integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
boolean unsigned = (U == '1');
```

Alias conditions

Alias	is preferred when
UXTL	`BitCount(immh) == 1 && immb == '000'`

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = `0`

[present] when Q = `1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the Rd field.

`<Ta>` Is an arrangement specifier, encoded in the immh field:

See Advanced SIMD modified immediate. when immh = `0000`

8H when immh = `0001`

4S when immh = `001x`

2D when immh = `01xx`

RESERVED when immh = `1xxx`

`<Vn>` Is the name of the SIMD&FP source register, encoded in the Rn field.

`<Tb>` Is an arrangement specifier, encoded in the immh:Q field:

See Advanced SIMD modified immediate. when immh = `0000`, Q = `x`

8B when immh = `0001`, Q = `0`

16B when immh = `0001`, Q = `1`

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

RESERVED when immh = 1xxx, Q = x

<shift> Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the immh:immb field:

See Advanced SIMD modified immediate. when immh = 0000

(UInt(immh:immb)-8) when immh = 0001

(UInt(immh:immb)-16) when immh = 001x

(UInt(immh:immb)-32) when immh = 01xx

RESERVED when immh = 1xxx

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(datasize*2) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

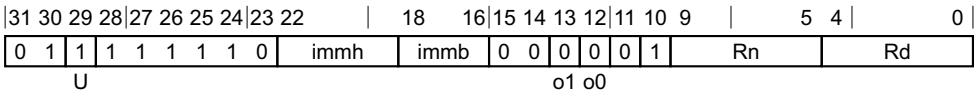
V[d] = result;
```

C7.3.340 USHR

Unsigned shift right (immediate)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

2D when immh = 1xxx, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the immh:immb field:

RESERVED when immh = 0xxx

(128-UInt(immh:immb)) when immh = 1xxx

<shift> For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the immh:immb field:

See Advanced SIMD modified immediate. when immh = 0000

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

(128-UInt(immh:immb)) when immh = 1xxx

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand  = V[n];
bits(datasize) operand2;
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

operand2 = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element = (Int(Elem[operand, e, esize], unsigned) + round_const) >> shift;
    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;

V[d] = result;
```

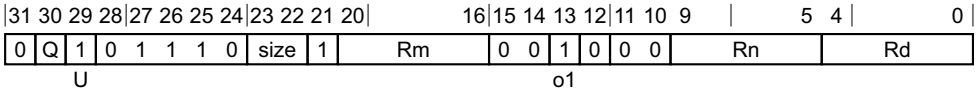
C7.3.343 USUBL, USUBL2

Unsigned subtract long



Three registers, not all the same type variant

```
USUBL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

2 — Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

- **[absent]** when Q = 0
- **[present]** when Q = 1

<Vd> — Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Ta> — Is an arrangement specifier, encoded in the size field:

- **8H** when size = 00
- **4S** when size = 01
- **2D** when size = 10
- **RESERVED** when size = 11

<Vn> — Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Tb> — Is an arrangement specifier, encoded in the size:Q field:

- **8B** when size = 00, Q = 0
- **16B** when size = 00, Q = 1
- **4H** when size = 01, Q = 0
- **8H** when size = 01, Q = 1
- **2S** when size = 10, Q = 0
- **4S** when size = 10, Q = 1
- **RESERVED** when size = 11, Q = x

<Vm> — Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize)   operand1 = Vpart[n, part];
bits(datasize)   operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

V[d] = result;
```

Part D

The AArch64 System Level Architecture

Chapter D1
The AArch64 System Level Programmers' Model

This chapter describes the AArch64 system level programmers' model. It contains the following sections:

D1.1 Exception levels

The ARMv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If EL*n* is the Exception level, increased values of *n* indicate increased software execution privilege.
- Execution at EL0 is called *unprivileged execution*.
- EL2 provides support for virtualization of Non-secure operation.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

Note

A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

Supported configurations on page D1-1524 shows some example implementations.

When executing in AArch64 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the *target Exception level* of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the system control registers.

An exception cannot target EL0.

Exception levels exist within a particular Security state. *The ARMv8-A security model* on page D1-1404 describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then when execution is at EL3, the PE can access all resources available at all Exception levels, for both Security states.

Each Exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see Chapter D4 *The AArch64 Virtual Memory System Architecture*.

D1.1.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

EL0 Applications.

EL1 OS kernel and associated functions that are typically described as *privileged*.

EL2 Hypervisor.

EL3 Secure monitor.

D1.2 Exception terminology

The following subsections define the terms used when describing exceptions:

- *Terminology for taking an exception*.
- *Terminology for returning from an exception*.
- *Exception levels*.
- *Definition of a precise exception*.
- *Definitions of synchronous and asynchronous exceptions* on page D1-1402.

D1.2.1 Terminology for taking an exception

An exception is *generated* when the PE first responds to an exceptional condition.The PE state at this time is the state the exception is *taken from*. The PE state immediately after taking the exception is the state the exception is *taken to*.

D1.2.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction.The PE state when an exception return instruction is committed for execution is the state the exception *returns from*. The PE state immediately after the execution of that instruction is the state the exception *returns to*.

D1.2.3 Exception levels

An Exception level, EL*n*, with a larger value of *n* than another Exception level, is described as being a *higher* Exception level than the other Exception level. For example, EL3 is a higher Exception level than EL1.

An Exception level with a smaller value of *n* than another Exception level is described as being a *lower* Exception level than the other Exception level. For example, EL0 is a lower Exception level than EL1.

An Exception level is described as:

- *Using AArch64* when execution in that Exception level is in the AArch64 Execution state.
- *Using AArch32* when execution in that Exception level is in the AArch32 Execution state.

D1.2.4 Definition of a precise exception

An exception is described as *precise* when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Other than the *SError interrupt*, all exceptions taken to AArch64 state are required to be precise. For each occurrence of an SError interrupt, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED

Where a synchronous exception that is taken to AArch64 state is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by the instructions can be UNKNOWN, provided that:

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
- The registers are not involved in the calculation of the memory address used by the instruction.

Examples of instructions that perform more than one single-copy atomic memory access are the AArch32 `LDM` and `STM` instructions and the AArch64 `LDP` and `STP` instructions.

Note

- For the definition of a single-copy atomic access, see *Single-copy atomicity* on page B2-79.
- SError interrupts are known as Asynchronous Aborts in AArch32 state.
- By definition, all synchronous aborts are precise.

D1.2.5 Definitions of synchronous and asynchronous exceptions

An exception is described as *synchronous* if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

For more information about synchronous exceptions, see *Synchronous exception types, routing and priorities* on page D1-1447.

An exception is described as *asynchronous* if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about asynchronous exceptions, see *Asynchronous exception types, routing, masking and priorities* on page D1-1453.

D1.3 Execution state

The Execution states are:

AArch64 The 64-bit Execution state.

AArch32 The 32-bit Execution state. Operation in this state is compatible with ARMv7-A operation.

Execution state on page A1-33 gives more information about them.

Exception levels *use* Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.
- The PE can change Execution states only either:
  - At reset.
  - On a change of Exception level.

Note

- *Typical Exception level usage model* on page D1-1400 shows which Exception levels different software layers might typically use.
- *Supported configurations* on page D1-1524 gives information on supported configurations of Exception levels and Execution states.

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. *Interprocessing* on page D1-1512 describes this.

D1.4 Security state

The ARMv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

Secure state When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space.

Non-secure state When in this state, the PE:

- Can access only the Non-secure physical address space.
- Cannot access the Secure system control resources.

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see *About the Virtual Memory System Architecture (VMSA)* on page D4-1634.

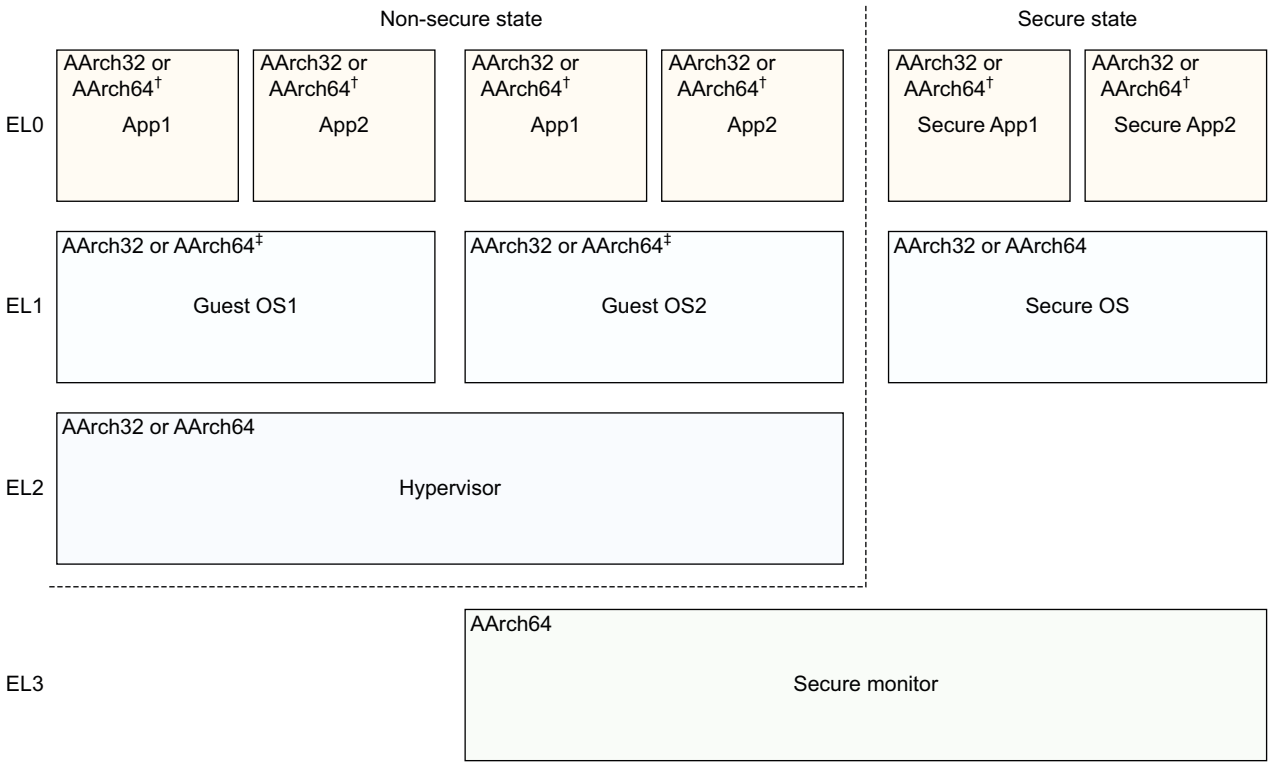
D1.4.1 The ARMv8-A security model

The general principles of the ARMv8-A security model are:

- If the implementation includes EL3 then it has two Security states, Secure and Non-secure, and:
  - EL3 exists only in Secure state.
  - A change from Non-secure state to Secure state can only occur on taking an exception to EL3.
  - A change from Secure state to Non-secure state can only occur on an exception return from EL3.
  - If EL2 is implemented, it exists only in Non-secure state.
- If the implementation does not include EL3 it has one Security state, that is:
  - IMPLEMENTATION DEFINED, if the implementation does not include EL2.
  - Non-secure state if the implementation includes EL2.

Security model when EL3 is using AArch64

Figure D1-1 on page D1-1405 shows the security model when EL3 is using AArch64. The figure shows how instances of EL0 and EL1 are present in both Security states. It also shows the expected software usage of the different Exception levels.



† AArch64 permitted only if EL1 is using AArch64
‡ AArch64 permitted only if EL2 is using AArch64

Figure D1-1 ARMv8-A security model when EL3 is using AArch64

For an overview of the Security model when EL3 is using AArch32, see Figure G1-1 on page G1-3374.

D1.5 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2.

EL2 provides a set of features that support virtualizing the Non-secure state of an ARMv8-A implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between *virtual machines*. A virtual machine is comprised of Non-secure EL1 and Non-secure EL0.
- A number of Guest operating systems, that each run in Non-secure EL1, on a virtual machine.
- For each Guest operating system, applications, that usually run in Non-secure EL0, on a virtual machine.

Note

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The ARMv8-A architecture supports both of these models.

The hypervisor assigns a *virtual machine identifier* (VMID) to each virtual machine.

EL2 is implemented only in Non-secure state, to support Guest OS management. EL2 provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.
- *Trap* various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2. See *Controls at higher Exception levels* on page D1-1459.
- Route interrupts to the appropriate one of:
  - The current Guest OS.
  - A Guest OS that is not currently running.
  - The hypervisor.

In Non-secure state:

- The implementation provides an independent *translation regime* for memory accesses from EL2.
- For the EL1&0 translation regime, address translation occurs in two stages:
  - Stage 1 maps the *Virtual Address* (VA) to an *Intermediate Physical Address* (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the *Physical Address* (PA).
  - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

For more information on the translation regimes, see Chapter D4 *The AArch64 Virtual Memory System Architecture*.

D1.5.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- Hypervisor Call (HVC) exception.
- Traps to EL2. *Trapping to EL2 using AArch64* on page D1-1467, describes these.
- All of the virtual interrupts:
  - Virtual SError.
  - Virtual IRQ.
  - Virtual FIQ.

Hypervisor call exceptions are always taken to EL2. All virtual interrupts are always taken to EL1, and can only be taken from Non-secure EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See *Virtual interrupts* on page D1-1407.

When a virtual interrupt is enabled, its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3.

For more information, see *Asynchronous exception types, routing, masking and priorities* on page D1-1453.

An implementation that includes EL2 also:

- Provides controls that can be used to route some synchronous exceptions, taken from Non-secure state, to EL2. For more information see:
  - *Routing general exceptions to EL2* on page D1-1447.
  - *Routing debug exceptions* on page D2-1534.
- Provides mechanisms to trap PE operations to EL2. See *Trapping to EL2 using AArch64* on page D1-1467.

  When an operation is trapped to EL2, the hypervisor typically either:
  - Emulates the required operation. The application running in the Guest OS is unaware of the trap.
  - Returns an error to the Guest OS.

Virtual interrupts

The virtual interrupts have names that correspond to the physical interrupts, as shown in Table D1-1.

Table D1-1 The virtual interrupt

Physical interrupt	Corresponding virtual interrupt
SError	Virtual SError
IRQ	Virtual IRQ
FIQ	Virtual FIQ

Software executing in EL2 can use virtual interrupts to signal physical interrupts to Non-secure EL1 and Non-secure EL0. Example D1-1 shows a usage model for virtual interrupts.

Example D1-1 Virtual interrupt usage model

A usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.
2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
   - If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
   - If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

A hypervisor can prevent Non-secure EL1 and Non-secure EL0 from distinguishing a virtual interrupt from a physical interrupt.

For more information see:

- *Asynchronous exception types, routing, masking and priorities* on page D1-1453.
- *Virtual interrupts* on page D1-1456.

D1.6 Registers for instruction processing and exception handling

In the ARM architecture, registers fall into two main categories:

- Registers that provide system control or status reporting. These are described in Chapter D7 *AArch64 System Register Descriptions*.
- Registers that are used in instruction processing, for example to accumulate a result, and in handling exceptions. This section introduces these registers, for execution in AArch64 state.

This section contains the following subsections:

D1.6.1 The general purpose registers, R0-R30

The general purpose register bank is used when processing instructions in the base instruction set. It comprises 31 general purpose registers, R0-R30.

These registers can be accessed as 31 64-bit registers, X0-X30, or 31 32-bit registers, W0-W30. See *Register size* on page C6-383.

For information on the format of these registers, see *Registers in AArch64 state* on page B1-59.

D1.6.2 The stack pointer registers

In AArch64 state, in addition to the general purpose registers, a dedicated stack pointer register is implemented for each implemented Exception level. The stack pointer registers are:

- SP_EL0 and SP_EL1.
- If the implementation includes EL2, SP_EL2.
- If the implementation includes EL3, SP_EL3.

Note

The four stack pointer register names define an architecture state requirement for four registers. For information on how to access these registers, and access restrictions, see *PSTATE and special purpose registers* on page C5-252.

For information on stack pointer alignment restrictions, see *Stack pointer alignment checking* on page D1-1416.

Stack pointer register selection

When executing at EL0, the PE uses the EL0 stack pointer, SP_EL0.

When executing at any other Exception level, the PE can be configured to use either SP_EL0 or the stack pointer for that Exception level, SP_ELx.

By default, taking an exception selects the stack pointer for the target Exception level, SP_ELx. For example, taking an exception to EL1 selects SP_EL1. Software executing at the target Exception level can then choose to change the stack pointer to SP_EL0 by updating PSTATE.SP.

This applies even if taking the exception does not change the Exception level. For example, if the PE is executing at EL1 and the PE is using the SP_EL0 stack pointer, then on taking an exception that targets EL1, the stack pointer changes to SP_EL1.

The selected stack pointer can be indicated by a suffix to the Exception level:

t Indicates use of the SP_EL0 stack pointer.

h Indicates use of the SP_ELx stack pointer.

Note

The t and h suffixes are based on the terminology of *thread* and *handler*, introduced in ARMv7-M

Table D1-2 shows the set of stack pointer options.

Table D1-2 AArch64 stack pointer options

Exception level	AArch64 stack pointer options
EL0	EL0t
EL1	EL1t, EL1h
EL2	EL2t, EL2h
EL3	EL3t, EL3h

D1.6.3 The SIMD and floating-point registers, V0-V31

The SIMD and floating-point instructions share a common bank of registers for floating-point, vector, and other SIMD-related scalar operations.

The SIMD and floating-point register bank comprises 32 quadword (128-bit) registers, V0-V31.

These registers can be accessed as:

- 32 doubleword (64-bit) registers, D0-D31.
- 32 word (32-bit) registers, S0-S31.
- 32 halfword (16-bit) registers, H0-H31.
- 32 byte (8-bit) registers, B0-B31.

For information on the format of these registers, see *Registers in AArch64 state* on page B1-59.

D1.6.4 Saved Program Status Registers (SPSRs)

The *Saved Program Status Registers* (SPSRs) are used to save PE state on taking exceptions.

In AArch64 state, there is an SPSR at each Exception level exceptions can be taken to, as follows:

- SPSR_EL1, for exceptions taken to EL1 using AArch64.
- If EL2 is implemented, SPSR_EL2, for exceptions taken to EL2 using AArch64.
- If EL3 is implemented, SPSR_EL3, for exceptions taken to EL3 using AArch64.

When the PE takes an exception, PE state is saved in the SPSR at the Exception level the exception is taken to. For example, if the PE takes an exception to EL1, PE state is saved in SPSR_EL1.

When the PE returns from an exception, PE state is restored to the state stored in the SPSR at the Exception level the exception is returning from. For example, on returning from EL1, PE state is restored to the state stored in SPSR_EL1.

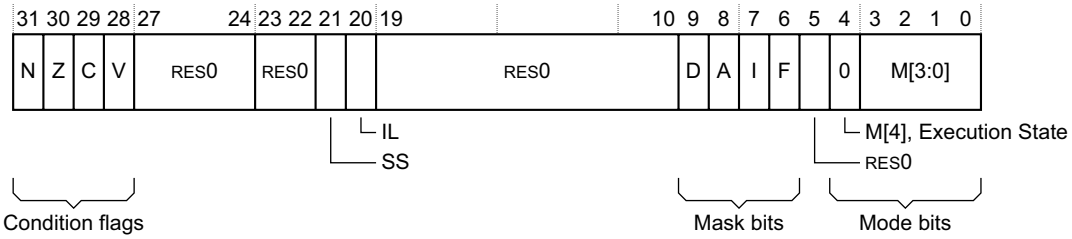
Note

Exceptions cannot be taken to EL0.

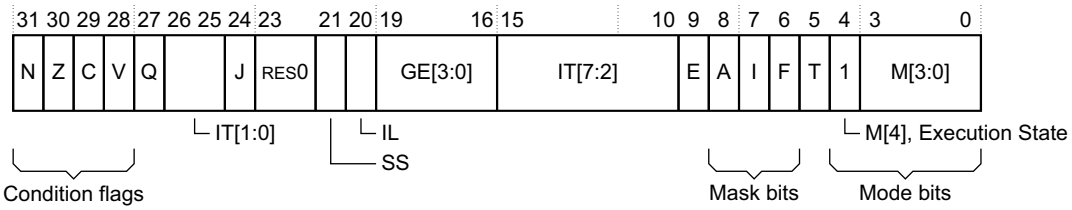
SPSR format for exceptions taken to AArch64 state

Exceptions can be taken to AArch64 state from AArch64 state or AArch32 state:

- For an exception taken to AArch64 state from AArch64 state, the SPSR bit assignments are:



- For an exception taken to AArch64 state from AArch32 state, the SPSR bit assignments are:



The following list describes the bit assignments:

Condition flags, bits[31:28]

Shows the values of the condition flags immediately before the exception was taken:

N, bit[31] Negative condition flag.

Z, bit[30] Zero condition flag.

C, bit[29] Carry condition flag.

V, bit[28] Overflow condition flag.

Bits[27:22] Reserved, RES0, for exceptions taken from AArch64 state.

For exceptions taken from AArch32 state:

Q Shows the value of PSTATE.Q immediately before the exception was taken.

IT[1:0] See *Bits[19:10]*.

J Shows the value of PSTATE.J immediately before the exception was taken.

For the definitions of the Q, IT, and J fields, see *Format of the CPSR and SPSRs* on page G1-3388.

Bit[21] SS, the Software Step bit.

SPSR_ELx.SS is used by a debugger to initiate a Software Step exception. The SS bit also indicates which software step state machine state the PE was in. See *Software Step exceptions* on page D2-1579.

IL, bit[20] Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken. See *Illegal return events* on page D1-1438. This bit is an Execution state bit, meaning it cannot be read or written in the AArch32 CPSR.

Bits[19:10] Reserved, RES0, for exceptions taken from AArch64 state.

For exceptions taken from AArch32 state:

GE[3:0] Shows the value of PSTATE.GE immediately before the exception was taken.

IT[7:2] In conjunction with IT[1:0], shows the value of PSTATE.IT before the exception was taken.

For the definitions of the GE and IT fields, see *Format of the CPSR and SPSRs* on page G1-3388.

Bit[9] D, the debug exception mask bit, for exceptions taken from AArch64 state. Shows the value of PSTATE.D immediately before the exception was taken. See *The PSTATE debug mask bit, D* on page D1-1509.

E, for exceptions taken from AArch32 state. Shows the value of PSTATE.E immediately before the exception was taken. For the definition of the E bit, see *Format of the CPSR and SPSRs* on page G1-3388.

Interrupt mask bits, bits[8:6]

Shows the values of the interrupt mask bits immediately before the exception was taken:

A, bit[8] SError interrupt mask bit.

I, bit[7] IRQ mask bit.

F, bit[6] FIQ mask bit.

See *Asynchronous exception masking* on page D1-1454.

Bit[5] Reserved, RES0, for exceptions taken from AArch64 state.

T, for exceptions taken from AArch32 state. Shows the value of PSTATE.T immediately before the exception was taken. For the definition of the T bit, see *Format of the CPSR and SPSRs* on page G1-3388.

M[4:0], bits[4:0]

Mode field.

Note

The name of this field is inherited from ARMv7, where the M field specified the PE *mode*.

For exceptions taken from AArch64 state:

M[4] The value of this is 0. M[4] encodes the value of PSTATE.nRW.

M[3:0] Encodes the Exception level and the stack pointer register selection, as shown in Table D1-3.

Table D1-3 M[3:0] encodings, for exceptions taken from AArch64 state

M[3:0][a]	Exception level and stack pointer
0b1101	EL3h
0b1100	EL3t
0b1001	EL2h
0b1000	EL2t
0b0101	EL1h
0b0100	EL1t
0b0000	EL0t

a. All M[3:0] encodings not shown in the table are reserved.

The M[3:0] encoding comprises:

M[3:2] Encodes the Exception level, 0-3.

M[1] Reserved, RES0. If set to 1 at the time of an exception return, then that exception return is treated as an Illegal Execution State Exception Return.

M[0] Selects the SP:

- **0** SP_EL0. Indicated by a t suffix on the Exception level.
- **1** SP_ELx, where *x* is the value of M[3:2]. Indicated by an h suffix on the Exception level.

See *Stack pointer register selection* on page D1-1408.

For exceptions taken from AArch32 state:

M[4] The value of this is 1. M[4] encodes the value of PSTATE.nRW.

M[3:0] Encodes the AArch32 mode that the PE was in immediately before the exception was taken, as shown in Table D1-4.

Table D1-4 M[3:0] encodings, for exceptions taken from AArch32 state

M[3:0]	AArch32 mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0111	Abort
0b1011	Undefined
0b1111	System

Bits [27:22] and [19:10] of an SPSR are ignored on an exception return to AArch64 state.

D1.6.5 Exception Link Registers (ELRs)

Exception Link Registers hold preferred exception return addresses.

Whenever the PE takes an exception, the preferred return address is saved in the ELR at the Exception level the exception is taken to. For example, whenever the PE takes an exception to EL1, the preferred return address is saved in ELR_EL1.

On an exception return, the PC is restored to the address stored in the ELR. For example, on returning from EL1, the PC is restored to the address stored in ELR_EL1.

AArch64 state provides an ELR for each Exception level exceptions can be taken to. The ELRs that AArch64 state provides are:

- ELR_EL1, for exceptions taken to EL1.
- If EL2 is implemented, ELR_EL2, for exceptions taken to EL2.
- If EL3 is implemented, ELR_EL3, for exceptions taken to EL3.

On taking an exception from AArch32 state to AArch64 state, bits[63:32] of the ELR are set to zero.

The preferred return address depends on the nature of the exception. For more information, see *Preferred exception return address* on page D1-1422.

D1.7 Process state, PSTATE

In the ARMv8-A architecture, Process state or *PSTATE* is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

PSTATE is defined in the ARMv8-A pseudocode as the `PSTATE` structure, of type `ProcState`. The definition of `ProcState` is:

```
type ProcState is (
    bits (1) N,        // Negative condition flag
    bits (1) Z,        // Zero condition flag
    bits (1) C,        // Carry condition flag
    bits (1) V,        // oVerflow condition flag
    bits (1) D,        // Debug mask bit                     [AArch64 only]
    bits (1) A,        // Asynchronous abort mask bit
    bits (1) I,        // IRQ mask bit
    bits (1) F,        // FIQ mask bit
    bits (1) SS,       // Software step bit
    bits (1) IL,       // Illegal execution state bit
    bits (2) EL,       // Exception Level (see above)
    bits (1) nRW,      // not Register Width: 0=64, 1=32
    bits (1) SP,       // Stack pointer select: 0=SP0, 1=SPx [AArch64 only]
    bits (1) Q,        // Cumulative saturation flag         [AArch32 only]
    bits (4) GE,       // Greater than or Equal flags        [AArch32 only]
    bits (8) IT,       // If-then execution state bits       [AArch32 only]
    bits (1) J,        // J execution state bit              [AArch32 only, RES0 in ARMv8]
    bits (1) T,        // T32 execution state bit            [AArch32 only]
    bits (1) E,        // Endian execution state bit         [AArch32 only]
    bits (5) M         // Mode field (see above)             [AArch32 only]
)
```

PSTATE includes both:

- Fields that are meaningful only in AArch32 state.
- Fields that hold AArch64 state.

The fields that hold AArch64 state are:

PSTATE.{N, Z, C, V} The condition flags. See *Process state, PSTATE* on page B1-62.

PSTATE.SS The Software Step bit. See *Software Step exceptions* on page D2-1579.

PSTATE.IL The Illegal Execution State bit. See *Illegal return events* on page D1-1438.

PSTATE.{D, A, I, F} The debug exception mask bit, D, and interrupt mask bits, A, I, and F. Software can modify the bits independently. See *The PSTATE debug mask bit, D* on page D1-1509 and *Asynchronous exception types, routing, masking and priorities* on page D1-1453.

PSTATE.nRW The current Execution state. See *Execution state* on page D1-1403.

PSTATE.EL The current Exception level. See *Exception levels* on page D1-1400.

PSTATE.SP The stack pointer register selection bit. See *Stack pointer register selection* on page D1-1408.

On taking an exception, the PSTATE values are preserved in the SPSR (*Saved Program Status Register*) at the Exception level the exception is taken to, so that the state information can be restored on the exception return.

The SPSRs are described in *Saved Program Status Registers (SPSRs)* on page D1-1409.

Note

Those PSTATE fields that are meaningful only in AArch32 state are visible in AArch64 state only in an SPSR_ELx, when an exception is taken from AArch32 state to AArch64 state.

Table D1-5 shows the instructions used to access the PSTATE fields that hold AArch64 state, when the PE is in AArch64 state. Unless otherwise stated, all instructions can be used at EL1 and higher, and are undefined at EL0.

Table D1-5 Accessibility of the PSTATE fields that hold AArch64 state

Field	Access in AArch64 state		Notes
	Direct read	Direct write	
NZCV	MRS	MSR (register)	Accessible at EL0. Accessed using the NZCV register.
SS	None	None	On a reset to AArch64 state, this bit is set to 0.
IL	None	None	On a reset to AArch64 state, this bit is set to 0.
DAIF	MRS	MSR (register) MSR (immediate)	Access at EL0 using AArch64 depends on SCTLR_EL1.UMA. See *Enabling EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks* on page D1-1463. Accessed using the DAIF register. MSR (immediate) can be used to modify these bits independently. On a reset to AArch64 state, each of these bits is set to 1.
nRW	None	None	On a reset to AArch64 state, this bit is set to 0. This bit is always 0 when in AArch64 state.
EL	MRS	None	Accessed using the CurrentEL register. On a reset to AArch64 state, this field holds the encoding for the highest implemented Exception level. **Note** The ARM architecture requires that a PE resets into the highest implemented Exception level.
SP	MRS	MSR (register) MSR (immediate)	Accessed using SPSel register. MSR (immediate) can be used to modify this bit. On a reset to AArch64 state, this bit is set to 1, meaning that SP_ELx is selected.

The A64 instruction set provides separate system accessing instructions to read and write the PSTATE fields that have direct read or write access. However, when an exception occurs, the saved PSTATE fields, for the Exception level that the exception was taken from, are accessed using the SPSR.

D1.8 Program counter and stack pointer alignment

This section contains the following:

- *PC alignment checking*.
- *Stack pointer alignment checking* on page D1-1416.

D1.8.1 PC alignment checking

PC alignment checking generates an exception associated with instruction fetch, when an instruction fetched with a misaligned PC in AArch64 is attempted to be architecturally executed. A misaligned PC is when bits[1:0] of the PC are not `0b00`.

Note

As with Instruction Aborts, speculative fetching of an instruction does not generate an exception. An exception occurs only on an attempt to architecturally execute the instruction.

If an exception is generated as a result of an instruction fetch at EL0, it is taken to EL1, unless the exception occurs in Non-secure state and HCR_EL2.TGE bit is 1, when it is taken to EL2 instead. If an exception is generated as a result of an instruction fetch at any other Exception level, the Exception level is unchanged.

A PC misalignment sets the EC field in the *Exception Syndrome Register* (ESR) to `0x22`, for the ESR associated with the target Exception level.

When the exception is taken to an Exception level using AArch64, the associated Exception Link Register holds the entire PC in its misaligned form, as does the FAR_ELx for the Exception level that the exception is taken to.

Exception return and PC alignment on page D1-1438 gives more information on PC alignment checking associated with exception returns.

Note

A misalignment of the PC is a common indication of a serious error, for example software corruption of an address.

```
// AArch64.CheckPCAlignment()
// ==========================

AArch64.CheckPCAlignment()

    bits(64) pc = ThisInstrAddr();
    if pc<1:0> != '00' then
        AArch64.PCAlignmentFault();

// AArch64.PCAlignmentFault()
// ==========================
// Called on unaligned program counter in AArch64 state.

AArch64.PCAlignmentFault()

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    exception = ExceptionSyndrome(Exception_PCAlignment);
    exception.vaddress = ThisInstrAddr();

    if UInt(PSTATE.EL) > UInt(EL1) then
        AArch64.TakeException(PSTATE.EL, exception, preferred_exception_return, vect_offset);
    elsif HaveEL(EL2) && !IsSecure() && HCR_EL2.TGE == '1' then
        AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
        AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
```

D1.8.2 Stack pointer alignment checking

A *misaligned stack pointer* is where bits[3:0] of the stack pointer are not `0b0000`, when the stack pointer is used as the base address of the calculation, regardless of any offset applied by the instruction.

The PE can be configured so that if a load or store instruction uses a misaligned stack pointer, the PE generates an exception on the attempt to execute the instruction.

Note

- As with Data Aborts, a speculative data access to memory using the stack pointer does not generate the exception. The exception occurs only on an attempt to architecturally execute the instruction.
- Prefetch memory abort instructions do not cause synchronous exceptions. See *Prefetch memory* on page C3-140.

Stack pointer alignment checking is only performed in AArch64, and can be enabled for each Exception level as follows:

- SCTLR_EL1.{SA0, SA} controls EL0 and EL1, respectively.
- SCTLR_EL2.SA controls EL2.
- SCTLR_EL3.SA controls EL3.

If an exception is generated as a result of a load or store at EL0, it is taken as an exception to EL1 unless the HCR_EL2.TGE bit is set in the Non-secure state, when it is taken to EL2. If an exception is generated as a result of a load or store at any other Exception level, the Exception level is unchanged.

A stack pointer misalignment sets the EC field to `0x26`, in the ESR associated with the target Exception level. If memory alignment checking and stack pointer alignment checking are enabled, then a stack pointer alignment fault has priority in setting the value of the EC field, in the ESR associated with the target Exception level.

```
// CheckSPAlignment()
// ==================
// Check correct stack pointer alignment for AArch64 state.

CheckSPAlignment()
    bits(64) sp = SP[];

    if PSTATE.EL == EL0 then
        stack_align_check = (SCTLR_EL1.SA0 != '0');
    else
        stack_align_check = (SCTLR[].SA != '0');

    if stack_align_check && sp != Align(sp, 16) then
        AArch64.SPAlignmentFault();

    return;

// AArch64.SPAlignmentFault()
// ==========================
// Called on an unaligned stack pointer in AArch64 state.

AArch64.SPAlignmentFault()

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    exception = ExceptionSyndrome(Exception_SPAlignment);

    if UInt(PSTATE.EL) > UInt(EL1) then
        AArch64.TakeException(PSTATE.EL, exception, preferred_exception_return, vect_offset);
    elsif HaveEL(EL2) && !IsSecure() && HCR_EL2.TGE == '1' then
        AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
        AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
```

D1.9 Reset

The ARMv8-A architecture supports the following resets:

Cold reset Resets the logic of the entire implementation, including the integrated debug functionality.

Warm reset Resets the logic of the PE, but does not reset the integrated debug functionality.

Note

The ARMv8-A architecture also supports an *external debug reset*. See *External debug register resets* on page H8-4537.

The difference between a Cold reset and a Warm reset is relevant only to the debug functionality and the RMR_ELx register, if an RMR_ELx register is implemented:

- A Warm reset permits debugging across a reset of the PE logic.
- Writing 1 to RMR_ELx.RR requests a Warm reset.

An implementation can define other resets according to the requirements the implementation or system must fulfil. These other resets are outside the scope of the ARMv8-A architecture. However, they can be mapped on to the resets described here.

For PE operation, a Cold reset and a Warm reset are equivalent. In the description that follows, the term *reset* is used in contexts where there is no difference between the effect of a Cold reset and the effect of a Warm reset.

On a reset, the PE enters the highest implemented Exception level.

If the highest implemented Exception level can use either Execution state, then:

- The implementation must include a *Reset Management Register* (RMR). Only one RMR is implemented. The RMR implemented is the RMR is associated with the highest Exception level.
- On a Cold reset, the Execution state entered is determined by a configuration input signal.
- On a Warm reset, the Execution state entered is determined by RMR_ELx.AA64.

If the highest implemented Exception level is configured to use AArch64 state, then on reset:

- The stack pointer for the highest implemented Exception level, SP_ELx, is selected.
- Execution starts at an IMPLEMENTATION DEFINED address, anywhere in the physical address range. The RVBAR associated with the highest implemented Exception level, RVBAR_EL1, RVBAR_EL2, or RVBAR_EL3, holds this address.

The remainder of this section contains the following:

- *PE state on reset to AArch64 state*.
- *Code sequence to request a Warm reset as a result of RMR_ELx.RR* on page D1-1419.

D1.9.1 PE state on reset to AArch64 state

Immediately after a reset, much of the PE state is UNKNOWN. However, some of the PE state is defined. If the PE resets to AArch64 state using either a Cold or a Warm reset, the PE state that is defined is as follows:

- Each of the PSTATE.{D, A, I, F} interrupt masks is set to 1.
- The Software step control bit, PSTATE.SS, is set to 0.
- The IL process state bit, PSTATE.IL, is set to 0.
- All general-purpose, and SIMD and floating-point registers are UNKNOWN.
- The ELR and SPSR for each Exception level are UNKNOWN.
- The stack pointer register for each Exception level is UNKNOWN.

- Unless explicitly defined in this subsection, each system control register at each Exception level is in an IMPLEMENTATION DEFINED state, that might be UNKNOWN.
- The TLBs and caches are in an IMPLEMENTATION DEFINED state. This means that the TLBs, the caches, or both, might require invalidation using IMPLEMENTATION DEFINED invalidation sequences before the memory management system or any cache is enabled.

  Note

  — The implementation might include IMPLEMENTATION DEFINED resets. If it does, each of these resets might treat the cache and TLB state differently. The ARMv8-A architecture permits this.

  — Different IMPLEMENTATION DEFINED invalidation sequences might be required for different IMPLEMENTATION DEFINED resets.

  — In some implementations, the IMPLEMENTATION DEFINED invalidation sequence might be a NOP.

- In the SCTLR_ELx for the highest implemented Exception level:
  — Each of the {M, C, I} bits is set to 0
  — The EE bit is set to an IMPLEMENTATION DEFINED value, typically defined by a configuration input.
- If an RMR is implemented, RMR_ELx.RR is set to 0. EL*x* in this context is the highest implemented Exception level.
- The enables for the timers and the counter event stream are set to 0. This means that the following bits are set to 0:
  — CNTV_CTL_EL0.ENABLE
  — CNTP_CTL_EL0.ENABLE
  — CNTPS_CTL_EL1.ENABLE
  — CNTKCTL_EL1.EVNTEN
  — If the implementation includes EL2, CNTHP_CTL_EL2.ENABLE
  — If the implementation includes EL2, CNTHCTL_EL2.EVNTEN.
- PMCR_EL0.E is set to 0.

  Note

  This means the Performance Monitors cannot assert interrupts at reset.

- OSDLR_EL1.DLK bit is set to 0.
- EDPRCR.CWRR is set to 0.
- Each of MDCCINT_EL1.{TX, RX} is set to 0.
- EDPRSR.SR is set to 1.
- If the implementation includes EL3, then each of MDCR_EL3.{EPMAD, EDAD, SPME} is set to 0.
- If the implementation includes EL2, then MDCR_EL2.HPMN is set to the value of PMCR_EL0.N.
- Each of EDESR.{SS, RC, OSUC} is reset to the value of EDECR.SS.

Additionally, for a Cold reset into AArch64 state:

- If an RMR is implemented, RMR_ELx.AA64 is set to 1. EL*x* in this context is the highest implemented Exception level.
- Each of MDCCSR_EL0.{TXfull, RXfull} is set to 0.
- The DBGPRCR_EL1.CORENPRDRQ is set to the value of EDPRCR.COREPURQ.
- DBGCLAIMSET_EL1[7:0] is set to 0.

- Each of EDSCR.{RXO, TXU, INTdis, TDA, MA, HDE, ERR, RXfull, TXfull} is set to 0.

  Note

  MDCCSR_EL0.{RXfull, TXfull} reflect the values in EDSCR.{RXfull, TXfull}.

- Each of EDECCR.{NSE, SE} is set to 0.
- OSLSR_EL1.OSLK is set to 1.
- Each of EDPRSR.{SPMAD, SDAD} is set to 0.
- EDPRSR.SPD is set to 1.

D1.9.2 Code sequence to request a Warm reset as a result of RMR_ELx.RR

```
; in addition, interrupts and debug requests for this core should be disabled
; in the system before running this sequence to ensure the WFI suspends execution
    MOV Wy, #3        ; for AArch64, #2 for AArch32; y is any register
    DSB               ; ensure all stores etc are complete
    MSR RMR_ELx, Wy   ; request the reset
    ISB               ; synchronise change to the RMR
Loop
    WFI               ; enter a quiescent state
    B Loop
```

D1.9.3 Pseudocode description of reset

```
// AArch64.TakeReset()
// ===================
// Reset into AArch64 state

AArch64.TakeReset(boolean cold_reset)
    assert !HighestELUsingAArch32();

    // Enter the highest implemented Exception level in AArch64 state
    PSTATE.nRW = '0';
    if HaveEL(EL3) then
        PSTATE.EL = EL3;
        SCR_EL3.NS = '0';                 // Secure state
    elsif HaveEL(EL2) then
        PSTATE.EL = EL2;
    else
        PSTATE.EL = EL1;

    // Reset the system registers and other system components
    AArch64.ResetControlRegisters(cold_reset);

    // Reset all other PSTATE fields
    PSTATE.SP = '1';                      // Select stack pointer
    PSTATE.<D,A,I,F>  = '1111';           // All asynchronous exceptions masked
    PSTATE.SS = '0';                      // Clear software step bit
    PSTATE.IL = '0';                      // Clear illegal execution state bit

    // All registers, bits and fields not reset by the above pseudocode or by the BranchTo() call
    // below are UNKNOWN bitstrings after reset. In particular, the return information registers
    // ELR_ELx and SPSR_ELx have UNKNOWN values, so that it is impossible to return from a reset
    // in an architecturally defined way.
    AArch64.ResetGeneralRegisters();
    AArch64.ResetSIMDFPRegisters();
    AArch64.ResetSpecialRegisters();
    ResetExternalDebugRegisters(cold_reset);

    bits(64) rv;                          // IMPLEMENTATION DEFINED reset vector
    if HaveEL(EL3) then
        rv = RVBAR_EL3;
```

```
    elsif HaveEL(EL2) then
        rv = RVBAR_EL2;
    else
        rv = RVBAR_EL1;

    // The reset vector must be correctly aligned
    assert IsZero(rv<63:PAMax()>) && IsZero(rv<1:0>);

    BranchTo(rv, BranchType_UNKNOWN);

// AArch64.ResetGeneralRegisters()
// ===============================

AArch64.ResetGeneralRegisters()

    for i = 0 to 30
        X[i] = bits(64) UNKNOWN;

    return;

// AArch64.ResetSIMDFPRegisters()
// ==============================

AArch64.ResetSIMDFPRegisters()

    for i = 0 to 31
        V[i] = bits(128) UNKNOWN;

    return;

// AArch64.ResetSpecialRegisters()
// ===============================

AArch64.ResetSpecialRegisters()

    // AArch64 special registers
    SP_EL0 = bits(64) UNKNOWN;
    SP_EL1 = bits(64) UNKNOWN;
    SPSR_EL1 = bits(32) UNKNOWN;
    ELR_EL1  = bits(64) UNKNOWN;
    if HaveEL(EL2) then
        SP_EL2 = bits(64) UNKNOWN;
        SPSR_EL2 = bits(32) UNKNOWN;
        ELR_EL2  = bits(64) UNKNOWN;
    if HaveEL(EL3) then
        SP_EL3 = bits(64) UNKNOWN;
        SPSR_EL3 = bits(32) UNKNOWN;
        ELR_EL3  = bits(64) UNKNOWN;

    // AArch32 special registers that are not architecturally mapped to AArch64 registers
    if HaveAArch32EL(EL1) then
        SPSR_fiq = bits(32) UNKNOWN;
        SPSR_irq = bits(32) UNKNOWN;
        SPSR_abt = bits(32) UNKNOWN;
        SPSR_und = bits(32) UNKNOWN;

    // External debug special registers
    DLR_EL0 = bits(64) UNKNOWN;
    DSPSR_EL0 = bits(32) UNKNOWN;

    return;
```

The `ResetSystemRegisters()` function resets all System registers to their reset state as defined in the register descriptions in *PE state on reset to AArch64 state* on page D1-1417 and Chapter D7 *AArch64 System Register Descriptions*.

Note

The `ResetSystemRegisters()` function only resets the System registers.

```
AArch64.ResetSystemRegisters(boolean cold_reset);
```

The `ResetExternalDebugRegisters()` function resets all external debug registers to their reset state as defined in the register descriptions in Chapter H9 *External Debug Register Descriptions*.

```
ResetExternalDebugRegisters(boolean cold_reset);
```

D1.10 Exception entry

Exceptions are targeted at particular Exception levels. The Exception level that an exception targets is either programmed by software, or is determined by the nature of the exception.

Under no circumstances do exceptions cause execution to move to a lower Exception level.

If an asynchronous exception targets a lower Exception level, the exception is not taken and remains pending. See *Asynchronous exception routing* on page D1-1454 and *Asynchronous exception masking* on page D1-1454.

Note

The construction of the architecture means that usually, it is impossible for an exception to target a lower Exception level.

The Security state can only change on taking an exception if the exception is taken from Non-secure state to EL3.

Note

Taking an exception to EL3 from any Exception level has no effect on the value of the SCR_EL3.NS bit.

On taking an exception to AArch64 state:

- The PE state is saved in the SPSR_ELx at the Exception level the exception is taken to. See *Saved Program Status Registers (SPSRs)* on page D1-1409.
- The preferred return address is saved in the ELR_ELx at the Exception level the exception is taken to. See *Exception Link Registers (ELRs)* on page D1-1412.
- All of PSTATE.{D, A, I, F} are set to 1. See *Process state, PSTATE* on page D1-1413.
- If the exception is a synchronous exception or an SError interrupt, information characterizing the reason for the exception is saved in the ESR_ELx at the Exception level the exception is taken to. See *Exception classes and the ESR_ELx syndrome registers* on page D1-1426.
- Execution moves to the target Exception level, and starts at the address defined by the exception vector. Which exception vector is used is also an indicator of whether the exception came from a lower Exception level or the current Exception level. See *Exception vectors* on page D1-1423.
- The stack pointer register selected is the dedicated stack pointer register for the target Exception level. See *The stack pointer registers* on page D1-1408.

The remainder of this section contains the following:

- *Preferred exception return address*.
- *Exception vectors* on page D1-1423.
- *Pseudocode description of exception entry to AArch64 state* on page D1-1424.
- *Exception classes and the ESR_ELx syndrome registers* on page D1-1426.

D1.10.1 Preferred exception return address

For an exception taken to an Exception level using AArch64, the Exception Link Register for that Exception level, ELR_ELx, holds the preferred exception return address. The preferred exception return address depends on the nature of the exception, as follows:

- For asynchronous exceptions, it is the address of the instruction following the instruction boundary at which the interrupt occurs. Therefore, it is the address of the first instruction that did not execute, or did not complete execution, as a result of taking the interrupt.
- For synchronous exceptions other than system calls, it is the address of the instruction that generates the exception.
- For system calls, it is the address of the instruction that follows the system call instruction.

Note

- If a system call instruction is trapped, disabled, or is UNDEFINED because the Exception level has insufficient privilege to execute the instruction, the preferred exception return address is the address of the system call instruction.
- A system call is generated by the execution of an SVC, HVC, or SMC instruction.

When an exception is taken from an Exception level using AArch32 to an Exception level using AArch64, the top 32 bits of the modified ELR_ELx are 0.

D1.10.2 Exception vectors

When the PE takes an exception to an Exception level that is using AArch64, execution is forced to an address that is the *exception vector* for the exception. The exception vector exists in a *vector table* at the Exception level the exception is taken to.

A vector table occupies a number of consecutive word-aligned addresses in memory, starting at the *vector base address*.

Each Exception level has an associated *Vector Base Address Register* (VBAR), that defines the exception base address for the table at that Exception level.

For exceptions taken to AArch64 state, the vector table provides the following information:

- Whether the exception is one of the following:
  - Synchronous exception.
  - SError.
  - IRQ.
  - FIQ.
- Information about the Exception level that the exception came from, combined with information about the stack pointer in use, and the state of the register file.

Table D1-6 shows this:

Table D1-6 Vector offsets from vector table base address

Exception taken from	Offset for exception type			
	Synchronous	IRQ or vIRQ	FIQ or vFIQ	SError or vSError
Current Exception level with SP_EL0.	0x000	0x080	0x100	0x180
Current Exception level with SP_ELx, x>0.	0x200	0x280	0x300	0x380
Lower Exception level, where the implemented level immediately lower than the target level is using AArch64.[a]	0x400	0x480	0x500	0x580
Lower Exception level, where the implemented level immediately lower than the target level is using AArch32.[a]	0x600	0x680	0x700	0x780

a. For exceptions taken to EL3, if EL2 is implemented, the level immediately lower than the target level is EL2 if the exception was taken from Non-secure state, but EL1 if the exception was taken from Secure EL1 or EL0.

Reset is treated as a special vector for the highest implemented Exception level. This special vector uses an IMPLEMENTATION DEFINED address that is typically set either by a hardwired configuration of the PE or by configuration input signals. The RVBAR_ELx register contains this reset vector address, where *x* is the number of the highest implemented Exception level.

D1.10.3 Pseudocode description of exception entry to AArch64 state

The following pseudocode shows behavior when the PE takes an exception to an Exception level that is using AArch64.

```
// AArch64.TakeException()
// =======================
// Take an exception to an Exception Level using AArch64.

AArch64.TakeException(bits(2) target_el, ExceptionRecord exception,
                      bits(64) preferred_exception_return, integer vect_offset)
    assert HaveEL(target_el) && !ELUsingAArch32(target_el) && UInt(target_el) >= UInt(PSTATE.EL);

    // If coming from AArch32 state, the top parts of the X[] registers might be set to zero
    from_32 = UsingAArch32();
    if from_32 then MaybeZeroRegisterUppers(target_el);

    if UInt(target_el) > UInt(PSTATE.EL) then
        boolean lower_32;
        if target_el == EL3 then
            if !IsSecure() && HaveEL(EL2) then
                lower_32 = ELUsingAArch32(EL2);
            else
                lower_32 = ELUsingAArch32(EL1);
        else
            lower_32 = ELUsingAArch32(target_el - 1);
        vect_offset = vect_offset + (if lower_32 then 0x600 else 0x400);

    elsif PSTATE.SP == '1' then
        vect_offset = vect_offset + 0x200;

    spsr = GetPSRFromPSTATE();

    if !(exception.type IN {Exception_IRQ, Exception_FIQ}) then
        AArch64.ReportException(exception, target_el);

    PSTATE.EL = target_el;  PSTATE.nRW = '0';  PSTATE.SP = '1';

    SPSR[] = spsr;
    ELR[] = preferred_exception_return;

    PSTATE.SS = '0';
    PSTATE.<D,A,I,F> = '1111';
    PSTATE.IL = '0';
    if from_32 then                             // Coming from AArch32
        PSTATE.IT = '00000000';  PSTATE.<J,T> = '00';

    BranchTo(VBAR[] + vect_offset, BranchType_EXCEPTION);
    EndOfInstruction();

// AArch64.ReportException()
// =========================
// Report syndrome information for exception taken to AArch64 state.

AArch64.ReportException(ExceptionRecord exception, bits(2) target_el)

    Exception type = exception.type;

    (ec,il) = AArch64.ExceptionClass(type, target_el);
    iss = exception.syndrome;

    // IL is not valid for Data Abort exceptions without valid instruction syndrome information
    if ec IN {0x24,0x25} && iss<24> == '0' then
        il = '1';

    ESR[target_el] = ec<5:0>:il:iss;
```

```
    if type IN {Exception_InstructionAbort, Exception_PCAlignment, Exception_DataAbort,
                Exception_Watchpoint} then
        FAR[target_el] = exception.vaddress;
    else
        FAR[target_el] = bits(64) UNKNOWN;

    if target_el == EL2 && exception.ipavalid then
        HPFAR_EL2<39:4> = exception.ipaddress<47:12>;

    return;

    return (ec,il);

// MaybeZeroRegisterUppers()
// =========================
// On taking an exception to "handle_el" using AArch64 from AArch32, it is CONSTRAINED
// UNPREDICTABLE whether the top 32 bits of registers visible at any lower Exception level
// using AArch32 are set to zero.
```

```
MaybeZeroRegisterUppers(bits(2) handle_el)
    assert UsingAArch32() && HaveEL(handle_el) && !ELUsingAArch32(handle_el);

    // Always called from AArch32 state before entering AArch64 state
    if PSTATE.EL == EL0 && !ELUsingAArch32(EL1) then
        first = 0;  last = 14;  include_R15 = FALSE;
    elsif PSTATE.EL IN {EL0,EL1} && HaveEL(EL2) && !IsSecure() && !ELUsingAArch32(EL2) then
        first = 0;  last = 30;  include_R15 = FALSE;
    else
        first = 0;  last = 30;  include_R15 = TRUE;

    for n = first to last
        if (n != 15 || include_R15) && ConstrainUnpredictableBool() then
            _R[n]<63:32> = Zeros();

    return;
```

D1.10.4 Exception classes and the ESR_ELx syndrome registers

If the exception is a synchronous exception or an SError interrupt, information characterizing the reason for the exception is saved in the ESR_ELx at the Exception level the exception is taken to. The information saved is determined at the time the exception is taken, and is not changed as a result of the explicit synchronization that takes place at the start of taking the exception. See *Synchronization requirements for System registers* on page D7-1794. The following sections give more information:

- *Use of the ESR_EL1, ESR_EL2, and ESR_EL3*.
- *EC encodings when routing general exceptions to EL2* on page D1-1436.

Use of the ESR_EL1, ESR_EL2, and ESR_EL3

An ESR_ELx holds the syndrome information for an exception that is taken to AArch64 state.

Note

This use of a syndrome is also the reporting model used for exceptions taken to Hyp mode when they are taken to EL2 using AArch32.

Figure D1-2 shows the general format of the ESR_ELx registers:

Figure D1-2 Overall format of the ESR_ELx registers

The ESR_ELx fields are:

EC, bits[31:26] The Exception class field, that indicates the cause of the exception.

IL, bit[25] The Instruction length bit, for synchronous exceptions, that indicates whether a trapped instruction was a 16-bit or a 32-bit instruction.

ISS, bits[24:0] The Instruction specific syndrome field. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

ESR_ELx, Exception Syndrome Register on page D7-1832 describes the register in full, including:

- Listing the valid EC field values.
- Describing the ISS for each Exception class.
- Giving a full description of the use of the IL field.

Table D1-7 shows the encoding of the ESR_ELx.EC field, the Exception class field. For each EC value, the table references a subsection that gives information about the cause of the exception, for example the configuration required to enable the trap, and gives a link to the description of the ISS format, that forms part of the ESR_ELx description.

Table D1-7 ESR_ELx.EC field encoding

EC	Exception class	From, state		To, Exception level			ISS description, or notes
		AArch32	AArch64	EL1	EL2	EL3	
000000	Unknown reason	Yes	Yes	Yes	Yes	Yes	*Exceptions with an unknown reason* on page D1-1429.
000001	WFI or WFE instruction execution[a]	Yes	Yes	Yes	Yes	Yes	*Exception from a WFI or WFE instruction, from AArch32 or AArch64 state* on page D1-1430.
000011	MCR or MRC access to CP15[a] that is not reported using EC 0b000000	Yes	No	Yes	Yes	Yes[b]	*Exception from an MCR or MRC access from AArch32 state* on page D1-1430.
000100	MCRR or MRRC access to CP15[a] that is not reported using EC 0b000000	Yes	No	Yes	Yes	Yes[c]	*Exception from an MCRR or MRRC access from AArch32 state* on page D1-1431.
000101	MCR or MRC access to CP14[a]	Yes	No	Yes	Yes	Yes	*Exception from an MCR or MRC access from AArch32 state* on page D1-1430.
000110	LDC or STC access to CP14[a]	Yes	No	Yes	Yes	Yes	*Exception from an LDC or STC access to CP14 from AArch32 state* on page D1-1432.
000111	Access to SIMD or floating-point registers[a], excluding (HCR_EL2.TGE==1) traps	Yes	Yes	Yes	Yes	Yes	*Exception from an access to SIMD or floating-point registers, from AArch32 or AArch64* on page D1-1432.
001000	MCR or MRC access to CP10 that is not reported using EC 0b000111. This applies only to ID Group traps[d]	Yes	No	No	Yes	No	*Exception from an MCR or MRC access from AArch32 state* on page D1-1430.
001100	MRRC access to CP14[a]	Yes	No	Yes	Yes	Yes	*Exception from an MCRR or MRRC access from AArch32 state* on page D1-1431.
001110	Illegal Execution State	Yes	Yes	Yes	Yes	Yes	*Exception from an illegal Execution State, misaligned PC, or misaligned stack pointer* on page D1-1432.
010001	SVC instruction execution	Yes	No	Yes	Yes[e]	No	*Exception from HVC or SVC instruction execution* on page D1-1432.
010010	HVC instruction execution, when HVC is not disabled	Yes	No	No	Yes	No	
010011	SMC instruction execution, when SMC is not disabled	Yes	No	No	Yes[f]	Yes	*Exception from SMC instruction execution in AArch32 state* on page D1-1433.

Table D1-7 ESR_ELx.EC field encoding (continued)

EC	Exception class	From, state		To, Exception level			ISS description, or notes
		AArch32	AArch64	EL1	EL2	EL3	
010101	SVC instruction execution	No	Yes	Yes	Yes	Yes	*Exception from HVC or SVC instruction execution* on page D1-1432.
010110	HVC instruction execution, when HVC is not disabled	No	Yes	No	Yes	Yes	
010111	SMC instruction execution, when SMC is not disabled	No	Yes	No	Yes[f]	Yes	*Exception from SMC instruction execution in AArch64 state* on page D1-1433.
011000	MSR, MRS, or System instruction execution, that is not reported using EC 0x00, 0x01, or 0x07	No	Yes	Yes	Yes	Yes	*Exception from MSR, MRS, or System instruction execution in AArch64 state* on page D1-1433.
100000	Instruction Abort from a lower Exception level[g]	Yes	Yes	Yes	Yes	Yes	*Exception from an Instruction abort* on page D1-1434.
100001	Instruction Abort taken without a change in Exception level[g]	Yes	Yes	Yes	Yes	Yes	
100010	Misaligned PC exception	Yes	Yes	Yes	Yes	Yes	*Exception from an illegal Execution State, misaligned PC, or misaligned stack pointer* on page D1-1432.
100100	Data Abort from a lower Exception level[h]	Yes	Yes	Yes	Yes	Yes	*Exception from a Data abort* on page D1-1434.
100101	Data Abort taken without a change in Exception level[h]	Yes	Yes	Yes	Yes	Yes	
100110	Stack Pointer Alignment exception	Yes	Yes	Yes	Yes	Yes	*Exception from an illegal Execution State, misaligned PC, or misaligned stack pointer* on page D1-1432.
101000	Floating-point exception, if supported	Yes	No	Yes	Yes	No	*Floating-point exceptions* on page D1-1435.
101100	Floating-point exception, if supported	No	Yes	Yes	Yes	Yes	
101111	SError interrupt	Yes[i]	Yes	Yes	Yes	Yes	*SError interrupt* on page D1-1435.
110000	Breakpoint exception from a lower Exception level	Yes	Yes	Yes	Yes[j]	No	*Breakpoint exception or Vector Catch exception* on page D1-1435.
110001	Breakpoint exception taken without a change in Exception level	Yes	Yes	Yes	Yes[j]	No	
110010	Software Step exception from a lower Exception level	Yes	Yes	Yes	Yes[j]	No	*Software Step exception* on page D1-1436.
110011	Software Step exception taken without a change in Exception level	Yes	Yes	Yes	Yes[j]	No	

Table D1-7 ESR_ELx.EC field encoding (continued)

EC	Exception class	From, state		To, Exception level			ISS description, or notes
		AArch32	AArch64	EL1	EL2	EL3	
110100	Watchpoint exception from a lower Exception level	Yes	Yes	Yes	Yes[j]	No	*Watchpoint exception* on page D1-1435.
110101	Watchpoint exception taken without a change in Exception level	Yes	Yes	Yes	Yes[j]	No	
111000	BKPT instruction execution	Yes	No	Yes	Yes[j]	No	*Software Breakpoint Instruction exception* on page D1-1436.
111010	Vector catch exception from AArch32 state	Yes	No	No	Yes[j]	No	*Breakpoint exception or Vector Catch exception* on page D1-1435.
111100	BRK instruction execution	No	Yes	Yes	Yes[j]	Yes[k]	*Software Breakpoint Instruction exception* on page D1-1436.

a. Exceptions caused by configurable traps, enables, or disables.
b. See *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32* on page D1-1490.
c. Only for MCRR or MRRC accesses to the PMCCNTR_EL0 or PMCCNTR.
d. Applies only to traps of accesses to MVFR0, MVFR1, MVFR2, or FPSID. Includes traps of VMRS accesses. Because the registers are read-only, there are no MCR accesses that can be trapped with this EC value.
e. Only as a result of HCR_EL2.TGE.
f. Only as a result of HCR_EL2.TSC.
g. Used for MMU faults generated by instruction accesses, and for synchronous external aborts, including synchronous parity errors. Not used for debug-related exceptions.
h. Used for MMU faults generated by data accesses, alignment faults other than stack pointer alignment faults, and for synchronous external aborts, including synchronous parity errors. Not used for debug-related exceptions.
i. In AArch32 state, these are known as Asynchronous aborts.
j. Only as a result of HCR_EL2.TGE ==1 or MDCR_EL2.TDE ==1.
k. Only if the BRK instruction is executed in EL3. This is the only debug exception that can be taken to EL3 when EL3 is using AArch64.

Exceptions with an unknown reason

These are the exceptions reported with an ESR_ELx.EC value of 0b000000

This encoding reports an exception with an unknown reason. Any exception not covered by a nonzero EC value defined in *EC, bits [31:26]* on page D7-1832 returns this value.

When ESR_ELx.EC returns a value of 0x00, all other fields of ESR_ELx are invalid, and defined as follows:

- IL is set to 1.
- ISS[24:0] is RES0.

An exception with an unknown reason occurs for the following reasons:

- The attempted execution of an instruction bit pattern that has no allocated instruction at the current Exception level and Security state, including:
  - A read access using a System register pattern that is not allocated for reads at the current Exception level and Security state.
  - A write access using a System register pattern that is not allocated for writes at the current Exception level and Security state.
  - Instruction encodings for instructions that are not implemented.
- In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.

- In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.
- An exception generated by any of the SCTLR_EL1.{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
  - An HVC instruction when disabled by HCR_EL2.HCD or SCR_EL3.HCE.
  - An SMC instruction when disabled by SCR_EL3.SMD.
  - An HLT instruction when disabled by EDSCR.HDE.
- Attempted execution of an MSR or MRS to SP_EL0 when the value of SPSel.SP is 0.
- Attempted execution, in Debug state, of:
  - A DCPS1 instruction in Non-secure state from EL0 when the value of HCR_EL2.TGE is 1.
  - A DCPS2 instruction from EL1 or EL0 when the value of SCR_EL3.NS is 0, or when EL2 is not implemented.
  - A DCPS3 instruction when the value of EDSCR.SDD is 1, or when EL3 is not implemented.
- When EL3 is using AArch64, attempted execution of an SRS instruction using R13_mon from Secure EL1. See *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32* on page D1-1490.
- In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.
- In AArch32 state, the attempted execution of an MRS (Banked register) or an MSR (Banked register) instruction to SPSR_mon, SP_mon, or LR_mon.
- An exception that is taken to EL2 because the value of HCR_EL2.TGE is 1 that, if the value of HCR_EL2.TGE was 0 would have been reported with an ESR_ELx.EC value of 0x07.

Exception from a WFI or WFE instruction, from AArch32 or AArch64 state

This is the exception syndrome with EC value 0b000001.

This reports exceptions from WFI or WFE instructions executed in either Execution state that result from configurable traps, enables, or disables.

The returned syndrome indicates whether the trapped instruction was a WFI or a WFE. *ISS encoding for an exception from a WFI or WFE instruction* on page D7-1837 describes the format of this syndrome.

The following sections describe configuration settings for generating these exceptions:

- *Trapping to EL1 using AArch64* on page D1-1459.
- *Traps to EL2 of Non-secure EL1 and EL0 execution of WFE and WFI instructions* on page D1-1479.
- *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32* on page D1-1490.

Exception from an MCR or MRC access from AArch32 state

These are the exception syndromes with the following EC values:

- 0b000011, MRC or MCR access to CP15.
- 0b000101, MRC or MCR access to CP14.
- 0b001000, MRC or VMRS access to CP10.

These report exceptions from MRC, MCR, or VMRS instructions executed in AArch32 state that result from configurable traps, enables, or disables and are not reported using the EC code of 0b000000.

The returned syndrome indicates whether the instruction was an MRC or an MCR, and the instruction arguments. *ISS encoding for an exception from an MCR or MRC access from AArch32 state* on page D7-1839 describes the format of this syndrome.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000011:

- *Traps to EL2 of Non-secure EL1 and EL0 reads of ID registers* on page D1-1475.
- *Traps to EL2 of Non-secure EL1 and EL0 accesses to lockdown, DMA, and TCM operations* on page D1-1474.
- *Traps to EL2 of Non-secure EL1 and EL0 execution of cache maintenance instructions* on page D1-1472.
- *Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions* on page D1-1471.
- *Traps to EL2 of Non-secure EL1 and EL0 accesses to the Auxiliary Control Register* on page D1-1473.
- *Traps to EL2 of Non-secure EL1 and EL0 accesses to Performance Monitors registers* on page D1-1487.
- *Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR* on page D1-1480.
- *Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers* on page D1-1469.
- *General trapping to EL2 of Non-secure EL1 and EL0 accesses to System registers, from AArch32 state only* on page D1-1482.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000101:

- *Traps to EL2 of Non-secure EL1 and EL0 reads of ID registers* on page D1-1475, for trapped accesses to the JIDR.
- *Traps to EL2 of Non-secure EL1 and EL0 System register accesses to Debug ROM registers* on page D1-1484.
- *Traps to EL2 of Non-secure EL1 System register accesses to OS-related debug registers* on page D1-1484.
- *Traps to EL2 of Non-secure EL1 and EL0 general System register accesses to debug registers* on page D1-1485.
- *Traps to EL2 of EL2, and Non-secure EL1 and EL0, System register accesses to the trace registers* on page D1-1481.

Traps to EL2 of Non-secure EL1 and EL0 reads of ID registers on page D1-1475 describes configuration settings for generating exceptions that are reported using EC value 0b001000.

Exception from an MCRR or MRRC access from AArch32 state

These are the exception syndromes with the following EC values:

- 0b000100, MRRC or MCRR access to CP15.
- 0b001100, MRRC access to CP14.

These report exceptions from MCRR or MRRC instructions executed in AArch32 state that result from configurable traps, enables, or disables and are not reported using the EC code of 0x00.

The returned syndrome indicates whether the instruction was an MCRR or an MRRC, and the instruction arguments. *ISS encoding for an exception from an MCRR or MRRC access from AArch32 state* on page D7-1840 describes the format of this syndrome.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000100:

- *Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers* on page D1-1469.
- *General trapping to EL2 of Non-secure EL1 and EL0 accesses to System registers, from AArch32 state only* on page D1-1482.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b001100:

- *Traps to EL2 of Non-secure EL1 and EL0 System register accesses to Debug ROM registers* on page D1-1484.
- *Traps to EL2 of EL2, and Non-secure EL1 and EL0, System register accesses to the trace registers* on page D1-1481.

Exception from an *LDC* or *STC* access to CP14 from AArch32 state

This is the exception syndrome with EC value 0b000110.

This reports exceptions from LDC, or STC instructions executed in AArch32 state that result from configurable traps, enables, or disables.

The returned syndrome indicates whether the instruction was an MCRR or an MRRC, and the instruction arguments. *ISS encoding for an exception from an LDC or STC access to CP14 from AArch32 state* on page D7-1842 describes the format of this syndrome.

Note

The only architected uses of these instructions to access CP14 are:

- An STC to write to DBGDTRRX_EL0 or DBGDTRRXint.
- An LDC to read DBGDTRTX_EL0 or DBGDTRTXint.

Traps to EL2 of Non-secure EL1 and EL0 general System register accesses to debug registers on page D1-1485 describes the configuration settings for generating the exception that is reported using EC value 0b000110.

Exception from an access to SIMD or floating-point registers, from AArch32 or AArch64

This is the exception syndrome with EC value 0000111.

This reports exceptions from accesses to the SIMD and floating-point register bank, or to SIMD and floating-point System registers, from either Execution state, that result from configurable traps, enables, other than exceptions that occur because the value of HCR_EL2.TGE is 1.

ISS encoding for an exception from an access to a SIMD or floating-point register on page D7-1844 describes the format of the returned syndrome.

General trapping to EL2 of Non-secure EL1 and EL0 accesses to the SIMD and floating-point registers on page D1-1480 describes the configuration settings for generating the exception that is reported using EC value 0000111.

Exception from an illegal Execution State, misaligned PC, or misaligned stack pointer

These are the exception syndromes with the following EC values:

- 0b001110, Illegal Execution State.
- 0b100010, Misaligned PC.
- 0b100110, Misaligned stack pointer.

When ESR_ELx.EC returns one of these values, the ISS field does not return any syndrome information and the ISS field is RES0.

There are no configuration settings for generating Illegal Execution State exceptions and Misaligned PC exceptions. *Stack pointer alignment checking* on page D1-1416 describes the configuration settings for generating Misaligned Stack Pointer exceptions.

Exception from HVC or SVC instruction execution

These are the exception syndromes with the following EC values:

- 0b010001, SVC instruction executed in AArch32 state.
- 0b010010, HVC instruction executed, when not disabled, in AArch32 state.

- 0b010101, SVC instruction executed in AArch64 state.
- 0b010110, HVC instruction executed, when not disabled, in AArch64 state.

The returned syndrome indicates the immediate value given as an instruction argument. *ISS encoding for an exception from HVC or SVC instruction execution* on page D7-1845 describes the format of this syndrome.

Note

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not include conditionality information.

See *SVC* on page C6-743 and *HVC* on page C6-480.

Exception from SMC instruction execution in AArch32 state

This is the exception syndrome with EC value 0b010011.

This reports the exception from an SMC that is not disabled and is executed in AArch32 state.

When ESR_ELx.EC returns this value, the ISS field does not return any syndrome information, and the ISS field is RES0.

Note

- An SMC instruction that fails its condition code check cannot generate this exception. Therefore, the syndrome information does not include conditionality information.
- The value of ISS[24:0] described here is used both:
  - When an SMC instruction is trapped from Non-secure EL1 modes.
  - When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1475 describes the configuration settings for trapping SMC instructions from Non-secure EL1 modes.

Exception from SMC instruction execution in AArch64 state

This is the exception syndrome with EC value 0b010111.

This reports the exception from an SMC that is not disabled and is executed in AArch64 state.

The returned syndrome indicates the immediate value given as an instruction argument. *ISS encoding for an exception from SMC instruction execution in AArch64 state* on page D7-1846 describes the format of this syndrome.

Note

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from Non-secure EL1.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1475 describes the configuration settings for generating this exception, for instructions executed in Non-secure EL1 modes.

Exception from MSR, MRS, or System instruction execution in AArch64 state

This is the exception syndrome with the EC value 0b011000.

These report exceptions from MSR, MRS, or System instructions executed in AArch64 state that result from configurable traps, enables, or disables and are not reported using the EC codes of 0b000000, 0b000001, or 0b000111.

Note

The System instruction class encoding space on page C5-233 identifies the System instructions referred to in this description.

The returned syndrome indicates whether the instruction was an `MSR` or an `MRS`, and the instruction arguments. *ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state* on page D7-1847 describes the format of this syndrome.

For exceptions caused by System instructions, see *System* on page C4-176 for the instruction arguments returned in the syndrome.

The following sections describe configuration settings for generating the exception that is reported using EC value `0b011000`:

- *Traps to EL2 of Non-secure EL1 and EL0 reads of ID registers* on page D1-1475.
- *Traps to EL2 of Non-secure EL1 and EL0 execution of cache maintenance instructions* on page D1-1472.
- *Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions* on page D1-1471.
- *Traps to EL2 of Non-secure EL1 and EL0 accesses to the Auxiliary Control Register* on page D1-1473.
- *Traps to EL2 of Non-secure EL1 and EL0 accesses to Performance Monitors registers* on page D1-1487.
- *Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR* on page D1-1480.
- *Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers* on page D1-1469.
- *Traps to EL2 of Non-secure EL1 and EL0 System register accesses to Debug ROM registers* on page D1-1484.
- *Traps to EL2 of Non-secure EL1 System register accesses to OS-related debug registers* on page D1-1484.
- *Traps to EL2 of Non-secure EL1 and EL0 general System register accesses to debug registers* on page D1-1485.
- *Traps to EL2 of EL2, and Non-secure EL1 and EL0, System register accesses to the trace registers* on page D1-1481.

Exception from an Instruction abort

These are the exception syndromes with the following EC values:

- `0100000`, for an Instruction abort exception taken from a lower Exception level, that could be using AArch64 or AArch32.
- `0b100001`, for an Instruction abort exception taken without a change in Exception level, meaning it is taken from an Exception level that is using AArch64.

These EC values are used for MMU faults and synchronous external aborts, including synchronous parity errors, that are generated by instruction accesses. They are not used for Debug exceptions.

The returned syndrome provides more information about the exception, including a fault code that indicates the cause of the exception. *ISS encoding for an exception from an Instruction abort exception* on page D7-1848 describes the format of this syndrome.

Exception from a Data abort

These are the exception syndromes with the following EC values:

- `0b100100`, for a Data abort exception taken from a lower Exception level, that could be using AArch64 or AArch32.
- `0b100101`, for a Data abort exception taken without a change in Exception level, meaning it is taken from an Exception level that is using AArch64.

These EC values are used for the following exceptions if the exception is generated by a data access:

- MMU faults.
- Alignment faults other than those caused by stack pointer misalignment.
- Synchronous external aborts, including synchronous parity errors.

They are not used for Debug exceptions.

The returned syndrome provides more information about the exception, including a fault code that indicates the cause of the exception. *ISS encoding for an exception from a Data abort exception* on page D7-1849 describes the format of this syndrome.

Floating-point exceptions

These are the exception syndromes with the following EC values:

- `0b101000`, trapped floating-point exception from AArch32.
- `0b101100`, trapped floating-point exception from AArch64.

These Exception classes are supported only when the SIMD and floating-point implementation supports the trapping of floating-point exceptions, see *Exception from an access to SIMD or floating-point registers, from AArch32 or AArch64* on page D1-1432. Otherwise, the `0x28` and `0x2C` EC values are reserved. That is, these EC values are used to report the floating-point exceptions defined by IEE 754, and input denormal.

The returned syndrome identifies the trapped floating-point exception or exceptions. *ISS encoding for an exception from a floating-point exception* on page D7-1852 describes the format of this syndrome.

In an implementation where the SIMD and floating-point implementation supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

SError interrupt

This is the exception syndrome with EC value `0b101111`.

It is used to report the exception caused by an SError interrupt.

The returned syndrome is IMPLEMENTATION SPECIFIC. *ISS encoding for an SError interrupt* on page D7-1854 describes the format of this syndrome.

Breakpoint exception or Vector Catch exception

These are the exception syndromes with the following EC values:

- `0b110000`, Breakpoint exception taken from a lower Exception level.
- `0b110001`, Breakpoint exception taken without a change of Exception level.
- `0b111010`, AArch32 Vector Catch exception.

The returned syndrome provides a fault code that indicates the cause of the exception. *ISS encoding for a Breakpoint exception or Vector Catch exception* on page D7-1854 describes the format of this syndrome.

For more information about generating these exceptions, see:

- *Breakpoint exceptions* on page D2-1546.
- *Vector Catch exceptions* on page D2-1578.

Watchpoint exception

These are the exception syndromes with the following EC values:

- `0b110100`, Watchpoint exception taken from a lower Exception level.
- `0b110101`, Watchpoint exception taken without a change of Exception level.

The returned syndrome provides more information about the watchpoint, including a fault code that indicates the cause of the exception. *ISS encoding for a Watchpoint exception* on page D7-1855 describes the format of this syndrome.

For more information about generating these exceptions, see *Watchpoint exceptions* on page D2-1564.

Software Step exception

These are the exception syndromes with the following EC values:

- `0b110010`, Software Step exception taken from a lower Exception level.
- `0b110011`, Software Step exception taken without a change of Exception level.

The returned syndrome provides more information about the watchpoint, including a fault code that indicates the cause of the exception. *ISS encoding for Software Step exception* on page D7-1857 describes the format of this syndrome.

For more information about generating these exceptions, see *Software Step exceptions* on page D2-1579.

Software Breakpoint Instruction exception

These are the exception syndromes with the following EC values:

- `0b111000`, `BKPT` instruction executed in AArch32 state.
- `0b111001`, `BRK` instruction executed in AArch64 state.

The returned syndrome provides the comment that was provided as an argument to the software breakpoint instruction. *ISS encoding for a Software Breakpoint Instruction exception* on page D7-1858 describes the format of this syndrome.

For more information about generating these exceptions, see *Software Breakpoint Instruction exceptions* on page D2-1544.

EC encodings when routing general exceptions to EL2

When an exception is taken to EL2 because the exception routing control HCR_EL2.TGE is enabled, the EC encoding that would have been used if the exception had been taken to EL1 is recorded in ESR_EL2.EC instead, unless that encoding is `0x07`.

Exceptions that use `0x07` when the HCR_EL2.TGE routing control is disabled use `0x00` when the HCR_EL2.TGE routing control is enabled.

D1.11 Exception return

In the ARMv8-A architecture, an exception return is always to the same Exception level or a lower Exception level. An exception return is used for:

- A return to a previously executing thread.
- Entry to a new execution thread. For example:
  - The initialization of a hypervisor by a Secure monitor.
  - The initialization of an operating system by a hypervisor.
  - Application entry from an operating system or hypervisor.

An exception return requires the simultaneous restoration of the PC and PSTATE to values that are consistent with the desired state of execution on returning from the exception.

In AArch64 state, an ERET instruction causes an exception return. On an ERET instruction:

- The PC is restored with the value held in the ELR_ELx.
- PSTATE is restored by using the contents of the SPSR_ELx.

The ELR_ELx and SPSR_ELx are the ELR_ELx and SPSR_ELx at the Exception level the exception is returning from.

Note

When returning from an Exception level using AArch64 to an Exception level using AArch32, the top 32 bits of the ELR_ELx are ignored.

An ERET instruction also:

- Sets the Event Register for the PE executing the ERET instruction. See *Mechanisms for entering a low-power state* on page D1-1503.
- Resets the local exclusive monitor for the PE executing the ERET instruction. This removes the risk of errors that might be caused when a path to an exception return fails to include a CLREX instruction.

  Note

  This behavior prevents self-hosted debug from software stepping through an LDREX/STREX pair. However, when self-hosted debug is using software step, it is highly probable that the exclusive monitor state would be lost anyway, for other reasons. *Stepping code that uses exclusive monitors* on page D2-1590 describes this.

  It is IMPLEMENTATION DEFINED whether the resetting of the local exclusive monitor also resets the global exclusive monitor.

The ERET instruction is UNDEFINED in EL0.

When returning from an Exception level using AArch64 to an Exception level using AArch32, the AArch32 context is restored. The ARMv8-A architecture defines the relationship between AArch64 state and AArch32 state, for:

- General purpose registers.
- Special purpose registers.
- System registers.

In an implementation that includes EL3, the Security state can only change on returning from an exception if the return is from EL3 to a lower Exception level.

The following sections give more information:

- *Pseudocode description of exception return* on page D1-1438.
- *Exception return and PC alignment* on page D1-1438.
- *Illegal return events* on page D1-1438.

D1.11.1 Pseudocode description of exception return

