraction operator
!	Boolean NOT
!=	Compare for non-equality (any type)
!=	Compare for non-equality (between integers and reals)
(…)	Around arguments of procedure
(…)	Around arguments of function
[…]	Around array index
[…]	Around arguments of array-like function
*	Multiplication of integers and reals
/	Division of integers and reals (real result)
/*…*/	Comment delimiters
//	Introduces comment terminated by end of line
&&	Boolean AND
<	*Less than* comparison of integers and reals
<…>	Extraction of specified bits of bitstring or integer
<<	Multiply integer by power of 2 (with rounding towards -infinity)
<=	*Less than or equal* comparison of integers and reals
=	Assignment
==	Compare for equality (any type)
==	Compare for equality (between integers and reals)
>	*Greater than* comparison of integers and reals
>=	*Greater than or equal* comparison of integers and reals
>>	Divide integer by power of 2 (with rounding towards -infinity)

Table I-1 Pseudocode operators and keywords (continued)

Operator	Meaning
`||`	Boolean OR
`x^N`	N[th] integer power of integers or real[a]
`AND`	Bitwise AND of bitstrings
`array`	Keyword introducing array type definition
`bit`	Bitstring type of length 1
`bits(N)`	Bitstring type of length N
`boolean`	Boolean type
`case … of …`	Control structure
`DIV`	Quotient from integer division
`enumeration`	Keyword introducing enumeration type definition
`EOR`	Bitwise EOR of bitstrings
`FALSE`	Boolean constant
`for …`	Control structure
`for ... downto`	Counts down
`if … then … else …`	Expression selecting between two values
`if … then … else …`	Control structure
`IN`	Tests membership of a set of values
`IMPLEMENTATION_DEFINED`	Describes IMPLEMENTATION DEFINED behavior
`integer`	Unbounded integer type
`MOD`	Remainder from integer division
`OR`	Bitwise OR of bitstrings
`otherwise`	Introduces default case in `case … of …` control structure
`real`	Real number type
`repeat … until …`	Control structure
`return`	Procedure or function return
`SEE`	Points to other pseudocode to use instead
`SUBARCHITECTURE_DEFINED`	Describes SUBARCHITECTURE DEFINED behavior
`TRUE`	Boolean constant
`type`	Names a type
`UNDEFINED`	Cause Undefined Instruction exception
`UNKNOWN`	Unspecified value

Table I-1 Pseudocode operators and keywords (continued)

Operator	Meaning
`UNPREDICTABLE`	Unspecified behavior
`when`	Introduces specific case in `case … of …` control structure
`while … do …`	Control structure

a. *N* must be an integer, *x* can be an integer or a real.

I.2 Pseudocode index

Note

ARM is continuing to work on the organization and linking of the pseudocode in this document. This pseudocode index is work that is in progress, and it contain TBDs. TBD means work that is To Be Done.

Table I-2 indexes the definitions of the pseudocode functions. The name of a pseudocode function might be prefixed with one of the following, to indicate its scope:

`AArch32.` The version of the pseudocode function that applies when executing in an Exception level that is using AArch32.

`AArch64.` The version of the pseudocode function that applies when executing in an Exception level that is using AArch64.

Table I-2 Pseudocode functions

Function	Meaning, or TBD	Link, TBD, or TBD with the proposed future link
`AbortSyndrome()`	TBD	TBD
`AccessFlagFault()`	Access flag fault MMU fault	AArch64, [TBD: Link to *Access flag fault pseudocode*.]
`AddressSizeFault()`	Address size fault MMU fault	AArch64, [TBD: Link to *Address size fault pseudocode*.]
`AddWithCarry()`	TBD	*Pseudocode details of addition and subtraction* on page E1-2206. *Pseudocode details of addition and subtraction* on page F2-2338. [TBD: Link to *Library pseudocode for integer/data instructions*.]
`AdvSIMDFPAccessTrap()`	TBD	TBD
`AlignmentFault()`	Alignment fault MMU fault	AArch64, [TBD: Link to *Alignment fault pseudocode*.]
`BadMode()`	Tests whether a mode number corresponds to a permitted mode	AArch32, *Pseudocode details of mode operations* on page G1-3383.
`BreakpointException()`	Breakpoint exceptions	AArch64, *Pseudocode descriptions of debug exceptions* on page D2-1542. AArch32, *Pseudocode descriptions of debug exceptions* on page G2-3522.
`CallHypervisor()`	Generates an Hypervisor Call exception	AArch64, TBD.
`CallSecureMonitor()`	Generates a Supervisor Call exception	AArch64, TBD.
`CallSupervisor()`	TBD	TBD
`CheckBreakpoint()`	TBD	AArch64, *Pseudocode descriptions of Breakpoint exceptions taken from AArch64 state* on page D2-1559.
`CheckAdvSIMDOrVFPEnabled()`	A calling function for `CheckAdvSIMDOrFPEnabled()`	AArch32, *Pseudocode details of enabling Advanced SIMD and floating-point functionality* on page G1-3471.
`CheckVFPEnabled()`	Checks whether floating-point operation is enabled	AArch32, *Pseudocode details of enabling Advanced SIMD and floating-point functionality* on page G1-3471.

Table I-2 Pseudocode functions (continued)

Function	Meaning, or TBD	Link, TBD, or TBD with the proposed future link
`CheckAdvSIMDEnabled()`	Checks whether Advanced SIMD operation is enabled	AArch32, *Pseudocode details of enabling Advanced SIMD and floating-point functionality* on page G1-3471.
`CheckAdvSIMDOrFPEnabled()`	Checks whether Advanced SIMD and floating-point operation is enabled	AArch32, *Pseudocode details of enabling Advanced SIMD and floating-point functionality* on page G1-3471.
`CheckFPAdvSIMDEnabled()`	TBD	TBD
`CheckIllegalState()`	TBD	TBD
`CheckPCAlignment()`	PC alignment check	AArch64, *PC alignment checking* on page D1-1415.
`CheckPermission()`	Access permissions check for a stage 1 translation table lookup	AArch64, *Access permission checking* on page D3-1627. AArch64, *Support functions* on page D4-1681.
`CheckS2Permission()`	Access permissions check for a stage 2 translation table lookup	AArch64, *Support functions* on page D4-1681.
`CheckSPAlignment()`	Stack pointer alignment check	AArch64, *Stack pointer alignment checking* on page D1-1416.
`CheckWatchpoint()`	TBD	AArch64, *Pseudocode description of Watchpoint exceptions taken from AArch64 state* on page D2-1575.
`CPRegTrap()`	TBD	TBD
`CurrentModeIsNotUser()`	Returns TRUE if the current mode is not User mode	AArch32, *Pseudocode details of mode operations* on page G1-3383.
`CurrentModeIsUserOrSystem()`	Returns TRUE if the current mode is User mode or System mode	AArch32, *Pseudocode details of mode operations* on page G1-3383.
`CurrentModeIsHyp()`	Returns TRUE if the current mode is Hyp mode	AArch32, *Pseudocode details of mode operations* on page G1-3383.
`CreateAbortRecord()`	TBD	TBD
`DataAbort()`	Data Abort exception	AArch64, *Abort exceptions* on page D3-1628.
`EnterHypMode()`	Changes the current PE mode to Hyp mode	AArch32, *Additional pseudocode functions for exception handling* on page G1-3452.
`EnterMonitorMode()`	Changes the current PE mode to Monitor mode	AArch32, *Additional pseudocode functions for exception handling* on page G1-3452.
`EventRegistered()`	Determine whether the Event Register of the current PE is set	AArch32, *Pseudocode details of the Wait For Event lock mechanism* on page G1-3460.
`ExceptionClass()`	TBD	AArch64, *Pseudocode description of exception entry to AArch64 state* on page D1-1424.
`ExceptionReturn()`	TBD	[TBD: Link to *Library pseudocode for integer/branch instructions*.]
`ExclusiveMonitorsPass()`	TBD	*Exclusive monitors operations* on page G3-3608. [TBD: Link to *Library pseudocode for integer/memory/exclusive instructions*.]

Table I-2 Pseudocode functions (continued)

Function	Meaning, or TBD	Link, TBD, or TBD with the proposed future link
`ExclusiveMonitorsStatus()`	TBD	[TBD: Link to *Library pseudocode for integer/memory/exclusive instructions*.]
`ExcVectorBase()`	Returns the exception base address for an exception taken to a mode other than Monitor mode or Hyp mode	AArch32, *Pseudocode determination of the exception base address* on page G1-3399.
`ExtendReg()`	TBD	[TBD: Link to *Library pseudocode for integer instructions*.]
`FirstStageTranslate()`	Stage 1 translation	AArch64, *Stage 1 translation* on page D4-1673.
`FPProcessException()`	TBD	AArch64, *Floating-point Exception traps* on page D1-1451.
`FPRecipStepFused()`	TBD	[TBD: Link to *Library pseudocode for vector instructions*.]
`FPRSqrtStepFused()`	TBD	[TBD: Link to *Library pseudocode for vector instructions*.]
`FPTrappedException()`	TBD	AArch64, *Floating-point Exception traps* on page D1-1451.
`FullTranslate()`	Full translation table walk	AArch64, *Performing the full address translation* on page D4-1673.
`GeneralExceptionsToEL2()`	TBD	TBD
`Halt()`	TBD	*Pseudocode details for entering Debug state* on page H2-4404. [TBD: Link to *Library pseudocode for system/exceptions/debug instructions*.]
`Halted()`	TBD	*Pseudocode details of Halting on debug events* on page H2-4401. [TBD: Link to *Library pseudocode for system/exceptions/debug instructions*.]
`HaltingAllowed()`	TBD	*Pseudocode details of Halting on debug events* on page H2-4401. [TBD: Link to *Library pseudocode for system/exceptions/debug instructions*.]
`HaveCRCExt()`	TBD	[TBD: Link to *Library pseudocode for crc instructions*.]
`HaveCryptoExt()`	TBD	[TBD: Link to *Library pseudocode for vector/data/crypto instructions*.]
`HVCInstruction()`	TBD	TBD
`InstructionAbort()`	Instruction Abort exception	AArch64, *Abort exceptions* on page D3-1628.
`IsExclusiveGlobal()`	Returns TRUE if the global monitor has the supplied address marked as exclusive	AArch32, *Exclusive monitors operations* on page G3-3608.

Table I-2 Pseudocode functions (continued)

Function	Meaning, or TBD	Link, TBD, or TBD with the proposed future link
`IsExclusiveLocal()`	Returns TRUE if the local monitor has the supplied address marked as exclusive	AArch32, *Exclusive monitors operations* on page G3-3608.
`MarkExclusiveLocal()`	Set a local exclusive access record	AArch32, *Exclusive monitors operations* on page G3-3608.
`MarkExclusiveGlobal()`	Set a global exclusive access record	AArch32, *Exclusive monitors operations* on page G3-3608.
`MaybeZeroRegisterUppers()`	TBD	AArch64, *Pseudocode description of exception entry to AArch64 state* on page D1-1424.
`MoveWidePreferred()`	TBD	[TBD: Link to *Library pseudocode for integer/data/logical instructions*.]
`PCAlignmentFault()`	TBD	AArch64, *PC alignment checking* on page D1-1415.
`PermissionFault()`	Permission fault MMU fault	AArch64, [TBD: Link to *Permission fault pseudocode*.]
`Poly32Mod2()`	TBD	[TBD: Link to *Library pseudocode for crc instructions*.]
`Prefetch()`	TBD	[TBD: Link to *Library pseudocode for integer/memory instructions*.]
`BranchTo()`	Performs a branch to the specified address	AArch32, *Pseudocode details of general-purpose register and PC operations* on page G1-3384.
`SP`	Accesses the stack pointer, R13	AArch32, *Pseudocode details of general-purpose register and PC operations* on page G1-3384.
`LR`	Accesses the link register, R14	AArch32, *Pseudocode details of general-purpose register and PC operations* on page G1-3384.
`PC`	Accesses the program counter, R15	AArch32, *Pseudocode details of general-purpose register and PC operations* on page G1-3384.
`R[]`	Accesses the specified register in the current PE mode	AArch32, *Pseudocode details of general-purpose register and PC operations* on page G1-3384.
`Rmode[]`	Accesses the specified register in the specified PE mode	AArch32, *Pseudocode details of general-purpose register and PC operations* on page G1-3384.
`LookUpRIndex()`	Looks up the register file entry for the specified register number and PE mode	AArch32, *Pseudocode details of general-purpose register and PC operations* on page G1-3384.
`RBankSelect()`	Evaluates the register banking for R8-R14	AArch32, *Pseudocode details of general-purpose register and PC operations* on page G1-3384.
`Reduce()`	TBD	[TBD: Link to *Library pseudocode for vector/data/processing/reduce instructions*.]
`ReduceOp`	TBD	[TBD: Link to *Library pseudocode for vector/data/processing/reduce instructions*.]
`ReportException()`	TBD	AArch64, *Pseudocode description of exception entry to AArch64 state* on page D1-1424.

Table I-2 Pseudocode functions (continued)

Function	Meaning, or TBD	Link, TBD, or TBD with the proposed future link
`_PC`	The program counter, defined as common for AArch32 and AArch64 operation.	AArch32, *Pseudocode details of general-purpose register and PC operations* on page G1-3384.
`_R`	The array of general-purpose registers. Defined as a common array for AArch32 and AArch64 operation.	AArch32, *Pseudocode details of general-purpose register and PC operations* on page G1-3384.
`ROL()`	TBD	[TBD: Link to *Library pseudocode for vector/data/crypto instructions*.]
`S1AttrDecode()`	Decodes the attributes from a stage 1 translation table lookup	AArch64, *Support functions* on page D4-1681.
`SecondStageTranslate()`	Stage 2 translation	AArch64, *Stage 2 translation* on page D4-1675.
`SecondStageWalk()`	TBD	AArch64, *Stage 2 translation* on page D4-1675.
`SetExclusiveMonitors()`	TBD	*Exclusive monitors operations* on page G3-3608.
`SHA256hash()`	TBD	[TBD: Link to *Library pseudocode for vector/data/crypto/sha3op instructions*.]
`SHAchoose()`	TBD	[TBD: Link to *Library pseudocode for vector/data/crypto/sha3op instructions*.]
`SHAhashSIGMA0()`	TBD	[TBD: Link to *Library pseudocode for vector/data/crypto/sha3op instructions*.]
`SHAhashSIGMA1()`	TBD	[TBD: Link to *Library pseudocode for vector/data/crypto/sha3op instructions*.]
`SHAmajority()`	TBD	[TBD: Link to *Library pseudocode for vector/data/crypto/sha3op instructions*.]
`SHAparity()`	TBD	[TBD: Link to *Library pseudocode for vector/data/crypto/sha3op instructions*.]
`ShiftReg()`	TBD	[TBD: Link to *Library pseudocode for integer instructions*.]
`SMCInstruction()`	TBD	TBD
`SMCTrap()`	TBD	TBD
`SoftwareBreakpoint()`	TBD	AArch64, *Pseudocode description of Software Breakpoint Instruction exceptions* on page D2-1545.
`SoftwareStepException()`	Software Step exceptions	AArch64, *Pseudocode descriptions of debug exceptions* on page D2-1542. AArch32, *Pseudocode descriptions of debug exceptions* on page G2-3522.
`CPSR[]`	Accesses the CPSR	AArch32, *Pseudocode details of PSR operations* on page G1-3391.
`CPSRWriteByInstr()`	Called by a T32 or A32 instruction to write to the CPSR	AArch32, *Pseudocode details of PSR operations* on page G1-3391.

Table I-2 Pseudocode functions (continued)

Function	Meaning, or TBD	Link, TBD, or TBD with the proposed future link
`SPSRWriteByInstr()`	Called by a T32 or A32 instruction to write to the SPSR	AArch32, *Pseudocode details of PSR operations* on page G1-3391.
`SPSR[]`	Accesses the SPSR	AArch32, *Pseudocode details of PSR operations* on page G1-3391.
`SynchExternalAbort()`	TBD	TBD
`SysOp_R()`	TBD	[TBD: Link to *Library pseudocode for system instructions*.]
`SysOp_W()`	TBD	[TBD: Link to *Library pseudocode for system instructions*.]
`System_Get()`	TBD	[TBD: Link to *Library pseudocode for system instructions*.]
`System_Put()`	TBD	[TBD: Link to *Library pseudocode for system instructions*.]
`SystemRegisterTrap()`	TBD	TBD
`TakeException()`	Behavior when a PE takes an exception to an Exception level that is using AArch64	AArch64, *Pseudocode description of exception entry to AArch64 state* on page D1-1424.
`TakePhysicalFIQException()`	Takes a Physical FIQ exception	AArch64, TBD. AArch32, *Pseudocode description of taking the FIQ exception* on page G1-3450.
`TakePhysicalIRQException()`	Takes a Physical IRQ exception	AArch64, TBD. AArch32, *Pseudocode description of taking the IRQ exception* on page G1-3447.
`TakePhysicalSystemErrorException()`	TBD	TBD
`TakeVirtualFIQException()`	Takes a Virtual FIQ exception	AArch64, TBD. AArch32, *Pseudocode description of taking the Virtual FIQ exception* on page G1-3451.
`TakeVirtualIRQException()`	Takes a Virtual IRQ exception	AArch64, TBD. AArch32, *Pseudocode description of taking the Virtual IRQ exception* on page G1-3449.
`TakeVirtualSystemErrorException()`	TBD	TBD
`TakeVirtualAsyncAbortException()`	Takes a Virtual Asynchronous Abort exception	AArch32, *Pseudocode description of taking the Hypervisor Call exception* on page G1-3436.
`TakePrefetchAbortException()`	Takes a Prefetch Abort exception	AArch32, *Pseudocode description of taking the Hypervisor Call exception* on page G1-3436.
`TakeHVCException()`	Takes a Hypervisor Call exception	AArch32, *Pseudocode description of taking the Hypervisor Call exception* on page G1-3436.
`TakeSMCException()`	Takes a Secure Monitor Call exception	AArch32, *Pseudocode description of taking the Secure Monitor Call exception* on page G1-3435.
`TakeSVCException()`	Takes a Supervisor Call exception	AArch32, *Pseudocode description of taking the Supervisor Call exception* on page G1-3434.

Table I-2 Pseudocode functions (continued)

Function	Meaning, or TBD	Link, TBD, or TBD with the proposed future link
`TakeHypTrapException()`	Takes an Hyp Trap exception	AArch32, *Pseudocode description of taking the Hyp Trap exception* on page G1-3432.
`TakeUndefInstrException()`	Takes an Undefined Instruction exception	AArch32, *Pseudocode description of taking the Undefined Instruction exception* on page G1-3429.
`ThisInstrAddr()`	TBD	[TBD: Link to *Library pseudocode for registers instructions*.]
`TranslateAddress()`	TBD	TBD
`TranslateAddressS1Off()`	Sets the memory attributes when stage 1 translation is disabled	AArch64, *Stage 1 translation* on page D4-1673.
`TranslationFault()`	Translation fault MMU fault	AArch64, [TBD: Link to *Translation fault pseudocode*.]
`TranslationTableWalk()`	Returns the result, in the form of a `TLBRecord`, of a translation table walk made for a memory access from an Exception level that is using AArch64	AArch64, *Translation table walk* on page D4-1676.
`UndefinedFault()`	TBD	TBD
`VectorCatchException()`	Vector Catch exceptions	AArch64, *Pseudocode descriptions of debug exceptions* on page D2-1542. AArch32, *Pseudocode descriptions of debug exceptions* on page G2-3522.
`WatchpointException()`	Watchpoint exceptions	AArch64, *Pseudocode descriptions of debug exceptions* on page D2-1542. AArch32, *Pseudocode descriptions of debug exceptions* on page G2-3522.
`WFEInstruction()`	TBD	TBD
`WFIInstruction()`	TBD	TBD
`WFxTrap()`	TBD	TBD
`BFXPreferred()`	TBD	[TBD: Link to *Library pseudocode for integer/data instructions*.]
`BitReverse()`	TBD	[TBD: Link to *Library pseudocode for crc instructions*.]
`BranchTo()`	Continue execution at specified address	[TBD: Link to *Library pseudocode for registers instructions*.]
`BRKInstruction()`	Appears twice in Excel sheet!!	[TBD: Link to *Library pseudocode for system/exceptions/debug instructions*.]
`BRKInstruction()`	TBD	TBD
`CheckAlignment()`	TBD	*Unaligned memory access* on page D3-1624. [TBD: Link to *Library pseudocode for integer/memory instructions*.]
`CheckAtomic()`	TBD	*Unaligned memory access* on page D3-1624. [TBD: Link to *Library pseudocode for integer/memory instructions*.]

Table I-2 Pseudocode functions (continued)

Function	Meaning, or TBD	Link, TBD, or TBD with the proposed future link
`CheckCryptoEnabled64()`	TBD	[TBD: Link to *Library pseudocode for vector/data/crypto instructions*.]
`CheckSystemAccess()`	TBD	[TBD: Link to *Library pseudocode for system instructions*.]
`DCPSInstruction()`	TBD	[TBD: Link to *Library pseudocode for system/exceptions/debug instructions*.]
`DecodeBitMasks()`	TBD	[TBD: Link to *Library pseudocode for integer/data instructions*.]
`DecodeRegExtend()`	TBD	[TBD: Link to *Library pseudocode for integer instructions*.]
`DecodeRegShift64()`	TBD	TBD

Appendix J
Registers Index

This appendix provides indexes to the register descriptions in this manual. It contains the following sections:

J.1 Introduction and register disambiguation

In some sections of this manual, registers are referred to by a *general name*, where the description applies to more than one context. Generally, this is one of the following:

- The description applies to both AArch32 state and AArch64 state, and therefore the register names could apply to either AArch32 system registers or AArch64 system registers.
- The description applies to multiple Exception levels, and therefore at a particular Exception level the register names need to take the appropriate Exception. level suffix, _EL0, _EL1, _EL2, or _EL3.

The following sections disambiguate the general register names:

- *Register name disambiguation by Execution state*.
- *Register name disambiguation by Exception level* on page AppxJ-5173.

J.1.1 Register name disambiguation by Execution state

Table J-1 disambiguates the general names of the registers by Execution state.

Table J-1 Disambiguation of general names of registers by Execution state

General name	Short description	AArch64 register	AArch32 register
CONTEXTIDR	Context ID	CONTEXTIDR_EL1	CONTEXTIDR
DBGBCR	Debug Breakpoint Control Registers	DBGBCR<n>_EL1	DBGBCR<n>
DBGBVR	Debug Breakpoint Value Registers	DBGBVR<n>_EL1	DBGBVR<n> DBGBXVR<n>
DBGCLAIMCLR	Debug Claim Tag Clear register	DBGCLAIMCLR_EL1	DBGCLAIMCLR
DBGCLAIMSET	Debug Claim Tag Set register	DBGCLAIMSET_EL1	DBGCLAIMSET
DBGDTRRX	Debug Data Transfer Register, Receive	DBGDTRRX_EL0	DBGDTRRXint
DBGDTRTX	Debug Data Transfer Register, Transmit	DBGDTRTX_EL0	DBGDTRTXint
DBGPRCR	Debug Power Control Register	DBGPRCR_EL1	DBGPRCR
DBGVCR	Debug Vector Catch Register	DBGVCR32_EL2	DBGVCR
DBGWCR	Debug Watchpoint Control Registers	DBGWCR<n>_EL1	DBGWCR<n>
DBGWVR	Debug Watchpoint Value Registers	DBGWVR<n>_EL1	DBGWVR<n>
DCCINT	Debug Communications Channel Interrupt Enable Register	MDCCINT_EL1	DBGDCCINT
DCCSR	Debug Communications Channel Status Register	MDCCSR_EL0	DBGDSCRint
DBGAUTHSTATUS	Debug Authentication Status	DBGAUTHSTATUS_EL1	DBGAUTHSTATUS
DLR	Debug Link Register	DLR_EL0[31:0]	DLR
DSCR	Debug System Control Register	MDSCR_EL1	DBGDSCRext
DSPSR	Debug Saved PE State Register	DSPSR_EL0	DSPSR
FAR	Fault Address Register	FAR_EL1 FAR_EL2 FAR_EL3 HPFAR_EL2	DFAR, IFAR HDFAR, HIFAR FAR_EL3 HPFAR

Table J-1 Disambiguation of general names of registers by Execution state (continued)

General name	Short description	AArch64 register	AArch32 register
HCR	Hypervisor Configuration Register	HCR_EL2	HCR HCR2
HDCR	Hyp or EL2 Debug Control Register	MDCR_EL2	HDCR
HSCTLR	Hypervisor System Control Register	SCTLR_EL2	HSCTLR
HTTBR	EL2 Translation Table Base Register	TTBR0_EL2	HTTBR
ISR	Interrupt Status Register	ISR_EL1	ISR
OSDLR	OS Double-Lock Register	OSDLR_EL1	DBGOSDLR
OSDTRRX	OS Lock Data Transfer Register, Receive	OSDTRRX_EL1	DBGDTRRXext
OSDTRTX	OS Lock Data Transfer Register, Transmit	OSDTRTX_EL1	DBGDTRTXext
OSECCR	OS Lock Exception Catch Control Register	OSECCR_EL1	DBGOSECCR
OSLAR	OS Lock Access Register	OSLAR_EL1	DBGOSLAR
OSLSR	OS Lock Status Register	OSLSR_EL1	DBGOSLSR
SCR	Secure Configuration Register	SCR_EL3	SCR
SCTLR	System Control Register	SCTLR_EL1 SCTLR_EL2 SCTLR_EL3	SCTLR (NS) HSCTLR SCTLR (S)
SDCR	Secure or EL3 Debug Configuration Register	MDCR_EL3	SDCR
SDER	Secure Debug Enable Register	SDER32_EL3	SDER
SPSR	Saved Program Status Register	SPSR_EL1 SPSR_EL2 SPSR_EL3	SPSR
TCR	Translation Control Register	TCR_EL1 TCR_EL2 TCR_EL3	TTBCR(NS) HTCR TTBCR(S)
TTBR	Translation Table Base Register	TTBR0_EL1 TTBR0_EL2 TTBR0_EL3 TTBR1_EL1	TTBR0 TTBR1
VCR	PL1&0 stage 2 Translation Control Register	VTCR_EL2	VTCR
VTTBR	PL1&0 stage 2 Translation Table Base Register	VTTBR_EL2	VTTBR

Table J-2 disambiguates the general names of the System registers that provide access to the Performance Monitors by Execution state.

Table J-2 Disambiguation of general names of the Performance Monitors System registers by Execution state

General name	Short description	AArch64 register	AArch32 register
PMCCFILTR	Cycle Count Filter Register	PMCCFILTR_EL0	PMCCFILTR
PMCCNTR	Cycle Count Register	PMCCNTR_EL0	PMCCNTR
PMCEID0	Performance Monitors Cycle Count Filter Register 0	PMCEID0_EL0	PMCEID0
PMCEID1	Performance Monitors Cycle Count Filter Register 1	PMCEID1_EL0	PMCEID1
PMCNTENCLR	Performance Monitors Count Enable Clear register	PMCNTENCLR_EL0	PMINTENCLR
PMCNTENSET	Performance Monitors Count Enable Set register	PMCNTENSET_EL0	PMCNTENSET
PMCR	Performance Monitors Control Register	PMCR_EL0	PMCR
PMEVCNTR<n>	Performance Monitors Event Count Registers, n = 0-30	PMEVCNTR<n>_EL0	PMEVCNTR<n>
PMEVTYPER<n>	Performance Monitors Event Type Registers, n = 0-30	PMEVTYPER<n>_EL0	PMEVTYPER<n>
PMINTENCLR	Performance Monitors Interrupt Enable Clear register	PMINTENCLR_EL1	PMINTENCLR
PMINTENSET	Performance Monitors Interrupt Enable Set register	PMINTENSET_EL1	PMINTENSET
PMOVSCLR	Performance Monitors Overflow Flag Status Register	PMOVSCLR_EL0	PMOVSR
PMOVSSET	Performance Monitors Overflow Flag Status Set register	PMOVSSET_EL0	PMOVSSET
PMSELR	Performance Monitors Event Counter Selection Register	PMSELR_EL0	PMSELR
PMSWINC	Performance Monitors Software Increment register	PMSWINC_EL0	PMSWINC
PMUSERENR	Performance Monitors User Enable Register	PMUSERENR_EL0	PMUSERENR
PMXEVCNTR	Performance Monitors Selected Event Count Register	PMXEVCNTR_EL0	PMXEVCNTR
PMXEVTYPER	Performance Monitors Selected Event Type Register	PMXEVTYPER_EL0	PMXEVTYPER

Table J-3 disambiguates the general names of the System registers that provide access to the Performance Monitors by Execution state.

Table J-3 Disambiguation of general names of the Generic Timer System registers by Execution state

General name	Short description	AArch64 register	AArch32 register
CNTFRQ	Counter-timer Frequency register	CNTFRQ_EL0	CNTFRQ
CNTHCTL	Counter-timer Hypervisor Control register	CNTHCTL_EL2	CNTHCTL
CNTHP_CTL	Counter-timer Hypervisor Physical Timer Control register	CNTHP_CTL_EL2	CNTHP_CTL
CNTHP_CVAL	Counter-timer Hypervisor Physical Timer CompareValue register	CNTHP_CVAL_EL2	CNTHP_CVAL
CNTHP_TVAL	Counter-timer Hypervisor Physical Timer TimerValue register	CNTHP_TVAL_EL2	CNTHP_TVAL
CNTKCTL	Counter-timer Kernel Control register	CNTKCTL_EL1	CNTKCTL

Table J-3 Disambiguation of general names of the Generic Timer System registers by Execution state (continued)

General name	Short description	AArch64 register	AArch32 register
CNTP_CTL	Counter-timer Physical Timer Control register	CNTP_CTL_EL0	CNTP_CTL
CNTP_CVAL	Counter-timer Physical Timer CompareValue register	CNTP_CVAL_EL0	CNTP_CVAL
CNTP_TVAL	Counter-timer Physical Timer TimerValue register	CNTP_TVAL_EL0	CNTP_TVAL
CNTPCT	Counter-timer Physical Count register	CNTPCT_EL0	CNTPCT
CNTPS_CTL	Counter-timer Physical Secure Timer Control register	CNTPS_CTL_EL1	-
CNTPS_CVAL	Counter-timer Physical Secure Timer CompareValue register	CNTPS_CVAL_EL1	-
CNTPS_TVAL	Counter-timer Physical Secure Timer TimerValue register	CNTPS_TVAL_EL1	-
CNTV_CTL	Counter-timer Virtual Timer Control register	CNTV_CTL_EL0	CNTV_CTL
CNTV_CVAL	Counter-timer Virtual Timer CompareValue register	CNTV_CVAL_EL0	CNTV_CVAL
CNTV_TVAL	Counter-timer Virtual Timer TimerValue register	CNTV_TVAL_EL0	CNTV_TVAL
CNTVCT	Counter-timer Virtual Count register	CNTVCT_EL0	CNTVCT
CNTVOFF	Counter-timer Virtual Offset register	CNTVOFF_EL2	CNTVOFF

J.1.2 Register name disambiguation by Exception level

Table J-4 disambiguates the general names of the AArch64 System registers by Exception level.

Table J-4 Disambiguation of AArch64 system registers by Exception level

General form	EL0	EL1	EL2	EL3
AFSR0_ELx	-	AFSR0_EL1	AFSR0_EL2	AFSR0_EL3
AFSR1_ELx	-	AFSR1_EL1	AFSR1_EL2	AFSR1_EL3
ELR_ELx	-	ELR_EL1	ELR_EL2	ELR_EL3
ESR_ELx	-	ESR_EL1	ESR_EL2	ESR_EL3
FAR_ELx	-	FAR_EL1	FAR_EL2	FAR_EL3
MAIR_ELx	-	MAIR_EL1	MAIR_EL2	MAIR_EL3
RMR_ELx	-	RMR_EL1	RMR_EL2	RMR_EL3
RVBAR_ELx	-	RVBAR_EL1	RVBAR_EL2	RVBAR_EL3
SCTLR_ELx	-	SCTLR_EL1	SCTLR_EL2	SCTLR_EL3
SP_ELx	SP_EL0	SP_EL1	SP_EL2	SP_EL3
SPSR_ELx	-	SPSR_EL1	SPSR_EL2	SPSR_EL3
TCR_ELx	-	TCR_EL1	TCR_EL2	TCR_EL3
VBAR_ELx	-	VBAR_EL1	VBAR_EL2	VBAR_EL3

J.2 Alphabetical index of AArch64 registers and system instructions

This section is an index of AArch64 registers and system instructions in alphabetical order.

Table J-5 Alphabetical index of AArch64 Registers

Register	Description, see
ACTLR_EL1	*ACTLR_EL1, Auxiliary Control Register (EL1)* on page D7-1798
ACTLR_EL2	*ACTLR_EL2, Auxiliary Control Register (EL2)* on page D7-1799
ACTLR_EL3	*ACTLR_EL3, Auxiliary Control Register (EL3)* on page D7-1800
AFSR0_EL1	*AFSR0_EL1, Auxiliary Fault Status Register 0 (EL1)* on page D7-1801
AFSR0_EL2	*AFSR0_EL2, Auxiliary Fault Status Register 0 (EL2)* on page D7-1802
AFSR0_EL3	*AFSR0_EL3, Auxiliary Fault Status Register 0 (EL3)* on page D7-1803
AFSR1_EL1	*AFSR1_EL1, Auxiliary Fault Status Register 1 (EL1)* on page D7-1804
AFSR1_EL2	*AFSR1_EL2, Auxiliary Fault Status Register 1 (EL2)* on page D7-1805
AFSR1_EL3	*AFSR1_EL3, Auxiliary Fault Status Register 1 (EL3)* on page D7-1806
AIDR_EL1	*AIDR_EL1, Auxiliary ID Register* on page D7-1807
AMAIR_EL1	*AMAIR_EL1, Auxiliary Memory Attribute Indirection Register (EL1)* on page D7-1808
AMAIR_EL2	*AMAIR_EL2, Auxiliary Memory Attribute Indirection Register (EL2)* on page D7-1809
AMAIR_EL3	*AMAIR_EL3, Auxiliary Memory Attribute Indirection Register (EL3)* on page D7-1810
AT S12E0R	*AT S12E0R, Address Translate Stages 1 and 2 EL0 Read* on page C5-320
AT S12E0W	*AT S12E0W, Address Translate Stages 1 and 2 EL0 Write* on page C5-321
AT S12E1R	*AT S12E1R, Address Translate Stages 1 and 2 EL1 Read* on page C5-322
AT S12E1W	*AT S12E1W, Address Translate Stages 1 and 2 EL1 Write* on page C5-323
AT S1E0R	*AT S1E0R, Address Translate Stage 1 EL0 Read* on page C5-324
AT S1E0W	*AT S1E0W, Address Translate Stage 1 EL0 Write* on page C5-325
AT S1E1R	*AT S1E1R, Address Translate Stage 1 EL1 Read* on page C5-326
AT S1E1W	*AT S1E1W, Address Translate Stage 1 EL1 Write* on page C5-327
AT S1E2R	*AT S1E2R, Address Translate Stage 1 EL2 Read* on page C5-328
AT S1E2W	*AT S1E2W, Address Translate Stage 1 EL2 Write* on page C5-329
AT S1E3R	*AT S1E3R, Address Translate Stage 1 EL3 Read* on page C5-330

J.3 Functional index of AArch64 registers and system instructions

This section is an index of the AArch64 registers and system instructions, divided by functional group.

J.3.1 Special-purpose registers

This section is an index to the registers in the Special purpose registers functional group.

Table J-6 Special-purpose registers

Register	Description, see
DLR_EL0	*DLR_EL0, Debug Link Register* on page D7-2016
DSPSR_EL0	*DSPSR_EL0, Debug Saved Program Status Register* on page D7-2017
ELR_EL1	*ELR_EL1, Exception Link Register (EL1)* on page C5-259
ELR_EL2	*ELR_EL2, Exception Link Register (EL2)* on page C5-260
ELR_EL3	*ELR_EL3, Exception Link Register (EL3)* on page C5-261
FPCR	*FPCR, Floating-point Control Register* on page C5-262
FPSR	*FPSR, Floating-point Status Register* on page C5-266
SP_EL0	*SP_EL0, Stack Pointer (EL0)* on page C5-271
SP_EL1	*SP_EL1, Stack Pointer (EL1)* on page C5-272
SP_EL2	*SP_EL2, Stack Pointer (EL2)* on page C5-273
SP_EL3	*SP_EL3, Stack Pointer (EL3)* on page C5-274
SPSR_abt	*SPSR_abt, Saved Program Status Register (Abort mode)* on page C5-276
SPSR_EL1	*SPSR_EL1, Saved Program Status Register (EL1)* on page C5-279
SPSR_EL2	*SPSR_EL2, Saved Program Status Register (EL2)* on page C5-284
SPSR_EL3	*SPSR_EL3, Saved Program Status Register (EL3)* on page C5-289
SPSR_fiq	*SPSR_fiq, Saved Program Status Register (FIQ mode)* on page C5-294
SPSR_irq	*SPSR_irq, Saved Program Status Register (IRQ mode)* on page C5-297
SPSR_und	*SPSR_und, Saved Program Status Register (Undefined mode)* on page C5-300

J.3.2 VMSA-specific registers

This section is an index to the registers in the Virtual memory control registers functional group.

Table J-7 VMSA-specific registers

Register	Description, see
AMAIR_EL1	*AMAIR_EL1, Auxiliary Memory Attribute Indirection Register (EL1)* on page D7-1808
AMAIR_EL2	*AMAIR_EL2, Auxiliary Memory Attribute Indirection Register (EL2)* on page D7-1809
AMAIR_EL3	*AMAIR_EL3, Auxiliary Memory Attribute Indirection Register (EL3)* on page D7-1810
CONTEXTIDR_EL1	*CONTEXTIDR_EL1, Context ID Register* on page D7-1815
DACR32_EL2	*DACR32_EL2, Domain Access Control Register* on page D7-1826

Table J-7 VMSA-specific registers (continued)

Register	Description, see
MAIR_EL1	*MAIR_EL1, Memory Attribute Indirection Register (EL1)* on page D7-1910
MAIR_EL2	*MAIR_EL2, Memory Attribute Indirection Register (EL2)* on page D7-1912
MAIR_EL3	*MAIR_EL3, Memory Attribute Indirection Register (EL3)* on page D7-1914
TCR_EL1	*TCR_EL1, Translation Control Register (EL1)* on page D7-1954
TCR_EL2	*TCR_EL2, Translation Control Register (EL2)* on page D7-1959
TCR_EL3	*TCR_EL3, Translation Control Register (EL3)* on page D7-1962
TTBR0_EL1	*TTBR0_EL1, Translation Table Base Register 0 (EL1)* on page D7-1970
TTBR0_EL2	*TTBR0_EL2, Translation Table Base Register 0 (EL2)* on page D7-1972
TTBR0_EL3	*TTBR0_EL3, Translation Table Base Register 0 (EL3)* on page D7-1974
TTBR1_EL1	*TTBR1_EL1, Translation Table Base Register 1* on page D7-1976
VTCR_EL2	*VTCR_EL2, Virtualization Translation Control Register* on page D7-1984
VTTBR_EL2	*VTTBR_EL2, Virtualization Translation Table Base Register* on page D7-1987

J.3.3 ID registers

This section is an index to the registers in the Identification registers functional group.

Table J-8 ID registers

Register	Description, see
AIDR_EL1	*AIDR_EL1, Auxiliary ID Register* on page D7-1807
CCSIDR_EL1	*CCSIDR_EL1, Current Cache Size ID Register* on page D7-1811
CLIDR_EL1	*CLIDR_EL1, Cache Level ID Register* on page D7-1813
CSSELR_EL1	*CSSELR_EL1, Cache Size Selection Register* on page D7-1822
CTR_EL0	*CTR_EL0, Cache Type Register* on page D7-1824
DCZID_EL0	*DCZID_EL0, Data Cache Zero ID register* on page D7-1827
ID_AA64AFR0_EL1	*ID_AA64AFR0_EL1, AArch64 Auxiliary Feature Register 0* on page D7-1876
ID_AA64AFR1_EL1	*ID_AA64AFR1_EL1, AArch64 Auxiliary Feature Register 1* on page D7-1877
ID_AA64DFR0_EL1	*ID_AA64DFR0_EL1, AArch64 Debug Feature Register 0* on page D7-1878
ID_AA64DFR1_EL1	*ID_AA64DFR1_EL1, AArch64 Debug Feature Register 1* on page D7-1880
ID_AA64ISAR0_EL1	*ID_AA64ISAR0_EL1, AArch64 Instruction Set Attribute Register 0* on page D7-1881
ID_AA64ISAR1_EL1	*ID_AA64ISAR1_EL1, AArch64 Instruction Set Attribute Register 1* on page D7-1883
ID_AA64MMFR0_EL1	*ID_AA64MMFR0_EL1, AArch64 Memory Model Feature Register 0* on page D7-1884
ID_AA64MMFR1_EL1	*ID_AA64MMFR1_EL1, AArch64 Memory Model Feature Register 1* on page D7-1886
ID_AA64PFR0_EL1	*ID_AA64PFR0_EL1, AArch64 Processor Feature Register 0* on page D7-1887

Table J-8 ID registers (continued)

Register	Description, see
ID_AA64PFR1_EL1	*ID_AA64PFR1_EL1, AArch64 Processor Feature Register 1* on page D7-1889
ID_AFR0_EL1	*ID_AFR0_EL1, AArch32 Auxiliary Feature Register 0* on page D7-1890
ID_DFR0_EL1	*ID_DFR0_EL1, AArch32 Debug Feature Register 0* on page D7-1891
ID_ISAR0_EL1	*ID_ISAR0_EL1, AArch32 Instruction Set Attribute Register 0* on page D7-1892
ID_ISAR1_EL1	*ID_ISAR1_EL1, AArch32 Instruction Set Attribute Register 1* on page D7-1893
ID_ISAR2_EL1	*ID_ISAR2_EL1, AArch32 Instruction Set Attribute Register 2* on page D7-1894
ID_ISAR3_EL1	*ID_ISAR3_EL1, AArch32 Instruction Set Attribute Register 3* on page D7-1895
ID_ISAR4_EL1	*ID_ISAR4_EL1, AArch32 Instruction Set Attribute Register 4* on page D7-1896
ID_ISAR5_EL1	*ID_ISAR5_EL1, AArch32 Instruction Set Attribute Register 5* on page D7-1897
ID_MMFR0_EL1	*ID_MMFR0_EL1, AArch32 Memory Model Feature Register 0* on page D7-1898
ID_MMFR1_EL1	*ID_MMFR1_EL1, AArch32 Memory Model Feature Register 1* on page D7-1899
ID_MMFR2_EL1	*ID_MMFR2_EL1, AArch32 Memory Model Feature Register 2* on page D7-1900
ID_MMFR3_EL1	*ID_MMFR3_EL1, AArch32 Memory Model Feature Register 3* on page D7-1901
ID_PFR0_EL1	*ID_PFR0_EL1, AArch32 Processor Feature Register 0* on page D7-1902
ID_PFR1_EL1	*ID_PFR1_EL1, AArch32 Processor Feature Register 1* on page D7-1903
MIDR_EL1	*MIDR_EL1, Main ID Register* on page D7-1916
MPIDR_EL1	*MPIDR_EL1, Multiprocessor Affinity Register* on page D7-1918
MVFR0_EL1	*MVFR0_EL1, AArch32 Media and Floating-point Feature Register 0* on page D7-1920
MVFR1_EL1	*MVFR1_EL1, AArch32 Media and Floating-point Feature Register 1* on page D7-1921
MVFR2_EL1	*MVFR2_EL1, AArch32 Media and Floating-point Feature Register 2* on page D7-1922
REVIDR_EL1	*REVIDR_EL1, Revision ID Register* on page D7-1926
VMPIDR_EL2	*VMPIDR_EL2, Virtualization Multiprocessor ID Register* on page D7-1982
VPIDR_EL2	*VPIDR_EL2, Virtualization Processor ID Register* on page D7-1983

J.3.4 Performance monitors registers

This section is an index to the registers in the Performance Monitors registers functional group.