```
// AArch64.ExceptionReturn()
// =========================

AArch64.ExceptionReturn(bits(64) new_pc, bits(32) spsr)

    // Attempts to change to an illegal state will invoke the Illegal Execution State mechanism
    SetPSTATEFromPSR(spsr);
    ClearExclusiveLocal(ProcessorID());
    EventRegisterSet();

    if spsr<4> == '1' then                // Attempted to change to AArch32 state
        // Align PC[1:0] according to the target instruction set state
        // If PSTATE.IL==1 then the state did not change, but the PC alignment might have occurred
        if PSTATE.IL == '0' || ConstrainUnpredictableBool() then
            if spsr<5> == '1' then        // T32 or T32EE state
                new_pc = Align(new_pc, 2);
            else                          // A32 state
                new_pc = Align(new_pc, 4);

        // Zero the 32 most significant bits of the target PC
        if PSTATE.IL == '0' || ConstrainUnpredictableBool() then
            new_pc<63:32> = Zeros();

    if PSTATE.nRW == '1' then
        BranchTo(new_pc<31:0>, BranchType_UNKNOWN);
    else
        BranchTo(new_pc, BranchType_ERET);
```

D1.11.2 Exception return and PC alignment

When returning to an Exception level using AArch64, as defined by SPSR_ELx.M[4] == 0, if the ELR_ELx contains a misaligned value, that value is transferred to the PC. Subsequent execution results in a Misaligned PC exception.

When returning from an Exception level using AArch64 to an Exception level using AArch32, as defined by SPSR_ELx.M[4] == 1, if the ELR_ELx contains a misaligned value, then:

- If SPSR_ELx.T is 0, ELR_ELx[1:0] are treated as being 0 for restoring the PC.
- If SPSR_ELx.T is 1, ELR_ELx[0] is treated as being 0 for restoring the PC.

This means that no Misaligned PC exception occurs after returning from AArch64 state to AArch32 state.

Note

An exception return with SPSR_ELx.M[4] == 1 that generates an illegal exception return into AArch64 state is permitted to result in alignment of the PC.

D1.11.3 Illegal return events

An *illegal return event* means one of:

- An illegal exception return.
- An illegal return from Debug state.
- A DRPS instruction executed in Debug state, that causes an illegal exception return situation.

In the description that follows, the term *return* is used to mean an exception return, a return from Debug state, or a return as a result of a DRPS executed in Debug state.

Note

If return means a return from Debug state, it is the DSPSR_EL0 that was used to save PE state, not the SPSR_ELx.

The following are illegal return events from AArch64 state:

- A return where the Exception level being returned to is higher than the current Exception level.
- A return to an Exception level that is not implemented, for example a return to EL2 when EL2 is not implemented.
- A return where the SPSR_ELx indicates a return to AArch32 state, but the Exception level being returned to is using AArch64, as programmed by SCR_EL3.RW or HCR_EL2.RW or as initialized from reset.
- A return to EL2 when SCR_EL3.NS is 0. The PE cannot return to Non-secure state when SCR_EL3.NS is 0.
- A return to Non-secure EL1 when HCR_EL2.TGE is 1.
- A return to AArch64 state when SPSR_ELx.M[1] is 1.
- The behavior is IMPLEMENTATION DEFINED on a return to AArch32 state when SPSR_ELx.{J, T} are `0b11` at the Exception level being returned to. Either:
  - The return is an illegal return.
  - SPSR_ELx.J is treated as 0.
- A return to AArch32 state using an SPSR_ELx.M[3:0] field value that is not allocated to a valid AArch32 mode.
- A return to EL0 using AArch64 when SPSR_ELx.M[0] is 1.
- Debug state exit from EL0 using AArch64, to EL0 using AArch32.

On an illegal return from an Exception level using AArch64:

- The IL bit, PSTATE.IL, is set to 1
- The Exception level, Execution state, and stack pointer selection are unchanged as a result of the return.
- The following PSTATE bits are restored using the contents of the SPSR_ELx:
  - The NZCV flag bits.
  - The DAIF mask bits.
- The PC is restored with the value held in the ELR_ELx.
- If the illegal return is an illegal exception return, the SS bit is handled as normal for an exception return.That is, the SS bit is handled in the same way as an exception return that is not an illegal exception return. See *Software Step exceptions* on page D2-1579.

When the value of the IL bit is 1, any attempt to execute any instruction results in an Illegal Execution State exception, and ESR_ELx.EC for the target Exception level takes the value `0b001110`. For the priority of this exception class, see *Synchronous exception prioritization* on page D1-1448.

On taking an exception, the value of the IL bit is copied into the SPSR associated with the Exception level that the exception is taken to, and then the IL bit is set to 0.

Note

This means that it is not possible for software to observe the value of PSTATE.IL.

If an exception return from AArch64 state to AArch32 state, as defined by SPSR_ELx.M[4] == 1, triggers an illegal exception return, it is CONSTRAINED UNPREDICTABLE whether the top 32 bits of the PC:

- Are all zero.
- Take the value held in the ELR_ELx, or the value held in the DLR_EL0 if returning from Debug state.

The implementation determines the choice of these two options, and the choice might vary dynamically. Therefore, software must tolerate both of these options.

Other than the effects described in this section, all other aspects of the return occur as normal.

D1.12 The Exception level hierarchy

The System registers provide controls that control PE behavior through the Exception level hierarchy.

If EL3 and EL2 are implemented, System registers at EL3 and EL2 provide controls that control the Execution state of lower Exception levels.

Table D1-8 shows the principal System control registers:

Table D1-8 Principal System control registers

EL3	EL2	EL1	Notes
SCTLR_EL3	SCTLR_EL2	SCTLR_EL1	Controls execution for its own Exception level.
SCR_EL3	HCR_EL2	-	Controls execution at lower Exception levels.
-	HSTR_EL2	-	Used only if at least one of EL1 and EL0 is using AArch32.

The following sections describe the Exception level hierarchy:

- *The hierarchy of configuration and routing control*.
- *Control of SIMD, floating-point and trace functionality* on page D1-1445.
- *Control of IMPLEMENTATION DEFINED features* on page D1-1445.
- *Routing general exceptions to EL2* on page D1-1447.

D1.12.1 The hierarchy of configuration and routing control

The following subsections give a summary of the controls available at each Exception level for controlling execution at that Exception level and all lower Exception levels:

- *Controls provided at EL3*.
- *Controls provided at EL2* on page D1-1441.
- *Controls provided at EL1* on page D1-1444.

For information on how the controls summarized in these subsections affect PE behavior, see the definitions of the control bits in the register descriptions.

Controls provided at EL3

See:

- *Controls provided by the SCR_EL3*.
- *Controls provided by the SCTLR_EL3* on page D1-1441.
- *Controls provided by the MDCR_EL3* on page D1-1441.

Controls provided by the SCR_EL3

SCR_EL3.NS Determines the Security state of execution at EL1 and EL0.

SCR_EL3.RW Determines the Execution state of the next-lower Exception level.

SCR_EL3.{EA, FIQ, IRQ}

Route:

EA Physical SError interrupts and synchronous External Aborts to EL3.

FIQ Physical FIQ interrupts to EL3.

IRQ Physical IRQ interrupts to EL3.

SCR_EL3.SMD Disables the Secure Monitor Call exception.

SCR_EL3.HCE Enables the Hypervisor Call exception.

SCR_EL3.ST Enables Secure EL1 access to the Secure timer.

SCR_EL3.SIF Secure Instruction Fetch. When in Secure state, disables instruction fetches from Non-secure memory.

SCR_EL3.TWI Trap Wait-For-Interrupt.

SCR_EL3.TWE Trap Wait-For-Event.

Controls provided by the SCTLR_EL3

SCTLR_EL3.{A, SA} Enable alignment checking:

- **A** On data accesses from EL3.
- **SA** On the SP, when executing at EL3.

SCTLR_EL3.[M, C, I, WXN}

Memory system control bits:

- **M** Enables EL3 stage 1 address translation.
- **C** Enables data and unified caches for accesses from EL3.
- **I** Enables instruction caches for accesses from EL3.
- **WXN** For accesses from EL3, enables treating all writable memory regions as XN, execute never.

SCTLR_EL3.EE Defines the endianness of data accesses from EL3, including stage 1 translation table walks at EL3.

Note

Instruction fetches are always little-endian.

Controls provided by the MDCR_EL3

MDCR_EL3.{EPMAD, EDAD}

Enable external debugger accesses to:

- **EPMAD** Performance Monitors registers.
- **EDAD** Breakpoint and Watchpoint registers.

MDCR_EL3.{SPME, SDD, SPD32}

Secure debug controls:

- **SPME** Secure Performance Monitors enable. Enables event counting in Secure state.
- **SDD** Disables all debug exceptions taken from Secure state, if the *debug target Exception level*, EL_D, is using AArch64.
- **SPD32** Enables debug exceptions from Secure EL1 using AArch32.

MDCR_EL3.{TDOSA, TDA, TPM}

These are trap enable controls, that enable traps to EL3 of EL2, EL1, and EL0 accesses to the following:

- **TDOSA** The OS-related debug registers.
- **TDA** Those debug registers not included in the MDCR_EL3.TDOSA trap.
- **TPM** The Performance Monitors registers.

For EL1 and EL0, these traps apply to accesses from both Security states.

Controls provided at EL2

EL2 is implemented only in Non-secure state, and its controls apply only to execution in Non-secure EL2, Non-secure EL1, and Non-secure EL0. See:

- *Controls provided by SCTLR_EL2* on page D1-1442.

- *Controls provided by HCR_EL2*.
- *Controls provided by the HSTR_EL2* on page D1-1443.
- *Controls provided by the MDCR_EL2* on page D1-1443.

Controls provided by SCTLR_EL2

SCTLR_EL2.{A, SA} Enable alignment checking:

A On data accesses from EL2.

SA On the SP, when executing at EL2.

SCTLR_EL2,{M, C, I, WXN}

Memory system control bits:

M Enables EL2 stage 1 address translation.

C Enables data and unified caches for accesses from EL2.

I Enables instruction caches for accesses from EL2.

WXN For accesses from EL2, enables treating all writable memory regions as XN, execute never.

SCTLR_EL2.EE Defines the endianness of data accesses from EL2, including stage 1 translation table walks at EL2.

Also defines the endianness of stage 2 translation table walks at Non-secure EL1 and EL0.

Note

Instruction fetches are always little-endian.

Controls provided by HCR_EL2

HCR_EL2.RW Determines the Execution state of the next-lower Exception level.

HCR_EL2.{AMO, IMO, FMO}

Route physical interrupts to EL2 and enable virtual interrupts:

AMO Route physical SError interrupts to EL2 and enable virtual SError interrupts

IMO Route physical IRQ interrupts to EL2 and enable virtual IRQ interrupts.

FMO Route physical FIQ interrupts to EL2 and enable virtual FIQ interrupts.

Note

If a physical interrupt is routed to both EL3 and EL2, routing to EL3 takes precedence over routing to EL2.

HCR_EL2.{VSE, VI, VF}

Cause a virtual interrupt to be pending:

VSE Virtual SError interrupt.

VI Virtual IRQ interrupt.

VF Virtual FIQ interrupt.

HCR_EL2.VM Enable bit for Non-secure EL1&0 stage 2 address translations.

HCR_EL2.{SWIO, PTW, FB, BSU, DC, CD, ID}

Controls for memory system behavior for accesses made from Non-secure EL1 and EL0:

SWIO Set/Way Invalidate Override.

PTW Protect Table Walk.

FB Force broadcast of TLB and instruction cache maintenance instructions.

BSU Barrier Shareability Upgrade.

DC Default Cacheable for EL1 and EL0 translations, when the EL1/EL0 stage translation regime is disabled.

CD Data Cache Disable, for stage 2 translations.

ID Instruction cache Disable, for stage 2 translations.

HCR_EL2.HCD Hypervisor Call Disable.

Note

If an implementation includes EL3, this bit is RES0.

HCR_EL2.{TRVM, TDZ, TVM, TTLB, TPU, TPC, TSW, TACR, TIDCP, TSC, TID1, TID2, TID3, TWE, TWI}

Trap operations performed at Non-secure EL1 or EL0 to EL2, as follows:

TRVM Trap Read of Virtual Memory controls.

TDZ Trap Data Cache Zero.

TVM Trap Virtual Memory controls.

TTLB Trap TLB maintenance instructions.

TPU Trap cache maintenance to the Point of Unification instructions.

TPC Trap data cache maintenance to the Point of Coherency instructions.

TSW Trap data cache maintenance by Set/Way instructions.

TACR Trap Auxiliary Control Register accesses.

TIDCP Trap Implementation-Dependent functionality.

TSC Trap Secure Monitor Call.

TID0 Trap ID Group 0 register accesses.

TID1 Trap ID Group 1 register accesses.

TID2 Trap ID Group 2 register accesses.

TID3 Trap ID Group 3 register accesses.

TWI Trap Wait-For-Interrupt.

TWE Trap Wait-For-Event.

Note

There are no AArch64 System registers in ID Group 0, therefore the TID0 trap is only relevant when Non-secure EL1 is using AArch32.

HCR_EL2.TGE Trap General Exceptions.

Controls provided by the HSTR_EL2

When EL2 is using AArch64 and at least one of Non-secure EL1 or EL0 is using AArch32, HSTR_EL2 provides the following trap of Non-secure AArch32 operation to EL2:

HSTR_EL2.T*n*, for values of *n* in the set {0-3, 5-13, 15}

Trap accesses to System registers in the AArch32 conceptual coprocessor CP15, by the coprocessor primary register number.

Controls provided by the MDCR_EL2

MDCR_EL2.{TDRA, TDOSA, TDA}

Trap enable controls, that enable traps to EL2 of Non-secure EL1 and EL0 System register accesses to the following:

TDRA The Debug ROM registers.

TDOSA The OS-related debug registers.

TDA Those debug registers not included in either of the MDCR_EL2.TDRA or MDCR_EL2.TDOSA traps.

MDCR_EL2.TDE Routes all debug exceptions taken from Non-secure EL1 and EL0 to EL2.

MDCR_EL2.{TPM, TPMCR}

These are trap enable controls, that enable traps to EL2 of Non-secure EL1 and EL0 accesses to the following registers:

TPM All Performance Monitors registers.

TPMCR The Performance Monitors Control Registers.

MDCR_EL2.HPMN Defines the number of Performance Monitors counters that are accessible from Non-secure EL1 and EL0.

Controls provided at EL1

See:

- *Controls provided by the SCTLR_EL1*.
- *Controls provided by the MDSCR_EL1* on page D1-1445.

Controls provided by the SCTLR_EL1

SCTLR_EL1.{A, SA} Enable alignment checking:

A On data accesses from EL1 and EL0.

SA On the SP, when executing at EL1.

SCTLR_EL1.SA0 Enable alignment checking on the SP when executing at EL0.

SCTLR_EL1.[M, C, I, WXN}

Memory system control bits:

M Enables EL1&0 stage 1 address translation.

C Enables data and unified caches for accesses from EL1 and EL0.

I Enables instruction caches for accesses from EL1 and EL0.

WXN For accesses from EL1 and EL0, enables treating all writable memory regions as XN, execute never.

SCTLR_EL1.EE Defines the endianness of data accesses from EL1, including stage 1 translation table walks at EL1 and EL0.

Note

Instruction fetches are always little-endian.

SCTLR_EL1.E0E EL0 Endianness. Defines the endianness used for explicit data accesses made from EL0.

SCTLR_EL1.{UCI, UCT, DZE, nTWI, nTWE}

Trap enables:

UCI Unprivileged Cache maintenance Instruction enable.

UCT Unprivileged Cache Type access enable.

DZE Data cache Zero Enable.

nTWI Not Trap Wait-For-Interrupt.

nTWE Not Trap Wait-For-Event.

SCTLR_EL1.UMA Unprivileged Mask Access.

SCTLR_EL1.{SED, ITD, CP15BEN}

These bits control AArch32 functionality that is deprecated, or OPTIONAL and deprecated:

SED Disables use of the `SETEND` instruction.

ITD Disables use of the `IT` instruction.

CP15BEN Enables use of the CP15 DMB, DSB, and ISB barrier operations.

Controls provided by the MDSCR_EL1

MDSCR_EL1.{MDE, SS}

Enable controls for the debug exceptions:

MDE Enables Breakpoint exceptions, Watchpoint exceptions, and Vector Catch exceptions.

SS Enables Software Step exceptions.

There is no enable control for Software Breakpoint Instruction exceptions. Software Breakpoint Instruction exceptions are always enabled.

MDSCR_EL1.KDE Enables debug exceptions from EL_D when EL_D is using AArch64.

MDSCR_EL1.TDCC Enables a trap to EL1 of EL0 accesses to the Debug Communications Channel registers.

D1.12.2 Control of SIMD, floating-point and trace functionality

In addition to the controls described in *The hierarchy of configuration and routing control* on page D1-1440, the following registers provide a hierarchy of control of access to SIMD and floating-point functionality, and to trace functionality that is accessible using the System registers:

CPTR_EL3 Traps operation at lower Exception levels to EL3, if the operation is not trapped to EL2 by CPTR_EL2 or is not trapped to EL1 by CPACR_EL1.

CPTR_EL2 Traps operation in Non-secure EL1 or EL0 to EL2, if the operation is not trapped to EL1 by CPACR_EL1.

The trap bits in the CPTR_EL3 and CPTR_EL2 are as follows:

TCPAC Traps accesses to the registers that control access to SIMD, floating-point, and trace functionality.

TTA Traps any System register access to trace functionality, unless that access is otherwise trapped to a lower Exception level.

TFP Traps any execution of an instruction that uses the SIMD and floating-point register bank, unless that access is otherwise trapped to a lower Exception level.

CPACR_EL1 Traps operation from EL1 or EL0 to EL1. Traps set in the CPACR_EL1 take precedence over any traps set in the CPTR_EL2 or CPTR_EL3. The trap fields are as follows:

TTA Traps to EL1 any System register access from EL0 or EL1 to trace functionality.

FPEN Traps to EL1 execution of instructions that uses the SIMD and floating-point register bank.

Note

In other context, the hierarchy of traps and routing controls is that controls that trap or route functionality to a higher Exception level take precedence over any control that would trap or route that functionality to a lower Exception level. However, the traps described in this subsection have the reverse precedence, with, for example, the CPACR_EL1 traps to EL1 taking precedence over the corresponding traps to EL2 or EL3. This hierarchy supports lazy context switching.

D1.12.3 Control of IMPLEMENTATION DEFINED features

The hierarchy of configuration and routing control on page D1-1440 and *Control of SIMD, floating-point and trace functionality* describe the controls of the trapping of architecturally-defined functionality. However, the architecture also defines registers that can be used to provide IMPLEMENTATION DEFINED traps of IMPLEMENTATION DEFINED functionality to the different Exception levels. Table D1-9 on page D1-1446 shows these control registers, for AArch64 state controls:

Table D1-9 Control of traps of IMPLEMENTATION DEFINED functionality

Traps to EL3	Traps to EL2	Traps to EL1	Notes
ACTLR_EL3	ACTLR_EL2	ACTLR_EL1	Registers also provide IMPLEMENTATION DEFINED configuration controls for the appropriate Exception level.
-	HACR_EL2	-	Provides traps of IMPLEMENTATION DEFINED Non-secure EL1 and EL0 functionality to EL2.

D1.13 Synchronous exception types, routing and priorities

Synchronous exceptions are:

- UNDEFINED exceptions generated by:
  - Attempts to execute instructions at an inappropriate Exception level.
  - Attempts to execute instruction bit patterns that have not been allocated.
- Illegal Execution State exceptions. These are caused by attempts to execute an instruction when the value of PSTATE.IL is 1, see *Illegal return events* on page D1-1438.
- Exceptions caused by the use of a misaligned Stack Pointer.
- Exceptions caused by attempting to execute an instruction with a misaligned PC.
- Exceptions caused by the exception-generating instructions `SVC`, `HVC`, or `SMC`.
- Traps on attempts to execute instructions that the System Control registers define as instructions that are *trapped to a higher Exception level*. See *Controls at higher Exception levels* on page D1-1459.
- Instruction Aborts generated by the memory address translation system, that are associated with attempts to execute instructions from areas of memory that generate Faults.
- Data Aborts generated by the memory address translation system, that are associated with attempts to read or write memory that generate Faults.
- Data Aborts caused by a misaligned address.
- All of the debug exceptions:
  - Software Breakpoint Instruction exceptions.
  - Breakpoint exceptions.
  - Watchpoint exceptions.
  - Vector Catch exceptions.
  - Software Step exceptions.
- In some implementations, exceptions caused by trapped IEEE floating-point exceptions, see *Floating-point Exception traps* on page D1-1451.
- In some implementations, External aborts. External aborts are failed memory accesses, and include accesses to those parts of the memory system that occur during the address translation. The ARMv8 architecture permits, but does not require, implementations to treat such exceptions synchronously. See *External aborts* on page D3-1619.

This remainder of this section contains the following:

- *Routing general exceptions to EL2*.
- *Synchronous exception prioritization* on page D1-1448.
- *Effect of Data Aborts* on page D1-1450.
- *Floating-point Exception traps* on page D1-1451.

D1.13.1 Routing general exceptions to EL2

When the value of HCR_EL2.TGE is 1, any exception taken from Non-secure EL0 that would otherwise be taken to Non-secure EL1 is, instead, routed to EL2. This means that an application can execute at Non-secure EL0 without using any functionality at Non-secure EL1.

Note

In Non-secure state, typically an implementation uses the following Exception level and software hierarchy, in Non-secure state:

EL2 Hypervisor.

EL1 Operating system.

EL0 Application.

In such an implementation, enabling the HCR_EL2.TGE trap means an application can run at Non-secure EL0 under the direct control of a hypervisor, executing at EL2, without any operating system involvement.

D1.13.2 Synchronous exception prioritization

In principle, any single instruction can generate a number of different synchronous exceptions, between the fetching of the instruction, its decode, and eventual execution. These are prioritized as follows, with 1 indicating the highest priority:

1. Software Step exceptions. See *Software Step exceptions* on page D2-1579.
2. Misaligned PC exceptions. See *PC alignment checking* on page D1-1415.
3. Instruction abort exceptions. See *ISS encoding for an exception from an Instruction abort exception* on page D7-1848.
4. Hardware Breakpoint exceptions or Vector Catch exceptions. See:
   - *Breakpoint exceptions* on page D2-1546.
   - *Vector Catch exceptions* on page D2-1578.

   Vector Catch exceptions are only taken from AArch32 state.
5. Illegal Execution State exceptions. See *Illegal return events* on page D1-1438.
6. Exceptions taken from EL1 to EL2 because of one of the following configuration settings:
   - For exceptions taken from AArch64 state:
     - HSTR_EL2.T*n*.
     - HCR_EL2.TIDCP.
   - For exceptions taken from AArch32 state:
     - HSTR.T*n*.
     - HCR.TIDCP.
7. Undefined Instruction exceptions that occur as a result of one or more of the following:
   - An attempt to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
   - An attempt to execute an instruction that is defined never to be accessible at the current Exception level regardless of any enables or traps.
   - Debug state execution of an instruction encoding that is unallocated in Debug state.
   - Non-debug state execution of an instruction encoding that is unallocated in Non-debug state.
   - Execution of an `HVC` instruction, when `HVC` instructions are disabled by SCR_EL3.HCE or HCR_EL2.HCD.
   - Execution of an `MSR` or `MRS` instruction to SP_EL0 when the value of SPSel is 0.
   - Execution of a `HLT` instruction when `HLT` instructions are disabled by EDSCR.HDE.
   - In Debug state, execution of:
     - A `DCPS1` instruction in Non-secure EL0 when HCR_EL2.TGE is 1.
     - A `DCPS2` instruction in EL1 or EL0 when SCR_EL3.NS is 0 or when EL2 is not implemented.
     - A `DCPS3` instruction when EDSCR.SDD is 1 or when EL3 is not implemented.
     - When the value of EDSCR.SDD is 1, execution in EL2, EL1, or EL0 of an instruction that is trapped to EL3.

- When executing in AArch32 state, execution of an instruction that is UNDEFINED as a result of any of:
  - Being in an IT block when SCTLR_EL1.ITD or SCTLR.ITD is 1, or when HSCTLR.ITD is 1.
  - A SETEND instruction executed when SCTLR_EL1.SED or SCTLR.SED is 1.
  - A CP15 DMB, DSB, or ISB barrier operation performed when SCTLR_EL1.CP15BEN or SCTLR.CP15BEN is 0.

  See *Enabling and disabling EL0 accesses to AArch32 deprecated functionality* on page D1-1463
- When executing in AArch32 state, execution of an instruction that is UNDEFINED because at least one of FPCR.LEN and FPSCR.STRIDE is nonzero when programming these bits to nonzero values is supported. See *Floating-point exception traps, serialization, and floating-point exception barriers* on page G1-3473.

8. Exceptions taken to EL1, or taken to EL2 because the value of HCR_EL2.TGE or HCR.TGE is 1, that are generated because of configurable access to instructions, and that are not covered by any of priorities 1-7.

9. Exceptions taken from EL0 to EL2 because of one of the following configuration settings:
   - For exceptions taken from AArch64 state:
     - HSTR_EL2.T*n*.
     - HCR_EL2.TIDCP.
   - For exceptions taken from AArch32 state:
     - HSTR.T*n*.
     - HCR.TIDCP.

10. Exceptions taken to EL2 because of one of the following configuration settings:
    - For exceptions taken from AArch64 state, settings in the CPTR_EL2.
    - For exceptions taken from AArch32 state, settings in the HCPTR.

11. Exceptions taken to EL2 because of one of the following configuration settings:
    - For exceptions taken from AArch64 state:
      - Any setting in HCR_EL2, other than the TIDCP bit.
      - Any setting in CNTHCTL_EL2.
      - Any setting in MDCR_EL2.
    - For exceptions taken from AArch32 state:
      - Any setting in HCR, other than the TIDCP bit.
      - Any setting in CNTHCTL.
      - Any setting in HDCR.

12. Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities 1-11.

13. Exceptions caused by the SMC instruction being UNDEFINED because the value of SCR_EL3.SMD is 1.

14. Exceptions caused by the execution of an Exception generating instruction:
    - For exceptions taken from AArch64 state, *Branches, Exception generating, and System instructions* on page C3-126 defines these instructions.
    - When executing in AArch32 state, the exception-generating instructions are SVC, HVC, SMC, and BKPT.

15. Exceptions taken to EL3 because of configuration settings in the CPTR_EL3.

16. Exceptions taken to EL3 from Secure EL1 using AArch32, because of execution of the instructions listed in *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32* on page D1-1490.

17. Exceptions taken to EL3 because of configuration settings in the MDCR_EL3. These might be taken from EL0, EL1, or EL2.

18. Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities 1-17.

19. Trapped floating-point exceptions, if supported. See *Floating-point Exception traps* on page D1-1451.
20. Stack Pointer Alignment faults. See *Stack pointer alignment checking* on page D1-1416.
21. Data abort exceptions. See *ISS encoding for an exception from a Data abort exception* on page D7-1849 and *Prioritization of synchronous aborts from a single stage of address translation* on page D4-1727.
22. Watchpoint exceptions. See *Watchpoint exceptions* on page D2-1564.

Note

The exception trapping form of vector catch is outside of this list of priorities, because it causes a second exception entry as a result of an exception entry that was prioritized according to this list.

D1.13.3 Effect of Data Aborts

If an instruction that stores to memory generates a Data Abort, the value of each memory location that instruction stores to is either:

- Unchanged, if one of the following applies:
  - An MMU fault is generated.
  - A Watchpoint exception is generated.
  - An external abort is generated, if that external abort is taken synchronously.

    Note

    If an external abort is taken asynchronously, using the SError interrupt, it is outside the scope of the architecture to define the effect of the store on the memory location, because it depends on the system-specific nature of the external abort. However, in general, ARM recommends that such memory locations are not updated.
- UNKNOWN for any location for which no exception is generated.

For external aborts and Watchpoint exceptions, the size of a memory location is defined as being the size for which a memory access is single-copy atomic.

Note

For the definition of a single-copy atomic access, see *Single-copy atomicity* on page B2-79.

For Data Aborts from load or store instructions executed in AArch64 state, if the:

Data Abort is taken synchronously

- If the load or store instruction specifies writeback of a new base address, the base address is restored to the original value on taking the exception.
- If the instruction was a load to either the base address register or the offset register, that register is restored to the original value. Any other destination registers become UNKNOWN.
- If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.

Data Abort is taken asynchronously, using the SError interrupt

If the instruction was a load, the destination registers of the load take an UNKNOWN value if the SError interrupt is taken at a point in the instruction stream after the load.

Note

Data Aborts taken asynchronously are known as Asynchronous Aborts in AArch32 state.

D1.13.4 Floating-point Exception traps

The ARMv8-A architecture supports synchronous exception generation in the event of any or all of the following floating-point exceptions:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

Whether an implementation includes synchronous exception generation for these floating-point exceptions is IMPLEMENTATION DEFINED.

For implementations that do include this capability, FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} are the control bits that enable synchronous exception generation for each of the different floating-point exceptions.

For implementations that do not include this capability, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits are RAZ/WI.

Note

The ARMv8-A architecture does not support asynchronous reporting of floating-point exceptions.

When generating synchronous exceptions for one or more floating-point exceptions is enabled, the synchronous exceptions are taken to the lowest Exception level that can handle such an exception, while adhering to the rule that exceptions can never be taken to a lower Exception level. This means that trapped floating-point exceptions taken from:

- EL0 are taken to EL1, unless they are taken from Non-secure state when HCR_EL2.TGE is 1, when they are taken to EL2 instead.
- EL1 are taken to EL1.
- EL2 are taken to EL2.
- EL3 are taken to EL3.

In an implementation that includes synchronous exception generation for floating-point exceptions:

- Synchronous exception generation applies to floating-point exceptions generated by scalar SIMD and floating-point instructions executed in AArch64 state.
- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception. An implementation is permitted not to restore the cumulative exception flags in the event of such an exception.
- When the execution of separate operations in separate SIMD elements causes multiple floating-point exceptions, the ELR_ELx reports one exception associated with one element that the instruction uses. The architecture does not specify which element is reported, however the element that is reported is identified in the ELR_ELx.

```
// AArch64.FPTrappedException()
// ============================

AArch64.FPTrappedException(boolean is_ase, integer element, bits(8) accumulated_exceptions)
    exception = ExceptionSyndrome(Exception_FPTrappedException);
    exception.syndrome<23>    = '1';                          // TFV
    exception.syndrome<7,4:0> = accumulated_exceptions<7,4:0>; // IDF,IXF,UFF,OFF,DZF,IOF

    route_to_el2 = HaveEL(EL2) && !IsSecure() && HCR_EL2.TGE == '1';

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;
```

```
    if UInt(PSTATE.EL) > UInt(EL1) then
        AArch64.TakeException(PSTATE.EL, exception, preferred_exception_return, vect_offset);
    elsif route_to_el2 then
        AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
        AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);

// FPProcessException()
// ====================
//
// The 'fpcr' argument supplies FPCR control bits. Status information is
// updated directly in the FPSR where appropriate.

FPProcessException(FPExc exception, FPCRType fpcr)
    // Determine the cumulative exception bit number
    case exception of
        when FPExc_InvalidOp     cumul = 0;
        when FPExc_DivideByZero  cumul = 1;
        when FPExc_Overflow      cumul = 2;
        when FPExc_Underflow     cumul = 3;
        when FPExc_Inexact       cumul = 4;
        when FPExc_InputDenorm   cumul = 7;
    enable = cumul + 8;
    if fpcr<enable> == '1' then
        // Trapping of the exception enabled.
        // It is IMPLEMENTATION DEFINED whether the enable bit may be set at all, and
        // if so then how exceptions may be accumulated before calling FPTrapException()
        IMPLEMENTATION_DEFINED "floating-point trap handling";
    else if UsingAArch32() then
        // Set the cumulative exception bit
        FPSCR<cumul> = '1';
    else
        // Set the cumulative exception bit
        FPSR<cumul> = '1';
    return;
```

D1.14 Asynchronous exception types, routing, masking and priorities

In the ARMv8-A architecture, asynchronous exceptions that are taken to AArch64 state are also known as *interrupts*.

There are two types of interrupts:

Physical interrupts Are signals sent to the PE from outside the PE. They are:
- SError. System Error.
- IRQ.
- FIQ.

Virtual interrupts Are interrupts that a Hypervisor executing in EL2 can enable. When enabled, a virtual interrupt is taken from Non-secure EL0 or Non-secure EL1 to a Guest OS running in Non-secure EL1.

Virtual interrupts have names that correspond to the physical interrupts:
- vSError.
- vIRQ.
- vFIQ.

Note

The AArch64 SError interrupt replaces the AArch32 asynchronous abort. The new name better describes the nature of the exception, and means that it is categorized as a unique exception class, with EC encoding `0x2F`.

An external abort generated by the memory system might be taken asynchronously using the SError interrupt. The effect of a failed memory access is described in *Effect of Data Aborts* on page D1-1450.

Each physical interrupt type can be assigned a target Exception level of EL1, EL2 or EL3, as shown in *Synchronous exception prioritization* on page D1-1448.

When an interrupt occurs:

- On taking an SError or a virtual SError interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is updated with the encoding for an SError interrupt. See *Exception classes and the ESR_ELx syndrome registers* on page D1-1426.
- On taking an IRQ, virtual IRQ, FIQ or virtual FIQ interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is not updated.

The remainder of this section contains the following:
- *Asynchronous exception routing* on page D1-1454.
- *Asynchronous exception masking* on page D1-1454.
- *Virtual interrupts* on page D1-1456.
- *Prioritization and recognition of asynchronous exceptions* on page D1-1457.
- *Taking an interrupt during a multiple-register load or store* on page D1-1458.

D1.14.1 Asynchronous exception routing

The following tables show the routing of physical interrupts when the highest implemented Exception level is using AArch64.

In the tables, P indicates that the interrupt is not taken and remains pending

Table D1-10 Routing when both EL3 and EL2 are implemented

SCR_EL3.EA SCR_EL3.IRQ SCR_EL3.FIQ	SCR_EL3.RW	AMO[a] IMO[a] FMO[a]	Target Exception level when executing in:					
			Non-secure			Secure		
			EL0	EL1	EL2	EL0	EL1	EL3
0	0	0	EL1	EL1	EL2	EL1	EL1	P
	X	1	EL2	EL2	EL2	EL1	EL1	P
	1	0	EL1	EL1	P	EL1	EL1	P
1	X	X	EL3	EL3	EL3	EL3	EL3	EL3

a. If EL2 is using AArch64, these are the HCR_EL2.{AMO, IMO, FMO} control bits. If EL2 is using AArch32, these are the HCR{AMO, IMO, FMO} control bits. If HCR_EL2.TGE or HCR.TGE is 1, these bits are treated as being 1 other than for a direct read.

Table D1-11 Routing when EL3 is implemented and EL2 is not implemented

SCR_EL3.EA SCR_EL3.IRQ SCR_EL3.FIQ	Target Exception level when executing in:				
	Non-secure		Secure		
	EL0	EL1	EL0	EL1	EL3
0	EL1	EL1	EL1	EL1	P
1	EL3	EL3	EL3	EL3	EL3

Table D1-12 Routing when EL3 is not implemented and EL2 is implemented

HCR_EL2.AMO[a] HCR_EL2.IMO[a] HCR_EL2.FMO[a]	Target Exception level when executing in:		
	Non-secure		
	EL0	EL1	EL2
1	EL2	EL2	EL2
0	EL1	EL1	P

a. If HCR_EL2.TGE is 1, these bits are treated as being 1 other than for a direct read.

D1.14.2 Asynchronous exception masking

When an interrupt is masked, it means that it cannot be taken. Instead, it remains pending.

When executing in AArch64 state, interrupts are masked implicitly when the target Exception level of the interrupt is lower than the current Exception level.

In addition, interrupts can be masked when the target Exception level is the current Exception level. The controls for this are:

SError PSTATE.A
IRQ PSTATE.I
FIQ PSTATE.F

When the target Exception level is higher than the current Exception level:

- If the target Exception level is EL2 or EL3, the interrupt cannot be masked by the PSTATE.{A, I, F} bits.
- If the target Exception level is EL1, the interrupt can be masked by the PSTATE.{A, I, F} bits.

Note

- The ability to execute in EL0 with interrupts to EL1 masked is required by some user level driver code.
- The PSTATE.{A, I, F} bits can mask both physical interrupts and virtual interrupts.
- The ARMv8-A architecture does not support *Non-maskable FIQ* (NMFI) operations. This means that it does not provide a configuration option to override the masking of FIQs by PSTATE.F.

On taking any exception to an Exception level using AArch64, all of PSTATE.{A, I, F} are set to 1, masking all interrupts that target that Exception level.

The following tables show the masking of physical interrupts when the highest implemented Exception level is using AArch64:

- For implementations that include both EL2 and EL3, see Table D1-13.
- For implementations that include EL3 but not EL2, see Table D1-14 on page D1-1456.
- For implementations that include EL2 but not EL3, see Table D1-15 on page D1-1456.

For the masking of virtual interrupts, see *Virtual interrupts* on page D1-1456.

In the tables:

M Indicates that the interrupt is subject to the relevant PSTATE.{A, I, F} mask bit.
T Indicates that the interrupt is taken regardless of the mask.
P Indicates that the interrupt is pending.

Table D1-13 Physical interrupt masking when both EL3 and EL2 are implemented

SCR_EL3.EA SCR_EL3.IRQ SCR_EL3.FIQ	SCR_EL3.RW	AMO[a] IMO[a] FMO[a]	Target EL	Effect of the interrupt mask when executing in:					
				Non-secure			Secure		
				EL0	EL1	EL2	EL0	EL1	EL3
0	0	0	EL1	M	M	M	M	M	P
		1	EL2	T	T	M	M	M	P
	1	0	EL1	M	M	P	M	M	P
		1	EL2	T	T	M	M	M	P
1	X	X	EL3	T	T	T	T	T	M

a. If EL2 is using AArch64, these are the HCR_EL2.{AMO, IMO, FMO} control bits. If EL2 is using AArch32, these are the HCR{AMO, IMO, FMO} control bits. If HCR_EL2.TGE or HCR.TGE is 1, these bits are treated as being 1 other than a direct read.

Table D1-14 Physical interrupt masking when EL3 is implemented and EL2 is not implemented

SCR_EL3.EA SCR_EL3.IRQ SCR_EL3.FIQ	Target EL	Effect of the interrupt mask when executing in:				
		Non-secure		Secure		
		EL0	EL1	EL0	EL1	EL3
0	EL1	M	M	M	M	P
1	EL3	T	T	T	T	M

Table D1-15 Physical interrupt masking when EL3 is not implemented and EL2 is implemented

HCR_EL2.AMO[a] HCR_EL2.IMO[a] HCR_EL2.FMO[a]	Target EL	Effect of the interrupt mask when executing in:		
		Non-secure		
		EL0	EL1	EL2
0	EL1	M	M	P
1	EL2	T	T	M

a. If HCR_EL2.TGE is 1, these bits are treated as being 1 other than for a direct read.

D1.14.3 Virtual interrupts

Setting the HCR_EL2.{FMO, IMO, AMO} routing control bits to 1 enables the virtual interrupts, unless HCR_EL2.TGE is 1.

Virtual interrupts can only be taken from Non-secure EL0 to EL1 or from Non-secure EL1 to EL1. When a virtual interrupt type is enabled, that type of interrupt can be generated by:

- Software setting the corresponding virtual interrupt pending bit, HCR_EL2.{VSE, VI, VF}, to 1.
- For a vIRQ or a vFIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller, for example from a Virtual GIC, as defined by the *ARM Generic Interrupt Controller Architecture Specification*.

Note

For a usage model for virtual interrupts, see *Virtual interrupt usage model* on page D1-1407.

Each virtual interrupt type can be masked when execution is in Non-secure EL1 or EL0, by using the same Process State mask bits that mask the physical interrupts, PSTATE.{A, I, F}.

When execution is in Secure state, or in EL3 or EL2, all types of virtual interrupt are always masked.

Table D1-16 summarizes the bits that enable virtual interrupts and the bits that cause virtual interrupts to be pending.

Table D1-16 HCR_EL2 interrupt control bits

Virtual interrupt type	Enable control	Cause a virtual interrupt to be pending
vSError	HCR_EL2.AMO	HCR_EL2.VSE
vIRQ	HCR_EL2.IMO	HCR_EL2.VI
vFIQ	HCR_EL2.FMO	HCR_EL2.VF

On taking a virtual IRQ or a virtual FIQ interrupt, the corresponding virtual interrupt pending bit in the HCR_EL2 retains its state.

On taking a virtual SError interrupt, HCR_EL2.VSE is cleared to 0.

Note

This means that if the virtual interrupt pending bits are used, the vIRQ or vFIQ exception handler must cause software executing in EL2 or EL3 to set their corresponding virtual interrupt pending bits to 0.

As with physical interrupts:

- Taking a virtual SError interrupt to an Exception level using AArch64 updates ESR_EL1 with the dedicated encoding for an SError interrupt. For the encoding, see *Exception classes and the ESR_ELx syndrome registers* on page D1-1426.
- Taking a virtual RQ or a virtual FIQ interrupt to an Exception level using AArch64 does not update the ESR_EL1.

The following table shows the masking of virtual interrupts when the highest implemented Exception level is using AArch64. In the table:

M Indicates that the interrupt is subject to the relevant PSTATE.{A, I, F} mask bit.

P Indicates that the interrupt is pending.

Table D1-17 Virtual interrupt masking

SCR_EL3.EA SCR_EL3.IRQ SCR_EL3.FIQ	FMO[a] IMO[a] AMO[a]	TGE[a]	Effect of the interrupt mask when executing in:					
			Non-secure			Secure		
			EL0	EL1	EL2	EL0	EL1	EL3
X	0	X	P	P	P	P	P	P
X	1	0	M	M	P	P	P	P
X	1	1	P	P	P	P	P	P

a. If EL2 is using AArch64, these are the HCR_EL2.{TGE, AMO, IMO, FMO} control bits. If EL2 is using AArch32, these are the HCR{TGE, AMO, IMO, FMO} control bits.

D1.14.4 Prioritization and recognition of asynchronous exceptions

The ARMv8-A architecture does not define when interrupts are taken. The prioritization of interrupts, including virtual interrupts, is IMPLEMENTATION DEFINED.

Any interrupts that are pending prior to one of the following context synchronizing events, are taken before the first instruction after the context synchronizing event, provided that the interrupt is not masked:

- An `ISB` instruction.
- Exception entry.
- Exception return.
- Exit from Debug state.

Note

- If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define whether the PE takes the interrupt or the synchronous exception first.
- The ISR_EL1 register indicates whether an interrupt is pending.

- Interrupts are masked when the PE is in Debug state, so this list of context synchronizing events does not include the DCPS and DRPS instructions.

In the absence of a specific requirement to take an interrupt, the architecture only requires that unmasked pending interrupts are taken in finite time.

D1.14.5 Taking an interrupt during a multiple-register load or store

In AArch64 state, interrupts can be taken during a sequence of memory accesses caused by a single load or store instruction. This is true regardless of the memory type being accessed.

Note

- This is in contrast to behavior in AArch32 state, when interrupts cannot be taken during a sequence of memory access caused by a single load or store instruction. This means that:
  - Behavior in AArch64 state is equivalent to ARMv7 behavior when the value of SCTLR.FI is 1, except that setting SCTLR.FI to 1 only permits this behavior for accesses to Normal memory.
  - Behavior in AArch32 state is equivalent to ARMv7 behavior when the value of SCTLR.FI is 0, for all Exception levels.
- Software must avoid using multiple-register load and store instructions for Device memory, particularly non-Gathering, because an interrupt taken during the load or store can result in repeated accesses.

D1.15 Controls at higher Exception levels

Trapping refers to configuration that causes an instruction to generate an exception rather than complete normally. Typically, this means that an instruction that would normally be executed at a lower Exception level instead generates an exception that is taken to a higher Exception level. The instruction is said to be *trapped* to the higher Exception level. However, some instructions are trapped to the same Exception level, rather than to a higher Exception level.

Enable and *disable* controls refer to configurations that cause an instruction to generate an Undefined Instruction exception when executed at a lower Exception level, rather than completing normally

Note

Routing is described elsewhere in this chapter:

- *Asynchronous exception routing* on page D1-1454 describes the routing options for asynchronous exceptions.
- *Routing general exceptions to EL2* on page D1-1447 describes a control that routes exceptions from Non-secure EL0 to EL2.

This section is organized as follows:

- *Trapping to EL1 using AArch64*.
- *Trapping to EL2 using AArch64* on page D1-1467.
- *Trapping to EL3 using AArch64* on page D1-1489.

Note

An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide finer-grained control of control of trapping of IMPLEMENTATION DEFINED features.

D1.15.1 Trapping to EL1 using AArch64

Traps to EL1 using AArch64 are controlled using _EL1 System registers, and the exception syndrome information is presented in ESR_EL1. The exceptions might be taken from AArch64 state or AArch32 state. The exception syndrome information indicates which Execution state the exception was taken from.

A trap to EL1 using AArch64 can only be generated if the instruction generating the trap does not also generate a higher priority exception. *Synchronous exception prioritization* on page D1-1448 defines the prioritization of different exceptions on the same instruction.

Table D1-18 shows the _EL1 System registers that contain controls that control trapping to EL1.

Table D1-18 Summary of the registers that control trapping to EL1 using AArch64

Register description	Register name
System Control Register, EL1	SCTLR_EL1
Architectural Feature Access Control Register	CPACR_EL1
Monitor System Debug Control Register	MDSCR_EL1
Performance Monitors User Enable Register	PMUSERENR_EL0

Table D1-19 on page D1-1460 summarizes the controls that control trapping to EL1 using AArch64.

Table D1-19 Summary of the EL1 controls that control trapping to EL1 using AArch64

Control	Type of control[a]	Trap description
SCTLR_EL1.{UCI, UCT}	T	*Traps to EL1 of EL0 accesses to cache maintenance instructions* on page D1-1461

a. T indicates Trap, E indicates Enable, and D indicates Disable.

Traps to EL1 of EL0 accesses to cache maintenance instructions

EL1 provides the following controls to enable accesses to cache maintenance functionality from EL0:

- SCTLR_EL1.**UCI:**
  - **1** Execution of cache maintenance instructions is enabled at EL0.
  - **0** Any attempt to execute a cache maintenance instruction at EL0 is trapped to EL1.
- SCTLR_EL1.**UCT:**
  - **1** EL0 accesses to the CTR_EL0 are enabled.
  - **0** EL0 accesses to the CTR_EL0 are trapped to EL1.

For:

- SCTLR_EL1.UCI == 0, Table D1-20 shows the instructions that are trapped to EL1, and how the exceptions are reported in ESR_EL1.
- SCTLR_EL1.UCT == 0, Table D1-21 shows how the exceptions are reported in ESR_EL1.

Table D1-20 Instructions trapped to EL1 when SCTLR_EL1.UCI is 0

Traps from	Trapped instructions	Syndrome reporting in ESR_EL1
AArch64 state	DC CVAU, DC CIVAC, DC CVAC, IC IVAU	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	n/a	n/a

Table D1-21 Register accesses trapped to EL1 when SCTLR_EL1.UCT is 0

Traps from	Register	Syndrome reporting in ESR_EL1
AArch64	CTR_EL0	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32	n/a	n/a

Traps to EL1 of EL0 execution of WFE and WFI instructions

EL1 provides the following controls to enable WFE and WFI instruction execution at EL0:

SCTLR_EL1.nTWE

1 WFE instruction execution is enabled at EL0.

0 Any attempt to execute a WFE instruction at EL0 is trapped to EL1, if the instruction would otherwise have caused the PE to enter a low-power state.

SCTLR_EL1.nTWI

1 WFI instruction execution is enabled at EL0.

0 Any attempt to execute a WFI instruction at EL0 is trapped EL1, if the instruction would otherwise have caused the PE to enter a low-power state.

Table D1-22 shows how the exceptions are reported in ESR_EL1.

Table D1-22 Instructions trapped to EL1 when SCTLR_EL1.{TWE, TWI} are 0

Enable control	Traps from	Trapped instructions	Syndrome reporting in ESR_EL1
SCTLR_EL1.nTWE	AArch64 state and AArch32 state	WFE	Trapped WFI or WFE instruction, using EC value 0x01
SCTLR_EL1.nTWI		WFI	

The traps that SCTLR_EL1.{TWE, TWI} enable trap the attempted execution of conditional WFE or WFI instructions only if the instructions pass their condition code check.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- *Wait for Event mechanism and Send event* on page D1-1503.
- *Wait For Interrupt* on page D1-1506.

Traps to EL1 of EL0 execution of DC ZVA instructions

SCTLR_EL1.DZE enables execution of DC ZVA instructions at EL0:

1 DC ZVA instruction execution is enabled at EL0.

0 Any attempt to execute a DC ZVA instruction at EL0 is trapped to EL1. Reading the DCZID_EL0 returns a value that indicates that DC ZVA instructions are not supported.

Table D1-23 shows how the exceptions are reported in ESR_EL1.

Table D1-23 Instructions trapped to EL1 when SCTLR_EL1.DZE is 0

Traps from	Trapped instruction	Syndrome reporting in ESR_EL1
AArch64 state	DC ZVA	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.
AArch32 state	n/a	n/a

Enabling EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks

SCTLR_EL1.UMA enables access to the PSTATE.{D, A, I, F} masks from EL0:

1 Execution of MSR and MRS instructions that access the DAIF is enabled at EL0.

0 Any attempt at EL0 to execute an MSR or MRS that accesses the DAIF is trapped to EL1.

Table D1-24 shows how the exceptions are reported in ESR_EL1.

Table D1-24 Instructions trapped to EL1 when SCTLR_EL1.UMA is 0

Traps from	Trapped instructions	Syndrome reporting in ESR_EL1
AArch64 state	MRS, MSR (register), MSR (immediate), that access the DAIF	Exception for an unknown reason, using EC value 0x00.
AArch32 state	n/a	n/a

Enabling and disabling EL0 accesses to AArch32 deprecated functionality

Table D1-25 shows the deprecated AArch32 functionality that can be trapped from EL0 using AArch32 to EL1 using AArch64.

When a particular functionality shown in Table D1-25 is disabled, any attempt to access that functionality at EL0 using AArch32 is trapped to EL1. The table shows how the exceptions are reported in ESR_EL1.

Table D1-25 Traps to EL1 on EL0 accesses to deprecated functionality

Deprecated AArch32 functionality	Enable or disable control in the SCTLR_EL1	Trapped instructions, or trapped accesses	Syndrome reporting in ESR_EL1
SETEND instructions	SED[a]	SETEND instructions	Exception for an unknown reason, using EC value 0x00.
Some uses of IT instructions	ITD[b]	See *Trapped instructions when SCTLR_EL1.ITD is 1*.	
Accesses to the CP15 DMB, DSB, and ISB barrier operations.	CP15BEN[c]	MCR accesses to the CP15DMB, CP15DSB, and CP15ISB	

a. SETEND disable control. SETEND instructions are disabled when this is 1.

b. IT disable control. Some uses of IT instructions are disabled when this is 1.

c. CP15 barrier operation enable control. Accesses to the CP15 DMB, DSB, and ISB barrier operations are disabled when this is 0.

Trapped instructions when SCTLR_EL1.ITD is 1

When SCTLR_EL1.ITD is 1, any attempt at EL0 using AArch32 to execute any of the following is UNDEFINED.

- All encodings of the IT instruction with hw1[3:0]!=1000.
- All encodings of the subsequent instruction with the following values for hw1:

  0b11xxxxxxxxxxxxxx

  - All 32-bit instructions.
  - All of the following 16-bit instructions:
    - B
    - UDF
    - SVC
    - LDM
    - STM

0b1011xxxxxxxxxxx

All instructions in *Miscellaneous 16-bit instructions* on page F3-2354.

0b1x100xxxxxxxxxx

`ADD Rd, PC, #imm`

0b01001xxxxxxxxxx

`LDR Rd, (PC, #imm)`

0b0100x1xxx1111xxx

- `ADD Rdn, PC`
- `CMP Rn, PC`
- `MOV Rd, PC`
- `BX, pc`
- `BLX, pc`

0b010001xx1xxxx111

- `ADD PC, Rm`
- `CMP PC, Rm`
- `MOV PC, Rm`

Note

This encoding also covers UNPREDICTABLE cases with `BLX Rn`.

Traps to EL1 of EL1 and EL0 System register accesses to the trace registers

CPACR_EL1.TTA enables a trap to EL1 of EL1 and EL0 System register accesses to the trace registers:

1 EL1 and EL0 System register accesses to the trace registers, except for accesses that the appropriate Trace Architecture Specification describes as UNPREDICTABLE or as UNDEFINED, are trapped to EL1.

0 EL1 and EL0 System register accesses to the trace registers are not trapped to EL1.

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
- EL1 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped to EL1 or generates an Undefined Instruction exception, no side-effects occur before the exception is taken, see *Traps to EL2 of System register access instructions* on page D1-1468.

Table D1-26 shows the registers for which accesses are trapped to EL1 when CPACR_EL1.TTA is 1, and how the exceptions are reported in ESR_EL1.

Table D1-26 Register accesses trapped to EL1 when CPACR_EL1.TTA is 1

Traps from	Registers	Syndrome reporting in ESR_EL1
AArch64 state	All implemented trace registers	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`.
AArch32 state	All implemented trace registers	For accesses using: • `MCR` or `MRC` instructions, trapped `MCR` or `MRC` CP14 access, using EC value `0x05`. • `MCRR` or `MRRC` instructions, trapped `MCRR` or `MRRC` CP14 access, using EC value `0x0C`.

Traps to EL1 of EL1 and EL0 accesses to SIMD and floating-point functionality

CPACR_EL1.FPEN enables a trap to EL1 of EL1 and EL0 accesses to the SIMD and floating-point registers.

Note

For the definition of when the CPACR_EL1.FPEN trap is enabled, see the CPACR_EL1 register description.

Table D1-27 shows the registers for which accesses are trapped to EL1 when the CPACR_EL1.FPEN trap is enabled, and how the exception is reported in ESR_EL1.

Table D1-27 Register accesses trapped to EL1 when the CPACR_EL1.FPEN trap is enabled

Traps from	Registers	Syndrome reporting in ESR_EL1
EL1 and EL0 using AArch64	FPCR, FPSR, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See *The SIMD and floating-point registers, V0-V31* on page D1-1409.	Trapped access to a SIMD or floating-point register, using EC value `0x07`[a]
EL0 using AArch32	FPSCR, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See *Advanced SIMD and floating-point system registers* on page G1-3472.	Trapped access to a SIMD or floating-point register, using EC value `0x07`[a]

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these trap exceptions are routed to EL2 and are reported in ESR_EL2 using EC value `0x00`.

Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers

MDSCR_EL1.TDCC enables a trap to EL1 of EL0 accesses to the DCC registers:

1 EL0 accesses to the DCC registers are trapped to EL1

0 EL0 accesses to the DCC registers are not trapped to EL1.

Table D1-28 shows the accesses that are trapped to EL1 when MDSCR_EL1.TDCC is 1, and how the exception is reported in ESR_EL1.

Table D1-28 Accesses trapped to EL1 when MDSCR_EL1.TDCC is 1

Traps from	Trapped accesses	Syndrome reporting in ESR_EL1
AArch64 state	Accesses to the MDCCSR_EL0, DBGDTR_EL0, DBGDTRTX_EL0 and DBGDTRRX_EL0	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`[a]
AArch32 state	• `MRC` of DBGDSCRint, DBGDTRRXint, and, if implemented, DBGDIDR, DBGDSAR and DBGDRAR. • `MCR` to DBGDTRTXint.	Trapped `MCR` or `MRC` CP14 access, using EC value `0x05`[a]
	• `LDC` of DBGDTRTXint. • `STC` of DBGDTRRXint.	Trapped `LDC` or `STC` access to CP14, using EC value `0x06`[a]
	If implemented, `MRRC` of DBGDSAR and DBGDRAR.	Trapped `MCRR` or `MRRC` CP14 access, using EC value `0x0C`[a]

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

Traps to EL1 of EL0 accesses to Performance Monitors registers

PMUSERENR_EL0.{ER, CR, SW, EN} enable EL0 accesses to the Performance Monitors registers. For each of these controls:

1 Accesses from EL0 are enabled.

0 Accesses from EL0 are not enabled.

The accesses that these controls enable might be reads, writes, or both.

Table D1-29 shows the registers for which EL0 accesses are trapped to EL1 when EL0 accesses are not enabled. For each register, the table shows the type of access trapped.

Table D1-29 Register accesses trapped to EL1 when disabled from EL0

Traps from	Enable control	Registers	Access type	Syndrome reporting in ESR_EL1
AArch64 state	ER	PMXEVCNTR_EL0, PMEVCNTR<n>_EL0	R	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18
		PMSELR_EL0	RW

D1.15.2 Trapping to EL2 using AArch64

Routing general exceptions to EL2 on page D1-1447 describes a control that routes exceptions from Non-secure EL0 to EL2. This control is HCR_EL2.TGE, and exceptions are routed from Non-secure EL0 to EL2 when it is 1.

To support different virtualization schemes, the architecture also provides a range of controls that enable traps to EL2 of Non-secure operations at EL1 and EL0. These traps can be used when HCR_EL2.TGE is 0. This section describes these controls and the traps that they enable.

Traps to EL2 using AArch64 are enabled using _EL2 System registers, and the exception syndrome information is presented in ESR_EL2. The exceptions might be taken from AArch64 state or AArch32 state. The exception syndrome information indicates which Execution state the exception was taken from.

A trap to EL2 can be generated only when all of the following apply:

- The PE is in Non-secure EL1 or EL0.
- The instruction that generates the trap does not also generate a higher priority exception. *Synchronous exception prioritization* on page D1-1448 defines the prioritization of different exceptions on the same instruction.
- For traps from an Exception level using AArch32, the trapped instruction is not UNPREDICTABLE in the PE state it is executed in. UNPREDICTABLE instructions can generate a trap to EL2, but the architecture does not require them to do so.

Table D1-30 shows the _EL2 System registers that contain trap enable controls.

Table D1-30 Summary of the registers that control trapping to EL2 using AArch64

Register description	Register name
Hypervisor Configuration Register	HCR_EL2
Hypervisor System Trap Register	HSTR_EL2
Architectural Feature Trap Register, EL2	CPTR_EL2
Monitor Debug Configuration Register, EL2	MDCR_EL2

Table D1-31 summarizes the trap enable controls that are in the _EL2 System registers.

Table D1-31 Summary of the EL2 controls that control trapping to EL2 using AArch64

Control	Type of control	Trap description
HCR_EL2.{TVRM, TVM}	T	*Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers* on page D1-1469

MDCR_EL2.TDOSA	T	*Traps to EL2 of Non-secure EL1 System register accesses to OS-related debug registers* on page D1-1484
MDCR_EL2.TDA	T	*Traps to EL2 of Non-secure EL1 and EL0 general System register accesses to debug registers* on page D1-1485
MDCR_EL2.{TPM, TPMCR}	T	*Traps to EL2 of Non-secure EL1 and EL0 accesses to Performance Monitors registers* on page D1-1487

Also see the following for more general information about traps to EL2:

- *Traps to EL2 of System register access instructions*.
- For traps from an Exception level using AArch32:
  - *Hyp traps on instructions that fail their condition code check* on page G1-3483.
  - *Hyp traps on instructions that are UNPREDICTABLE* on page G1-3484.

Traps to EL2 of System register access instructions

When an instruction is trapped to EL2, the trap is taken before execution of the instruction. This means that if the trapped instruction is a System register access instruction, none of the following happens before the exception is taken to EL2:

- The System register access.
- Any effects normally associated with the System register access.

Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers

EL2 provides the following traps for reads and writes to the virtual memory control registers:

- HCR_EL2.TRVM, for read accesses:
  - **1** Non-secure EL1 reads of the virtual memory control registers are trapped to EL2.
  - **0** Non-secure EL1 reads of the virtual memory control registers are not trapped to EL2.
- HCR_EL2.TVM, for write access:
  - **1** Non-secure EL1 writes to the virtual memory control registers are trapped to EL2.
  - **0** Non-secure writes to the virtual memory control registers are not trapped to EL2.

Table D1-32 shows the registers for which:

- Reads are trapped to EL2 when HCR_EL2.TRVM is 1.
- Writes are trapped to EL2 when HCR_EL2.TVM is 1.

The table also shows how the exceptions are reported in ESR_EL2.

Table D1-32 Register read and write accesses trapped when HCR_EL2.{TRVM, TVM} are 1

Traps from	Registers	Syndrome reporting in ESR_EL2
AArch64 state	SCTLR_EL1, TTBR0_EL1, TTBR1_EL1, TCR_EL1, ESR_EL1, FAR_EL1, AFSR0_EL1, AFSR1_EL1, MAIR_EL1, AMAIR_EL1, CONTEXTIDR_EL1.	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`.
AArch32 state	SCTLR, TTBR0, TTBR1, TTBCR, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`. Trapped `MCRR` or `MRRC` CP15 access, using EC value `0x04`.

Note

EL2 provides a second stage of address translation, that a hypervisor can use to remap the address map defined by a Guest OS. In addition, a hypervisor can trap attempts by a Guest OS to write to the registers that control the Non-secure memory system. A hypervisor might use this trap as part of its virtualization of memory management.

Disabling Non-secure state execution of HVC instructions

HCR_EL2.HCD is only implemented if EL3 is not implemented. Otherwise, it is RES0. See the HCR_EL2 register description.

HCR_EL2.HCD disables HVC instruction execution in Non-secure state:

1 Any attempt to execute a HVC instruction in Non-secure state generates an exception that is taken without a change of Exception level. For example, an attempt to execute a HVC instruction at EL1 generates an exception that is taken to EL1.

0 HVC instruction execution is enabled at EL2 and Non-secure EL1.

Note

HVC instructions are always UNDEFINED at EL0.

Table D1-33 shows how the exceptions are reported in ESR_ELx.

Table D1-33 Instruction that causes exceptions when HCR_EL2.HCD is 1

Attempted execution in	Instruction	Syndrome reporting in ESR_ELx
AArch64 state	HVC	Exception for an unknown reason, using EC value 0x00
AArch32 state	HVC	

Traps to EL2 of Non-secure EL1 and EL0 execution of DC ZVA instructions

HCR_EL2.TDZ enables a trap to EL2 of Non-secure EL1 and EL0 execution of DC ZVA instructions:

1 Any attempt to execute a DC ZVA instruction at Non-secure EL1 or EL0 is trapped to EL2. Reading the DCZID_EL0 returns a value that indicates that DC ZVA instructions are not supported.

0 Non-secure EL1 and EL0 execution of DC ZVA instructions is not trapped to EL2.

Table D1-34 shows how the exceptions are reported in ESR_EL2.

Table D1-34 Instruction trapped to EL1 when HCR_EL2.TDZ is 0

Traps from	Trapped instruction	Syndrome reporting in ESR_EL2
AArch64 state	DC ZVA	Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18.
AArch32 state	n/a	n/a

Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions

In the ARMv8-A architecture, the system instruction encoding space includes TLB maintenance instructions.

HCR_EL2.TTLB enables a trap to EL2 of Non-secure EL1 execution of TLB maintenance instructions:

1 Any attempt to execute a `TLBI` instruction at Non-secure EL1 is trapped to EL2.

0 Non-secure EL1 execution of `TLBI` instructions is not trapped to EL2.

Table D1-35 shows the instructions that are trapped, and how the exceptions are reported in ESR_EL2.

Table D1-35 Instructions trapped to EL2 when HCR_EL2.TTLB is 1

Traps from	Trapped instructions	Syndrome reporting in ESR_EL2
AArch64 state	TLBI VMALLE1IS, TLBI VAE1IS, TLBI ASIDE1IS, TLBI VAAE1IS, TLBI VALE1IS, TLBI VAALE1IS, TLBI VMALLE1, TLBI VAE1, TLBI ASIDE1, TLBI VAAE1, TLBI VALE1, TLBI VAALE1	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	TLBIALLIS, TLBIMVAIS, TLBIASIDIS, TLBIMVAAIS, TLBIMVAA, DTLBIALL, DTLBIMVA, DTLBIASID, ITLBIALL, ITLBIASID, ITLBIMVA	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`

For more information about these instructions, see:

- *TLB maintenance instructions* on page D4-1735, for the AArch64 state instructions.
- *The scope of TLB maintenance instructions* on page G4-3696, for the AArch32 state instructions.

Traps to EL2 of Non-secure EL1 and EL0 execution of cache maintenance instructions

Table D1-36 shows the HCR_EL2 trap controls that trap cache maintenance instructions to EL2. When one of these controls is 1, any attempt to execute the corresponding cache maintenance instruction at Non-secure EL1, or at Non-secure EL0 if permitted by SCTLR_EL1.UCI, is trapped to EL2.

Table D1-36 Controls for trapping cache maintenance instructions to EL2

Trap control	Trapped instructions
HCR_EL2.TSW	Data cache maintenance by set/way
HCR_EL2.TPC	Data cache maintenance to point of coherency
HCR_EL2.TPU	Cache maintenance to point of unification

For:

- HCR_EL2.TSW == 1, Table D1-37 shows the instructions that are trapped to EL2, and how the exceptions are reported in ESR_EL2.
- HCR_EL2.TPC == 1, Table D1-38 shows the instructions that are trapped to EL2, and how the exceptions are reported in ESR_EL2.
- HCR_EL2.TPU == 1, Table D1-39 shows the instructions that are trapped to EL2, and how the exceptions are reported in ESR_EL2.

Table D1-37 Instructions trapped to EL2 when HCR_EL2.TSW is 1

Traps from	Trapped instructions	Syndrome reporting in ESR_EL2
AArch64 state	DC ISW, DC CSW, DC CISW	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	DCISW, DCCSW, DCCISW	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`

Table D1-38 Instructions trapped to EL2 when HCR_EL2.TPC is 1

Traps from	Trapped instructions	Syndrome reporting in ESR_EL2
AArch64 state	DC IVAC, ~~DC IVAC,~~ DC CVAC, DC CIVAC	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	DCIMVAC, DCCIMVAC, DCCMVAC	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`

Table D1-39 Instructions trapped to EL2 when HCR_EL2.TPU is 1

Traps from	Trapped instructions	Syndrome reporting in ESR_EL2
AArch64 state	IC IALLUIS, IC IALLU, IC IVAU, DC CVAU	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	ICIMVAU, ICIALLU, ICIALLUIS, DCCMVAU	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`

For more information about these instructions, see:

- *Cache maintenance instructions, and data cache zero* on page C5-239 for the AArch64 instructions.
- *Cache maintenance instructions, functional group* on page G4-3794 for the AArch32 instructions.

Note

If virtualizing a uniprocessor system within an multiprocessor system, permitting a virtual machine to move between different PEs makes cache maintenance by set/way difficult. This is because a set/way operation might be interrupted part way through its operation, and therefore the hypervisor must reproduce the effect of the maintenance on both PEs

Traps to EL2 of Non-secure EL1 ~~and EL0~~ accesses to the Auxiliary Control Register

HCR_EL2.TACR enables a trap to EL2 of accesses to the Auxiliary Control Register from Non-secure EL1 ~~or EL0~~:

1 Non-secure EL1 ~~or EL0~~ accesses to the Auxiliary Control Register are trapped to EL2.

0 Non-secure EL1 ~~or EL0~~ accesses to the Auxiliary Control Register are not trapped to EL2.

Table D1-40 shows the registers for which accesses are trapped to EL2, and how the exceptions are reported in ESR_EL2:

Table D1-40 Register accesses trapped to EL2 when HCR_EL2.TACR is 1

Traps from	Registers	Syndrome reporting in ESR_EL2
AArch64 state	ACTLR_EL1	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	ACTLR	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`

Note

The Auxiliary Control Register is an IMPLEMENTATION DEFINED register that might implement global control bits for the PE. An attempt by a Guest OS to access the Auxiliary Control Register is a potential virtualization problem. Trapping these accesses to the hypervisor means the hypervisor can respond, typically by emulating the required function or signaling a virtualization error.

Traps to EL2 of Non-secure EL1 and EL0 accesses to lockdown, DMA, and TCM operations

The lockdown, DMA, and TCM features of the ARM architecture are IMPLEMENTATION DEFINED. The ARMv8-A architecture reserves the encodings of a number of system control registers for control of these features.

The HCR_EL2.TIDCP bit can be used as a trap enable control, to enable a trap that traps accesses to lockdown, DMA, and TCM operations from Non-secure EL1 and EL0 to EL2. Whether HCR_EL2.TIDCP is used as a trap enable control is IMPLEMENTATION DEFINED. If it is, then when it is 1:

- At Non-secure EL1, any attempt to execute a system control register access instruction with one of the reserved register encodings is trapped to EL2.
- At Non-secure EL0, on an attempt to execute a system control register access instruction with one of the reserved register encodings, it is IMPLEMENTATION DEFINED whether:
  - The instruction is trapped to EL2.
  - The instruction is UNDEFINED, and the PE takes an Undefined Instruction exception to EL1.

If HCR_EL2.TIDCP is used as a trap enable control, Table D1-41 shows the register encodings for which accesses are trapped to EL2 when it is 1, and how the exceptions are reported in ESR_EL2.

Table D1-41 Encodings trapped to EL2 when HCR_EL2.TIDCP is 1

Traps from	Register encodings	Syndrome reporting in ESR_EL2
AArch64 state	Any access to any of the encodings described in *Reserved control space for IMPLEMENTATION DEFINED functionality* on page C5-251.	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	An access to any of the following encodings: • CRn==c9, opc1=={0-7}, CRm=={c0-c2, c5-c8}, opc2=={0-7}. See *VMSAv8-32 CP15 c9 register summary* on page G4-3770. • CRn==c10, opc1=={0-7}, CRm=={c0, c1, c4, c8}, opc2=={0-7}. See *VMSAv8-32 CP15 c10 register summary* on page G4-3771. • CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}. See *VMSAv8-32 CP15 c11 register summary* on page G4-3771.	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

Note

The trapping of accesses to these registers from Non-secure EL1 is higher priority than Undefined Instruction exceptions.

Traps to EL2 of Non-secure EL1 execution of SMC instructions

HCR_EL2.TSC enables a trap to EL2 of Non-secure EL1 execution of SMC instructions:

1 Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to EL2, regardless of the value of SCR_EL3.SMD.

0 Non-secure EL1 execution of SMC instructions is not trapped to EL2.

Table D1-42 shows how the exceptions are reported in ESR_EL2:

Table D1-42 SMC Instruction trapped to EL2 when HCR_EL2.TSC is 1

Traps from	Trapped instruction	Syndrome reporting in ESR_EL2
AArch64 state	SMC	Trapped SMC instruction execution in AArch64 state, using EC value 0x17
AArch32 state	*SMC* on page F7-3022	Trapped SMC instruction execution in AArch32 state, using EC value 0x13

The trap that HCR_EL2.TSC enables traps the attempted execution of a conditional SMC instruction only if the instruction passes its condition code check.

For more information about SMC instructions, see *SMC* on page C6-658.

Note

- This trap is implemented only if the implementation includes EL3.
- SMC instructions are UNDEFINED at EL0.

Note

Typically, a hypervisor determines whether a Guest OS can access Secure state directly. If the hypervisor does not permit a Guest OS to access Secure state directly, and that Guest OS attempts to change the PE Security state to Secure state, the hypervisor must either report a virtualization error or emulate the required Secure state operation.

Traps to EL2 of Non-secure EL1 and EL0 reads of ID registers

Other than the MIDR_EL1 and MPIDR_EL1, the ID registers are divided into groups, with a trap enable control in the HCR_EL2 for each group.

When the value of one of these trap enable controls is 1, any attempt at Non-secure EL1 or EL0 to read any register in the corresponding group is trapped to EL2.

The trap enable controls have no effect on writes to the ID registers.

Table D1-43 shows the trap enable controls for the ID register groups, and shows the subsections that list the ID registers in each group. Each subsection describes how the trap is reported in ESR_EL2.

Table D1-43 ID register groups for traps of Non-secure EL1 and EL0 reads of the ID registers

Trap control	Register group
HCR_EL2.TID0	*ID group 0, Primary device identification registers* on page D1-1476
HCR_EL2.TID1	*ID group 1, Implementation identification registers* on page D1-1476
HCR_EL2.TID2	*ID group 2, Cache identification registers* on page D1-1477
HCR_EL2.TID3	*ID group 3, Detailed feature identification registers* on page D1-1477

For the MIDR_EL1 and MPIDR_EL1 registers, EL2 provides read/write aliases of the registers. The original register becomes accessible only from EL2 or Secure state, and a read of the original register from Non-secure EL1 returns the value of the read/write alias. This register substitution is invisible to the software reading the register.

Table D1-44 ID register substitution provided by EL2 using AArch64

Register	Original	Alias, EL2 using AArch64
Main ID	MIDR_EL1	VPIDR_EL2
Multiprocessor Affinity	MPIDR_EL1	VMPIDR_EL2

Reads of the MIDR_EL1 or MPIDR_EL1 from EL2 or Secure state are unchanged by the implementation of VPIDR_EL2 and VMPIDR_EL2.

Note

- A hypervisor often has to virtualize one or both of the MIDR_EL1 and MPIDR_EL1 because:
  - The MIDR_EL1 provides information about the implementation, the PE name, and revision information.
  - In a multiprocessor implementation, the MPIDR_EL1 defines the position of a PE within a cluster.
- The PE ID registers that can be accessed from Non-secure state can present a virtualization hole, because system software can use them to determine information about the PE that a hypervisor might want to conceal.

  However, many uses of virtualization do not require the hypervisor to disguise the identity of the PE.

ID group 0, Primary device identification registers

In AArch32 state, these registers identify some top-level implementation choices.

In AArch64 state, there are no ID group 0 registers.

Table D1-45 shows the ID registers that are in ID group 0 for traps to EL2, and how the exceptions are reported in ESR_EL2.

Table D1-45 ID group 0 registers

Traps from	Group 0 registers	Syndrome reporting in ESR_EL2
AArch64 state	n/a	n/a
AArch32 state	FPSID	Trapped CP10 access, using EC value `0x08`
	JIDR	Trapped CP14 access, using EC value `0x05`

Note

If CPTR_EL2.TFP traps accesses to SIMD and floating-point functionality, then for a read of FPSID, that trap has priority over this trap.

ID group 1, Implementation identification registers

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

Table D1-46 shows the ID registers that are in ID group 1 for traps to EL2, and how the exceptions are reported in ESR_EL2:

Table D1-46 ID group 1 registers

Traps from	Group 1 registers	Syndrome reporting in ESR_EL2
AArch64 state	AIDR_EL1, REVIDR_EL1	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	TCMTR, TLBTR, REVIDR, AIDR	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`

ID group 2, Cache identification registers

These registers describe and control the cache implementation.

Table D1-47 shows the ID registers that are in ID group 2 for traps to EL2, and how the exceptions are reported in ESR_EL2:

Table D1-47 ID group 2 registers

Traps from	Group 2 registers	Syndrome reporting in ESR_EL2
AArch64 state	CTR_EL0, CCSIDR_EL1, CLIDR_EL1, CSSELR_EL1	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	CTR, CCSIDR, CLIDR, CSSELR	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`

ID group 3, Detailed feature identification registers

These registers provide detailed information about the features of the implementation.

Note

In AArch32 state, these registers are called the CPUID registers. There is no requirement for this trap to apply to those registers that the CPUID Identification Scheme defines as reserved. See *The CPUID identification scheme* on page G4-3788.

Table D1-48 shows the ID registers that are in ID group 3 for traps to EL2, and how the exceptions are reported in ESR_EL2:

Table D1-48 ID group 3 registers

Traps from	Group 3 registers	Syndrome reporting in ESR_EL2
AArch64 state	ID_PFR0_EL1, ID_PFR1_EL1. ID_DFR0_EL1. ID_AFR0_EL1. ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1. ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, ID_ISAR5_EL1. MVFR0_EL1, MVFR1_EL1, MVFR2_EL1. ID_AA64PFR0_EL1, ID_AA64PFR1_EL1. ID_AA64DFR0_EL1, ID_AA64DFR1_EL1. ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1. ID_AA64ISAR0_EL1, ID_AA64ISAR1_EL1. ID_AA64AFR0_EL1, ID_AA64AFR1_EL1.	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	MVFR0, MVFR1, MVFR2.	Trapped CP10 access, using EC value `0x08`
	ID_PFR0, ID_PFR1. ID_DFR0. ID_AFR0. ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3. ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5.	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`
	An `MRC` access to any of the following encodings: • `opc1` == 0, `CRn` == c0, `CRm` == {c3-c7}, `opc2` == {0, 1}. • `opc` == 0, `CRn` == 0, `CRm` == {c3-c7}, `opc2` == 2. • `opc` == 0, `CRn` == 0, `CRm` == 5, `opc2` == {4, 5}.	

Note

If CPTR_EL2.TFP traps accesses to SIMD and floating-point functionality, then for reads of MVFR0_EL1, MVFR1_EL1, MVFR2_EL1, MVFR0, MVFR1, and MVFR2, that trap has priority over this trap.

Traps to EL2 of Non-secure EL1 and EL0 execution of WFE and WFI instructions

EL2 provides the following traps for WFE and WFI instructions:

- HCR_EL2.TWE:
  - **1** Any attempt to execute a WFE instruction at Non-secure EL1 or EL0 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.
  - **0** Non-secure EL1 or EL0 execution of WFE instructions is not trapped to EL2.
- HCR_EL2.TWI
  - **1** Any attempt to execute a WFI instruction at Non-secure EL1 or EL0 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.
  - **0** Non-secure EL1 or EL0 execution of WFI instructions is not trapped to EL2.

Table D1-49 shows how the exceptions are reported in ESR_EL2.

Table D1-49 Instructions trapped to EL2 when HCR_EL2.{TWE, TWI} are 1

Trap control	Traps from	Trapped instructions	Syndrome reporting in ESR_EL2
HCR_EL2.TWE	AArch64 state and AArch32 state	WFE	Trapped WFI or WFE instruction, using EC value 0x01
HCR_EL2.TWI		WFI	

The traps that HCR_EL2.{TWE, TWI} enable trap the attempted execution of conditional WFE or WFI instructions only if the instructions pass their condition code check.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:
- *Wait for Event mechanism and Send event* on page D1-1503.
- *Wait For Interrupt* on page D1-1506.

Note

An operating system can use WFI instructions to signal to the PE that the PE can enter a low-power state until it receives an interrupt. In a virtualized system, the hypervisor might use a WFI instruction as an indication that it can switch to another Guest OS.

Software can use WFE instructions to signal to the PE that the PE can suspend execution during polling of a variable, such as a spinlock. In a virtualized system, this signal might indicate an opportunity for the hypervisor to reschedule. However, WFE generally requires a shorter wait than WFI, and therefore there might be situations where rescheduling on a WFE entry request is not appropriate.

Traps to EL2 of Non-secure EL1 accesses to SIMD and floating-point functionality

This section comprises the following subsections:

- *Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR*.
- *General trapping to EL2 of Non-secure EL1 and EL0 accesses to the SIMD and floating-point registers*.

Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR

CPTR_EL2.TCPAC enables a trap to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR:

1 Non-secure EL1 accesses to the CPACR_EL1 and CPACR are trapped to EL2.

0 Non-secure EL1 accesses to the CPACR_EL1 or CPACR are not trapped to EL2.

Table D1-50 shows how the exceptions are reported in ESR_EL2:

Table D1-50 Register accesses trapped to EL2 when CPTR_EL2.TCPAC is 1

Traps from	Registers	Syndrome reporting in ESR_EL2
AArch64 state	CPACR_EL1	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	CPACR	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`

Note

In ARMv7 and earlier versions of the ARM architecture, one function of the CPACR is as an ID register that identifies what coprocessor functionality is implemented. Legacy software might use this identification mechanism. A hypervisor can use this trap to emulate this mechanism.

General trapping to EL2 of Non-secure EL1 and EL0 accesses to the SIMD and floating-point registers

CPTR_EL2.TFP enables a trap to EL2 of Non-secure EL1 and EL0 accesses to SIMD and floating-point registers:

1 Any attempt at Non-secure EL1 or EL0 to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL2

0 Non-secure EL1 or EL0 execution of instructions that access the SIMD or floating-point registers is not trapped to EL2.

Table D1-51 shows the registers for which accesses are trapped to EL2 when CPTR_EL2.TFP is 1, and how the exceptions are reported in ESR_EL2.

Table D1-51 Register accesses trapped to EL2 when CPTR_EL2.TFP is 1

Traps from	Registers	Syndrome reporting in ESR_EL2
AArch64 state	FPCR, FPSR, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See *The SIMD and floating-point registers, V0-V31* on page D1-1409.	Trapped access to a SIMD or floating-point register, using EC value `0x07`
AArch32 state	FPSID, MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See *Advanced SIMD and floating-point system registers* on page G1-3472.	Trapped access to a SIMD or floating-point register, using EC value `0x07`[ab]

a. The architecture defines writes to the FPSID from EL1 as an access to a SIMD and floating-point register.

b. Writes to the MVFR0, MVFR1, and MVFR2 from EL1 using AArch32 are UNPREDICTABLE. This means that it is IMPLEMENTATION DEFINED whether these writes are defined as accesses to SIMD and floating-point registers.

Note

- A hypervisor might use these traps when lazy switching between Guest OSs.
- If CPACR_EL1.TTA traps EL1 and EL0 accesses to SIMD and floating-point registers to EL1, that trap has priority over this trap.

Traps to EL2 of EL2, and Non-secure EL1 and EL0, System register accesses to the trace registers

CPTR_EL2.TTA enables a trap to EL2 of System register accesses to the trace registers, from both:

- EL2.
- Non-secure EL1 and EL0.

When CPTR_EL2.TTA is:

1 EL2, and Non-secure EL1 and EL0, System register accesses to the trace registers, except for accesses that the appropriate Trace Architecture Specification describes as UNPREDICTABLE or as UNDEFINED, are trapped to EL2.

0 EL2, and Non-secure EL1 or EL0, System register accesses to the trace registers are not trapped to EL2.

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
- EL2 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped to EL2 or generates an Undefined Instruction exception, no side-effects occur before the exception is taken, see *Traps to EL2 of System register access instructions* on page D1-1468.

Table D1-52 shows the registers for which accesses are trapped to EL2 when CPTR_EL2.TTA is 1, and how the exceptions are reported in ESR_EL2.

Table D1-52 Register accesses trapped to EL2 when CPTR_EL2.TTA is 1

Traps from	Registers	Syndrome reporting in ESR_EL2
AArch64 state	All implemented trace registers	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`.
AArch32 state	All implemented trace registers	For accesses using: • `MCR` or `MRC` instructions, trapped `MCR` or `MRC` CP14 access, using EC value `0x05`. • `MCRR` or `MRRC` instructions, trapped `MCRR` or `MRRC` CP14 access, using EC value `0x0C`.

Note

If CPACR_EL1.TTA traps EL1 and EL0 accesses to the CPACR_EL1 or CPACR to EL1, that trap has priority over this trap.

General trapping to EL2 of Non-secure EL1 and EL0 accesses to System registers, from AArch32 state only

HSTR_EL2.{T0-T3, T5-T13, T15} enable traps to EL2 of accesses to the CP15 System registers, by the accessed primary CP15 register number, {c0-c3, c5-c13, c15}. These traps are from AArch32 state only, so are from both:

- Non-secure EL1 using AArch32.
- Non-secure EL0 using AArch32.

When the value of a HSTR_EL2.Tx trap controls is:

1 Any AArch32 state Non-secure EL1 or EL0 access to the corresponding register is trapped to EL2.

0 AArch32 state Non-secure EL1 or EL0 accesses to the corresponding register are not trapped to EL2.

Table D1-53 shows the accesses that are trapped to EL2, and how the exceptions are reported in ESR_EL2.

Table D1-53 Accesses trapped to EL2 when a HSTR_EL2.Tx trap is enabled

Traps from	Trapped accesses	Syndrome reporting in ESR_EL2
AArch64 state	n/a	n/a
EL1 using AArch32	`MCR` and `MRC` instructions, where `CRn` in the instruction corresponds to the trapped primary CP15 register.	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`.
	`MCRR` and `MRRC` instructions, where `CRm` in the instruction corresponds to the trapped primary CP15 register.	Trapped `MCRR` or `MRRC` CP15 access, using EC value `0x04`.
EL0 using AArch32	`MCR` and `MRC` instructions, where `CRn` in the instruction corresponds to the trapped primary CP15 register.	See *Syndrome reporting in ESR_EL2 for accesses to primary CP15 registers from EL0 using AArch32* on page D1-1483
	`MCRR` and `MRRC` instructions, where `CRm` in the instruction corresponds to the trapped primary CP15 register.	

Note

Bit[14] of the HSTR_EL2 is reserved, RES0, despite the Generic Timer control registers being implemented in CP15 c14. EL2 does not provide a trap on accesses to the Generic Timer CP15 registers.

Note

- Many of the traps to EL2 described in this section trap specific System register operations to EL2. However, because of the large number of possible usage models for virtualization, the traps on specific functions might not meet all possible requirements. Therefore, EL2 also provides a set of generic traps for trapping AArch32 System register accesses to EL2, as described in this section.
- ARM expects that trapping of Non-secure EL0 accesses to EL2 will be unusual, and used only when the hypervisor must virtualize EL0 operation. ARM recommends that, whenever possible, Non-secure EL0 accesses to the System registers behave as they would if the implementation did not include EL2.This means that, if the architecture does not support the Non-secure EL0 access, that access generates an Undefined Instruction exception that is taken to Non-secure EL1.

Syndrome reporting in ESR_EL2 for accesses to primary CP15 registers from EL0 using AArch32

For MCR and MRC instructions, syndrome reporting is as follows:

- If the architecture permits EL0 accesses to the CP15 register:
  - Trapped MCR or MRC CP15 access, using EC value 0x03.
- If the architecture defines EL0 accesses to the CP15 register as UNDEFINED:
  - Exception for an unknown reason, using EC value 0x00.
- If the architecture defines that it is IMPLEMENTATION DEFINED whether EL0 accesses to the CP15 register are UNDEFINED, then it is IMPLEMENTATION DEFINED whether the exception is reported as:
  - A trapped MCR or MRC CP15 access, using EC value 0x03.
  - An exception for an unknown reason, using EC value 0x00.

For MCRR and MRRC instructions, syndrome reporting is as follows:

- If the architecture permits EL0 accesses to the CP15 register:
  - Trapped MCRR or MRRC CP15 access, using EC value 0x04.
- If the architecture defines EL0 accesses to the CP15 register as UNDEFINED:
  - Exception for an unknown reason, using EC value 0x00.
- If the architecture defines that it is IMPLEMENTATION DEFINED whether EL0 accesses to the CP15 register are UNDEFINED, then it is IMPLEMENTATION DEFINED whether the exception is reported as:
  - Trapped MCRR or MRRC CP15 access, using EC value 0x04.
  - An exception for an unknown reason, using EC value 0x00.

Traps to EL2 of Non-secure EL1 and EL0 System register accesses to debug registers

EL2 provides traps to EL2 of Non-secure EL1 and EL0 System register accesses to the debug registers.

Note

EL2 does not provide traps on debug register accesses through the Memory-mapped or External debug interfaces.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2. See *Traps to EL2 of System register access instructions* on page D1-1468.

Table D1-54 shows the trap enable controls, and shows the subsections that list the accesses trapped. Each subsection describes how the trap is reported in ESR_EL2.

Table D1-54 Traps of Non-secure EL1 and EL0 accesses to debug registers

Trap control	Trap description
MDCR_EL2.TDRA	*Traps to EL2 of Non-secure EL1 and EL0 System register accesses to debug registers*
MDCR_EL2.TDOSA	*Traps to EL2 of Non-secure EL1 System register accesses to OS-related debug registers*
MDCR_EL2.TDA	*Traps to EL2 of Non-secure EL1 and EL0 general System register accesses to debug registers* on page D1-1485

Traps to EL2 of Non-secure EL1 and EL0 System register accesses to Debug ROM registers

MDCR_EL2.TDRA enables a trap to EL2 of Non-secure EL1 and EL0 System register accesses to the Debug ROM registers:

1 Non-secure EL1 or EL0 System register accesses to the Debug ROM registers are trapped to EL2.

0 Non-secure EL1 or EL0 System register accesses to the Debug ROM registers are not trapped to EL2.

This trap applies to Non-secure EL0 only if it is using AArch32.

Table D1-55 shows the register accesses that are trapped to EL2 when MDCR_EL2.TDRA is 1, and how the exceptions are reported in ESR_EL2:

Table D1-55 Register accesses trapped to EL2 when MDCR_EL2.TDRA is 1

Traps from	Registers	Syndrome reporting in ESR_EL2
AArch64 state	MDRAR_EL1	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`.
AArch32 state	DBGDRAR, DBGDSAR	For accesses using: • `MCR` or `MRC` instructions, trapped `MCR` or `MRC` CP14 access, using EC value `0x05`. • `MCRR` or `MRRC` instructions, trapped `MCRR` or `MRRC` CP14 access, using EC value `0x0C`.

If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDRA is 1 other than for the purpose of a direct read.

Traps to EL2 of Non-secure EL1 System register accesses to OS-related debug registers

MDCR_EL2.TDOSA enables a trap to EL2 of Non-secure EL1 System register accesses to the OS-related debug registers:

1 Non-secure EL1 System register accesses to the OS-related debug registers are trapped to EL2.

0 Non-secure EL1 System register accesses to the OS-related debug registers are not trapped to EL2.

Table D1-56 shows the register accesses that are trapped to EL2 when MDCR_EL2.TDOSA is 1, and how the exceptions are reported in ESR_EL2.

Table D1-56 Register accesses trapped to EL2 when MDCR_EL2.TDOSA is 1

Traps from	Registers	Syndrome reporting in ESR_EL2
AArch64 state	OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, DBGPRCR_EL1.	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`.
AArch32 state	DBGOSLSR, DBGOSLAR, DBGOSDLR, DBGPRCR.	For accesses using: • `MCR` or `MRC` instructions, trapped `MCR` or `MRC` CP14 access, using EC value `0x05`. • `MCRR` or `MRRC` instructions, trapped `MCRR` or `MRRC` CP14 access, using EC value `0x0C`.

If MDCR_EL2.TDE is 1, behavior is as if MDCR_EL2.TDOSA is 1 other than for the purpose of a direct read.

Traps to EL2 of Non-secure EL1 and EL0 general System register accesses to debug registers

MDCR_EL2.TDA enables a trap to EL2 of Non-secure EL1 and EL0 System register accesses to those debug System registers that are not mentioned in either of the following:

- *Traps to EL2 of Non-secure EL1 and EL0 System register accesses to debug registers* on page D1-1484.
- *Traps to EL2 of Non-secure EL1 System register accesses to OS-related debug registers* on page D1-1484.

That is, MDCR_EL2.TDA enables a trap to EL2 of Non-secure EL1 and EL0 System register accesses to all debug System registers, except all of the following:

- Any access from:
  - AArch64 state to the MDRAR_EL1.
  - AArch32 state to the DBGDRAR or DBGDSAR.

  These are the registers for which accesses from Non-secure EL1 and EL0 are trapped to EL2 when MDCR_EL2.TDRA is 1.

- Any access from:
  - AArch64 state to the OSLAR_EL1, OSLSR_EL1, OSDLR_EL1 or DBGPRCR_EL1.
  - AArch32 state to the DBGOSLSR, DBGOSLAR, OSDLR_EL1 or DBGPRCR.

  These are the registers for which accesses from Non-secure EL1 and EL0 are trapped to EL2 when MDCR_EL2.TDOSA is 1.

When MDCR_EL2.TDA is:

1 Non-secure EL1 or EL0 System register accesses to any of the registers shown in Table D1-57 on page D1-1486 are trapped to EL2.

0 Non-secure EL1 or EL0 System register accesses to the registers shown in Table D1-57 on page D1-1486 are not trapped to EL2.

Table D1-57 shows how the exceptions are reported in ESR_EL2.

Table D1-57 Accesses trapped to EL2 when MDCR_EL2.TDA is 1

Traps from	Trapped accesses	Syndrome reporting in ESR_EL2
AArch64 state	Accesses to the MDCCSR_EL0, MDCCINT_EL1, DBGDTR_EL0, DBGDTRRX_EL0, DBGDTRTX_EL0, OSDTRRX_EL1, MDSCR_EL1, OSDTRTX_EL1, OSECCR_EL1, DBGBVR<n>_EL1, DBGBCR<n>_EL1, DBGWVR<n>_EL1, DBGWCR<n>_EL1, DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, and DBGAUTHSTATUS_EL1.	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	Accesses to the DBGDIDR, DBGDSCRint, DBGDCCINT, DBGDTRRXint, DBGDTRTXint, DBGWFAR, DBGVCR, DBGDSCRext, DBGDTRTXext, DBGDTRRXext, DBGBVR<n>, DBGBCR<n>, DBGBXVR<n>, DBGWCR<n>, DBGWVR<n>, DBGOSLAR, DBGCLAIMSET, DBGCLAIMCLR, DBGAUTHSTATUS, DBGDEVID, DBGDEVID1, DBGDEVID2, and DBGOSECCR.	For accesses using: • `MCR` or `MRC` instructions, trapped `MCR` or `MRC` CP14 access, using EC value `0x05`. • `MCRR` or `MRRC` instructions, trapped `MCRR` or `MRRC` access, using EC value `0x0C`.
	`STC` accesses to DBGDTRRXint.[a] `LDC` accesses to DBGDTRTXint.[a]	`LDC` or `STC`, trapped `LDC` or `STC` access to CP14, using EC value `0x06`.

a. If the access would be permitted when MDCR_EL2.TDA is 0.

If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDA is 1 other than for the purpose of a direct read.

Traps to EL2 of Non-secure EL1 and EL0 accesses to Performance Monitors registers

EL2 provides the following traps associated with the performance monitors:

- MDCR_EL2**.TPM:**
  - **1** Non-secure EL1 and EL0 accesses to all Performance Monitors registers are trapped to EL2.
  - **0** Non-secure EL1 and EL0 accesses to any Performance Monitors register is not trapped to EL2.
- MDCR_EL2**.TPMCR:**
  - **1** Non-secure EL1 and EL0 accesses to the Performance Monitors Control Registers are trapped to EL2.
  - **0** Non-secure EL1 and EL0 accesses to the Performance Monitors Control Registers are not trapped to EL2.

For:

- MDCR_EL2**.TPM == 1,** Table D1-58 shows the registers for which accesses are trapped to EL2, and how the exceptions are reported in ESR_EL2.
- MDCR_EL2**.TPMCR == 1,** Table D1-59 shows the registers for which accesses are trapped to EL2, and how the exceptions are reported in ESR_EL2.

Table D1-58 Register accesses trapped to EL2 when MDCR_EL2.TPM is 1

Traps from	Registers	Syndrome reporting in ESR_EL2
AArch64 state	All of the following registers, unless the register description states that the register encoding is unallocated. PMCR_EL0, PMCNTENSET_EL0, PMCNTENCLR_EL0, PMOVSCLR_EL0, PMSWINC_EL0, PMSELR_EL0, PMCEID0_EL0, PMCEID1_EL0, PMCCNTR_EL0, PMXEVTYPER_EL0, PMXEVCNTR_EL0, PMUSERENR_EL0, PMINTENSET_EL1, PMINTENCLR_EL1, PMOVSSET_EL0, PMEVCNTR<n>_EL0, PMEVTYPER<n>_EL0, PMCCFILTR_EL0.	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	All of the following registers, unless the register description indicates that the attempted access is UNDEFINED. PMCR, PMCNTENSET, PMINTENCLR, PMOVSR, PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTYPER, PMXEVCNTR, PMUSERENR, PMINTENSET, PMINTENCLR, PMOVSSET, PMEVCNTR<n>, PMEVTYPER<n>, PMCCFILTR.	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`

Table D1-59 Register accesses trapped to EL2 when MDCR_EL2.TPMCR is 1

Traps from	Registers	Syndrome reporting in ESR_EL2
AArch64 state	PMCR_EL0	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	PMCR	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`

Note

MDCR_EL2.HPMN affects whether a counter can be accessed from Non-secure EL1 or EL0. See the register description of MDCR_EL2 for more information.

Note

- A hypervisor might assign Performance Monitors functionality to a particular Guest OS, or might virtualize performance monitoring. EL2 provides:
  - Trapping of all Non-secure accesses to the Performance Monitors to EL2. A hypervisor might use this as part of a lazy context switch that assigns the Performance Monitors to a particular Guest OS, or might use it as part of a virtualization approach.
  - Trapping of Non-secure accesses to the Performance Monitors Control Register, PMCR_EL0 or PMCR, to EL2. The hypervisor can use this in emulating the Performance Monitors identification bits.

D1.15.3 Trapping to EL3 using AArch64

Traps to EL3 using AArch64 are controlled using _EL3 System registers, and the exception syndrome information is presented in ESR_EL3. The exceptions might be taken from AArch64 state or AArch32 state. The exception syndrome information indicates which Execution state the exception was taken from.

A trap to EL3 using AArch64 can only be generated if the instruction generating the trap does not also generate a higher priority exception. *Synchronous exception prioritization* on page D1-1448 defines the prioritization of different exceptions on the same instruction.

Table D1-60 shows the _EL3 System registers that contain controls that control trapping to EL3.

Table D1-60 Summary of the registers that control trapping to EL3 using AArch64

Register description	Register name
Secure Configuration Register	SCR_EL3
Architectural Feature Trap Register, EL3	CPTR_EL3
Monitor Debug Configuration Register, EL3	MDCR_EL3

Table D1-61 summarizes the controls that control trapping to EL3 using AArch64.

Table D1-61 Summary of the EL3 controls that control trapping to EL3 using AArch64

Control	Type of control[a]	Trap description
SCR_EL3.{TWE, TWI}	T	*Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions* on page D1-1491
SCR_EL3.ST	T	*Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers* on page D1-1492
SCR_EL3.HCE	E	*Enabling EL3, EL2, and EL1 execution of HVC instructions* on page D1-1493

CPTR_EL3.TFP	T	*Traps to EL3 of all accesses to the SIMD and floating-point registers* on page D1-1497
MDCR_EL3.TDOSA	T	*Traps to EL3 of EL2, EL1, and EL0 System register accesses to OS-related debug registers* on page D1-1498
MDCR_EL3.TDA	T	*Traps to EL3 of EL2, EL1, and EL0 general System register accesses to debug registers* on page D1-1498
MDCR_EL3.TPM	T	*Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers* on page D1-1500

a. T indicates Trap, E indicates Enable, and D indicates Disable.

Also see the following for more general information about traps to EL3:

- *Traps to EL3 of System register access instructions* on page D1-1490.
- *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32* on page D1-1490.

Traps to EL3 of System register access instructions

When an instruction is trapped to EL3, the trap is taken before execution of the instruction. This means that if the trapped instruction is a System register access instruction, none of the following happens before the exception is taken to EL3:

- The System register access.
- Any effects normally associated with the System register access.

Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32

If EL1 is using AArch32, all of the following are trapped to EL3:

- Secure EL1 reads and writes to any of the SCR, NSACR, MVBAR or SDCR.
- Any attempt at Secure EL1 to execute any of the following:
  - `ATS12NSOxx` instructions.
  - `SRS` instructions that use the R13_mon banked register.
  - `MRS` or `MSR` instructions that access any of the SPSR_mon, R13_mon or R14_mon banked registers.

In addition, if EL1 is using AArch32:

- Secure EL1 write accesses to the CNTFRQ register are UNDEFINED. They are not trapped to EL3.
- Any attempt at Secure EL1 to change the mode to Monitor mode, by using a `CPS` or an `MSR` instruction, or by performing an exception return, is treated as an illegal change of the CPSR Mode field. See *Illegal changes to the CPSR.M field* on page G1-3415.

Table D1-62 shows the accesses that are trapped to EL3, and how the exceptions are reported in ESR_EL3.

Table D1-62 Accesses trapped to EL3 from Secure EL1 using AArch32

Trapped instructions, or trapped accesses	Syndrome reporting in ESR_EL3
Secure EL1 reads and writes to any of the SCR, NSACR, MVBAR or SDCR	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`.
`ATS12NSOxx` instructions.	
`SRS` instructions that use the R13_mon banked register.	Exception for an unknown reason, using EC value `0x00`.
`MRS` or `MSR` instructions that accesses any of the SPSR_mon, R13_mon or R14_mon banked registers	

Note

- This functionality permits the scenario where 32-bit Secure Virtual Machine code executes in Secure EL1 and EL0 using AArch32, and EL3 using AArch64 allows Non-secure state to be in AArch64.
- Reads of the NSACR from either Non-secure EL1 using AArch32 or Non-secure EL2 using AArch32 return the value `0x00000C00`. See *Restricted access System registers* on page G4-3750.

Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions

EL3 provides the following traps for WFE and WFI instructions:

- SCR_EL3.TWE:
  - **1** Any attempt to execute a WFE instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.
  - **0** EL2, EL1, and EL0 execution of WFE instructions is not trapped to EL3.
- SCR_EL3.TWI
  - **1** Any attempt to execute a WFI instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.
  - **0** EL2, EL1, and EL0 execution of WFI instructions is not trapped.

For EL1 and EL0, these traps apply to WFE and WFI instruction execution in both Security states.

Table D1-63 shows how the exceptions are reported in ESR_EL3.

Table D1-63 Instructions trapped to EL3 when SCR_EL3.{TWE, TWI} are 1.

Trap control	Traps from	Trapped instructions	Syndrome reporting in ESR_EL3
SCR_EL3.TWE	AArch64 state and AArch32 state	WFE	Trapped WFI or WFE instruction, using EC value 0x01
SCR_EL3.TWI		WFI	

The traps that SCR_EL3.{TWE, TWI} enable trap the attempted execution of conditional WFE or WFI instructions only if the instructions pass their condition code check.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:
- *Wait for Event mechanism and Send event* on page D1-1503.
- *Wait For Interrupt* on page D1-1506.

Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers

SCR_EL3.ST enables access to the Counter-timer Physical Secure timer registers from Secure EL1:

1 Accesses from Secure EL1 are enabled.

0 Secure EL1 accesses to the Counter-timer Physical Secure timer registers are trapped to EL3.

Note

Accesses to the Counter-timer Physical Secure timer registers are always enabled from EL3.

Table D1-64 shows the registers for which accesses are trapped to EL3 when SCR_EL3.ST is 0, and how the exceptions are reported in ESR_EL3.

Table D1-64 Register accesses trapped to EL3 when SCR_EL3.ST is 0

Traps from	Registers	Syndrome reporting in ESR_EL3
AArch64 state	CNTPS_TVAL_EL1 CNTPS_CTL_EL1 CNTPS_CVAL_EL1	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	n/a	n/a

Enabling EL3, EL2, and EL1 execution of HVC instructions

SCR_EL3.HCE enables HVC instruction execution at EL1 and above:

1 HVC instruction execution is enabled at EL1 and above.

0 Any attempt to execute a HVC instruction at EL1 or above generates an exception that is taken without a change of Exception level. For example, an attempt to execute a HVC instruction at EL1 generates an exception that is taken to EL1.

For EL1, this enable applies to HVC instruction execution in Non-secure state only.

Note

HVC instructions are always UNDEFINED at EL0.

Table D1-65 shows how the exceptions are reported in ESR_ELx.

Table D1-65 Instruction that causes exceptions when SCR_EL3.HCE is 0

Attempted execution in	Instruction	Syndrome reporting in ESR_ELx
AArch64 state	HVC	Exception for an unknown reason, using EC value 0x00
AArch32 state	HVC	

Disabling EL3, EL2, and EL1 execution of SMC instructions

SCR_EL3.SMD disables SMC instruction execution at EL1 and above:

1 Any attempt to execute an SMC instruction at EL1 or above generates an exception without a change of Exception level. For example, an attempt to execute an SMC instruction at EL1 generates an exception that is taken to EL1.

0 SMC instructions are enabled at EL1 and above.

For EL1, this disable applies to SMC instruction execution in both Security states.

Note

SMC instructions are always UNDEFINED at EL0.

Table D1-66 shows how the exceptions are reported in ESR_ELx.

Table D1-66 Exceptions generated when SCR_EL3.SMD is 1

Attempted execution in	Instruction	Syndrome reporting in ESR_ELx
AArch64 state	SMC	Exception for an unknown reason, using EC value 0x00
AArch32 state	SMC	

Note

If HCR_EL2.TSC traps attempted EL1 execution of SMC instructions to EL2, that trap has priority over this disable.

Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTR, and EL1 and EL0 accesses to the CPACR_EL1 or CPACR

CPTR_EL3.TCPAC enables a trap to EL3 of all of the following:

- EL2 accesses to the CPTR_EL2 or HCPTR.
- EL1 and EL0 accesses to the CPACR_EL1 or CPACR.

When CPTR_EL3.TCPAC is:

1 EL2 accesses to the CPTR_EL2 or HCPTR, and EL1 and EL0 accesses to the CPACR_EL1 or CPACR, are trapped to EL3.

0 EL2 accesses to the CPTR_EL2 or HCPTR, and EL1 and EL0 accesses to the CPACR_EL1 or CPACR, are not trapped to EL3.

For EL1 and EL0, this trap applies to accesses from both Security states.

Table D1-67 shows how the exceptions are reported in ESR_EL3.

Table D1-67 Register accesses trapped to EL3 when CPTR_EL3.TCPAC is 1

Traps from	Registers	Syndrome reporting in ESR_EL3
AArch64 state	CPTR_EL2 CPACR_EL1	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	HCPTR CPACR	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`

Note

If CPTR_EL2.TCPAC traps EL1 accesses to the CPACR_EL1 or CPACR to EL2, that trap has priority over this trap.

Traps to EL3 of all System register accesses to the trace registers

CPTR_EL3.TTA enables a trap to EL3 of System register accesses to the trace registers, from all Exception levels:

1 All System register accesses to the trace registers, except for any accesses that the appropriate Trace Architecture Specification describes as UNPREDICTABLE or as UNDEFINED, are trapped to EL3.

0 System register accesses to the trace registers are not trapped to EL3.

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
- EL3 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped to EL3 or generates an Undefined Instruction exception, no side-effects occur before the exception is taken, see *Traps to EL3 of System register access instructions* on page D1-1490.

For EL1 and EL0, this trap applies to accesses from both Security states.

Table D1-68 shows the registers for which accesses are trapped to EL3 when CPTR_EL3.TTA is 1, and how the exceptions are reported in ESR_EL3.

Table D1-68 Register accesses trapped to EL3 when CPTR_EL3.TTA is 1

Traps from	Registers	Syndrome reporting in ESR_EL3
AArch64 state	All implemented trace registers	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`.
AArch32 state	All implemented trace registers	For accesses using: • `MCR` or `MRC` instructions, trapped `MCR` or `MRC` CP14 access, using EC value `0x05`. • `MCRR` or `MRRC` instructions, trapped `MCRR` or `MRRC` CP14 access, using EC value `0x0C`.

Note

If CPTR_EL2.TTA traps EL2, EL1, and EL0 accesses to the CPACR_EL1 or CPACR to EL2, or if CPACR_EL1.TTA traps EL1 and EL0 accesses to the CPACR_EL1 or CPACR to EL1, those traps have priority over this trap.

Traps to EL3 of all accesses to the SIMD and floating-point registers

CPTR_EL3.TFP enables a trap to EL3 of accesses to SIMD and floating-point registers, from all Exception levels:

1 Any attempt at any Exception level to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL3

0 Execution of instructions that access the SIMD or floating-point registers is not trapped to EL3.

For EL1 and EL0, this trap applies to accesses from both Security states.

Table D1-69 shows the registers for which accesses are trapped to EL3 when CPTR_EL3.TFP is 1, and how the exceptions are reported in ESR_EL3.

Table D1-69 Register accesses trapped to EL3 when CPTR_EL3.TFP is 1

Traps from	Registers	Syndrome reporting in ESR_EL3
AArch64 state	FPCR, FPSR, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See *The SIMD and floating-point registers, V0-V31* on page D1-1409.	Trapped access to a SIMD or floating-point register, using EC value `0x07`
AArch32 state	FPSID, MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See *Advanced SIMD and floating-point system registers* on page G1-3472.	Trapped access to a SIMD or floating-point register, using EC value `0x07`[ab]

a. The architecture defines writes to the FPSID from EL1 as an access to a SIMD and floating-point register.

b. Writes to the MVFR0, MVFR1, and MVFR2 from EL1 using AArch32 are UNPREDICTABLE. This means that it is IMPLEMENTATION DEFINED whether these writes are defined as accesses to SIMD and floating-point registers.

Note

If CPTR_EL2.TFP traps EL2, EL1, and EL0 accesses to SIMD and floating-point registers to EL2, or if CPACR_EL1.FPEN traps EL1 and EL0 accesses to the SIMD and floating-point registers to EL1, those traps have priority over this trap.

Traps to EL3 of EL2, EL1, and EL0 System register accesses to debug registers

EL3 provides traps to EL3 of EL2, EL1, and EL0 System register accesses to the debug registers, from both Security states.

Note

EL3 does not provide traps on debug register accesses through the Memory-mapped or External debug interfaces.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL3, no side-effects occur before the exception is taken to EL3. See *Traps to EL3 of System register access instructions* on page D1-1490.

Table D1-70 shows the trap controls, and shows the subsections that list the accesses trapped. Each subsection describes how the trap is reported in ESR_EL3.

Table D1-70 Traps of EL2, EL1, and EL0 accesses to debug registers

Trap control	Trap description
MDCR_EL3.TDOSA	*Traps to EL3 of EL2, EL1, and EL0 System register accesses to OS-related debug registers*
MDCR_EL3.TDA	*Traps to EL3 of EL2, EL1, and EL0 general System register accesses to debug registers*

Traps to EL3 of EL2, EL1, and EL0 System register accesses to OS-related debug registers

MDCR_EL3.TDOSA enables a trap to EL3 of EL2, EL1, and EL0 accesses to the OS-related debug registers:

1 EL2, EL1, and EL0 System register accesses to the OS-related debug registers are trapped to EL3.

0 EL2, EL1, and EL0 System register accesses to the OS-related debug registers are not trapped to EL3.

For EL1 and EL0, this trap applies to accesses from both Security states.

Table D1-71 shows the register accesses that are trapped to EL3 when MDCR_EL3.TDOSA is 1, and how the exceptions are reported in ESR_EL3.

Table D1-71 Register accesses trapped to EL3 when MDCR_EL3.TDOSA is 1

Traps from	Registers	Syndrome reporting in ESR_EL3
AArch64 state	OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, DBGPRCR_EL1.	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`.
AArch32 state	DBGOSLSR, DBGOSLAR, DBGOSDLR, DBGPRCR.	For accesses using: • `MCR` or `MRC` instructions, trapped `MCR` or `MRC` CP14 access, using EC value `0x05`. • `MCRR` or `MRRC` instructions, trapped `MCRR` or `MRRC` CP14 access, using EC value `0x0C`.

Traps to EL3 of EL2, EL1, and EL0 general System register accesses to debug registers

MDCR_EL3.TDA enables a trap to EL3 of EL2, EL1, and EL0 System register accesses to those debug System registers that are not mentioned in *Traps to EL3 of EL2, EL1, and EL0 System register accesses to OS-related debug registers*.

That is, MDCR_EL3.TDA enables a trap to EL3 of EL2, EL1, and EL0 System register accesses to all debug System registers except both of the following:

- Accesses from AArch64 state to the OSLAR_EL1, OSLSR_EL1, OSDLR_EL1 or DBGPRCR_EL1.
- Accesses from AArch32 state to the DBGOSLSR, DBGOSLAR, OSDLR_EL1 or DBGPRCR.

When MDCR_EL3.TDA is:

1 EL2, EL1, and EL0 System register accesses to any of the registers shown in Table D1-72 are trapped to EL3.

0 EL2, EL1, and EL0 System register accesses to the registers shown in Table D1-72 are not trapped to EL3.

For EL1 and EL0, this trap applies to accesses from both Security states.

Table D1-72 shows how the exceptions are reported in ESR_EL3.

Table D1-72 Accesses trapped to EL3 when MDCR_EL3.TDA is 1

Traps from	Trapped accesses	Syndrome reporting in ESR_EL3
AArch64 state	Accesses to the MDRAR_EL1, MDCCSR_EL0, MDCCINT_EL1, DBGDTR_EL0, DBGDTRRX_EL0, DBGDTRTX_EL0, OSDTRRX_EL1, MDSCR_EL1, OSDTRTX_EL1, OSECCR_EL1, DBGBVR<n>_EL1, DBGBCR<n>_EL1, DBGWVR<n>_EL1, DBGWCR<n>_EL1, DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, and DBGAUTHSTATUS_EL1.	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	Accesses to the DBGDRAR, DBGDSAR, DBGDIDR, DBGDSCRint, DBGDCCINT, DBGDTRRXint, DBGDTRTXint, DBGWFAR, DBGVCR, DBGDSCRext, DBGDTRTXext, DBGDTRRXext, DBGBVR<n>, DBGBCR<n>, DBGBXVR<n>, DBGWCR<n>, DBGWVR<n>, DBGOSLAR, DBGCLAIMSET, DBGCLAIMCLR, DBGAUTHSTATUS, DBGDEVID, DBGDEVID1, DBGDEVID2 and DBGOSECCR.	For accesses using: • `MCR` or `MRC` instructions, trapped `MCR` or `MRC` CP14 access, using EC value `0x05`. • `MCRR` or `MRRC` instructions, trapped `MCRR` or `MRRC` access, using EC value `0x0C`.
	`STC` accesses to DBGDTRRXint.[a] `LDC` accesses to DBGDTRTXint.[a]	`LDC` or `STC`, trapped `LDC` or `STC` access to CP14, using EC value `0x06`.

a. If the access would be permitted when MDCR_EL3.TDA is 0.

Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers

MDCR_EL3.TPM enables a trap to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers:

1 EL2, EL1, and EL0 System register accesses to all Performance Monitors registers are trapped to EL3.

0 EL2, EL1, and EL0 System register accesses to Performance Monitors registers are not trapped to EL3.

For EL1 and EL0, this trap applies to accesses from both Security states.

Table D1-73 shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in ESR_EL3.

Table D1-73 Register accesses trapped to EL3 when MDCR_EL3.TPM is 1

Traps from	Registers	Syndrome reporting in ESR_EL3
AArch64 state	All of the following registers, unless the register description states that the register encoding is unallocated. PMCR_EL0, PMCNTENSET_EL0, PMCNTENCLR_EL0, PMOVSCLR_EL0, PMSWINC_EL0, PMSELR_EL0, PMCEID0_EL0, PMCEID1_EL0, PMCCNTR_EL0, PMXEVTYPER_EL0, PMXEVCNTR_EL0, PMUSERENR_EL0, PMINTENSET_EL1, PMINTENCLR_EL1, PMOVSSET_EL0, PMEVCNTR<n>_EL0, PMEVTYPER<n>_EL0, PMCCFILTR_EL0.	Trapped AArch64 `MSR`, `MRS`, or system instruction, using EC value `0x18`
AArch32 state	All of the following registers, unless the register description indicates that the attempted access is UNDEFINED. PMCR, PMCNTENSET, PMINTENCLR, PMOVSR, PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTYPER, PMXEVCNTR, PMUSERENR, PMINTENSET, PMINTENCLR, PMOVSSET, PMEVCNTR<n>, PMEVTYPER<n>, PMCCFILTR.	Trapped `MCR` or `MRC` CP15 access, using EC value `0x03`

D1.16 System calls

A system call is generated by the execution of an SVC, HVC, or SMC instruction:

- By default, the execution of an SVC instruction generates a Supervisor Call, a synchronous exception that targets EL1. This provides a mechanism for software executing at EL0 to make a call to an operating system or other software executing at EL1.
- In an implementation that includes EL2, the execution of an HVC instruction generates a Hypervisor Call, a synchronous exception that targets EL2 by default.

  The HVC instruction is UNDEFINED:
  — At EL0.
  — At EL1 in Secure state.

  Note

  Software executing at EL0 cannot directly generate a Hypervisor Call.
- In an implementation that includes EL3, by default the execution of an SMC instruction generates a Secure Monitor Call, a synchronous exception that targets EL3.

  The SMC instruction is UNDEFINED at EL0, meaning software executing at EL0 cannot directly generate a Secure Monitor Call.

The default behavior applies when the instruction is not UNDEFINED and both of the following are true:
- The instruction is executed at an Exception level that is the same as or lower than the target Exception level.
- The instruction is not trapped to a different Exception level.

If an SVC or HVC instruction is executed at an Exception level that is higher than the target Exception then the exception it generates is taken to the current Exception level.

EL2 and EL3 can disable Hypervisor Call exceptions, see:
- *Disabling Non-secure state execution of HVC instructions* on page D1-1470.
- *Enabling EL3, EL2, and EL1 execution of HVC instructions* on page D1-1493.

EL2 can trap use of the SMC instruction, see *Traps to EL2 of Non-secure EL1 execution of SMC instructions* on page D1-1475.

EL3 can disable Secure Monitor Call exceptions, see *Disabling EL3, EL2, and EL1 execution of SMC instructions* on page D1-1494.

D1.16.1 Pseudocode details of system calls

The pseudocode for the CallSupervisor() function is as follows:

```
// AArch64.CallSupervisor()
// ========================
// Calls the Supervisor

AArch64.CallSupervisor(bits(16) immediate)

    if UsingAArch32() then AArch32.ITAdvance();
    SSAdvance();

    route_to_el2 = HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} && HCR_EL2.TGE == '1';

    bits(64) preferred_exception_return = NextInstrAddr();
    vect_offset = 0x0;

    exception = ExceptionSyndrome(Exception_SupervisorCall);
    exception.syndrome<15:0> = immediate;

    if UInt(PSTATE.EL) > UInt(EL1) then
        AArch64.TakeException(PSTATE.EL, exception, preferred_exception_return, vect_offset);
```

```
    elsif route_to_el2 then
        AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
        AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
```

The pseudocode for the `CallHypervisor()` function is as follows:

```
// AArch64.CallHypervisor()
// ========================
// Performs a HVC call

AArch64.CallHypervisor(bits(16) immediate)
    assert HaveEL(EL2);

    if UsingAArch32() then AArch32.ITAdvance();
    SSAdvance();

    bits(64) preferred_exception_return = NextInstrAddr();
    vect_offset = 0x0;

    exception = ExceptionSyndrome(Exception_HypervisorCall);
    exception.syndrome<15:0> = immediate;

    if PSTATE.EL == EL3 then
        AArch64.TakeException(EL3, exception, preferred_exception_return, vect_offset);
    else
        AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
```

The pseudocode details for the `CallSecureMonitor()` function is as follows:

```
// AArch64.CallSecureMonitor()
// ===========================

AArch64.CallSecureMonitor(bits(16) immediate)
    assert HaveEL(EL3) && !ELUsingAArch32(EL3);

    if UsingAArch32() then AArch32.ITAdvance();
    SSAdvance();

    bits(64) preferred_exception_return = NextInstrAddr();
    vect_offset = 0x0;

    exception = ExceptionSyndrome(Exception_MonitorCall);
    exception.syndrome<15:0> = immediate;

    AArch64.TakeException(EL3, exception, preferred_exception_return, vect_offset);
```

D1.17 Mechanisms for entering a low-power state

The ARM architecture provides mechanisms that software can use to indicate that the PE can enter a low-power state, if it supports that state. The following sections describe those mechanisms:

- *Wait for Event mechanism and Send event*.
- *Wait For Interrupt* on page D1-1506.

D1.17.1 Wait for Event mechanism and Send event

A PE can use the *Wait for Event* (WFE) mechanism to enter a low-power state, depending on the value of an Event Register for that PE. To enter the low-power state, the PE executes a Wait For Event instruction, `WFE`, and if the Event Register is clear, the PE can enter the low-power state.

If the PE does enter the low-power state, it remains in that low-power state until it receives a *WFE wake-up event*.

The architecture does not define the exact nature of the low-power state, except that the execution of a `WFE` instruction must not cause a loss of memory coherency.

WFE mechanism behavior depends on the interaction of all of the following, that are described in the subsections that follow:

- The Event Register for the PE. See subsection *The Event Register* on page D1-1504.
- The Wait For Event instruction, `WFE`. See subsection *The Wait For Event instruction* on page D1-1504.
- *WFE wake-up events*. See subsection *WFE wake-up events in AArch64 state* on page D1-1505
- The Send Event instructions, `SEV` and `SEVL` that can cause WFE wake-up events. See subsection *The Send Event instructions* on page D1-1505.

Note

Because the Wait for Event mechanism is associated with suspending execution on a PE for the purpose of power saving, ARM recommends that the Event Register is set only infrequently. However, software must only use the setting of the Event Register as a hint, and must not assume that any particular message is sent as a result of the setting of the Event Register.

Example D1-2 describes how a spinlock implementation might use the WFE mechanism to save energy.

Example D1-2 Spinlock as an example of using Wait For Event and Send Event

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device, it might need to add data received from the device to a queue. If another PE is removing data from the same queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the second PE has released the lock. The first PE cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in *Synchronization and semaphores* on page B2-99.
- If the PE obtains the lock it performs its memory operation and then releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. When the lock becomes available, the PE again attempts to obtain it.

A spin-lock mechanism is not ideal for all situations:

- In a low-power system the tight read loop is undesirable because it uses energy to no effect.
- In a multi-PE implementation the execution of spin-locks by multiple waiting PEs can degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock:

- A PE that fails to obtain a lock executes a `WFE` instruction to request entry to a low-power state, at the time when the exclusive monitor is set holding the address of the location holding the lock.
- When a PE releases a lock, the write to the lock location causes the exclusive monitor of any PE monitoring the lock location to be cleared. This clearing of the exclusive monitors generates a WFE wake-up event for each of those PEs. Then, these PEs can attempt to obtain the lock again.

For large systems, more advanced locking systems, such as ticket locks, can avoid unfairness caused by having multiple PEs simultaneously reading the lock. In such systems, the WFE mechanism can be used in a similar way to monitor the next ticket value.

The Event Register

The Event Register is a single bit register for each PE. When set, an Event Register indicates that an event has occurred since the register was last cleared, that might require some action by the PE. Therefore, when the Event Register is set, the PE must not suspend operation on executing a `WFE` instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register for a PE is set by any of the following:

- A Send Event instruction, `SEV`, executed by any PE in the system.
- A Send Event Local instruction, `SEVL`, executed by the PE.
- The clearing of the global monitor for the PE.
- An exception return.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

The Event Register is cleared only by a Wait For Event instruction.

Note

Software cannot read or write the value of the Event Register directly.

The Wait For Event instruction

The action of the Wait For Event instruction, `WFE`, depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately.
- If the Event Register is clear the PE can suspend execution and enter a low-power state. It remains in that state until the PE detects a WFE wake-up event, or earlier if the implementation chooses, or a until a reset. When the PE detects a WFE wake-up event, or earlier if chosen, the WFE instruction completes. If the wake-up event sets the Event Register, it is IMPLEMENTATION DEFINED whether on restarting execution, the Event Register is cleared.

The `WFE` is available at all Exception levels. Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 can be trapped to a higher Exception level. See:

- *Traps to EL1 of EL0 execution of WFE and WFI instructions* on page D1-1462.
- *Traps to EL2 of Non-secure EL1 and EL0 execution of WFE and WFI instructions* on page D1-1479.
- *Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions* on page D1-1491.

Note

Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake-ups.

WFE wake-up events in AArch64 state

The following are WFE wake-up events:

- The execution of an SEV instruction on any PE in the multiprocessor system.
- The execution of an SEVL instruction by the PE.
- An SError interrupt received by the PE, unless masked by PSTATE.A or EDSCR.INTdis.
- A physical IRQ interrupt received by the PE, unless masked by PSTATE.I or EDSCR.INTdis.
- A physical FIQ interrupt received by the PE, unless masked by PSTATE.F or EDSCR.INTdis.
- In Non-secure EL1 or EL1, all of the following:
  - When HCR_EL2.FMO is 1, a virtual FIQ interrupt, unless masked by PSTATE.F or EDSCR.INTdis.
  - When HCR_EL2.IMO is 1, a virtual IRQ interrupt, unless masked by PSTATE.I or EDSCR.INTdis.
  - When HCR_EL2.AMO is 1, a virtual SError interrupt, unless masked by PSTATE.A or EDSCR.INTdis.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of halting is allowed, see *Halting allowed and halting prohibited* on page H2-4395. Also see *External Debug Request debug event* on page H3-4452.
- An event sent by the timer event stream for the PE. See *Event streams* on page D6-1787.
- An event caused by the clearing of the global monitor for the PE.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

Not all of these wake-up events set the Event Register.

Note

- EDSCR.INTdis masking applies only when external debug is disabled.
- For more information about the masking of physical and virtual interrupts see *Asynchronous exception types, routing, masking and priorities* on page D1-1453. If the configuration of HCR_EL2.{AMO, IMO, FMO} or HCR.{AMO, IMO, FMO}, or SCR_EL3.{EA, TRQ, FIQ}, means that a PSTATE mask bit cannot mask a physical or virtual interrupt, then that interrupt is a WFE wake-up event, regardless of the value of the PSTATE mask bit.

The Send Event instructions

The Send Event instructions are:

SEV, Send Event This causes an event to be signaled to all PEs in the multiprocessor system.

SEVL, Send Event Local
This must set the local Event Register. It might signal an event to other PEs, but is not required to do so.

The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED. The PE is not required to guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the SEV instruction. Therefore, ARM recommends that software includes a DSB instruction before any SEV instruction.

Note

A DSB instruction ensures that no instructions, including any SEV instructions, that appear in program order after the DSB instruction, can execute until the DSB instruction has completed. See *Data Synchronization Barrier (DSB)* on page B2-86.

The SEVL instruction appears to execute in program order relative to any subsequent WFE instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.

The receipt of a signaled SEV or SEVL event by a PE sets the Event Register on that PE.

The SEV and SEVL instructions are available at all Exception levels.

Pseudocode details of the Wait For Event mechanism

This section defines pseudocode functions that describe the behavior of the Wait For Event mechanism.

The ClearEventRegister() pseudocode procedure clears the Event Register of the current PE.

```
ClearEventRegister();
```

The EventRegistered() pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear:

```
boolean EventRegistered();
```

The WaitForEvent() pseudocode procedure optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes a ClearEventRegister() to occur.

```
WaitForEvent();
```

The SendEvent() pseudocode procedure sets the Event Register of every PE in the multiprocessor system.

```
SendEvent();
```

The EventRegisterSet() pseudocode procedure sets the event register for this PE.