Table J-9 Performance monitors registers

Register	Description, see
PMCCFILTR_EL0	*PMCCFILTR_EL0, Performance Monitors Cycle Count Filter Register* on page D7-2046
PMCCNTR_EL0	*PMCCNTR_EL0, Performance Monitors Cycle Count Register* on page D7-2048
PMCEID0_EL0	*PMCEID0_EL0, Performance Monitors Common Event Identification register 0* on page D7-2050
PMCEID1_EL0	*PMCEID1_EL0, Performance Monitors Common Event Identification register 1* on page D7-2052

Table J-9 Performance monitors registers (continued)

Register	Description, see
PMCNTENCLR_EL0	*PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register* on page D7-2054
PMCNTENSET_EL0	*PMCNTENSET_EL0, Performance Monitors Count Enable Set register* on page D7-2056
PMCR_EL0	*PMCR_EL0, Performance Monitors Control Register* on page D7-2058
PMEVCNTR<n>_EL0	*PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30* on page D7-2061
PMEVTYPER<n>_EL0	*PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30* on page D7-2063
PMINTENCLR_EL1	*PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register* on page D7-2066
PMINTENSET_EL1	*PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register* on page D7-2068
PMOVSCLR_EL0	*PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear Register* on page D7-2070
PMOVSSET_EL0	*PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register* on page D7-2072
PMSELR_EL0	*PMSELR_EL0, Performance Monitors Event Counter Selection Register* on page D7-2074
PMSWINC_EL0	*PMSWINC_EL0, Performance Monitors Software Increment register* on page D7-2076
PMUSERENR_EL0	*PMUSERENR_EL0, Performance Monitors User Enable Register* on page D7-2078
PMXEVCNTR_EL0	*PMXEVCNTR_EL0, Performance Monitors Selected Event Count Register* on page D7-2080
PMXEVTYPER_EL0	*PMXEVTYPER_EL0, Performance Monitors Selected Event Type Register* on page D7-2081

J.3.5 Debug registers

This section is an index to the registers in the Debug registers functional group.

Table J-10 Debug registers

Register	Description, see
DBGAUTHSTATUS_EL1	*DBGAUTHSTATUS_EL1, Debug Authentication Status register* on page D7-1989
DBGBCR<n>_EL1	*DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15* on page D7-1991
DBGBVR<n>_EL1	*DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15* on page D7-1994
DBGCLAIMCLR_EL1	*DBGCLAIMCLR_EL1, Debug Claim Tag Clear register* on page D7-1997
DBGCLAIMSET_EL1	*DBGCLAIMSET_EL1, Debug Claim Tag Set register* on page D7-1998
DBGDTR_EL0	*DBGDTR_EL0, Debug Data Transfer Register, half-duplex* on page D7-1999
DBGDTRRX_EL0	*DBGDTRRX_EL0, Debug Data Transfer Register, Receive* on page D7-2001
DBGDTRTX_EL0	*DBGDTRTX_EL0, Debug Data Transfer Register, Transmit* on page D7-2003
DBGPRCR_EL1	*DBGPRCR_EL1, Debug Power Control Register* on page D7-2005
DBGVCR32_EL2	*DBGVCR32_EL2, Debug Vector Catch Register* on page D7-2007
DBGWCR<n>_EL1	*DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15* on page D7-2011
DBGWVR<n>_EL1	*DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15* on page D7-2014
DLR_EL0	*DLR_EL0, Debug Link Register* on page D7-2016

Table J-10 Debug registers (continued)

Register	Description, see
DSPSR_EL0	*DSPSR_EL0, Debug Saved Program Status Register* on page D7-2017
MDCCINT_EL1	*MDCCINT_EL1, Monitor DCC Interrupt Enable Register* on page D7-2022
MDCCSR_EL0	*MDCCSR_EL0, Monitor DCC Status Register* on page D7-2024
MDCR_EL2	*MDCR_EL2, Monitor Debug Configuration Register (EL2)* on page D7-2026
MDCR_EL3	*MDCR_EL3, Monitor Debug Configuration Register (EL3)* on page D7-2029
MDRAR_EL1	*MDRAR_EL1, Monitor Debug ROM Address Register* on page D7-2032
MDSCR_EL1	*MDSCR_EL1, Monitor Debug System Control Register* on page D7-2034
OSDLR_EL1	*OSDLR_EL1, OS Double Lock Register* on page D7-2037
OSDTRRX_EL1	*OSDTRRX_EL1, OS Lock Data Transfer Register, Receive* on page D7-2038
OSDTRTX_EL1	*OSDTRTX_EL1, OS Lock Data Transfer Register, Transmit* on page D7-2039
OSECCR_EL1	*OSECCR_EL1, OS Lock Exception Catch Control Register* on page D7-2040
OSLAR_EL1	*OSLAR_EL1, OS Lock Access Register* on page D7-2041
OSLSR_EL1	*OSLSR_EL1, OS Lock Status Register* on page D7-2042
SDER32_EL3	*SDER32_EL3, AArch32 Secure Debug Enable Register* on page D7-2044

J.3.6 Generic timer registers

This section is an index to the registers in the Generic Timer registers functional group.

Table J-11 Generic timer registers

Register	Description, see
CNTFRQ_EL0	*CNTFRQ_EL0, Counter-timer Frequency register* on page D7-2082
CNTHCTL_EL2	*CNTHCTL_EL2, Counter-timer Hypervisor Control register* on page D7-2083
CNTHP_CTL_EL2	*CNTHP_CTL_EL2, Counter-timer Hypervisor Physical Timer Control register* on page D7-2085
CNTHP_CVAL_EL2	*CNTHP_CVAL_EL2, Counter-timer Hypervisor Physical Timer CompareValue register* on page D7-2087
CNTHP_TVAL_EL2	*CNTHP_TVAL_EL2, Counter-timer Hypervisor Physical Timer TimerValue register* on page D7-2088
CNTKCTL_EL1	*CNTKCTL_EL1, Counter-timer Kernel Control register* on page D7-2089
CNTP_CTL_EL0	*CNTP_CTL_EL0, Counter-timer Physical Timer Control register* on page D7-2091
CNTP_CVAL_EL0	*CNTP_CVAL_EL0, Counter-timer Physical Timer CompareValue register* on page D7-2093
CNTP_TVAL_EL0	*CNTP_TVAL_EL0, Counter-timer Physical Timer TimerValue register* on page D7-2094
CNTPCT_EL0	*CNTPCT_EL0, Counter-timer Physical Count register* on page D7-2095
CNTPS_CTL_EL1	*CNTPS_CTL_EL1, Counter-timer Physical Secure Timer Control register* on page D7-2096
CNTPS_CVAL_EL1	*CNTPS_CVAL_EL1, Counter-timer Physical Secure Timer CompareValue register* on page D7-2098
CNTPS_TVAL_EL1	*CNTPS_TVAL_EL1, Counter-timer Physical Secure Timer TimerValue register* on page D7-2099

Table J-11 Generic timer registers (continued)

Register	Description, see
CNTV_CTL_EL0	*CNTV_CTL_EL0, Counter-timer Virtual Timer Control register* on page D7-2100
CNTV_CVAL_EL0	*CNTV_CVAL_EL0, Counter-timer Virtual Timer CompareValue register* on page D7-2102
CNTV_TVAL_EL0	*CNTV_TVAL_EL0, Counter-timer Virtual Timer TimerValue register* on page D7-2103
CNTVCT_EL0	*CNTVCT_EL0, Counter-timer Virtual Count register* on page D7-2104
CNTVOFF_EL2	*CNTVOFF_EL2, Counter-timer Virtual Offset register* on page D7-2105

J.3.7 Generic Interrupt Controller CPU interface registers

This section is an index to the registers in the GIC registers functional group.

Table J-12 Generic Interrupt Controller CPU interface registers

Register	Description, see
ICC_AP0R0_EL1	*ICC_AP0R0_EL1, Interrupt Controller Active Priorities Register (0,0)* on page D7-2106
ICC_AP0R1_EL1	*ICC_AP0R1_EL1, Interrupt Controller Active Priorities Register (0,1)* on page D7-2108
ICC_AP0R2_EL1	*ICC_AP0R2_EL1, Interrupt Controller Active Priorities Register (0,2)* on page D7-2110
ICC_AP0R3_EL1	*ICC_AP0R3_EL1, Interrupt Controller Active Priorities Register (0,3)* on page D7-2112
ICC_AP1R0_EL1	*ICC_AP1R0_EL1, Interrupt Controller Active Priorities Register (1,0)* on page D7-2114
ICC_AP1R1_EL1	*ICC_AP1R1_EL1, Interrupt Controller Active Priorities Register (1,1)* on page D7-2116
ICC_AP1R2_EL1	*ICC_AP1R2_EL1, Interrupt Controller Active Priorities Register (1,2)* on page D7-2118
ICC_AP1R3_EL1	*ICC_AP1R3_EL1, Interrupt Controller Active Priorities Register (1,3)* on page D7-2120
ICC_ASGI1R_EL1	*ICC_ASGI1R_EL1, Interrupt Controller Alias Software Generated Interrupt group 1 Register* on page D7-2122
ICC_BPR0_EL1	*ICC_BPR0_EL1, Interrupt Controller Binary Point Register 0* on page D7-2124
ICC_BPR1_EL1	*ICC_BPR1_EL1, Interrupt Controller Binary Point Register 1* on page D7-2126
ICC_CTLR_EL1	*ICC_CTLR_EL1, Interrupt Controller Control Register (EL1)* on page D7-2128
ICC_CTLR_EL3	*ICC_CTLR_EL3, Interrupt Controller Control Register (EL3)* on page D7-2131
ICC_DIR_EL1	*ICC_DIR_EL1, Interrupt Controller Deactivate Interrupt Register* on page D7-2134
ICC_EOIR0_EL1	*ICC_EOIR0_EL1, Interrupt Controller End Of Interrupt Register 0* on page D7-2135
ICC_EOIR1_EL1	*ICC_EOIR1_EL1, Interrupt Controller End Of Interrupt Register 1* on page D7-2137
ICC_HPPIR0_EL1	*ICC_HPPIR0_EL1, Interrupt Controller Highest Priority Pending Interrupt Register 0* on page D7-2139
ICC_HPPIR1_EL1	*ICC_HPPIR1_EL1, Interrupt Controller Highest Priority Pending Interrupt Register 1* on page D7-2141
ICC_IAR0_EL1	*ICC_IAR0_EL1, Interrupt Controller Interrupt Acknowledge Register 0* on page D7-2142
ICC_IAR1_EL1	*ICC_IAR1_EL1, Interrupt Controller Interrupt Acknowledge Register 1* on page D7-2144
ICC_IGRPEN0_EL1	*ICC_IGRPEN0_EL1, Interrupt Controller Interrupt Group 0 Enable register* on page D7-2145
ICC_IGRPEN1_EL1	*ICC_IGRPEN1_EL1, Interrupt Controller Interrupt Group 1 Enable register* on page D7-2147

Table J-12 Generic Interrupt Controller CPU interface registers (continued)

Register	Description, see
ICC_IGRPEN1_EL3	*ICC_IGRPEN1_EL3, Interrupt Controller Interrupt Group 1 Enable register (EL3)* on page D7-2149
ICC_PMR_EL1	*ICC_PMR_EL1, Interrupt Controller Interrupt Priority Mask Register* on page D7-2151
ICC_RPR_EL1	*ICC_RPR_EL1, Interrupt Controller Running Priority Register* on page D7-2153
ICC_SEIEN_EL1	*ICC_SEIEN_EL1, Interrupt Controller System Error Interrupt Enable register* on page D7-2154
ICC_SGI0R_EL1	*ICC_SGI0R_EL1, Interrupt Controller Software Generated Interrupt group 0 Register* on page D7-2155
ICC_SGI1R_EL1	*ICC_SGI1R_EL1, Interrupt Controller Software Generated Interrupt group 1 Register* on page D7-2157
ICC_SRE_EL1	*ICC_SRE_EL1, Interrupt Controller System Register Enable register (EL1)* on page D7-2159
ICC_SRE_EL2	*ICC_SRE_EL2, Interrupt Controller System Register Enable register (EL2)* on page D7-2161
ICC_SRE_EL3	*ICC_SRE_EL3, Interrupt Controller System Register Enable register (EL3)* on page D7-2163
ICH_AP0R0_EL2	*ICH_AP0R0_EL2, Interrupt Controller Hyp Active Priorities Register (0,0)* on page D7-2165
ICH_AP0R1_EL2	*ICH_AP0R1_EL2, Interrupt Controller Hyp Active Priorities Register (0,1)* on page D7-2167
ICH_AP0R2_EL2	*ICH_AP0R2_EL2, Interrupt Controller Hyp Active Priorities Register (0,2)* on page D7-2169
ICH_AP0R3_EL2	*ICH_AP0R3_EL2, Interrupt Controller Hyp Active Priorities Register (0,3)* on page D7-2171
ICH_AP1R0_EL2	*ICH_AP1R0_EL2, Interrupt Controller Hyp Active Priorities Register (1,0)* on page D7-2173
ICH_AP1R1_EL2	*ICH_AP1R1_EL2, Interrupt Controller Hyp Active Priorities Register (1,1)* on page D7-2175
ICH_AP1R2_EL2	*ICH_AP1R2_EL2, Interrupt Controller Hyp Active Priorities Register (1,2)* on page D7-2177
ICH_AP1R3_EL2	*ICH_AP1R3_EL2, Interrupt Controller Hyp Active Priorities Register (1,3)* on page D7-2179
ICH_EISR_EL2	*ICH_EISR_EL2, Interrupt Controller End of Interrupt Status Register* on page D7-2181
ICH_ELSR_EL2	*ICH_ELSR_EL2, Interrupt Controller Empty List Register Status Register* on page D7-2183
ICH_HCR_EL2	*ICH_HCR_EL2, Interrupt Controller Hyp Control Register* on page D7-2185
ICH_LR<n>_EL2	*ICH_LR<n>_EL2, Interrupt Controller List Registers, n = 0 - 15* on page D7-2189
ICH_MISR_EL2	*ICH_MISR_EL2, Interrupt Controller Maintenance Interrupt State Register* on page D7-2192
ICH_VMCR_EL2	*ICH_VMCR_EL2, Interrupt Controller Virtual Machine Control Register* on page D7-2194
ICH_VSEIR_EL2	*ICH_VSEIR_EL2, Interrupt Controller Virtual System Error Interrupt Register* on page D7-2196
ICH_VTR_EL2	*ICH_VTR_EL2, Interrupt Controller VGIC Type Register* on page D7-2197

J.3.8 Cache maintenance system instructions

This section is an index to the registers in the Cache maintenance instructions functional group.

Table J-13 Cache maintenance system instructions

Register	Description, see
DC CISW	*DC CISW, Data or unified Cache line Clean and Invalidate by Set/Way* on page C5-304
DC CIVAC	*DC CIVAC, Data or unified Cache line Clean and Invalidate by VA to PoC* on page C5-306
DC CSW	*DC CSW, Data or unified Cache line Clean by Set/Way* on page C5-307
DC CVAC	*DC CVAC, Data or unified Cache line Clean by VA to PoC* on page C5-309
DC CVAU	*DC CVAU, Data or unified Cache line Clean by VA to PoU* on page C5-310
DC ISW	*DC ISW, Data or unified Cache line Invalidate by Set/Way* on page C5-311
DC IVAC	*DC IVAC, Data or unified Cache line Invalidate by VA to PoC* on page C5-313
DC ZVA	*DC ZVA, Data Cache Zero by VA* on page C5-314
IC IALLU	*IC IALLU, Instruction Cache Invalidate All to PoU* on page C5-316
IC IALLUIS	*IC IALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable* on page C5-317
IC IVAU	*IC IVAU, Instruction Cache line Invalidate by VA to PoU* on page C5-318

J.3.9 Address translation system instructions

This section is an index to the registers in the Address translation instructions functional group.

Table J-14 Address translation system instructions

Register	Description, see
AT S12E0R	*AT S12E0R, Address Translate Stages 1 and 2 EL0 Read* on page C5-320
AT S12E0W	*AT S12E0W, Address Translate Stages 1 and 2 EL0 Write* on page C5-321
AT S12E1R	*AT S12E1R, Address Translate Stages 1 and 2 EL1 Read* on page C5-322
AT S12E1W	*AT S12E1W, Address Translate Stages 1 and 2 EL1 Write* on page C5-323
AT S1E0R	*AT S1E0R, Address Translate Stage 1 EL0 Read* on page C5-324
AT S1E0W	*AT S1E0W, Address Translate Stage 1 EL0 Write* on page C5-325
AT S1E1R	*AT S1E1R, Address Translate Stage 1 EL1 Read* on page C5-326
AT S1E1W	*AT S1E1W, Address Translate Stage 1 EL1 Write* on page C5-327
AT S1E2R	*AT S1E2R, Address Translate Stage 1 EL2 Read* on page C5-328
AT S1E2W	*AT S1E2W, Address Translate Stage 1 EL2 Write* on page C5-329
AT S1E3R	*AT S1E3R, Address Translate Stage 1 EL3 Read* on page C5-330
AT S1E3W	*AT S1E3W, Address Translate Stage 1 EL3 Write* on page C5-331

J.3.10 TLB maintenance system instructions

This section is an index to the registers in the TLB maintenance instructions functional group.

Table J-15 TLB maintenance system instructions

Register	Description, see
TLBI ALLE1	*TLBI ALLE1, TLB Invalidate All, EL1* on page C5-333
TLBI ALLE1IS	*TLBI ALLE1IS, TLB Invalidate All, EL1, Inner Shareable* on page C5-334
TLBI ALLE2	*TLBI ALLE2, TLB Invalidate All, EL2* on page C5-335
TLBI ALLE2IS	*TLBI ALLE2IS, TLB Invalidate All, EL2, Inner Shareable* on page C5-336
TLBI ALLE3	*TLBI ALLE3, TLB Invalidate All, EL3* on page C5-337
TLBI ALLE3IS	*TLBI ALLE3IS, TLB Invalidate All, EL3, Inner Shareable* on page C5-338
TLBI ASIDE1	*TLBI ASIDE1, TLB Invalidate by ASID, EL1* on page C5-339
TLBI ASIDE1IS	*TLBI ASIDE1IS, TLB Invalidate by ASID, EL1, Inner Shareable* on page C5-340
TLBI IPAS2E1	*TLBI IPAS2E1, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1* on page C5-341
TLBI IPAS2E1IS	*TLBI IPAS2E1IS, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable* on page C5-342
TLBI IPAS2LE1	*TLBI IPAS2LE1, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1* on page C5-343
TLBI IPAS2LE1IS	*TLBI IPAS2LE1IS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Inner Shareable* on page C5-344
TLBI VAAE1	*TLBI VAAE1, TLB Invalidate by VA, All ASID, EL1* on page C5-345
TLBI VAAE1IS	*TLBI VAAE1IS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable* on page C5-347
TLBI VAALE1	*TLBI VAALE1, TLB Invalidate by VA, All ASID, Last level, EL1* on page C5-349
TLBI VAALE1IS	*TLBI VAALE1IS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable* on page C5-351
TLBI VAE1	*TLBI VAE1, TLB Invalidate by VA, EL1* on page C5-353
TLBI VAE1IS	*TLBI VAE1IS, TLB Invalidate by VA, EL1, Inner Shareable* on page C5-355
TLBI VAE2	*TLBI VAE2, TLB Invalidate by VA, EL2* on page C5-357
TLBI VAE2IS	*TLBI VAE2IS, TLB Invalidate by VA, EL2, Inner Shareable* on page C5-359
TLBI VAE3	*TLBI VAE3, TLB Invalidate by VA, EL3* on page C5-361
TLBI VAE3IS	*TLBI VAE3IS, TLB Invalidate by VA, EL3, Inner Shareable* on page C5-363
TLBI VALE1	*TLBI VALE1, TLB Invalidate by VA, Last level, EL1* on page C5-365
TLBI VALE1IS	*TLBI VALE1IS, TLB Invalidate by VA, Last level, EL1, Inner Shareable* on page C5-367
TLBI VALE2	*TLBI VALE2, TLB Invalidate by VA, Last level, EL2* on page C5-369
TLBI VALE2IS	*TLBI VALE2IS, TLB Invalidate by VA, Last level, EL2, Inner Shareable* on page C5-371
TLBI VALE3	*TLBI VALE3, TLB Invalidate by VA, Last level, EL3* on page C5-373
TLBI VALE3IS	*TLBI VALE3IS, TLB Invalidate by VA, Last level, EL3, Inner Shareable* on page C5-375

Table J-15 TLB maintenance system instructions (continued)

Register	Description, see
TLBI VMALLE1	*TLBI VMALLE1, TLB Invalidate by VMID, All at stage 1, EL1* on page C5-377
TLBI VMALLE1IS	*TLBI VMALLE1IS, TLB Invalidate by VMID, All at stage 1, EL1, Inner Shareable* on page C5-378
TLBI VMALLS12E1	*TLBI VMALLS12E1, TLB Invalidate by VMID, All at Stage 1 and 2, EL1* on page C5-379
TLBI VMALLS12E1IS	*TLBI VMALLS12E1IS, TLB Invalidate by VMID, All at Stage 1 and 2, EL1, Inner Shareable* on page C5-380

J.3.11 Base system registers

This section is an index to the registers in the functional group.