```
EventRegisterSet();
```

D1.17.2 Wait For Interrupt

Software can use the *Wait for Interrupt* (WFI) instruction to cause the PE to enter a low-power state. The PE then remains in that low-power state until it receives a *WFI wake-up event*, or until some other IMPLEMENTATION DEFINED reason causes it to leave the low-power state. The architecture permits a PE to leave the low-power state for any reason, but requires that it must leave the low-power state on receipt of any architected WFI wake-up event.

Note

Because the architecture permits a PE to leave the low-power state for any reason, it is permissible for a PE to treat WFI as a NOP, but this is not recommended for lowest power operation.

When the PE leaves a low-power state that was entered as a result of a WFI instruction, that WFI instruction completes.

The architecture does not define the exact nature of the low-power state, except that the execution of a WFI instruction must not cause a loss of memory coherency.

Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 can be trapped to a higher Exception level. See:

- *Traps to EL1 of EL0 execution of WFE and WFI instructions* on page D1-1462.
- *Traps to EL2 of Non-secure EL1 and EL0 execution of WFE and WFI instructions* on page D1-1479.
- *Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions* on page D1-1491.

WFI wake-up events

The following are *WFI wake-up events*:

- A SError interrupt, regardless of the value of PSTATE.A or EDSCR.INTdis.
- A physical IRQ interrupt, regardless of the value of PSTATE.I or EDSCR.INTdis.
- A physical FIQ interrupt, regardless of the value of PSTATE.F or EDSCR.INTdis.
- In Non-secure state when executing at EL0 or EL1:
  - When HCR_EL2.AMO is 1, a virtual SError interrupt, regardless of the value of PSTATE.A or EDSCR.INTdis.
  - When HCR_EL2.IMO is 1, a virtual IRQ interrupt, regardless of the value of PSTATE.I or EDSCR.INTdis.
  - When HCR_EL2.FMO is 1, a virtual FIQ interrupt, regardless of the value of PSTATE.F or EDSCR.INTdis.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of halting is allowed, see *Halting allowed and halting prohibited* on page H2-4395. Also see *External Debug Request debug event* on page H3-4452.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

Note

- Because debug events are WFI wake-up events, ARM recommends that Wait For Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures that the intervention of debug while waiting does not significantly change the function of the program being debugged.
- The WFI mechanism can be used while interrupts are masked. If it is, then an interrupt is still a WFI wake-up event, but the interrupt is not taken.
- Some implementations of the WFI mechanism drain down any pending memory activity before suspending execution. This increases power saving, by increasing the area over which clocks can be stopped. The architecture does not require this operation, therefore software must not rely on the WFI mechanism operating in this way.

Using WFI to indicate an idle state on bus interfaces

Software can use the WFI mechanism to force quiescence on a PE, and, combined with preventing any possible WFI wakeup events, this can be used to complete an entry into a powerdown state.

Because mechanisms for entering powerdown states are inherently IMPLEMENTATION DEFINED, whether an implementation uses the WFI mechanism is IMPLEMENTATION DEFINED. If it does, the `WFI` instruction forces the suspension of execution, and of all associated bus activity.

The control logic that does this also tracks the activity on the bus interfaces of the PE, so that when the PE has completed all current operations and any associated bus activity has completed, it can signal to an external power controller that there is no ongoing bus activity.

However, the PE must continue to process memory-mapped and external debug interface accesses to debug registers when in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

When the OS Double Lock control, OSDLR_EL1.DLK, is 1, the PE must not signal this idle state to the control logic unless it can also guarantee that the debug interface is idle. For more information about the OS Double Lock, see *Debug behavior when the OS Double Lock is locked* on page H6-4504.

Note

In a PE that implements separate core and debug power domains, the debug interface referred to in this section is the interface between the core and debug power domains, since the signal to the power controller indicates that the core power domain is idle. For more information about the power domains see *Power domains and debug* on page H6-4497.

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

Pseudocode details of Wait For Interrupt

The `WaitForInterrupt()` pseudocode procedure optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.

D1.18 Self-hosted debug

The ARMv8-A architecture supports both of the following:

Self-hosted debug

The PE itself hosts a debugger. The debugger programs the PE to generate *debug exceptions*. Debug exceptions are accommodated in the ARMv8-A Exception model.

External debug

The PE is controlled by an external debugger. The debugger programs the PE to generate *Halting debug events*, that cause the PE to enter *Debug state*. In Debug state, the PE is halted.

This section describes self-hosted debug. It includes:

- *Debug exceptions*.
- *The PSTATE debug mask bit, D*.

For external debug, see part E.

D1.18.1 Debug exceptions

Debug exceptions occur during normal program flow, if a debugger has programmed the PE to generate them.

For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions.

The possible debug exceptions are:

- Software Breakpoint Instruction exceptions.
- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

Chapter D2 *AArch64 Self-hosted Debug* describes these in detail for AArch64.

For the PE to generate a debug exception requires that:

- The debug exception is enabled. *The debug exception enable controls* on page D2-1533 gives the controls for the different debug exceptions.
- Debug exceptions are enabled from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level and Security state* on page D2-1536.

Debug exceptions are synchronous exceptions, and are accommodated in the ARMv8 Exception model.

Note

Breakpoints and Watchpoints can cause entry to Debug state instead of causing debug exceptions. See Chapter H1 *Introduction to External Debug*.

D1.18.2 The PSTATE debug mask bit, D

As with all other exceptions, when a debug exception is taken, software must take care to avoid generating another instance of an exception within the exception handler, to avoid recursive entry into the exception handler and loss of return state.

To help avoid this, the ARMv8 architecture provides a debug exception mask bit, PSTATE.D, that can mask Watchpoint, Breakpoint, and Software Step exceptions when the target Exception level is the current Exception level.

PSTATE.D is set to 1 on taking an exception. This means that while handling an exception in AArch64 state, Watchpoint, Breakpoint, and Software Step exceptions are masked. This prevents recursive entry at the Exception level that debug exceptions are targeted to.

When execution is in AArch64 state, debug exceptions are also masked implicitly when the target Exception level is lower than the current Exception level.

When the target Exception level is higher than the current Exception level, debug exceptions cannot be masked by PSTATE.D.

Because debug exceptions are synchronous, the architecture requires that debug exceptions are not generated when PSTATE.D is 1. By preventing debug exception generation, debug exceptions cannot be taken at a subsequent time when the Process state D mask bit is cleared to 0.

Note

This differs from the behavior for interrupts, where the PSTATE.{A, I, F} mask has the effect of preventing the interrupt from being taken, but instead the interrupt remains pending.

D1.19 The Performance Monitors Extension

The System registers provide access to a Performance Monitors Unit (PMU), defined as the OPTIONAL Performance Monitors Extension to the architecture, a non-invasive debug resource that provides information about the operation of the PE. The PMU provides:

- A 64-bit cycle counter.
- An IMPLEMENTATION DEFINED number of 32-bit event counters. Each event counter can be configured to count occurrences of a specified event. The events that can be counted are:
  - Architectural and microarchitectural events that are likely to be consistent across many microarchitectures. The PMU architecture uses event numbers to identify an event, and the PMU specification defines which event number must be used for each of these architectural and microarchitectural events.
  - Implementation-specific events. The PMU specification reserves event numbers for implementation-specific events. See Appendix C *Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events*.

For more information, see Chapter D5 *The Performance Monitors Extension*.

D1.20 Interprocessing

Interprocessing is the term used to describe moving between the AArch64 and AArch32 Execution states.

The Execution state can change only on a change of Exception level. This means that the Execution state can change only on taking an exception to a higher Exception level, or returning from an exception to a lower Exception level.

On taking an exception to a higher Exception level, the Execution state either:

- Remains unchanged.
- Changes from AArch32 state to AArch64 state.

On returning from an exception to a lower Exception level, the Execution state either:

- Remains unchanged.
- Changes from AArch64 state to AArch32 state.

Note

If, on taking or returning from an exception, the Exception level remains the same, the Execution state cannot change.

For the description of:

- Exception entry to an Exception level using AArch64, see *Exception entry* on page D1-1422.
- Exception return from an Exception level using AArch64 state, see *Exception return* on page D1-1437.
- Exception return to AArch32 state, see *Exception return to an Exception level using AArch32* on page G1-3412.

  Note

  The description in *Handling exceptions that are taken to an Exception level using AArch32* on page G1-3396 is outside the scope of interprocessing, because such exceptions must have been taken from an Exception level that is using AArch32, and therefore there is no change of Execution state.

The following sections describe the behavior associated with interprocessing.

- *Register mappings between AArch32 state and AArch64 state*.
- *State of the general-purpose registers on taking an exception to AArch64 state* on page D1-1520.
- *SPSR, ELR, and AArch64 SP relationships on changing Execution state* on page D1-1522.

D1.20.1 Register mappings between AArch32 state and AArch64 state

This section defines the architectural mappings between AArch32 state registers and AArch64 state registers.

The mappings describe:

- For exceptions taken from AArch32 state to AArch64 state, where the AArch32 register content is found.
- For exception returns from AArch64 state to AArch32 state, how the AArch32 register content is derived.

The general model is:

- The AArch32 register contents are situated in the bottom 32 bits of the AArch64 registers.
- In AArch32 state, the upper 32 bits of AArch64 registers are inaccessible and are ignored.

Note

System software that executes in AArch64 state, such as an OS or Hypervisor, can use these mappings for context save and restore, or to interpret and modify the AArch32 registers of an application or virtual machine.

For more information see the following subsections:

- *Mapping of the general-purpose registers between the Execution states*.
- *Mapping of the SIMD and floating-point registers between the Execution states* on page D1-1514.
- *Mapping of the System registers between the Execution states* on page D1-1515.

Mapping of the general-purpose registers between the Execution states

Table D1-74 shows how each of the AArch32 general-purpose registers, R0-R12, SP, and LR, including the banked copies of these registers, maps to an AArch64 general-purpose register.

Table D1-74 Base instruction set register mapping between AArch32 state and AArch64 state

AArch32 register	AArch64 register
R0	X0
R1	X1
R2	X2
R3	X3
R4	X4
R5	X5
R6	X6
R7	X7

Note

For a description of the banking of AArch32 general-purpose registers R8-R12, SP, and LR, see *AArch32 general-purpose registers, and the PC* on page G1-3383.

Mapping of the SIMD and floating-point registers between the Execution states

Table D1-75 shows the mapping between the AArch64 V registers and the AArch32 Q registers.

Table D1-75 SIMD and floating-point register mapping between AArch64 state and AArch32 state

AArch64 register	AArch32 register
V0	Q0
V1	Q1
V2	Q2
. . .	. . .
V15	Q15

The AArch64 registers V16-V31 are not accessible from AArch32 state.

The mapping between the V, D, and S registers in AArch64 state is not the same as the mapping between the Q, D, and S registers in AArch32 state:

- In AArch64 state, there are:
  - 32 128-bit V registers, V0-V31.
  - 32 64-bit D registers, D0-D31.
  - 32 32-bit S registers, S0-S31.

  A smaller register occupies the least-significant bytes of the corresponding larger register. For example, S5 is the least-significant word of D5 and V5. Figure D1-3 shows this mapping.

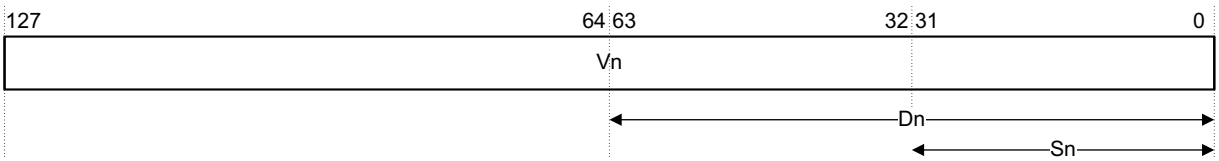

Figure D1-3 AArch64 state SIMD and floating-point register mappings

- In AArch 32 state, there are:
  - 16 128-bit Q registers, Q0-Q15.
  - 32 64-bit D registers, D0-D31.
  - 32 32-bit S registers, S0-S31.

  Smaller registers are packed into larger registers. Figure D1-4 shows this mapping.

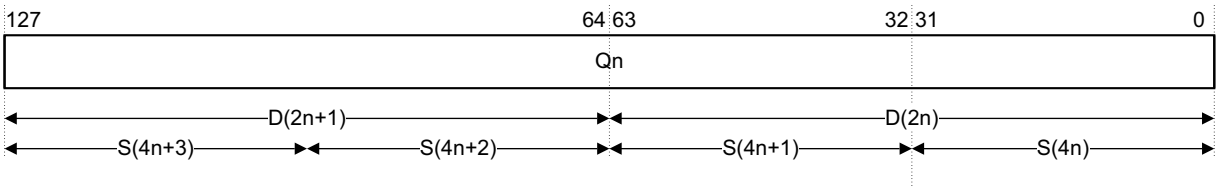

Figure D1-4 AArch32 state SIMD and floating-point register mappings

In AArch32 state:

- There are no S registers that correspond to Q8-Q15.
- D16-D31 pack into Q8-Q15. For example, D16 and D17 pack into Q8.

Note

A consequence of this mapping is that if software executing in AArch64 state interprets D or S registers from AArch32 state, it must unpack the D or S registers from the V registers before it uses them.

Mapping of the System registers between the Execution states

ARMv8 architecturally defines the relationship between the AArch64 System registers and the AArch32 System registers, to allow supervisory code such as a hypervisor, that is executing in AArch64 state, to save, restore, and interpret the System registers belonging to a lower Exception level that is using AArch32.

Any modifications made to AArch32 System registers affects only those parts of those AArch64 registers that are mapped to the AArch32 System registers. Bits[63:32] of AArch64 registers, where they are not mapped to AArch32 registers, are unchanged by AArch32 state execution.

Note

This model is different to the model for the general-purpose registers described in *Mapping of the general-purpose registers between the Execution states* on page D1-1513. In this model, there are several cases where two AArch32 System registers are packed into a single AArch64 System register.

When EL3 is implemented and is using AArch32, some System registers are banked between the two Security states. When a register is banked in this way, there is an instance of the register in Secure state, and another instance of the register in Non-secure state. This banking is not supported when EL3 is using AArch64 or if EL3 is not implemented. For the registers that are banked in this way when EL3 is using AArch32, the architected mapping is between the Non-secure AArch32 register and the AArch64 register. This use of the Non-secure instance of the AArch32 register applies in all cases where EL3 is using AArch64 state. This includes execution at EL1 or EL0, using AArch32, in Secure state.

Note

Although the architecture does not require this, because it is not architecturally visible, ARM expects that implementations will map many of the AArch64 registers for use by EL3 to the Secure instances of banked AArch32 registers. However, if EL2 and EL3 are implemented and both support use of AArch32, this is not possible for the following registers:

IFAR This is because when EL3 is using AArch32, HIFAR is an alias of the Secure IFAR.

DFAR This is because when EL3 is using AArch32, HDFAR is an alias of the Secure DFAR.

Table D1-76 shows the mappings between the writable AArch64 System registers and the AArch32 System registers.

PMXEVTYPER_EL0	PMXEVTYPER

a. As described in this section, AArch32 System register banking between Non-secure and Secure states is supported only when EL3 is using AArch32.

b. These registers have overlapping register content. One or more bits of one register appear in the other register.

There are a small number of AArch32 System registers that are not mapped to any AArch64 System registers. The AArch64 registers listed in Table D1-77 can be used to access these from a higher Exception level that is using AArch64. The registers shown in the table are UNDEFINED if EL1 cannot use AArch32.

Table D1-77 AArch64 registers for accessing registers that are only used in AArch32 state

AArch32 register	AArch64 register provided for accessing the AArch32 register	Short description
DACR	DACR32_EL2	Domain Access Control Register
DBGVCR	DBGVCR32_EL2	Debug Vector Catch Register

Table D1-77 AArch64 registers for accessing registers that are only used in AArch32 state

AArch32 register	AArch64 register provided for accessing the AArch32 register	Short description
FPEXC	FPEXC32_EL2	Floating-Point Exception Control Register
IFSR	IFSR32_EL2	Instruction Fault Status Register
SDER	SDER32_EL3	AArch32 Secure Debug Enable Register

Table D1-78 shows the AArch64 System registers that allow access from AArch64 state to the AArch32 ID registers. These registers are RAZ if no Exception level can use AArch32.

Table D1-78 AArch64 registers that access the AArch32 ID registers

AArch32 register	AArch64 register for access to the AArch32 register	Short description
ID_AFR0	ID_AFR0_EL1	AArch32 Auxiliary Feature Register 0
ID_DFR0	ID_DFR0_EL1	AArch32 Debug Feature Register 0
ID_ISAR0	ID_ISAR0_EL1	EL1, AArch32 Instruction Set Attribute Register 0
ID_ISAR1	ID_ISAR1_EL1	EL1, AArch32 Instruction Set Attribute Register 1

ID_PFR1	ID_PFR1_EL1	AArch32 PE Feature Register 1

D1.20.2 State of the general-purpose registers on taking an exception to AArch64 state

When an exception is taken from AArch32 state to AArch64 state, the state of a general-purpose register depends on whether, immediately before the exception, the register was accessible from AArch32 state, as follows:

If the general-purpose register was accessible from AArch32 state

The upper 32 bits either become zero, or hold the value that the same architectural register held before any AArch32 execution. The choice between these two options is IMPLEMENTATION DEFINED, and might vary dynamically within an implementation. Correspondingly, software must regard the value as being a CONSTRAINED UNPREDICTABLE choice between these two values.

This behavior applies regardless of whether any execution occurred at the Exception level that was using AArch32. That is, this behavior applies even if AArch32 state was entered by an exception return from AArch64 state, and another exception was immediately taken to AArch64 state without any instruction execution in AArch32 state.

Which general-purpose registers have their upper 32 bits affected in this way depends on both:

- The AArch64 state target Exception level.
- The values of both:
  - SCR_EL3.RW.
  - HCR_EL2.RW or HCR.RW, where HCR.RW is a notional bit that is RES0.

Table D1-79 shows which general-purpose registers can have their upper 32 bits set to zero.

Table D1-79 General-purpose registers that can have their upper 32 bits set to zero on taking an exception to AArch64 state from AArch32 state

SCR_EL3.RW	HCR_EL2.RW or HCR.RW[a]	Registers when the target Exception level is:		
		EL3	EL2	EL1
0	0	X0-X30	-[b]	-[b]
0	1	-[c]	-[c]	-[c]
1	0	X0-X14, X16-X30	X0-X14, X16-X30	-[b]
1	1	X0-X14	X0-X14	X0-X14

a. HCR.RW is a notional bit that is RES0.
b. The RW bit values are not valid for the targeted EL.
c. Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.

Note

If EL2 is not implemented, or the SCR_EL3.NS or SCR.NS bit prevents its use, then as described in *The effects of supporting fewer than four Exception levels* on page D1-1526, the behavior is consistent with HCR_EL2.RW taking the value of SCR_EL3.RW.

If the general-purpose register was not accessible from AArch32 state

The general rule is that the register retains the state it had before any AArch32 execution.

There is one exception to this rule, that is when taking an exception to EL3 using AArch64 when either EL2 is not implemented or EL1 is in Secure state. In these cases, the X15 register must be treated as if it is accessible when the value of SCR_EL3.RW is 0, and therefore the upper bits of X15 might either be set to zero or retain their previous value.

Which general-purpose registers retain their state depends on both:

- The AArch64 state target Exception level.
- The values of both:
  - SCR_EL3.RW.
  - HCR_EL2.RW or HCR.RW, where HCR.RW is a notional bit that is RES0.

Table D1-80 shows which general-purpose registers can retain their state.

Table D1-80 General-purpose registers that can retain their state on taking an exception to AArch64 from AArch32

SCR_EL3.RW	HCR_EL2.RW or HCR.RW[a]	Registers when the target Exception level is:		
		EL3	EL2	EL1
0	0	None	-[b]	-[b]
0	1	-[c]	-[c]	-[c]
1	0	X15	X15	-[b]
1	1	X15-X30	X15-X30	X15-X30

a. HCR.RW is a notional bit that is RES0.
b. The RW bit values are not valid for the targeted EL.
c. Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.

Note

If EL2 is not implemented, or the SCR_EL3.NS bit prevents its use, then as described in *The effects of supporting fewer than four Exception levels* on page D1-1526, the behavior is consistent with HCR_EL2.RW taking the value of SCR_EL3.RW.

D1.20.3 SPSR, ELR, and AArch64 SP relationships on changing Execution state

Table D1-81 shows the SPSR and ELR registers that are architecturally mapped between AArch32 state and AArch64 state.

Table D1-81 SPSR and ELR mappings between AArch32 state and AArch64 state

AArch32 register	AArch64 register
SPSR_svc	SPSR_EL1
SPSR_hyp	SPSR_EL2
ELR_hyp	ELR_EL2

On exception entry to EL3 using AArch64 state from an Exception level using AArch32 state, when EL2 has been using AArch32 state, the upper 32-bits of ELR_EL2 are either set to zero or they retain the value before the AArch32 state execution. The implementation determines the choice between these two options, and the choice might vary dynamically within an implementation. Therefore, software must regard the upper 32-bits as being UNKNOWN.

On exception entry to an Exception level using AArch64 state from an Exception level using AArch32 state, the AArch64 Stack Pointers and Exception Link Registers associated with an Exception level that are not accessible during execution in AArch32 state at that Exception level, retain the state that they had before the execution in AArch32 state.

The following AArch32 registers are used only during execution in AArch32 state. However, they retain their state when there is execution at EL1 with EL1 using AArch64 state:

- SPSR_abt
- SPSR_und
- SPSR_irq
- SPSR_fiq.

Note

- These registers are accessible during execution in AArch64 state at Exception levels higher than EL1, for context switching.
- If EL1 does not support execution in AArch32 state then these registers are RES0.

D1.21 Supported configurations

ARMv8 supports three configuration choices:

- The number of Exception levels implemented.
- Which Exception levels support AArch32 and which Exception levels support AArch64.
- Whether SIMD and floating-point support is implemented.

The following subsections provide further information:

- *Implication of Exception levels implemented*.
- *Support for Exception levels and Execution states* on page D1-1525.
- *Implementations not including Advanced SIMD and floating-point instructions* on page D1-1526.
- *The effects of supporting fewer than four Exception levels* on page D1-1526.

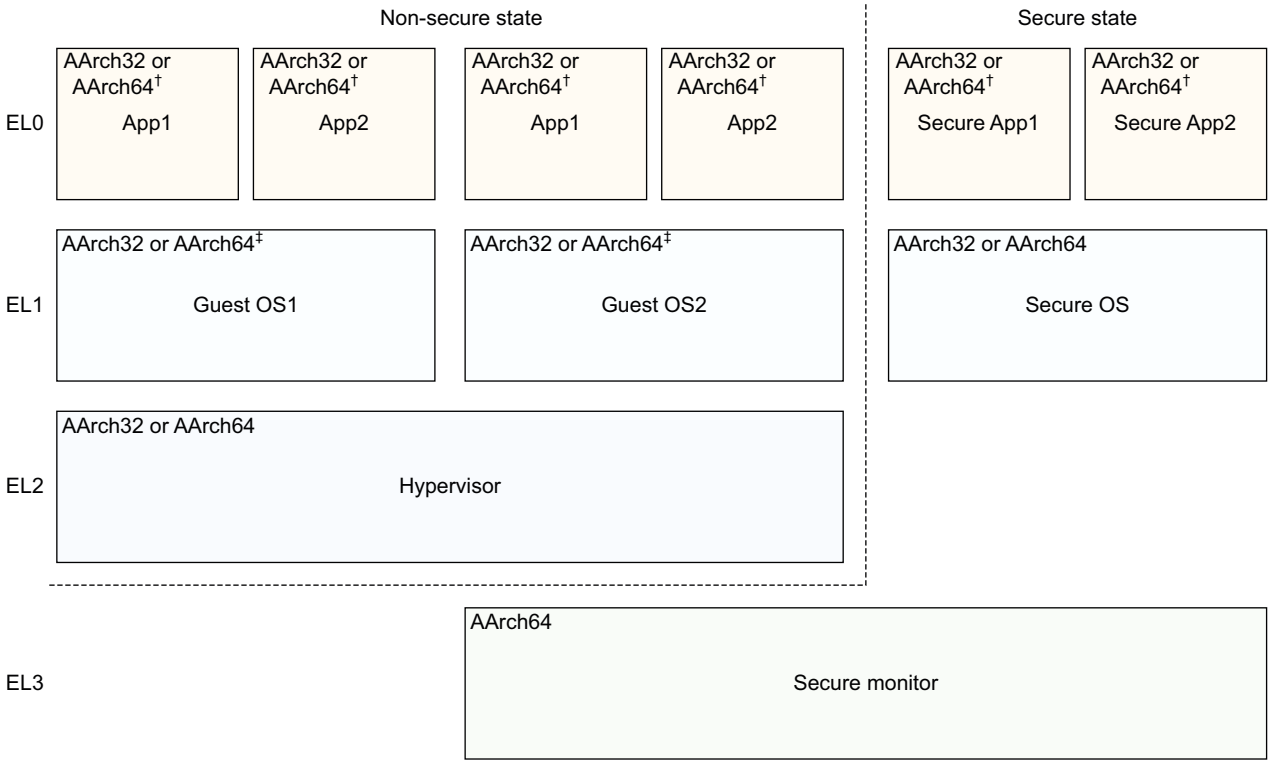
D1.21.1 Implication of Exception levels implemented

All implementations must include EL0 and EL1.

EL2 and EL3 are optional. The architecture permits all combinations of EL2 and EL3.

See also *Implementations not including Advanced SIMD and floating-point instructions* on page D1-1526 and *The effects of supporting fewer than four Exception levels* on page D1-1526.

For an implementation that includes all of the Exception levels Figure D1-5 shows the implemented Exception levels and the possible Execution states at lower Exception levels when EL3 is using AArch64. Figure D1-5 applies regardless of whether EL3 also supports use of AArch32.



† AArch64 permitted only if EL1 is using AArch64
‡ AArch64 permitted only if EL2 is using AArch64

Figure D1-5 ARMv8-A security model when EL3 is using AArch64

The possible combinations of Exception levels are as follows:

- EL0, EL1, and EL2. The implementation supports only Non-secure state.
- EL0, EL1, and EL3. The implementation does not support Virtualization. The Exception levels and Execution states depend on whether EL3 is using AArch64 state or AArch32 state, as follows:
  - If EL3 is using AArch64, the Exception levels and Execution states are as shown in Figure D1-5 on page D1-1524 with EL2 removed and no Non-secure state virtualization of EL1 and EL0.
  - If EL3 is using AArch32, the Exception levels and Execution states are as shown in Figure G1-1 on page G1-3374 with EL2 removed and no Non-secure state virtualization of EL1 and EL0.
- EL0 and EL1 only. The implementation supports only a single Security state. This might be either Secure state or Non-secure state, see *Behavior when only EL1 and EL0 are implemented* on page D1-1527.
- EL0, EL1, EL2, and EL3, as described in this section.

For more information, see *The effects of supporting fewer than four Exception levels* on page D1-1526.

D1.21.2 Support for Exception levels and Execution states

Subject to the interprocessing rules defined in *Interprocessing* on page D1-1512, an implementation of the ARM architecture could support:

- AArch64 state only.
- AArch64 and AArch32 states.
- AArch32 state only.

This means the ARMv8-A architecture can, potentially, support implementations with very large number of combinations of Execution state and Exception level. ARM intends to license only a subset of the possible combinations Table D1-82 shows the combinations of Exception levels and Execution states that are currently licensed.

Table D1-82 Supported combinations of Exception levels and Execution state

Number of Exception levels	Supported Security states	Exception levels, AArch64 state				Exception levels, AArch32 state			
		EL3	EL2	EL1	EL0	EL3	EL2	EL1	EL0
Four	Both	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
		Yes	Yes	Yes	Yes	No	No	Yes	Yes
		Yes	Yes	Yes	Yes	No	No	No	Yes
		Yes	Yes	Yes	Yes	No	No	No	No
Three	Both	Yes	No	Yes	Yes	No	No	No	Yes
		Yes	No	Yes	Yes	No	No	Yes	Yes
		Yes	No	Yes	Yes	No	No	No	No
	Non-secure only	No	Yes	Yes	Yes	No	No	Yes	Yes
		No	Yes	Yes	Yes	No	No	No	No
Two	Either	No	No	Yes	Yes	No	No	No	Yes
		No	No	Yes	Yes	No	No	No	No

D1.21.3 Implementations not including Advanced SIMD and floating-point instructions

In general, ARMv8-A requires the inclusion of the Floating-point and Advanced SIMD instructions in all instruction sets. Exceptionally, for implementations targeting specialized markets, ARM might produce or license an ARMv8-A implementation that does not provide any support for Floating-point and Advanced SIMD instructions. In such an implementation:

In AArch64 state

- The CPACR_EL1.FPEN field is RES0.
- The CPTR_EL2.TFP bit is RES1.
- The CPTR_EL3.TFP bit is RES1.
- Each of the ID_AA64PFR0_EL1.{AdvSIMD, FP} fields is `0b1111`.

D1.21.4 The effects of supporting fewer than four Exception levels

Supported configurations on page D1-1524 defines the permitted combinations of Exception levels in an ARMv8-A implementation.

In every implementation that supports the highest Exception level using either AArch64 state or AArch32 state, an IMPLEMENTATION DEFINED mechanism determines whether the highest implemented Exception level uses AArch64 state or AArch32 state from a Cold reset. Typically, this mechanism is a configuration input. When the highest level is configured to be AArch64 state, then after a Cold reset execution starts at the reset vector in that Exception level.

The unimplemented Exception levels have no effect on execution:

- No interrupts are routed to these Exception levels, and no virtual interrupts defined by these Exception levels are active.
- No traps that target these Exception levels are active
- All systems calls to unimplemented Exception levels from lower Exception levels are treated as UNDEFINED.
- There is no support for address translation from these Exception levels.
- Any exception return that targets an unimplemented Exception level is treated as an illegal exception return as described in *Illegal return events* on page D1-1438.
- Every accessible register associated with an unimplemented Exception level is RES0 unless the register is associated with the Exception level only to provide the ability to transfer execution to a lower Exception level.

  Note

  If, for example, EL3 is not implemented and EL2 is the highest implemented Exception level, then because none of the EL3 registers are accessible from EL2, the content of those registers is not architecturally visible.

The following subsections give more information about each of the permitted combinations of Exception levels that do not include all Exception levels.

Behavior when EL2 is not implemented

If EL2 is not implemented and EL3 is implemented:

- If EL1 can use AArch32 then the following registers are not RES0:
  - DACR32_EL2.
  - IFSR32_EL2.
  - FPEXC32_EL2.
  - DBGVCR32_EL2.

- The VMPIDR_EL2 and VPIDR_EL2 are RO and:
  - VMPIDR_EL2 takes the value of MPIDR_EL1.
  - VPIDR_EL2 takes the value of MIDR_EL1.
- Behavior is consistent with the HCR_EL2.RW bit taking the value of the SCR_EL3.RW bit for all purposes other than reading the HCR_EL2.
- The following address translation and TLB invalidation instructions are UNDEFINED:
  - AT S1E2R and AT S1E2W.
  - TLBI VAE2, TLBI VALE2, TLBI VAE2IS, TLBI VALE2IS, TLBI ALLE2, TLBI ALLE2IS.

  Note

  No other TLB or address translation instructions become UNDEFINED with this combination of Exception levels.
- The SCR_EL3.HCE bit is RES0.
- The CNTHCTL_EL2[1:0] bits are treated as if they have the value `0b11` for all purposes other than reading the CNTHCTL_EL2 register.

Behavior when EL3 is not implemented

If EL3 is not implemented and EL2 is implemented, then:

- All memory transactions can only access a single physical memory address space.
- The PE behaves as if the value of the SCR_EL3.NS bit is 1, even though the SCR_EL3 is not accessible.

This means that if the PE is part of a system that supports two Security states, it behaves as if it is in Non-secure state, and can only access Non-secure memory.

Behavior when only EL1 and EL0 are implemented

If EL3 and EL2 are not implemented, it is IMPLEMENTATION DEFINED whether the PE behaves as if the value of the SCR_EL3.NS bit is 1 or the PE behaves as if the value of the SCR_EL3.NS bit is 0.

This means that if the PE is part of a system that supports two Security states:

- If it behaves as if the value of the SCR_EL3.NS bit is 1, it can only access Non-secure memory.
- If it behaves as if the value of the SCR_EL3.NS bit is 0, it can access both Secure memory and Non-secure memory.

Note

- The behavior described in this subsection still applies if EL1 is configured to use AArch32.
- The implementation can provide a configuration input that determines, from reset, whether the it behaves as if the value of the SCR_EL3.NS bit is 1, or as if the value of the SCR_EL3.NS bit is 0.

Chapter D2
AArch64 Self-hosted Debug

When the PE is using self-hosted debug, it generates *debug exceptions*. This chapter describes the AArch64 self-hosted debug exception model. It is organized as follows:

- Introductory information:
  - *About debug exceptions* on page D2-1530.
  - *The debug exception enable controls* on page D2-1533.
- The debug Exception model:
  - *Routing debug exceptions* on page D2-1534.
  - *Enabling debug exceptions from the current Exception level and Security state* on page D2-1536.
  - *The effect of powerdown on debug exceptions* on page D2-1539.
  - *Summary of the permitted routing and enabling of debug exceptions* on page D2-1540.
  - *Pseudocode descriptions of debug exceptions* on page D2-1542.
- The debug exceptions:
  - *Software Breakpoint Instruction exceptions* on page D2-1544.
  - *Breakpoint exceptions* on page D2-1546.
  - *Watchpoint exceptions* on page D2-1564.
  - *Vector Catch exceptions* on page D2-1578.
  - *Software Step exceptions* on page D2-1579.
- The behavior of self-hosted debug after changes to system registers, or after changes to the authentication interface, but before a *Context Synchronization Operation* (CSO) guarantees the effects of the changes:
  - *Synchronization and debug exceptions* on page D2-1593.

D2.1 About debug exceptions

Debug exceptions occur during normal program flow, if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions. The debug exceptions that can be generated in an AArch64 translation regime are:

- *Software Breakpoint Instruction exceptions*.
- *Breakpoint exceptions*, generated by hardware breakpoints.
- *Watchpoint exceptions* on page D2-1531, generated by hardware watchpoints.
- *Software Step exceptions* on page D2-1531.

In addition, *Vector Catch exceptions* can be generated in an AArch32 stage 1 translation regime and routed to an Exception level that is using AArch64. *Vector Catch exceptions* on page D2-1531 describes these.

The PE can only generate a particular debug exception when both:

1. Debug exceptions are enabled from the current Exception level and Security state.

   See *Enabling debug exceptions from the current Exception level and Security state* on page D2-1536. Software Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

2. A debugger has enabled that particular debug exception.

   All of the debug exceptions except for Software Breakpoint Instruction exceptions have an enable control contained in the MDSCR_EL1. See *The debug exception enable controls* on page D2-1533.

Note

If *halting is allowed* and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.

For the definition of halting is allowed, see *Halting allowed and halting prohibited* on page H2-4395.

The following list summarizes each of the debug exceptions:

Software Breakpoint Instruction exceptions

Breakpoint instructions generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A64 instruction set is `BRK #<immediate>`. Whenever one of these is committed for execution, the PE takes a Software Breakpoint Instruction exception.

PE behavior

Software Breakpoint Instruction exceptions cannot be masked. The PE takes Software Breakpoint Instruction exceptions regardless of both of the following:

- The current Exception level.
- The current Security state.

For more information, see *Software Breakpoint Instruction exceptions* on page D2-1544.

Breakpoint exceptions

The ARMv8-A architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address `0x1000` is committed for execution.

The ARMv8-A architecture supports the following types of hardware breakpoint for use in an AArch64 stage 1 translation regime:

- Address.
  - — Comparisons are made with the virtual address of each instruction in the program flow.

- Context:
  - Context ID Match. Matches with the Context ID held in the CONTEXTIDR_EL1.
  - VMID Match. Matches with the VMID value held in the VTTBR_EL2.
  - Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

PE behavior

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 *Debug State*.

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see *Breakpoint exceptions* on page D2-1546.

Watchpoint exceptions

The ARMv8-A architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range `0x1000 - 0x101F`.

A hardware watchpoint can link to a hardware breakpoint, if the hardware breakpoint is a *Linked Context* type. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

PE behavior

If halting is allowed and EDSCR.HDE is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 *Debug State*.

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see *Watchpoint exceptions* on page D2-1564.

Vector Catch exceptions

These are not generated in an AArch64 translation regime. They can only be generated in an AArch32 translation regime. See *Vector Catch exceptions* on page D2-1578.

Software Step exceptions

Software step is a resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can debug software executing at a lower Exception level, by making it single-step instructions.

After the software being debugged has single-stepped an instruction, the PE takes a Software Step exception.

PE behavior

Software step can only be used by a debugger executing in an Exception level that is using AArch64. However, the instruction stepped might be executed in either Execution state, and therefore Software Step exceptions can be taken from either Execution state.

If debug exceptions are enabled, Software Step exceptions can be generated.

If debug exceptions are disabled, software step is inactive.

For more information, see *Software Step exceptions* on page D2-1579.

Table D2-1 summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

Table D2-1 PE behavior and pseudocode for each of the debug exceptions

Debug exception	PE behavior if debug exceptions are:		Pseudocode
	Enabled	Disabled	
Software Breakpoint Instruction exceptions	Takes the exception	Takes the exception	page D2-1545
Breakpoint exceptions	Takes the exception[a]	Ignored	page D2-1559
Watchpoint exceptions	Takes the exception[a]	Ignored	page D2-1575
Vector Catch exceptions	Takes the exception	Ignored	page G2-3570
Software Step exceptions	Takes the exception	Not applicable[b]	page D2-1591

a. If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See Chapter H2 *Debug State*.

b. Software Step is inactive if debug exceptions are disabled. No Software Step exceptions can be generated.

D2.2 The debug exception enable controls

The enable controls for each debug exception are as follows:

Software Breakpoint Instruction exceptions

None. Software Breakpoint Instruction exceptions are always enabled.

Breakpoint exceptions

MDSCR_EL1.MDE, plus an enable control for each breakpoint, DBGBCR<n>_EL1.E.

Watchpoint exceptions

MDSCR_EL1.MDE, plus an enable control for each watchpoint, DBGWCR<n>_EL1.E.

Software Step exceptions

MDSCR_EL1.SS.

In addition, for all debug exceptions other than Software Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level and Security state* on page D2-1536.

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Software Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

D2.3 Routing debug exceptions

The Exception level that debug exceptions target is called the *debug target Exception level*, EL_D. EL_D is usually EL1. However:

If EL3 is implemented:

Software Breakpoint Instruction exceptions taken from EL3 are taken to EL3.

These are the only debug exceptions that can be taken from EL3 using AArch64. All other debug exceptions are disabled at EL3 using AArch64.

If EL2 is implemented:

Both of the following apply:

- Debug exceptions taken from EL2 are taken to EL2.
- If MDCR_EL2.TDE is:

  1 All debug exceptions taken from Non-secure EL1 and EL0 are routed to EL2.

  0 All debug exceptions taken from EL1 and EL0 are taken to EL1.

Note

If HCR_EL2.TGE is 1, MDCR_EL2.TDE is treated as being 1 except for a direct read of MDCR_EL2.

Table D2-2 shows this.

Table D2-2 The effect of the TGE and TDE control bits on debug exception routing

HCR_EL2.TGE	MDCR_EL2.TDE	Debug exceptions taken from Non-secure EL1 and EL0 are taken to:
0	0	Non-secure EL1
0	1	EL2
1	X	EL2

Note

If EL2 is not implemented, all of the following apply:

- The PE behaves as if both HCR_EL2.TGE and MDCR_EL2.TDE are 0.
- The HCR_EL2 is RES0.
- The MDCR_EL2 is RES0.

The following tables show the routing of debug exceptions:

Table D2-3 Routing when both EL3 and EL2 are implemented

MDCR_EL2.TDE[a]	EL_D when executing in:					
	Non-secure:			Secure:		
	EL0	EL1	EL2	EL0	EL1	EL3
0	EL1	EL1	EL2	EL1	EL1	EL3[b]
1	EL2	EL2	EL2	EL1	EL1	EL3[b]

a. If HCR_EL2.TGE is 1, this bit is treated as being 1 other than for a direct read of MDCR_EL2.

b. Only Software Breakpoint Instruction exceptions can be taken to EL3 if EL3 is using AArch64, and only if they are taken from EL3.

Table D2-4 Routing when EL3 is implemented and EL2 is not implemented

EL_D when executing in:				
Non-secure:			Secure:	
EL0	EL1	EL0	EL1	EL3
EL1	EL1	EL1	EL1	EL3[a]

a. Only Software Breakpoint Instruction exceptions can be taken to EL3 if EL3 is using AArch64, and only if they are taken from EL3.

Table D2-5 Routing when EL3 is not implemented and EL2 is implemented

MDCR_EL2.TDE[a]	EL_D when executing in Non-secure:		
	EL0	EL1	EL2
0	EL1	EL1	EL2
1	EL2	EL2	EL2

a. If HCR_EL2.TGE is 1, this bit is treated as being 1 other than for a direct read of MDCR_EL2.

D2.3.1 Pseudocode description of routing debug exceptions

`DebugTarget()` returns the current debug target Exception level.

```
// DebugTarget()
// =============

bits(2) DebugTarget()
    secure = IsSecure();
    return DebugTargetFrom(secure);
```

DebugTargetFrom() returns the debug target Exception level for the specified Security state.

```
// DebugTargetFrom()
// =================
// Returns the debug exception target Exception level

bits(2) DebugTargetFrom(boolean secure)

    if HaveEL(EL2) && !secure then
        if ELUsingAArch32(EL2) then
            route_to_el2 = (HDCR.TDE == '1' || HCR.TGE == '1');
        else
            route_to_el2 = (MDCR_EL2.TDE == '1' || HCR_EL2.TGE == '1');
    else
        route_to_el2 = FALSE;

    if route_to_el2 then
        target = EL2;
    elsif HaveEL(EL3) && HighestELUsingAArch32() && secure then
        target = EL3;
    else
        target = EL1;

    return target;
```

D2.4 Enabling debug exceptions from the current Exception level and Security state

A debug exception can only be taken if it is enabled from both the current Exception level and the current Security state.

See the following:

- *Enabling debug exceptions from the current Exception level*.
- *Enabling debug exceptions from the current Security state* on page D2-1537.
- *Pseudocode descriptions of enabling debug exceptions* on page D2-1538.

D2.4.1 Enabling debug exceptions from the current Exception level

Table D2-6 shows when debug exceptions are enabled from the current Exception level. In the table:

- Y means that those exceptions are enabled.
- N means that those exceptions are disabled.

Table D2-6 Whether debug exceptions are enabled from the current Exception level

Current Exception level	Software Breakpoint Instruction exceptions	All other debug exceptions
EL3	Y	N
Any Exception level that is higher than EL_D	Y	N
Any Exception level that is lower than EL_D	Y	N if either of the following is true: • The OS lock is locked. • EDPRSR.DLK is 1. Otherwise Y[a].
EL_D	Y	N if any of the following is true: • The OS lock is locked. • EDPRSR.DLK is 1. • The Kernel Debug Enable bit, MDSCR_EL1.KDE, is 0[b]. • The Debug exception mask bit, PSTATE.D, is 1[b]. Otherwise Y[a].

a. If EL3 is implemented there is an additional control, MDCR_EL3.SDD, that must be 0 to enable Breakpoint, Watchpoint, and Software Step exceptions from Secure state. See *Enabling debug exceptions from the current Exception level and Security state*.

b. This means that a debugger must explicitly enable debug exceptions other than Software Breakpoint Instruction exceptions from EL_D, by setting MDSCR_EL1.KDE to 1 and PSTATE.D to 0.

Note

PSTATE.D is set to 1 at reset and on exception entry.

D2.4.2 Enabling debug exceptions from the current Security state

Table D2-7 shows when debug exceptions are enabled from the current Security state. In the table, Y means that those exceptions are enabled.

Table D2-7 Whether debug exceptions are enabled from the current Security state

Current Security state	Software Breakpoint Instruction exceptions	All other debug exceptions
Non-secure	Y	Y[a]
Secure	Y	Y[a] if MDCR_EL3.SDD is 0. See *The secure debug disable bit*.

a. A Breakpoint, Watchpoint, or Software Step exception cannot be taken unless it is also enabled from the current Exception level. See *Enabling debug exceptions from the current Exception level* on page D2-1536.

The ARMv8-A architecture does not support disabling debug in Non-secure state.

The secure debug disable bit

The *Secure Debug Disable* bit is MDCR_EL3.SDD.

If EL3 is implemented, a Secure monitor can set MDCR_EL3.SDD to 1 to disable all debug exceptions taken from Secure state, other than Software Breakpoint Instruction exceptions:

0 All debug exceptions are enabled from Secure state.

1 Debug exceptions other than Software Breakpoint Instruction exceptions are disabled from Secure state.

The Breakpoint, Watchpoint, Vector Catch and Software Step exceptions that MDCR_EL3.SDD applies to are those taken from:

- Secure EL0 using AArch32 to Secure EL1 using AArch64.
- Secure EL0 using AArch64 to Secure EL1 using AArch64.
- Secure EL1 using AArch64 to Secure EL1 using AArch64.

Note

- If the boot software executed when reset is deasserted sets MDCR_EL3.SDD to 1, software operating at EL3 never has to switch the debug registers between Secure state and Non-secure state.
- The PE cannot take a debug exception unless it is enabled from the current Exception level. See *Enabling debug exceptions from the current Exception level* on page D2-1536.
- If either the OS lock or the OS double-lock is locked, debug exceptions other than Software Breakpoint Instruction exceptions are disabled.
- If EL3 and EL2 are not implemented, and the implementation is a Secure state only implementation, the PE behaves as if MDCR_EL3.SDD is 0.

D2.4.3 Pseudocode descriptions of enabling debug exceptions

`AArch64.GenerateDebugExceptions()` determines whether debug exceptions are enabled from the current Exception level and Security state.

```
// AArch64.GenerateDebugExceptions()
// =================================

boolean AArch64.GenerateDebugExceptions()
    return AArch64.GenerateDebugExceptionsFrom(PSTATE.EL, IsSecure(), PSTATE.D);
```

`AArch64.GenerateDebugExceptionsFrom()` determines whether debug exceptions are enabled from the specified Exception level and Security state.

```
// AArch64.GenerateDebugExceptionsFrom()
// =====================================

boolean AArch64.GenerateDebugExceptionsFrom(bits(2) from, boolean secure, bit mask)

    if OSLSR_EL1.OSLK == '1' || DoubleLockStatus() || Halted() then
        return FALSE;

    route_to_el2 = HaveEL(EL2) && !secure && (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1');

    if HaveEL(EL3) && secure then
        enabled = MDCR_EL3.SDD == '0' && from != EL3;
    else
        enabled = TRUE;

    target = if route_to_el2 then EL2 else EL1;
    if from == target then
        enabled = enabled && MDSCR_EL1.KDE == '1' && mask == '0';

    return enabled;
```

D2.5 The effect of powerdown on debug exceptions

Debug OS Save and Restore sequences on page H6-4502 describes the *powerdown save routine* and the *restore routine*.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

Debug exceptions other than Software Breakpoint Instruction exceptions are enabled only if both the OS Lock is unlocked and EDPRSR.DLK is 0.

Software Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and EDPRSR.DLK.

D2.6 Summary of the permitted routing and enabling of debug exceptions

Behavior is as follows:

Software Breakpoint Instruction exceptions

These are always enabled, regardless of the current Exception level and Security state. Table D2-8 shows the routing of these. In the table, n/a means not applicable.

Table D2-8 Routing of Software Breakpoint Instruction exceptions

Current Security state	MDCR_EL2.TDE is:[a]	EL_D when enabled from:			
		EL0	EL1	EL2	EL3
Secure	X	Secure EL1	Secure EL1	n/a	EL3
Non-secure	0	Non-secure EL1	Non-secure EL1	EL2	n/a
	1	EL2	EL2	EL2	n/a

a. If EL2 is not implemented, behavior is as if this is 0. If HCR_EL2.TGE is 1, MDCR_EL2.TDE is treated as being 1 other than for a direct read of MDCR_EL2.

All other debug exceptions

Table D2-9 shows the valid combinations of MDCR_EL3.SDD, MDCR_EL2.TDE, MDSCR_EL1.KDE, and PSTATE.D, and for each combination shows where these exceptions are enabled from and where they are taken to.

In the table, n/a means not applicable and a dash, -, means that debug exceptions are disabled from that Exception level.

Table D2-9 Routing of Breakpoint, Watchpoint, Software Step, and Vector Catch exceptions

Debug state	Lock[a]	Current Security state	SDD[b]	TDE[c]	KDE	D	EL_D when enabled from:			
							EL0	EL1	EL2	EL3
Yes	X	X	X	X	X	X	-	-	-	-
No	1	X	X	X	X	X	-	-	-	-
No	0	Secure	1	X	X	X	-	-	n/a	-
No	0	Secure	0	X	0	X	Secure EL1	-	n/a	-
No	0	Secure	0	X	1	1	Secure EL1	-	n/a	-
No	0	Secure	0	X	1	0	Secure EL1	Secure EL1	n/a	-
No	0	Non-secure	X	0	0	X	Non-secure EL1	-	-	n/a
No	0	Non-secure	X	0	1	1	Non-secure EL1	-	-	n/a
No	0	Non-secure	X	0	1	0	Non-secure EL1	Non-secure EL1	-	n/a
No	0	Non-secure	X	1	0	X	EL2	EL2	-	n/a
No	0	Non-secure	X	1	1	1	EL2	EL2	-	n/a
No	0	Non-secure	X	1	1	0	EL2	EL2	EL2	n/a

a. The value of (OSLSR_EL1.OSLK OR EDPRSR.DLK).

b. If EL3 is not implemented, behavior is as if this is 0.
c. If HCR_EL2.TGE is 1, this bit is treated as being 1 other than for a direct read of MDCR_EL2. If EL2 is not implemented, behavior is as if TDE is 0.

D2.7 Pseudocode descriptions of debug exceptions

DebugFault() returns a FaultRecord object that indicates that a memory access has generated a debug exception:

```
// AArch64.DebugFault()
// ====================

FaultRecord AArch64.DebugFault(AccType acctype, boolean iswrite)

    ipaddress = bits(48) UNKNOWN;
    level = integer UNKNOWN;
    extflag = bit UNKNOWN;
    secondstage = FALSE;
    s2fs1walk = FALSE;

    return AArch64.CreateFaultRecord(Fault_Debug, ipaddress,  level, acctype, iswrite,
                                     extflag, secondstage, s2fs1walk);
```

The Abort() function processes FaultRecord objects, as described in *Abort exceptions* on page D3-1628, and generates a debug exception.

Abort() calls one of the following:

```
// AArch64.BreakpointException()
// =============================

AArch64.BreakpointException(FaultRecord fault)
    assert PSTATE.EL != EL3;

    route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                    (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1'));

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    vaddress = bits(64) UNKNOWN;
    exception = AArch64.AbortSyndrome(Exception_Breakpoint, fault, vaddress);

    if PSTATE.EL == EL2 || route_to_el2 then
        AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
        AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);

// AArch64.WatchpointException()
// =============================

AArch64.WatchpointException(bits(64) vaddress, FaultRecord fault)
    assert PSTATE.EL != EL3;

    route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                    (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1'));

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    exception = AArch64.AbortSyndrome(Exception_Watchpoint, fault, vaddress);

    if PSTATE.EL == EL2 || route_to_el2 then
        AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
        AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);

// AArch64.VectorCatchException()
// ==============================
// Vector Catch taken from EL0 or EL1 to EL2. This can only be called when debug exceptions are
```

```
// being routed to EL2, as Vector Catch is a legacy debug event.

AArch64.VectorCatchException(FaultRecord fault)
    assert PSTATE.EL != EL2;
    assert HaveEL(EL2) && !IsSecure() && (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1');

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    vaddress = bits(64) UNKNOWN;
    exception = AArch64.AbortSyndrome(Exception_VectorCatch, fault, vaddress);

    AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);

// AArch64.SoftwareStepException()
// ===============================

AArch64.SoftwareStepException()
    assert PSTATE.EL != EL3;

    route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                    (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1'));

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    exception = ExceptionSyndrome(Exception_SoftwareStep);
    if SoftwareStep_DidNotStep() then
        exception.syndrome<24> = '0';
    else
        exception.syndrome<24> = '1';
        exception.syndrome<6> = if SoftwareStep_SteppedEX() then '1' else '0';

    if PSTATE.EL == EL2 || route_to_el2 then
        AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
        AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
```

D2.8 Software Breakpoint Instruction exceptions

This section describes Software Breakpoint Instruction exceptions in an AArch64 translation regime.

It contains the following subsections:

- *About Software Breakpoint Instruction exceptions*.
- *Breakpoint instruction in the A64 instruction set*.
- *Exception syndrome information and preferred return address*.
- *Pseudocode description of Software Breakpoint Instruction exceptions* on page D2-1545.

D2.8.1 About Software Breakpoint Instruction exceptions

A *breakpoint* is a debug event that results from the execution of an instruction, based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint.*
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Software Breakpoint Instruction exceptions, that this section describes, are software breakpoints. *Breakpoint exceptions* on page D2-1546 describes hardware breakpoints.

There is no enable control for Software Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Software Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:

- The current Exception level.
- The current Security state.
- Whether the *debug target Exception level*, EL_D, is using AArch64 or AArch32.

Note

- The debug target exception level, EL_D, is the Exception level that debug exceptions are targeting. *Routing debug exceptions* on page D2-1534 describes how EL_D is derived.
- Debuggers using breakpoint instructions must be aware of the ARMv8 rules for concurrent modification and execution of instructions. See *Concurrent modification and execution of instructions* on page B2-80.

D2.8.2 Breakpoint instruction in the A64 instruction set

The breakpoint instruction is `BRK #<immediate>`. It is unconditional.

For details of the instruction encoding, see *BRK* on page C6-428.

D2.8.3 Exception syndrome information and preferred return address

See the following:

- *Exception syndrome information*.
- *Preferred return address* on page D2-1545.

Exception syndrome information

On taking a Software Breakpoint Instruction exception, the PE records information about the exception in the *Exception Syndrome Register* (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- ESR_EL1.
- ESR_EL2.
- ESR_EL3.

Note

Software Breakpoint Instruction exceptions are the only debug exception that can be taken to EL3 using AArch64.

Table D2-10 shows the information that the PE records.

Table D2-10 Information recorded in the ESR_ELx

ESR_ELx field	Information recorded in ESR_EL1, ESR_EL2, or ESR_EL3.
Exception Class, EC	Whether the breakpoint instruction was executed in AArch64 state or AArch32 state. The PE sets this to: • `0x3C` for an A64 `BRK` instruction. • `0x38` for an A32 or T32 `BKPT` instruction.
Instruction Length, IL	The PE sets this to: • 0 for a 16-bit T32 `BKPT` instruction. • 1 for an A64 `BRK` instruction, or an A32 `BKPT` instruction.
Instruction Specific Syndrome, ISS	**ISS[24:16]** RES0. **ISS[15:0]** The PE copies the instruction Comment field value into here, zero extended as necessary.

Note

- If debug exceptions are routed to EL2, it is the exception that is routed, not the instruction that is trapped. Therefore, if a Software Breakpoint Instruction exception is routed to EL2, ESR_EL2.EC is set to the same value as if the exception was taken to EL1.
- For information about how debug exceptions can be routed to EL2, see *Routing debug exceptions* on page D2-1534.

Preferred return address

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like `SVC`.

D2.8.4 Pseudocode description of Software Breakpoint Instruction exceptions

`AArch64.SoftwareBreakpoint()` generates a Software Breakpoint Instruction exception that is taken to AArch64 state.

```
// AArch64.SoftwareBreakpoint()
// ============================

AArch64.SoftwareBreakpoint(bits(16) immediate)

    route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                    (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1'));

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    exception = ExceptionSyndrome(Exception_SoftwareBreakpoint);
    exception.syndrome<15:0> = immediate;

    if UInt(PSTATE.EL) > UInt(EL1) then
        AArch64.TakeException(PSTATE.EL, exception, preferred_exception_return, vect_offset);
    elsif route_to_el2 then
        AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
        AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
```

D2.9 Breakpoint exceptions

This section describes Breakpoint exceptions in an AArch64 stage 1 translation regime.

The PE is using an AArch64 stage 1 translation regime when it is executing at either:

- An Exception level that is using AArch64.
- EL0 using AArch32 when EL1 is using AArch64.

It contains the following subsections:

- *About Breakpoint exceptions*.
- *Breakpoint types and linking of breakpoints* on page D2-1547.
- *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page D2-1553.
- *Instruction address comparisons* on page D2-1554.
- *Context comparisons* on page D2-1556.
- *Usage constraints* on page D2-1556.
- *Exception syndrome information and preferred return address* on page D2-1558.
- *Pseudocode descriptions of Breakpoint exceptions taken from AArch64 state* on page D2-1559.

D2.9.1 About Breakpoint exceptions

A *breakpoint* is a debug event that results from the execution of an instruction, based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint exceptions are generated by *Breakpoint debug events*. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in *Software Breakpoint Instruction exceptions* on page D2-1544.

An implementation can include between 2-16 hardware breakpoints. ID_AA64DFR0_EL1.BRPs shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:

- The *Breakpoint Control Register*, DBGBCR<n>_EL1. This contains controls for the breakpoint, for example an enable control.
- The *Breakpoint Value Register*, DBGBVR<n>_EL1. This holds the value used for breakpoint matching, that is one of:
  - An instruction virtual address.
  - A Context ID.
  - A VMID value.
  - A concatenation of both a Context ID value and a VMID value.

These registers are numbered, so that:

- DBGBCR1_EL1 and DBGBVR1_EL1 are for breakpoint number one.
- DBGBCR2_EL1 and DBGBVR2_EL1 are for breakpoint number two.
- …
- …
- DBGBCRn_EL1 and DBGBVRn_EL1 are for breakpoint number n.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the breakpoint enable control for it, DBGBCR<n>_EL1.E, is 1.
- The conditions specified in the DBGBCR<n>_EL1 are met.
- The comparison with the value held in the DBGBVR<n>_EL1 is successful.
- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:

- Whether the instruction passes its condition code check.
- The instruction type.

Note

The PE tests all breakpoints before it executes each instruction. The PE might test all breakpoints when an instruction is fetched speculatively. However, a breakpoint does not generate a Breakpoint debug event until the instruction is committed for execution.

If halting is allowed and EDSCR.HDE is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Breakpoint debug events generate Breakpoint exceptions.
- Disabled, Breakpoint debug events are ignored.

Note

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions.

However, the behavior described also applies if breakpoints are causing entry to Debug state.

The debug exception enable controls on page D2-1533 describes the enable controls for Breakpoint debug events.

D2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A *context-aware* breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  - An instruction address match.
  - A Context ID match, with the value held in the CONTEXTIDR_EL1.
  - A VMID match, with the VMID value held in the VTTBR_EL2.
  - Both a Context ID match and a VMID match.
- A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match.

ID_AA64DFR0_EL1.CTX_CMPs shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match is categorized as an *Address breakpoint*. Breakpoints that are programmed to match on anything else are categorized as *Context breakpoints*.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case the breakpoint is called an *Unlinked breakpoint*.
- Enabled for linking to another breakpoint. In this case the breakpoint is called a *Linked breakpoint*.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match occurs. For example, a debugger might:

1. Program breakpoint number one to be a *Linked Address Match breakpoint*.
2. Program breakpoint number five to be a *Linked Context ID Match breakpoint*.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The *Breakpoint Type* field for a breakpoint, DBGBCR<n>_EL1.BT, controls the breakpoint type and whether the breakpoint is enabled for linking. If BT[0] is 1, the breakpoint is enabled for linking.

Figure D2-1 shows all of the possible breakpoint types that an AArch64 stage 1 translation regime supports, and their associated BT field values.

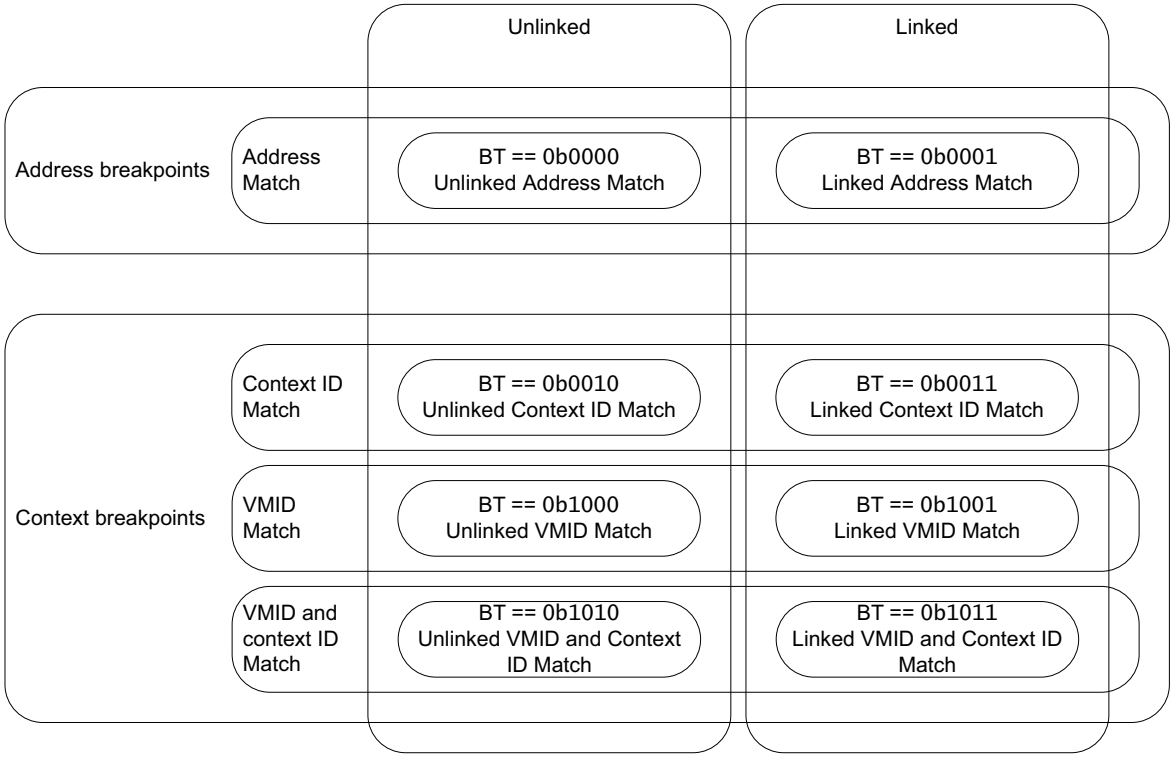


Figure D2-1 Breakpoint types and their associated BT field values

If AArch32 state is implemented, Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See *Specifying the halfword-aligned address that an Address breakpoint matches on* on page D2-1555.

Note

AArch32 stage 1 translation regimes support two additional breakpoint types, Unlinked and Linked Address Mismatch breakpoints, BT == `0b0100` and BT == `0b0101`. These types are reserved in an AArch64 stage 1 translation regime, and are therefore not described in this section. See *Reserved BT values* on page D2-1556. For information about Address Mismatch breakpoints in an AArch32 stage 1 translation regime, see Chapter G2 *AArch32 Self-hosted Debug*.

Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked breakpoint types can be linked.
- Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, DBGBCR<n>_EL1.LBN, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
  - DBGBCR<n>_EL1.{SSC, HMC, PMC} for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page D2-1553.
  - DBGBCR<n>_EL1.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.
- Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.
- Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.
- If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See *Other usage constraints for Address breakpoints* on page D2-1558.
- If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.
- Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

  Note

  Multiple Linked watchpoints can also link to a single Linked Context breakpoint. *Watchpoint exceptions* on page D2-1564 describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

- Multiple Linked Address Match breakpoints.
- Multiple Linked watchpoints.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

Figure D2-2 on page D2-1550 shows an example of permitted breakpoint and watchpoint linking.

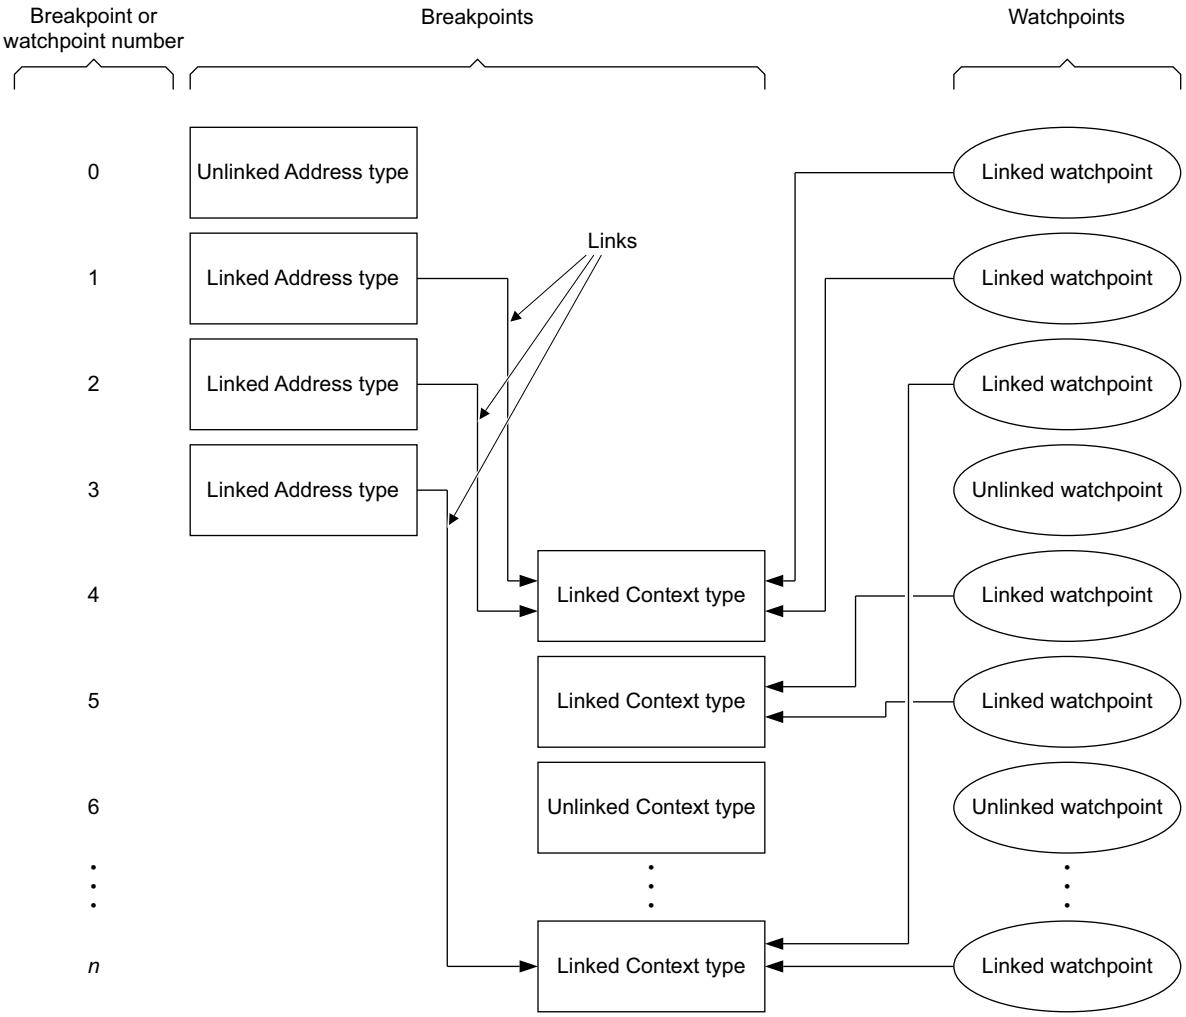

Figure D2-2 The role of linking in Breakpoint and Watchpoint exception generation

In Figure D2-2, each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

Breakpoint types defined by DBGBCRn_EL1.BT

The following list provides more detail about each breakpoint type:

`0b0000`, Unlinked Address Match breakpoint

Generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page D2-1553.
- A successful address match, as described in *Instruction address comparisons* on page D2-1554.

DBGBCR<n>_EL1.LBN for this breakpoint is ignored.

0b0001, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- DBGBCR<n>_EL1.{SSC, HMC, PMC} for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page D2-1553.
- A successful address match defined by this breakpoint, as described in *Instruction address comparisons* on page D2-1554.
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

DBGBCR<n>_EL1.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0010, Unlinked Context ID Match breakpoint

BT == 0b0010 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page D2-1553.
- A successful Context ID match, as described in *Context comparisons* on page D2-1556.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored

0b0011, Linked Context ID Match breakpoint

BT == 0b0011 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see *Instruction address comparisons* on page D2-1554.
  - A successful Context ID match defined by this breakpoint, as described in *Context comparisons* on page D2-1556.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Data address comparisons* on page D2-1568.
  - A successful Context ID match defined by this breakpoint, as described in *Context comparisons* on page D2-1556.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b0100, Unlinked Address Mismatch breakpoint

BT == 0b0100 is a reserved value in an AArch64 stage 1 translation regime. See *Reserved BT values* on page D2-1556.

0b0100, Unlinked Address Mismatch breakpoint on page G2-3531 describes the behavior of Address Mismatch breakpoints in an AArch32 stage 1 translation regime.

0b0101, Linked Address Mismatch breakpoint

BT == 0b0101 is a reserved value in an AArch64 stage 1 translation regime. See *Reserved BT values* on page D2-1556.

0b0101, Linked Address Mismatch breakpoint on page G2-3532 describes the behavior of Address Mismatch breakpoints in an AArch32 stage 1 translation regime.

0b1000, Unlinked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page D2-1553.
- A successful VMID match, as described in *Context comparisons* on page D2-1556.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1001, Linked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See *Instruction address comparisons* on page D2-1554.
  - A successful VMID match defined by this breakpoint, as described in *Context comparisons* on page D2-1556.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Data address comparisons* on page D2-1568.
  - A successful VMID match defined by this breakpoint, as described in *Context comparisons* on page D2-1556.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1010, Unlinked Context ID and VMID Match breakpoint

BT == 0b1010 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on all of the following:

- DBGBCR<n>_EL1.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates a Breakpoint exception for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page D2-1553.
- A successful Context ID match.
- A successful VMID match.

Context comparisons on page D2-1556 describes the requirements for a successful Context ID match and a successful VMID match.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1011, Linked Context ID and VMID Match breakpoint

BT == 0b1011 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on all of the following:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see *Instruction address comparisons* on page D2-1554.
  - A successful Context ID match defined by this breakpoint.
  - A successful VMID match defined by this breakpoint.
- Generation of a Watchpoint exception depends on all of the following:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Data address comparisons* on page D2-1568.
  - A successful Context ID match defined by this breakpoint.
  - A successful VMID match defined by this breakpoint.

Context comparisons on page D2-1556 describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

Note

See *Reserved DBGBCR<n>_EL1.BT values* on page D2-1556 for the behavior of breakpoints programmed with reserved BT values.

D2.9.3 Execution conditions that a breakpoint generates Breakpoint exceptions for

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at EL0 in Secure state.

DBGBCR<n>_EL1.{SSC, HMC, PMC} defines the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states. The comparison is made with the Security state of the PE, not the NS attribute of the physical instruction fetch address.

Higher Mode Control, HMC, and Privileged Mode Control, PMC

HMC and PMC together control which Exception levels the breakpoint generates Breakpoint exceptions in.

Table D2-11 on page D2-1554 shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Exception levels breakpoints generate Breakpoint exceptions in.

In the table:

Y or - Means that a breakpoint programmed with the values of HMC, SSC and PMC shown in that row:

Y Can generate Breakpoint exceptions in that Exception level.

- Cannot generate Breakpoint exceptions in that Exception level.

Res Means that the combination of HMC, SSC, and PMC is reserved. See *Reserved DBGBCR<n>_EL1.{HMC, SSC, PMC} values* on page D2-1557.

Table D2-11 Summary of breakpoint HMC, SSC, and PMC encodings

HMC	SSC	PMC	Security state the breakpoint is programmed to match in	EL3[a]	EL2	EL1	EL0	Implementation	
								No EL3	No EL3 and no EL2
0	00	01	Both	-	-	Y	-	-	-
0	00	10		-	-	-	Y	-	-
0	00	11		-	-	Y	Y	-	-
0	01	01	Non-secure	-	-	Y	-	Res	Res
0	01	10		-	-	-	Y	Res	Res
0	01	11		-	-	Y	Y	Res	Res
0	10	01	Secure	-	-	Y	-	Res	Res
0	10	10		-	-	-	Y	Res	Res
0	10	11		-	-	Y	Y	Res	Res
1	00	01	Both	Y	Y	Y	-	-	Res
1	00	11		Y	Y	Y	Y	-	Res
1	01	01	Non-secure	-	Y	Y	-	Res	Res
1	01	11		-	Y	Y	Y	Res	Res
1	10	00	Secure	Y	-	-	-	Res	Res
1	10	01		Y	-	Y	-	Res	Res
1	10	11		Y	-	Y	Y	Res	Res
1	11	00	Non-secure	-	Y	-	-	Res	Res

a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at EL3 using AArch64.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See *Reserved DBGBCR<n>_EL1.{HMC, SSC, PMC} values* on page D2-1557.

D2.9.4 Instruction address comparisons

An address comparison is successful if bits [48:2] of the current instruction address are equal to DBGBVR<n>_EL1[48:2].

Note

DBGBVR<n>_EL1 is a 64-bit register. The most significant bits of this register are sign-extension bits. DBGBVR<n>_EL1[1:0] are RES0 and are ignored.

Specifying the halfword-aligned address that an Address breakpoint matches on

For Address Match breakpoints, if the implementation supports AArch32 state, a debugger can program the *Byte Address Selection* field, DBGBCR<n>_EL1.BAS, so that the address comparison is successful on one of:

- The whole word starting at address DBGBVR<n>_EL1[48:2]:00.
- The halfword starting at address DBGBVR<n>_EL1[48:2]:00.
- The halfword starting at address ((DBGBVR<n>_EL1[48:2]:00) + 2).

This makes it possible to breakpoint on T32 instructions.

If EL1 is using AArch64 and EL0 is using AArch32, A32 and T32 instructions can be executed in an AArch64 stage 1 translation regime. In this case, the instruction addresses are zero-extended before comparison with the breakpoint.

To breakpoint on an A64 instruction, ARM recommends that the debugger programs DBGBCR<n>_EL1.BAS so that the breakpoint generates Breakpoint exceptions on the whole word starting at address DBGBVR<n>_EL1[48:2]:00. The BAS field value for this is `0b1111`.

If the implementation is an AArch64-only implementation, all instructions are word-aligned and DBGBCR<n>_EL1.BAS is RES1.

Figure D2-3 shows a summary of when Address Match breakpoints programmed with particular BAS values generate Breakpoint exceptions. The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example, row 7 shows that a breakpoint with DBGBCR<n>_EL1.BAS programmed as either `0b0011` or `0b1111` generates Breakpoint exceptions for A64 instructions. A64 instructions are always at word-aligned addresses.

In the figure:

Yes Means that the breakpoint generates a Breakpoint exception.

No Means that the breakpoint does not generate a Breakpoint exception.

UNP Means that is it CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See *Other usage constraints for Address breakpoints* on page D2-1558.

	Instruction set	Size	Location of instruction[a] -2	-1	0	+1	+2	+3	+4	+5	BAS[3:0] 0b0011	0b1100	0b1111
Row 1	T32	16-bit			■	■					Yes	No	Yes
Row 2		16-bit					■	■			No	Yes	UNP
Row 3	T32	32-bit	■	■	■	■					UNP	No	UNP
Row 4		32-bit			■	■	■	■			Yes	UNP	Yes
Row 5		32-bit					■	■	■	■	No	Yes	UNP
Row 6	A32	32-bit			■	■	■	■			Yes	UNP	Yes
Row 7	A64	32-bit			■	■	■	■			Yes	UNP	Yes

a. 0 means the word-aligned address held in the DBGBVR<n>_EL1[48:2]:00. The other locations are as follows:
- -2 means ((DBGBVR<n>_EL1[48:2]:00) – 2).
- -1 means ((DBGBVR<n>_EL1[48:2]:00) – 1).
- ...
- ...
- +5 means ((DBGBVR<n>_EL1[48:2]:00) + 5).

The solid areas show the location of the instruction.

Figure D2-3 Summary of BAS field meanings for Address Match breakpoints

D2.9.5 Context comparisons

A context comparison is successful if, depending on the breakpoint type set by DBGBCR<n>_EL1.BT, one of the following is true:

- The current Context ID value is equal to DBGBVR<n>_EL1[31:0].
- The current VMID value is equal to DBGBVR<n>_EL1[39:32].
- The current Context ID value is equal to DBGBVR<n>_EL1[31:0], and the current VMID value is equal to DBGBVR<n>_EL1[39:32].

For all Context breakpoints, DBGBCR<n>_EL1.BAS is RES1 and is ignored.

In addition, for Linked Context breakpoints, DBGBCR<n>_EL1.{LBN, SSC, HMC, PMC} are RES0 and are ignored.

D2.9.6 Usage constraints

See the following:

- *Reserved DBGBCR<n>_EL1.BT values*.
- *Reserved DBGBCR<n>_EL1.{HMC, SSC, PMC} values* on page D2-1557.
- *Reserved DBGBCR<n>_EL1.BAS values* on page D2-1557.
- *Reserved DBGBCR<n>_EL1.LBN values* on page D2-1558.
- *Other usage constraints for Address breakpoints* on page D2-1558.
- *Other usage constraints for Context breakpoints* on page D2-1558.

Reserved DBGBCR<n>_EL1.BT values

Table D2-12 shows when particular DBGBCR<n>_EL1.BT values are reserved.

Table D2-12 Reserved BT values

BT value	Breakpoint type	Reserved
0b001x	Context ID Match	For non context-aware breakpoints.
0b010x	Address Mismatch	In an AArch64 stage 1 translation regime, or if EDSCR.HDE is 1 and halting is allowed.
0b011x	-	Always.
0b100x	VMID Match	For non context-aware breakpoints, or if EL2 is not implemented.
0b101x	Context ID and VMID Match	
0b11xx	-	Always.

If an enabled breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BT value that is not reserved, other than for a direct read of DBGBCR<n>_EL1.
- For a direct read of DBGBCR<n>_EL1, if the reserved BT value:
  - Has no function for any execution conditions, the value read back is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGBCR<n>_EL1.{HMC, SSC, PMC} values

Table D2-13 shows when particular combinations of DBGBCR<n>_EL1.{HMC, SSC, PMC} are reserved.

Table D2-13 Reserved HMC, SSC, and PMC combinations

HMC, SSC, and PMC combination	Reserved
All combinations with HMC set to 0, PMC set to `0b00`, and SSC not set to `0b011`.	In an AArch64 stage 1 translation regime.
All combinations with SSC set to `0b01` or `0b10`.	When EL3 is not implemented and EL2 is implemented.
Any combination where HMC or SSC is nonzero.	When both of EL2 and EL3 are not implemented.
Combinations not included in Table D2-11 on page D2-1554.	Always

For all breakpoints except Linked Context breakpoints, if an enabled breakpoint is programmed with one of these reserved combinations:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct read of DBGBCR<n>_EL1.
- For a direct read of DBGBCR<n>_EL1, if the reserved combination:
  - Has no function for any execution conditions, the value read back for each of HMC, SSC, and PMC is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the breakpoint functions for the other execution conditions.

Linked Context breakpoints ignore the values of HMC, SSC, and PMC. See *Other usage constraints for Context breakpoints* on page D2-1558.

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGBCR<n>_EL1.BAS values

In an AArch64-only implementation, DBGBCR<n>_EL1.BAS for all breakpoints is RES1.

Otherwise:

- For all Context breakpoints, DBGBCR<n>_EL1.BAS is RES1 and is ignored.
- For all Address breakpoints:
  - The BAS field values `0bxx01` and `0b01xx` are reserved. A breakpoint programmed with `0bxx01` or `0b01xx` must behave as if it is programmed with `0bxx11` or `0b11xx` respectively.
  - The BAS field values `0bxx10` and `0b10xx` are reserved. A breakpoint programmed with `0bxx10` or `0b10xx` must behave as if it is programmed with `0bxx00` or `0b00xx` respectively.
  - The BAS field value `0b0000` is reserved. A breakpoint programmed with `0b0000` must behave either as if it is disabled, or programmed with `0b0011`, `0b1100`, or `0b1111`.

Reserved DBGBCR<n>_EL1.LBN values

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any DBGBCR<n>_EL1.LBN value that is not for a context-aware breakpoint is reserved.

Other usage constraints for Address breakpoints

For all Address breakpoints:

- DBGBVR<n>_EL1[1:0] are RES0 and are ignored.
- If the implementation supports AArch32 state:
  - For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
  - If DBGBCR<n>.BAS is `0b1111`, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address ((DBGBVR<n>[48:2]:00) + 2). For T32 instructions, ARM recommends that the debugger programs the BAS field with either `0b0011` or `0b1100`.

For Unlinked Address breakpoints, DBGBCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

For Linked Address breakpoints:

- If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:
  - Disabled, and DBGBCR<n>_EL1.LBN for it reads UNKNOWN.
  - Links to an UNKNOWN context-aware breakpoint. In this case, it generates Breakpoint exceptions and DBGBCR<n>_EL1.LBN indicates which context-aware breakpoint it has linked to.
- If a Linked Address breakpoint links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

Other usage constraints for Context breakpoints

For all Context breakpoints:

- Any bits of DBGBVR<n>_EL1 that are not used to specify Context ID or VMID are RES0 and are ignored.
- DBGBCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

For Linked Context breakpoints:

- DBGBCR<n>_EL1.{LBN, SSC, HMC, PMC} are ignored.
- If no Linked Address breakpoints or Linked watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

D2.9.7 Exception syndrome information and preferred return address

See the following:

- *Exception syndrome information*.
- *Preferred return address* on page D2-1559.

Exception syndrome information

On taking a Breakpoint exception, the PE records information about the exception in the *Exception Syndrome Register* (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- ESR_EL1.
- ESR_EL2.

Note

Breakpoint exceptions cannot be taken to EL3 using AArch64.

Table D2-14 shows the information that the PE records.

Table D2-14 Information recorded in the ESR_ELx

ESR_ELx field	Information recorded in ESR_EL1 or ESR_EL2.	
Exception Class, EC	The PE sets this to: • `0x30`, if the exception was taken from a lower Exception level. • `0x31`, if the exceptions was taken without a change of Exception level.	
Instruction Length, IL	The PE sets this to 1.	
Instruction Specific Syndrome, ISS	**ISS[24:6]**	RES0.
	ISS[5:0]	*Instruction Fault Status Code* (IFSC). The PE sets this to the code for a debug exception, `0b100010`.

Preferred return address

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.9.8 Pseudocode descriptions of Breakpoint exceptions taken from AArch64 state

`AArch64.BreakpointValueMatch()` tests the value in DBGBVR<n>_EL1.

```
// AArch64.BreakpointValueMatch()
// ==============================

boolean AArch64.BreakpointValueMatch(integer n, bits(64) vaddress, boolean linked_to)

    // "n" is the identity of the breakpoint unit to match against
    // "vaddress" is the current instruction address, ignored if linked_to is TRUE and for Context
    //    matching breakpoints.
    // "linked_to" is TRUE if this is a call from StateMatch for linking.

    // If a non-existant breakpoint then it is CONSTRAINED UNPREDICTABLE whether this gives
    // no match or the breakpoint is mapped to another UNKNOWN implemented breakpoint.
    if n > UInt(ID_AA64DFR0_EL1.BRPs) then
        (c, n) = ConstrainUnpredictableInteger(0, UInt(ID_AA64DFR0_EL1.BRPs));
        assert c IN {Constraint_NONE, Constraint_UNKNOWN};
        if c == Constraint_NONE then return FALSE;

    // If this breakpoint is not enabled, it cannot generate a match. (This could also happen on a
    // call from StateMatch for linking.)
    if DBGBCR_EL1[n].E == '0' then return FALSE;

    context_aware = (n >= UInt(ID_AA64DFR0_EL1.BRPs) - UInt(ID_AA64DFR0_EL1.CTX_CMPs));

    // If BT is set to a reserved type, behaves either as disabled or as a not-reserved type.
    type = DBGBCR_EL1[n].BT;
    if (type == 'x1xx' ||                                          // Reserved
          (type != '0x0x' && !context_aware) ||                    // Context matching
          (type == '1xxx' && !HaveEL(EL2))) then                   // VMID match
        (c, type) = ConstrainUnpredictableBits();
        assert c IN {Constraint_NONE, Constraint_UNKNOWN};
        if c == Constraint_NONE then return FALSE;
        // Otherwise the value returned by ConstrainUnpredictableBits must be a not-reserved value
```

```
    // Determine what to compare against.
    match_addr = type == '0x0x';
    match_vmid = type == '10xx';
    match_cid  = type == 'x01x';
    linked     = type == 'xxx1';

    // If this is a call from StateMatch, return FALSE if the breakpoint is not programmed for a
    // VMID and/or context ID match, of if not context-aware. The above assertions mean that the
    // code can just test for match_addr == TRUE to confirm all these things.
    if linked_to && (!linked || match_addr) then return FALSE;

    // If this is a call from BreakpointMatch return FALSE for Linked context ID and/or VMID matches.
    if !linked_to && linked && !match_addr then return FALSE;

    // Do the comparison.
    if match_addr then
        byte = UInt(vaddress<1:0>);
        if HaveAnyAArch32() then
            // T32 instructions can be executed at EL0 in an AArch64 translation regime.
            assert byte IN {0,2};                 // "vaddress" is halfword aligned.
            byte_select_match = (DBGBCR_EL1[n].BAS<byte> == '1');
        else
            assert byte == 0;                     // "vaddress" is word aligned
            byte_select_match = TRUE;             // DBGBCR_EL1[n].BAS<byte> is RES1
        top = AddrTop(vaddress);
        BVR_match = vaddress<top:2> == DBGBVR_EL1[n]<top:2> && byte_select_match;
    elsif match_cid then
        BVR_match = (PSTATE.EL IN {EL0,EL1} && CONTEXTIDR_EL1 == DBGBVR_EL1[n]<31:0>);
    if match_vmid then
        vmid = VTTBR_EL2.VMID;
        BXVR_match = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} && vmid ==
DBGBVR_EL1[n]<39:32>);

    match = (!match_vmid || BXVR_match) && (!(match_addr || match_cid) || BVR_match);
    return match;
```

AArch64.StateMatch() tests the values in DBGBCR<n>_EL1.{SSC, HMC, PMC} and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

For a watchpoint, AArch64.StateMatch() tests the values in DBGWCR<n>_EL1.{SSC, HMC, PAC} and, if the watchpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

```
// AArch64.StateMatch()
// ====================
// Determine whether a breakpoint or watchpoint is enabled in the current mode and state.

boolean AArch64.StateMatch(bits(2) SSC, bit HMC, bits(2) PxC, boolean linked, bits(4) LBN,
                           boolean ispriv)
    // "SSC", "HMC", "PxC" are the control fields from the DBGBCR[n] or DBGWCR[n] register.
    // "LBN" is the linked breakpoint number from the DBGBCR[n] or DBGWCR[n] register.
    // "ispriv" is valid for watchpoints, and selects between privileged and unprivileged accesses.
    // "linked" is TRUE if this is a linked breakpoint/watchpoint type.

    // If parameters are set to a reserved type, behaves either as disabled or not a reserved-type

        // The above notwithstanding, if DBGBCR_EL1[n].BAS == '1111', then it is CONSTRAINED
        // UNPREDICTABLE whether or not a Breakpoint debug event is generated for an instruction
        // at the address DBGBVR_EL1[n]+2.
        if value_match then value_match = ConstrainUnpredictableBool();
```

```
    match = value_match && state_match && enabled;

    return match;
```

AArch64.CheckBreakpoint() generates a FaultRecord that AArch64.Abort raises a Breakpoint exception for if all of the following are true:

- MDSCR_EL1.MDE is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level and Security state* on page D2-1536.
- All of the conditions required for Breakpoint exception generation are met. See *About Breakpoint exceptions* on page D2-1546.

Note

AArch64.CheckBreakpoint() might halt the PE and cause it to enter Debug state. External debug uses Debug state.

```
// AArch64.CheckBreakpoint()
// =========================
// Called before executing the instruction of length "size" bytes at "vaddress" in an AArch64
// translation regime.
// The breakpoint can in fact be evaluated well ahead of execution, for example, at instruction
// fetch. This is the simple sequential execution of the program.

FaultRecord AArch64.CheckBreakpoint(bits(64) vaddress, integer size)
    assert !ELUsingAArch32(TranslationRegime());
    assert (UsingAArch32() && size IN {2,4}) || size == 4;

    match = FALSE;

    for i = 0 to UInt(ID_AA64DFR0_EL1.BRPs)
        match_i = AArch64.BreakpointMatch(i, vaddress, size);
        match = match || match_i;

    if match && HaltOnBreakpointOrWatchpoint() then
        reason = DebugHalt_Breakpoint;
        Halt(reason);
    elsif match && MDSCR_EL1.MDE == '1' && AArch64.GenerateDebugExceptions() then
        acctype = AccType_IFETCH;
        iswrite = FALSE;
        return AArch64.DebugFault(acctype, iswrite);
    else
        return AArch64.NoFault();
```

AArch64.BreakpointException() is called to generate a Breakpoint exception.

```
// AArch64.BreakpointException()
// =============================

AArch64.BreakpointException(FaultRecord fault)
    assert PSTATE.EL != EL3;

    route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                    (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1'));

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    vaddress = bits(64) UNKNOWN;
    exception = AArch64.AbortSyndrome(Exception_Breakpoint, fault, vaddress);
```

```
if PSTATE.EL == EL2 || route_to_el2 then
    AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
else
    AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
```

D2.10 Watchpoint exceptions

This section describes Watchpoint exceptions in an AArch64 stage 1 translation regime.

The PE is using an AArch64 stage 1 translation regime when it is executing at either:

- An Exception level that is using AArch64.
- EL0 using AArch32 when EL1 is using AArch64.

It contains the following subsections:

D2.10.1 About Watchpoint exceptions

A *watchpoint* is a debug event that results from the execution of an instruction, based on a data address. Watchpoints are also known as *data breakpoints*.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a *Watchpoint debug event* on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, ID_AA64DFR0_EL1.WRPs shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

- The *Watchpoint Control Register*, DBGWCR<n>_EL1. This contains controls for the watchpoint, for example an enable control.
- The *Watchpoint Value Register*, DBGWVR<n>_EL1. This holds the data address value used for watchpoint matching.

These registers are numbered, so that:

- DBGWCR1_EL1 and DBGWVR1_EL1 are for watchpoint number one.
- DBGWCR2_EL2 and DBGWVR2_EL1 are for watchpoint number two.
- …
- …
- DBGWCRn_EL1 and DBGWVRn_EL1 are for watchpoint number n.

A watchpoint can:

- Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
- Link to a *Linked Context breakpoint*, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.

A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the *Byte Address Select* field, DBGWCR<n>_EL1.BAS, to select the bytes. See *Programming a watchpoint with eight bytes or fewer* on page D2-1569.
- Eight bytes to 2GB, provided that both of the following are true:
  - The number of bytes is a power-of-two.
  - The range starts at an address that is aligned to the range size.

  A debugger uses the *MASK* field, DBGWCR<n>_EL1.MASK, to program a watchpoint with eight bytes to 2GB. See *Programming a watchpoint with eight or more bytes* on page D2-1570.

A debugger must use either the BAS field or the MASK field. If it uses both, whether the watchpoint generates Watchpoint debug events is CONSTRAINED UNPREDICTABLE. See *Programming dependencies of the BAS and MASK fields* on page D2-1573.

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, DBGWCR<n>_EL1.E, is 1.
- The conditions specified in the DBGWCR<n>_EL1 are met.
- The comparison with the address held in the DBGWVR<n>_EL1 is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint also are successful. See Figure D2-2 on page D2-1550. See also *Context comparisons* on page D2-1556.
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its condition code check.

Note

The debug logic tests all watchpoints before the execution of each instruction that initiates a memory access. The debug logic might test all watchpoints when data is fetched speculatively. However, a watchpoint does not generate a Watchpoint debug event unless the instruction that initiates the memory access passes its condition code check and is committed for execution.

If halting is allowed and EDSCR.HDE is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

Note

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.

However, the behavior described also applies if watchpoints are causing entry to Debug state.

The debug exception enable controls on page D2-1533 describes the enable controls for Watchpoint debug events.

D2.10.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case the watchpoint is called an *Unlinked watchpoint*.
- Enabled for linking to a Linked Context breakpoint. In this case the watchpoint is called a *Linked watchpoint*.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a *Linked VMID Match breakpoint*.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the VMID matches.

The *Watchpoint Type* field for a watchpoint, DBGWCR<n>_EL1.WT, controls whether the watchpoint is enabled for linking. If DBGWCR<n>_EL1.WT is 1, the watchpoint is enabled for linking.

Rules for linking watchpoints

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, DBGWCR<n>_EL1.LBN, for the Linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
  - DBGWCR<n>_EL1.WT.{SSC, HMC, PAC} for the Linked watchpoint defines the execution conditions that the watchpoint generates Watchpoint exceptions for. See *Execution conditions a watchpoint generates Watchpoint exceptions for*.
  - DBGBCR<n>_EL1.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.
- A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
- If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is CONSTRAINED UNPREDICTABLE. See *Usage constraints* on page D2-1572.
- If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.
- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

  Note

  Multiple Address breakpoints can also link to a single Linked Context breakpoint. *Breakpoint exceptions* on page D2-1546 describes breakpoints.

Figure D2-2 on page D2-1550 shows an example of permitted watchpoint linking.

D2.10.3 Execution conditions a watchpoint generates Watchpoint exceptions for

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only when the PE is executing at EL0 in Secure state.

DBGWCR<n>_EL1.{SSC, HMC, PAC} define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states. The comparison is made with the Security state of the PE, not the NS attribute of the physical instruction fetch address.

Higher Mode Control, HMC, and Privileged Access Control, PAC

HMC and PAC together control which Exception levels the watchpoint generates Watchpoint exceptions in.

Note

PAC controls which access privilege the watchpoint matches. This means that if the PE is executing an unprivileged load/store instruction at EL1 or higher, the data access might trigger a watchpoint that is programmed to match on EL0 accesses.

Table D2-15 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Exception levels watchpoints generate Watchpoint exceptions in.

In the table:

Y or - Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:

Y Can generate Watchpoint exceptions in that Exception level.

- Cannot generate Watchpoint exceptions in that Exception level.

Res Means that the combination of HMC, SSC, and PAC is reserved. See *Reserved DBGWCR<n>_EL1.{HMC, SSC, PAC} values* on page D2-1573.

Table D2-15 Summary of watchpoint HMC, SSC, and PAC encodings

HMC	SSC	PAC	Security state the watchpoint is programmed to match in	EL3[a]	EL2	EL1	EL0	Implementation	
								No EL3	No EL3 and no EL2
0	00	01	Both	-	-	Y	-	-	-
0	00	10		-	-	-	Y	-	-
0	00	11		-	-	Y	Y	-	-
0	01	01	Non-secure	-	-	Y	-	Res	Res
0	01	10		-	-	-	Y	Res	Res
0	01	11		-	-	Y	Y	Res	Res
0	10	01	Secure	-	-	Y	-	Res	Res
0	10	10		-	-	-	Y	Res	Res
0	10	11		-	-	Y	Y	Res	Res
1	00	01	Both	Y	Y	Y	-	-	Res
1	00	11		Y	Y	Y	Y	-	Res
1	01	01	Non-secure	-	Y	Y	-	Res	Res
1	01	11		-	Y	Y	Y	Res	Res
1	10	00	Secure	Y	-	-	-	Res	Res
1	10	01		Y	-	Y	-	Res	Res
1	10	11		Y	-	Y	Y	Res	Res
1	11	00	Non-secure	-	Y	-	-	-	Res

a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PAC are only relevant if watchpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Watchpoint exceptions at EL3 using AArch64.

All combinations of HMC, SSC, and PAC that this table does not show are reserved. See *Reserved DBGWCR<n>_EL1.{HMC, SSC, PAC} values* on page D2-1573.

D2.10.4 Data address comparisons

An address comparison is successful if bits [48:2] of the current data address are equal to DBGWVR<n>_EL1[48:2], taking into all of the following:

- The size of the access. See *Size of the data access*.

  If EL1 is using AArch64 and EL0 is using AArch32, AArch32 instructions can be executed in an AArch64 stage 1 translation regime. In this case, data addresses are zero-extended before comparison with the watchpoint.

- The bytes selected by DBGWVR<n>_EL1.BAS. See *Programming a watchpoint with eight bytes or fewer* on page D2-1569.

- Any address ranges indicated by DBGWVR<n>_EL1.MASK. See *Programming a watchpoint with eight or more bytes* on page D2-1570.

Note

- DBGWVR<n>_EL1 is a 64-bit register. The most significant bits of this register are sign-extension bits.
- DBGWVR<n>_EL1[1:0] are RES0 and are ignored

Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each data access must be taken into account. See Example D2-1.

Example D2-1 Why the size of each data access must be taken into account

1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address `0x1009` is accessed.
2. The PE accesses the unaligned doubleword starting at address `0x1003`.

In this scenario, the watchpoint must generate a Watchpoint exception.

The size of data accesses initiated by `DC ZVA` instructions is the DC ZVA block size that DCZID_EL0.BS defines.

The size of data accesses initiated by `DC IVAC` instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
  - The size that CTR_EL0.DminLine defines.
  - 2KB.
- A power-of-two.

For both of these instructions:

- The lowest address accessed by the instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.
- The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, *Watchpoint behavior on accesses by cache maintenance instructions* on page D2-1572.

Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, DBGWCR<n>_EL1.BAS, selects which bytes in the doubleword starting at the address contained in the DBGWVR<n>_EL1 the watchpoint generates Watchpoint exceptions for.

If the address programmed into the DBGWVR<n>_EL1 is:

- Doubleword-aligned:
  - All eight bits of DBGWCR<n>_EL1.BAS are used, and the descriptions given in Table D2-16 apply.
- Word-aligned but not doubleword-aligned:
  - Only DBGWCR<n>_EL1.BAS[3:0] are used, and the descriptions given in Table D2-17 apply. In this case, DBGWCR<n>_EL1.BAS[7:4] are RES0.

Table D2-16 Supported BAS values when the DBGWVRn_EL1 address alignment is doubleword

BAS value	Description
0b00000000	Watchpoint never generates a Watchpoint exception.
BAS[0] == 1	Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[48:3]:000 is accessed.
BAS[1] == 1	Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[48:3]:001 is accessed.
BAS[2] == 1	Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[48:3]:010 is accessed.
BAS[3] == 1	Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[48:3]:011 is accessed.
BAS[4] == 1	Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[48:3]:100 is accessed.
BAS[5] == 1	Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[48:3]:101 is accessed.
BAS[6] == 1	Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[48:3]:110 is accessed.
BAS[7] == 1	Generates a Watchpoint exception if the byte at address DBGWVR<n>_EL1[48:3]:111 is accessed.

Table D2-17 Supported BAS values when the DBGWVRn_EL1 address alignment is word

BAS value[a]	Description
0b00000000	Watchpoint never generates a Watchpoint exception
BAS[0] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>_EL1[48:2]:00 is accessed.
BAS[1] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>_EL1[48:2]:01 is accessed.
BAS[2] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>_EL1[48:2]:10 is accessed.
BAS[3] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>_EL1[48:2]:11 is accessed.

a. DBGWCR<n>_EL1.BAS[7:4] are RES0.

If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see *Other usage constraints* on page D2-1574.

When programming the BAS field with anything other than 0b11111111, a debugger must program DBGWCR<n>_EL1.MASK to be 0b00000. See *Programming dependencies of the BAS and MASK fields* on page D2-1573.

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.

- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the DBGWVR<n>_EL1[48:3]. See Example D2-1 on page D2-1568.

The following are some example configurations of the BAS field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address `0x1003`, program:
  - DBGWVR<n>_EL1 with `0x1000`.
  - DBGWCR<n>_EL1.BAS to be `0b00001000`.
- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses `0x2003`, `0x2004` and `0x2005`, program:
  - DBGWVR<n>_EL1 with `0x2000`.
  - DBGWCR<n>_EL1.BAS to be `0b00111000`.
- If the address programmed into the DBGWVR<n>_EL1 is doubleword-aligned:
  - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program DBGWCR<n>_EL1.BAS to be `0b00001111`.
  - To generate a Watchpoint exception when any byte in the word starting at address DBGWVR<n>_EL1[31:3]:100 is accessed, program DBGWCR<n>_EL1.BAS to be `0b11110000`.

Note

ARM deprecates programming a DBGWVR<n>_EL1 with an address that is not doubleword-aligned.

Programming a watchpoint with eight or more bytes

A debugger can use the *MASK* field, DBGWCR<n>_EL1.MASK, to program a single watchpoint with a data address range. The range must meet all of the following criteria:

- It is a size that is both:
  - A power-of-two.
  - Eight bytes to 2GB.
- It starts at an address that is aligned to the size.

The MASK field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

MASK	`0b00000`	No bits are masked.
	`0b00001`	Reserved.
	`0b00010`	Reserved.
	`0b00011`	Three least significant bits are masked.
	`0b00100`	Four least significant bits are masked.
	`0b00101`	Five least significant bits are masked.
	…	…
	`0b11111`	31 least significant bits are masked.

If *n* least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address DBGWVR<n>_EL1[48:*n*]:000…
- Address DBGWVR<n>_EL1[48:*n*]:111…
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between DBGWVR<n>_EL1[48:4]:0000 and DBGWVR<n>_EL1[48:4]:1111, including these addresses.

Note

- The 17 most significant bits cannot be masked. This means that the full address cannot be masked.
- For watchpoint behavior when its MASK field is programmed with a reserved value, see *Reserved DBGWCR<n>_EL1.MASK values* on page D2-1574.

When masking address bits, a debugger must both:

- Program DBGWCR<n>_EL1.BAS to be `0b11111111`. See *Programming dependencies of the BAS and MASK fields* on page D2-1573.
- In the DBGWVR<n>_EL1, set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see *Other usage constraints* on page D2-1574.

D2.10.5 Determining the memory location that caused a Watchpoint exception

On taking a Watchpoint exception, the PE records an address in a *Fault Address Register* that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- FAR_EL1, if the exception is taken to EL1.
- FAR_EL2, if the exception is taken to EL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the EDWAR.

For more information, see the subsections that follow. These are:

- *Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions*
- *Address recorded for Watchpoint exceptions generated by Data Cache instructions* on page D2-1572

Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions

The address recorded must be both:

- From the inclusive range between:
  - The lowest address accessed by the memory access that triggered the watchpoint.
  - The highest *watchpointed address* accessed by the memory access. A watchpointed address is an address that the watchpoint is watching.
- Within a naturally-aligned block of memory that is all of the following:
  - A power-of-two size.
  - No larger than the `DC ZVA` block size.
  - Contains a watchpointed address accessed by the memory access.

  The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

Example D2-2 Address recorded for a watchpoint programmed on `0x8019`

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte `0x8019`.

An A32 load multiple instruction then loads nine registers starting from address `0x8004` upwards. This triggers the watchpoint.

If the `DC ZVA` block size is:

- 32 bytes, the address that the PE records must be between `0x8004` and `0x8019` inclusive.

- 16 bytes, the address that the PE records must be between `0x8010` and `0x8019` inclusive.

Address recorded for Watchpoint exceptions generated by Data Cache instructions

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.

D2.10.6 Watchpoint behavior on instructions other than Load/Store instructions

See the following:

- *Watchpoint behavior on accesses by prefetch instructions*.
- *Watchpoint behavior on accesses by Store-Exclusive instructions*.
- *Watchpoint behavior on accesses by cache maintenance instructions*.

Watchpoint behavior on accesses by prefetch instructions

Memory prefetch instructions never cause Watchpoint exceptions.

Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the write to memory is successful, the watchpoint generates a Watchpoint exception.
- If the write to memory fails because the Store-Exclusive instruction does not have possession of the exclusive monitors, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.

Watchpoint behavior on accesses by cache maintenance instructions

`DC IVAC` and `DC ZVA` operations are treated as data stores. This means that for a watchpoint to match on an access caused by one of these instructions, the debugger must program DBGWCR<n>_EL1.LSC to be one of the following:

10 Match on data stores only.
11 Match on data stores and data loads.

No other data cache maintenance instructions can generate Watchpoint exceptions.

Instruction cache maintenance instructions never generate Watchpoint exceptions.

Note

For the size of data accesses performed by cache maintenance instructions, see *Data address comparisons* on page D2-1568. The size of all data accesses must be considered because watchpoints can be programmed to match only on particular address bytes.

D2.10.7 Usage constraints

See the following:

- *Reserved DBGWCR<n>_EL1.{HMC, SSC, PAC} values* on page D2-1573.
- *Reserved DBGWCR<n>_EL1.LBN values* on page D2-1573.
- *Programming dependencies of the BAS and MASK fields* on page D2-1573.
- *Reserved DBGWCR<n>_EL1.BAS values* on page D2-1574.
- *Reserved DBGWCR<n>_EL1.MASK values* on page D2-1574.
- *Other usage constraints* on page D2-1574.

Reserved DBGWCR<n>_EL1.{HMC, SSC, PAC} values

Table D2-18 shows when particular combinations of DBGWCR<n>_EL1.{HMC, SSC, PAC} are reserved.

Table D2-18 Reserved HMC, SSC, and PAC combinations

HMC, SSC, and PMC combination	Reserved
All combinations with SSC set to `0b01` or `0b10`.	When EL3 is not implemented and EL2 is implemented.
All combinations where HMC or SSC is nonzero.	When both of EL2 and EL3 are not implemented.
Combinations not included in Table D2-15 on page D2-1567.	Always

If an enabled watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct read of DBGWCR<n>_EL1.
- For a direct read of DBGWCR<n>_EL1, if the reserved combination:
  - Has no function for any execution conditions, the value read back for each of HMC, SSC, and PMC is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of HMC, SSC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGWCR<n>_EL1.LBN values

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any DBGWCR<n>_EL1.LBN value that is not for a context-aware breakpoint is reserved.

Programming dependencies of the BAS and MASK fields

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the DBGWVR<n>_EL1 the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be `0b11111111`, so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be `0b00000`, so that the MASK field does not indicate any address ranges.

If the debugger uses both of these fields, behavior of the watchpoint is CONSTRAINED UNPREDICTABLE. Either:

- The watchpoint treats the MASK field as if it is programmed with `0b00000`. In this case, the watchpoint is programmed with a single address and it generates Watchpoint exceptions for the bytes that the BAS field indicates.
- For each byte in the masked region, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception.

Reserved DBGWCR<n>_EL1.BAS values

If DBGWVR<n>_EL1[2] is 1, DBGWCR<n>_EL1.BAS[7:4] are RES0 and are ignored.

Reserved DBGWCR<n>_EL1.MASK values

If DBGWCR<n>_EL1.MASK is programmed with a reserved value, the watchpoint must behave as if it is either:

- Disabled.
- Programmed with an UNKNOWN value that is not reserved, that might be `0b00000`.

Other usage constraints

For all watchpoints:

- DBGWVR<n>_EL1[1:0] are RES0 and are ignored.
- If DBGWCR<n>_EL1.BAS is programmed with non-contiguous bytes of memory, it is CONSTRAINED UNPREDICTABLE whether the Watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the DBGWCR<n>_EL1.
- If DBGWCR<n>_EL1.MASK is non-zero, and any masked bits of DBGWVR<n>_EL1 are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if DBGWCR<n>_EL1.LSC is `0b00`.

For Unlinked watchpoints, DBGWCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

For Linked watchpoints:

- If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, behavior is CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:
  - Disabled, and DBGWCR<n>_EL1.LBN for it reads UNKNOWN.
  - Links to an UNKNOWN context-aware breakpoint. In this case, it generates Watchpoint exceptions and DBGWCR<n>_EL1.LBN indicates which context-aware breakpoint it has linked to.
- If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

D2.10.8 Exception syndrome information and preferred return address

See the following:

- *Exception syndrome information*.
- *Preferred return address* on page D2-1575.

Exception syndrome information

On taking a Watchpoint exception, the PE records all of the following:

- Information about the exception in the *Exception Syndrome Register* (ESR) at the Exception level the exception is taken to.
- An address that the debugger can use to determine the memory location that caused the exception. The PE records this in a *Fault Address Register* (FAR).

The ESR and FAR used is either:

- ESR_EL1 and FAR_EL1, if the exception is taken to EL1.
- ESR_EL2 and FAR_EL2, if the exception is taken to EL2.

Note

Watchpoint exceptions cannot be taken to EL3 using AArch64.

Table D2-19 shows the recorded information.

Table D2-19 Information recorded in the ESR_ELx

ESR_ELx field	Information recorded in ESR_EL1 or ESR_EL2	
Exception Class, EC	This is set to: • `0x34`, if the exception was taken from a lower Exception level. • `0x35`, if the exception was taken without a change of Exception level.	
Instruction Length, IL	This is set to 1.	
Instruction Specific Syndrome, ISS	**ISS[24]**	*Instruction Syndrome Valid* (ISV). This is 0, because Watchpoint exceptions are not stage 2 aborts.
	ISS[23:9]	RES0.
	ISS[8]	*Cache Maintenance* (CM). This indicates whether a cache maintenance instruction generated the exception: **0** Not generated by a cache maintenance instruction. **1** Generated by a cache maintenance instruction. If a `DC ZVA` instruction generated the exception, CM is 0.
	ISS[7]	RES0.
	ISS[6]	*Write-not-Read* (WnR). This indicates whether the access was by a read instruction or a write instruction: **0** Read instruction. **1** Write instruction.
	ISS[5:0]	*Data Fault Status Code* (DFSC). The PE sets this to the code for a debug exception, `0b100010`.

Preferred return address

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.10.9 Pseudocode description of Watchpoint exceptions taken from AArch64 state

`AArch64.WatchpointByteMatch()` tests an individual byte accessed by an operation.

```
// AArch64.WatchpointByteMatch()
// =============================

boolean AArch64.WatchpointByteMatch(integer n, bits(64) vaddress)

    top = AddrTop(vaddress);
    bottom = if DBGWVR_EL1[n]<2> == '1' then 2 else 3;
    byte_select_match = (DBGWCR_EL1[n].BAS<UInt(vaddress<bottom-1:0>)> != '0');
    mask = UInt(DBGWCR_EL1[n].MASK);

    // If the address mask is set to a reserved value, the behavior is CONSTRAINED UNPREDICTABLE.
    if mask <= 2 then
        if ConstrainUnpredictableBool() then return FALSE;            // Disabled
        else (-, mask) = ConstrainUnpredictableInteger(bottom, 31); // Map to a not reserved value

    // If masked bits of DBGWVR_EL1[n] are not zero, the behavior is CONSTRAINED UNPREDICTABLE.
    if mask > bottom then
        WVR_match = (vaddress<top:mask> == DBGWVR_EL1[n]<top:mask> &&
```

```
                    (IsZero(DBGWVR_EL1[n]<mask-1:bottom>) || ConstrainUnpredictableBool()));
    else
        WVR_match = vaddress<top:bottom> == DBGWVR_EL1[n]<top:bottom>;

    // If DBGWCR_EL1[n].MASK is non-zero value and DBGWCR_EL1[n].BAS is not set to '11111111', the
    // behavior is CONSTRAINED UNPREDICTABLE.
    if !IsZero(DBGWCR_EL1[n].MASK) && !IsOnes(DBGWCR_EL1[n].BAS) then
        c = ConstrainUnpredictable();
        case c of
            when Constraint_IGNOREMASK
                WVR_match = vaddress<top:bottom> == DBGWVR_EL1[n]<top:bottom>;
            when Constraint_IGNOREBAS
                byte_select_match = TRUE;
            when Constraint_REPEATBAS
                /*do nothing*/
            otherwise  Unreachable();
    else
        // If DBGWCR_EL1[n].BAS specifies a non-contiguous set of bytes, the generation of
        // Watchpoint debug events for the doubleword is CONSTRAINED UNPREDICTABLE.
        LSB = (DBGWCR_EL1[n].BAS AND NOT(DBGWCR_EL1[n].BAS - 1));  MSB = (DBGWCR_EL1[n].BAS + LSB);
        if !IsZero(MSB AND (MSB - 1)) && vaddress<top:3> == DBGWVR_EL1[n]<top:3> then
            byte_select_match = ConstrainUnpredictableBool();

    return WVR_match && byte_select_match;
```

`AArch64.StateMatch()` tests the values in DBGWCR<n>_EL1.{HMC, SSC, PAC}, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to. `AArch64.StateMatch()` is given in the Breakpoint exceptions section. See page D2-1560.

`AArch64.WatchpointMatch()` tests the value in DBGWVR<n>_EL1.

```
// AArch64.WatchpointMatch()
// =========================
// Watchpoint matching in an AArch64 translation regime.

boolean AArch64.WatchpointMatch(integer n, bits(64) vaddress, integer size, boolean ispriv,
                                boolean iswrite)
    assert !ELUsingAArch32(TranslationRegime());
    assert n <= UInt(ID_AA64DFR0_EL1.WRPs);

    // "ispriv" is FALSE for LDTR/STTR instructions executed at EL1 and all
    // load/stores at EL0, TRUE for all other load/stores. "iswrite" is TRUE for stores, FALSE for
    // loads.
    enabled = DBGWCR_EL1[n].E == '1';
    linked = DBGWCR_EL1[n].WT == '1';

    state_match = AArch64.StateMatch(DBGWCR_EL1[n].SSC, DBGWCR_EL1[n].HMC, DBGWCR_EL1[n].PAC,
                                     linked, DBGWCR_EL1[n].LBN, ispriv);

    ls_match = (DBGWCR_EL1[n].LSC<(if iswrite then 1 else 0)> == '1');

    value_match = FALSE;
    for byte = 0 to size - 1
        value_match = value_match || AArch64.WatchpointByteMatch(n, vaddress + byte);

    return value_match && state_match && ls_match && enabled;
```

`AArch64.CheckWatchpoint()` generates a FaultRecord that `AArch64.Abort` raises a Watchpoint exception for if all of the following are true:

- MDSCR_EL1.MDE is 1.

- Debug exceptions are enabled from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level and Security state* on page D2-1536.
- All of the conditions required for Watchpoint exception generation are met. See *About Watchpoint exceptions* on page D2-1564.

Note

`AArch64.CheckWatchpoint()` might halt the PE and cause it to enter Debug state. External debug uses Debug state.

```
// AArch64.CheckWatchpoint()
// =========================
// Called before accessing the memory location of “size” bytes at “address”.

FaultRecord AArch64.CheckWatchpoint(bits(64) vaddress, AccType acctype,
                                    boolean iswrite, integer size)
    assert !ELUsingAArch32(TranslationRegime());

    match = FALSE;
    ispriv = PSTATE.EL != EL0 && !(PSTATE.EL == EL1 && acctype == AccType_UNPRIV);

    for i = 0 to UInt(ID_AA64DFR0_EL1.WRPs)
        match = match || AArch64.WatchpointMatch(i, vaddress, size, ispriv, iswrite);

    if match && HaltOnBreakpointOrWatchpoint() then
        reason = DebugHalt_Watchpoint;
        Halt(reason);
    elsif match && MDSCR_EL1.MDE == ‘1’ && AArch64.GenerateDebugExceptions() then
        return AArch64.DebugFault(acctype, iswrite);
    else
        return AArch64.NoFault();
```

`AArch32.WatchpointExeption()` is called to generate a Watchpoint exception.

```
// AArch64.WatchpointException()
// =============================

AArch64.WatchpointException(bits(64) vaddress, FaultRecord fault)
    assert PSTATE.EL != EL3;

    route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                    (HCR_EL2.TGE == ‘1’ || MDCR_EL2.TDE == ‘1’));

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    exception = AArch64.AbortSyndrome(Exception_Watchpoint, fault, vaddress);

    if PSTATE.EL == EL2 || route_to_el2 then
        AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
        AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
```

D2.11 Vector Catch exceptions

Vector Catch exceptions are not generated in AArch64 stage 1 translation regimes.

Note

This means that they are only supported if at least EL1 using AArch32 is supported.

A debugger that is executing in EL2 using AArch64 can route Vector Catch exceptions to EL2 using AArch64, by setting MDCR_EL2.TDE to 1. See *Routing debug exceptions* on page D2-1534.

`AArch64.VectorCatchException()` is called to generate a Vector Catch exception:

```
// AArch64.VectorCatchException()
// ==============================
// Vector Catch taken from EL0 or EL1 to EL2. This can only be called when debug exceptions are
// being routed to EL2, as Vector Catch is a legacy debug event.

AArch64.VectorCatchException(FaultRecord fault)
    assert PSTATE.EL != EL2;
    assert HaveEL(EL2) && !IsSecure() && (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1');

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    vaddress = bits(64) UNKNOWN;
    exception = AArch64.AbortSyndrome(Exception_VectorCatch, fault, vaddress);

    AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
```

Vector Catch exceptions on page G2-3564 describes Vector Catch exceptions.

D2.12 Software Step exceptions

The following subsections describe Software Step exceptions:

D2.12.1 About Software Step exceptions

Software step is an ARMv8-A resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can single-step instructions at a lower Exception level.

Operation is as follows:

1. A debugger:
   a. Enables software step by setting MDSCR_EL1.SS to 1. See *The debug exception enable controls* on page D2-1533.
   b. Executes an exception return instruction, `ERET`, to branch to the instruction to be single-stepped in the software being debugged.
2. The PE then:
   a. Executes the instruction to be single-stepped.
   b. Takes a Software Step exception on the next instruction, returning control to the debugger.

The PE can only take a Software Step exception if debug exceptions are enabled from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level and Security state* on page D2-1536.

A state machine describes the behavior of software step, shown in *The software step state machine*.

Note

In the remainder of this Software Step exceptions section, including in all subsections, EL_D is used to mean the Exception level that Software Step exceptions are targeting. *Routing debug exceptions* on page D2-1534 defines EL_D as the *debug target Exception level*.

D2.12.2 Rules for setting MDSCR_EL1.SS to 1

Debugger software must be executing in an Exception level and Security state that debug exceptions are disabled from when it sets MDSCR_EL1.SS to 1.

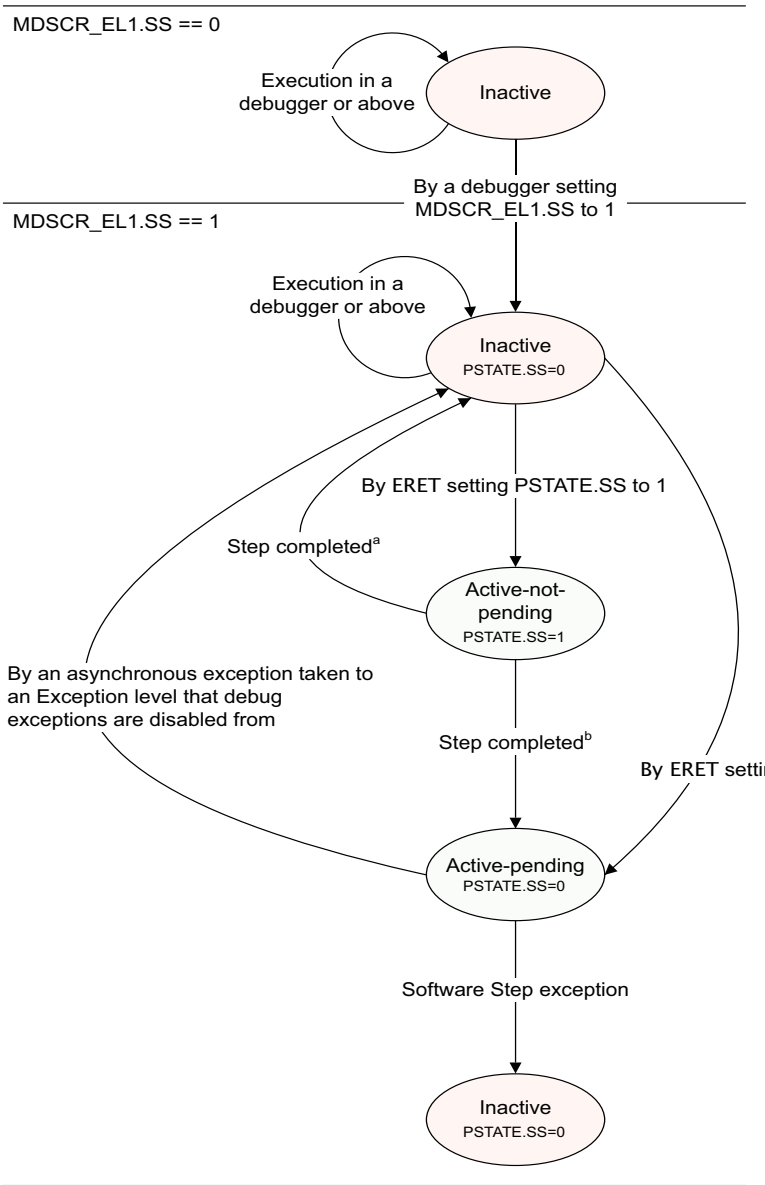
The Exception level that hosts the debugger software must be using AArch64.

D2.12.3 The software step state machine

In the following figure:

- The OS Lock is unlocked and EDPRSR.DLK is 0.

- The PE is not in Secure state with MDCR_EL3.SDD set to 1. That is, the PE is in Non-secure state, or is in Secure state with MDCR_EL3.SDD set to 0, or the implementation does not include EL3.



Execution is at either:
- An Exception level that is higher than EL_D.
- EL_D with (PSTATE.D == 1 || MDSCR_EL1.KDE == 0).

This is termed *execution in a debugger or above*.

To make the PE single-step an instruction, the debugger:
1. Sets SPSR_ELx.SS to 1.
2. Programs the ELR_ELx to point to the instruction to be stepped.
3. Executes an ERET instruction.

Execution is in the software being debugged, at either:
- An Exception level that is lower than EL_D.
- EL_D with (PSTATE.D == 0 && MDSCR_EL1.KDE == 1).

Execution is in the software being debugged, at either:
- An Exception level that is lower than EL_D.
- EL_D with (PSTATE.D == 0 && MDSCR_EL1.KDE == 1).

A Software Step exception is pending.

Execution has returned to the debugger.

a. The step is the PE either:
- Taking an exception to an Exception level that debug exceptions are disabled from.
- If execution is at EL_D with MDSCR_EL1.KDE == 1, executing an instruction that sets PSTATE.D to 1.

Software step is inactive when debug exceptions are disabled from the current Exception level, and debug exceptions are disabled from EL_D when PSTATE.D is 1.

b. The step is the PE either:
- Executing the instruction to be stepped without taking an exception.
- Taking an exception to an Exception level that debug exceptions are enabled from. The Exception level might be using AArch64 or AArch32.

c. Or, if execution is at EL_D with MDSCR_EL1.KDE == 1, by software setting PSTATE.D to 0.

Figure D2-4 Software step state machine

For a description of when debug exceptions are enabled or disabled from an Exception level, see *Enabling debug exceptions from the current Exception level and Security state* on page D2-1536.

For more information about how a step is completed, see *Behavior in the active-not-pending state* on page D2-1585.

The software step states are:

Inactive Software step is inactive. It cannot generate any Software Step exceptions or affect PE execution. Software step is inactive whenever any of the following are true:

- MDSCR_EL1.SS is 0.
- EL_D is using AArch32.
- Debug exceptions are disabled from the current Exception level or Security state.

Active-not-pending

None of the conditions mentioned in *Inactive* are true, therefore software step is active.

The current instruction is the instruction to be stepped.

Active-pending

None of the conditions mentioned in *Inactive* are true, therefore software step is active.

A Software Step exception is pending on the current instruction.

Whenever software step is active, whether the state machine is in the active-not pending state or the active-pending state depends on PSTATE.SS. Table D2-20 shows this.

Table D2-20 State machine states

MDSCR_EL1.SS	EL_D is using:	Debug exceptions enabled or disabled from the current Exception level and Security state	PSTATE.SS	State
0	X	X	X	Inactive
1	AArch32	X	X	Inactive
1	AArch64	Disabled	X	Inactive
1	AArch64	Enabled	1	Active-not-pending
1	AArch64	Enabled	0	Active-pending

D2.12.4 Entering the active-not-pending state

Software step can only enter the active-not-pending state when an ERET instruction writes 1 to PSTATE.SS, by copying from SPSR_ELx.SS when it restores PSTATE.

However, an ERET only copies 1 from SPSR_ELx.SS to PSTATE.SS if all of the following are true:

- MDSCR_EL1.SS is 1.
- EL_D is using AArch64.
- Debug exceptions are disabled from the current Exception level.
- Debug exceptions are enabled from the Exception level that the ERET instruction targets.

Otherwise, ERET instructions set PSTATE.SS to 0, regardless of the value of SPSR_ELx.SS.

Table D2-21 on page D2-1582 shows this. In the table:

Lock Means the value of (OSLSR_EL1.OSLK OR EDPRSR.DLK).

NS Is SCR_EL3.NS.

SDD Is MDCR_EL3.SDD. See *Enabling debug exceptions from the current Security state* on page D2-1537.

TDE Is MDCR_EL2.TDE. See *Routing debug exceptions* on page D2-1534.

Table D2-21 Value an ERET writes to PSTATE.SS

MDSCR_EL1.SS	Lock	NS	SDD	TDE	EL1 is using	EL2 is using	Value an ERET writes to PSTATE.SS
0	X	X	X	X	X	X	0
1	1	X	X	X	X	X	0
	0	0	1	X	X	n/a	0
			0	X	AArch32	n/a	0
					AArch64	n/a	See Table D2-22 on page D2-1583
		1	X	0	AArch32	X	0
					AArch64	AArch64	See Table D2-22 on page D2-1583
				1	AArch32	AArch32	0
					X	AArch64	See Table D2-23 on page D2-1584

For:

- SCR_EL3.NS == 0 or MDCR_EL3.TDE == 0, and EL1 using AArch64, so that EL_D is EL1 using AArch64, Table D2-22 on page D2-1583 shows the value an ERET writes to PSTATE.SS.
- SCR_EL3.NS == 1 and MDCR_EL3.TDE == 1 and EL2 using AArch64, so that EL_D is EL2 using AArch64, Table D2-23 on page D2-1584 shows the value an ERET writes to PSTATE.SS.

In both tables:

From EL Means the Exception level that the PE executes the ERET at.

Target EL Is the target Exception level of the ERET.

Note

If the ERET is an illegal exception return, the target Exception level of the ERET is the current Exception level. See *Illegal return events* on page D1-1438.

KDE Is MDSCR_EL1.KDE. See *Enabling debug exceptions from the current Exception level* on page D2-1536.

Table D2-22 Value an ERET writes to PSTATE.SS if EL_D is EL1 using AArch64

From EL	Target EL	KDE	PSTATE.D	SPSR_ELx.D	Software Step exceptions are enabled or disabled		Value an ERET writes to PSTATE.SS
					From EL	Target EL	
EL3	EL3	X	X	X	Disabled	Disabled	0
	EL2	X	X	X	Disabled	Disabled	0
	EL1	0	X	X	Disabled	Disabled	0
		1	X	1	Disabled	Disabled	0
				0	Disabled	Enabled	SPSR_EL3.SS
	EL0	X	X	X	Disabled	Enabled	SPSR_EL3.SS
EL2	EL2	X	X	X	Disabled	Disabled	0
	EL1	0	X	X	Disabled	Disabled	0
		1	X	1	Disabled	Disabled	0
				0	Disabled	Enabled	SPSR_EL2.SS
	EL0	X	X	X	Disabled	Enabled	SPSR_EL2.SS
EL1	EL1	0	X	X	Disabled	Disabled	0
		1	0	X	Enabled[a]	-[b]	0
			1	1	Disabled	Disabled	0
				0	Disabled	Enabled	SPSR_EL1.SS
	EL0	0	X	X	Disabled	Enabled	SPSR_EL1.SS
		1	0	X	Enabled[a]	Enabled	0
			1	X	Disabled	Enabled	SPSR_EL1.SS

a. Because MDSCR_EL1.SS == 1, it means that the ERET is itself being stepped.
b. Depends on SPSR_EL1.D.

Table D2-23 Value an ERET writes to PSTATE.SS if EL_D is EL2 using AArch64

From EL	Target EL	KDE	PSTATE.D	SPSR_ELx.D	Software Step exceptions are enabled or disabled		Value an ERET writes to PSTATE.SS
					From EL	Target EL	
EL3	EL3	X	X	X	Disabled	Disabled	0
	EL2	0	X	X	Disabled	Disabled	0
		1	X	1	Disabled	Disabled	0
				0	Disabled	Enabled	SPSR_EL3.SS
	EL1	X	X	X	Disabled	Enabled	SPSR_EL3.SS
	EL0	X	X	X	Disabled	Enabled	SPSR_EL3.SS
EL2	EL2	0	X	X	Disabled	Disabled	0
		1	0	X	Enabled[a]	-[b]	0
			1	1	Disabled	Disabled	0
				0	Disabled	Enabled	SPSR_EL2.SS
	EL1	0	X	X	Disabled	Enabled	SPSR_EL2.SS
		1	0	X	Enabled[a]	Enabled	0
			1	X	Disabled	Enabled	SPSR_EL2.SS
	EL0	0	X	X	Disabled	Enabled	SPSR_EL2.SS
		1	0	X	Enabled[a]	Enabled	0
			1	X	Disabled	Enabled	SPSR_EL2.SS
EL1	EL1	X	X	X	Enabled[a]	Enabled	0
	EL0	X	X	X	Enabled[a]	Enabled	0

a. Because MDSCR_EL1.SS == 1, it means that the ERET is itself being stepped.
b. Depends on SPSR_EL2.D.

Note

No AArch32 instruction that can update the CPSR can set PSTATE.SS to 1.

D2.12.5 Behavior in the active-not-pending state

In this state, the PE either:

- Executes the instruction to be stepped and either:
  - Completes it without taking a synchronous exception.
  - Takes a synchronous exception if the instruction generates one.
- Takes an asynchronous exception without executing any instructions.

If the PE takes either a synchronous or an asynchronous exception, behavior is as described in one of the following:

- *If the PE takes an exception to an Exception level that is using AArch64*.
- *If the PE takes an exception to an Exception level that is using AArch32*.

If the PE executes the instruction without taking any exceptions, then after it has executed the instruction, it sets PSTATE.SS to 0 and software step advances to the active-pending state. See *Behavior in the active-pending state* on page D2-1587.

If the PE takes an exception to an Exception level that is using AArch64

As part of exception entry, the PE does all of the following:

- Sets SPSR_ELx.SS to 0 or 1, depending on the exception. See Table D2-24.
- Sets PSTATE.SS to 0. This causes software step to enter either the active-pending state or the inactive state, depending on whether debug exceptions are enabled or disabled from the Exception level that the exception is taken to:

  Enabled Software step enters the active-pending state.

  Disabled Software step enters the inactive state.

  In either case, on taking the exception, a step is complete.
- Sets PSTATE.D to 1.

Table D2-24 Categorization of exceptions, for setting SPSR_ELx.SS to 0 or 1

Exception description	Exceptions	SPSR_ELx.SS
Exceptions whose preferred return address is for the instruction that follows the instruction to be stepped.	Supervisor Call (SVC) exceptions. Hypervisor Call (HVC) exceptions. Secure Monitor Call (SMC) exceptions.	0
Exceptions whose preferred return address is the address of the instruction to be stepped.	All other synchronous exceptions, and asynchronous exceptions that are taken before the instruction to be stepped.	1

If the PE takes an exception to an Exception level that is using AArch32

This can only happen when all of the following is true:

- EL2 is implemented and is using AArch64, the PE is executing in Non-secure state, and MDCR_EL2.TDE is 1. Because MDCR_EL2.TDE is 1, EL_D is EL2.
- The exception is taken to Non-secure EL1 using AArch32.

As part of exception entry, the PE sets PSTATE.SS to 0. This causes software step to enter the active-pending state.

Note

- Software step always enters the active-pending state because the exception is taken to an Exception level that debug exceptions are enabled from, EL1. Debug exceptions are enabled from EL1 because EL_D is EL2, and debug exceptions are always enabled from Exception levels that are lower than EL_D.
- AArch32 SPSRs have no SS bit. Where an SPSR_ELx register architecturally maps to an AArch32 SPSR_<mode> register, SPSR_ELx.SS maps to SPSR_<mode>[21].

  SPSR_<mode>[21] is always RES0. The PE always sets SPSR_<mode>[21] to 0 on taking an exception to an Exception level that is using AArch32.

Summary of behavior in the active-not-pending state

Table D2-25 summarizes behavior in the active-not-pending state.

Table D2-25 Summary of behavior in the active-not-pending state

Event	Value written to PSTATE.SS	Execution state of the target Exception level	Exception type	Value written to SPSR_ELx.SS	Next state
No exception	0	n/a	n/a	n/a	Active-pending
Exception	0	AArch64	Supervisor Call (SVC) Hypervisor Call (HVC) Secure Monitor Call (SMC)	0	Active-pending or inactive[a]
			Other	1	
		AArch32	All	0[b]	Active-pending

a. Which state software step enters depends on whether debug exceptions are enabled or disabled from the target Exception level. See Figure D2-4 on page D2-1580.

b. SPSR_<mode>[21] is RES0.

D2.12.6 Entering the active-pending state

Software step enters the active-pending state after any of the following operations, provided that both:

- MDSCR_EL1.SS is 1.
- Debug exceptions are enabled from the Exception level and Security state that execution is in after the operation.

The operations are:

While software step is in the active-not-pending state

The PE either:

- Executing the instruction to be stepped without taking any exceptions.
- Taking an exception.

Note

If entry to the active-pending state is because of the PE taking an exception, it means that the exception is one that is taken to Non-secure EL1 when MDCR_EL2.TDE is 1. Otherwise, debug exceptions are masked by PSTATE.D, therefore they would be disabled from the target Exception level of the exception.

While software step is in the inactive state

Any of:

- Executing an `ERET` instruction when SPSR_ELx.SS is 0.
- Exiting Debug state when DSPSR_EL0.SS or DSPSR.SS is 0.
- If MDSCR_EL1.KDE is 1, executing an `MSR DAIF` or `MSR DAIFClr` instruction that clears PSTATE.D to 0.

In addition, software step might enter the active-pending state following a direct write to a system register, for example a write to MDSCR_EL1.KDE or MDSCR_EL1.SS. These writes require explicit synchronization to guarantee their effect. See *Synchronization and the software step state machine* on page D2-1590.

D2.12.7 Behavior in the active-pending state

In this state, a Software Step exception is pending, and the PE takes it on the current instruction.

Software Step exceptions have priority over all other exceptions except asynchronous exceptions taken to an Exception level or Security state that debug exceptions are disabled from.

This means that there are some asynchronous exceptions that Software Step exceptions have priority over.

Note

- This is the only case where a synchronous exception explicitly has a higher priority than asynchronous exceptions.
- For a description of when debug exceptions are enabled or disabled from an Exception level or Security state, see *Enabling debug exceptions from the current Exception level and Security state* on page D2-1536.

In cases where both a Software Step exception is pending and an asynchronous exception taken to an Exception level or Security state that debug exceptions are disabled from is pending, the architecture does not define which exception is taken first.

D2.12.8 Stepping T32 IT instructions

The ARMv8-A architecture permits a combination of an `IT` instruction and another 16-bit T32 instruction to comprise one 32-bit instruction.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:

- The PE considers this combination to be one instruction.
- The PE considers this combination to be two instructions.

It is then IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable IT Disable bit, ITD. For example:

- The PE might consider this combination to be one instruction, regardless of the state of the applicable ITD bit.
- The PE might consider this combination to be two instructions, regardless of the state of the applicable ITD bit.
- The PE might consider this combination to be one instruction when the applicable ITD bit is 1, and two instructions when it is 0.

The applicable ITD bit is either:

- SCTLR_EL1.ITD if execution is in EL0 using AArch32 when EL1 is using AArch64.
- SCTLR.ITD if execution is in EL1 using AArch32 when EL2 is using AArch64.

D2.12.9 Exception syndrome information and preferred return address

See the following:

- *Exception syndrome information* on page D2-1588.

- *Preferred return address* on page D2-1589.

Exception syndrome information

On taking a Software Step exception, the PE records information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- ESR_EL1.
- ESR_EL2.

Note

Software Step Exceptions cannot be taken to EL3.

Table D2-19 on page D2-1575 shows the information that the PE records.

Table D2-26 Information recorded in the ESR_ELx

ESR_ELx field	Information recorded in ESR_EL1 or ESR_EL2	
Exception Class, EC	The PE sets this to: • `0x32`, if the exception was taken from a lower Exception level. • `0x33`, if the exception was taken from the current Exception level.	
Instruction Length, IL	The PE sets this to 1.	
Instruction Specific Syndrome, ISS	**ISS[24]**	*Instruction Syndrome Valid* (ISV). This indicates whether the EX bit, ISS[6], is valid. The PE sets this to: **0** Not valid. **1** Valid.
	ISS[23:7]	RES0.
	ISS[6]	*Exclusive operation* (EX). The PE sets this to indicate whether the instruction stepped was a Load-Exclusive class of instruction: **0** The stepped instruction was not a Load-Exclusive instruction. **1** The stepped instruction was a Load-Exclusive instruction. A debugger can use this information when stepping code that uses exclusive monitors. See *Stepping code that uses exclusive monitors* on page D2-1590
	ISS[5:0]	*Instruction Fault Status Code* (IFSC). The PE sets this to the code for a debug exception, `0b100010`.

The PE only sets ISV to 1 if an instruction was stepped. If the PE sets ISV to 1, it must also set EX to indicate whether the instruction stepped was a Load-Exclusive class of instruction.

If no instruction was stepped because software step entered the active-pending state from the inactive state without passing through the active-not-pending state, the PE sets both ESR_ELx.{ISV, EX} to 0.

Note

An implementation that always sets ISV to 0 and never sets EX is not compliant.

Table D2-27 shows the permitted scenarios.

Table D2-27 Values that the PE can record in ESR_ELx.{ISV, EX}

Description	ESR_ELx.ISV	ESR_ELx.EX
Syndrome data is not available because no instruction was stepped.	0	0
Syndrome data is available because an instruction was stepped. The instruction stepped was an instruction other than a Load-Exclusive class of instruction.	1	0
Syndrome data is available because an instruction was stepped. The instruction stepped was a Load-Exclusive class of instruction.	1	1

Note

- A Load-Exclusive class of instruction is any one of the following:
  - In the A64 instruction set, any instruction that has a mnemonic starting with either LDX or LDAX.
  - In the A32 and T32 instruction sets, any instruction that has a mnemonic starting with either LDREX or LDAEX.
- ESR_ELx.EX is UNKNOWN if the stepped instruction was a conditional Load-Exclusive instruction that failed its condition code test.

Preferred return address

The preferred return of a Software Step exception is the address of the instruction that was not executed because the PE took the Software Step exception instead.

D2.12.10 Additional considerations

This section contains the following:

- *Behavior when an ERET instruction is an illegal exception return*.
- *Behavior when the instruction stepped writes a misaligned PC value* on page D2-1590.
- *Stepping code that uses exclusive monitors* on page D2-1590.
- *Synchronization and the software step state machine* on page D2-1590.

Behavior when an ERET instruction is an illegal exception return

If the conditions for entering the active-not-pending state in *Entering the active-not-pending state* on page D2-1581 are met, but the PE executes an ERET instruction that is an illegal exception return, the exception return must be taken to the same Exception level that it was taken from. In this scenario, even though the Exception level remains the same before and after the ERET, software step can advance from the inactive state to one of the active states. Consider the following case:

1. MDSCR_EL1.SS is 1 and software step is inactive. The current Exception level is EL1 using AArch64, the OS Lock and OS Double Lock are unlocked, and MDCR_EL2.TDE is 0, MDSCR_EL1.KDE is 1, and PSTATE.D is 1.

   PSTATE.D == 1 is the reason why software step is inactive, because PSTATE.D == 1 means that debug exceptions are disabled from the current Exception level.

2. The PE executes an ERET instruction.

3. The intended target of the ERET is EL2. This means that the ERET is an illegal exception return because the intended target is higher than the Exception level the ERET it is executed at. In this case, the ERET must target EL1 instead of EL2.

If SPSR_EL1.D is 0, then on the ERET PSTATE.D becomes 0 and debug exceptions become enabled from the current Exception level. Software step therefore advances from the inactive state to one of the active states.

Which active state software step advances to depends on whether SPSR_ELx.SS is 1 or 0:

- If SPSR_ELx.SS is 1, software step advances to the active-not-pending state.

  In this case, an Illegal Execution State exception is pending on the instruction to be stepped, and the PE takes the Illegal Execution State exception instead of executing the instruction to be stepped.

- If SPSR_ELx.SS is 0, software step advances to the active-pending state.

  In this case, a Software Step exception and an Illegal Execution State exception are both pending. The Software Step exception has higher priority. On taking the Software Step exception, the PE sets SPSR_ELx.IL to 1.

Note

Synchronous exception prioritization on page D1-1448 shows the relative priorities of synchronous exceptions.

Behavior when the instruction stepped writes a misaligned PC value

An indirect branch that writes a misaligned PC value might generate a Misaligned PC exception at the target of the branch. However, if the indirect branch is stepped using software step, the PE takes a Software Step exception instead, because the Software Step exception has higher priority. Behavior on returning from the Software Step exception depends on which Execution state the Exception level being returned to is using:

AArch64 A Misaligned PC exception is generated.

AArch32 The return from the Software Step exception forces the PC to the correct alignment, and no Misaligned PC exception is generated.

Debugger software must therefore take care when using software step to single-step an indirect branch instruction executed in AArch32 state, that it does not hide a Misaligned PC exception.

Stepping code that uses exclusive monitors

The ARMv8-A architecture provides no mechanism for preserving the state of the exclusive monitors when a Load-Exclusive or a Store-Exclusive instruction is stepped.

However, for certain progressions through the software step state machine, on taking a Software Step exception, the PE provides an indication of whether the instruction stepped was a Load-Exclusive class of instruction.

Debugger software can use this to detect the state of the exclusive monitors. For example, if the PE reports that the instruction stepped was a Load-Exclusive class of instruction, the debugger is aware that the next Store-Exclusive operation will fail, because all exclusive monitors are cleared on returning from the Software Step exception. The debugger must then take action to ensure that the code being stepped makes forwards progress.

For more information on how the PE reports whether the instruction stepped was a Load-Exclusive instruction, see *Exception syndrome information and preferred return address* on page D2-1587.

Synchronization and the software step state machine

Any of the following can cause transitions between software step states:

- A direct write to a system register.
- A write to an external debug register that affects the routing of debug exceptions.

Because the software step state machine indirectly reads these registers, it is not guaranteed to observe any new values until after a *Context Synchronization Operation* (CSO) has occurred.

In the time between a write to one of these registers and the next CSO, it is CONSTRAINED UNPREDICTABLE whether software step uses the state of the PE before the write, or the state of the PE after the write.

After a CSO, the state machine must use the state of the PE after the write.

Example D2-3

1. Software changes MDSCR_EL1.SS from 0 to 1 when debug exceptions are enabled.
2. The PE executes some instructions.
3. A CSO occurs.

During step 2, it is CONSTRAINED UNPREDICTABLE whether software step remains in the inactive state, as if MDSCR_EL1.SS is 0, or enters the active-pending state because MDSCR_EL1.SS is 1. If it is in the:

- Inactive state, then after the CSO, it must enter the active-pending state.
- Active-pending state, the PE might take a Software Step exception before the CSO.

D2.12.11 Pseudocode description of Software Step exceptions

`SSAdvance()` advances software step from the active-not-pending state to the active-pending state, by setting PSTATE.SS to 0. It is called on completing execution of each instruction.

```
// SSAdvance()
// ===========
// Advance the Software Step state machine.

SSAdvance()

    // A simpler implementation of this function just clears PSTATE.SS to zero regardless of the
    // current Software Step state machine. However, this check is made to illustrate that the
    // processor only needs to consider advancing the state machine from the active-not-pending
    // state.
    target = DebugTarget();
    step_enabled = !ELUsingAArch32(target) && MDSCR_EL1.SS == '1';
    active_not_pending = step_enabled && PSTATE.SS == '1';

    if active_not_pending then PSTATE.SS = '0';

    return;
```

`CheckSoftwareStep()` checks whether software step is in the active-pending state, and if it is, generates a Software Step exception. It is called before each instruction executed, regardless of Execution state, before checking for any other synchronous exceptions.

```
// CheckSoftwareStep()
// ===================
// Take a Software Step exception if in the active-pending state

CheckSoftwareStep()

    if (!ELUsingAArch32(DebugTarget()) && AArch64.GenerateDebugExceptions() &&
        MDSCR_EL1.SS == '1' && PSTATE.SS == '0') then
        AArch64.SoftwareStepException();
```

`DebugExceptionReturnSS()` returns the value to write to PSTATE.SS on an exception return or an exit from Debug state. See *Entering the active-not-pending state* on page D2-1581.