Table J-16 Base system registers

Register	Description, see
ACTLR_EL1	*ACTLR_EL1, Auxiliary Control Register (EL1)* on page D7-1798
ACTLR_EL2	*ACTLR_EL2, Auxiliary Control Register (EL2)* on page D7-1799
ACTLR_EL3	*ACTLR_EL3, Auxiliary Control Register (EL3)* on page D7-1800
AFSR0_EL1	*AFSR0_EL1, Auxiliary Fault Status Register 0 (EL1)* on page D7-1801
AFSR0_EL2	*AFSR0_EL2, Auxiliary Fault Status Register 0 (EL2)* on page D7-1802
AFSR0_EL3	*AFSR0_EL3, Auxiliary Fault Status Register 0 (EL3)* on page D7-1803
AFSR1_EL1	*AFSR1_EL1, Auxiliary Fault Status Register 1 (EL1)* on page D7-1804
AFSR1_EL2	*AFSR1_EL2, Auxiliary Fault Status Register 1 (EL2)* on page D7-1805
AFSR1_EL3	*AFSR1_EL3, Auxiliary Fault Status Register 1 (EL3)* on page D7-1806
CPACR_EL1	*CPACR_EL1, Architectural Feature Access Control Register* on page D7-1816
CPTR_EL2	*CPTR_EL2, Architectural Feature Trap Register (EL2)* on page D7-1818
CPTR_EL3	*CPTR_EL3, Architectural Feature Trap Register (EL3)* on page D7-1820
CurrentEL	*CurrentEL, Current Exception Level* on page C5-253
DAIF	*DAIF, Interrupt Mask Bits* on page C5-255
ESR_EL1	*ESR_EL1, Exception Syndrome Register (EL1)* on page D7-1829
ESR_EL2	*ESR_EL2, Exception Syndrome Register (EL2)* on page D7-1830
ESR_EL3	*ESR_EL3, Exception Syndrome Register (EL3)* on page D7-1831
ESR_ELx	*ESR_ELx, Exception Syndrome Register* on page D7-1832
FAR_EL1	*FAR_EL1, Fault Address Register (EL1)* on page D7-1860
FAR_EL2	*FAR_EL2, Fault Address Register (EL2)* on page D7-1861
FAR_EL3	*FAR_EL3, Fault Address Register (EL3)* on page D7-1863
FPEXC32_EL2	*FPEXC32_EL2, Floating-point Exception Control register* on page D7-1864
HACR_EL2	*HACR_EL2, Hypervisor Auxiliary Control Register* on page D7-1865

Table J-16 Base system registers (continued)

Register	Description, see
HCR_EL2	*HCR_EL2, Hypervisor Configuration Register* on page D7-1866
HPFAR_EL2	*HPFAR_EL2, Hypervisor IPA Fault Address Register* on page D7-1873
HSTR_EL2	*HSTR_EL2, Hypervisor System Trap Register* on page D7-1874
IFSR32_EL2	*IFSR32_EL2, Instruction Fault Status Register (EL2)* on page D7-1904
ISR_EL1	*ISR_EL1, Interrupt Status Register* on page D7-1908
NZCV	*NZCV, Condition Flags* on page C5-269
PAR_EL1	*PAR_EL1, Physical Address Register* on page D7-1923
RMR_EL1	*RMR_EL1, Reset Management Register (if EL2 and EL3 not implemented)* on page D7-1927
RMR_EL2	*RMR_EL2, Reset Management Register (if EL3 not implemented)* on page D7-1929
RMR_EL3	*RMR_EL3, Reset Management Register (if EL3 implemented)* on page D7-1931
RVBAR_EL1	*RVBAR_EL1, Reset Vector Base Address Register (if EL2 and EL3 not implemented)* on page D7-1933
RVBAR_EL2	*RVBAR_EL2, Reset Vector Base Address Register (if EL3 not implemented)* on page D7-1934
RVBAR_EL3	*RVBAR_EL3, Reset Vector Base Address Register (if EL3 implemented)* on page D7-1935
S3_<op1>_<Cn>_<Cm>_<op2>	*S3_<op1>_<Cn>_<Cm>_<op2>, IMPLEMENTATION DEFINED registers* on page D7-1936
SCR_EL3	*SCR_EL3, Secure Configuration Register* on page D7-1937
SCTLR_EL1	*SCTLR_EL1, System Control Register (EL1)* on page D7-1940
SCTLR_EL2	*SCTLR_EL2, System Control Register (EL2)* on page D7-1946
SCTLR_EL3	*SCTLR_EL3, System Control Register (EL3)* on page D7-1950
SPSel	*SPSel, Stack Pointer Select* on page C5-275
TPIDR_EL0	*TPIDR_EL0, EL0 Read/Write Software Thread ID Register* on page D7-1965
TPIDR_EL1	*TPIDR_EL1, EL1 Software Thread ID Register* on page D7-1966
TPIDR_EL2	*TPIDR_EL2, EL2 Software Thread ID Register* on page D7-1967
TPIDR_EL3	*TPIDR_EL3, EL3 Software Thread ID Register* on page D7-1968
TPIDRRO_EL0	*TPIDRRO_EL0, EL0 Read-Only Software Thread ID Register* on page D7-1969
VBAR_EL1	*VBAR_EL1, Vector Base Address Register (EL1)* on page D7-1978
VBAR_EL2	*VBAR_EL2, Vector Base Address Register (EL2)* on page D7-1979
VBAR_EL3	*VBAR_EL3, Vector Base Address Register (EL3)* on page D7-1981

J.4 Alphabetical index of AArch32 registers and system instructions

This section is an index of AArch32 registers and system instructions in alphabetical order.

Table J-17 Alphabetical index of AArch32 Registers

Register	Description, see
ACTLR	*ACTLR, Auxiliary Control Register* on page G5-3824
ADFSR	*ADFSR, Auxiliary Data Fault Status Register* on page G5-3826
AIDR	*AIDR, Auxiliary ID Register* on page G5-3828
AIFSR	*AIFSR, Auxiliary Instruction Fault Status Register* on page G5-3829
AMAIR0	*AMAIR0, Auxiliary Memory Attribute Indirection Register 0* on page G5-3831
AMAIR1	*AMAIR1, Auxiliary Memory Attribute Indirection Register 1* on page G5-3833
APSR	*APSR, Application Program Status Register* on page G5-3835
ATS12NSOPR	*ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read* on page G5-3837
ATS12NSOPW	*ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write* on page G5-3838
ATS12NSOUR	*ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read* on page G5-3839
ATS12NSOUW	*ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write* on page G5-3840
ATS1CPR	*ATS1CPR, Address Translate Stage 1 Current state PL1 Read* on page G5-3841
ATS1CPW	*ATS1CPW, Address Translate Stage 1 Current state PL1 Write* on page G5-3842
ATS1CUR	*ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read* on page G5-3843
ATS1CUW	*ATS1CUW, Address Translate Stage 1 Current state Unprivileged Write* on page G5-3844
ATS1HR	*ATS1HR, Address Translate Stage 1 Hyp mode Read* on page G5-3845
ATS1HW	*ATS1HW, Address Translate Stage 1 Hyp mode Write* on page G5-3846
BPIALL	*BPIALL, Branch Predictor Invalidate All* on page G5-3847
BPIALLIS	*BPIALLIS, Branch Predictor Invalidate All, Inner Shareable* on page G5-3848
BPIMVA	*BPIMVA, Branch Predictor Invalidate by VA* on page G5-3849
CCSIDR	*CCSIDR, Current Cache Size ID Register* on page G5-3850
CLIDR	*CLIDR, Cache Level ID Register* on page G5-3852
CNTFRQ	*CNTFRQ, Counter-timer Frequency register* on page G5-4271
CNTHCTL	*CNTHCTL, Counter-timer Hyp Control register* on page G5-4273
CNTHP_CTL	*CNTHP_CTL, Counter-timer Hyp Physical Timer Control register* on page G5-4275
CNTHP_CVAL	*CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register* on page G5-4277
CNTHP_TVAL	*CNTHP_TVAL, Counter-timer Hyp Physical Timer TimerValue register* on page G5-4278
CNTKCTL	*CNTKCTL, Counter-timer Kernel Control register* on page G5-4279

Table J-17 Alphabetical index of AArch32 Registers (continued)

Register	Description, see
CNTP_CTL	*CNTP_CTL, Counter-timer Physical Timer Control register* on page G5-4281
CNTP_CVAL	*CNTP_CVAL, Counter-timer Physical Timer CompareValue register* on page G5-4283
CNTP_TVAL	*CNTP_TVAL, Counter-timer Physical Timer TimerValue register* on page G5-4285
CNTPCT	*CNTPCT, Counter-timer Physical Count register* on page G5-4287
CNTV_CTL	*CNTV_CTL, Counter-timer Virtual Timer Control register* on page G5-4288
CNTV_CVAL	*CNTV_CVAL, Counter-timer Virtual Timer CompareValue register* on page G5-4290
CNTV_TVAL	*CNTV_TVAL, Counter-timer Virtual Timer TimerValue register* on page G5-4291
CNTVCT	*CNTVCT, Counter-timer Virtual Count register* on page G5-4292
CNTVOFF	*CNTVOFF, Counter-timer Virtual Offset register* on page G5-4293
CONTEXTIDR	*CONTEXTIDR, Context ID Register* on page G5-3854
CP15DMB	*CP15DMB, CP15 Data Memory Barrier operation* on page G5-3856
CP15DSB	*CP15DSB, CP15 Data Synchronization Barrier operation* on page G5-3857
CP15ISB	*CP15ISB, CP15 Instruction Synchronization Barrier operation* on page G5-3858
CPACR	*CPACR, Architectural Feature Access Control Register* on page G5-3859
CPSR	*CPSR, Current Program Status Register* on page G5-3861
CSSELR	*CSSELR, Cache Size Selection Register* on page G5-3864
CTR	*CTR, Cache Type Register* on page G5-3866
DACR	*DACR, Domain Access Control Register* on page G5-3868
DBGAUTHSTATUS	*DBGAUTHSTATUS, Debug Authentication Status register* on page G5-4158
DBGBCR<n>	*DBGBCR<n>, Debug Breakpoint Control Registers, n = 0 - 15* on page G5-4160
DBGBVR<n>	*DBGBVR<n>, Debug Breakpoint Value Registers, n = 0 - 15* on page G5-4163
DBGBXVR<n>	*DBGBXVR<n>, Debug Breakpoint Extended Value Registers, n = 0 - 15* on page G5-4165
DBGCLAIMCLR	*DBGCLAIMCLR, Debug Claim Tag Clear register* on page G5-4167
DBGCLAIMSET	*DBGCLAIMSET, Debug Claim Tag Set register* on page G5-4169
DBGDCCINT	*DBGDCCINT, DCC Interrupt Enable Register* on page G5-4171
DBGDEVID	*DBGDEVID, Debug Device ID register 0* on page G5-4173
DBGDEVID1	*DBGDEVID1, Debug Device ID register 1* on page G5-4176
DBGDEVID2	*DBGDEVID2, Debug Device ID register 2* on page G5-4178
DBGDIDR	*DBGDIDR, Debug ID Register* on page G5-4179
DBGDRAR	*DBGDRAR, Debug ROM Address Register* on page G5-4181
DBGDSAR	*DBGDSAR, Debug Self Address Register* on page G5-4183
DBGDSCRext	*DBGDSCRext, Debug Status and Control Register, External View* on page G5-4185

Table J-17 Alphabetical index of AArch32 Registers (continued)

Register	Description, see
DBGDSCRint	*DBGDSCRint, Debug Status and Control Register, Internal View* on page G5-4189
DBGDTRRXext	*DBGDTRRXext, Debug Data Transfer Register, Receive, External View* on page G5-4192
DBGDTRRXint	*DBGDTRRXint, Debug Data Transfer Register, Receive, Internal View* on page G5-4194
DBGDTRTXext	*DBGDTRTXext, Debug Data Transfer Register, Transmit, External View* on page G5-4196
DBGDTRTXint	*DBGDTRTXint, Debug Data Transfer Register, Transmit, Internal View* on page G5-4198
DBGOSDLR	*DBGOSDLR, Debug OS Double Lock Register* on page G5-4200
DBGOSECCR	*DBGOSECCR, Debug OS Lock Exception Catch Control Register* on page G5-4202
DBGOSLAR	*DBGOSLAR, Debug OS Lock Access Register* on page G5-4203
DBGOSLSR	*DBGOSLSR, Debug OS Lock Status Register* on page G5-4204
DBGPRCR	*DBGPRCR, Debug Power Control Register* on page G5-4206
DBGVCR	*DBGVCR, Debug Vector Catch Register* on page G5-4208
DBGWCR<n>	*DBGWCR<n>, Debug Watchpoint Control Registers, n = 0 - 15* on page G5-4214
DBGWFAR	*DBGWFAR, Debug Watchpoint Fault Address Register* on page G5-4217
DBGWVR<n>	*DBGWVR<n>, Debug Watchpoint Value Registers, n = 0 - 15* on page G5-4218
DCCIMVAC	*DCCIMVAC, Data Cache line Clean and Invalidate by VA to PoC* on page G5-3870
DCCISW	*DCCISW, Data Cache line Clean and Invalidate by Set/Way* on page G5-3871
DCCMVAC	*DCCMVAC, Data Cache line Clean by VA to PoC* on page G5-3873
DCCMVAU	*DCCMVAU, Data Cache line Clean by VA to PoU* on page G5-3874
DCCSW	*DCCSW, Data Cache line Clean by Set/Way* on page G5-3875
DCIMVAC	*DCIMVAC, Data Cache line Invalidate by VA to PoC* on page G5-3877
DCISW	*DCISW, Data Cache line Invalidate by Set/Way* on page G5-3878
DFAR	*DFAR, Data Fault Address Register* on page G5-3880
DFSR	*DFSR, Data Fault Status Register* on page G5-3882
DLR	*DLR, Debug Link Register* on page G5-4220
DSPSR	*DSPSR, Debug Saved Program Status Register* on page G5-4221
DTLBIALL	*DTLBIALL, Data TLB Invalidate All* on page G5-3887
DTLBIASID	*DTLBIASID, Data TLB Invalidate by ASID match* on page G5-3888
DTLBIMVA	*DTLBIMVA, Data TLB Invalidate by VA* on page G5-3889
ELR_hyp	*ELR_hyp, Exception Link Register (Hyp mode)* on page G5-3891
FCSEIDR	*FCSEIDR, FCSE Process ID register* on page G5-3892
FPEXC	*FPEXC, Floating-Point Exception Control register* on page G5-3894
FPSCR	*FPSCR, Floating-Point Status and Control Register* on page G5-3898

Table J-17 Alphabetical index of AArch32 Registers (continued)

Register	Description, see
FPSID	*FPSID, Floating-Point System ID register* on page G5-3903
HACR	*HACR, Hyp Auxiliary Configuration Register* on page G5-3905
HACTLR	*HACTLR, Hyp Auxiliary Control Register* on page G5-3906
HADFSR	*HADFSR, Hyp Auxiliary Data Fault Status Register* on page G5-3907
HAIFSR	*HAIFSR, Hyp Auxiliary Instruction Fault Status Register* on page G5-3908
HAMAIR0	*HAMAIR0, Hyp Auxiliary Memory Attribute Indirection Register 0* on page G5-3909
HAMAIR1	*HAMAIR1, Hyp Auxiliary Memory Attribute Indirection Register 1* on page G5-3910
HCPTR	*HCPTR, Hyp Architectural Feature Trap Register* on page G5-3911
HCR	*HCR, Hyp Configuration Register* on page G5-3914
HCR2	*HCR2, Hyp Configuration Register 2* on page G5-3920
HDCR	*HDCR, Hyp Debug Control Register* on page G5-4225
HDFAR	*HDFAR, Hyp Data Fault Address Register* on page G5-3922
HIFAR	*HIFAR, Hyp Instruction Fault Address Register* on page G5-3923
HMAIR0	*HMAIR0, Hyp Memory Attribute Indirection Register 0* on page G5-3924
HMAIR1	*HMAIR1, Hyp Memory Attribute Indirection Register 1* on page G5-3927
HPFAR	*HPFAR, Hyp IPA Fault Address Register* on page G5-3930
HRMR	*HRMR, Hyp Reset Management Register* on page G5-3931
HSCTLR	*HSCTLR, Hyp System Control Register* on page G5-3933
HSR	*HSR, Hyp Syndrome Register* on page G5-3938
HSTR	*HSTR, Hyp System Trap Register* on page G5-3954
HTCR	*HTCR, Hyp Translation Control Register* on page G5-3956
HTPIDR	*HTPIDR, Hyp Software Thread ID Register* on page G5-3958
HTTBR	*HTTBR, Hyp Translation Table Base Register* on page G5-3959
HVBAR	*HVBAR, Hyp Vector Base Address Register* on page G5-3961
ICC_AP0R0	*ICC_AP0R0, Interrupt Controller Active Priorities Register (0,0)* on page G5-4294
ICC_AP0R1	*ICC_AP0R1, Interrupt Controller Active Priorities Register (0,1)* on page G5-4296
ICC_AP0R2	*ICC_AP0R2, Interrupt Controller Active Priorities Register (0,2)* on page G5-4298
ICC_AP0R3	*ICC_AP0R3, Interrupt Controller Active Priorities Register (0,3)* on page G5-4300
ICC_AP1R0	*ICC_AP1R0, Interrupt Controller Active Priorities Register (1,0)* on page G5-4302
ICC_AP1R1	*ICC_AP1R1, Interrupt Controller Active Priorities Register (1,1)* on page G5-4304
ICC_AP1R2	*ICC_AP1R2, Interrupt Controller Active Priorities Register (1,2)* on page G5-4306
ICC_AP1R3	*ICC_AP1R3, Interrupt Controller Active Priorities Register (1,3)* on page G5-4308

Table J-17 Alphabetical index of AArch32 Registers (continued)

Register	Description, see
ICC_ASGI1R	*ICC_ASGI1R, Interrupt Controller Alias Software Generated Interrupt group 1 Register* on page G5-4310
ICC_BPR0	*ICC_BPR0, Interrupt Controller Binary Point Register 0* on page G5-4312
ICC_BPR1	*ICC_BPR1, Interrupt Controller Binary Point Register 1* on page G5-4314
ICC_CTLR	*ICC_CTLR, Interrupt Controller Control Register* on page G5-4316
ICC_DIR	*ICC_DIR, Interrupt Controller Deactivate Interrupt Register* on page G5-4319
ICC_EOIR0	*ICC_EOIR0, Interrupt Controller End Of Interrupt Register 0* on page G5-4320
ICC_EOIR1	*ICC_EOIR1, Interrupt Controller End Of Interrupt Register 1* on page G5-4322
ICC_HPPIR0	*ICC_HPPIR0, Interrupt Controller Highest Priority Pending Interrupt Register 0* on page G5-4324
ICC_HPPIR1	*ICC_HPPIR1, Interrupt Controller Highest Priority Pending Interrupt Register 1* on page G5-4326
ICC_HSRE	*ICC_HSRE, Interrupt Controller Hyp System Register Enable register* on page G5-4327
ICC_IAR0	*ICC_IAR0, Interrupt Controller Interrupt Acknowledge Register 0* on page G5-4329
ICC_IAR1	*ICC_IAR1, Interrupt Controller Interrupt Acknowledge Register 1* on page G5-4331
ICC_IGRPEN0	*ICC_IGRPEN0, Interrupt Controller Interrupt Group 0 Enable register* on page G5-4333
ICC_IGRPEN1	*ICC_IGRPEN1, Interrupt Controller Interrupt Group 1 Enable register* on page G5-4335
ICC_MCTLR	*ICC_MCTLR, Interrupt Controller Monitor Control Register* on page G5-4336
ICC_MGRPEN1	*ICC_MGRPEN1, Interrupt Controller Monitor Interrupt Group 1 Enable register* on page G5-4339
ICC_MSRE	*ICC_MSRE, Interrupt Controller Monitor System Register Enable register* on page G5-4341
ICC_PMR	*ICC_PMR, Interrupt Controller Interrupt Priority Mask Register* on page G5-4343
ICC_RPR	*ICC_RPR, Interrupt Controller Running Priority Register* on page G5-4345
ICC_SEIEN	*ICC_SEIEN, Interrupt Controller System Error Interrupt Enable register* on page G5-4346
ICC_SGI0R	*ICC_SGI0R, Interrupt Controller Software Generated Interrupt group 0 Register* on page G5-4347
ICC_SGI1R	*ICC_SGI1R, Interrupt Controller Software Generated Interrupt group 1 Register* on page G5-4349
ICC_SRE	*ICC_SRE, Interrupt Controller System Register Enable register* on page G5-4351
ICH_AP0R0	*ICH_AP0R0, Interrupt Controller Hyp Active Priorities Register (0,0)* on page G5-4353
ICH_AP0R1	*ICH_AP0R1, Interrupt Controller Hyp Active Priorities Register (0,1)* on page G5-4355
ICH_AP0R2	*ICH_AP0R2, Interrupt Controller Hyp Active Priorities Register (0,2)* on page G5-4357
ICH_AP0R3	*ICH_AP0R3, Interrupt Controller Hyp Active Priorities Register (0,3)* on page G5-4359
ICH_AP1R0	*ICH_AP1R0, Interrupt Controller Hyp Active Priorities Register (1,0)* on page G5-4361

Table J-17 Alphabetical index of AArch32 Registers (continued)

Register	Description, see
ICH_AP1R1	*ICH_AP1R1, Interrupt Controller Hyp Active Priorities Register (1,1)* on page G5-4363
ICH_AP1R2	*ICH_AP1R2, Interrupt Controller Hyp Active Priorities Register (1,2)* on page G5-4365
ICH_AP1R3	*ICH_AP1R3, Interrupt Controller Hyp Active Priorities Register (1,3)* on page G5-4367
ICH_EISR	*ICH_EISR, Interrupt Controller End of Interrupt Status Register* on page G5-4369
ICH_ELSR	*ICH_ELSR, Interrupt Controller Empty List Register Status Register* on page G5-4371
ICH_HCR	*ICH_HCR, Interrupt Controller Hyp Control Register* on page G5-4373

TLBTR	*TLBTR, TLB Type Register* on page G5-4130
TPIDRPRW	*TPIDRPRW, PL1 Software Thread ID Register* on page G5-4131
TPIDRURO	*TPIDRURO, PL0 Read-Only Software Thread ID Register* on page G5-4133
TPIDRURW	*TPIDRURW, PL0 Read/Write Software Thread ID Register* on page G5-4135
TTBCR	*TTBCR, Translation Table Base Control Register* on page G5-4137
TTBR0	*TTBR0, Translation Table Base Register 0* on page G5-4142
TTBR1	*TTBR1, Translation Table Base Register 1* on page G5-4146
VBAR	*VBAR, Vector Base Address Register* on page G5-4150
VMPIDR	*VMPIDR, Virtualization Multiprocessor ID Register* on page G5-4152
VPIDR	*VPIDR, Virtualization Processor ID Register* on page G5-4153
VTCR	*VTCR, Virtualization Translation Control Register* on page G5-4154
VTTBR	*VTTBR, Virtualization Translation Table Base Register* on page G5-4156

J.5 Functional index of AArch32 registers and system instructions

This section is an index of the AArch32 registers and system instructions, divided by functional group.

J.5.1 Special-purpose registers

This section is an index to the registers in the Processor state registers functional group.