```
// DebugExceptionReturnSS()
// ========================
// Returns value to write to PSTATE.SS on an exception return or Debug state exit.

bit DebugExceptionReturnSS(bits(32) spsr)
    assert Halted() || Restarting() ||  PSTATE.EL != EL0;

    SS_bit = '0';
```

```
if MDSCR_EL1.SS == '1' then
    if Restarting() then
        enabled_at_source = FALSE;
    elsif UsingAArch32() then
        enabled_at_source = AArch32.GenerateDebugExceptions();
    else
        enabled_at_source = AArch64.GenerateDebugExceptions();

    if IllegalExceptionReturn(spsr) then
        dest = PSTATE.EL;
    else
        (valid, dest) = ELFromSPSR(spsr);  assert valid;

    secure = IsSecureBelowEL3() || dest == EL3;

    if ELUsingAArch32(dest) then
        enabled_at_dest = AArch32.GenerateDebugExceptionsFrom(dest, secure);
    else
        mask = spsr<9>;
        enabled_at_dest = AArch64.GenerateDebugExceptionsFrom(dest, secure, mask);

    ELd = DebugTargetFrom(secure);
    if !ELUsingAArch32(ELd) && !enabled_at_source && enabled_at_dest then
        SS_bit = spsr<21>;

return SS_bit;
```

D2.13 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a *Context Synchronization Operation* (CSO) has occurred. Similarly, the effect of the change on the software step state machine cannot be relied on until after a CSO has occurred.

For any instructions executed between the time when the change is made and the time when the next CSO occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

Example D2-4

1. Software changes MDSCR_EL1.MDE from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A CSO occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

Example D2-5

1. Software unlocks the OS lock.
2. The PE executes some instructions.
3. A CSO occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Software Breakpoint Instruction exceptions can be generated.

Note

- Some register updates are self synchronizing. Others require an explicit CSO. For more information, see both:
  - *Synchronization requirements for System registers* on page D7-1794.
  - *Synchronization of changes to the external debug registers* on page H8-4517.
- See *Context synchronization operation* for the definition of this term.

Chapter D3
The AArch64 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

D3.1 About the memory system architecture

The ARM architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see *Memory hierarchy* on page B2-70.

D3.1.1 Form of the memory system architecture

The ARMv8 A-profile architecture includes a *Virtual Memory System Architecture* (VMSA), described in Chapter D4 *The AArch64 Virtual Memory System Architecture*.

D3.1.2 Memory attributes

Memory types and attributes on page B2-89 describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

Table D3-1 shows the memory attributes that are visible at the system level.

Table D3-1 Memory attribute summary

Memory type	Shareability	Cacheability
Device[a]	Outer Shareable	Non-cacheable.
Normal	One of: • Non-shareable. • Inner Shareable. • Outer Shareable.	One of: • Non-cacheable[b]. • Write-Through Cacheable. • Write-Back Cacheable.

a. Takes additional attributes, see *Device memory* on page B2-91.

b. See also *Cacheability, cache allocation hints, and cache transient hints* on page D3-1601.

For more information on cacheability and shareability see *Shareable Normal memory* on page B2-90, *Non-shareable Normal memory* on page B2-91, and *Caches and memory hierarchy* on page B2-70.

D3.2 Address space

The ARMv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of *physical address* (PA) sizes, and provides associated control and identification mechanisms. For more information, see *Address size configuration* on page D4-1641.

D3.2.1 Instruction address space overflow

When a PE performs a normal, sequential execution of instructions, it calculates:

```
(address_of_current_instruction) + (size_of_executed_instruction)
```

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an instruction overflows `0xFFFF FFFF FFFF FFFF`, the program counter becomes UNKNOWN.

Note

Address tags are not propagated to the program counter, so the tag does not affect the address calculation.

Where an instruction accesses a sequential set of bytes that crosses the `0xFFFF_FFFF_FFFF_FFFF` boundary when tagged addresses are not used, or the `0xxxFF_FFFF_FFFF_FFFF` boundary when tagged addresses are used, then the virtual address accessed for the bytes above this boundary is UNKNOWN. When tagged addresses are used, the value of the tag associated with the address also becomes UNKNOWN.

D3.3 Mixed-endian support

A control bit, SCTLR_EL1.E0E is provided to allow the endianness of explicit data accesses made while executing at EL0 to be controlled independently of those made while executing at EL1. Table D3-2 shows the endianness of explicit data accesses and translation table walks.

Table D3-2 Endianness support

Exception level	Explicit data accesses	Stage 1 translation table walks	Stage 2 translation table walks
EL0	SCTLR_EL1.E0E	SCTLR_EL1.EE	SCTLR_EL2.EE
EL1	SCTLR_EL1.EE	SCTLR_EL1.EE	SCTLR_EL2.EE
EL2	SCTLR_EL2.EE	SCTLR_EL2.EE	N/A
EL3	SCTLR_EL3.EE	SCTLR_EL3.EE	N/A

Note

SCTLR_EL1.E0E has no effect on the endianness of the LDTR, LDTRH, LDTRSH, and LDTRSW instructions, or on the endianness of the STTR and STTRH instructions, when these are executed at EL1.

ARMv8 provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - SCTLR_ELx.EE is R/W and SCTLR_EL1 is R/W.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
  - SCTLR_ELx is RES0 and SCTLR_EL1.E0E is R/W.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
  - SCTLR_ELx is RES1 and SCTLR_EL1.E0E is R/W.
- All Exception levels support only little-endianness:
  - SCTLR_ELx is RES0 and SCTLR_EL1.E0E is RES0.
- All Exception levels support only big-endianness:
  - SCTLR_ELx is RES1 and SCTLR_EL1.E0E is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by PSTATE.E. For exception returns to AArch32 state, PSTATE.E is copied from SPSR_ELx.E. If the target Exception level supports only little-endian accesses, SPSR_ELx.E is RES0. If the target Exception level supports only big-endian accesses, SPSR_ELx.E is RES1. PSTATE.E is ignored in AArch64 state.

The `BigEndian()` function determines whether the current Exception level and Execution state is using big-endian data:

```
// BigEndian()
// ===========

boolean BigEndian()
    boolean bigend;
    if UsingAArch32() then
        bigend = (PSTATE.E != '0');
    elsif PSTATE.EL == EL0 then
        bigend = (SCTLR_EL1.E0E != '0');
    else
        bigend = (SCTLR[].EE != '0');
    return bigend;
```

D3.4 Cache support

This section describes the ARMv8 cache identification and control mechanisms, and the cache maintenance instructions, in the following sections:

- *General behavior of the caches*
- *Cache identification* on page D3-1600.

D3.4.1 General behavior of the caches

When a memory location is marked with a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  - A particular implementation.
  - Some memory attributes.
- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.
- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

Note

For more information, see *The interaction of cache lockdown with cache maintenance instructions* on page D3-1616.

- If a memory location both has permissions that mean it can be accessed, either by reads or by writes, for the translation regime at either the current Exception level or at a higher Exception level, and is marked as Cacheable for that translation regime, then there is no mechanism that can guarantee that the memory location cannot be allocated to an enabled cache at any time.

  Any application must assume that any memory location with such access permissions and cacheability attributes can be allocated to any enabled cache at any time.

- It is guaranteed that no memory location that does not have a Cacheable attribute is allocated into the cache.

- It is guaranteed that no memory location is allocated to the cache if the access permissions for that location are such that the location cannot be accessed by reads and cannot be accessed by writes in both:
  — The translation regime at the current Exception level.
  — The translation regime at a higher Exception level.

- For data accesses, any memory location that is marked as Normal Shareable is guaranteed to be coherent with all masters in that shareability domain.

- Any memory location is not guaranteed to remain incoherent with the rest of memory.

- The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the *Cache Write-back Granule*. In some implementations the CTR_EL0 identifies the Cache Write-back Granule.

- The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer, if it was previously visible to that observer.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to its size.

In the following situations it is UNPREDICTABLE whether the location is returned from cache or from memory:

- The location is not marked as Cacheable but is contained in the cache. This situation can occur if a location is marked as Non-cacheable after it has been allocated into the cache.
- The location is marked as Cacheable and might be contained in the cache, but the cache is disabled.

D3.4.2 Cache identification

The ARMv8 cache identification registers describe the implemented caches that are under the control of the PE:

- The Cache Type Register, CTR_EL0, defines:
  — The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  — The minimum line length of any of the data or unified caches, affected by the data cache maintenance instructions.
  — The cache indexing and tagging policy of the Level 1 instruction cache.

- A single Cache Level ID Register defines:
  — The type of cache implemented at each cache level, up to the maximum of seven levels.
  — The Level of Coherence for the caches. See *Terms used in describing the maintenance instructions* on page D3-1604 for a definition of these terms.
  — The Level of Unification for the caches. See *Terms used in describing the maintenance instructions* on page D3-1604 for a definition of these terms.

  For more information, see *CLIDR_EL1, Cache Level ID Register* on page D7-1813.

- A single Cache Size Selection Register selects the cache level and cache type of the current Cache Size Identification Register, see *CSSELR_EL1, Cache Size Selection Register* on page D7-1822.

- For each implemented cache, across all the levels of caching, a Cache Size Identification Register defines:
  — Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.

— The number of sets, associativity and line length of the cache. See *Terms used in describing the maintenance instructions* on page D3-1604 for a definition of these terms.

For more information, see *CCSIDR_EL1, Current Cache Size ID Register* on page D7-1811.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.
2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also provides the Level of Unification and the Level of Coherence for the cache implementation.
3. For each cache identified at stage 2:
   - Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
     — An instruction cache.
     — A data or unified cache.
   - Read the Cache Size ID Register to find details of the cache.

D3.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and can be defined independently for Inner and Outer cache locations.

As described in *Memory types and attributes* on page B2-89, the memory attributes include a cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

Cacheability attributes other than Non-cacheable can be complemented by a *cache allocation hint*. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. A *cache transient hint* provides a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future.

The following cache allocation hints can be used in ARMv8:

- Read-Allocate, Transient Read-Allocate, or No Read-Allocate.
- Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

Note

A Cacheable location with both no Read-Allocate and no Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, no Read-Allocate, no Write-Allocate.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

D3.4.4 Behavior of caches at reset

In ARMv8:

- All caches are disabled at reset.

- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.
- If an implementation permits cache hits when the cache is disabled the cache initialization routine must:
  - Provide a mechanism to ensure the correct initialization of the caches.
  - Be documented clearly as part of the documentation of the device.

  In particular, if an implementation permits cache hits when the cache is disabled and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.
- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 cache maintenance instructions.

When it is enabled, the state of a cache is UNPREDICTABLE if the appropriate initialization routine has not been performed.

D3.4.5 Cache enabling and disabling

When a data cache or unified cache is disabled for a translation regime, data accesses and translation table walks from that translation regime to all Normal memory types behave as Non-cacheable for all levels of data caches and unified caches.

For the EL1&0 translation regime:

- When SCTLR_EL1.C == 0, this makes all stage 1 translations for data accesses to Normal memory Non-cacheable. It also makes all accesses to the EL1&0 stage 1 translation tables Non-cacheable.
- When HCR_EL2.CD == 1, this makes all stage 2 translations for data accesses to Normal memory Non-cacheable. It also makes all accesses to the EL1&0 stage 2 translation tables Non-cacheable.

  Note
  - In Non-secure state, the stage 1 and stage 2 cacheability attributes are combined as described in *Combining the stage 1 and stage 2 cacheability attributes for Normal memory* on page D4-1720.
  - The SCTLR_EL1.C bit has no effect on the EL2 and EL3 translation regimes.
  - The HCR_EL2.CD bit affects only stage 2 of the Non-secure EL1&0 translation regime.
- When HCR_EL2.DC == 1, this makes all stage 1 translations for data accesses and all accesses to the EL1&0 stage 1 translation tables Normal Non-shareable Inner Write-Back Cacheable Read Allocate Write Allocate, Outer Write-Back Cacheable Read Allocate Write Allocate.

For the EL2 translation regime:

- When SCTLR_EL2.C == 0, all data accesses to Normal memory using the EL2 translation regime are Non-cacheable. This means all accesses made by the EL2 translation table walks are Non-cacheable.

  Note

  The SCTLR_EL2.C bit has no effect on the EL1&0 and EL3 translation regimes.

For the EL3 translation regime:

- When SCTLR_EL3.C == 0, all data accesses to Normal memory using the EL3 translation regime are Non-cacheable. It also makes all accesses made by the EL3 translation table walks are Non-cacheable.

  Note

  The SCTLR_EL3.C bit has no effect on the EL1&0 and EL2 translation regimes.

The effect of SCTLR_ELx.C, HCR_EL2.DC and HCR_EL2.CD is reflected in the result of the address translation instructions in the PAR when these bits have an effect on the stages of translation being reported in the PAR.

When an instruction cache is disabled for a translation regime, data accesses and translation table walks from that translation regime to all Normal memory types behave as Non-cacheable for all levels of data caches and unified caches

For the EL1&0 translation regime:

- When SCTLR_EL1.I == 0, this makes all stage 1 translations for instruction accesses to Normal memory Non-cacheable. It also makes all accesses to the EL1&0 stage 1 translation tables Non-cacheable.
- When HCR_EL2.CD == 1, this makes all stage 2 translations for instruction accesses to Normal memory Non-cacheable. It also makes all accesses to the EL1&0 stage 2 translation tables Non-cacheable.

  Note

  — In Non-secure state, the stage 1 and stage 2 cacheability attributes are combined as described in *Combining the stage 1 and stage 2 cacheability attributes for Normal memory* on page D4-1720.

  — The SCTLR_EL1.C bit has no effect on the EL2 and EL3 translation regimes.

  — The HCR_EL2.CD bit affects only stage 2 of the Non-secure EL1&0 translation regime.

- If HCR_EL2.DC == 1, then the Non-secure stage 1 EL1&0 translation regime is cacheable regardless of the value of SCTLR_EL1.I.

For the EL2 translation regime:

- When SCTLR_EL2.I == 0, all instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

  Note

  The SCTLR_EL2.I bit has no effect on the EL1&0 and EL3 translation regimes.

For the EL3 translation regime:

- When SCTLR_EL3.I == 0, all instruction accesses to Normal memory using the EL3 translation regime are Non-cacheable.

  Note

  The SCTLR_EL3.I bit has no effect on the EL1&0 and EL2 translation regimes

In addition, when SCTLR_ELx.M == 0, indicating that the stage 1 translations are disabled for that translation regime, the SCTLR_ELx.I bit has the following effect:

- If SCTLR_ELx.I == 0, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If SCTLR_ELx.I == 1, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Write-Through, Outer Write-Through.

When the MMU is off, all instruction accesses are to Normal memory and:

- If SCTLR_ELx.I == 0, the behavior is Normal Non-cacheable.
- If SCTLR_ELx.I == 1, the behavior is Normal Outer Shareable, Inner Write-Through Cacheable, Outer Write-Through Cacheable.

For the Non-secure EL1 translation regime, when the MMU is off and SCTLR_EL1.M == 0 and HCR_EL2.DC == 0, all instruction accesses are to Normal memory and:

- If SCTLR_ELx.I == 0, the behavior is Normal Non-cacheable.

- If SCTLR_ELx.I == 1, the behavior is Normal Outer Shareable, Inner Write-Through Cacheable, Outer Write-Through Cacheable.

Note

In conjunction with the requirements in *Non-cacheable accesses and instruction caches*, this means that the architecturally required effect of SCTLR_ELx.I is limited to its effect on caching instruction accesses in unified caches.

D3.4.6 Non-cacheable accesses and instruction caches

Instruction accesses to Non-cacheable Normal memory can be held in instruction caches.

Correspondingly, the sequence for ensuring that modifications to instructions are available for execution must include invalidation of the modified locations from the instruction cache, even if the instructions are held in Normal Non-cacheable memory. This includes cases where the instruction cache is disabled.

Therefore when using self-modified code in non-cacheable space in a uniprocessor system, the following sequence is required:

```
; Enter this code with <Wt> containing the new 32-bit instruction
; to be held at a location pointed to by <Xn> in Normal Non-cacheable memory.
STR <Wt>, [Xn]
DSB ; Ensure visibility of the data stored
IC IVAU, Xn] ; Invalidate instruction cache by VA to PoU
DSB ; Ensure completion of the invalidations
ISB ;
```

In a multiprocessor system, the IC IVAU is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence, but additional software steps might be required to synchronize the threads with other PEs. This might be necessary so that the PEs executing the modified instructions can execute an `ISB` after completing the invalidation, and to avoid issues associated with concurrent modification and execution of instruction sequences.

Larger blocks of instructions can be modified using the IC IALLU instruction for a uniprocessor system, or a IC IALLUIS for a multiprocessor system.

Note

This section applies even when the instruction cache is disabled in AArch64, as described in *Cache enabling and disabling* on page D3-1602.

D3.4.7 Overview of the cache maintenance instructions

The following sections give general information about cache maintenance:

- *Terms used in describing the maintenance instructions*.
- *The ARMv8 abstraction of the cache hierarchy* on page D3-1607.

The following sections describe cache maintenance instruction:

- *Instruction cache maintenance instructions (IC*)* on page D3-1609.
- *Data cache maintenance instructions (DC*)* on page D3-1609.

Terms used in describing the maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instructions can be defined:

- By the address of the memory location to be maintained, referred to as operating *by VA*.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating *by set/way*.

In addition, for instruction caches, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- *Terminology for cache maintenance instruction operating by virtual address, VA*.
- *Terminology for cache maintenance instructions operating by set/way*.
- *Terminology for Clean, Invalidate, and Clean and Invalidate instructions* on page D3-1606.

Terminology for cache maintenance instruction operating by virtual address, VA

The addresses used by the PE are VAs. When all applicable stages of translation are disabled, the virtual address is identical to the physical address.

Note

For more information about memory system behavior when MMUs are disabled, see *The effects of disabling a stage of address translation* on page D4-1670.

For the cache maintenance instruction, any instruction described as operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current system *Address Space IDentifier* (ASID).
- The current Security state.
- Whether the instruction was performed from Hyp mode, or from Non-secure EL1 state.
- For an instruction executed from a Non-secure EL1 state, the *Virtual Machine IDentifier*, VMID.

For a data or unified cache maintenance instruction by VA, the operation cannot generate a Data Abort exception for a Permission fault, except for the Permission fault cases described in:

- *Data cache maintenance instructions (DC*)* on page D3-1609.
- *Stage 2 fault on a stage 1 translation table walk* on page D4-1727.

For an instruction cache maintenance instruction by VA:

- It is IMPLEMENTATION DEFINED whether the operation can generate a Data Abort exception for a Translation fault or an Access flag fault.
- The operation cannot generate a Data Abort exception for a Permission fault, except for the Permission fault case described in *Stage 2 fault on a stage 1 translation table walk* on page D4-1727.

For more information about these faults, see *MMU faults* on page D4-1722.

Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

Level The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED and can be determined from the Cache Level ID register. See *CLIDR_EL1, Cache Level ID Register* on page D7-1813.

In the ARM architecture, the lower numbered levels are those closest to the PE. See *Memory hierarchy* on page B2-70.

Set Each level of a cache is split up into a number of *sets*. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.

In the ARM architecture, sets are numbered from 0.

Way The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The *way* number specifies one of these locations.

In the ARM architecture, ways are numbered from 0.

Note

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, ARM expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.

2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or *stale*, copy of the memory location that has been updated.

The *Clean* and *Invalidate* instructions address these two issues. The definitions of these instructions are:

Clean A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the shareability domain of that memory location.

Invalidate A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates does not have a Normal Cacheable attribute, or if the cache is disabled, then an invalidate instruction also ensures that this address is not present in the cache.

Note

Entries for addresses with a Normal Cacheable attribute can be allocated to an enabled cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in an enabled cache.

Clean and Invalidate

A cache *clean and invalidate* instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.

- For instruction operating by VA, two conceptual points are defined:

  Point of Coherency (PoC)

  For a particular VA, the PoC is the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. In many cases, this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherence between memory system agents.

Point of Unification (PoU)

The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

The following fields in the CLIDR_EL1 relate to these conceptual points:

LoC, Level of Coherence

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is `0x0`, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

LoUU, Level of Unification, uniprocessor

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is `0x0`, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the Point of Unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

LoUIS, Level of Unification, Inner Shareable

In any implementation:

- This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is `0x0`, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

For more information, see *CLIDR_EL1, Cache Level ID Register* on page D7-1813.

The ARMv8 abstraction of the cache hierarchy

The following subsections describe the ARMv8 abstraction of the cache hierarchy:

- *Cache maintenance instructions that operate by address* on page D3-1608.
- *Cache maintenance instructions that operate by set/way* on page D3-1608.

Cache maintenance instructions that operate by address

The address-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being either:

- Performed to the Point of Coherency.
- Performed to the Point of Unification.

See *Terms used in describing the maintenance instructions* on page D3-1604 for definitions of Point of Coherency and Point of Unification, and more information about possible meanings of VA.

Cache maintenance instructions lists the address-based maintenance instructions.

The CTR_EL0 holds minimum line length values for:

- The instruction caches.
- The data and unified caches.

These values support efficient invalidation of a range of addresses, because this value is the most efficient address stride to use to apply a sequence of address-based maintenance instructions to a range of addresses.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the CTR_EL0 defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

Cache maintenance instructions that operate by set/way

Cache maintenance instructions lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

D3.4.8 Cache maintenance instructions

Cache maintenance instructions that are performed using the A64 instruction set are a part of the system instruction class in the register encoding space. For encoding details and other general information on system instructions, see *System instructions* on page C3-128, *SYS* on page C6-747 and *Cache maintenance instructions, and data cache zero* on page C5-239.

The instruction and data cache maintenance instructions have the same functionality in AArch32 state and in AArch64 state. Table D3-3 shows these system instructions. Instructions that take an argument include Xt in the instruction description.

Note

In Table D3-3 the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.

Table D3-3 System instructions for cache maintenance

Register	Instruction	Notes
Instruction cache maintenance instructions, see *System instructions* on page C3-128		
IC IALLUIS	Invalidate all to Point of Unification, Inner Shareable	EL1 or higher access.
IC IALLU	Invalidate all to Point of Unification	EL1 or higher access.
IC IVAU, Xt	Invalidate by virtual address to Point of Unification	When SCTLR_EL1.UCI == 1, EL0 access. Otherwise, EL1 or higher access.

Table D3-3 System instructions for cache maintenance (continued)

Register	Instruction	Notes
Data cache maintenance instructions, see *System instructions* on page C3-128		
DC IVAC, Xt	Invalidate by virtual address to Point of Coherency	EL1 or higher access.
DC ISW, Xt	Invalidate by set/way	EL1 or higher access.
DC CVAC, Xt	Clean by virtual address to Point of Coherency	When SCTLR_EL1.UCI == 1, EL0 access. Otherwise EL1 or higher access.
DC CSW, Xt	Clean by set/way	EL1 or higher access.
DC CVAU, Xt	Clean by virtual address to Point of Unification	When SCTLR_EL1.UCI == 1, EL0 access. Otherwise EL1 or higher access.
DC CIVAC, Xt	Clean and invalidate by virtual address to Point of Coherency	When SCTLR_EL1.UCI == 1, EL0 access. Otherwise EL1 or higher access.
DC CISW, Xt	Clean and invalidate by set/way	EL1 or higher access.

Instruction cache maintenance instructions (IC*)

The A64 assembly syntax for these instructions is described in *System instructions* on page C3-128.

Where an address argument for these instructions is required, it takes the form of a 64-bit register that holds the virtual address argument. No restrictions apply for this address.

All instruction cache maintenance instructions can execute in any order relative to other instruction cache maintenance instructions, data cache maintenance instructions, and loads and stores, unless a `DSB` is executed between the instructions.

An instruction cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a `DSB` instruction executed by the PE that executed the cache maintenance instruction.

Data cache maintenance instructions (DC*)

The A64 assembly syntax for these instructions is described in *System instructions* on page C3-128.

Where an address argument for these instructions is required, it takes the form of a 64-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Data cache maintenance instructions that take a set/way/level argument take a 64-bit register, the upper 32 bits of which are RES0.

DC IVAC requires write permission or else a Permission fault is generated.

DC IVAC and DC ISW at EL1 is performed by the PE as clean and invalidate, that is DC CIVAC or DC CISW, if all of the following apply:

- EL2 is implemented.
- HCR_EL2.VM is set to 1 to enable the second stage of address translation, meaning that execution is in Non-secure state.
- SCR_EL3.NS is set to 1 or EL3 is not implemented.

Note

This also applies to the AArch32 cache maintenance instructions DCIMVAC and DCISW. see *Data cache maintenance instructions (DC*)* on page G3-3590.

If a memory fault that sets the FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.

Note

Despite its mnemonic, DC ZVA is not a cache maintenance instruction. For more information, see *DC ZVA, Data Cache Zero by VA* on page C5-314

EL0 accessibility to cache maintenance instructions

The SCTLR_EL1.UCI bit enables EL0 access for the DC CVAU, DC CVAC, DC CIVAC, and IC IVAU instructions.

For these instructions read access permission is required. If the address specified in the argument cannot be read at EL0, executing the instruction at EL0 generates a Permission fault. When disabled, SCTLR_EL1.UCI == 0, these instructions generate a trap to EL1, that is reported using EC = `0x18`.

In addition, SCTLR_EL1.UCT bit enables EL0 access to the Cache Type register, CTR_EL0. When software accesses the CTR_EL0 it can discover the stride necessary for cache maintenance instructions. When EL0 access to the Cache Type register is disabled, the instruction is trapped to EL1 using EC = `0x18`.

General requirements for the scope of maintenance instructions

The ARMv8 specification of the cache maintenance instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in *General behavior of the caches* on page D3-1599, *Behavior of caches at reset* on page D3-1601, and *Preloading caches* on page B2-74.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

Note

ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

Effects of instructions that operate by VA to the Point of Coherency

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the Point of Coherency.

Table D3-4 shows the scope of the Data and unified cache maintenance instructions.

Table D3-4 PEs affected by cache maintenance instructions to the Point of Coherency

Shareability	PEs affected	Effective to
Non-shareable	The PE performing the operation	The Point of Coherency of the entire system
Inner Shareable	All PEs in the same Inner Shareable shareability domain as the PE performing the operation	The Point of Coherency of the entire system
Outer Shareable	All PEs in the same Outer Shareable shareability domain as the PE performing the operation	The Point of Coherency of the entire system

Effects of instructions operate by VA but not to the Point of Coherency

For these instructions, Table D3-5 shows how, for a VA in a Normal or Device memory location, the shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

Table D3-5 PEs affected by cache maintenance instructions to the Point of Unification

Shareability	PEs affected	Effective to
Non-shareable	The PE executing the instruction	The point of unification of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction
Inner Shareable or Outer Shareable	All PEs in the same Inner Shareable shareability domain as the PE executing the instruction	The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain as the PE executing the instruction

Note

The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable shareability domain containing the PE executing the instruction.

Effects of All and set/way maintenance instructions

The IC IALLU and DC set/way instructions apply only to the caches of the PE that performs the instruction.

The IC IALLUIS instruction can affect the caches of all PEs in the same Inner Shareable shareability domain as the PE that performs the instruction. This instruction has an effect to the Point of Unification of instruction cache fills, data cache fills, write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain.

Effects of virtualization and security on the cache maintenance instructions

Each Security state has its own physical address space, and therefore cache entries are associated with physical address space. In addition, cache maintenance instructions performed in Non-secure state have to take account of:

- Whether the instruction was performed at EL1 or at EL2.
- For instructions that operate by VA, the current VMID.

Table D3-6 shows the effects of virtualization and security on these maintenance instructions.

Table D3-6 Effects of virtualization and security on the maintenance instructions

Cache maintenance instructions	Security state	Targeted entry
Data or unified cache maintenance instructions		
Invalidate, Clean, or Clean and Invalidate by VA: IVAC, CVAC, CVAU, CIVAC	Either	All lines that hold the PA that, in the current Security state, is mapped to by the combination of all of: • The specified VA. • For an instruction executed at EL1 or EL0, the current ASID. • For an instruction executed at Non-secure EL1 or Non-secure EL0, the current VMID[b].
Invalidate, Clean, or Clean and Invalidate by set/way: ISW, CSW, CISW	Non- secure	Line specified by set/way provided that the entry comes from the Non-secure PA space.
	Secure	Line specified by set/way regardless of the PA space that the entry has come from.
Instruction cache maintenance instructions		
Invalidate by VA: IVAU	Either	Implementation without the IVIPT Extension[a]:
		All Lines that match the specified VA and, for an instruction executed at EL1 or EL0, the current ASID, and come from the same VA space as the current Security state. For an instruction executed in Non-secure state, lines are invalidated only if they also match the current VMID[b] and security level, EL1 or EL2.
		Implementation with the IVIPT Extension[a]:
		All lines that hold the PA that, in the current Security state, is mapped to by the combination of all of: • The specified VA. • For an instruction executed at EL1 or EL0, the current ASID. • For an instruction executed in Non-secure EL1 or Non-secure EL0, the current VMID[b]
Invalidate All: IALLU, IALLUIS		• Can invalidate any unlocked entry in the instruction cache. • Are required to invalidate any entries relevant to the software component that executed it. The Non-secure and Secure descriptions give more information: **Non-secure** An instruction executed at EL1 must operate on all instruction cache lines that contain entries associated with the current virtual machine, meaning any entry with the current VMID[b]. An instruction executed at EL2 must operate on all instruction cache lines that contain entries that can be accessed from Non-secure state. **Secure** The instruction must invalidate all instruction cache lines.

a. See *The IVIPT Extension* on page D4-1746.
b. Dependencies on the VMID apply even when HCR_EL2.VM is set to 0. However, VTTBR_EL2.VMID resets to zero, meaning there is a valid VMID from reset.

For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in *The interaction of cache lockdown with cache maintenance instructions* on page D3-1616 applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, Non-secure clean by set/way operations can be upgraded to clean and invalidate by set/way.
- The AArch64 Data Cache Invalidate instructions, DC IVAC and DC ISW, at EL1 and EL0, and the AArch32 Data Cache Invalidate instructions DCIMVAC and DCISW, perform a cache clean as well as a cache invalidation if all of the following apply:
  — EL2 is implemented.
  — HCR.VM is set.
  — SCR.NS is set or EL3 is not implemented.
- When the value of HCR_EL2.FB is 1, TLB and instruction cache invalidate instructions executed in the Non-secure EL1 Exception level are broadcast across the Inner Shareable domain. When Non-secure EL1 is using AArch64, this applies to the TLBI VMALLE1, TLBI VAE1, TLBI ASIDE1, TLBI VAAE1, TLBI VALE1, TLBI VAALE1, and IC IALLU instructions. This means the instruction is upgraded to the corresponding Inner Shareable instruction, for example IC IALLU is upgraded to IC IALLUIS.
- When the value of HCR_EL2.SWIO is 1, a cache invalidate by set/way instructions executed in the Non-secure EL1 Exception level is upgraded to a clean and invalidate by set/way. When Non-secure EL1 is using AArch64, this means the DC ISW instruction is upgraded to DC CISW.

For more information about the cache maintenance instructions, see *Overview of the cache maintenance instructions* on page D3-1604, *Cache maintenance instructions* on page D3-1608, and Chapter D4 *The AArch64 Virtual Memory System Architecture*.

Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches when the caches are enabled or when they are disabled.

For address-based cache maintenance instructions, the instructions operate on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
  — Is Normal memory or Device memory.
  — Has the Cacheable attribute or the Non-cacheable attribute.
- Any applicable domain control of the address accessed.
- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

Ordering and completion of data and instruction cache instructions

All data cache instructions, other than DC ZVA, that specify an address:

- Execute in program order relative to loads or stores that access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.
- Can execute in any order relative to loads or stores that access any address with the Device memory attribute, or with Normal memory with Inner Non-cacheable attribute unless a `DMB` or `DSB` is executed between the instructions.
- Execute in program order relative to other data cache maintenance instructions, other than `DC ZVA`, that specify an address within the same cache line of minimum size, as indicated by CTR_EL0.DMinLine.
- Can execute in any order relative to loads or stores that access an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a `DMB` or `DSB` is executed between the instructions.
- Can execute in any order relative to other data cache maintenance instructions, other than `DC ZVA`, that specify an address in a different cache line of minimum size, as indicated by CTR_EL0.DMinLine, unless a `DMB` or `DSB` is executed between the instructions.
- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a `DMB` or `DSB` is executed between the instructions.
- Can execute in any order relative to instruction cache maintenance instructions unless a `DSB` is executed between the instructions.

Note

Data cache zero instruction on page D3-1616 describes the ordering and completion rules for Data Cache Zero.

All data cache maintenance instructions that do not specify an address:

- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a `DMB` or `DSB` is executed between the instructions.
- Can execute in any order relative to data cache maintenance instructions that specify an address, other than Data Cache Zero, unless a `DMB` or `DSB` is executed between the instructions.
- Can execute in any order relative to loads or stores unless a `DMB` or `DSB` is executed between the instructions.

A cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a `DSB` instruction executed by the PE that executed the cache maintenance instruction.

Note

In all cases, where the text in this section refers to a `DMB` or a `DSB`, this means a `DMB` or `DSB` whose required access type is both loads and stores.

Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

- For data or unified cache maintenance, uses the CTR_EL0.DMinLine value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the CTR_EL0.IMinLine value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

Example code for cache maintenance instructions

The cache maintenance instructions by set/way can clean or invalidate, or both, the entirety of one or more levels of cache attached to a processing element. However, unless all processing elements attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

Note

In multi-processing environments, the cache maintenance instructions that operate by set/way are not broadcast within the shareability domains, and so allocations can occur from other, unmaintained, locations, in caches in other locations. For this reason, the use of cache maintenance instructions that operate by set/way for the maintenance of large buffers of memory is not recommended in the architectural sequence. The expected usage of the cache maintenance instructions that operate by set/way is associated with the cache maintenance instructions associated with the powerdown and powerup of caches, if this is required by the implementation.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency.

```
        MRS     X0, CLIDR_EL1
        AND     W3, W0, #0x07000000     // get 2 x level of coherency
        LSR     W3, W3, #23
        CBZ     W3, Finished
        MOV     W10, #0                 // W10 = 2 x cache level
        MOV     W8, #1                  // W8 = constant 0b1
Loop1:  ADD     W2, W10, W10, LSR #1    // calculate 3 x cache level
        LSR     W1, W0, W2              // extract 3-bit cache type for this level
        AND     W1, W1, #0x7
        CMP     W1, #2
        B.LT    Skip                    // no data or unified cache at this level
        MSR     CSSELR_EL1, X10         // select this cache level
        ISB                             // sync change of CSSELR
        MRS     X1, CCSIDR_EL1          // read CCSIDR
        AND     W2, W1, #7              // W2 = log2(linelen)-4
        ADD     W2, W2, #4              // W2 = log2(linelen)
        UBFX    W4, W1, #3, #10         // W4 = max way number, right aligned
        CLZ     W5, W4                  // W5 = 32-log2(ways), bit position of way in DC operand
        LSL     W9, W4, W5              // W9 = max way number, aligned to position in DC operand
        LSL     W16, W8, W5             // W16 = amount to decrement way number per iteration
Loop2:  UBFX    W7, W1, #13, #15        // W7 = max set number, right aligned
        LSL     W7, W7, W2              // W7 = max set number, aligned to position in DC operand
        LSL     W17, W8, W2             // W17 = amount to decrement set number per iteration
Loop3:  ORR     W11, W10, W9            // W11 = combine way number and cache number ...
        ORR     W11, W11, W7            //  ... and set number for DC operand
        DC      CSW, X11                // do data cache clean by set and way
        SUBS    W7, W7, W17             // decrement set number
        B.GE    Loop3
        SUBS    X9, X9, X16             // decrement way number
        B.GE    Loop2
Skip:   ADD     W10, W10, #2            // increment 2 x cache level
        CMP     W3, W10
        DSB                             // ensure completion of previous cache maintenance operation
        B.GT    Loop1
        DSB
Finished:
```

Similar approaches can be used for all cache maintenance instructions.

D3.4.9 Data cache zero instruction

The Data Cache Zero by Address instruction, DC ZVA, writes `0b00` to each of a block of N bytes, aligned in memory to N bytes in size, where the block in memory is identified by the address passed. There are no alignment restrictions on the address supplied. The DCZID_EL0 register indicates the block size that is written with byte values of zero.

Software can restrict access to this operation. See *Controls at higher Exception levels* on page D1-1459.

If disabled, the operation at EL0 is trapped to EL1.

The `DC ZVA` instruction behaves as a set of stores to the location being accessed, and:

- Generates a Permission fault if the translation regime being used when the instruction is executed does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instruction.

In addition:

- When the instruction is executed, it can generate memory faults or watchpoints that are prioritized in the same way as other memory related faults or watchpoints. Where a synchronous Data Abort fault or a watchpoint is generated, the CM bit in the syndrome field is not set to 1, which would be the case for all other cache maintenance instructions. See *ISS encoding for an exception from a Data abort exception* on page D7-1849 for more information about the encoding of ESR_ELx and the associated ISS field.
- If the memory region being zeroed is any type of Device memory, then `DC ZVA` generates an Alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

Note

The architecture makes no statements about whether or not a DC ZVA instruction causes allocation to any particular level of the cache, for addresses that have a cacheable attribute for those levels of cache.

D3.4.10 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by set/way, DC CSW.
  - Cache invalidate by set/way, DC ISW.
  - Cache clean and invalidate by set/way, DC CISW.
  - Instruction cache invalidate all, IC IALLU and IC IALLUIS.

  However, one of the following approaches must be adopted in all these cases:

  1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
  2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.

3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See *ISS encoding for an exception from a Data abort exception* on page D7-1849.

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, DC CVAC and DC CVAU.
- Cache invalidate by virtual address, DC IVAC.
- Cache clean and invalidate by virtual address, DC CIVAC.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See *ESR_ELx* on page AppxJ-5173.

In an implementation that includes EL2, if HCR_EL2.TIDCP is set to 1, any exception relating to lockdown of an entry associated with Non-secure memory is routed to EL2.

Note

An implementation that uses an abort mechanisms for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

Additional cache functions for the implementation of lockdown

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED spaces reserved for Cache Lockdown, see *Reserved control space for IMPLEMENTATION DEFINED functionality* on page C5-251.

D3.4.11 System level caches

The system level architecture might define further aspects of the software view of caches and the memory model that are not defined by the ARMv8 architecture. These aspects of the system level architecture can affect the requirements for software management of caches and coherency. For example, a system design might introduce additional levels of caching that cannot be managed using the architecturally-defined maintenance instructions. Such caches are referred to as *system caches* and are managed through the use of memory-mapped operations. The ARMv8 architecture does not forbid the presence of system caches that are outside the scope of the architecture, but ARM strongly recommends that such caches are always placed after the Point of Coherency for all memory locations that might be held in a cache. Placing such system caches after the Point of Coherency means that coherency management does not require maintenance of these system caches.

ARM also strongly recommends:

- For the maintenance of any such system cache:
  - Physical, rather than virtual, addresses are used for address-based cache maintenance instructions.
  - Any IMPLEMENTATION DEFINED system cache maintenance instruction includes at least the set of maintenance options defined by *Cache maintenance instructions* on page D3-1608, with the number of levels of system cache operated on by the cache maintenance instructions being IMPLEMENTATION DEFINED.
- Wherever possible, all caches that require maintenance to ensure coherency are included in the caches affected by the architecturally-defined cache maintenance instructions, so that the architecturally-defined software sequences for managing the memory model and coherency are sufficient for managing all caches in the system.

D3.4.12 Branch prediction

ARMv8 does not define any branch predictor maintenance instructions for AArch64 state.

If branch prediction is architecturally visible, cache maintenance must also apply to branch prediction.

D3.5 External aborts

The ARM architecture defines external aborts as errors that occur in the memory system, other than those that are detected by the MMU or debug logic. External aborts include parity errors detected by the caches or other parts of the memory system. For example, an uncorrectable parity or ECC failure on a Level 2 Memory structure might generate an external abort.

An external abort is one of the following:

- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see *Exception terminology* on page D1-1401.

The ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous aborts.

In AArch64 state, asynchronous aborts are reported using the SError interrupt exception. See *Asynchronous exception types, routing, masking and priorities* on page D1-1453.

Synchronous external aborts are reported using the Instruction Abort and Data Abort exceptions. See *Synchronous exception types, routing and priorities* on page D1-1447.

VMSAv8-64 permits external aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which external aborts, if any, are supported.

Normally, external aborts are rare. An imprecise asynchronous external abort is likely to be fatal to the process that is running, ARM recommends that implementations make external aborts precise wherever possible.

The following subsections give more information about possible external aborts:

- *External abort on an instruction fetch*.
- *External abort on data read or write*.
- *Provision for the classification of external aborts*.
- *Parity error reporting* on page D3-1620.

D3.5.1 External abort on an instruction fetch

An external abort on an instruction fetch can be either synchronous or asynchronous.

A synchronous external abort on an instruction fetch is taken precisely using the Instruction Abort exception.

An implementation can report the external abort asynchronously from the instruction that it applies to. In such an implementation the abort is taken using the SError interrupt exception.

D3.5.2 External abort on data read or write

Externally-generated errors that occur during a data read or write can be either synchronous or asynchronous.

A synchronous external abort on a data read or write is taken precisely using the Data Abort exception.

An implementation can report the external abort asynchronously from the instruction that generated the access. In such an implementation the abort is taken using the SError interrupt exception.

D3.5.3 Provision for the classification of external aborts

In AArch64 state, an implementation can use ESR_ELx.EA, ISS[9], to provide more information about synchronous external aborts. For more information, see *ISS encoding for an exception from an Instruction abort exception* on page D7-1848 and *ISS encoding for an exception from a Data abort exception* on page D7-1849.

For all aborts other than synchronous external aborts reported using the EC values `0x20`, `0x21`, `0x24`, and `0x25`, ESR_ELx.EA, ISS[9], returns a value of 0.

D3.5.4 Parity error reporting

The ARM architecture supports the reporting of both synchronous and asynchronous parity errors from the cache system. It is IMPLEMENTATION DEFINED what parity errors in the cache systems, if any, result in synchronous or asynchronous parity errors.

A fault code is defined for reporting parity errors, see *Use of the ESR_EL1, ESR_EL2, and ESR_EL3* on page D1-1426. However, when parity error reporting is implemented, it is IMPLEMENTATION DEFINED whether a parity error is reported using the assigned fault code or using another appropriate encoding.

For all purposes other than the fault status encoding, parity errors are treated as external aborts.

D3.6 Memory barrier instructions

Memory barriers on page B2-85 describes the memory barrier instructions. This section describes the system level controls of those instructions.

D3.6.1 EL2 control of the shareability of data barrier instructions executed at Non-secure EL0 or EL1

In an implementation that includes EL2 and supports shareability limitations on the data barrier instructions, the HCR_EL2.BSU field can upgrade the required shareability of an instruction that is executed at EL0 or EL1 in Non-secure state. Table D3-7 shows the encoding of this field:

Table D3-7 EL2 control of shareability of barrier instructions executed at Non-secure EL0 or EL1

HCR_EL2.BSU	Minimum shareability of barrier instructions
00	No effect, shareability is as specified by the instruction
01	Inner Shareable
10	Outer Shareable
11	Full system

For an instruction executed at EL0 or EL1 in Non-secure state, Table D3-8 shows how the HCR_EL2.BSU is combined with the shareability specified by the argument of the `DMB` or `DSB` instruction to give the scope of the instruction:

Table D3-8 Effect of HCR_EL2.BSU on barrier instructions executed at Non-secure EL1 or EL0

Shareability specified by the `DMB` or `DSB` argument	HCR_EL2.BSU	Resultant shareability
Full system	Any	Full system
Outer Shareable	`00`, `01`, or `10`	Outer Shareable
	`11`, Full system	Full system
Inner Shareable	`00` or `01`	Inner Shareable
	`10`, Outer Shareable	Outer Shareable
	`11`, Full system	Full system
Non-shareable	`00`, No effect	Non-shareable
	`01`, Inner Shareable	Inner Shareable
	`10`, Outer Shareable	Outer Shareable
	`11`, Full system	Full system

D3.7 Pseudocode details of general memory system instructions

This section contains the following pseudocode describing general memory operations:

- *Memory data type definitions*.
- *Basic memory access* on page D3-1623.
- *Aligned memory access* on page D3-1623.
- *Unaligned memory access* on page D3-1624.
- *Exclusive monitors operations* on page D3-1625.
- *Access permission checking* on page D3-1627.
- *Abort exceptions* on page D3-1628.
- *Memory barriers* on page D3-1630.

D3.7.1 Memory data type definitions

This section describes the memory data type definitions.

The address descriptor type is defined as follows:

```
type AddressDescriptor is (
    FaultRecord      fault,      // fault.type indicates whether the address is valid
    MemoryAttributes memattrs,
    FullAddress      paddress
)
```

The full address type is defined as follows:

```
type FullAddress is (
    bits(48) physicaladdress,
    bit      NS                  // '0' = Secure, '1' = Non-secure
)
```

The memory attributes types are defined is as follows:

```
type MemoryAttributes is (
    MemType      type,

    DeviceType   device,     // For Device memory types
    MemAttrHints inner,      // Inner hints and attributes
    MemAttrHints outer,      // Outer hints and attributes

    boolean      shareable,
    boolean      outershareable
)
```

The memory type is defined as follows.

```
enumeration MemType {MemType_Normal, MemType_Device};
```

The Device memory types are defined as follows:

```
enumeration DeviceType {DeviceType_GRE, DeviceType_nGRE, DeviceType_nGnRE, DeviceType_nGnRnE};
```

For Normal memory, the inner and outer attributes are defined is as follows:

```
type MemAttrHints is (
    bits(2) attrs,  // The possible encodings for each attributes field are as below
    bits(2) hints,  // The possible encodings for the hints are below
    boolean transient
)
```

The cacheability attributes are defined as follows:

```
constant bits(2) MemAttr_NC = '00';     // Non-cacheable
constant bits(2) MemAttr_WT = '10';     // Write-through
constant bits(2) MemAttr_WB = '11';     // Write-back
```

The allocation hints are defined as follows:

```
constant bits(2) MemHint_No = '00';     // No allocate
constant bits(2) MemHint_WA = '01';     // Write-allocate, Read-no-allocate
constant bits(2) MemHint_RA = '10';     // Read-allocate, Write-no-allocate
constant bits(2) MemHint_RWA = '11';    // Read-allocate and Write-allocate
```

The access permissions type is defined as follows:

```
type Permissions is (
    bits(3) ap,   // Access permission bits
    bit     xn,   // Execute-never bit
    bit     pxn   // Privileged execute-never bit
)
```

D3.7.2 Basic memory access

The two _Mem[] accessors, Non-assignment (memory read) and Assignment (memory write), are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

```
bits(8*size) _Mem[AddressDescriptor desc, integer size, AccType acctype];

_Mem[AddressDescriptor desc, integer size, AccType acctype] = bits(8*size) value;
```

The functions address the array using desc.paddress which supplies:

- A 48-bit physical address.
- A single NS bit to select between Secure and Non-secure parts of the array.

The AccType parameter describes the access type, such as normal, exclusive, ordered, and streaming. For a definition of AccType, see *Address space* on page B2-68.

The actual implemented array of memory might be smaller than the 2^{48} bytes implied. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space might give rise to external aborts or a System Error.

The attributes in memaddrdesc.memattrs are used by the memory system to determine caching and ordering behaviors as described in *Memory types and attributes* on page B2-89, *Memory ordering* on page B2-82, and *Atomicity in the ARM architecture* on page B2-79.

PAMax() returns the IMPLEMENTATION DEFINED size of the physical address.

```
integer PAMax();
```

D3.7.3 Aligned memory access

The MemSingle[] function makes an atomic, little-endian accesses of size bytes.

```
// MemSingle[] - non-assignment (read) form
// ========================================

bits(size*8) MemSingle[bits(64) address, integer size, AccType acctype, boolean wasaligned]
    assert size IN {1, 2, 4, 8, 16};
    assert address == Align(address, size);

    AddressDescriptor memaddrdesc;
    bits(size*8) value;
    iswrite = FALSE;

    // MMU or MPU
    memaddrdesc = AArch64.TranslateAddress(address, acctype, iswrite, wasaligned, size);

    // Check for aborts or debug exceptions
    if IsFault(memaddrdesc) then
        AArch64.Abort(address, memaddrdesc.fault);
```

```
    // Memory array access
    value = _Mem[memaddrdesc, size, acctype];
    return value;

// MemSingle[] - assignment (write) form
// =====================================

MemSingle[bits(64) address, integer size, AccType acctype, boolean wasaligned] = bits(size*8) value
    assert size IN {1, 2, 4, 8, 16};
    assert address == Align(address, size);

    AddressDescriptor memaddrdesc;
    iswrite = TRUE;

    // MMU or MPU
    memaddrdesc = AArch64.TranslateAddress(address, acctype, iswrite, wasaligned, size);

    // Check for aborts or debug exceptions
    if IsFault(memaddrdesc) then
        AArch64.Abort(address, memaddrdesc.fault);

    // Effect on exclusives
    if memaddrdesc.mematttrs.shareable then
        ClearExclusiveByAddress(memaddrdesc.paddress, ProcessorID(), size);

    // Memory array access
    _Mem[memaddrdesc, size, acctype] = value;
    return;
```

D3.7.4 Unaligned memory access

The `Mem[]` function makes an access of the required type. If that access is not architecturally defined to be atomic, it synthesizes accesses from multiple calls to `MemSingle[]`. It also reverses the byte order if the access is big-endian.

```
// Mem[] - non-assignment (read) form
// ==================================

bits(size*8) Mem[bits(64) address, integer size, AccType acctype]
    assert size IN {1, 2, 4, 8, 16};
    bits(size*8) value;
    integer i;
    boolean iswrite = FALSE;

    aligned = AArch64.CheckAlignment(address, size, acctype, iswrite);
    atomic = (aligned && !(acctype IN {AccType_VEC, AccType_VECSTREAM})) || size == 1;

    if !atomic then
        assert size > 1;
        value<7:0> = MemSingle[address, 1, acctype, aligned];

        // For subsequent bytes it is CONSTRAINED UNPREDICTABLE whether an unaligned Device memory
        // access will generate an Alignment Fault, as to get this far means the first byte did
        // not, so we must be changing to a new translation page.
        if !aligned then
            c = ConstrainUnpredictable();
            assert c IN {Constraint_FAULT, Constraint_NONE};
            if c == Constraint_NONE then aligned = TRUE;

        for i = 1 to size-1
            value<8*i+7:8*i> = MemSingle[address+i, 1, acctype, aligned];
    else
        value = MemSingle[address, size, acctype, aligned];

    if BigEndian() then
        value = BigEndianReverse(value);
    return value;
```

```
// Mem[] - assignment (write) form
// ===============================

Mem[bits(64) address, integer size, AccType acctype] = bits(size*8) value
    integer i;
    boolean iswrite = TRUE;

    if BigEndian() then
        value = BigEndianReverse(value);

    aligned = AArch64.CheckAlignment(address, size, acctype, iswrite);
    atomic = (aligned && !(acctype IN {AccType_VEC, AccType_VECSTREAM})) || size == 1;

    if !atomic then
        assert size > 1;
        MemSingle[address, 1, acctype, aligned] = value<7:0>;

        // For subsequent bytes it is CONSTRAINED UNPREDICTABLE whether an unaligned Device memory
        // access will generate an Alignment Fault, as to get this far means the first byte did
        // not, so we must be changing to a new translation page.
        if !aligned then
            c = ConstrainUnpredictable();
            assert c IN {Constraint_FAULT, Constraint_NONE};
            if c == Constraint_NONE then aligned = TRUE;

        for i = 1 to size-1
            MemSingle[address+i, 1, acctype, aligned] = value<8*i+7:8*i>;
    else
        MemSingle[address, size, acctype, aligned] = value;
    return;
```

The `CheckAlignment()` function is:

```
// AArch64.CheckAlignment()
// ========================

boolean AArch64.CheckAlignment(bits(64) address, integer size, AccType acctype, boolean iswrite)

    aligned = (address == Align(address, size));
    A = SCTLR[].A;

    if !aligned && (acctype == AccType_ATOMIC || acctype == AccType_ORDERED || A == '1') then
        secondstage = FALSE;
        AArch64.Abort(address, AArch64.AlignmentFault(acctype, iswrite, secondstage));

    return aligned;
```

D3.7.5 Exclusive monitors operations

The `SetExclusiveMonitors()` function sets the exclusive monitors for a block of bytes, the size of which is determined by `size`, at the virtual address defined by `address`.

```
// AArch64.SetExclusiveMonitors()
// ==============================

// Sets the Exclusive Monitors for the current PE to record the addresses associated
// with the virtual address region of size bytes starting at address.

AArch64.SetExclusiveMonitors(bits(64) address, integer size)

    acctype = AccType_ATOMIC;
    iswrite = FALSE;
    aligned = (address != Align(address, size));

    memaddrdesc = AArch64.TranslateAddress(address, acctype, iswrite, aligned, size);

    // Check for aborts or debug exceptions
```

```
    if IsFault(memaddrdesc) then
        return;

    if memaddrdesc.memattrs.shareable then
        MarkExclusiveGlobal(memaddrdesc.paddress, ProcessorID(), size);

    MarkExclusiveLocal(memaddrdesc.paddress, ProcessorID(), size);

    AArch64.MarkExclusiveVA(address, ProcessorID(), size);
```

The ExclusiveMonitorsPass() function checks whether the exclusive monitors are set to include the location of a number of bytes specified by size, at the virtual address defined by address. The atomic write that follows after the exclusive monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to SetExclusiveMonitors().

```
// AArch64.ExclusiveMonitorsPass()
// ===============================

// Return TRUE if the Exclusive Monitors for the current PE include all of the addresses
// associated with the virtual address region of size bytes starting at address.
// The immediately following memory write must be to the same addresses.

boolean AArch64.ExclusiveMonitorsPass(bits(64) address, integer size)

    // It is IMPLEMENTATION DEFINED whether the detection of memory aborts happens
    // before or after the check on the local Exclusive Monitor. As a result a failure
    // of the local monitor can occur on some implementations even if the memory
    // access would give an memory abort.

    acctype = AccType_ATOMIC;
    iswrite = TRUE;
    aligned = (address == Align(address, size));

    if !aligned then
        secondstage = FALSE;
        AArch64.Abort(address, AArch64.AlignmentFault(acctype, iswrite, secondstage));

    passed = AArch64.IsExclusiveVA(address, ProcessorID(), size);
    if !passed then
        return FALSE;

    memaddrdesc = AArch64.TranslateAddress(address, acctype, iswrite, aligned, size);

    // Check for aborts or debug exceptions
    if IsFault(memaddrdesc) then
        AArch64.Abort(address, memaddrdesc.fault);

    passed = IsExclusiveLocal(memaddrdesc.paddress, ProcessorID(), size);
    if passed && memaddrdesc.memattrs.shareable then
        passed = IsExclusiveGlobal(memaddrdesc.paddress, ProcessorID(), size);

    if passed then
        ClearExclusiveLocal(ProcessorID());

    return passed;
```

The ExclusiveMonitorsStatus() function returns 0 if the previous atomic write was to the same physical memory locations selected by ExclusiveMonitorsPass() and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

```
bit ExclusiveMonitorsStatus();
```

The MarkExclusiveGlobal() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure records that the PE processorid has requested exclusive access covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED,

up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

```
MarkExclusiveGlobal(FullAddress paddress, integer processorid, integer size);
```

The `MarkExclusiveLocal()` procedure takes as arguments a `FullAddress paddress`, the PE identifier `processorid` and the size of the transfer. The procedure records in a local record that PE `processorid` has requested exclusive access to an address covering at least `size` bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a `MarkExclusiveGlobal()` using the same parameters.

```
MarkExclusiveLocal(FullAddress paddress, integer processorid, integer size);
```

The `IsExclusiveGlobal()` function takes as arguments a `FullAddress paddress`, the PE identifier `processorid` and the size of the transfer. The function returns TRUE if the PE `processorid` has marked in a global record an address range as exclusive access requested that covers at least `size` bytes from address `paddress`. It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, `IsExclusiveGlobal()` returns FALSE.

```
boolean IsExclusiveGlobal(FullAddress paddress, integer processorid, integer size);
```

The `IsExclusiveLocal()` function takes as arguments a `FullAddress paddress`, the PE identifier `processorid` and the size of the transfer. The function returns TRUE if the PE `processorid` has marked an address range as exclusive access requested that covers at least the `size` bytes from address `paddress`. It is IMPLEMENTATION DEFINED whether this function returns TRUE or FALSE if the address marked as exclusive access requested does not cover all of `size` bytes from address `paddress`. If no address is marked as exclusive access requested, then this function returns FALSE. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

```
boolean IsExclusiveLocal(FullAddress paddress, integer processorid, integer size);
```

The `ClearExclusiveByAddress()` procedure takes as arguments a `FullAddress paddress`, the PE identifier `processorid` and the size of the transfer. The procedure clears the global records of all PEs, other than `processorid`, for which an address region including any of `size` bytes starting from `paddress` has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE `processorid` is also cleared if any of `size` bytes starting from `paddress` has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

```
ClearExclusiveByAddress(FullAddress paddress, integer processorid, integer size);
```

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier `processorid`. The procedure clears the local record of PE `processorid` for which an address has had a request for an exclusive access. It is implementation defined whether this operation also clears the global record of PE `processorid` that an address has had a request for an exclusive access.

```
ClearExclusiveLocal(integer processorid);
```

D3.7.6 Access permission checking

The function `CheckPermission()` is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors. It returns the result of the call to `AArch64.NoFault()`.

The interpretation of access permission is shown in *Memory access control* on page D4-1707.

The pseudocode function for checking access permissions is as follows:

```
// AArch64.CheckPermission()
// =========================
// Function used for permission checking from AArch64 stage 1 translations

FaultRecord AArch64.CheckPermission(Permissions perms, bits(64) vaddress, integer level,
                                    bit NS, AccType acctype, boolean iswrite)
```

```
    assert !ELUsingAArch32(TranslationRegime());

    wxn = SCTLR[].WXN == '1';

    if PSTATE.EL IN {EL0,EL1} then
        priv_r = TRUE;
        priv_w = perms.ap<2> == '0';
        user_r = perms.ap<1> == '1';
        user_w = perms.ap<2:1> == '01';
        user_xn = perms.xn == '1' || (user_w && wxn);
        priv_xn = perms.pxn == '1' || (priv_w && wxn) || user_w;
        ispriv = PSTATE.EL == EL1 && acctype != AccType_UNPRIV;

        if ispriv then
            (r, w, xn) = (priv_r, priv_w, priv_xn);
        else
            (r, w, xn) = (user_r, user_w, user_xn);
    else
        // Access from EL2 or EL3
        r = TRUE;
        w = perms.ap<2> == '0';
        xn = perms.xn == '1' || (w && wxn);

    // Restriction on Secure instruction fetch
    if HaveEL(EL3) && IsSecure() && NS == '1' && SCR_EL3.SIF == '1' then
        xn = TRUE;

    if acctype == AccType_IFETCH then
        fail = xn;
    elsif iswrite then
        fail = !w;
    else
        fail = !r;

    if fail then
        secondstage = FALSE;
        s2fs1walk = FALSE;
        ipaddress = bits(48) UNKNOWN;
        return AArch64.PermissionFault(ipaddress, level, acctype, iswrite, secondstage,
                                       s2fs1walk);
    else
        return AArch64.NoFault();
```

D3.7.7 Abort exceptions

The `Abort()` function generates either a Data Abort or an Instruction Abort exception by calling `AArch64.DataAbort()` or `AArch64.InstructionAbort()`. It also can generate a debug exception for debug related faults, see Chapter D2 *AArch64 Self-hosted Debug*.

```
// AArch64.Abort()
// ===============
// Abort and Debug exception handling in an AArch64 translation regime.

AArch64.Abort(bits(64) vaddress, FaultRecord fault)

    if IsDebugException(fault) then
        if fault.acctype == AccType_IFETCH then
            if UsingAArch32() && fault.debugmoe == DebugException_VectorCatch then
                AArch64.VectorCatchException(fault);
            else
                AArch64.BreakpointException(fault);
        else
            AArch64.WatchpointException(vaddress, fault);
    elsif fault.acctype == AccType_IFETCH then
        AArch64.InstructionAbort(vaddress, fault);
    else
        AArch64.DataAbort(vaddress, fault);
```

The DataAbort() function generates a Data Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, ESR_ELx. See *ISS encoding for an exception from a Data abort exception* on page D7-1849. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, DataAbort() also sets the FAR to the VA of the abort.

The pseudocode for the DataAbort() function is as follows:

```
// AArch64.DataAbort()
// ===================

AArch64.DataAbort(bits(64) vaddress, FaultRecord fault)

    route_to_el3 = HaveEL(EL3) && SCR_EL3.EA == '1' && IsExternalAbort(fault);
    route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                    (HCR_EL2.TGE == '1' || IsSecondStage(fault)));

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    exception = AArch64.AbortSyndrome(Exception_DataAbort, fault, vaddress);

    if PSTATE.EL == EL3 || route_to_el3 then
        AArch64.TakeException(EL3, exception, preferred_exception_return, vect_offset);
    elsif PSTATE.EL == EL2 || route_to_el2 then
        AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
        AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
```

The InstructionAbort() function generates an Instruction Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, ESR_ELx. See *ISS encoding for an exception from an Instruction abort exception* on page D7-1848. A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, InstructionAbort() also sets the FAR to the VA of the abort.

The pseudocode for the InstructionAbort() function is as follows:

```
// AArch64.InstructionAbort()
// ==========================

AArch64.InstructionAbort(bits(64) vaddress, FaultRecord fault)

    route_to_el3 = HaveEL(EL3) && SCR_EL3.EA == '1' && IsExternalAbort(fault);
    route_to_el2 = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                    (HCR_EL2.TGE == '1' || IsSecondStage(fault)));

    bits(64) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x0;

    exception = AArch64.AbortSyndrome(Exception_InstructionAbort, fault, vaddress);

    if PSTATE.EL == EL3 || route_to_el3 then
        AArch64.TakeException(EL3, exception, preferred_exception_return, vect_offset);
    elsif PSTATE.EL == EL2 || route_to_el2 then
        AArch64.TakeException(EL2, exception, preferred_exception_return, vect_offset);
    else
        AArch64.TakeException(EL1, exception, preferred_exception_return, vect_offset);
```

The FaultRecord type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. *Pseudocode details of the MMU faults* on page D4-1729 provides a number of wrappers to generate FaultRecords.

The NoFault() function returns a null record that indicates no fault. The IsFault() function tests whether a FaultRecord contains a fault.

```
enumeration Fault {Fault_None,
```

```
                    Fault_AccessFlag,
                    Fault_Alignment,
                    Fault_Background,
                    Fault_Domain,
                    Fault_Permission,
                    Fault_Translation,
                    Fault_AddressSize,
                    Fault_SyncExternal,
                    Fault_SyncExternalOnWalk,
                    Fault_SyncParity,
                    Fault_SyncParityOnWalk,
                    Fault_AsyncParity,
                    Fault_AsyncExternal,
                    Fault_Debug,
                    Fault_TLBConflict,
                    Fault_Lockdown,
                    Fault_Coproc,
                    Fault_ICacheMaint};
type FaultRecord is (Fault    type,         // Fault Status
                     AccType  acctype,      // Type of access that faulted
                     bits(48) ipaddress,    // Intermediate physical address
                     boolean  s2fs1walk,    // Is on a Stage 1 page table walk
                     boolean  write,        // TRUE for a read, FALSE for a write
                     integer  level,        // For translation, access flag and permission faults
                     bit      extflag,      // IMPLEMENTATION DEFINED syndrome for external aborts
                     boolean  secondstage,  // Is a Stage 2 abort
                     bits(4)  domain,       // Domain number, AArch32 only
                     bits(4)  debugmoe)     // Debug method of entry, from AArch32 only
// AArch64.NoFault()
// =================

FaultRecord AArch64.NoFault()

    ipaddress = bits(48) UNKNOWN;
    level = integer UNKNOWN;
    acctype = AccType_NORMAL;
    iswrite = boolean UNKNOWN;
    extflag = bit UNKNOWN;
    secondstage = FALSE;
    s2fs1walk = FALSE;

    return AArch64.CreateFaultRecord(Fault_None, ipaddress,  level, acctype, iswrite,
                                     extflag, secondstage, s2fs1walk);
// IsFault()
// =========
// Return true if a fault is associated with an address descriptor

boolean IsFault(AddressDescriptor addrdesc)
    return addrdesc.fault.type != Fault_None;
```

D3.7.8 Memory barriers

The definition for the memory barrier functions is:

```
enumeration MBReqDomain    {MBReqDomain_Nonshareable, MBReqDomain_InnerShareable,
                            MBReqDomain_OuterShareable, MBReqDomain_FullSystem};

enumeration MBReqTypes     {MBReqTypes_Reads, MBReqTypes_Writes, MBReqTypes_All};
```

These functions define the required shareability domains and required access types used as arguments for DMB and DSB instructions.

The following procedures perform the memory barriers:

```
DataMemoryBarrier(MBReqDomain domain, MBReqTypes types);

DataSynchronizationBarrier(MBReqDomain domain, MBReqTypes types);
```

```
InstructionSynchronizationBarrier();
```

Chapter D4
The AArch64 Virtual Memory System Architecture

This chapter provides a system level view of the AArch64 Virtual Memory System Architecture (VMSA), the memory system architecture of an ARMv8 implementation that is executing in AArch64 state. It contains the following sections:

D4.1 About the Virtual Memory System Architecture (VMSA)

This chapter describes the *Virtual Memory System Architecture* (VMSA) that applies to a PE executing in AArch64 state. This is VMSAv8-64, as defined in *ARMv8 VMSA naming* on page D4-1638.

A VMSA provides a *Memory Management Unit* (MMU), that controls address translation, access permissions, and memory attribute determination and checking, for memory accesses made by the PE.

The process of address translation maps the *virtual addresses* (VAs) used by the PE onto the *physical addresses* (PAs) of the physical memory system. These translations are defined independently for different Exception levels and Security states, and Figure D4-1 shows:

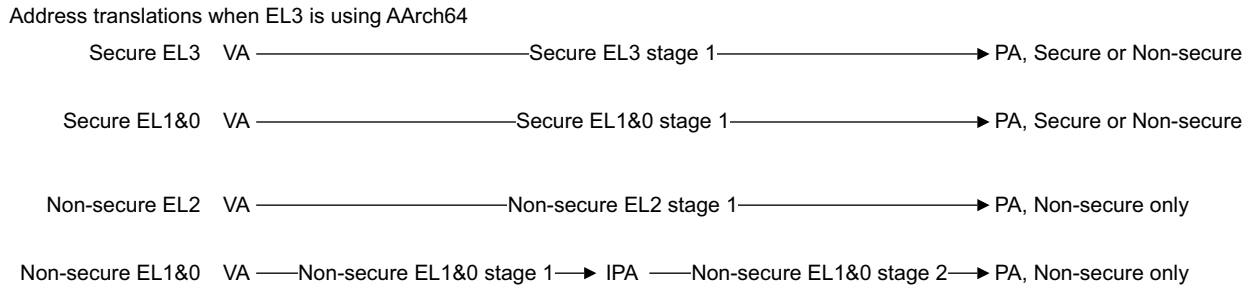

Figure D4-1 Address translations for different Exception levels and Security states

VMSAv8-64 supports tagging of VAs, as described in *Address tagging in AArch64 state*. As that section describes, this address tagging has no effect on the address translation process.

The remainder of this chapter gives a full description of VMSAv8-64 for an implementation that includes all of the Exception levels. *The implemented Exception levels and the resulting translation stages and regimes* on page D4-1672 describes the differences in the VMSA if some Exception levels are not implemented.

D4.1.1 Address tagging in AArch64 state

In AArch64 state, the ARMv8 architecture supports tagged addresses for data values. In these cases the top eight bits of the virtual address are ignored when determining:

- Whether the address causes a Translation fault from being out of range if the translation system is enabled.
- Whether the address causes an Address size fault from being out of range if the translation system is not enabled.
- Whether the address requires invalidation when performing a TLB invalidation instruction by address.

The use of address tags is controlled as follows:

For addresses using the VMSAv8-64 EL1&0 translation regime

The value of bit[55] of the VA determines the register bit that controls the use of address tags, as follows:

VA[55]==0 TCR_EL1.TBI0 determines whether address tags are used. If stage 1 translation is enabled, TTBR0_EL1 holds the base address of the translation tables used to translate the address.

VA[55]==1 TCR_EL1.TBI1 determines whether address tags are used. If stage 1 translation is enabled, TTBR1_EL1 holds the base address of the translation tables used to translate the address.

For addresses using the VMSAv8-64 EL2 translation regime

TCR_EL2.TBI determines whether address tags are used. If stage 1 translation is enabled, TTBR0_EL2 holds the base address of the translation tables used to translate the address.

For addresses using the VMSAv8-64 EL3 translation regime

TCR_EL3.TBI determines whether address tags are used. If stage 1 translation is enabled, TTBR0_EL3 holds the base address of the translation tables used to translate the address.

Note

The TCR_ELx.TBI*n* bits determine whether address tags are use regardless of whether the corresponding translation regime is enabled.

An address tag enable bit also has an effect on the PC value in the following cases:

- Any branch or procedure return within the controlled Exception level.
- On taking an exception to the controlled Exception level, regardless of whether this is also the Exception level from which the exception was taken.
- On performing an exception return to the controlled Exception level, regardless of whether this is also the Exception level from which the exception return was performed.
- Exiting from debug state to the controlled Exception level.

Note

As an example of what is meant by the *controlled Exception level*, TCR_EL2.TBI controls this effect for:

- A branch or procedure return within EL2.
- Taking an exception to EL2.
- Performing an exception return or a debug state exit to EL2.

The effect of the controlling TBI{*n*} bit is:

For EL0 or EL1 If the controlling TBI*n* bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be a sign extension of bit[55] of that address.

For EL2 or EL3 If the controlling TBI bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be `0x00`.

The `AddrTop()` pseudocode function shows the algorithm determining the most significant bit of the VA, and therefore whether the virtual address is using tagging. For the EL1&0 translation regime, this pseudocode includes the selection between TTBR0_EL1 and TTBR1_EL1 described in *Selection between TTBR0 and TTBR1* on page D4-1663.