Table J-18 Special-purpose registers

Register	Description, see
DLR	*DLR, Debug Link Register* on page G5-4220
DSPSR	*DSPSR, Debug Saved Program Status Register* on page G5-4221
ELR_hyp	*ELR_hyp, Exception Link Register (Hyp mode)* on page G5-3891
FPSCR	*FPSCR, Floating-Point Status and Control Register* on page G5-3898
SPSR_abt	*SPSR_abt, Saved Program Status Register (Abort mode)* on page G5-4075
SPSR_fiq	*SPSR_fiq, Saved Program Status Register (FIQ mode)* on page G5-4078
SPSR_hyp	*SPSR_hyp, Saved Program Status Register (Hyp mode)* on page G5-4081
SPSR_irq	*SPSR_irq, Saved Program Status Register (IRQ mode)* on page G5-4084
SPSR_mon	*SPSR_mon, Saved Program Status Register (Monitor mode)* on page G5-4087
SPSR_svc	*SPSR_svc, Saved Program Status Register (Sup. Call mode)* on page G5-4090
SPSR_und	*SPSR_und, Saved Program Status Register (Undefined mode)* on page G5-4093

J.5.2 VMSA-specific registers

This section is an index to the registers in the Virtual memory control registers functional group.

Table J-19 VMSA-specific registers

Register	Description, see
AMAIR0	*AMAIR0, Auxiliary Memory Attribute Indirection Register 0* on page G5-3831
AMAIR1	*AMAIR1, Auxiliary Memory Attribute Indirection Register 1* on page G5-3833
CONTEXTIDR	*CONTEXTIDR, Context ID Register* on page G5-3854
DACR	*DACR, Domain Access Control Register* on page G5-3868
HAMAIR0	*HAMAIR0, Hyp Auxiliary Memory Attribute Indirection Register 0* on page G5-3909
HAMAIR1	*HAMAIR1, Hyp Auxiliary Memory Attribute Indirection Register 1* on page G5-3910
HMAIR0	*HMAIR0, Hyp Memory Attribute Indirection Register 0* on page G5-3924
HMAIR1	*HMAIR1, Hyp Memory Attribute Indirection Register 1* on page G5-3927
HTCR	*HTCR, Hyp Translation Control Register* on page G5-3956
HTTBR	*HTTBR, Hyp Translation Table Base Register* on page G5-3959
MAIR0	*MAIR0, Memory Attribute Indirection Register 0* on page G5-4020
MAIR1	*MAIR1, Memory Attribute Indirection Register 1* on page G5-4023

Table J-19 VMSA-specific registers (continued)

Register	Description, see
NMRR	*NMRR, Normal Memory Remap Register* on page G5-4041
PRRR	*PRRR, Primary Region Remap Register* on page G5-4052
TTBCR	*TTBCR, Translation Table Base Control Register* on page G5-4137
TTBR0	*TTBR0, Translation Table Base Register 0* on page G5-4142
TTBR1	*TTBR1, Translation Table Base Register 1* on page G5-4146
VTCR	*VTCR, Virtualization Translation Control Register* on page G5-4154
VTTBR	*VTTBR, Virtualization Translation Table Base Register* on page G5-4156

J.5.3 ID registers

This section is an index to the registers in the Identification registers functional group.

Table J-20 ID registers

Register	Description, see
AIDR	*AIDR, Auxiliary ID Register* on page G5-3828
CCSIDR	*CCSIDR, Current Cache Size ID Register* on page G5-3850
CLIDR	*CLIDR, Cache Level ID Register* on page G5-3852
CSSELR	*CSSELR, Cache Size Selection Register* on page G5-3864
CTR	*CTR, Cache Type Register* on page G5-3866
FPSID	*FPSID, Floating-Point System ID register* on page G5-3903
ID_AFR0	*ID_AFR0, Auxiliary Feature Register 0* on page G5-3965
ID_DFR0	*ID_DFR0, Debug Feature Register 0* on page G5-3966
ID_ISAR0	*ID_ISAR0, Instruction Set Attribute Register 0* on page G5-3969
ID_ISAR1	*ID_ISAR1, Instruction Set Attribute Register 1* on page G5-3971
ID_ISAR2	*ID_ISAR2, Instruction Set Attribute Register 2* on page G5-3974
ID_ISAR3	*ID_ISAR3, Instruction Set Attribute Register 3* on page G5-3977
ID_ISAR4	*ID_ISAR4, Instruction Set Attribute Register 4* on page G5-3980
ID_ISAR5	*ID_ISAR5, Instruction Set Attribute Register 5* on page G5-3983
ID_MMFR0	*ID_MMFR0, Memory Model Feature Register 0* on page G5-3985
ID_MMFR1	*ID_MMFR1, Memory Model Feature Register 1* on page G5-3988
ID_MMFR2	*ID_MMFR2, Memory Model Feature Register 2* on page G5-3993
ID_MMFR3	*ID_MMFR3, Memory Model Feature Register 3* on page G5-3997
ID_PFR0	*ID_PFR0, Processor Feature Register 0* on page G5-4000
ID_PFR1	*ID_PFR1, Processor Feature Register 1* on page G5-4002

Table J-20 ID registers (continued)

Register	Description, see
MIDR	*MIDR, Main ID Register* on page G5-4026
MPIDR	*MPIDR, Multiprocessor Affinity Register* on page G5-4029
MVFR0	*MVFR0, Media and Floating-point Feature Register 0* on page G5-4033
MVFR1	*MVFR1, Media and Floating-point Feature Register 1* on page G5-4036
MVFR2	*MVFR2, Media and Floating-point Feature Register 2* on page G5-4039
REVIDR	*REVIDR, Revision ID Register* on page G5-4055
TCMTR	*TCMTR, TCM Type Register* on page G5-4096
TLBTR	*TLBTR, TLB Type Register* on page G5-4130
VMPIDR	*VMPIDR, Virtualization Multiprocessor ID Register* on page G5-4152
VPIDR	*VPIDR, Virtualization Processor ID Register* on page G5-4153

J.5.4 Performance monitors registers

This section is an index to the registers in the Performance Monitors registers functional group.

Table J-21 Performance monitors registers

Register	Description, see
PMCCFILTR	*PMCCFILTR, Performance Monitors Cycle Count Filter Register* on page G5-4232
PMCCNTR	*PMCCNTR, Performance Monitors Cycle Count Register* on page G5-4234
PMCEID0	*PMCEID0, Performance Monitors Common Event Identification register 0* on page G5-4236
PMCEID1	*PMCEID1, Performance Monitors Common Event Identification register 1* on page G5-4239
PMCNTENCLR	*PMCNTENCLR, Performance Monitors Count Enable Clear register* on page G5-4241
PMCNTENSET	*PMCNTENSET, Performance Monitors Count Enable Set register* on page G5-4243
PMCR	*PMCR, Performance Monitors Control Register* on page G5-4245
PMEVCNTR<n>	*PMEVCNTR<n>, Performance Monitors Event Count Registers, n = 0 - 30* on page G5-4248
PMEVTYPER<n>	*PMEVTYPER<n>, Performance Monitors Event Type Registers, n = 0 - 30* on page G5-4250
PMINTENCLR	*PMINTENCLR, Performance Monitors Interrupt Enable Clear register* on page G5-4253
PMINTENSET	*PMINTENSET, Performance Monitors Interrupt Enable Set register* on page G5-4255
PMOVSR	*PMOVSR, Performance Monitors Overflow Flag Status Register* on page G5-4257
PMOVSSET	*PMOVSSET, Performance Monitors Overflow Flag Status Set register* on page G5-4259
PMSELR	*PMSELR, Performance Monitors Event Counter Selection Register* on page G5-4261
PMSWINC	*PMSWINC, Performance Monitors Software Increment register* on page G5-4263

Table J-21 Performance monitors registers (continued)

Register	Description, see
PMUSERENR	*PMUSERENR, Performance Monitors User Enable Register* on page G5-4265
PMXEVCNTR	*PMXEVCNTR, Performance Monitors Selected Event Count Register* on page G5-4267
PMXEVTYPER	*PMXEVTYPER, Performance Monitors Selected Event Type Register* on page G5-4269

J.5.5 Debug registers

This section is an index to the registers in the Debug registers functional group.

Table J-22 Debug registers

Register	Description, see
DBGAUTHSTATUS	*DBGAUTHSTATUS, Debug Authentication Status register* on page G5-4158
DBGBCR<n>	*DBGBCR<n>, Debug Breakpoint Control Registers, n = 0 - 15* on page G5-4160
DBGBVR<n>	*DBGBVR<n>, Debug Breakpoint Value Registers, n = 0 - 15* on page G5-4163
DBGBXVR<n>	*DBGBXVR<n>, Debug Breakpoint Extended Value Registers, n = 0 - 15* on page G5-4165
DBGCLAIMCLR	*DBGCLAIMCLR, Debug Claim Tag Clear register* on page G5-4167
DBGCLAIMSET	*DBGCLAIMSET, Debug Claim Tag Set register* on page G5-4169
DBGDCCINT	*DBGDCCINT, DCC Interrupt Enable Register* on page G5-4171
DBGDEVID	*DBGDEVID, Debug Device ID register 0* on page G5-4173
DBGDEVID1	*DBGDEVID1, Debug Device ID register 1* on page G5-4176
DBGDEVID2	*DBGDEVID2, Debug Device ID register 2* on page G5-4178
DBGDIDR	*DBGDIDR, Debug ID Register* on page G5-4179
DBGDRAR	*DBGDRAR, Debug ROM Address Register* on page G5-4181
DBGDSAR	*DBGDSAR, Debug Self Address Register* on page G5-4183
DBGDSCRext	*DBGDSCRext, Debug Status and Control Register, External View* on page G5-4185
DBGDSCRint	*DBGDSCRint, Debug Status and Control Register, Internal View* on page G5-4189
DBGDTRRXext	*DBGDTRRXext, Debug Data Transfer Register, Receive, External View* on page G5-4192
DBGDTRRXint	*DBGDTRRXint, Debug Data Transfer Register, Receive, Internal View* on page G5-4194
DBGDTRTXext	*DBGDTRTXext, Debug Data Transfer Register, Transmit, External View* on page G5-4196
DBGDTRTXint	*DBGDTRTXint, Debug Data Transfer Register, Transmit, Internal View* on page G5-4198
DBGOSDLR	*DBGOSDLR, Debug OS Double Lock Register* on page G5-4200
DBGOSECCR	*DBGOSECCR, Debug OS Lock Exception Catch Control Register* on page G5-4202
DBGOSLAR	*DBGOSLAR, Debug OS Lock Access Register* on page G5-4203
DBGOSLSR	*DBGOSLSR, Debug OS Lock Status Register* on page G5-4204
DBGPRCR	*DBGPRCR, Debug Power Control Register* on page G5-4206

Table J-22 Debug registers (continued)

Register	Description, see
DBGVCR	*DBGVCR, Debug Vector Catch Register* on page G5-4208
DBGWCR<n>	*DBGWCR<n>, Debug Watchpoint Control Registers, n = 0 - 15* on page G5-4214
DBGWFAR	*DBGWFAR, Debug Watchpoint Fault Address Register* on page G5-4217
DBGWVR<n>	*DBGWVR<n>, Debug Watchpoint Value Registers, n = 0 - 15* on page G5-4218
DLR	*DLR, Debug Link Register* on page G5-4220
DSPSR	*DSPSR, Debug Saved Program Status Register* on page G5-4221
HDCR	*HDCR, Hyp Debug Control Register* on page G5-4225
SDCR	*SDCR, Secure Debug Configuration Register* on page G5-4228
SDER	*SDER, Secure Debug Enable Register* on page G5-4230

J.5.6 Generic timer registers

This section is an index to the registers in the Generic Timer registers functional group.

Table J-23 Generic timer registers

Register	Description, see
CNTFRQ	*CNTFRQ, Counter-timer Frequency register* on page G5-4271
CNTHCTL	*CNTHCTL, Counter-timer Hyp Control register* on page G5-4273
CNTHP_CTL	*CNTHP_CTL, Counter-timer Hyp Physical Timer Control register* on page G5-4275
CNTHP_CVAL	*CNTHP_CVAL, Counter-timer Hyp Physical CompareValue register* on page G5-4277
CNTHP_TVAL	*CNTHP_TVAL, Counter-timer Hyp Physical Timer TimerValue register* on page G5-4278
CNTKCTL	*CNTKCTL, Counter-timer Kernel Control register* on page G5-4279
CNTP_CTL	*CNTP_CTL, Counter-timer Physical Timer Control register* on page G5-4281
CNTP_CVAL	*CNTP_CVAL, Counter-timer Physical Timer CompareValue register* on page G5-4283
CNTP_TVAL	*CNTP_TVAL, Counter-timer Physical Timer TimerValue register* on page G5-4285
CNTPCT	*CNTPCT, Counter-timer Physical Count register* on page G5-4287
CNTV_CTL	*CNTV_CTL, Counter-timer Virtual Timer Control register* on page G5-4288
CNTV_CVAL	*CNTV_CVAL, Counter-timer Virtual Timer CompareValue register* on page G5-4290
CNTV_TVAL	*CNTV_TVAL, Counter-timer Virtual Timer TimerValue register* on page G5-4291
CNTVCT	*CNTVCT, Counter-timer Virtual Count register* on page G5-4292
CNTVOFF	*CNTVOFF, Counter-timer Virtual Offset register* on page G5-4293

J.5.7 Generic Interrupt Controller CPU interface registers

This section is an index to the registers in the GIC registers functional group.

Table J-24 Generic Interrupt Controller CPU interface registers

Register	Description, see
ICC_AP0R0	*ICC_AP0R0, Interrupt Controller Active Priorities Register (0,0)* on page G5-4294
ICC_AP0R1	*ICC_AP0R1, Interrupt Controller Active Priorities Register (0,1)* on page G5-4296
ICC_AP0R2	*ICC_AP0R2, Interrupt Controller Active Priorities Register (0,2)* on page G5-4298
ICC_AP0R3	*ICC_AP0R3, Interrupt Controller Active Priorities Register (0,3)* on page G5-4300
ICC_AP1R0	*ICC_AP1R0, Interrupt Controller Active Priorities Register (1,0)* on page G5-4302
ICC_AP1R1	*ICC_AP1R1, Interrupt Controller Active Priorities Register (1,1)* on page G5-4304
ICC_AP1R2	*ICC_AP1R2, Interrupt Controller Active Priorities Register (1,2)* on page G5-4306
ICC_AP1R3	*ICC_AP1R3, Interrupt Controller Active Priorities Register (1,3)* on page G5-4308
ICC_ASGI1R	*ICC_ASGI1R, Interrupt Controller Alias Software Generated Interrupt group 1 Register* on page G5-4310
ICC_BPR0	*ICC_BPR0, Interrupt Controller Binary Point Register 0* on page G5-4312
ICC_BPR1	*ICC_BPR1, Interrupt Controller Binary Point Register 1* on page G5-4314
ICC_CTLR	*ICC_CTLR, Interrupt Controller Control Register* on page G5-4316
ICC_DIR	*ICC_DIR, Interrupt Controller Deactivate Interrupt Register* on page G5-4319
ICC_EOIR0	*ICC_EOIR0, Interrupt Controller End Of Interrupt Register 0* on page G5-4320
ICC_EOIR1	*ICC_EOIR1, Interrupt Controller End Of Interrupt Register 1* on page G5-4322
ICC_HPPIR0	*ICC_HPPIR0, Interrupt Controller Highest Priority Pending Interrupt Register 0* on page G5-4324
ICC_HPPIR1	*ICC_HPPIR1, Interrupt Controller Highest Priority Pending Interrupt Register 1* on page G5-4326
ICC_HSRE	*ICC_HSRE, Interrupt Controller Hyp System Register Enable register* on page G5-4327
ICC_IAR0	*ICC_IAR0, Interrupt Controller Interrupt Acknowledge Register 0* on page G5-4329
ICC_IAR1	*ICC_IAR1, Interrupt Controller Interrupt Acknowledge Register 1* on page G5-4331
ICC_IGRPEN0	*ICC_IGRPEN0, Interrupt Controller Interrupt Group 0 Enable register* on page G5-4333
ICC_IGRPEN1	*ICC_IGRPEN1, Interrupt Controller Interrupt Group 1 Enable register* on page G5-4335
ICC_MCTLR	*ICC_MCTLR, Interrupt Controller Monitor Control Register* on page G5-4336
ICC_MGRPEN1	*ICC_MGRPEN1, Interrupt Controller Monitor Interrupt Group 1 Enable register* on page G5-4339
ICC_MSRE	*ICC_MSRE, Interrupt Controller Monitor System Register Enable register* on page G5-4341
ICC_PMR	*ICC_PMR, Interrupt Controller Interrupt Priority Mask Register* on page G5-4343
ICC_RPR	*ICC_RPR, Interrupt Controller Running Priority Register* on page G5-4345
ICC_SEIEN	*ICC_SEIEN, Interrupt Controller System Error Interrupt Enable register* on page G5-4346
ICC_SGI0R	*ICC_SGI0R, Interrupt Controller Software Generated Interrupt group 0 Register* on page G5-4347
ICC_SGI1R	*ICC_SGI1R, Interrupt Controller Software Generated Interrupt group 1 Register* on page G5-4349

Table J-24 Generic Interrupt Controller CPU interface registers (continued)

Register	Description, see
ICC_SRE	*ICC_SRE, Interrupt Controller System Register Enable register* on page G5-4351
ICH_AP0R0	*ICH_AP0R0, Interrupt Controller Hyp Active Priorities Register (0,0)* on page G5-4353
ICH_AP0R1	*ICH_AP0R1, Interrupt Controller Hyp Active Priorities Register (0,1)* on page G5-4355
ICH_AP0R2	*ICH_AP0R2, Interrupt Controller Hyp Active Priorities Register (0,2)* on page G5-4357
ICH_AP0R3	*ICH_AP0R3, Interrupt Controller Hyp Active Priorities Register (0,3)* on page G5-4359
ICH_AP1R0	*ICH_AP1R0, Interrupt Controller Hyp Active Priorities Register (1,0)* on page G5-4361
ICH_AP1R1	*ICH_AP1R1, Interrupt Controller Hyp Active Priorities Register (1,1)* on page G5-4363
ICH_AP1R2	*ICH_AP1R2, Interrupt Controller Hyp Active Priorities Register (1,2)* on page G5-4365
ICH_AP1R3	*ICH_AP1R3, Interrupt Controller Hyp Active Priorities Register (1,3)* on page G5-4367
ICH_EISR	*ICH_EISR, Interrupt Controller End of Interrupt Status Register* on page G5-4369
ICH_ELSR	*ICH_ELSR, Interrupt Controller Empty List Register Status Register* on page G5-4371
ICH_HCR	*ICH_HCR, Interrupt Controller Hyp Control Register* on page G5-4373
ICH_LRC<n>	*ICH_LRC<n>, Interrupt Controller List Registers, n = 0 - 15* on page G5-4377
ICH_LR<n>	*ICH_LR<n>, Interrupt Controller List Registers, n = 0 - 15* on page G5-4379
ICH_MISR	*ICH_MISR, Interrupt Controller Maintenance Interrupt State Register* on page G5-4380
ICH_VMCR	*ICH_VMCR, Interrupt Controller Virtual Machine Control Register* on page G5-4382
ICH_VSEIR	*ICH_VSEIR, Interrupt Controller Virtual System Error Interrupt Register* on page G5-4384
ICH_VTR	*ICH_VTR, Interrupt Controller VGIC Type Register* on page G5-4385

J.5.8 Cache maintenance system instructions

This section is an index to the registers in the Cache maintenance instructions functional group.

Table J-25 Cache maintenance system instructions

Register	Description, see
BPIALL	*BPIALL, Branch Predictor Invalidate All* on page G5-3847
BPIALLIS	*BPIALLIS, Branch Predictor Invalidate All, Inner Shareable* on page G5-3848
BPIMVA	*BPIMVA, Branch Predictor Invalidate by VA* on page G5-3849
DCCIMVAC	*DCCIMVAC, Data Cache line Clean and Invalidate by VA to PoC* on page G5-3870
DCCISW	*DCCISW, Data Cache line Clean and Invalidate by Set/Way* on page G5-3871
DCCMVAC	*DCCMVAC, Data Cache line Clean by VA to PoC* on page G5-3873
DCCMVAU	*DCCMVAU, Data Cache line Clean by VA to PoU* on page G5-3874
DCCSW	*DCCSW, Data Cache line Clean by Set/Way* on page G5-3875
DCIMVAC	*DCIMVAC, Data Cache line Invalidate by VA to PoC* on page G5-3877

Table J-25 Cache maintenance system instructions (continued)

Register	Description, see
DCISW	*DCISW, Data Cache line Invalidate by Set/Way* on page G5-3878
ICIALLU	*ICIALLU, Instruction Cache Invalidate All to PoU* on page G5-3962
ICIALLUIS	*ICIALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable* on page G5-3963
ICIMVAU	*ICIMVAU, Instruction Cache line Invalidate by VA to PoU* on page G5-3964

J.5.9 Address translation system instructions

This section is an index to the registers in the Address translation instructions functional group.

Table J-26 Address translation system instructions

Register	Description, see
ATS12NSOPR	*ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read* on page G5-3837
ATS12NSOPW	*ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write* on page G5-3838
ATS12NSOUR	*ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read* on page G5-3839
ATS12NSOUW	*ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write* on page G5-3840
ATS1CPR	*ATS1CPR, Address Translate Stage 1 Current state PL1 Read* on page G5-3841
ATS1CPW	*ATS1CPW, Address Translate Stage 1 Current state PL1 Write* on page G5-3842
ATS1CUR	*ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read* on page G5-3843
ATS1CUW	*ATS1CUW, Address Translate Stage 1 Current state Unprivileged Write* on page G5-3844
ATS1HR	*ATS1HR, Address Translate Stage 1 Hyp mode Read* on page G5-3845
ATS1HW	*ATS1HW, Address Translate Stage 1 Hyp mode Write* on page G5-3846

J.5.10 TLB maintenance system instructions

This section is an index to the registers in the TLB maintenance instructions functional group.