```
// AddrTop()
// =========

integer AddrTop(bits(64) address)
    // Return the MSB number of a virtual address in the current stage 1 translation
    // regime. If EL1 is using AArch64 then addresses from EL0 using AArch32
    // are zero-extended to 64 bits.
    if UsingAArch32() && !(PSTATE.EL == EL0 && !ELUsingAArch32(EL1)) then
        // AArch32 translation regime.
        return 31;
    else
        // AArch64 translation regime.
        case PSTATE.EL of
            when EL0, EL1
                tbi = if address<55> == '1' then TCR_EL1.TBI1 else TCR_EL1.TBI0;
            when EL2
                tbi = TCR_EL2.TBI;
            when EL3
                tbi = TCR_EL3.TBI;
        return (if tbi == '1' then 55 else 63);
```

Note

The required behavior prevents a tagged address being propagated to the program counter.

D4.2 The VMSAv8-64 address translation system

This section describes the VMSAv8-64 address translation system, that maps VAs to PAs. Related to this:

- *Translation table walk examples* on page D4-1686 gives detailed descriptions of typical examples of translating a VA to a final PA, and obtaining the memory attributes of that PA.
- *VMSAv8-64 translation table format descriptors* on page D4-1698 describes the translation table entries.
- *Access controls and memory region attributes* on page D4-1707 describes the attributes that are held in the translation table entries, including how different attributes can interact.
- *Translation Lookaside Buffers (TLBs)* on page D4-1730 describes the caching of translation table lookups in TLBs, and the architected instructions for maintaining TLBs.

In this section, the following subsections describe the VMSAv8-64 address translation system:

- *About the VMSAv8-64 address translation system*.
- *Controlling address translation stages* on page D4-1640.
- *Memory translation granule size* on page D4-1644.
- *Translation tables and the translation process* on page D4-1648.
- *Overview of the VMSAv8-64 address translation stages* on page D4-1651.
- *The VMSAv8-64 translation table format* on page D4-1660.
- *The algorithm for finding the translation table entries* on page D4-1666.
- *The effects of disabling a stage of address translation* on page D4-1670.
- *The implemented Exception levels and the resulting translation stages and regimes* on page D4-1672.
- *Pseudocode details of VMSAv8-64 address translation* on page D4-1672.
- *Address translation instructions* on page D4-1683.

D4.2.1 About the VMSAv8-64 address translation system

The *Memory Management Unit* (MMU) controls address translation, memory access permissions, and memory attribute determination and checking, for memory accesses made by the PE.

The general model of MMU operation is that the MMU takes information about a required memory access, including an *input address* (IA), and either:

- Returns an associated *output address* (OA), and the *memory attributes* for that address.
- Is unable to perform the translation for one of a number of reasons, and therefore causes an exception to be generated. This exception is called an MMU fault. An MMU fault is generated by a particular stage of translation, and can be described as either a stage 1 MMU fault or a stage 2 MMU fault.

The process of mapping an IA to an OA is an *address translation*, or more precisely a single stage of address translation.

The architecture defines a number of *translation regimes*, where a translation regime comprises either:

- A single stage of address translation.

  This maps an input *Virtual Address* (VA) to an output *Physical Address* (PA).
- Two, sequential, stages of address translation, where:
  - Stage 1 maps an input VA to an output *Intermediate Physical Address* (IPA).
  - Stage 2 maps an input IPA to an output PA.

The *translation granule* specifies the granularity of the mapping from IA to OA. That is, it defines both:

- The *page size* for a stage of address translation, where a page is the smallest block of memory for which an IA to OA mapping can be specified.
- The size of a complete translation table for that stage of address translation.

The MMU is controlled by System registers, that provide independent control of each address translation stage, including a control to disable the stage of address translation. *The effects of disabling a stage of address translation* on page D4-1670 defines how the MMU handles an access for which a required address translation stage is disabled.

Note

- In the ARM architecture, a software agent, such as an operating system, that uses or defines stage 1 memory translations, might be unaware of the second stage of translation, and of the distinction between IPA and PA.
- A more generalized description of the translation regimes is that a regime always comprises two sequential stages of translation, but in some regimes the stage 2 translation both:
  - Returns an OA that equals the IA. This is called a *flat mapping* of the IA to the OA.
  - Does not change the memory attributes returned by the stage 1 address translation.

For an access to a stage of address translation that does not generate an MMU fault, the MMU translates the IA to the corresponding OA. System registers are used to report any faults that occur on a memory access.

This section describes the address translation system for an implementation that includes all of the Exception levels, and gives a complete description of translations that are controlled by an Exception level that is using AArch64.

Figure D4-2 shows these translation stages and translation regimes when EL3 is using AArch64.

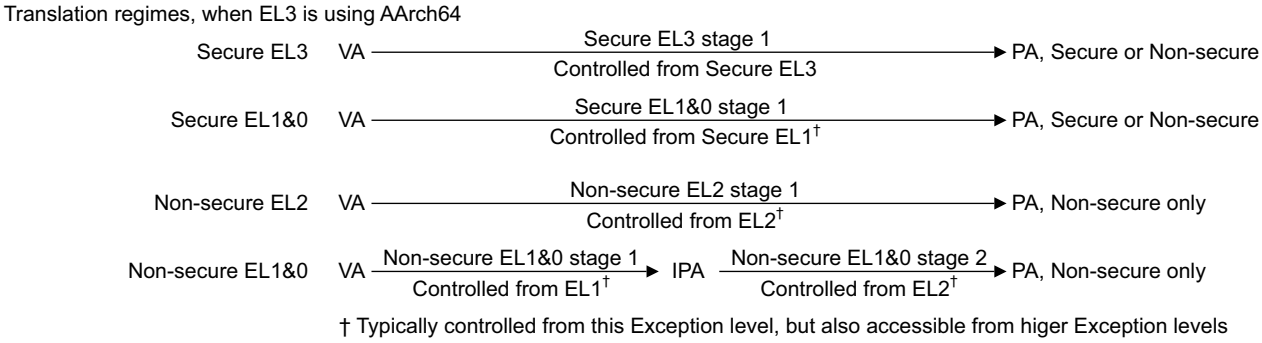

Figure D4-2 VMSAv8 AArch64 translation regimes, translation stages, and associated controls

ARMv8 VMSA naming on page D4-1638 gives more information about the options for the different stages of address translation shown in Figure D4-2, and:

- Chapter G4 *The AArch32 Virtual Memory System Architecture* describes:
  - The translation stages and translation regimes when EL3 is using AArch32.
  - Any stages of address translation that are using VMSAv8-32 when EL3 is using AArch64.
- *The implemented Exception levels and the resulting translation stages and regimes* on page D4-1672 describes the effect on the address translation model when some Exception levels are not implemented.

Each enabled stage of address translation uses a set of address translations and associated memory properties held in memory mapped tables called *translation tables*. A single translation table lookup can resolve only a limited number of bits of the IA, and therefore a single address translation can require multiple lookups. These are described as different *levels* of lookup.

Translation table entries can be cached in a *Translation Lookaside Buffer* (TLB).

As well as defining the OA that corresponds to the IA, the translation table entries define the following properties:

- Access to the Secure or Non-secure address map, for accesses made from Secure state.
- Memory access permission control.
- Memory region attributes.

For more information, see *Memory attribute fields in the VMSAv8-64 translation table format descriptors* on page D4-1702.

The following subsections give more information:

- *ARMv8 VMSA naming*.
- *VMSA address types and address spaces*.
- *About address translation* on page D4-1639.
- *The VMSAv8-64 translation table format* on page D4-1639.

ARMv8 VMSA naming

The ARMv8 VMSA naming model reflects the possible stages of address translation, as follows:

VMSAv8 The overall translation scheme, within which an address translation has one or two stages.

VMSAv8-32 The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch32.

VMSAv8-64 The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch64.

VMSA address types and address spaces

A description of the VMSA refers to the following address types.

Note

These descriptions relate to the VMSAv8 description and therefore give more detail than the generic definitions given in the glossary.

Virtual Address (VA)

An address used in an instruction, as a data or instruction address, is a Virtual Address (VA).

Note

This means that an address held in the PC, LR, SP, or an ELR, is a VA.

In AArch64 state, the VA address space has a maximum address width of 48 bits. With a single VA range this gives a maximum VA space of 256TB, with VA range of `0x0000_0000_0000_0000` to `0x0000_FFFF_FFFF_FFFF`.

However, for the EL1&0 translation stage the VA range is split into two subranges, one at the bottom of the full 64-bit address range of the PC, and one at the top, as follows:

- The bottom VA range runs up from address `0x0000_0000_0000_0000`. With the maximum address width of 48 bits this gives a VA range of `0x0000_0000_0000_0000` to `0x0000_FFFF_FFFF_FFFF`.
- The top VA subrange runs up to address `0xFFFF_FFFF_FFFF_FFFF`. With the maximum address width of 48 bits this gives a VA range of `0xFFFF_0000_0000_0000` to `0xFFFF_FFFF_FFFF_FFFF`. Reducing the address width for this subrange increases the bottom address of the range.

This means that there are two VA subranges, each of up to 256TB.

Each translation regime, that takes a VA as an input address, can be configured to support fewer than 48 bits of virtual address space, see *Address size configuration* on page D4-1641.

Intermediate Physical Address (IPA)

In a translation regime that provides two stages of address translation, the IPA is:

- The OA from the stage 1 translation.
- The IA for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the PA. Alternatively, the translation regime can be considered as having no concept of IPAs.

The IPA address space has a maximum address width of 48 bits, see *Address size configuration* on page D4-1641.

Physical Address (PA)

The address of a location in a physical memory map. That is, an output address from the PE to the memory system.

The EL3 and Secure EL1 Exception levels provide independent definition of physical address spaces for Secure and Non-secure operation. This means they provide two independent address spaces, where:

- A VA accessed in Secure state can be translated to either the Secure or the Non-secure physical address space.
- When in Non-secure state, a VA is always mapped to the Non-secure physical address space.

Each PA address space has a maximum address width of 48 bits, but an implementation can implement fewer than 48 bits of physical address. See *Address size configuration* on page D4-1641.

About address translation

For a single stage of address translation, a *Translation table base register* (TTBR) indicates the start of the first translation table required for the mapping from input address to output address. Each implemented translation stage shown in *VMSAv8 AArch64 translation regimes, translation stages, and associated controls* on page D4-1637 requires its own set of translation tables.

For the EL1&0 stage 1 translation, the split of the VA mapping into two subranges requires two tables, one for the lower part of the VA space, and the other for the upper part of the VA space. *Example use of the split VA range, and the TTBR0_EL1 and TTBR1_EL1 controls* on page D4-1663 shows how these ranges might be used.

Controlling address translation stages on page D4-1640 summarizes the system control registers that control address translation by the MMU.

A full translation table lookup is called a *translation table walk*. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single IA to OA translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a *level* of address lookup. The final level of the lookup defines:

- The high bits of the required output address.
- The *attributes* and *access permissions* of the addressed memory.

Translation table entries can be cached in a *Translation Lookaside Buffer*, see *Translation Lookaside Buffers (TLBs)* on page D4-1730.

The VMSAv8-64 translation table format

Stages of address translation that are controlled by an Exception level that is using AArch64 use the VMSAv8-64 translation table format. This format uses 64-bit descriptor entries in the translation tables.

Note

This format is an extension of the VMSAv8-32 Long-descriptor translation table format originally defined by the ARMv7 Large Physical Address Extension, and extended slightly by ARMv8. VMSAv8-32 also supports a Short-descriptor translation table format. Chapter G4 *The AArch32 Virtual Memory System Architecture* describes both of these formats.

The VMSAv8-64 translation table format provides:

- Up to four levels of address lookup.
- Input addresses of up to 48 bits.
- Output addresses of up to 48 bits.
- A translation granule size of 4KB, 16KB, or 64KB.

D4.2.2 Controlling address translation stages

The implemented Exception levels and the resulting translation stages and regimes on page D4-1672 defines the translation regimes and stages. For each supported address translation stage:

- A system control register bit enables the stage of address translation.
- A system control register bit determines the endianness of the translation table lookups.
- A *Translation Control Register* (TCR) controls the stage of address translation.
- If a stage of address translation supports splitting the VA range into two subranges then that stage of translation provides a *Translation Table Base Register* (TTBR) for each VA subrange, and the stage of address translation has:
  — A single TCR.
  — A TTBR for each VA subrange.

  Otherwise, a single TTBR holds the address of the translation table that must be used for the first lookup for the stage of address translation.

For address translation stages controlled from AArch64:

- Table D4-1 shows the endianness bit and the enable bit for each stage of address translation. Each register entry in the table gives the endianness bit followed by the enable bit. Except for the Non-secure EL1&0 stage 2 translation, these two bits are in the same register.

Table D4-1 Enable and endianness bits for the AArch64 translation stages

Translation stage	Controlled from	Controlling register
Secure EL3 stage 1	EL3	SCTLR_EL3.{EE, M}
Secure EL1&0 stage 1	Secure EL1	SCTLR_EL1.{EE, M}
Non-secure EL2 stage 1	EL2	SCTLR_EL2.{EE, M}
Non-secure EL1&0 stage 2	EL2	SCTLR_EL2.EE, HCR_EL2.VM
Non-secure EL1&0 stage 1	Non-secure EL1	SCTLR_EL1.{EE, M}

Note

If the PA of the software that enables or disables a particular stage of address translation differs from its VA, speculative instruction fetching can cause complications. ARM strongly recommends that the PA and VA of any software that enables or disables a stage of address translation are identical if that stage of translation controls translations that apply to the software currently being executed.

- Table D4-2 shows the TCR and TTBR, or TTBRs, for each stage of address translation. In the table, each *Controlling registers* entry gives the TCR followed by the TTBR or TTBRs.

Table D4-2 TCRs and TTBRs for the AArch64 translation stages

Translation stage	Controlled from	Controlling registers
Secure EL3 stage 1	EL3	TCR_EL3, TTBR0_EL3
Secure EL1&0 stage 1	Secure EL1	TCR_EL1, TTBR0_EL1, TTBR1_EL1
Non-secure EL2 stage 1	EL2	TCR_EL2, TTBR0_EL2
Non-secure EL1&0 stage 2	EL2	VTCR_EL2, VTTBR_EL2
Non-secure EL1&0 stage 1	Non-secure EL1	TCR_EL1, TTBR0_EL1, TTBR1_EL1

System control registers relevant to MMU operation

In AArch64 state, system control registers have a suffix, that indicates the lowest Exception level from which they can be accessed. In some general descriptions of MMU control and address translation, this chapter uses a *Common abbreviation* for each of the system control registers that affects MMU operation, as Table D4-3 shows. The common abbreviation is used when describing features that apply to all the translation regimes.

Note

The only translation regime that supports a stage 2 translation is the Non-secure EL1&0 translation regime.

Table D4-3 Abbreviations for system control registers used in this chapter

Common abbreviation	Translation stage	Exception level		
		EL1	EL2	EL3
HCR	-	-	HCR_EL2	-
SCTLR	-	SCTLR_EL1	SCTLR_EL2	SCTLR_EL3
TCR	Stage 1	TCR_EL1	TCR_EL2	TCR_EL3
	Stage 2	-	VTCR_EL2	-
TTBR	Stage 1	TTBR0_EL1, TTBR1_EL1	TTBR0_EL2	TTBR0_EL3
	Stage 2	-	VTTBR_EL2	-

Address size configuration

The following subsubsections specify the configuration of the physical address size and of the input and output address sizes for each of the stages of address translation:

- *Physical address size*.
- *Output address size* on page D4-1642.
- *Input address size* on page D4-1642.
- *Supported IPA size* on page D4-1643.

Physical address size

The ID_AA64MMFR0_EL1.PARange field indicates the implemented physical address size, as Table D4-4 shows:

Table D4-4 Physical address size implementation options

ID_AA64MMFR0_EL1.PARange	Total PA size	PA address size
0000	4 GB	32 bits, PA[31:0]
0001	64 GB	36 bits, PA[35:0]
0010	1 TB	40 bits, PA[39:0]
0011	4 TB	42 bits, PA[41:0]
0100	16 TB	44 bits, PA[43:0]
0101	256 TB	48 bits. PA[47:0]

All other PARange values are reserved.

Output address size

For each enabled stage of address translation, TCR.{I}PS must be programmed to maximum output address size for that stage of translation, using the encodings as shown in Table D4-4 on page D4-1641, ignoring the first `0`. In these cases, if an {I}PS field is programmed to a reserved value, the PE behaves as if the field is programmed to `0b101`, but software must not rely on this behavior.

Note

- This field is called IPS in the TCR_EL1, and PS in the other TCRs.
- The {I}PS fields are 3-bit fields, corresponding to the least-significant PARange bits shown in Table D4-4 on page D4-1641.

This field is used to check that translation table entries and the TTBR for the stage of address translation have the address bits above the specified PA size set to zero. If this is not the case, an Address size fault is generated for the level of translation that caused the fault. An Address size fault from the TTBR is reported as a Level 0 fault.

If the specified output address size is larger than the implemented physical address size then an Address size fault is generated for the translation stage and level that generates the output address. When stage 2 translation is disabled, if the output address from the stage 1 translation is larger than the implemented physical address size, this is reported as a Stage 1 Address size fault.

If stage 1 translation is disabled, if the input address is larger than the implemented physical address size then an Address size fault is generated and reported as a Stage 1 level 0 fault.

Input address size

For each enabled stage of address translation, the TCR.T*x*SZ fields specify the input address size:

- TCR_EL1 has two T*x*SZ fields, corresponding to the two VA subranges:
  - TCR_EL1.T0SZ specifies the size for the lower VA range, translated using TTBR0_EL1.
  - TCR_EL1.T1SZ specifies the size for the upper VA range, translated using TTBR1_EL1.
- Each of the other TCRs has a single T0SZ field.

For the Non-secure EL1&0 translation regime, when both stages of translation are enabled, if the output address from the stage 1 translation does not generate a stage 1 address size fault, and is larger than the input address specified by VTCR_EL2.T0SZ, then the input address size check for the stage 2 translation generates a Translation fault.

Overview of the VMSAv8-64 address translation stages on page D4-1651 gives more information about the relationship between the required input address size, the value of T*x*SZ, and the required initial lookup level, and how these are affected by the translation granule size. However:

For all translation stages

The maximum T*x*SZ value is 39. If T*x*SZ is programmed to a value larger than 39 then the implementation behaves as if the field is programmed to 39 for all purposes other than reading back the value of the field.

For a stage 1 translation

The minimum T*x*SZ value is 16. If T*x*SZ is programmed to a value smaller than 16 then the implementation behaves as if the field were programmed to 16 for all purposes other than reading back the value of the field.

For a stage 2 translation

Supported IPA size on page D4-1643 defines the effective minimum value of T0SZ, that depends on the supported PA size, and also describes the possible effects of programming T0SZ to a value that is smaller than this effective minimum value.

Supported IPA size

For the Non-secure EL1&0 translation regime, the maximum IPA size is the maximum input address size for the second stage of translation, that must be specified by VTCR_EL2.T0SZ, see *Input address size* on page D4-1642. This value is constrained by the implemented PA size that is specified by ID_AA64MMFR0_EL1.PARange, see *Physical address size* on page D4-1641. This implemented PA size also constrains the maximum value of VTCR_EL2.SL0, that specifies the level of the initial lookup. SL0 also depends on the translation granule, as described in *Overview of the VMSAv8-64 address translation stages* on page D4-1651.

Table D4-5 PA size implications for the VTCR_EL2.{T0SZ, SL0} fields

Supported PA size	Effective minimum T0SZ value	Maximum SL0 value		
		4KB granule	16KB granule	64KB granule
32 bits	32 if EL1 is using AArch64 24 if EL1 is using AArch32	1	1	1
36 bits	28 if EL1 is using AArch64 24 if EL1 is using AArch32	1	1	1
40 bits	24	1	1	1
42 bits	22	1	2	1
44 bits	20	2	2	2
48 bits	16	2	2	2

If VTCR_EL2.SL0 is programmed to a value larger than the maximum value shown in Table D4-5 then any memory access that uses the second stage of translation generates a stage 2 level 0 Translation fault.

If VTCR_EL2.T0SZ is programmed to a value smaller than the effective minimum value shown in Table D4-5 then the implementation consistently does one of the following:

- Treat the VTCR_EL2.T0SZ field as being programmed to the effective minimum value for all purposes other than reading back the value of the field.
- Treat the VTCR_EL2.T0SZ field as being programmed to the effective minimum value for all purposes other than:
  - Reading back the value of the field.
  - Checking whether the value of VTCR_EL2.T0SZ is consistent with the value of VTCR_EL2.SL0.
- Generate a stage 2 level 0 Translation fault on any memory access that uses the second stage of translation.

Note

Programming VTCR_EL2.T0SZ to a value smaller than the effective minimum value shown in Table D4-5 can never provide support for a larger address range than the range given by the effective minimum value, because the stage 1 output address will give an Address size fault if it is larger than either:

- The PA size, for a VMSAv8-64 stage 1 translation.
- 40 bits, for a VMSAv8-32 stage 1 translation.

D4.2.3 Memory translation granule size

The memory translation granule size defines both:

- The maximum size of a single translation table.
- The memory *page* size. That is, the granularity of a translation table lookup.

VMSAv8-64 supports translation granule sizes of 4KB, 16KB, and 64KB, and each translation stage is configured to use one of these granule sizes.

Note

Using a larger granule size can reduce the maximum required number of levels of address lookup because:

- The increased translation table size means the translation table holds more entries. This means a single lookup can resolve more bits of the input address.
- The increased page size means more of the least-significant address bits are required to address a page. These address bits are flat mapped from the input address to the output address, and therefore do not require translation.

Table D4-6 summarizes the effects of the different granule sizes.

Table D4-6 Effect of granule size on a stage of address translation

Property	4KB granule	16KB granule	64KB granule	Notes
Maximum number of entries in a translation table	512	2048 (2K)	8192 (8K)	-
Address bits resolved in one level of lookup	9	11	13	2^9=512, 2^{11}=2K, 2^{13}=8K
Page size	4KB	16KB	64KB	-
Page address range	VA[11:0]= PA[11:0]	VA[13:0]= PA[13:0]	VA[15:0]= PA[15:0]	2^{12}=4K, 2^{14}=16K, 2^{16}=64K

How the granule size affects the address translation process

As Table D4-6 shows, the translation granule determines the number of address bits:

- Required to address a memory page.
- That can be resolved in a single translation table lookup.

This means the translation granule determines how the *input address* (IA) is resolved to an *output address* (OA) by the translation process.

Because a single translation table lookup can resolve only a limited number of address bits, the IA to OA resolution requires multiple *levels* of lookup.

Considering the resolution of the maximum IA range of 48 bits, with a translation granule size of 2^n bytes:

- The least-significant n bits of the IA address the memory page. This means OA[(n-1):0]=IA[(n-1):0].
- The remaining (48-n) bits of the IA, IA[47:n], must be resolved by the address translation.
- A translation table descriptor is 8 bytes. Therefore:
  - A complete translation table holds $2^{(n-3)}$ descriptors.
  - A single level of translation can resolve a maximum of (n-3) bits of address.

  Consider the translation process, working back from the final level of lookup, that resolves the least significant of the address bits that require translation. Because a level of lookup can resolve (n-3) bits of address:
  - The final level of lookup resolves IA[(2n-4):n].

— The previous level of lookup resolves IA[(3*n*-7):(2*n*-3)].

However, the level of lookup that resolves the most significant bits of the IA might not require a full-sized translation table. Therefore, in general, the address bits resolved in a level of lookup are:

IA[Min(47, ((*x*-3)(*n*-3)+2*n*-4)):(*n*+(*x*-3)(*n*-3))], where:

Min(*a*, *b*) Is a function that returns the minimum of *a* and *b*.

x Indicates the level of lookup. This is defined so that the level that resolves the least significant bit of the translated IA bits is level 3.

The following diagrams show this model, for each of the permitted granule sizes.

Figure D4-3 shows how a 48-bit IA is resolved when using the 4KB translation granule.

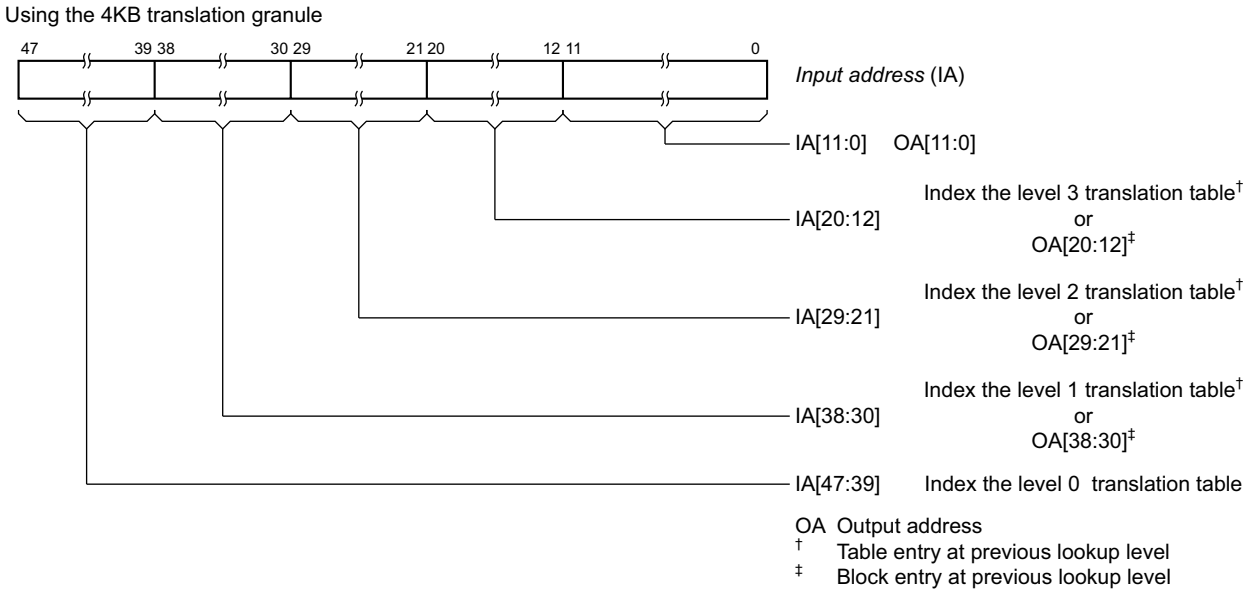

Figure D4-3 How the IA is resolved when using the 4KB translation granule

Figure D4-4 shows how a 48-bit IA is resolved when using the 16KB translation granule.

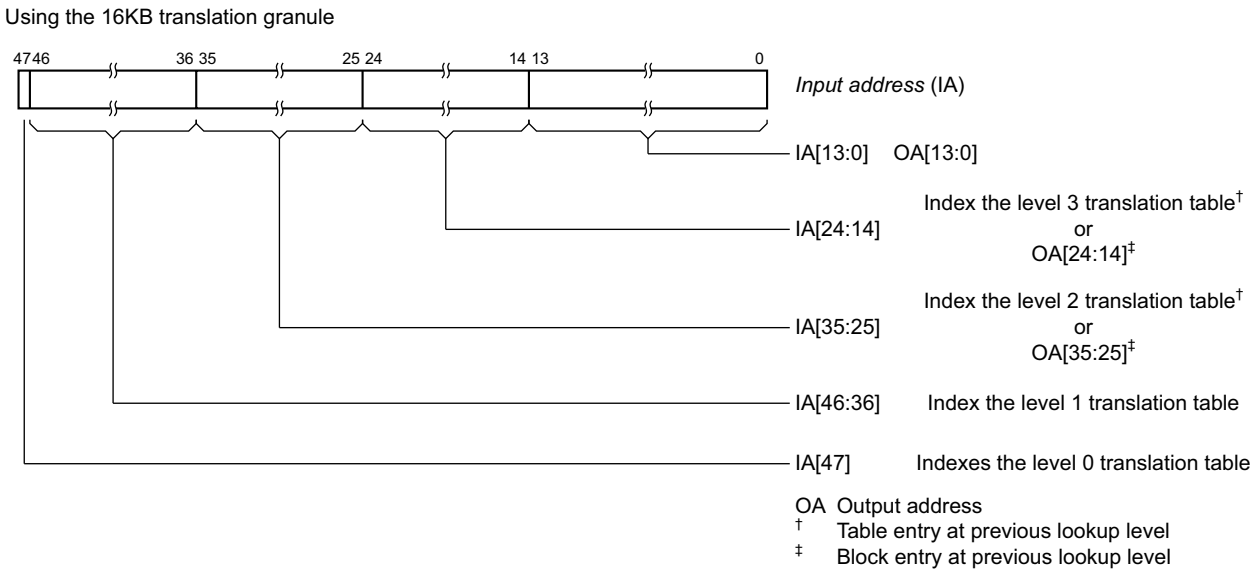

Figure D4-4 How the IA is resolved when using the 16KB translation granule

Figure D4-5 shows how a 48-bit IA is resolved when using the 64KB translation granule.

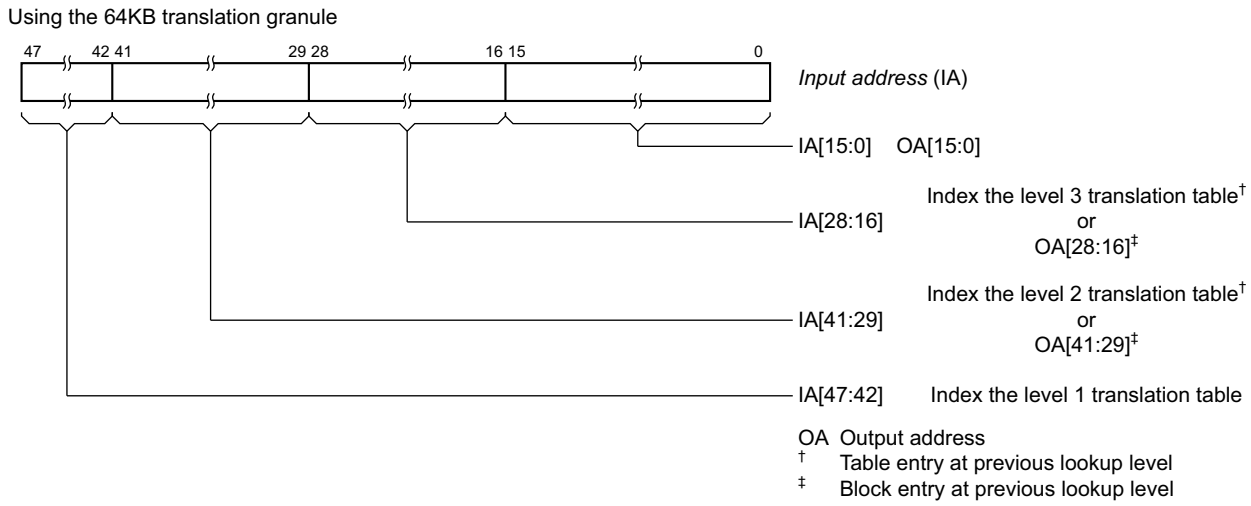

Figure D4-5 How the IA is resolved when using the 64KB translation granule

Later sections of this chapter give more information about the translation process, and explain the terminology used in these figures.

Effect of granule size on translation table addressing and indexing

Table D4-7 shows the effect of the translation granule size on the addressing and indexing of the TTBR, and on the input address range that must be resolved:

Table D4-7 The effect of translation granule size on the translation tables

Granule size	Translation table		Translation resolves[a]	Notes
	Addressed by	Indexed by[b]		
4KB	TTBR[47:12]	IA[(x + 8):x]	IA[47:12]	One level of lookup resolves up to[c] 9 bits of IA
16KB	TTBR[47:14]	IA[(x + 10):x]	IA[47:14]	One level of lookup resolves up to[c] 11 bits of IA
64KB	TTBR[47:16]	IA[(x + 12):x]	IA[47:16]	One level of lookup resolves up to[c] 13 bits of IA

a. When translating a maximum-sized input address of 48 bits, and accessing a page of memory.
b. Where the value of x depends on the lookup level, see Table D4-8.
c. Depending on the IA size, the initial lookup might resolve fewer bits of the IA.

Table D4-8 shows the IA bits resolved at each level of lookup, and how these correspond to the possible values of x in Table D4-7.

Table D4-8 IA bits resolved at different levels of lookup

Lookup level	4KB granule size	16KB granule size	64KB granule size
Zero	IA[47:39], x = 39	IA[47[a]], x = 47	-[b]
First	IA[38:30], x = 30	IA[46:36], x = 36	IA[47[a]:42], x = 42
Second	IA[29:21], x = 21	IA[35:25], x = 25	IA[41:29], x = 29
Third	IA[20:12], x = 12	IA[24:14], x = 14	IA[28:16], x = 16

a. Smaller value than indicated in Table D4-7 on page D4-1646, as explained in this section.
b. Level 0 lookup not possible with 64KB granule size

Table D4-7 on page D4-1646 refers to accessing a complete translation table, of 4KB, 16KB, or 64KB. However, the ARMv8 translation system supports the following possible variations from the information in Table D4-7 on page D4-1646:

Reduced IA width

Depending on the configuration and implementation choices, the required input address width for the initial level of lookup might be smaller than the number of address bits that can be resolved at that level. This means that, for this initial level of lookup:

- The translation table size is reduced. For each 1 bit reduction in the input address size the size of the translation table is halved.

  Note

  — This has no effect on the translation table size for subsequent levels of lookup, for which the lookups always use full-sized translation tables.

  — For a stage 2 translation, it might be possible to start the translation at a lower level, see *Concatenated translation tables*.

- More low-order TTBR bits are needed to hold the translation table base address.

Example D4-1 shows how this applies to translating a 35-bit input address range using the 4KB granule.

Example D4-1 Effect of an IA width of 35 bits when using the 4KB granule size

With a 4KB granule size, a single level of lookup can resolve up to 9 bits of IA. If an implementation has a 35-bit input address range, IA[34:0], Table D4-8 on page D4-1646 shows that lookup must start at level 1, and that the initial lookup must resolve IA[34:30], meaning it resolves 5 bits of address: This 4-bit reduction in the required resolution means:

- The translation table size is divided by 2^4, giving a size of 256B.
- The TTBR requires 4 more bits for the translation table base address, which becomes TTBR[47:8].

When using the 64KB translation granule to translate the maximum IA size of 48 bits, Table D4-8 on page D4-1646 shows that a level 1 lookup must resolve only IA[47:42]. This is 6 bits of address, compared to the 13 bits that can be resolved at a single level of lookup. This 7-bit reduction in the required resolution means:

- The translation table size is divided by 2^7, giving a size of 512B.
- The TTBR requires 7 more bits for the translation table base address, which becomes TTBR[47:9].

Concatenated translation tables

For stage 2 address translations, for the initial lookup, up to 16 translation tables can be concatenated. This means additional IA bits can be resolved at that lookup level. Each additional IA bit resolved:

- Doubles the number of translation tables required. Resolving an additional n bits requires 2^n concatenated translation tables at the initial lookup level.
- Reduces by 1 bit the width of the translation table base address held in the TTBR.

This means that, for the initial lookup of a stage 2 translation table, the IA ranges shown in Table D4-8 on page D4-1646 can be extended by up to 4 bits. Example D4-2 on page D4-1648 shows how concatenation can be used to resolve a 40-bit IA when using the 4KB translation granule.

Example D4-2 Concatenating translation tables to resolve a 40-bit IA range, with the 4K granule

Table D4-8 on page D4-1646 shows that, when using the 4KB translation granule, a level 1 lookup can resolve a 39-bit IA, with the first lookup resolving IA[38:30]. For a stage 2 translation, to extend the IA width to 40 bits and resolve IA[39:30] with the first lookup:

- Two translation tables are concatenated, giving a total size of 8KB.
- The TTBR requires 1 fewer bit for the translation table base address, which becomes TTBR[47:13].

For more information, see *Concatenated translation tables for the initial stage 2 lookup* on page D4-1664.

In all cases, the translation table, or block of concatenated translation tables, must be aligned to the actual size of the table or block of concatenated tables.

The translation table base address held in the TTBR is defined in the OA map for that stage of address translation. The information given in this section assumes this stage of translation has an OA size of 48 bits, meaning the translation table base address is:

- TTBR[47:12] if using the 4KB translation granule.
- TTBR[47:14] if using the 16KB translation granule.
- TTBR[47:16] if using the 64KB translation granule.

If the OA address is smaller than 48 bits then the upper bits of this field must be written as zero. For example, for a 40-bit OA range:

- If using the 4KB translation granule:
  - TTBR[47:40] must be set to zero.
  - TTBR[39:12] holds the translation table base address.
- If using the 16KB translation granule:
  - TTBR[47:40] must be set to zero.
  - TTBR[39:14] holds the translation table base address.
- If using the 64KB translation granule:
  - TTBR[47:40] must be set to zero.
  - TTBR[39:16] holds the translation table base address.

In all cases, if TTBR[47:40] is not zero, any attempt to access the translation table generates an Address size fault.

D4.2.4 Translation tables and the translation process

The following subsections describe general properties of the translation tables and translation table walks, that are largely independent of the translation table format:

- *Translation table walks*.
- *Security state of translation table lookups* on page D4-1650.
- *Control of translation table walks* on page D4-1651.
- *Security state of translation table lookups* on page D4-1650.

See also *Selection between TTBR0 and TTBR1* on page D4-1663.

Translation table walks

A *translation table walk* comprises one or more *translation table lookups*. The translation table walk is the set of lookups that are required to translate the virtual address to the physical address. For the Non-secure EL1&0 translation regime, this set includes lookups for both the stage1 translation and the stage 2 translation. The information returned by a successful translation table walk is:

- The required physical address. If the access is from Secure state this includes identifying whether the access is to the Secure physical address space or the Non-secure physical address space, see *Security state of translation table lookups* on page D4-1650.

- The memory attributes for the target memory region, as described in *Memory types and attributes* on page B2-89. For more information about how the translation table descriptors specify these attributes see *Memory region attributes* on page D4-1714.
- The access permissions for the target memory regions. For more information about how the translation table descriptors specify these permissions see *Memory access control* on page D4-1707.

The translation table walk starts with a read of the translation table for the initial lookup. The TTBR for the stage of translation holds the base address of this table. Each translation table lookup returns a descriptor, that indicates one of the following:

- The entry is the final entry of the walk. In this case, the entry contains the OA, and the permissions and attributes for the access.
- An additional level of lookup is required. In this case, the entry contains the translation table base address for that lookup. In addition:
  - The descriptor provides hierarchical attributes that are applied to the final translation, see *Hierarchical control of Secure or Non-secure memory accesses* on page D4-1706 and *Hierarchical control of data access permissions* on page D4-1709.
  - If the translation is in a Secure translation regime, the descriptor indicates whether that base address is in the Secure or Non-secure address space, unless a hierarchical control at a previous level of lookup has indicated that it must be in the Non-secure address space.
- The descriptor is invalid. In this case, the memory access generates a Translation fault.

Figure D4-6 gives a generalized view of a single stage of address translation, where three levels of lookup are required.

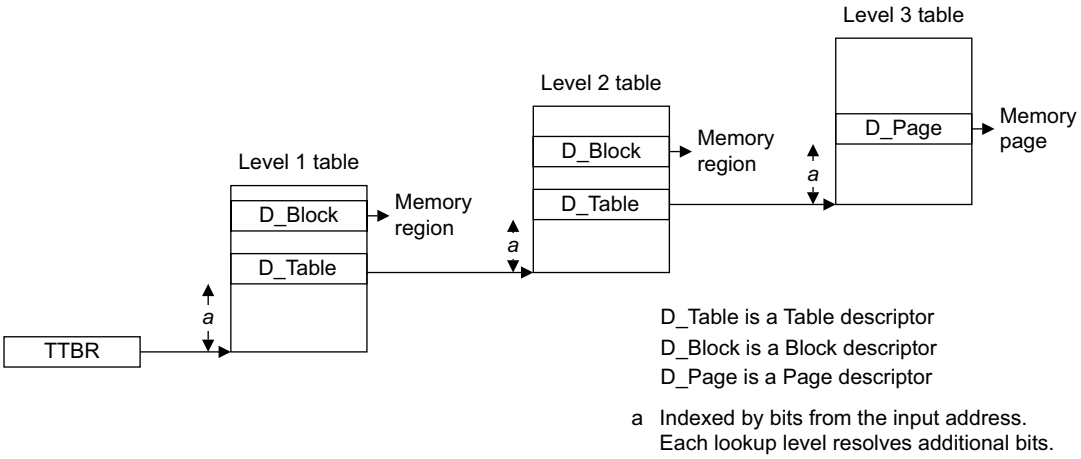

Figure D4-6 Generalized view of a stage of address translation

A translation table lookup from VMSAv8-64 performs a single-copy atomic 64-bit access to the translation table entry. This means the translation table entry is treated as a 64-bit object for the purpose of endianness. SCTLR.EE determines the endianness of the translation table lookups.

Note

Dynamically changing translation table endianness

Because any change to an SCTLR.EE, bit requires synchronization before it is visible to subsequent operations, ARM strongly recommends that any EE bit is changed only when either:

- Executing at an Exception level that does not use the translation tables affected by the EE bit being changed.
- Executing with address translation disabled for any stage of translation affected by the EE bit being changed.

Address translation stages are disabled by setting an SCTLR.M bit to 0. See the appropriate register description for more information.

The appropriate TTBR holds the output address of the base of the translation table used for the initial lookup, and:

- For all address translation stages other than Non-secure EL1&0 stage 1 translations, the output address held in the TTBR, and any translation table base address returned by a translation table descriptor, is the PA of the base of the translation table.
- For Non-secure EL1&0 stage 1 translations, the output address held in the TTBR, and any translation table base address returned by a translation table descriptor, is the IPA of the base of the translation table. This means that if stage 2 address translation is enabled, each of these OAs is subject to second stage translation.

  Note

  TLB caching can be used to minimise the number of translation table lookups that must be performed. Because each stage 1 OA generated during a translation table walk is subject to a stage 2 translation, if the caching of translation table entries is ineffective, a VA to PA address translation with two stages of translation can give rise to multiple translation table lookups. The number of lookups required is given by the following equation:

  (S1+1)*(S2+1) - 1

  Where, for the Non-secure EL1&0 translation regime, S1 is the number of levels of lookup required for at stage 1translation, and S2 is the number of levels of lookup required for a stage 2 translation.

The TTBR also determines the memory cacheability and shareability attributes that apply, for that stage of translation, to all translation table lookups generated by that stage of translation.

The Normal memory type is the memory type defined for a translation table lookup for a stage of translation.

Note

- In a two stage translation system, a translation table lookup from stage 1, that has the Normal memory type defined at stage 1 by this rule, can still be given the Device memory type as part of the stage 2 translation of that address. ARM strongly recommends against such a remapping of the memory type, and the architecture includes a trap of this behavior to EL2. For more information, see *Stage 2 fault on a stage 1 translation table walk* on page D4-1727.
- The rules about mismatched attributes given in *Mismatched memory attributes* on page B2-97 apply to the relationship between translation table walks and explicit memory accesses to the translation tables in the same way that they apply to the relationship between different explicit memory accesses to the same location. For this reason, ARM strongly recommends that the attributes that the TTBR applies to the translation tables are the same as the attributes that are applied for explicit accesses to the memory that holds the translation tables.

For more information see *Overview of the VMSAv8-64 address translation stages* on page D4-1651.

See also*Selection between TTBR0 and TTBR1* on page D4-1663.

Security state of translation table lookups

For a Non-secure translation regime, all translation table lookups are performed to Non-secure output addresses.

For a Secure translation regimes, the initial translation table lookup is performed to a Secure output address.

If the translation table descriptor returned as a result of that initial lookup points to a second translation table, then the NSTable bit in that descriptor determines whether that translation table lookup is made to Secure or to Non-secure output addresses.

This applies for all subsequent translation table lookups as part of that translation table walk, with the additional rule that any translation table descriptor that is returned from Non-secure memory is treated as if the NSTable bit in that descriptor indicates that the subsequent translation table lookup is to Non-secure memory.

Control of translation table walks

For the first stage of the EL1&0 translation regime, the TCR_EL1.{EPD0, EPD1} bits determine whether the translation tables for that regime are valid. EPD0 indicates whether the table that TTBR0_EL1 points to is valid, and EPD1 indicates whether the table that TTBR1_EL1 points to is valid. The effect of these bits is:

EPD*n* == 0 The translation table is valid, and can be used for a translation table lookup.

EPD*n* == 1 If a TLB miss occurs based on TTBR*n*, a Translation fault is returned, and no translation table walk is performed. The fault is reported as a level 0 fault.

D4.2.5 Overview of the VMSAv8-64 address translation stages

As shown in *Memory translation granule size* on page D4-1644, the granule size determines significant aspects of the address translation process. *Effect of granule size on translation table addressing and indexing* on page D4-1646 shows, for each granule size:

- How the required input address range determines the required initial lookup levels.
- For stage 2 translations, the possible effect described in *Concatenated translation tables* on page D4-1647.
- The TTBR addressing and indexing for the initial lookup.

The following subsections summarize the multiple levels of lookup that can be required for a single stage of address translation that might require the maximum number of lookups:

- *Overview of VMSAv8-64 address translation using the 4KB translation granule*.
- *Overview of VMSAv8-64 address translation using the 16KB translation granule* on page D4-1654.
- *Overview of VMSAv8-64 address translation using the 64KB translation granule* on page D4-1658.

Overview of VMSAv8-64 address translation using the 4KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 4KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding TCR.TxSZ field. When using the 4KB translation granule, Table D4-9 shows this requirement.

Table D4-9 TCR.T*n*SZ values and IA ranges when there is no concatenation of translation tables

Initial lookup level	T*n*SZ values for and input address ranges[a] for starting at this level			
	$T nSZ_{min}$	IA_{max}	$T nSZ_{max}$	IA_{min}
Zero	16	IA[47:12]	24	IA[39:12]
First	25	IA[38:12]	33	IA[30:12]
Second	34	IA[29:12]	39	IA[24:12]

a. The IAs show the address bits to be resolved when addressing a page of memory, see the *Note* that follows.

These configuration options are also permitted for stage 2 translations.

Note

- When using the 4KB translation granule, the initial lookup cannot be at level 3.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA, When using the 4KB translation granule, IA[11:0] = OA[11:0] for all translations.

Figure D4-7 shows the stage 1 address translation, for an address translation using the 4KB granule with an input address size greater than 39 bits.

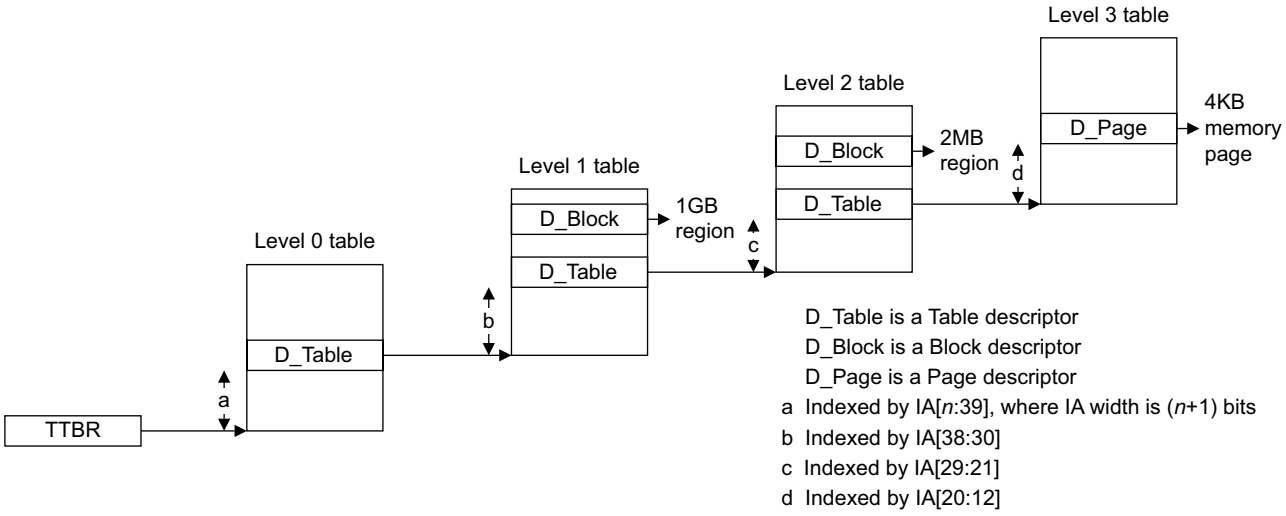

Figure D4-7 General view of VMSAv8-64 stage 1 address translation, 4KB granule

Overview of stage 2 translations, 4KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see *Concatenated translation tables for the initial stage 2 lookup* on page D4-1664.

When using the 4KB translation granule, Table D4-10 shows all possibilities for the initial lookup for a stage 2 translation.

Table D4-10 VTCR_EL2.T0SZ values and IA ranges, including cases where translation tables are concatenated

Tables[a]	1		2		4		8		16	
Initial lookup level	T0SZ values and input address ranges[b] for starting at this level									
	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA
Zero	16-24	IA[47:12]-IA[39:12]	-	-	-	-	-	-	--	-
First	25-33	IA[38:12]-IA[30:12]	24	IA[39:12]	23	IA[40:12]	22	IA[41:12]	21	IA[42:12]
Second	34-39	IA[29:12]-IA[24:12]	33	IA[30:12]	32	IA[31:12]	31	IA[32:12]	30	IA[33:12]

a. Number of concatenated translation tables at the initial lookup level. *1 table* corresponds to no concatenation, see Table D4-9 on page D4-1651.

b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the *Note* that follows.

Note

- When using the 4KB translation granule, the initial lookup cannot be at level 3.
- Because concatenating translation tables reduces the number of levels of lookup required, when using the 4KB translation granule, tables cannot be concatenated at level 0.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 4KB translation granule, IA[11:0] = OA[11:0] for all translations.

In addition, VTCR_EL2.SL0 indicates the required initial lookup level, as Table D4-11 shows.

Table D4-11 VTCR_EL2.SL0 values, 4KB granule

Initial lookup level	VTCR_EL2.SL0
Zero	0b10
First	0b01
Second	0b00

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.{T0SZ, SL0} values. If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, a stage 2 level 0 translation fault is generated.

Figure D4-8 on page D4-1654 shows the stage 2 address translation, for an input address size of between 40 and 43 bits. This means the lookup can start at either level 0 or level 1.

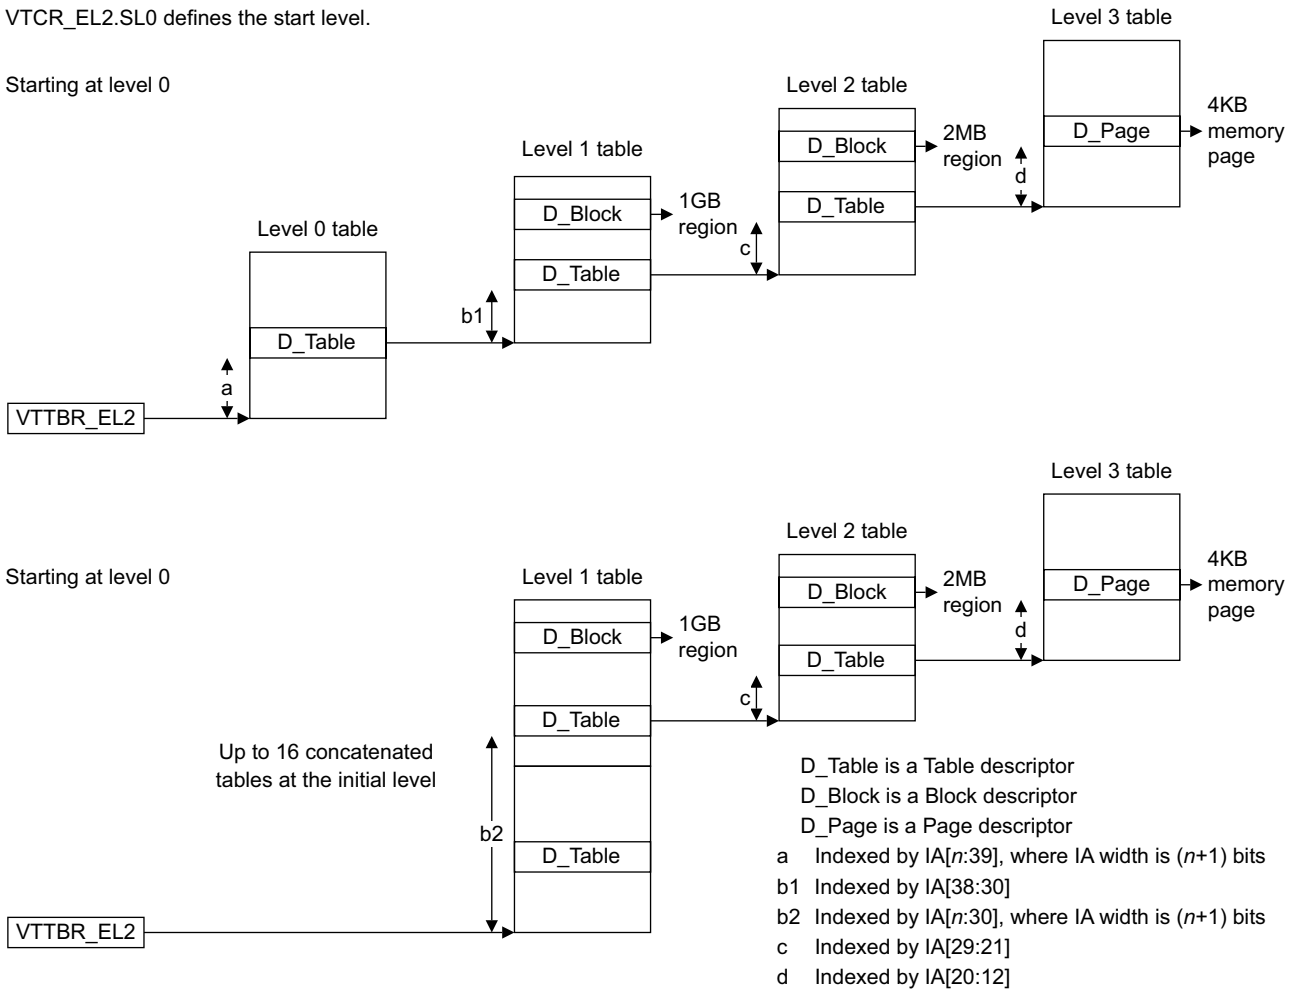

Figure D4-8 General view of VMSAv8-64 stage 2 address translation, 4KB granule

Overview of VMSAv8-64 address translation using the 16KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 16KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding TCR.TxSZ field. When using the 4KB translation granule, Table D4-9 on page D4-1651 shows this requirement.

Table D4-12 TCR.T*n*SZ values and IA ranges when there is no concatenation of translation tables

Initial lookup level	T*n*SZ values for and input address ranges[a] for starting at this level			
	$TnSZ_{min}$	IA_{max}	$TnSZ_{max}$	IA_{min}
Zero	16	IA[47:14]	-	-
First	17	IA[46:14]	27	IA[36:14]
Second	28	IA[35:14]	38	IA[25:14]
Third	39	IA[24:14]	-	-

a. The IAs show the address bits to be resolved when addressing a page of memory, see the *Note* that follows.

The configuration options for an initial lookup at level 1, level 2, or level 3 are also permitted for stage 2 translations, but stage 2 translation does not permit an initial lookup at level 0.

Note

- When using the 16KB translation granule, a maximum of 1 bit of IA is resolved by a level 0 lookup.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA, When using the 16KB translation granule, IA[13:0] = OA[13:0] for all translations.

Figure D4-9 shows the stage 1 address translation, for an address translation using the 16KB granule with an input address size of 48 bits.

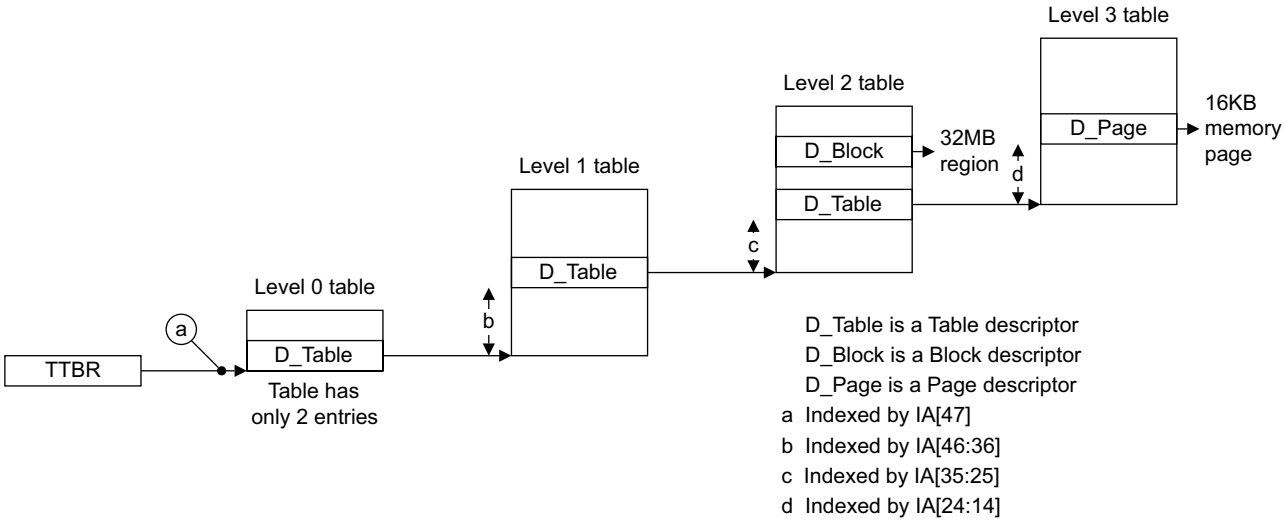

Figure D4-9 General view of VMSAv8-64 stage 1 address translation, 16KB granule

Overview of stage 2 translations, 16KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see *Concatenated translation tables for the initial stage 2 lookup* on page D4-1664.

When using the 16KB granule, for a stage 2 translation with an input address sized of 48 bits, the initial lookup must be at level 1, with two concatenated translation tables at this level.

When using the 4KB translation granule, Table D4-10 on page D4-1652 shows all possibilities for the initial lookup for a stage 2 translation.

Table D4-13 VTCR_EL2.T0SZ values and IA ranges, including cases where translation tables are concatenated

Tables[a]	1		2		4		8		16	
Initial lookup level	T0SZ values and input address ranges[b] for starting at this level									
	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA
First	17-27	IA[46:14]-IA[36:14]	16	IA[47:14]	-	-	-	-	-	-
Second	28-38	IA[35:14]-IA[25:14]	27	IA[36:14]	26	IA[37:14]	25	IA[38:14]	24	IA[39:14]
Third	39	IA[24:14]	38	IA[25:14]	37	IA[26:14]	36	IA[27:14]	35	IA[28:14]

a. Number of concatenated translation tables at the initial lookup level. *1 table* corresponds to no concatenation, see Table D4-9 on page D4-1651.

b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the *Note* that follows.

Note

- When using the 16KB translation granule for a stage 2 translation, the initial lookup cannot be at level 0. When a 48-bit input address is required, translation must start with a level 1 lookup using two concatenated translation tables.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 16KB translation granule, IA[13:0] = OA[13:0] for all translations.

In addition, VTCR_EL2.SL0 indicates the required initial lookup level, as Table D4-11 on page D4-1653 shows.

Table D4-14 VTCR_EL2.SL0 values, 16KB granule

Initial lookup level	VTCR_EL2.SL0
First	0b10
Second	0b01
Third	0b00

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.{T0SZ, SL0} values. If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, a stage 2 level 0 translation fault is generated.

When stage 2 translation supports a 48-bit input address range, translation must start with a level 1 lookup using two concatenated translation tables. Figure D4-10 shows the translation for this case.

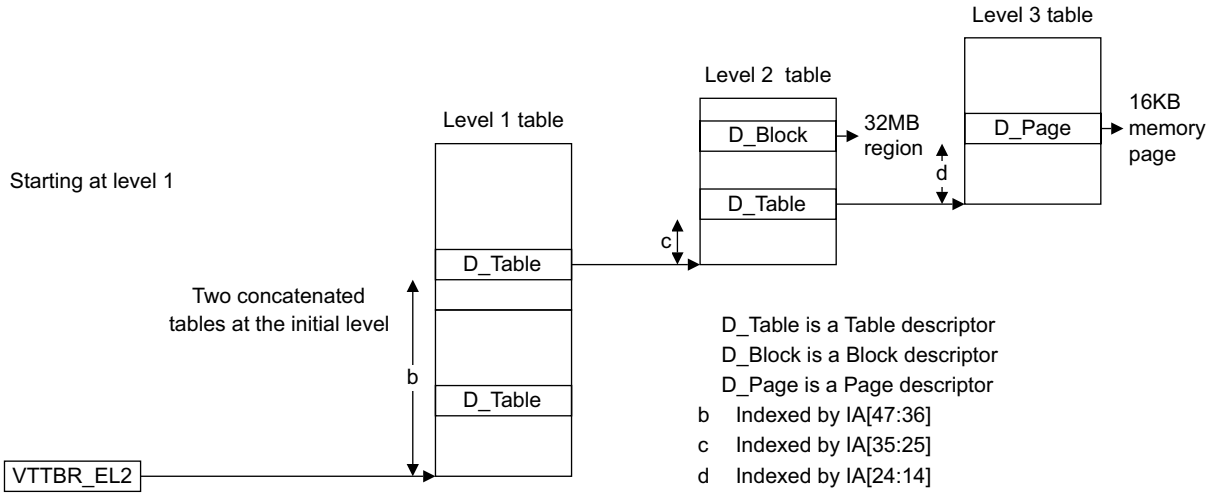

Figure D4-10 VMSAv8-64 stage 2 address translation, 16KB granule, 48 bit input address

However, for an input address size of between 37 and 40 bits, Table D4-13 on page D4-1656 shows that translation can start with either a level 1 lookup or a level 2 lookup, and Figure D4-11 shows these options.

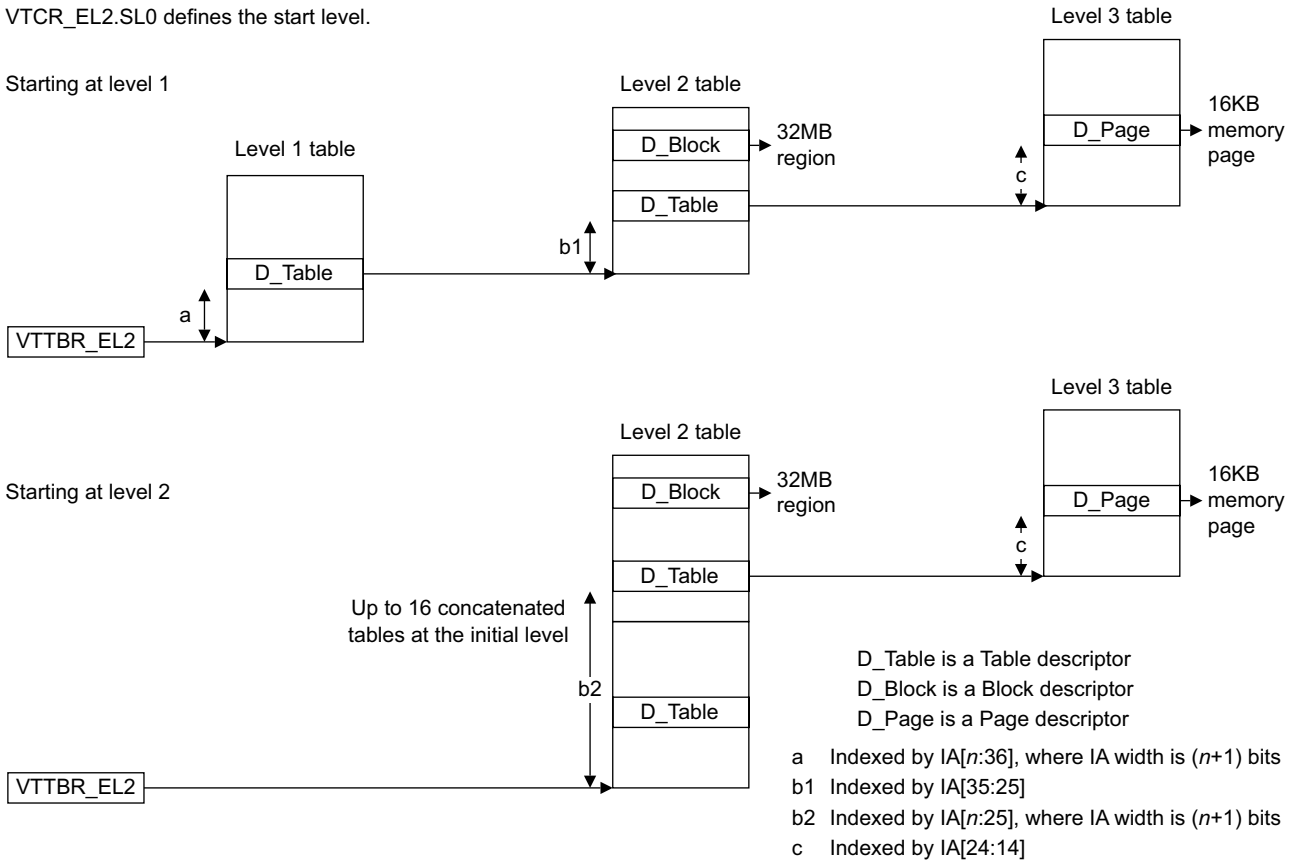

Figure D4-11 General view of VMSAv8-64 stage 2 address translation, 16KB granule

Overview of VMSAv8-64 address translation using the 64KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 64KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding TCR.TxSZ field. When using the 64KB translation granule, Table D4-15 shows this requirement.

Table D4-15 TCR.T*n*SZ values and IA ranges when there is no concatenation of translation tables

Lookup level	T*n*SZ values for and input address ranges[a] for starting at this level			
	$T nSZ_{min}$	IA_{max}	$T nSZ_{max}$	IA_{min}
First	16	IA[47:16]	21	IA[42:16]
Second	22	IA[41:16]	34	IA[29:16]
Third	35	IA[28:16]	39	IA[24:16]

a. The IAs show the address bits to be resolved when addressing a page of memory, see the *Note* that follows.

These configuration options are also permitted for stage 2 translations.

Note

- When using the 64KB translation granule, there are no level 0 lookups.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 64KB translation granule, IA[15:0] = OA[15:0] for all translations.

Figure D4-12 shows the stage 1 address translation, for an address translation using the 64KB granule with a an input address size greater than 42 bits.

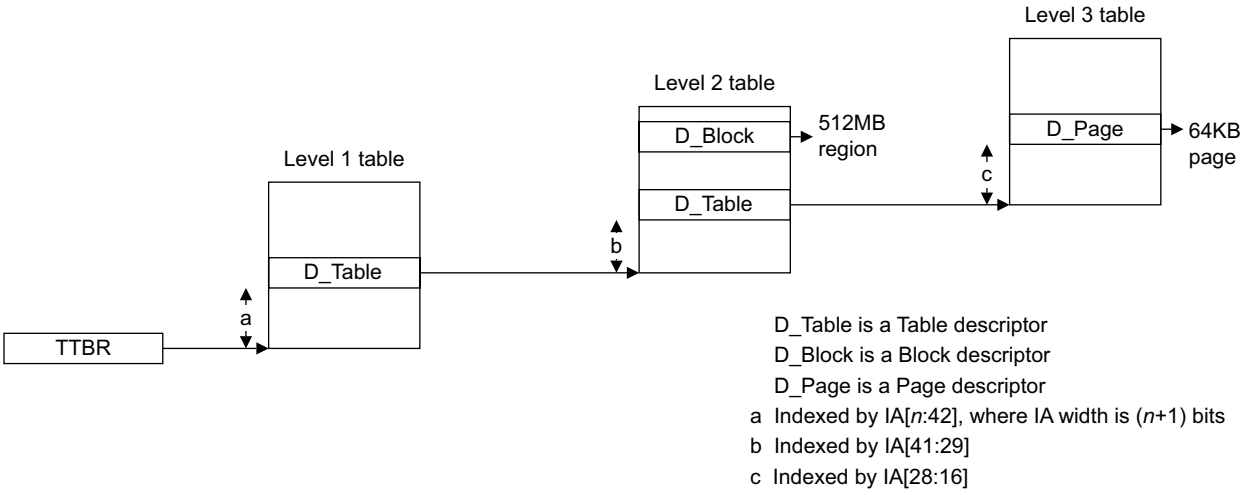

Figure D4-12 General view of VMSAv8-64 stage 1 address translation, 64KB granule

Overview of stage 2 translations, 64KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see *Concatenated translation tables for the initial stage 2 lookup* on page D4-1664.

When using the 64KB translation granule, Table D4-16 shows all possibilities for the initial lookup for a stage 2 translation.

Table D4-16 VTCR_EL2.T0SZ values and IA ranges when translation tables are concatenated

Tables[a]	1		2		4		8		16	
Initial lookup level	T0SZ values and input address ranges[b] for starting at this level									
	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA	T0SZ	IA
First	16-21	IA[47:16]-IA[42:16]	-	-	-	-	-	-	-	-
Second	22-34	IA[41:16]-IA[29:16]	21	IA[42:16]	20	IA[43:16]	19	IA[44:16]	18	IA[45:16]
Third	35-39	IA[28:16]-IA[24:16]	34	IA[29:16]	33	IA[30:16]	32	IA[31:16]	31	IA[32:16]

a. Number of concatenated translation tables at the initial lookup level. *1 table* corresponds to no concatenation, see Table D4-15 on page D4-1658.

b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the *Note* that follows.

Note

- When using the 64KB translation granule, there are no level 0 lookups.
- Because concatenating translation tables reduces the number of levels of lookup required, when using the 64KB translation granule, tables cannot be concatenated at level 1.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 64KB translation granule, IA[15:0] = OA[15:0] for all translations.

VTCR_EL2.SL0 indicates the required initial lookup level, as Table D4-17 shows.

Table D4-17 VTCR_EL2.SL0 values, 64K granule

Initial lookup level	VTCR_EL2.SL0
First	0b10
Second	0b01
Third	0b00

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.{T0SZ, SL0} values. If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, a stage 2 level 0 translation fault is generated.

Figure D4-13 shows the stage 2 address translation, for an input address size of between 43 and 46 bits. This means the lookup can start at either level 1 or level 2.

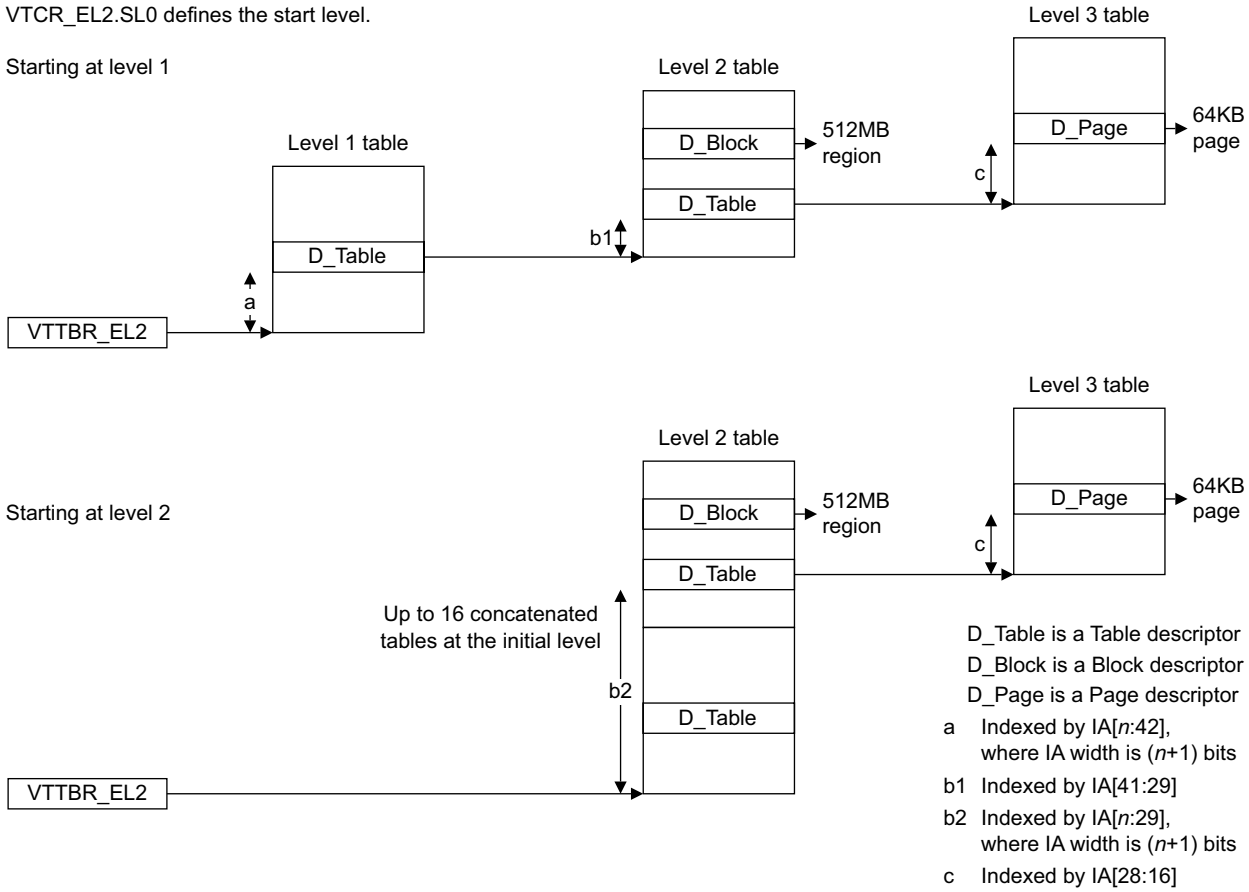

Figure D4-13 General view of VMSAv8-64 stage 2 address translation, 64KB granule

D4.2.6 The VMSAv8-64 translation table format

This section provides the full description of the VMSAv8-64 translation table format, its use for address translations that are controlled by an Exception level using AArch64.

For the address translations that are controlled by an Exception level that is using AArch64:

- The TCR_EL1.{SH0, ORGN0, IRGN0, SH1, ORGN1, IRGN1} fields define memory region attributes for the translation table walk, for each of TTBR0_EL1 and TTBR1_EL1.
- For the Secure and Non-secure EL1&0 stage 1 translations, each of TTBR0_EL1 and TTBR1_EL1 contains an ASID field, and the TCR_EL1.A1 field selects which ASID to use.

For this translation table format, *Overview of the VMSAv8-64 address translation stages* on page D4-1651 summarizes the lookup levels, and *Descriptor encodings, ARMv8 level 0, level 1, and level 2 formats* on page D4-1699 describes the translation table entries.

The following subsections describe the use of this translation table format:

- *Translation granule size and associate block and page sizes* on page D4-1661.
- *Selection between TTBR0 and TTBR1* on page D4-1663.
- *Concatenated translation tables for the initial stage 2 lookup* on page D4-1664.
- *Possible translation table registers programming errors* on page D4-1665.

Translation granule size and associate block and page sizes

Table D4-18 shows the supported granule sizes, block sizes and page sizes, for the different granule sizes. For completeness, this table includes information for AArch32 state. In the table, the OA bit ranges are the OA bits that the translation table descriptor specifies to address the block or page of memory, in an implementation that supports a 48-bit OA range.

Table D4-18 Translation table granule sizes, with block and page sizes, and output address ranges

Granule size	Table level	Block size and OA bit range	Page size and OA bit range
4KB	Zero	-	-
	First	1GB, OA[47:30]	-
	Second	2MB, OA[47:21]	-
	Third	-	4KB, OA[47:12]
16KB	Zero	-	-
	First	-	-
	Second	32MB, OA[47:25]	-
	Third	-	16KB, OA[47:14]
64KB	First	-	-
	Second	512MB, OA[47:29]	-
	Third	-	64KB, OA[47:16]

Bit[1] of a translation table descriptor identifies whether the descriptor is a block descriptor, and:

- The 4KB granule size supports block descriptors only in level and level 2 translation tables.
- The 16KB and 64KB granule sizes support block descriptors only in level 2 translation tables,

Setting bit[1] of a descriptor to 1 in a translation table that does not support block descriptors gives a Translation fault.

For translations managed from AArch64 state, the following tables expand the information for each granule size, showing for each lookup level and when accessing a single translation table:

- The maximum IA size, and the address bits that are resolved for that maximum size.
- The maximum OA range resolved by the translation table descriptors at this level, and the corresponding memory region size.
- The maximum size of the translation table. This is the size required for the maximum IA size.

Table D4-19 shows this information for the 4KB translation granule size, Table D4-20 on page D4-1662 shows this information for the 16KB translation granule size, and Table D4-21 on page D4-1662 shows this information for the 64KB translation granule size.

Table D4-19 Properties of the address lookup levels, 4KB granule size

Level	Maximum input address		Maximum output address		Number of entries	Block entries supported?
	Size	Address range	Address range	Size of addressed region[a]		
Zero	256TB	Address[47:39]	Address[47:39]	512GB	Up to 512	No
First	512GB	Address[38:30]	Address[47:30]	1GB	Up to 512	Yes

Table D4-19 Properties of the address lookup levels, 4KB granule size (continued)

Level	Maximum input address		Maximum output address		Number of entries	Block entries supported?
	Size	Address range	Address range	Size of addressed region[a]		
Second	1GB	Address[29:21]	Address[47:21]	2MB	Up to 512	Yes
Third	2MB	Address[20:12]	Address[47:12]	4KB	512	Page only

a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.

Table D4-20 Properties of the address lookup levels, 16KB granule size

Level	Maximum input address		Maximum output address		Number of entries	Block entries supported?
	Size	Address range	Address range	Size of addressed region[a]		
Zero	256TB	Address[47]	Address[47]	128TB	2[b]	No
First	128TB	Address[46:36]	Address[47:36]	64GB	Up to 2048	No
Second	64GB	Address[35:25]	Address[47:25]	32MB	Up to 2048	Yes
Third	32MB	Address[24:14]	Address[47:14]	16KB	2048	Page only

a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.
b. The translation table size is less than the maximum for this granule size, and therefore the number of entries is reduced.

Table D4-21 Properties of the address lookup levels, 64KB granule size

Level	Maximum input address		Maximum output address		Number of entries	Block entries supported?
	Size	Address range	Address range	Size of addressed region[a]		
First	256TB	Address[47:42]	Address[47:42]	4TB	Up to 64[b]	No
Second	4TB	Address[41:29]	Address[47:29]	512MB	Up to 8192	Yes
Third	512MB	Address[28:16]	Address[47:16]	64KB	8192	Page only

a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.
b. The translation table size is less than the maximum for this granule size, and therefore the number of entries is reduced.

For the initial lookup level:

- If the IA range specified by the TCR.TxSZ field is smaller than the maximum size shown in these table then this reduces the number of addresses in the table and therefore reduces the table size. The smaller translation table is aligned to its table size.
- For stage 2 translations, multiple translation tables can be concatenated to extend the maximum IA size beyond that shown in these tables. For more information see the stage 2 translation overviews in *Overview of the VMSAv8-64 address translation stages* on page D4-1651 and *Concatenated translation tables for the initial stage 2 lookup* on page D4-1664.

If a supplied input address is larger than the configured input address size, a Translation fault is generated.

Note

Larger translation granule sizes typically requires fewer levels of translation tables to translate a particular size of virtual address.

For the TCR programming requirements for the initial lookup, see *Overview of the VMSAv8-64 address translation stages* on page D4-1651.

Selection between TTBR0 and TTBR1

Every translation table walk starts by accessing the translation table addressed by the TTBR for the stage 1 translation for the required translation regime.

For the EL1&0 translation regime, the VA range is split into two subranges as shown in Figure D4-14, and:

- TTBR0_EL1 points to the initial translation table for the lower VA subrange, that starts at address `0x0000_0000_0000_0000`,
- TTBR1_EL1 points to the initial translation table for the upper VA subrange, that runs up to address `0xFFFF_FFFF_FFFF_FFFF`.

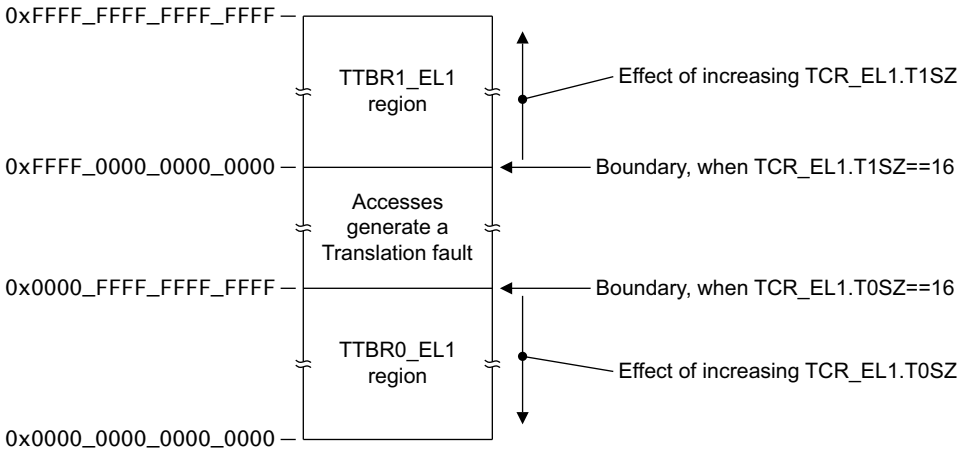

Figure D4-14 AArch64 TTBR boundaries and VA ranges

Which TTBR is used depends only on the VA presented for translation:

- If the top bits of the VA are zero, then TTBR0_EL1 is used.
- If the top bits of the VA are one, then TTBR1_EL1 is used.

It is configurable whether this determination depends on the values of VA[63:56] or on the values of VA[63:48], see *Address tagging in AArch64 state* on page D4-1634.

Example D4-3 shows a typical application of this VA split.

Example D4-3 Example use of the split VA range, and the TTBR0_EL1 and TTBR1_EL1 controls

An example of using the split VA range is:

TTBR0_EL1 Used for process-specific addresses.

Each process maintains a separate level 1 translation table. On a context switch:

- TTBR0_EL1 is updated to point to the level 1 translation table for the new context
- TCR_EL1 is updated if this change changes the size of the translation table
- CONTEXTIDR_EL1 is updated.

TTBR1_EL1 Used for operating system and I/O addresses, that do not change on a context switch.

For each VA subrange, the input address size is $2^{(64-T\mathit{n}SZ)}$, where T*n*SZ is one of TCR_EL1.{T0SZ, T1SZ},

This means the two VA subranges are:

Lower VA subrange `0x0000_0000_0000_0000` to $(2^{(64-T0SZ)} - 1)$.

Upper VA subrange $(2^{64} - 2^{(64-T1SZ)})$ to `0xFFFF_FFFF_FFFF_FFFF`.

The minimum T*n*SZ value is 16, corresponding to the maximum input address range of 48 bits. Example D4-4 shows the two VA subranges when T0SZ and T1SZ are both set to this minimum value.

Example D4-4 Maximum VA ranges for EL1&0 stage 1 translations

The maximum VA subranges correspond to T0SZ and T1SZ each having the minimum value of 16. In this case the subranges are:

Lower VA subrange `0x0000_0000_0000_0000` to `0x0000_FFFF_FFFF_FFFF`.

Upper VA subrange `0xFFFF_0000_0000_0000` to `0xFFFF_FFFF_FFFF_FFFF`.

Figure D4-14 on page D4-1663 indicates the effect of varying the T*n*SZ values.

As described in *Overview of the VMSAv8-64 address translation stages* on page D4-1651, the T*n*SZ values also determine the initial lookup level for the translation.

Concatenated translation tables for the initial stage 2 lookup

Overview of the VMSAv8-64 address translation stages on page D4-1651 introduced the ability to concatenate translation tables for the initial stage 2 translation lookup. This section gives more information about that concatenation.

Where a stage 2 translation would require 16 entries or fewer in its top-level translation table, the system designer can instead:

- Require the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.
- Start the translation at that next translation level.

In addition, when using the 16KB translation granule and requiring a 48-bit input address size for the stage 2 translations, lookup must start with two concatenated translation tables at level 1.

Note

This translation scheme:

- Avoids the overhead of an additional level of translation.
- Requires the software that is defining the translation to:
  - Define the concatenated translation tables with the required overall alignment.
  - Program VTTBR_EL2 to hold the address of the first of the concatenated translation tables.
  - Program VTCR_EL2 to indicate the required input address range and initial lookup level.

Concatenating additional translation tables at the initial level of look up resolves additional address bits at that level. To resolve *n* additional address bits requires 2^n concatenated translation tables. Example D4-5 on page D4-1665 shows how, for level 1 lookups using the 4KB translation granule, translation tables can be concatenated to resolve three additional address bits.

Example D4-5 Adding three bits of address resolution at level 1 lookup, using the 4KB granule

When using the 4KB translation granule, a level 1 lookup with a single translation table resolves address bits[38:30]. To add three more address bits requires 2^3 translation tables, that is, eight translation tables. This means:

- The total size of the concatenated translation tables is $8 \times 4KB = 32KB$.
- This block of concatenated translation tables must be aligned to 32KB.
- The address range resolved at this lookup level is A[41:30].of which:
  - Bits A[41:38] select the 4KB translation table.
  - Bits A[38:30] index a descriptor within that translation table.

As an example of the concatenation of translation tables at the initial lookup level, when using the 4KB translation granule, Table D4-22 shows the possible uses of concatenated translation tables to permit lookup to start at level 1 rather than at level 0. For completeness, the table starts with the case where the required IPA range means lookup starts at level 1with a single translation table at that level.

Table D4-22 Possible uses of concatenated translation tables for level 1 lookup, 4KB granule

Configured stage 2 IA size		Lookup starts at level 0	Lookup starts at level 1	
IPA range	Size	Required level 0 entries	Number of concatenated tables	Required alignment[a]
IPA[38:0]	2^{36} bytes	-	1	4KB
IPA[39:0]	2^{37} bytes	2	2	8KB
IPA[40:0]	2^{38} bytes	4	4	16KB
IPA[41:0]	2^{39} bytes	8	8	32KB
IPA[42:0]	2^{40} bytes	16	16	64KB

a. Required alignment of the set of concatenated level 2 tables.

Note

Because concatenation is permitted only for a stage 2 translation, the input addresses in the table are IPAs.

Overview of the VMSAv8-64 address translation stages on page D4-1651 identifies all of the possible uses of concatenation. In all cases, the block of concatenated translation tables must be aligned to the block size.

Possible translation table registers programming errors

For a stage 2 translation, the programming of the VTCR_EL2.{T0SZ, SL0} fields must be consistent, see *Overview of the VMSAv8-64 address translation stages* on page D4-1651.

Where the contiguous bit is used to mark a set of blocks as contiguous, if the address range translated by a set of blocks marked as contiguous is larger than the size of the input address supported at a stage of translation used to translate that address at that stage of translation, as defined by the TCR.TxSZ field, then this is a programming error. An implementation is permitted, but not required, to:

- Treat such a block within a contiguous set of blocks as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation, as defined by the TCR.TxSZ field.

- Treat such a block within a contiguous set of blocks as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, as defined by the TCR.TxSZ field, provided that both of the following apply:
  - The block is valid.
  - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.

The contiguous bit must apply:

- When using the 4KB translation granule, to 16 adjacent translation table entries, aligned so that the upper five bits of the input address range required to index the table entries are all the same.
- When using the 16KB translation granule, to:
  - 128 adjacent translation table entries, aligned so that the upper four bits of the input address range required to index the table entries are all the same, for entries in a level 3 translation table.
  - 32 adjacent translation table entries, aligned so that the upper six bits of the input address range required to index the table entries are all the same, for entries in a level 2 translation table.
- When using the 64KB translation granule, to 32 adjacent translation table entries, aligned so that the upper eight bits of the input address range required to index the table entries are all the same.

For more information about the contiguous bit see *The Contiguous bit* on page D4-1718.

D4.2.7 The algorithm for finding the translation table entries

This subsection gives the algorithms for finding the translation table entry that corresponds to a given IA, for each required level of lookup. The algorithms encode the descriptions of address translation given earlier in this section. The algorithm details depend on the translation granule size for the stage of address translation, see:

- *Finding the translation table entry when using the 4KB translation granule* on page D4-1667.
- *Finding the translation table entry when using the 16KB translation granule* on page D4-1668.
- *Finding the translation table descriptor when using the 64KB translation granule* on page D4-1669.

Each subsection uses the following terms:

BaseAddress The base address for the level of lookup, as defined by:
- For the initial lookup level, the appropriate TTBR.
- Otherwise, the translation table address returned by the previous level of lookup.

PAMax The supported PA width, in bits.

IA The supplied IA for this stage of translation.

T*n*SZ The translation table size for this stage of translation:

For EL1&0 stage 1	TCR_EL1.T0SZ or TCR_EL1.T1SZ, as appropriate.
For EL1&0 stage 2	VTCR_EL2.T0SZ.
For EL2 stage 1	TCR_EL2.T0SZ.
For EL3 stage 1	TCR_EL3.T0SZ.

SL0 VTCR_EL2.SL0. Applies to the Non-secure EL1&0 stage 2 translation only.

These subsections show only architecturally-valid programming of the TCR. See also *Possible translation table registers programming errors* on page D4-1665.

Finding the translation table entry when using the 4KB translation granule

Table D4-23 shows the translation table descriptor address, for each level of lookup, when using the 4KB translation granule. See the start of *The algorithm for finding the translation table entries* on page D4-1666 for more information about terms used in the table.

Table D4-23 Translation table entry addresses when using the 4KB translation granule

Lookup level	Entry address and conditions		General conditions
	Stage 1 translation	Stage 2 translation	
Zero	BaseAddr[PAMax-1:*x*]:IA[*y*:39]:0b000 if[a] 16 ≤ T*n*SZ ≤ 24 then *x* = (28 - T*n*SZ)	BaseAddr[PAMax-1:*x*]:IA[*y*:39]:0b000 if SL0[b] == 2 then if[a] 16 ≤ T0SZ ≤ 24 then *x* = (28 - T0SZ)	if T*n*SZ < 16 then *x* = 12 *y* = (*x* + 35)
First	BaseAddr[PAMax-1:*x*]:IA[*y*:30]:0b000 if[a] 25 ≤ T*n*SZ ≤ 33 then *x* = (37 - T*n*SZ) else[c] *x* =12	BaseAddr[PAMax-1:*x*]:IA[*y*:30]:0b000 if SL0[b] == 1 then if[a] 21 ≤ T0SZ ≤ 33 then *x* = (37 - T0SZ) elsif SL0[b] == 2 then *x* = 12	*y* = (*x* + 26)

Second	BaseAddr[PAMax-1:*x*]:IA[*y*:30]:0b000
	if[a] 34 ≤ T*n*SZ ≤ 39 then *x* = (46 - T*n*SZ)
	elsif 39 < T*n*SZ then *x* = 7
	else[c] *x* =12
		BaseAddr[PAMax-1:*x*]:IA[*y*:30]:0b000
		if SL0[b] == 0 then
		  if[a] 30 ≤ T0SZ ≤ 39 then *x* = (46 - T0SZ)
		  elsif 39 < T0SZ then *x* = 7
		elsif 0 < SL0[b] then *x* = 12
			y = (*x* + 17)

Third	BaseAddr[PAMax-1:12]:IA[20:30]:0b000	BaseAddr[PAMax-1:12]:IA[20:30]:0b000	-

a. This line indicates the range of permitted values for T*n*SZ, for a lookup that starts at this level.
b. SL0 == 0 if the initial lookup is level 2, SL0 == 1 if the initial lookup is level 1, and SL0 ==2 if the initial lookup level is level 0.
c. This is the case where this level of lookup is not the initial level of lookup.

Identifying support for the 4KB granule

The ID_AA64MMFR0_EL1.4Kgranule identifies whether an implementation supports the 4KB translation granule, as follows:

0b0000 4KB granule size supported.
0b1111 4KB granule size not supported.

Finding the translation table entry when using the 16KB translation granule

Table D4-23 on page D4-1667 shows the translation table descriptor address, for each level of lookup, when using the 16KB translation granule. See the start of *The algorithm for finding the translation table entries* on page D4-1666 for more information about terms used in the table.

Table D4-24 Translation table entry addresses when using the 16KB translation granule

Lookup level	Entry address and conditions		General conditions
	Stage 1 translation	**Stage 2 translation**	
Zero	BaseAddr[PAMax-1:4]:IA[47]:0b000 [a] 16 ≤ T*n*SZ	-	Only applies to stage 1
First	BaseAddr[PAMax-1:*x*]:IA[*y*:36]:0b000 if[a] 17 ≤ T*n*SZ ≤ 27 then *x* = (31 - T*n*SZ) else[b] *x* =14	BaseAddr[PAMax-1:*x*]:IA[*y*:36]:0b000 if SL0[c] == 2 then if[a] T0SZ ≤ 27 then *x* = (31 - T0SZ)	*y* = (*x* + 32)
Second	BaseAddr[PAMax-1:*x*]:IA[*y*:25]:0b000 if[a] 28 ≤ T*n*SZ ≤ 38 then *x* = (42 - T*n*SZ) else[b] *x* =14	BaseAddr[PAMax-1:*x*]:IA[*y*:25]:0b000 if SL0[c] == 1 then if[a] 24 ≤ T0SZ ≤ 38 then *x* = (42 - T0SZ) elsif SL0[c] == 2 then *x* = 14	*y* = (*x* + 21)
Third	BaseAddr[PAMax-1:14]:IA[24:14]:0b000	BaseAddr[PAMax-1:*x*]:IA[*y*:14]:0b000 if SL0[c] == 0 then if[a] 35 ≤ T0SZ ≤ 39 then *x* = (53 - T0SZ) elsif SL0[c] >0 then *x* = 14	*y* = (*x* + 10)

a. This line indicates the range of permitted values for T*n*SZ, for a lookup that starts at this level.
b. This is the case where this level of lookup is not the initial level of lookup.
c. SL0 == 0 if the initial lookup is level 3, SL0 == 1 if the initial lookup is level 2, and SL0 ==2 if the initial lookup level is level 1.

Identifying support for the 16KB granule

The ID_AA64MMFR0_EL1.16Kgranule identifies whether an implementation supports the 4KB translation granule, as follows:

0b0000 16KB granule size not supported.
0b0001 16KB granule size supported.

Finding the translation table descriptor when using the 64KB translation granule

Table D4-25 shows the translation table descriptor address, for each level of lookup, when using the 64KB translation granule. See the start of *The algorithm for finding the translation table entries* on page D4-1666 for more information about terms used in the table.

Table D4-25 Translation table entry addresses when using the 64KB translation granule

Lookup level	Entry address and conditions		General conditions
	Stage 1 translation	**Stage 2 translation**	

First	BaseAddr[PAMax-1:*x*]:IA[*y*:42]:`0b000`
	if[a] 16 ≤ T*n*SZ ≤ 21 then *x* = (25 - T*n*SZ)
	elsif T*n*SZ < 16 then *x* = 9
		BaseAddr[PAMax-1:*x*]:IA[*y*:42]:`0b000`
		if SL0[b] == 2 then
		  if[a] 16 ≤ T0SZ ≤ 21 then *x* = (25 - T0SZ)
		  elsif T*n*SZ < 16 then *x* = 9
			y = (*x* + 38)

Second	BaseAddr[PAMax-1:*x*]:IA[*y*:29]:`0b000` if[a] 22 ≤ T*n*SZ ≤ 34 then *x* = (38 - T*n*SZ) else[c] *x* =16	BaseAddr[PAMax-1:*x*]:IA[*y*:29]:`0b000` if SL0[b] == 1 then if[a] 18 ≤ T0SZ ≤ 34 then *x* = (38 - T0SZ) elsif SL0[b] == 2 then *x* = 16	*y* = (*x* + 25)

Third	BaseAddr[PAMax-1:*x*]:IA[*y*:16]:`0b000`
	if[a] 35 ≤ T*n*SZ ≤ 39 then *x* = (51 - T*n*SZ)
	elsif 39 < T*n*SZ then *x* = 12
	else[c] *x* =16
		BaseAddr[PAMax-1:*x*]:IA[*y*:16]:`0b000`
		if SL0[b] == 0 then
		  if[a] 31 ≤ T0SZ ≤ 39 then *x* = (51 - T0SZ)
		  elsif 39 < T0SZ then *x* = 12
		elsif 0 < SL0[b] then *x* = 16
			y = (*x* + 12)

a. This line indicates the range of permitted values for T*n*SZ, for a lookup that starts at this level.
b. SL0 == 0 if the initial lookup is level 3, SL0 == 1 if the initial lookup is level 2, and SL0 ==2 if the initial lookup level is at level 1.
c. This is the case where this level of lookup is not the initial level of lookup.

Identifying support for the 64KB granule

The ID_AA64MMFR0_EL1.64Kgranule identifies whether an implementation supports the 4KB translation granule, as follows:

0b0000 64KB granule size supported.
0b1111 64KB granule size not supported.

D4.2.8 The effects of disabling a stage of address translation

The following sections describe the effect on MMU behavior of disabling each stage of translation:

- *Behavior when stage 1 address translation is disabled*
- *Behavior when stage 2 address translation is disabled* on page D4-1671
- *Behavior of instruction fetches when all associated stages of translation are disabled* on page D4-1671.

Behavior when stage 1 address translation is disabled

When a stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of translation are treated as follows:

Non-secure EL1 and EL0 accesses if the HCR_EL2.DC bit is set to 1

For the Non-secure EL1&0 translation regime, when the value of HCR_EL2.DC is 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Read-Write-Allocate, Outer Write-Back Read-Write-Allocate memory attributes.

Note

This applies for both instruction and data accesses.

All other accesses

For all other accesses, when stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

Data access

The stage 1 translation assigns the Device-nGnRnE memory type.

Instruction access

The stage 1 translation assigns the Normal memory attribute, with the cacheability and shareability attributes determined by the value of the SCTLR.I bit for the translation regime, as follows:

When the value of I is 0

The stage 1 translation assigns the Non-cacheable and Outer Shareable attributes.

When the value of I is 1

The stage 1 translation assigns the Cacheable, Inner Write-Through no Write-Allocate Read-Allocate, Outer Write-Through no Write-Allocate Read Allocate Outer Shareable attribute.

For this stage of translation, no memory access permission checks are performed, and therefore no MMU faults can be generated for this stage of address translation.

Note

Alignment checking is performed, and therefore Alignment faults can occur.

For every access, the input address of the stage 1 translation is flat-mapped to the output address.

For a Non-secure EL1 or EL0 access, if EL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

When the value of HCR_EL2.DC is 1, in Non-secure state:

- The SCTLR_EL1.M bit behaves as if it is 0, for all purposes other than reading the value of the bit. This means Non-secure EL1&0 stage 1 address translation is disabled.
- The HCR_EL2.VM bit behaves as if it is 1, for all purposes other than reading the value of the bit. This means that Non-secure EL1&0 stage 2 address translation is enabled.

See also *Behavior of instruction fetches when all associated stages of translation are disabled* on page D4-1671.

Effect of disabling address translation on maintenance and address translation instructions

Cache maintenance instructions act on the target cache regardless of whether any stages of address translation are disabled, and regardless of the values of the memory attributes. However, if a stage of address translation is disabled, they use the flat address mapping for that translation stage.

TLB invalidate operations act on the target TLB regardless of whether any stage of address translation is disabled.

The value of HCR_EL2.DC affect some address translation instructions, see *Address translation instructions, AT** on page D4-1683.

Behavior when stage 2 address translation is disabled

When stage 2 address translation is disabled:

- The IPA output from the stage 1 translation maps flat to the PA.
- The memory attributes and permissions from the stage 1 translation apply to the PA.

When both stages of address translation are disabled, see also *Behavior of instruction fetches when all associated stages of translation are disabled*.

Behavior of instruction fetches when all associated stages of translation are disabled

When EL3 is using AArch64, this section applies to:

- The Secure EL1&0 translation regime when Secure EL1&0 stage 1 address translation is disabled.
- The Secure EL3 translation regime, when Secure EL3 stage 1 address translation is disabled.
- The Non-secure EL2 translation regime, when Non-secure EL2 stage 1 address translation is disabled
- The Non-secure EL1&0 translation regime, when both stages of address translation are disabled.

Note

- The behaviors in Non-secure state apply regardless of the Execution state that EL3 is using.
- When the value of HCR_EL2.DC is 1, then the behavior of the Non-secure EL1&0 translation regime is as if stage 1 translation is disabled and stage 2 translation is enabled, as described in *Behavior when stage 1 address translation is disabled* on page D4-1670.

In these cases, a memory location might be accessed as a result of an instruction fetch if one of the following conditions is met:

- The memory location is in the same block of memory, of the translation granule size, as an instruction that a simple sequential execution of the program requires to be fetched, or is in the block of memory of the translation granule size immediately following such a block.
- The memory location is in the same block of memory of the translation granule size from which a simple sequential execution of the program with all associated stages of address translation disabled has previously required an instruction to be fetched, or is in the block of the translation granule size immediately following such a block.

Each block of memory referred to in this section must be aligned to the translation granule size. These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.

Note

To ensure architectural compliance, software must ensure that both of the following apply:

- Instructions that will be executed when all associated stages of address translation are disabled are located in blocks of the address space, of the translation granule size, that contain only memory that is tolerant to speculative accesses.
- Each block of the address space, of the translation granule size, that immediately follows a similar block that holds instructions that will be executed when all associated stages address translation are disabled, contains only memory that is tolerant to speculative accesses.

D4.2.9 The implemented Exception levels and the resulting translation stages and regimes

Elsewhere, this chapter describes an implementation that includes all Exception levels, and describes the control of address translation by Exception levels that are using AArch64. This subsection describes how the address translation scheme changes if an implementation does not include all of the Exception levels.

If an implementation does not include EL3, it has only a single Security state, with MMU controls equivalent to the Secure state MMU controls.

If an implementation does not include EL2 then:

- If it also does not include EL3, the MMU provides only a single EL1&0 stage 1 translation regime.
- If it includes EL3, the MMU provides an EL1&0 stage 1 translation regime in each Security state.

Figure D4-2 on page D4-1637 shows the set of translation regimes for an implementation that implements all of the Exception levels. Table D4-26 shows how the supported translation stages depend on the implemented Exception levels, and in some cases on the Execution state being used by the highest implemented Exception level:

Table D4-26 The relation between the implemented translation stages and Exception levels for AArch64

Translation stage	Requires
Secure EL3 stage 1	EL3 implemented and using AArch64.
Secure EL1&0 stage 1	Either: • EL3 implemented and using AArch64. • Only EL1 and EL0 implemented, all operation is in Secure state, and EL1 is using AArch64.
Non-secure EL2 stage 1	EL2 implemented.
Non-secure EL1&0 stage 2	EL2 implemented.
Non-secure EL1&0 stage 1	Any implementation except: • Only EL1 and EL0 implemented, with all operation in the Secure state.

D4.2.10 Pseudocode details of VMSAv8-64 address translation

The following subsections gives a pseudocode description of the translation table walk:

- *Definitions required for address translation* on page D4-1673.
- *Performing the full address translation* on page D4-1673.
- *Stage 1 translation* on page D4-1673.
- *Stage 2 translation* on page D4-1675.
- *Translation table walk* on page D4-1676.
- *Support functions* on page D4-1681.

Definitions required for address translation

In pseudocode, the result of a translation table lookup, in either Execution state, is returned in a TLBRecord structure.