Table J-27 TLB maintenance system instructions

Register	Description, see
DTLBIALL	*DTLBIALL, Data TLB Invalidate All* on page G5-3887
DTLBIASID	*DTLBIASID, Data TLB Invalidate by ASID match* on page G5-3888
DTLBIMVA	*DTLBIMVA, Data TLB Invalidate by VA* on page G5-3889
ITLBIALL	*ITLBIALL, Instruction TLB Invalidate All* on page G5-4013
ITLBIASID	*ITLBIASID, Instruction TLB Invalidate by ASID match* on page G5-4014
ITLBIMVA	*ITLBIMVA, Instruction TLB Invalidate by VA* on page G5-4015
TLBIALL	*TLBIALL, TLB Invalidate All* on page G5-4097

Table J-27 TLB maintenance system instructions (continued)

Register	Description, see
TLBIALLH	*TLBIALLH, TLB Invalidate All, Hyp mode* on page G5-4098
TLBIALLHIS	*TLBIALLHIS, TLB Invalidate All, Hyp mode, Inner Shareable* on page G5-4099
TLBIALLIS	*TLBIALLIS, TLB Invalidate All, Inner Shareable* on page G5-4100
TLBIALLNSNH	*TLBIALLNSNH, TLB Invalidate All, Non-Secure Non-Hyp* on page G5-4101
TLBIALLNSNHIS	*TLBIALLNSNHIS, TLB Invalidate All, Non-Secure Non-Hyp, Inner Shareable* on page G5-4102
TLBIASID	*TLBIASID, TLB Invalidate by ASID match* on page G5-4103
TLBIASIDIS	*TLBIASIDIS, TLB Invalidate by ASID match, Inner Shareable* on page G5-4104
TLBIIPAS2	*TLBIIPAS2, TLB Invalidate by Intermediate Physical Address, Stage 2* on page G5-4105
TLBIIPAS2IS	*TLBIIPAS2IS, TLB Invalidate by Intermediate Physical Address, Stage 2, Inner Shareable* on page G5-4106
TLBIIPAS2L	*TLBIIPAS2L, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level* on page G5-4107
TLBIIPAS2LIS	*TLBIIPAS2LIS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, Inner Shareable* on page G5-4108
TLBIMVA	*TLBIMVA, TLB Invalidate by VA* on page G5-4110
TLBIMVAA	*TLBIMVAA, TLB Invalidate by VA, All ASID* on page G5-4112
TLBIMVAAIS	*TLBIMVAAIS, TLB Invalidate by VA, All ASID, Inner Shareable* on page G5-4113
TLBIMVAAL	*TLBIMVAAL, TLB Invalidate by VA, All ASID, Last level* on page G5-4114
TLBIMVAALIS	*TLBIMVAALIS, TLB Invalidate by VA, All ASID, Last level, Inner Shareable* on page G5-4115
TLBIMVAH	*TLBIMVAH, TLB Invalidate by VA, Hyp mode* on page G5-4116
TLBIMVAHIS	*TLBIMVAHIS, TLB Invalidate by VA, Hyp mode, Inner Shareable* on page G5-4118
TLBIMVAIS	*TLBIMVAIS, TLB Invalidate by VA, Inner Shareable* on page G5-4120
TLBIMVAL	*TLBIMVAL, TLB Invalidate by VA, Last level* on page G5-4122
TLBIMVALH	*TLBIMVALH, TLB Invalidate by VA, Last level, Hyp mode* on page G5-4124
TLBIMVALHIS	*TLBIMVALHIS, TLB Invalidate by VA, Last level, Hyp mode, Inner Shareable* on page G5-4126
TLBIMVALIS	*TLBIMVALIS, TLB Invalidate by VA, Last level, Inner Shareable* on page G5-4128

J.5.11 Legacy feature registers and system instructions

This section is an index to the registers in the Legacy feature registers functional group.

Table J-28 Legacy feature registers and system instructions

Register	Description, see
CP15DMB	*CP15DMB, CP15 Data Memory Barrier operation* on page G5-3856
CP15DSB	*CP15DSB, CP15 Data Synchronization Barrier operation* on page G5-3857
CP15ISB	*CP15ISB, CP15 Instruction Synchronization Barrier operation* on page G5-3858
FCSEIDR	*FCSEIDR, FCSE Process ID register* on page G5-3892

Table J-28 Legacy feature registers and system instructions (continued)

Register	Description, see
JIDR	*JIDR, Jazelle ID Register* on page G5-4017
JMCR	*JMCR, Jazelle Main Configuration Register* on page G5-4018
JOSCR	*JOSCR, Jazelle OS Control Register* on page G5-4019

J.5.12 Base system registers

This section is an index to the registers in the functional group.

Table J-29 Base system registers

Register	Description, see
ACTLR	*ACTLR, Auxiliary Control Register* on page G5-3824
ADFSR	*ADFSR, Auxiliary Data Fault Status Register* on page G5-3826
AIFSR	*AIFSR, Auxiliary Instruction Fault Status Register* on page G5-3829
APSR	*APSR, Application Program Status Register* on page G5-3835
CPACR	*CPACR, Architectural Feature Access Control Register* on page G5-3859
CPSR	*CPSR, Current Program Status Register* on page G5-3861
DFAR	*DFAR, Data Fault Address Register* on page G5-3880
DFSR	*DFSR, Data Fault Status Register* on page G5-3882
FPEXC	*FPEXC, Floating-Point Exception Control register* on page G5-3894
HACR	*HACR, Hyp Auxiliary Configuration Register* on page G5-3905
HACTLR	*HACTLR, Hyp Auxiliary Control Register* on page G5-3906
HADFSR	*HADFSR, Hyp Auxiliary Data Fault Status Register* on page G5-3907
HAIFSR	*HAIFSR, Hyp Auxiliary Instruction Fault Status Register* on page G5-3908
HCPTR	*HCPTR, Hyp Architectural Feature Trap Register* on page G5-3911
HCR	*HCR, Hyp Configuration Register* on page G5-3914
HCR2	*HCR2, Hyp Configuration Register 2* on page G5-3920
HDFAR	*HDFAR, Hyp Data Fault Address Register* on page G5-3922
HIFAR	*HIFAR, Hyp Instruction Fault Address Register* on page G5-3923
HPFAR	*HPFAR, Hyp IPA Fault Address Register* on page G5-3930
HRMR	*HRMR, Hyp Reset Management Register* on page G5-3931
HSCTLR	*HSCTLR, Hyp System Control Register* on page G5-3933
HSR	*HSR, Hyp Syndrome Register* on page G5-3938
HSTR	*HSTR, Hyp System Trap Register* on page G5-3954
HTPIDR	*HTPIDR, Hyp Software Thread ID Register* on page G5-3958

Table J-29 Base system registers (continued)

Register	Description, see
HVBAR	*HVBAR, Hyp Vector Base Address Register* on page G5-3961
IFAR	*IFAR, Instruction Fault Address Register* on page G5-4005
IFSR	*IFSR, Instruction Fault Status Register* on page G5-4007
ISR	*ISR, Interrupt Status Register* on page G5-4011
MVBAR	*MVBAR, Monitor Vector Base Address Register* on page G5-4031
NSACR	*NSACR, Non-Secure Access Control Register* on page G5-4043
PAR	*PAR, Physical Address Register* on page G5-4046
RMR (at EL1)	*RMR (at EL1), Reset Management Register* on page G5-4056
RMR (at EL3)	*RMR (at EL3), Reset Management Register* on page G5-4058
RVBAR	*RVBAR, Reset Vector Base Address Register* on page G5-4060
SCR	*SCR, Secure Configuration Register* on page G5-4061
SCTLR	*SCTLR, System Control Register* on page G5-4065
SPSR	*SPSR, Saved Program Status Register* on page G5-4072
TPIDRPRW	*TPIDRPRW, PL1 Software Thread ID Register* on page G5-4131
TPIDRURO	*TPIDRURO, PL0 Read-Only Software Thread ID Register* on page G5-4133
TPIDRURW	*TPIDRURW, PL0 Read/Write Software Thread ID Register* on page G5-4135
VBAR	*VBAR, Vector Base Address Register* on page G5-4150

J.6 Alphabetical index of memory-mapped registers

This section is an index of memory-mapped registers in alphabetical order.

Table J-30 Alphabetical index of Memory-Mapped Registers

Register	Description, see
ASICCTL	*ASICCTL, CTI External Multiplexer Control register* on page H9-4626
CNTACR<n>	*CNTACR<n>, Counter-timer Access Control Registers, n = 0 - 7* on page I3-4745
CNTCR	*CNTCR, Counter Control Register* on page I3-4748
CNTCV	*CNTCV, Counter Count Value register* on page I3-4750
CNTEL0ACR	*CNTEL0ACR, Counter-timer EL0 Access Control Register* on page I3-4751
CNTFID0	*CNTFID0, Counter Frequency ID* on page I3-4753
CNTFID<n>	*CNTFID<n>, Counter Frequency IDs, n = 1 - 23* on page I3-4754
CNTFRQ	*CNTFRQ, Counter-timer Frequency* on page I3-4756
CNTNSAR	*CNTNSAR, Counter-timer Non-secure Access Register* on page I3-4757
CNTP_CTL	*CNTP_CTL, Counter-timer Physical Timer Control* on page I3-4759
CNTP_CVAL	*CNTP_CVAL, Counter-timer Physical Timer CompareValue* on page I3-4761
CNTP_TVAL	*CNTP_TVAL, Counter-timer Physical Timer TimerValue* on page I3-4763
CNTPCT	*CNTPCT, Counter-timer Physical Count* on page I3-4764
CNTSR	*CNTSR, Counter Status Register* on page I3-4766
CNTTIDR	*CNTTIDR, Counter-timer Timer ID Register* on page I3-4768
CNTV_CTL	*CNTV_CTL, Counter-timer Virtual Timer Control* on page I3-4770
CNTV_CVAL	*CNTV_CVAL, Counter-timer Virtual Timer CompareValue* on page I3-4772
CNTV_TVAL	*CNTV_TVAL, Counter-timer Virtual Timer TimerValue* on page I3-4774
CNTVCT	*CNTVCT, Counter-timer Virtual Count* on page I3-4775
CNTVOFF	*CNTVOFF, Counter-timer Virtual Offset* on page I3-4777
CNTVOFF<n>	*CNTVOFF<n>, Counter-timer Virtual Offsets, n = 0 - 7* on page I3-4778
CounterID<n>	*CounterID<n>, Counter ID registers, n = 0 - 11* on page I3-4780
CTIAPPCLEAR	*CTIAPPCLEAR, CTI Application Trigger Clear register* on page H9-4627
CTIAPPPULSE	*CTIAPPPULSE, CTI Application Pulse register* on page H9-4628
CTIAPPSET	*CTIAPPSET, CTI Application Trigger Set register* on page H9-4629
CTIAUTHSTATUS	*CTIAUTHSTATUS, CTI Authentication Status register* on page H9-4630
CTICHINSTATUS	*CTICHINSTATUS, CTI Channel In Status register* on page H9-4632
CTICHOUTSTATUS	*CTICHOUTSTATUS, CTI Channel Out Status register* on page H9-4633
CTICIDR0	*CTICIDR0, CTI Component Identification Register 0* on page H9-4634
CTICIDR1	*CTICIDR1, CTI Component Identification Register 1* on page H9-4635

Table J-30 Alphabetical index of Memory-Mapped Registers (continued)

Register	Description, see
CTICIDR2	*CTICIDR2, CTI Component Identification Register 2* on page H9-4636
CTICIDR3	*CTICIDR3, CTI Component Identification Register 3* on page H9-4637
CTICLAIMCLR	*CTICLAIMCLR, CTI Claim Tag Clear register* on page H9-4638
CTICLAIMSET	*CTICLAIMSET, CTI Claim Tag Set register* on page H9-4639
CTICONTROL	*CTICONTROL, CTI Control register* on page H9-4640
CTIDEVAFF0	*CTIDEVAFF0, CTI Device Affinity register 0* on page H9-4641
CTIDEVAFF1	*CTIDEVAFF1, CTI Device Affinity register 1* on page H9-4642
CTIDEVARCH	*CTIDEVARCH, CTI Device Architecture register* on page H9-4643
CTIDEVID	*CTIDEVID, CTI Device ID register 0* on page H9-4645
CTIDEVID1	*CTIDEVID1, CTI Device ID register 1* on page H9-4647
CTIDEVID2	*CTIDEVID2, CTI Device ID register 2* on page H9-4648
CTIDEVTYPE	*CTIDEVTYPE, CTI Device Type register* on page H9-4649
CTIGATE	*CTIGATE, CTI Channel Gate Enable register* on page H9-4650
CTIINEN<n>	*CTIINEN<n>, CTI Input Trigger to Output Channel Enable registers, n = 0 - 31* on page H9-4651
CTIINTACK	*CTIINTACK, CTI Output Trigger Acknowledge register* on page H9-4652
CTIITCTRL	*CTIITCTRL, CTI Integration mode Control register* on page H9-4654
CTILAR	*CTILAR, CTI Lock Access Register* on page H9-4655
CTILSR	*CTILSR, CTI Lock Status Register* on page H9-4656
CTIOUTEN<n>	*CTIOUTEN<n>, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31* on page H9-4658
CTIPIDR0	*CTIPIDR0, CTI Peripheral Identification Register 0* on page H9-4659
CTIPIDR1	*CTIPIDR1, CTI Peripheral Identification Register 1* on page H9-4660
CTIPIDR2	*CTIPIDR2, CTI Peripheral Identification Register 2* on page H9-4661
CTIPIDR3	*CTIPIDR3, CTI Peripheral Identification Register 3* on page H9-4662
CTIPIDR4	*CTIPIDR4, CTI Peripheral Identification Register 4* on page H9-4663
CTITRIGINSTATUS	*CTITRIGINSTATUS, CTI Trigger In Status register* on page H9-4664
CTITRIGOUTSTATUS	*CTITRIGOUTSTATUS, CTI Trigger Out Status register* on page H9-4665
DBGAUTHSTATUS_EL1	*DBGAUTHSTATUS_EL1, Debug Authentication Status register* on page H9-4540
DBGBCR<n>_EL1	*DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15* on page H9-4542
DBGBVR<n>_EL1	*DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15* on page H9-4545
DBGCLAIMCLR_EL1	*DBGCLAIMCLR_EL1, Debug Claim Tag Clear register* on page H9-4548
DBGCLAIMSET_EL1	*DBGCLAIMSET_EL1, Debug Claim Tag Set register* on page H9-4549
DBGDTRRX_EL0	*DBGDTRRX_EL0, Debug Data Transfer Register, Receive* on page H9-4550

Table J-30 Alphabetical index of Memory-Mapped Registers (continued)

Register	Description, see
DBGDTRTX_EL0	*DBGDTRTX_EL0, Debug Data Transfer Register, Transmit* on page H9-4551
DBGWCR<n>_EL1	*DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15* on page H9-4552
DBGWVR<n>_EL1	*DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15* on page H9-4555
EDACR	*EDACR, External Debug Auxiliary Control Register* on page H9-4557
EDCIDR0	*EDCIDR0, External Debug Component Identification Register 0* on page H9-4558
EDCIDR1	*EDCIDR1, External Debug Component Identification Register 1* on page H9-4559
EDCIDR2	*EDCIDR2, External Debug Component Identification Register 2* on page H9-4560
EDCIDR3	*EDCIDR3, External Debug Component Identification Register 3* on page H9-4561
EDCIDSR	*EDCIDSR, External Debug Context ID Sample Register* on page H9-4562
EDDEVAFF0	*EDDEVAFF0, External Debug Device Affinity register 0* on page H9-4563
EDDEVAFF1	*EDDEVAFF1, External Debug Device Affinity register 1* on page H9-4564
EDDEVARCH	*EDDEVARCH, External Debug Device Architecture register* on page H9-4565
EDDEVID	*EDDEVID, External Debug Device ID register 0* on page H9-4567
EDDEVID1	*EDDEVID1, External Debug Device ID register 1* on page H9-4569
EDDEVID2	*EDDEVID2, External Debug Device ID register 2* on page H9-4570
EDDEVTYPE	*EDDEVTYPE, External Debug Device Type register* on page H9-4571
EDECCR	*EDECCR, External Debug Exception Catch Control Register* on page H9-4572
EDECR	*EDECR, External Debug Execution Control Register* on page H9-4574
EDESR	*EDESR, External Debug Event Status Register* on page H9-4576
EDITCTRL	*EDITCTRL, External Debug Integration mode Control register* on page H9-4578
EDITR	*EDITR, External Debug Instruction Transfer Register* on page H9-4580
EDLAR	*EDLAR, External Debug Lock Access Register* on page H9-4582
EDLSR	*EDLSR, External Debug Lock Status Register* on page H9-4583
EDPCSR	*EDPCSR, External Debug Program Counter Sample Register* on page H9-4585
EDPIDR0	*EDPIDR0, External Debug Peripheral Identification Register 0* on page H9-4587
EDPIDR1	*EDPIDR1, External Debug Peripheral Identification Register 1* on page H9-4588
EDPIDR2	*EDPIDR2, External Debug Peripheral Identification Register 2* on page H9-4589
EDPIDR3	*EDPIDR3, External Debug Peripheral Identification Register 3* on page H9-4590
EDPIDR4	*EDPIDR4, External Debug Peripheral Identification Register 4* on page H9-4591
EDPRCR	*EDPRCR, External Debug Power/Reset Control Register* on page H9-4592
EDPRSR	*EDPRSR, External Debug Processor Status Register* on page H9-4595
EDRCR	*EDRCR, External Debug Reserve Control Register* on page H9-4601

Table J-30 Alphabetical index of Memory-Mapped Registers (continued)

Register	Description, see
EDSCR	*EDSCR, External Debug Status and Control Register* on page H9-4603
EDVIDSR	*EDVIDSR, External Debug Virtual Context Sample Register* on page H9-4607
EDWAR	*EDWAR, External Debug Watchpoint Address Register* on page H9-4609
ID_AA64DFR0_EL1	*ID_AA64DFR0_EL1, Debug Feature Register 0* on page H9-4610
ID_AA64DFR1_EL1	*ID_AA64DFR1_EL1, Debug Feature Register 1* on page H9-4612
ID_AA64ISAR0_EL1	*ID_AA64ISAR0_EL1, Instruction Set Attribute Register 0* on page H9-4613
ID_AA64ISAR1_EL1	*ID_AA64ISAR1_EL1, Instruction Set Attribute Register 1* on page H9-4615
ID_AA64MMFR0_EL1	*ID_AA64MMFR0_EL1, Memory Model Feature Register 0* on page H9-4616
ID_AA64MMFR1_EL1	*ID_AA64MMFR1_EL1, Memory Model Feature Register 1* on page H9-4619
ID_AA64PFR0_EL1	*ID_AA64PFR0_EL1, Processor Feature Register 0* on page H9-4620
ID_AA64PFR1_EL1	*ID_AA64PFR1_EL1, Processor Feature Register 1* on page H9-4622
MIDR_EL1	*MIDR_EL1, Main ID Register* on page H9-4623
OSLAR_EL1	*OSLAR_EL1, OS Lock Access Register* on page H9-4625
PMAUTHSTATUS	*PMAUTHSTATUS, Performance Monitors Authentication Status register* on page I3-4693
PMCCFILTR_EL0	*PMCCFILTR_EL0, Performance Monitors Cycle Counter Filter Register* on page I3-4695
PMCCNTR_EL0	*PMCCNTR_EL0, Performance Monitors Cycle Counter* on page I3-4697
PMCEID0_EL0	*PMCEID0_EL0, Performance Monitors Common Event Identification register 0* on page I3-4699
PMCEID1_EL0	*PMCEID1_EL0, Performance Monitors Common Event Identification register 1* on page I3-4701
PMCFGR	*PMCFGR, Performance Monitors Configuration Register* on page I3-4703
PMCIDR0	*PMCIDR0, Performance Monitors Component Identification Register 0* on page I3-4705
PMCIDR1	*PMCIDR1, Performance Monitors Component Identification Register 1* on page I3-4706
PMCIDR2	*PMCIDR2, Performance Monitors Component Identification Register 2* on page I3-4707
PMCIDR3	*PMCIDR3, Performance Monitors Component Identification Register 3* on page I3-4708
PMCNTENCLR_EL0	*PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register* on page I3-4709
PMCNTENSET_EL0	*PMCNTENSET_EL0, Performance Monitors Count Enable Set register* on page I3-4711
PMCR_EL0	*PMCR_EL0, Performance Monitors Control Register* on page I3-4713
PMDEVAFF0	*PMDEVAFF0, Performance Monitors Device Affinity register 0* on page I3-4716

PMDEVARCH	*PMDEVARCH, Performance Monitors Device Architecture register* on page I3-4718
PMDEVTYPE	*PMDEVTYPE, Performance Monitors Device Type register* on page I3-4720
PMEVCNTR<n>_EL0	*PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30* on page I3-4721
PMEVTYPER<n>_EL0	*PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30* on page I3-4722

Table J-30 Alphabetical index of Memory-Mapped Registers (continued)

Register	Description, see
PMINTENCLR_EL1	*PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register* on page I3-4724
PMINTENSET_EL1	*PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register* on page I3-4726
PMITCTRL	*PMITCTRL, Performance Monitors Integration mode Control register* on page I3-4728
PMLAR	*PMLAR, Performance Monitors Lock Access Register* on page I3-4730
PMLSR	*PMLSR, Performance Monitors Lock Status Register* on page I3-4731
PMOVSCLR_EL0	*PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear register* on page I3-4733
PMOVSSET_EL0	*PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register* on page I3-4735
PMPIDR0	*PMPIDR0, Performance Monitors Peripheral Identification Register 0* on page I3-4737
PMPIDR1	*PMPIDR1, Performance Monitors Peripheral Identification Register 1* on page I3-4738
PMPIDR2	*PMPIDR2, Performance Monitors Peripheral Identification Register 2* on page I3-4739
PMPIDR3	*PMPIDR3, Performance Monitors Peripheral Identification Register 3* on page I3-4740
PMPIDR4	*PMPIDR4, Performance Monitors Peripheral Identification Register 4* on page I3-4741
PMSWINC_EL0	*PMSWINC_EL0, Performance Monitors Software Increment register* on page I3-4742

J.7 Functional index of memory-mapped registers

This section is an index of the memory-mapped registers, divided by functional group.

J.7.1 ID registers

This section is an index to the registers in the Identification registers functional group.

Table J-31 ID registers

Register	Description, see
ID_AA64DFR0_EL1	*ID_AA64DFR0_EL1, Debug Feature Register 0* on page H9-4610
ID_AA64DFR1_EL1	*ID_AA64DFR1_EL1, Debug Feature Register 1* on page H9-4612
ID_AA64ISAR0_EL1	*ID_AA64ISAR0_EL1, Instruction Set Attribute Register 0* on page H9-4613
ID_AA64ISAR1_EL1	*ID_AA64ISAR1_EL1, Instruction Set Attribute Register 1* on page H9-4615
ID_AA64MMFR0_EL1	*ID_AA64MMFR0_EL1, Memory Model Feature Register 0* on page H9-4616
ID_AA64MMFR1_EL1	*ID_AA64MMFR1_EL1, Memory Model Feature Register 1* on page H9-4619
ID_AA64PFR0_EL1	*ID_AA64PFR0_EL1, Processor Feature Register 0* on page H9-4620
ID_AA64PFR1_EL1	*ID_AA64PFR1_EL1, Processor Feature Register 1* on page H9-4622
MIDR_EL1	*MIDR_EL1, Main ID Register* on page H9-4623

J.7.2 Performance monitors registers

This section is an index to the registers in the Performance Monitors registers functional group.

Table J-32 Performance monitors registers

Register	Description, see
PMAUTHSTATUS	*PMAUTHSTATUS, Performance Monitors Authentication Status register* on page I3-4693
PMCCFILTR_EL0	*PMCCFILTR_EL0, Performance Monitors Cycle Counter Filter Register* on page I3-4695
PMCCNTR_EL0	*PMCCNTR_EL0, Performance Monitors Cycle Counter* on page I3-4697
PMCEID0_EL0	*PMCEID0_EL0, Performance Monitors Common Event Identification register 0* on page I3-4699
PMCEID1_EL0	*PMCEID1_EL0, Performance Monitors Common Event Identification register 1* on page I3-4701
PMCFGR	*PMCFGR, Performance Monitors Configuration Register* on page I3-4703
PMCIDR0	*PMCIDR0, Performance Monitors Component Identification Register 0* on page I3-4705
PMCIDR1	*PMCIDR1, Performance Monitors Component Identification Register 1* on page I3-4706
PMCIDR2	*PMCIDR2, Performance Monitors Component Identification Register 2* on page I3-4707
PMCIDR3	*PMCIDR3, Performance Monitors Component Identification Register 3* on page I3-4708
PMCNTENCLR_EL0	*PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register* on page I3-4709
PMCNTENSET_EL0	*PMCNTENSET_EL0, Performance Monitors Count Enable Set register* on page I3-4711
PMCR_EL0	*PMCR_EL0, Performance Monitors Control Register* on page I3-4713
PMDEVAFF0	*PMDEVAFF0, Performance Monitors Device Affinity register 0* on page I3-4716

Table J-32 Performance monitors registers (continued)

Register	Description, see
PMDEVAFF1	*PMDEVAFF1, Performance Monitors Device Affinity register 1* on page I3-4717
PMDEVARCH	*PMDEVARCH, Performance Monitors Device Architecture register* on page I3-4718
PMDEVTYPE	*PMDEVTYPE, Performance Monitors Device Type register* on page I3-4720
PMEVCNTR<n>_EL0	*PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30* on page I3-4721
PMEVTYPER<n>_EL0	*PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30* on page I3-4722
PMINTENCLR_EL1	*PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register* on page I3-4724
PMINTENSET_EL1	*PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register* on page I3-4726
PMITCTRL	*PMITCTRL, Performance Monitors Integration mode Control register* on page I3-4728
PMLAR	*PMLAR, Performance Monitors Lock Access Register* on page I3-4730
PMLSR	*PMLSR, Performance Monitors Lock Status Register* on page I3-4731
PMOVSCLR_EL0	*PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear register* on page I3-4733
PMOVSSET_EL0	*PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register* on page I3-4735
PMPIDR0	*PMPIDR0, Performance Monitors Peripheral Identification Register 0* on page I3-4737
PMPIDR1	*PMPIDR1, Performance Monitors Peripheral Identification Register 1* on page I3-4738
PMPIDR2	*PMPIDR2, Performance Monitors Peripheral Identification Register 2* on page I3-4739
PMPIDR3	*PMPIDR3, Performance Monitors Peripheral Identification Register 3* on page I3-4740
PMPIDR4	*PMPIDR4, Performance Monitors Peripheral Identification Register 4* on page I3-4741
PMSWINC_EL0	*PMSWINC_EL0, Performance Monitors Software Increment register* on page I3-4742

J.7.3 Debug registers

This section is an index to the registers in the Debug registers functional group.

Table J-33 Debug registers

Register	Description, see
DBGAUTHSTATUS_EL1	*DBGAUTHSTATUS_EL1, Debug Authentication Status register* on page H9-4540
DBGBCR<n>_EL1	*DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15* on page H9-4542
DBGBVR<n>_EL1	*DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15* on page H9-4545
DBGCLAIMCLR_EL1	*DBGCLAIMCLR_EL1, Debug Claim Tag Clear register* on page H9-4548
DBGCLAIMSET_EL1	*DBGCLAIMSET_EL1, Debug Claim Tag Set register* on page H9-4549
DBGDTRRX_EL0	*DBGDTRRX_EL0, Debug Data Transfer Register, Receive* on page H9-4550
DBGDTRTX_EL0	*DBGDTRTX_EL0, Debug Data Transfer Register, Transmit* on page H9-4551
DBGWCR<n>_EL1	*DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15* on page H9-4552
DBGWVR<n>_EL1	*DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15* on page H9-4555

Table J-33 Debug registers (continued)

Register	Description, see
EDACR	*EDACR, External Debug Auxiliary Control Register* on page H9-4557
EDCIDR0	*EDCIDR0, External Debug Component Identification Register 0* on page H9-4558
EDCIDR1	*EDCIDR1, External Debug Component Identification Register 1* on page H9-4559

J.7.4 Cross-trigger interface registers

This section is an index to the registers in the Cross-Trigger Interface registers functional group.

Table J-34 Cross-trigger interface registers

Register	Description, see
ASICCTL	*ASICCTL, CTI External Multiplexer Control register* on page H9-4626
CTIAPPCLEAR	*CTIAPPCLEAR, CTI Application Trigger Clear register* on page H9-4627
CTIAPPPULSE	*CTIAPPPULSE, CTI Application Pulse register* on page H9-4628
CTIAPPSET	*CTIAPPSET, CTI Application Trigger Set register* on page H9-4629
CTIAUTHSTATUS	*CTIAUTHSTATUS, CTI Authentication Status register* on page H9-4630
CTICHINSTATUS	*CTICHINSTATUS, CTI Channel In Status register* on page H9-4632
CTICHOUTSTATUS	*CTICHOUTSTATUS, CTI Channel Out Status register* on page H9-4633
CTICIDR0	*CTICIDR0, CTI Component Identification Register 0* on page H9-4634
CTICIDR1	*CTICIDR1, CTI Component Identification Register 1* on page H9-4635
CTICIDR2	*CTICIDR2, CTI Component Identification Register 2* on page H9-4636
CTICIDR3	*CTICIDR3, CTI Component Identification Register 3* on page H9-4637
CTICLAIMCLR	*CTICLAIMCLR, CTI Claim Tag Clear register* on page H9-4638
CTICLAIMSET	*CTICLAIMSET, CTI Claim Tag Set register* on page H9-4639
CTICONTROL	*CTICONTROL, CTI Control register* on page H9-4640
CTIDEVAFF0	*CTIDEVAFF0, CTI Device Affinity register 0* on page H9-4641
CTIDEVAFF1	*CTIDEVAFF1, CTI Device Affinity register 1* on page H9-4642
CTIDEVARCH	*CTIDEVARCH, CTI Device Architecture register* on page H9-4643
CTIDEVID	*CTIDEVID, CTI Device ID register 0* on page H9-4645
CTIDEVID1	*CTIDEVID1, CTI Device ID register 1* on page H9-4647
CTIDEVID2	*CTIDEVID2, CTI Device ID register 2* on page H9-4648
CTIDEVTYPE	*CTIDEVTYPE, CTI Device Type register* on page H9-4649
CTIGATE	*CTIGATE, CTI Channel Gate Enable register* on page H9-4650
CTIINEN<n>	*CTIINEN<n>, CTI Input Trigger to Output Channel Enable registers, n = 0 - 31* on page H9-4651
CTIINTACK	*CTIINTACK, CTI Output Trigger Acknowledge register* on page H9-4652

Table J-34 Cross-trigger interface registers (continued)

Register	Description, see
CTIITCTRL	*CTIITCTRL, CTI Integration mode Control register* on page H9-4654
CTILAR	*CTILAR, CTI Lock Access Register* on page H9-4655
CTILSR	*CTILSR, CTI Lock Status Register* on page H9-4656
CTIOUTEN<n>	*CTIOUTEN<n>, CTI Input Channel to Output Trigger Enable registers, n = 0 - 31* on page H9-4658
CTIPIDR0	*CTIPIDR0, CTI Peripheral Identification Register 0* on page H9-4659
CTIPIDR1	*CTIPIDR1, CTI Peripheral Identification Register 1* on page H9-4660
CTIPIDR2	*CTIPIDR2, CTI Peripheral Identification Register 2* on page H9-4661
CTIPIDR3	*CTIPIDR3, CTI Peripheral Identification Register 3* on page H9-4662
CTIPIDR4	*CTIPIDR4, CTI Peripheral Identification Register 4* on page H9-4663
CTITRIGINSTATUS	*CTITRIGINSTATUS, CTI Trigger In Status register* on page H9-4664
CTITRIGOUTSTATUS	*CTITRIGOUTSTATUS, CTI Trigger Out Status register* on page H9-4665

Glossary

Note

The update of the Glossary from ARMv7 to ARMv8 has been started but remains work-in-progress.

A32 instruction A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in A32 state. A32 instructions must be word-aligned.

A32 instructions were previously called ARM instructions.

See also A32 state, A64 instruction, T32 instruction.

A32 state The AArch32 Instruction set state in which the PE executes A32 instructions.

A32 state was previously called ARM state.

See also T32 instruction, T32 state.

A64 instruction A word that specifies an operation to be performed by a PE that is executing in an Exception level that is using AArch64. A64 instructions must be word-aligned.

See also A32 instruction, T32 instruction.

AArch32 The 32-bit Execution state. In AArch32 state, addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets

See also AArch64, A32 instruction, T32 instruction.

AArch64 The 64-bit Execution state. In AArch64 state, addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

See also AArch32, A64 instruction.

Abort An exception caused by an illegal memory access. Aborts can be caused by the external memory system or the MMU.

Addressing mode
Means a method for generating the memory address used by a load/store instruction.

Advanced SIMD A feature of the ARM architecture that provides SIMD operations on a register file of SIMD and floating-point registers. Where an implementation supports both Advanced SIMD and floating-point instructions, these instructions operate on the same register file.

Aligned A data item stored at an address that is divisible by the highest power of 2 that divides into its size in bytes. Aligned halfwords, words and doublewords therefore have addresses that are divisible by 2, 4 and 8 respectively.

An aligned access is one where the address of the access is aligned to the size of each element of the access.

Architecturally executed
An instruction is architecturally executed only if it would be executed in a simple sequential execution of the program. When such an instruction has been executed and retired is has been *architecturally executed*. Any instruction that, in a simple sequential execution of a program, is treated as a `NOP` because it fails its condition code check, is an architecturally executed instruction.

In a PE that performs speculative execution, an instruction is not architecturally executed if the PE discards the results of a speculative execution.

See also Condition code check.

ARM core registers
Some older documentation uses *ARM core registers* to refer to the following set of registers for execution in AArch32 state:

- The thirteen general-purpose registers, R0-R12, that software can use for processing.
- SP, the *stack pointer*, that can also be referred to as R13.
- LR, the *link register*, that can also be referred to as R14.
- PC, the *program counter*, that can also be referred to as R15.

See also General-purpose registers.

ARM instruction
See A32 instruction.

Associativity *See* Cache associativity.

Atomicity Describes either single-copy atomicity or multi-copy atomicity. *Atomicity in the ARM architecture* on page B2-79 defines these forms of atomicity for the ARM architecture.

See also Multi-copy atomicity, Single-copy atomicity.

Banked register A register that has multiple instances, with the instance that is in use depending on the PE mode, Security state, or other PE state.

Base register A register specified by a load/store instruction that is used as the base value for the address calculation for the instruction. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the virtual address that is sent to memory.

Base register writeback
Describes writing back a modified value to the base register used in an address calculation.

Big-endian memory
Means that, for example:

- A byte or halfword at a word-aligned address is the most significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the most significant byte in the halfword at that address.

Blocking Describes an operation that does not permit following instructions to be executed before the operation completes.

A non-blocking operation can permit following instructions to be executed before the operation completes, and in the event of encountering an exception does not signal an exception to the PE. This enables implementations to retire following instructions while the non-blocking operation is executing, without the need to retain precise PE state.

Branch prediction
Is where a PE selects a future execution path to fetch along. For example, after a branch instruction, the PE can choose to speculatively fetch either the instruction following the branch or the instruction at the branch target.

See also Prefetching.

Breakpoint A debug event triggered by the execution of a particular instruction, specified by one or both of the address of the instruction and the state of the PE when the instruction is executed.

Byte An 8-bit data item.

Cache associativity
The number of locations in a cache set to which an address can be assigned. Each location is identified by its *way* value.

Cache level The position of a cache in the cache hierarchy. In the ARM architecture, the lower numbered levels are those closest to the PE. For more information see *Terms used in describing the maintenance instructions* on page D3-1604.

Cache line The basic unit of storage in a cache. Its size in words is always a power of two, usually 4 or 8 words. A cache line must be aligned to a suitable memory boundary. A *memory cache line* is a block of memory locations with the same size and alignment as a cache line. Memory cache lines are sometimes loosely called cache lines.

Cache lockdown
Enables critical software and data to be loaded into the cache so that the cache lines containing them are not subsequently reallocated. It alleviates the delays caused by accessing a cache in a worst-case situation. This ensures that all subsequent accesses to the software and data concerned are cache hits and so complete quickly.

Cache miss A memory access that cannot be processed at high speed because the data it addresses is not in the cache.

Cache sets Areas of a cache, divided up to simplify and speed up the process of determining whether a cache hit occurs. The number of cache sets is always a power of two.

Cache way A cache way consists of one cache line from each cache set. The cache ways are indexed from 0 to (Associativity-1). Each cache line in a cache way is chosen to have the same index as the cache way. For example, cache way *n* consists of the cache line with index *n* from each cache set.

Coherence order
See Coherent.

Coherent Data accesses from a set of observers to a byte in memory are coherent if accesses to that byte in memory by the members of that set of observers are consistent with there being a single total order of all writes to that byte in memory by all members of the set of observers. This single total order of all to writes to that memory location is the *coherence order* for that byte in memory.

Condition code check
The process of determining whether a conditional instruction executes normally or is treated as a `NOP`. For an instruction that includes a condition code field, that field is compared with the condition flags to determine whether the instruction is executed normally. For a T32 instruction in an IT block, the value of the ITSTATE register determines whether the instruction is executed normally.

See also Condition code field, Condition flags, Conditional execution.

Condition code field
A 4-bit field in an instruction that specifies the condition under which the instruction executes.

See also Condition code check.

Condition flags The N, Z, C, and V bits of PSTATE, or of the APSR, CPSR, SPSR, or FPSCR. See the register descriptions for more information.

See also Condition code check, PSTATE.

Conditional execution
When a conditional instruction starts executing, if the condition code check returns TRUE, the instruction executes normally. Otherwise, it is treated as a NOP.

See also Condition code check.

CONSTRAINED UNPREDICTABLE
Where an instruction can result in UNPREDICTABLE behavior, the ARMv8 architecture specifies a narrow range of permitted behaviors. This range is the range of CONSTRAINED UNPREDICTABLE behavior. All implementations that are compliant with the architecture must follow the CONSTRAINED UNPREDICTABLE behavior.

See also UNPREDICTABLE.

Context switch The saving and restoring of computational state when switching between different threads or processes. In this manual, the term context switch describes any situation where the context is switched by an operating system and might or might not include changes to the address space.

Context synchronization operation
One of:

- Performing an ISB operation. An ISB operation is performed when an ISB instruction is executed and does not fail its condition code check.
- Taking an exception.
- Returning from an exception.
- Exit from Debug state.
- Executing a DCPS instruction.
- Executing a DRPS instruction.

The architecture requires a context synchronization operation to guarantee visibility of any change to a System register.

Digital signal processing (DSP)
Algorithms for processing signals that have been sampled and converted to digital form. DSP algorithms often use saturated arithmetic.

Direct Memory Access (DMA)
An operation that accesses main memory directly, without the PE performing any accesses to the data concerned.

DMA *See* Direct Memory Access (DMA).

DNM *See* Do-Not-Modify (DNM).

Domain In the ARM architecture, *domain* is used in the following contexts.

Shareability domain Defines a set of observers for which the shareability attributes make the data or unified caches transparent for data accesses.

Power domain Defines a block of logic with a single, common, power supply.

Memory regions domain
When using the Short-descriptor translation table format, defines a collection of Sections, Large pages and Small pages of memory, that can have their access permissions switched rapidly by writing to the *Domain Access Control Register* (DACR). ARM deprecates any use of memory regions domains.

Do-Not-Modify (DNM)
Means the value must not be altered by software. DNM fields read as UNKNOWN values, and must only be written with the value read from the same field on the same PE.

Double-precision value
Consists of two consecutive 32-bit words that are interpreted as a basic double-precision floating-point number according to the IEEE 754 standard.

Deprecated Something that is present in the ARM architecture for backwards compatibility. Whenever possible software must avoid using deprecated features. Features that are deprecated but are not optional are present in current implementations of the ARM architecture, but might not be present, or might be deprecated and OPTIONAL, in future versions of the ARM architecture.

See also OPTIONAL.

Doubleword A 64-bit data item. Doublewords are normally at least word-aligned in ARM systems.

Doubleword-aligned
Means that the address is divisible by 8.

DSP *See* Digital signal processing (DSP).

Endianness An aspect of the system memory mapping.

See also Big-endian memory and Little-endian memory.

Exception Handles an event. For example, an exception could handle an external interrupt or an undefined instruction.

Exception vector
A fixed address that contains the address of the first instruction of the corresponding exception handler.

Execution stream
The stream of instructions that would have been executed by sequential execution of the program.

Explicit access A read from memory, or a write to memory, generated by a load or store instruction executed by the PE. Reads and writes generated by hardware translation table accesses are not explicit accesses.

External abort An abort that is generated by the external memory system.

Fast Context Switch Extension (FCSE)
Modifies the behavior of an ARM memory system to enable multiple programs running on the ARM PE to use identical address ranges, while ensuring that the addresses they present to the rest of the memory system differ. From ARMv6, ARM deprecates any use of the FCSE. The FCSE is:

- Optional in an ARMv7 implementation that does not include the Multiprocessing Extensions.
- Obsolete from the introduction of the Multiprocessing Extensions.

FCSE *See* Fast Context Switch Extension (FCSE).

Flat address mapping
Is where the physical address for every access is equal to its virtual address.

Flush-to-zero mode
A special processing mode that optimizes the performance of some floating-point algorithms by replacing the denormalized operands and intermediate results with zeros, without significantly affecting the accuracy of their final results.

General-purpose registers
The registers that the base instructions use for processing:

- In AArch32 state the general-purpose registers are R0-R14, that can also be described as R0-R12, SP, LR.

  Note

  Older documentation defines the AArch32 general-purpose registers as R0-R12, and the ARM core registers as R0-R12, SP, LR, and PC.

- In AArch64 state the general-purpose registers are:
  — W0-W30 when accessed as 32-bit registers.
  — X0-X30 when accessed as 64-bit registers.

See also High registers, Low registers.

Halfword A 16-bit data item. Halfwords are normally halfword-aligned in ARM systems.

Halfword-aligned
Means that the address is divisible by 2.

High registers InAArch32 state, the general-purpose registers R8-R14. Most 16-bit T32 instructions cannot access the high registers.

Note

- In some contexts, *high registers* refers to R8-R15, meaning R8-R14 and the PC.

See also General-purpose registers, Low registers.

High vectors An alternative location for the exception vectors. The high vector address range is near the top of the address space, rather than at the bottom.

Immediate and offset fields
Are unsigned unless otherwise stated.

Immediate value
A value that is encoded directly in the instruction and used as numeric data when the instruction is executed. Many A64, A32, and T32 instructions can be used with an immediate argument.

IMP An abbreviation used in diagrams to indicate that one or more bits have IMPLEMENTATION DEFINED behavior.

IMPLEMENTATION DEFINED
Means that the behavior is not architecturally defined, but must be defined and documented by individual implementations. In body text, the term IMPLEMENTATION DEFINED is shown in SMALL CAPITALS.

Index register A register specified in some load and store instructions. The value of this register is used as an offset to be added to or subtracted from the base register value to form the virtual address that is sent to memory. Some instruction forms permit the index register value to be shifted before the addition or subtraction.

Inline literals These are constant addresses and other data items held in the same area as the software itself. They are automatically generated by compilers, and can also appear in assembler code.

Intermediate Physical Address (IPA)
An implementation of virtualization, the address to which an Guest OS maps a VA. A hypervisor might then map the IPA to a PA. Typically, the Guest OS is unaware of the translation from IPA to PA.

See also Physical address (PA), Virtual address (VA).

Interworking A method of working that permits branches between software using the A32 and T32 instruction sets.

IPA *See* Intermediate Physical Address (IPA).

Level *See* Cache level.

Level of coherence (LoC)
The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of coherency. For more information see *Terms used in describing the maintenance instructions* on page D3-1604.

See also Cache level, Point of coherency (PoC).

Level of unification, Inner Shareable (LoUIS)
The last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for the Inner Shareable shareability domain. For more information see *Terms used in describing the maintenance instructions* on page D3-1604.

See also Cache level, Point of unification (PoU).

Level of unification, uniprocessor (LoUU)
For a PE, the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the point of unification for that PE. For more information see *Terms used in describing the maintenance instructions* on page D3-1604.

See also Cache level, Point of unification (PoU).

Line *See* Cache line.

Little-endian memory
Means that:

- A byte or halfword at a word-aligned address is the least significant byte or halfword in the word at that address.
- A byte at a halfword-aligned address is the least significant byte in the halfword at that address.

Load/Store architecture
An architecture where data-processing operations only operate on register contents, not directly on memory contents.

LoC *See* Level of coherence (LoC).

LoUIS *See* Level of unification, Inner Shareable (LoUIS).

LoUU *See* Level of unification, uniprocessor (LoUU).

Lockdown *See* Cache lockdown.

Low registers InAArch32 state, general-purpose registers R0-R7. Unlike the high registers, all T32 instructions can access the Low registers.

See also General-purpose registers. High registers.

Memory barrier *See Memory barriers* on page B2-85

Memory coherency
The problem of ensuring that when a memory location is read, either by a data read or an instruction fetch, the value actually obtained is always the value that was most recently written to the location. This can be difficult when there are multiple possible physical locations, such as main memory and at least one of a write buffer and one or more levels of cache.

Memory Management Unit (MMU)
Provides detailed control of the part of a memory system that provides a single stage of address translation. Most of the control is provided using translation tables that are held in memory, and define the attributes of different regions of the physical memory map.

Memory Protection Unit (MPU)
A hardware unit whose registers provide simple control of a limited number of protection regions in memory.

Miss *See* Cache miss.

MMU *See* Memory Management Unit (MMU).

MPU *See* Memory Protection Unit (MPU).

Multi-copy atomicity
The form of atomicity described in *Requirements for multi-copy atomicity* on page B2-80.

See also Atomicity, Single-copy atomicity.

NaN Special floating-point values that can be used when neither a numeric value nor an infinity is appropriate. NaNs can be *quiet* NaNs that propagate through most floating-point operations, or *signaling* NaNs that cause Invalid Operation floating-point exceptions when used. For more information, see the IEEE 754 standard.

Natural eviction A natural eviction is an eviction that occurs in the course of the normal operation of the memory system, rather than because of an operation that explicitly causes an eviction from the cache, such as a cache maintenance operation. Typically, a natural eviction occurs when the caching algorithm requires data to be cached but the cache does not have room for that data.

Observer A PE or mechanism in the system, such as a peripheral device, that can generate reads from or writes to memory.

Obsolete Obsolete indicates something that is no longer supported by ARM. When an architectural feature is described as obsolete, this indicates that the architecture has no support for that feature, although an earlier version of the architecture did support it.

Offset addressing
Means that the memory address is formed by adding or subtracting an offset to or from the base register value.

OPTIONAL When applied to a feature of the architecture, OPTIONAL indicates a feature that is not required in an implementation of the ARM architecture:

- If a feature is OPTIONAL and deprecated, this indicates that the feature is being phased out of the architecture. ARM expects such a features to be included in a new implementation only if there is a known backwards-compatibility reason for the inclusion of the feature.

  A feature that is OPTIONAL and deprecated might not be present in future versions of the architecture.

- A feature that is OPTIONAL but not deprecated is, typically, a feature added to a version of the ARM architecture after the initial release of that version of the architecture. ARM recommends that such features are included in all new implementations of the architecture.

In body text, these meanings of the term OPTIONAL are shown in SMALL CAPITALS.

Note: Do not confuse these ARM-specific uses of OPTIONAL with other uses of *optional*, where it has its usual meaning. These include:

- Optional arguments in the syntax of many instructions.
- Behavior determined by an implementation choice.

See also Deprecated.

PA *See* Physical address (PA).

PE *See* Processing element (PE).

Physical address (PA)
An address that identifies a location in the physical memory map.

See also Intermediate Physical Address (IPA), Virtual address (VA).

PoC *See* Point of coherency (PoC).

PoU *See* Point of unification (PoU).

Point of coherency (PoC)
For a particular virtual address, the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. For more information see *Terms used in describing the maintenance instructions* on page D3-1604.

Point of unification (PoU)
For a particular PE, the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. For more information see *Terms used in describing the maintenance instructions* on page D3-1604.

Post-indexed addressing
Means that the memory address is the base register value, but an offset is added to or subtracted from the base register value and the result is written back to the base register.

Prefetching Prefetching refers to speculatively fetching instructions or data from the memory system. In particular, instruction prefetching is the process of fetching instructions from memory before the instructions that precede them, in simple sequential execution of the program, have finished executing. Prefetching an instruction does not mean that the instruction has to be executed.

In this manual, references to instruction or data fetching apply also to prefetching, unless the context explicitly indicates otherwise.

Note: The Prefetch Abort exception can be generated on any instruction fetch, and is not limited to speculative instruction fetches.

Pre-indexed addressing
Means that the memory address is formed in the same way as for offset addressing, but the memory address is also written back to the base register.

Processing element (PE)
The abstract machine defined in the ARM architecture, as documented in an ARM Architecture Reference Manual. A PE implementation compliant with the ARM architecture must conform with the behaviors described in the corresponding ARM Architecture Reference Manual.

Protection region
A memory region whose position, size, and other properties are defined by Memory Protection Unit registers.

Protection Unit *See* Memory Protection Unit (MPU).

Pseudo-instruction
UAL assembler syntax that assembles to an instruction encoding that is expected to disassemble to a different assembler syntax, and is described in this manual under that other syntax. For example, `MOV <Rd>, <Rm>, LSL #<n>` is a pseudo-instruction that is expected to disassemble as `LSL <Rd>, <Rm>, #<n>`.

PSTATE An abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

See also Condition flags.

Quadword A 128-bit data item. Quadwords are normally at least word-aligned in ARM systems.

Quadword-aligned
Means that the address is divisible by 16.

Quiet NaN A NaN that propagates unchanged through most floating-point operations.

RAO *See* Read-As-One (RAO)

RAZ *See* Read-As-Zero (RAZ).

RAO/SBOP In versions of the ARM architecture before ARMv8, Read-As-One, Should-Be-One-or-Preserved on writes.

In ARMv8, RES1 replaces this description.

See also UNK/SBOP, Read-As-One (RAO), Should-Be-One-or-Preserved (SBOP).

RAO/WI Read-As-One, Writes Ignored.

Hardware must implement the field as read as Read-as-One, and must ignore writes to the field.

Software can rely on the field reading as all 1s, and on writes being ignored.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

See also Read-As-One (RAO).

RAZ/SBZP In versions of the ARM architecture before ARMv8, Read-As-Zero, Should-Be-Zero-or-Preserved on writes.

In ARMv8, RES0 replaces this description.

See also UNK/SBZP, Read-As-Zero (RAZ), Should-Be-Zero-or-Preserved (SBZP).

RAZ/WI Read-As-Zero, Writes Ignored.

Hardware must implement the field as Read-as-Zero, and must ignore writes to the field.

Software can rely on the field reading as all 0s, and on writes being ignored.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

See also Read-As-Zero (RAZ).

Read-allocate cache
A cache in which a cache miss on reading data causes a cache line to be allocated into the cache.

Read-As-One (RAO)

Hardware must implement the field as reading as all 1s.

Software:

- Can rely on the field reading as all 1s.
- Must use a SBOP policy to write to the field.

This description can apply to a single bit that reads as 1, or to a field that reads as all 1s.

Read-As-Zero (RAZ)

Hardware must implement the field as reading as all 0s.

Software:

- Can rely on the field reading as all 0s
- Must use a SBZP policy to write to the field.

This description can apply to a single bit that reads as 0, or to a field that reads as all 0s.

Read, modify, write

In a read, modify, write instruction sequence, a value is read to a general-purpose register, the relevant fields updated in that register, and the new value written back.

RES0

Within the architecture, there are some cases where a register bit or bitfield:

- Is RES0 in some defined architectural context.
- Has different defined behavior in a different architectural context.

This means the definition of RES0 is:

If a bit is RES0 in all contexts

It is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 0. In this case:
   - Reads of the bit always return 0.
   - Writes to the bit are ignored.

   The bit might be described as RES0, WI, to distinguish it from a bit that behaves as described in 2.
2. The bit can be written. In this case:
   - A read of the bit returns the last value successfully written to the bit.

     Note

     As indicated in this list, this value might be written by an indirect write to the register.

     If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
   - A direct write to the bit must update a storage location associated with the bit.
   - An indirect write to the register sets the bit to 0.
   - The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit.

Whether RES0 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

If a bit is RES0 only in some contexts

When the bit is described as RES0:

- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

  Note

  As indicated in this list, this value might be written by an indirect write to the register.

If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.

- A direct write to the bit must update a storage location associated with the bit.
- An indirect write to the register sets the bit to 0.
- While the use of the register is such that the bit is described as RES0, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit.

For any RES0 bit, software:

- Must not rely on the bit reading as 0.
- Must use an SBZP policy to write to the bit.

The RES0 description can apply to bits or bitfields that are read-only, or are write-only:

- For a read-only bit, RES0 indicates that the bit reads as 0, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES0 indicates that software must treat the bit as SBZ.

This RES0 description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

In body text, the term RES0 is shown in SMALL CAPITALS.

See also Read-As-Zero (RAZ), Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.

RES1

Within the architecture, there are some cases where a register bit or bitfield:

- Is RES1 in some defined architectural context.
- Has different defined behavior in a different architectural context.

This means the definition of RES1 is:

If a bit is RES1 in all contexts

It is IMPLEMENTATION DEFINED whether:

1. The bit is hardwired to 1. In this case:
   - Reads of the bit always return 1.
   - Writes to the bit are ignored.

   The bit might be described as RES1, WI, to distinguish it from a bit that behaves as described in 2.
2. The bit can be written. In this case:
   - A read of the bit returns the last value successfully written to the bit.

     Note

     As indicated in this list, this value might be written by an indirect write to the register.

     If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
   - A direct write to the bit must update a storage location associated with the bit.
   - An indirect write to the register sets the bit to 1.
   - The value of the bit must have no effect on the operation of the PE, other than determining the value read back from the bit.

Whether RES1 bits or fields follow behavior 1 or behavior 2 is IMPLEMENTATION DEFINED on a field-by-field basis.

If a bit is RES1 only in some contexts

When the bit is described as RES1:

- A read of the bit must return the value last successfully written to the bit, regardless of the use of the register when the bit was written.

  Note

  As indicated in this list, this value might be written by an indirect write to the register.

  If the bit has not been successfully written since reset, then the read of the bit returns the reset value if there is one, or otherwise returns an UNKNOWN value.
- A direct write to the bit must update a storage location associated with the bit.
- An indirect write to the register sets the bit to 1.
- While the use of the register is such that the bit is described as RES1, the value of the bit must have no effect on the operation of the PE, other than determining the value read back from that bit.

For any RES1 bit, software:

- Must not rely on the bit reading as 0.
- Must use an SBOP policy to write to the bit.

The RES1 description can apply to bits or bitfields that are read-only, or are write-only:

- For a read-only bit, RES1 indicates that the bit reads as 0, but software must treat the bit as UNKNOWN.
- For a write-only bit, RES1 indicates that software must treat the bit as SBO.

This RES1 description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

In body text, the term RES1 is shown in SMALL CAPITALS.

See also Read-As-One (RAO), Should-Be-One-or-Preserved (SBOP), UNKNOWN.

Reserved Unless otherwise stated:

- Instructions that are reserved or that access reserved registers have UNPREDICTABLE behavior.
- Bit positions described as reserved are:
  - In an RW register, RES0.
  - In an RO register, UNK.
  - In a WO register, RES0.

RISC Reduced Instruction Set Computer.

Rounding error The value of the rounded result of an arithmetic operation minus the exact result of the operation.

Rounding mode Specifies how the exact result of a floating-point operation is rounded to a value that is representable in the destination format.

Round to Nearest (RN) mode
Means that the rounded result is the nearest representable number to the unrounded result.

Round towards Plus Infinity (RP) mode
Means that the rounded result is the nearest representable number that is greater than or equal to the exact result.

Round towards Minus Infinity (RM) mode
Means that the rounded result is the nearest representable number that is less than or equal to the exact result.

Round towards Zero (RZ) mode
Means that results are rounded to the nearest representable number that is no greater in magnitude than the unrounded result.

Saturated arithmetic
Integer arithmetic in which a result that would be greater than the largest representable number is set to the largest representable number, and a result that would be less than the smallest representable number is set to the smallest representable number. Signed saturated arithmetic is often used in DSP algorithms. It contrasts with the normal signed integer arithmetic used in ARM processors, in which overflowing results wrap around from $+2^{31}–1$ to $–2^{31}$ or vice versa.

SBO *See* Should-Be-One (SBO).

SBOP *See* Should-Be-One-or-Preserved (SBOP).

SBZ *See* Should-Be-Zero (SBZ).

SBZP *See* Should-Be-Zero-or-Preserved (SBZP).

Security hole A mechanism by which execution at the current level of privilege can achieve an outcome that cannot be achieved at the current or a lower level of privilege using instructions that are not UNPREDICTABLE. The ARM architecture forbids security holes.

Self-modifying code
Code that writes one or more instructions to memory and then executes them. When using self-modifying code you must use cache maintenance and barrier instructions to ensure synchronization. For more information see *Caches and memory hierarchy* on page B2-70.

Set *See* Cache sets.

Should-Be-One (SBO)
Hardware must ignore writes to the field.

Software should write the field as all 1s. If software writes a value that is not all 1s, it must expect an UNPREDICTABLE result.

This description can apply to a single bit that should be written as 1, or to a field that should be written as all 1s.

Should-Be-One-or-Preserved (SBOP)
From the introduction of the ARMv7 Large Physical Address Extension the definition of SBOP is modified for register bits that are SBOP in some but not all contexts. For more information see *Meaning of fixed bit values in register diagrams* on page G4-3762. The generic definition of SBOP given here applies only to bits that are not affected by this modification.

Hardware must ignore writes to the field.

If software has read the field since the PE implementing the field was last reset and initialized, it should preserve the value of the field by writing the value that it previously read from the field. Otherwise, it should write the field as all 1s.

If software writes a value to the field that is not a value previously read for the field and is not all 1s, it must expect an UNPREDICTABLE result.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

Should-Be-Zero (SBZ)
Hardware must ignore writes to the field.

Software should write the field as all 0s. If software writes a value that is not all 0s, it must expect an UNPREDICTABLE result.

This description can apply to a single bit that should be written as 0, or to a field that should be written as all 0s.

Should-Be-Zero-or-Preserved (SBZP)
From the introduction of the ARMv7 Large Physical Address Extension, the definition of SBZP is modified for register bits that are SBZP in some but not all contexts. For more information see *Meaning of fixed bit values in register diagrams* on page G4-3762. The generic definition of SBZP given here applies only to bits that are not affected by this modification.

Hardware must ignore writes to the field.

If software has read the field since the PE implementing the field was last reset and initialized, it must preserve the value of the field by writing the value that it previously read from the field. Otherwise, it must write the field as all 0s.

If software writes a value to the field that is not a value previously read for the field and is not all 0s, it must expect an UNPREDICTABLE result.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

Signaling NaNs Cause an Invalid Operation exception whenever any floating-point operation receives a signaling NaN as an operand. Signaling NaNs can be used in debugging, to track down some uses of uninitialized variables.

Signed immediate and offset fields
Are encoded in two's complement notation unless otherwise stated.

SIMD Single-Instruction, Multiple-Data.

The SIMD instructions in AArch32 state are:

- The instructions summarized in *Parallel addition and subtraction instructions* on page F1-2306.
- The Advanced SIMD instructions summarized in *Advanced SIMD and floating-point instructions* on page E1-2216, when operating on vectors.

Note

In ARMv7, some VFP instructions can operate on vectors. However, ARM deprecates those instruction uses, and strongly recommends that Advanced SIMD instructions are always used for vector operations.

Simple sequential execution
The behavior of an implementation that fetches, decodes and completely executes each instruction before proceeding to the next instruction. Such an implementation performs no speculative accesses to memory, including to instruction memory. The implementation does not pipeline any phase of execution. In practice, this is the theoretical execution model that the architecture is based on, and ARM does not expect this model to correspond to a realistic implementation of the architecture.

Single-copy atomicity
The form of atomicity described in *Single-copy atomicity* on page B2-79.

See also Atomicity, Multi-copy atomicity.

Single-precision value
A 32-bit word that is interpreted as a basic single-precision floating-point number according to the IEEE 754 standard.

Spatial locality The observed effect that after a program has accessed a memory location, it is likely to also access nearby memory locations in the near future. Caches with multi-word cache lines exploit this effect to improve performance.

SUBARCHITECTURE DEFINED
Means that the behavior is expected to be specified by a subarchitecture definition. This definition might be shared by multiple implementations, but it must not be relied on by architecturally-portable software.

Subarchitecture definitions are used for:

- The interface between an ARMv7 VFP Extension implementation and its support code.
- The interface between an ARMv7 implementation of the Jazelle extension and an Enabled JVM.

In body text, the term SUBARCHITECTURE DEFINED is shown in SMALL CAPITALS.

T32 instruction One or two halfwords that specify an operation to be performed by a PE that is executing in an Exception level that is using AArch32 and is in T32 state. T32 instructions must be halfword-aligned.

T32 instructions were previously called Thumb instructions.

See also A32 instruction, A64 instruction, T32 state.

T32 state The AArch32 Instruction set state in which the PE executes T32 instructions.

T32 state was previously called Thumb state.

See also A32 state, T32 instruction.

Temporal locality
The observed effect that after a program has accesses a memory location, it is likely to access the same memory location again in the near future. Caches exploit this effect to improve performance.

Thumb instruction
See T32 instruction.

TLB *See* Translation Lookaside Buffer (TLB).

TLB lockdown A way to prevent specific translation table walk results being accessed. This ensures that accesses to the associated memory areas never cause a translation table walk.

Translation Lookaside Buffer (TLB)
A memory structure containing the results of translation table walks. They help to reduce the average cost of a memory access. Usually, there is a TLB for each memory interface of the ARM implementation.

Translation table
A table held in memory that defines the properties of memory areas of various sizes from 1KB to 1MB.

Translation table walk
The process of doing a full translation table lookup. It is performed automatically by hardware.

Trap enable bits In VFPv2, VFPv3U, and VFPv4U, determine whether trapped or untrapped exception handling is selected. If trapped exception handling is selected, the way it is carried out is IMPLEMENTATION DEFINED.

Unaligned An unaligned access is an access where the address of the access is not aligned to the size of an element of the access.

Unaligned memory accesses
Are memory accesses that are not, or might not be, appropriately halfword-aligned, word-aligned, or doubleword-aligned.

Unallocated Except where otherwise stated in this manual, an instruction encoding is unallocated if the architecture does not assign a specific function to the entire bit pattern of the instruction, but instead describes it as CONSTRAINED UNPREDICTABLE, UNDEFINED, UNPREDICTABLE, or an unallocated hint instruction.

A bit in a register is unallocated if the architecture does not assign a function to that bit.

UNDEFINED Indicates an instruction that generates an Undefined Instruction exception.

In body text, the term UNDEFINED is shown in SMALL CAPITALS.

See also *Undefined Instruction exception* on page G1-3428.

Unified cache Is a cache used for both processing instruction fetches and processing data loads and stores.

Unindexed addressing
Means addressing in which the base register value is used directly as the virtual address to send to memory, without adding or subtracting an offset. In most types of load/store instruction, unindexed addressing is performed by using offset addressing with an immediate offset of 0. The `LDC`, `LDC2`, `STC`, and `STC2` instructions have an explicit unindexed addressing mode that permits the offset field in the instruction to specify additional coprocessor options.

UNK An abbreviation indicating that software must treat a field as containing an UNKNOWN value.

Hardware must implement the bit as read as 0, or all 0s for a bit field. Software must not rely on the field reading as zero.

See also UNKNOWN.

UNK/SBOP Hardware must implement the field as Read-As-One, and must ignore writes to the field.

Software must not rely on the field reading as all 1s, and except for writing back to the register it must treat the value as if it is UNKNOWN. Software must use an SBOP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 1, or to a field that should be written as its preserved value or as all 1s.

See also Read-As-One (RAO), Should-Be-One-or-Preserved (SBOP), UNKNOWN.

UNK/SBZP Hardware must implement the bit as Read-As-Zero, and must ignore writes to the field.

Software must not rely on the field reading as all 0s, and except for writing back to the register must treat the value as if it is UNKNOWN. Software must use an SBZP policy to write to the field.

This description can apply to a single bit that should be written as its preserved value or as 0, or to a field that should be written as its preserved value or as all 0s.

See also Read-As-Zero (RAZ), Should-Be-Zero-or-Preserved (SBZP), UNKNOWN.

UNKNOWN An UNKNOWN value does not contain valid data, and can vary from moment to moment, instruction to instruction, and implementation to implementation. An UNKNOWN value must not return information that cannot be accessed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE and do not return UNKNOWN values.

An UNKNOWN value must not be documented or promoted as having a defined value or effect.

In body text, the term UNKNOWN is shown in SMALL CAPITALS.

See also UNK.

UNPREDICTABLE

Means the behavior cannot be relied upon. UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or a lower level of privilege using instructions that are not UNPREDICTABLE.

UNPREDICTABLE behavior must not be documented or promoted as having a defined effect.

An instruction that is UNPREDICTABLE can be implemented as UNDEFINED.

Execution in a Non-secure EL1 or EL0 mode of an instruction that is UNPREDICTABLE can be implemented as generating a Hyp Trap exception, provided that at least one instruction that is not UNPREDICTABLE causes a Hyp Trap exception.

In body text, the term UNPREDICTABLE is shown in SMALL CAPITALS.

See also CONSTRAINED UNPREDICTABLE.

VA *See* Virtual address (VA).

VFP In ARMv7, an extension to the ARM architecture, that provides single-precision and double-precision floating-point arithmetic.

Virtual address (VA)

An address generated by an ARM PE. This means it is an address that might be held in the program counter of the PE. For a PMSA implementation, the virtual address is identical to the physical address.

See also Intermediate Physical Address (IPA), Physical address (PA).

Watchpoint A debug event triggered by an access to memory, specified in terms of the address of the location in memory being accessed.

Way *See* Cache way.

WI Writes Ignored. In a register that software can write to, a WI attribute applied to a bit or field indicates that the bit or field ignores the value written by software and retains the value it had before that write.

See also RAO/WI, RAZ/WI, RES0, RES1.

Word A 32-bit data item. Words are normally word-aligned in ARM systems.

Word-aligned Means that the address is divisible by 4.

Write-allocate cache

A cache in which a cache miss on storing data causes a cache line to be allocated into the cache.

Write-back cache

A cache in which when a cache hit occurs on a store access, the data is only written to the cache. Data in the cache can therefore be more up-to-date than data in main memory. Any such data is written back to main memory when the cache line is cleaned or reallocated. Another common term for a write-back cache is a *copy-back cache*.

Write-through cache

A cache in which when a cache hit occurs on a store access, the data is written both to the cache and to main memory. This is normally done via a write buffer, to avoid slowing down the PE.

Write buffer A block of high-speed memory that optimizes stores to main memory.