```
type TLBRecord is (
    Permissions       perms,
    bit               nG,             // '0' = Global, '1' = not Global
    bits(4)           domain,         // AArch32 only
    boolean           contiguous,     // Contiguous bit from page table
    integer           level,          // In AArch32 Short-descriptort format, indicates Section/Page
    integer           blocksize,      // Describes size of memory translated in KBytes
    AddressDescriptor addrdesc
)
```

Memory data type definitions on page D3-1622 includes definitions of the Permissions and AddressDescriptor parameters.

Performing the full address translation

The function AArch64.FullTranslate() performs a full translation table walk. For any translation regime it performs a stage 1 translation for the supplied virtual address, and for the Non-secure EL1&0 translation regime it then performs a stage 2 translation of the returned address.

```
// AArch64.FullTranslate()
// =======================
// Perform both stage 1 and stage 2 translation walks for the current translation regime. The
// function used by Address Translation operations is similar except it uses the translation
// regime specified for the instruction.

AddressDescriptor AArch64.FullTranslate(bits(64) vaddress, AccType acctype, boolean iswrite,
                                        boolean wasaligned, integer size)

    // First Stage Translation
    S1 = AArch64.FirstStageTranslate(vaddress, acctype, iswrite, wasaligned, size);

    if !IsFault(S1) && HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} then
        s2fs1walk = FALSE;
        result = AArch64.SecondStageTranslate(S1, vaddress, acctype, iswrite, wasaligned, s2fs1walk,
                                              size);
    else
        result = S1;

    return result;
```

Stage 1 translation

The function AArch64.FirstStageTranslate() performs a stage 1 translation, calling the function AArch64.TranslationTableWalk(), described in *Translation table walk* on page D4-1676, to perform the required translation table walk. However, if stage 1 translation is disabled, it calls the function AArch64.TranslateAddressS1Off(), described in this section, to set the memory attributes.

```
// AArch64.FirstStageTranslate()
// =============================
// Perform a stage 1 translation walk. The function used by Address Translation operations is similar
// except it uses the translation regime specified for the instruction.

AddressDescriptor AArch64.FirstStageTranslate(bits(64) vaddress, AccType acctype, boolean iswrite,
                                              boolean wasaligned, integer size)

    if HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} then
        s1_enabled = HCR_EL2.TGE == '0' && SCTLR_EL1.M == '1';
    else
        s1_enabled = SCTLR[].M == '1';

    ipaddress = bits(48) UNKNOWN;
    secondstage = FALSE;
```

```
    s2fs1walk = FALSE;

    boolean permissioncheck = TRUE;            // By default, permissions will need to be checked

    if s1_enabled then                         // First stage enabled
        S1 = AArch64.TranslationTableWalk(ipaddress, vaddress, acctype, iswrite, secondstage,
                                          s2fs1walk, size);
    else
        S1 = AArch64.TranslateAddressS1Off(vaddress, acctype, iswrite);
        permissioncheck = FALSE;

    // Check for unaligned data accesses to Device memory
    if (!wasaligned && !IsFault(S1.addrdesc) && S1.addrdesc.memattrs.type == MemType_Device &&
        acctype != AccType_IFETCH) then
        S1.addrdesc.fault = AArch64.AlignmentFault(acctype, iswrite, secondstage);

    if !IsFault(S1.addrdesc) && permissioncheck then
        S1.addrdesc.fault = AArch64.CheckPermission(S1.perms, vaddress, S1.level,
                                                    S1.addrdesc.paddress.NS,
                                                    acctype, iswrite);

    // Check for instruction fetches from Device memory not marked as execute-never. If there has
    // not been a Permission Fault then the memory is not marked execute-never.
    if (!IsFault(S1.addrdesc) && S1.addrdesc.memattrs.type == MemType_Device &&
        acctype == AccType_IFETCH) then
        S1.addrdesc = AArch64.InstructionDevice(S1.addrdesc, vaddress, ipaddress, S1.level,
                                                acctype, iswrite,
                                                secondstage, s2fs1walk);

    return S1.addrdesc;
```

When stage 1 translation is disabled, the function `AArch64.TranslateAddressS1Off()` sets the memory attributes.

```
// AArch64.TranslateAddressS1Off()
// ===============================
// Called for stage 1 translations when translation is disabled to supply a default translation.
// Note that there are additional constraints on instruction prefetching that are not described in
// this pseudocode.

TLBRecord AArch64.TranslateAddressS1Off(bits(64) vaddress, AccType acctype, boolean iswrite)
    assert !ELUsingAArch32(TranslationRegime());

    result.addrdesc.paddress.NS = if IsSecure() then '0' else '1';
    result.addrdesc.fault = AArch64.NoFault();

    return result;
```

Stage 2 translation

In the Non-secure EL1&0 translation regime, a descriptor address returned by stage 1 lookup is in the IPA address space, and must be mapped to a PA by a stage 2 translation. Function `AArch64.SecondStageWalk()` performs this translation, by calling the `AArch64.SecondStageTranslate()` function.

```
// AArch64.SecondStageWalk()
// =========================
// Perform a stage 2 translation on a stage 1 translation page table walk access.

AddressDescriptor AArch64.SecondStageWalk(AddressDescriptor S1, bits(64) vaddress, AccType acctype,
                                          integer size)
    assert HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1};

    iswrite = FALSE;
    s2fs1walk = TRUE;
    wasaligned = TRUE;
    return AArch64.SecondStageTranslate(S1, vaddress, acctype, iswrite, wasaligned, s2fs1walk,
                                        size);
```

The `AArch64.SecondStageTranslate()` function performs the stage 2 address translation.

```
// AArch64.SecondStageTranslate()
// ==============================
// Perform a stage 2 translation walk. The function used by Address Translation operations is
// similar except it uses the translation regime specified for the instruction.

AddressDescriptor AArch64.SecondStageTranslate(AddressDescriptor S1, bits(64) vaddress,
                                               AccType acctype, boolean iswrite, boolean wasaligned,
                                               boolean s2fs1walk, integer size)
    assert HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1};
```

```
    s2_enabled = HCR_EL2.VM == '1';
    secondstage = TRUE;

    if s2_enabled then                          // Second stage enabled
        ipaddress = S1.paddress.physicaladdress<47:0>;
        S2 = AArch64.TranslationTableWalk(ipaddress, vaddress, acctype, iswrite, secondstage,
                                          s2fs1walk, size);

        // Check for unaligned data accesses to Device memory
        if (!wasaligned && !IsFault(S2.addrdesc) && S2.addrdesc.memattrs.type == MemType_Device &&
            acctype != AccType_IFETCH) then
            S2.addrdesc.fault = AArch64.AlignmentFault(acctype, iswrite, secondstage);

        if !IsFault(S2.addrdesc) then
            S2.addrdesc.fault = AArch64.CheckS2Permission(S2.perms, vaddress, ipaddress, S2.level,
                                                          acctype, iswrite, s2fs1walk);

        // Check for instruction fetches from Device memory not marked as execute-never. As there
        // has not been a Permission Fault then the memory is not marked execute-never.
        if (!IsFault(S2.addrdesc) && S2.addrdesc.memattrs.type == MemType_Device &&
            acctype == AccType_IFETCH) then
            S2.addrdesc = AArch64.InstructionDevice(S2.addrdesc, vaddress, ipaddress, S2.level,
                                                    acctype, iswrite,
                                                    secondstage, s2fs1walk);

        // Check for protected table walk
        if (s2fs1walk && !IsFault(S2.addrdesc) && HCR_EL2.PTW == '1' &&
            S2.addrdesc.memattrs.type == MemType_Device) then
            S2.addrdesc.fault = AArch64.PermissionFault(ipaddress, S2.level, acctype,
                                                        iswrite, secondstage, s2fs1walk);
        result = CombineS1S2Desc(S1, S2.addrdesc);
    else
        result = S1;

    return result;
```

Translation table walk

The function `AArch64.TranslationTableWalk()` returns the result, in the form of a `TLBRecord`, of a translation table walk made for a memory access from an Exception level that is using AArch64.

```
// AArch64.TranslationTableWalk()
// ==============================
// Returns a result of a translation table walk
//
// Implementations might cache information from memory in any number of non-coherent TLB
// caching structures, and so avoid memory accesses that have been expressed in this
// pseudocode. The use of such TLBs is not expressed in this pseudocode.

TLBRecord AArch64.TranslationTableWalk(bits(48) ipaddress, bits(64) vaddress,
                                       AccType acctype, boolean iswrite, boolean secondstage,
                                       boolean s2fs1walk, integer size)
    if !secondstage then
        assert !ELUsingAArch32(TranslationRegime());
    else
        assert HaveEL(EL2) && !IsSecure() && !ELUsingAArch32(EL2) && PSTATE.EL != EL2;

Support functions

In the translation table walk functions, the `WalkAttrDecode()` function determines the attributes for a translation table lookup.

```
// WalkAttrDecode()
// ================

MemoryAttributes WalkAttrDecode(bits(2) SH, bits(2) ORGN, bits(2) IRGN)

    MemoryAttributes memattrs;

    AccType acctype = AccType_NORMAL;

    memattrs.type = MemType_Normal;
    memattrs.device = DeviceType UNKNOWN;
    memattrs.inner = ShortConvertAttrsHints(IRGN, acctype);
    memattrs.outer = ShortConvertAttrsHints(ORGN, acctype);
    memattrs.shareable = SH<1> == '1';
    memattrs.outershareable = SH == '10';

    return memattrs;
```

The function AArch64.S1AttrDecode() decodes the attributes from a stage 1 translation table lookup.

```
// AArch64.S1AttrDecode()
// ======================
// Converts the Stage 1 attribute fields, using the MAIR, to orthogonal
// attributes and hints.

MemoryAttributes AArch64.S1AttrDecode(bits(2) SH, bits(3) attr, AccType acctype)

    MemoryAttributes memattrs;

    mair = MAIR[];
    index = 8 * UInt(attr);
    attrfield = mair<index+7:index>;

    if ((attrfield<7:4> != '0000' && attrfield<3:0> == '0000') ||
        (attrfield<7:4> == '0000' && attrfield<3:0> != 'xx00')) then
        // Reserved, maps to an allocated value
        (-, attrfield) = ConstrainUnpredictableBits();

    if attrfield<7:4> == '0000' then            // Device
        memattrs.type = MemType_Device;
        memattrs.inner = MemAttrHints UNKNOWN;
        memattrs.outer = MemAttrHints UNKNOWN;
        memattrs.shareable = TRUE;
        memattrs.outershareable = TRUE;
        case attrfield<3:0> of
            when '0000'  memattrs.device = DeviceType_nGnRnE;
            when '0100'  memattrs.device = DeviceType_nGnRE;
            when '1000'  memattrs.device = DeviceType_nGRE;
            when '1100'  memattrs.device = DeviceType_GRE;
            otherwise    Unreachable();         // Reserved, handled above

    elsif attrfield<3:0> != '0000'  then        // Normal
        memattrs.type = MemType_Normal;
        memattrs.outer = LongConvertAttrsHints(attrfield<7:4>, acctype);
        memattrs.inner = LongConvertAttrsHints(attrfield<3:0>, acctype);
        memattrs.device = DeviceType UNKNOWN;
        memattrs.shareable = SH<1> == '1';
        memattrs.outershareable = SH == '10';

    else
        Unreachable();                          // Reserved, handled above

    return memattrs;
```

The function AArch64.CheckPermission() checks the access permissions returned by a stage 1 translation table lookup, see *Access permission checking* on page D3-1627.

The function AArch64.CheckS2Permission() checks the access permissions returned by a stage 2 translation table lookup.

```
// AArch64.CheckS2Permission()
// ===========================
// Function used for permission checking from AArch64 stage 2 translations

FaultRecord AArch64.CheckS2Permission(Permissions perms, bits(64) vaddress, bits(48) ipaddress,
                                      integer level, AccType acctype, boolean iswrite,
                                      boolean s2fs1walk)
    assert HaveEL(EL2) && !IsSecure() && !ELUsingAArch32(EL2) && PSTATE.EL != EL2;

    r = perms.ap<1> == '1';
    w = perms.ap<2> == '1';
    xn = perms.xn == '1';

    // Stage 1 walk is checked as a read, regardless of the original type
    if acctype == AccType_IFETCH && !s2fs1walk then
        fail = xn;
```

```
elsif iswrite && !s2fs1walk then
    fail = !w;
else
    fail = !r;

if fail then
    domain = bits(4) UNKNOWN;
    secondstage = TRUE;
    return AArch64.PermissionFault(ipaddress, level, acctype, iswrite, secondstage,
                                   s2fs1walk);
else
    return AArch64.NoFault();
```

The `AddrTop()` function returns the bit number of the most significant valid bit of a VA in the current translation regime. If EL1 is using AArch64 and EL0 is using AArch32 then an address from EL0 is zero-extended to 64 bits.

```
integer AddrTop(bits(64) address);
```

D4.2.11 Address translation instructions

Each of the ARMv8 instruction sets provides instructions that return the result of translating an input address, supplied as an argument to the instruction, using a specified translation stage or regime.

The available instructions only perform translations that are accessible from the Security state and Exception level at which the instruction is executed. That is:

- No instruction executed in Non-secure state can return the result of a Secure address translation stage.
- No instruction can return the result of an address translation stage that is controlled by an Exception level that is higher than the Exception level at which the instruction is executed.

*Address translation instructions, AT** summarizes the A64 address translation instructions.

See also *A64 system instructions for address translation* on page C5-319.

Address translation instructions, AT*

The A64 assembly language syntax for address translation instructions is:

```
AT <operation>, <Xt>
```

Where:

`<operation>`. Is one of `S1E1R`, `S1E1W`, `S1E0R`, `S1E0W`, `S12E1R`, `S12E1W`, `S12E0R`, `S12E0W`, `S1E2R`, `S1E2W`, `S1E3R`, or `S1E3W`.

`<operation>` has a structure of `<stages><level><read|write>`, where:

`<stages>`. Is one of:

- `S1`. Stage 1 translation.
- `S12`. Stage 1 translation followed by stage 2 translation.

`<level>`. Describes the Exception Level that the translation applies to. Is one of:

- `E0`. EL0.
- `E1`. EL1.
- `E2`. EL2.
- `E3`. EL3.

If `<level>` is higher than the current Exception Level the instruction is UNDEFINED.

`<read|write>`

Is one of:

- `R`. Read.
- `W`. Write.

`<Xt>`. The address to be translated. No alignment restrictions apply for the address.

If EL2 is not implemented, the `AT S1E2R` and `AT S1E2W` instructions are UNDEFINED.

Note

If EL2 is not implemented but EL3 is implemented, the `AT S12E*` instructions are not UNDEFINED, but behave the same way as the equivalent `AT S1E*` instructions. This is consistent with the behavior if EL2 is implemented but stage 2 translation is disabled.

In each case, the address being translated is held in the 64-bit address argument register, `Xt`. If the address translation instruction uses a translation regime that is using AArch32, meaning it requires a VA of only 32 bits, then VA[63:32] is RES0.

If the address translation is successful, the resulting PA is returned in PAR_EL1.PA, and PAR_EL1.F is set to 0 to indicate that the translation was successful. Otherwise, see *Synchronous faults generated by address translation instructions*.

Note

The architecture provides a single PAR, PAR_EL1, that is used regardless of:

- The Exception level at which the instruction was executed.
- The Exception level that controls the stage or stages of translation used by the instruction.

For all of these instructions, the current context information determines which entries in TLB caching structures are used, and how the translation table walk is performed.

When Non-secure EL1&0 stage 1 address translation is disabled, any AT S1E0*, AT S1E1*, AT S12E0*, or ATS12E1* address translation instruction that accesses the Non-secure state translation reflects the effect of the HCR_EL2.DC bit as described in *Behavior when stage 1 address translation is disabled* on page D4-1670.

Executing `AT S1E2R` or `AT S1E2W` at EL3 with SCR_EL3.NS==0 is UNDEFINED.

Note

`AT S12E*` instructions at EL3 with SCR_EL3.NS==0 are not UNDEFINED but behave the same way as the equivalent `AT S1E*` instructions.

Synchronous faults generated by address translation instructions

The address translation instructions use the translation mechanism, and that mechanism can generate the following synchronous faults:

- Translation fault.
- Access flag fault.
- Permission fault.
- Domain fault, when translating using the AArch32 translation systems.
- Address size fault.
- TLB conflict fault.
- Synchronous external aborts during a translation table walk.

In addition:

- If the address translation instruction requires two stages of translation then these faults could arise from either stage 1 or stage 2.
- For a stage 1 translation for the Non-secure EL1&0 translation regime, the fault might be generated on the stage 2 translation of an address accessed as part of the stage 1 translation table walk, see *Stage 2 fault on a stage 1 translation table walk* on page D4-1727.

Except as described in this section, these faults are not taken as an exception for the address translation instructions, but instead the PAR_EL1.FST field holds the fault status information. In these cases the PAR_EL1.PA field does not hold the output address of the translation.

The exceptions to this reporting the fault in PAR_EL1 are:

- Synchronous external aborts during a translation table walk are taken as a Data Abort exception.

  For an address translation instruction executed at a particular Exception level, if the synchronous external abort is generated on a stage 1 translation table walk, the Data Abort exception is taken to the Exception level to which a synchronous external abort on a stage 1 translation table walk for a memory access from that Exception level would be taken.

  If the synchronous external abort is generated on a stage 2 translation table walk then:

  — If the address translation instruction was executed at EL3, the synchronous Data Abort exception is taken to EL3.

  — If the address translation instruction was executed at EL2 or EL1, the Data Abort exception is taken to the Exception level to which a synchronous external abort on a stage 2 translation table walk for a memory access from that Exception level would be taken.

  In any case where the address translation instruction causes a synchronous Data Abort exception to be taken:

  — The PAR_EL1 is UNKNOWN.

  — The ESR_ELx of the target Exception Level of the exception indicates that the fault was due to a translation table walk for a cache maintenance instruction.

  — The FAR_ELx of the target Exception Level holds the virtual address for the translation request.

- For the `AT S1E0*` and `AT S1E1*` instructions executed from the Non-secure EL1 Exception level, if there is a stage 2 fault on a memory access made as part of the translation table walk.If SCR_EL3.EA==1 then a synchronous external abort on a stage 2 translation table walk is taken to EL3. In all other cases, the fault is taken as an exception to EL2, and:

  — PAR_EL1 is UNKNOWN

  — ESR_EL2 indicates that the fault occurred on a translation table walk, and that the operation that faulted was a cache maintenance instruction.

  — HPFAR_EL2 holds the IPA that faulted

  — FAR_EL2 holds the VA that the executing software supplied to the address translation instruction.

  — For any exception other than the synchronous external abort on a stage 2 translation table walk, the HPFAR_EL2 holds the IPA that faulted.

  This fault can occur for any of the following reasons:

  — Stage 2 Translation fault.

  — Stage 2 Access fault.

  — Stage 2 Permission fault.

  — Stage 2 Address size fault.

  — Synchronous external abort on a stage 2 translation table walk.

Synchronization requirements of the address translation instructions

Where an instruction results in an update to a system register, as is the case with the `AT *` address translation instructions, explicit synchronization must be performed before the result is guaranteed to be visible to subsequent direct reads of the PAR_EL1.

Note

This is consistent with the AArch32 requirement, where the VA to PA translation instructions are expressed as CP15 register writes, and the effect of those writes to other registers require explicit synchronization before the result is guaranteed to be visible to subsequent instructions.

D4.3 Translation table walk examples

Figure D4-2 on page D4-1637 shows the VMSAv8 address translation stages that are controlled by an Exception level that is using AArch64. *The VMSAv8-64 address translation system* on page D4-1636 describes the VMSAv8-64 address translation scheme. This section gives examples of the use of that scheme, for common translation requirements.

System control registers relevant to MMU operation on page D4-1641 specifies the relevant registers, including the TCR and TTBR, or TTBRs, for each stage of address translation.

For any stage of translation, a TCR.T*n*SZ field indicates the supported input address size. For a stage of address translation controlled from an Exception level using AArch64, the supported input address size is $2^{(64-T\mathit{n}SZ)}$.

This section describes:

- Performing the initial lookup, for an address for which the initial lookup is either:
  - At the highest lookup level used for the appropriate translation granule size.
  - Because of the concatenation of translation tables at the initial lookup level, one level down from the highest level used for the translation granule size.

  These descriptions take account of the following cases:
  - The IA size is smaller than the largest size for the translation level, see *Reduced IA width* on page D4-1647.
  - For a stage 2 translation, translation tables are concatenated, to move the initial lookup level down by one level, see *Concatenated translation tables* on page D4-1647.

  For examples of performing the initial lookup, see *Examples of performing the initial lookup*.
- The full translation flow for resolving a page of memory. These examples describe resolving the largest IA size supported by the initial lookup level. For these examples, see *Full translation flows for VMSAv8-64 address translation* on page D4-1692.

D4.3.1 Examples of performing the initial lookup

The address ranges used for the initial translation table lookup depend on the translation granule, as described in:

- *Performing the initial lookup using the 4KB translation granule*.
- *Performing the initial lookup using the 16KB granule* on page D4-1688.
- *Performing the initial lookup using the 64KB translation granule* on page D4-1690.

Performing the initial lookup using the 4KB translation granule

This subsection describes examples of the initial lookup when using the 4KB translation granule that Table D4-10 on page D4-1652 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system* on page D4-1636.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D4-10 on page D4-1652 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 0, 4KB translation granule* on page D4-1687.
- *Initial lookup at level 0, 4KB translation granule* on page D4-1687.

In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see *Overview of stage 2 translations, 4KB granule* on page D4-1652.

Initial lookup at level 0, 4KB translation granule

This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0]. As Table D4-10 on page D4-1652 shows, a stage 1 or stage 2 initial lookup at level 0 is required when 39 ≤ n ≤ 47. For these lookups:

- TTBR[47:(n-35)] specify the translation table base address.
- Bits[n:39] of the input address are bits[(n-36):3] of the descriptor offset in the translation table.

Note

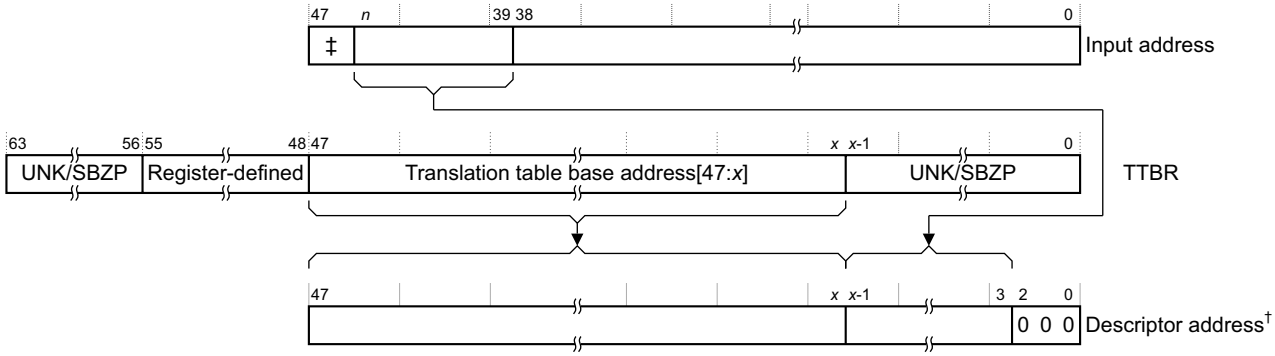
This means that, when the input address width is less than 48 bits

- The size of the translation table is reduced.
- More low-order bits of the TTBR are required to specify the translation table base address.
- Fewer input address bit are used to specify the descriptor offset in the translation table.

For example, if the input address width is 46 bits:

- The translation table size is 1KB,
- TTBR bits[47:10] specify the translation table base address.
- Input address bits[45:39] specify bits[9:3] of the descriptor offset.

Figure D4-15 shows this lookup.



Supported input address range is IA[n:0], 4 ≤ x ≤ 12, n = x + 35. When n is 47 the field marked ‡ is absent.
† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

Figure D4-15 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 0

Initial lookup at level 0, 4KB translation granule

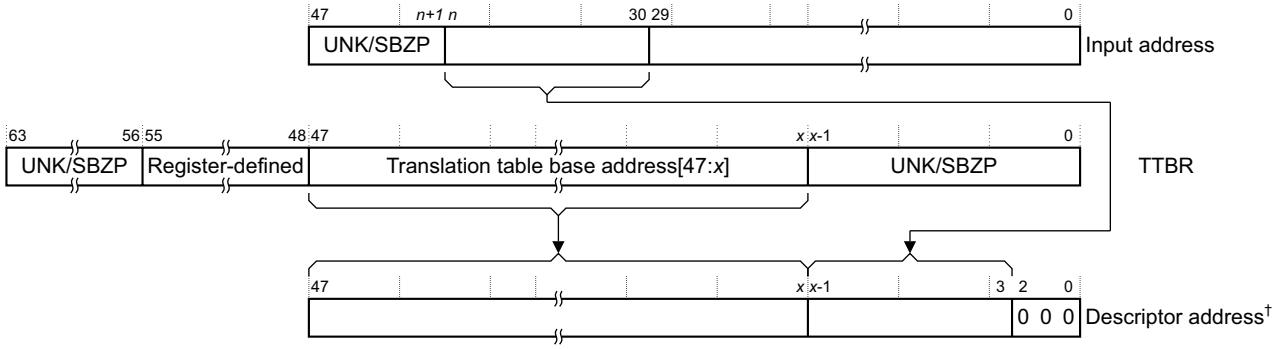
This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0].

For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D4-10 on page D4-1652 shows, this applies to IA[n:0], where 30 ≤ n ≤ 38. For these lookups:

- There is a single translation table at this level.
- TTBR[47:(n-26)] specify the translation table base address.
- Bits[n:30] of the input address are bits[(n-27):3] of the descriptor offset in the translation table.

Figure D4-16 on page D4-1688 shows this lookup.



Supported input address range is IA[*n*:0], 4 ≤ *x* ≤ 12, *n* = *x* + 26.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

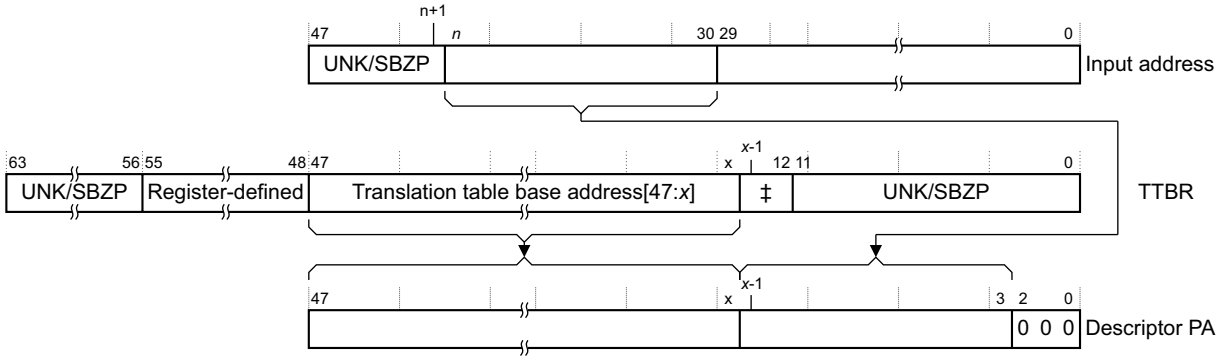
Figure D4-16 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, without concatenation

For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D4-10 on page D4-1652 shows, this applies to IA[*n*:0], where 39 ≤ *n* ≤ 42. For these lookups:

- There are $2^{(n-38)}$ concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2^{(n-38)}\times$4KB. This means TTBR[(*n*-27):12] must be zero.
- TTBR[47:(*n*-26)] specify the base address of the block of concatenated translation tables.
- Bits[*n*:30] of the input address are bits[(*n*-27):3] of the descriptor offset from the base address of the block of concatenated translation tables.

Figure D4-17 shows this lookup.



Supported input address range is IPA[*n*:0], 13 ≤ *x* ≤ 16, *n* = *x* + 26. The field marked ‡ must be zero.

Figure D4-17 Initial lookup for VMSAv8-64 using the 4KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 16KB granule

This subsection describes examples of the initial lookup when using the 16KB translation granule that Table D4-13 on page D4-1656 shows as starting at level 0 or at level 1. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 1. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system* on page D4-1636.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D4-13 on page D4-1656 shows as starting at level 1. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 2.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 0, 16KB translation granule*.
- *Initial lookup at level 1, 16KB translation granule*.

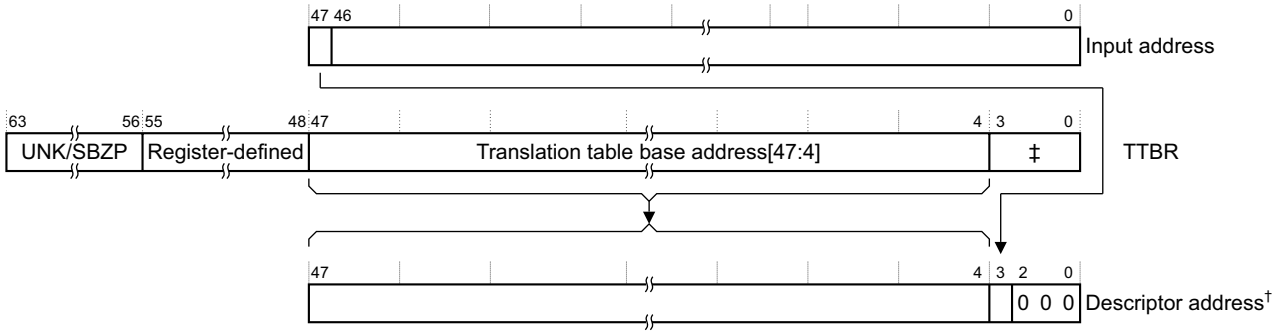
In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see *Overview of stage 2 translations, 16KB granule* on page D4-1655.

Initial lookup at level 0, 16KB translation granule

This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0]. As Table D4-12 on page D4-1654 shows, the only case where an address translation using the 16KB granule starts at level 0 is a stage 1 translation of a 48-bit input address, IA[47:0]. For this lookup:

- The required translation table has only two entries, meaning its size is 16bytes, and it must be aligned to 16 bytes.
- TTBR[47:4] specify the translation table base address.
- Bit[47] of the input address is bits[3] of the descriptor offset in the translation table.

Figure D4-18 shows this lookup.



Supported input address range is IA[47:0]. The field marked ‡ is UNK/SBZP.
† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

Figure D4-18 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 0

Initial lookup at level 1, 16KB translation granule

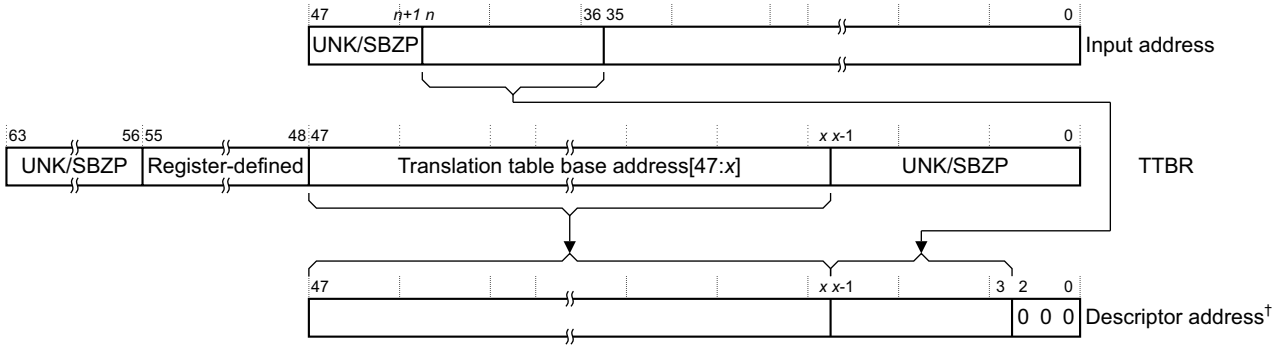
This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0].

For a stage 1 or stage 2 initial lookup at level 1, without use of concatenated translation tables

As Table D4-13 on page D4-1656 shows, this applies to IA[n:0], where $36 \le n \le 46$. For these lookups:

- There is a single translation table at this level.
- TTBR[47:(n-32)] specify the translation table base address.
- Bits[n:36] of the input address are bits[(n-33):3] of the descriptor offset in the translation table.

Figure D4-19 on page D4-1690 shows this lookup.



Supported input address range is IA[*n*:0], 4 ≤ *x* ≤ 14, *n* = *x* + 32.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

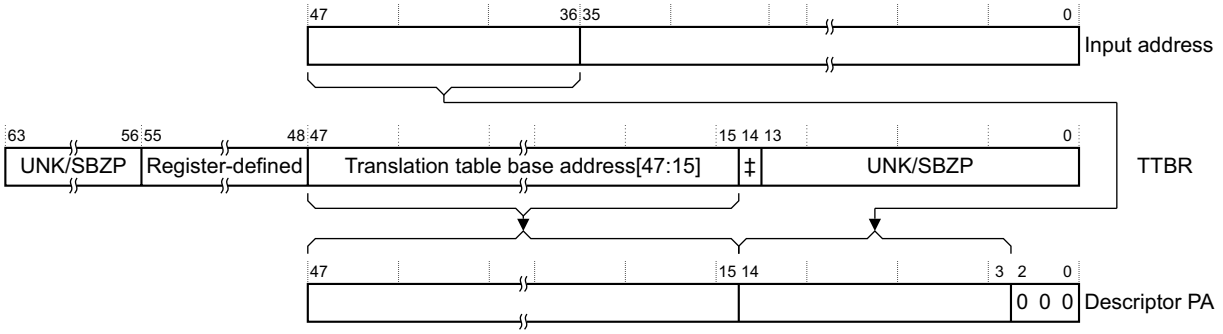
Figure D4-19 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, without concatenation

For a stage 2 initial lookup at level 1, with concatenated translation tables

As Table D4-13 on page D4-1656 shows, the only case where an address translation using the 16KB granule starts at level 1 because of concatenation of translation tables is a stage 2 translation of a 48-bit input address, IA[47:0]. For this lookup:

- There are two concatenated translation tables at this level.
- These concatenated translation tables must be aligned to 2×16KB. This means TTBR[14] must be zero.
- TTBR[47:15] specify the base address of the block of two concatenated translation tables.
- Bits[47:36] of the input address are bits[14:3] of the descriptor offset from the base address of the block of concatenated translation tables.

Figure D4-20 shows this lookup.



Supported input address range is IPA[47:0]. The bit marked ‡ must be zero.

Figure D4-20 Initial lookup for VMSAv8-64 using the 16KB granule, starting at level 1, with concatenation

Performing the initial lookup using the 64KB translation granule

This subsection describes examples of the initial lookup when using the 64KB translation granule that Table D4-16 on page D4-1659 shows as starting at level 1 or at level 2. It includes those stage 2 translations where concatenation of translation tables is required for the lookup to start at level 2. This means that it gives specific examples of the mechanisms described in *The VMSAv8-64 address translation system* on page D4-1636.

Note

For stage 2 translations, the same principles apply to an initial lookup that Table D4-16 on page D4-1659 shows as starting at level 2. In this case, for some IA sizes concatenation of translation tables means the lookup can, instead, start at level 3.

The following subsections describe these examples of the initial lookup:

- *Initial lookup at level 1, 64KB translation granule*.
- *Initial lookup at level 2, 64KB translation granule*.

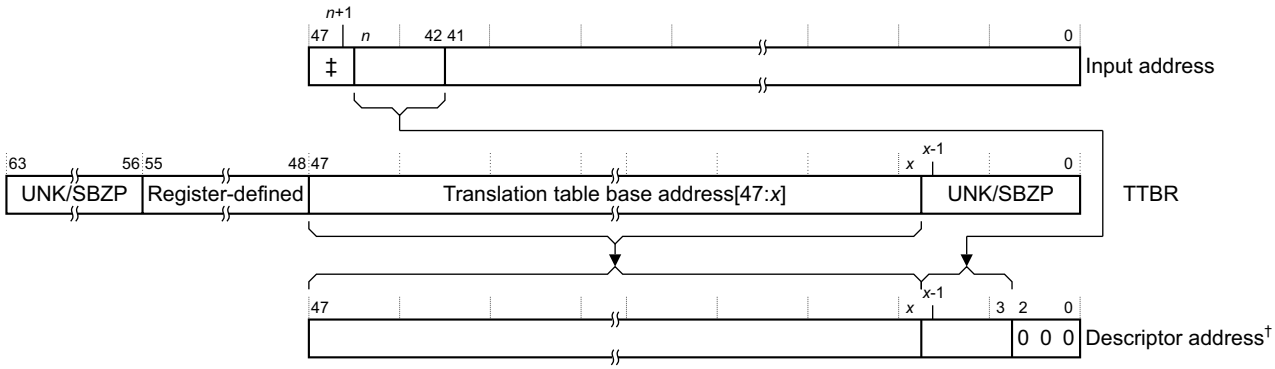
In all cases, for a stage 2 translation, the VTCR_EL2.SL0 field must indicate the required initial lookup level, and this level must be consistent with the value of the VTCR_EL2.T0SZ field, see *Overview of stage 2 translations, 64KB granule* on page D4-1659.

Initial lookup at level 1, 64KB translation granule

This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0]. As Table D4-16 on page D4-1659 shows, a stage 1 or stage 2 initial lookup at level 1 is required when 42 ≤ n ≤ 47. For these lookups:

- The size of the translation table is $2^{(n-39)}$ bytes. This means the size of the translation table, at this level, is always less than the granule size. The address of this translation table must align to the size of the table.
- Bits[n:42] of the input address are bits[(n-39):3] of the descriptor offset in the translation table.
- Bits[47:(n-38)] of the TTBR specify the translation table base address.

Figure D4-21 shows this lookup.



Supported input address range is IA[n:0], 42 ≤ n ≤ 47, x = n-38. When n is 47 the field marked ‡ is absent.
† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

Figure D4-21 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 1

Initial lookup at level 2, 64KB translation granule

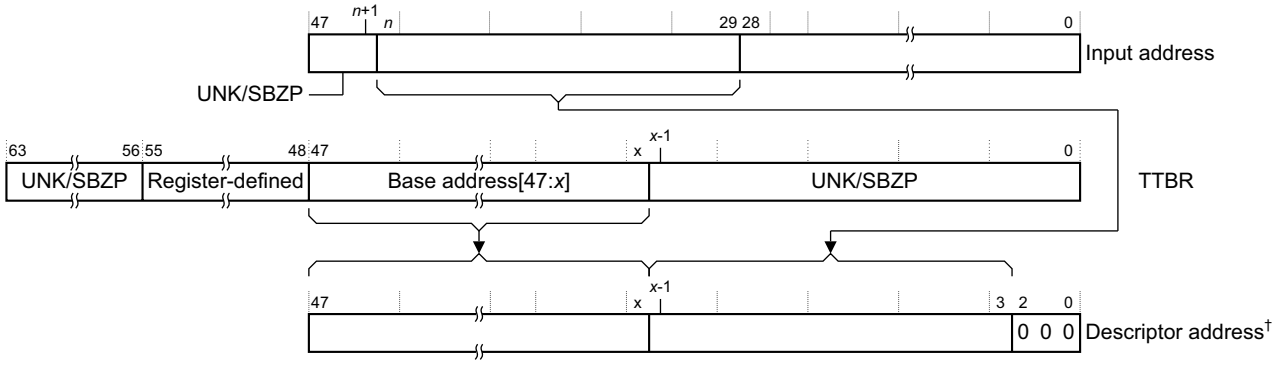
This subsection describes initial lookups with an input address width of (n+1) bits, meaning the input address is IA[n:0].

For a stage 1 or stage 2 initial lookup at level 2, without the use of concatenated translation tables

As Table D4-16 on page D4-1659 shows, this applies to IA[n:0], where 29 ≤ n ≤ 41. For these lookups:

- There is a single translation table at this level.
- TTBR[47:(n-25)] of the specify the translation table base address.
- Bits[n:29] of the input address are bits[(n-26):3] of the descriptor offset in the translation table.

Figure D4-22 on page D4-1692 shows this lookup.



Supported input address range is IA[*n*:0]. 4 ≤ *x* ≤ 16, *n* = *x* + 25.

† For a Non-secure EL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

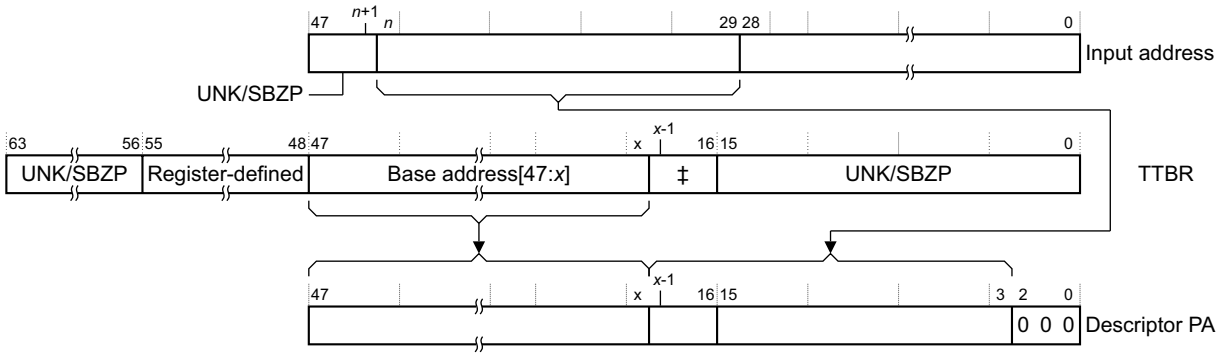
Figure D4-22 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, without concatenation

For a stage 2 initial lookup at level 2, with concatenated translation tables

As Table D4-16 on page D4-1659 shows, this applies to IA[*n*:0], where 42 ≤ *n* ≤ 45. For these lookups:

- There are $2^{(n-41)}$ concatenated translation tables at this level.
- These concatenated translation tables must be aligned to $2^{(n-41)}$×64KB. This means TTBR[(*n*-26):16] must be zero.
- TTBR[47:(*n*-25)] specify the base address of the block of translation tables.
- Bits[*n*:42] of the input address are bits[(*n*-26):16] of the descriptor offset from the base address of the block of translation tables.

Figure D4-23 shows this lookup.



Supported input address range is IPA[*n*:0], 17 ≤ *x* ≤ 20, *n* = *x* + 25. The field marked ‡ must be zero.

Figure D4-23 Initial lookup for VMSAv8-64 using the 64KB granule, starting at level 2, with concatenation

D4.3.2 Full translation flows for VMSAv8-64 address translation

In a translation table walk, only the first lookup uses the translation table base address from the appropriate TTBR. Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

This section describes example full translation flows, from the initial lookup to the address of a memory page. The described flows:

- Resolve the maximum-sized IA range supported by the initial lookup level.
- Do not have any concatenation of translation tables.

Examples of performing the initial lookup on page D4-1686 described how either reducing the IA range or concatenating translation tables affects the initial lookup.

Note

Reducing the IA range or concatenating translation tables affects only the initial lookup.

The following sections describe full VMSAv8-64 translation flows, down to an entry for a memory page:

- *The address and properties fields shown in the translation flows*.
- *Full translation flow using the 4KB granule and starting at level 0* on page D4-1694.
- *Full translation flow using the 4KB granule and starting at level 1* on page D4-1695.
- *Full translation flow using the 64KB granule and starting at level 1* on page D4-1696.
- *Full translation flow using the 64KB granule and starting at level 2* on page D4-1697.

The address and properties fields shown in the translation flows

For the Non-secure EL1&0 stage 1 translation:

- Any descriptor address is the IPA of the required descriptor.
- The final output address is the IPA of the block or page.

In these cases, an EL1&0 stage 2 translation is performed to translate the IPA to the required PA.

For all other translations, the final output address is the PA of the block or page, and any descriptor address is the PA of the descriptor.

Properties indicates register or translation table fields that return information, other than address information, about the translation or the targeted memory region. For more information see *Memory attribute fields in the VMSAv8-64 translation table format descriptors* on page D4-1702.

Full translation flow using the 4KB granule and starting at level 0

Figure D4-24 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page D4-1693.

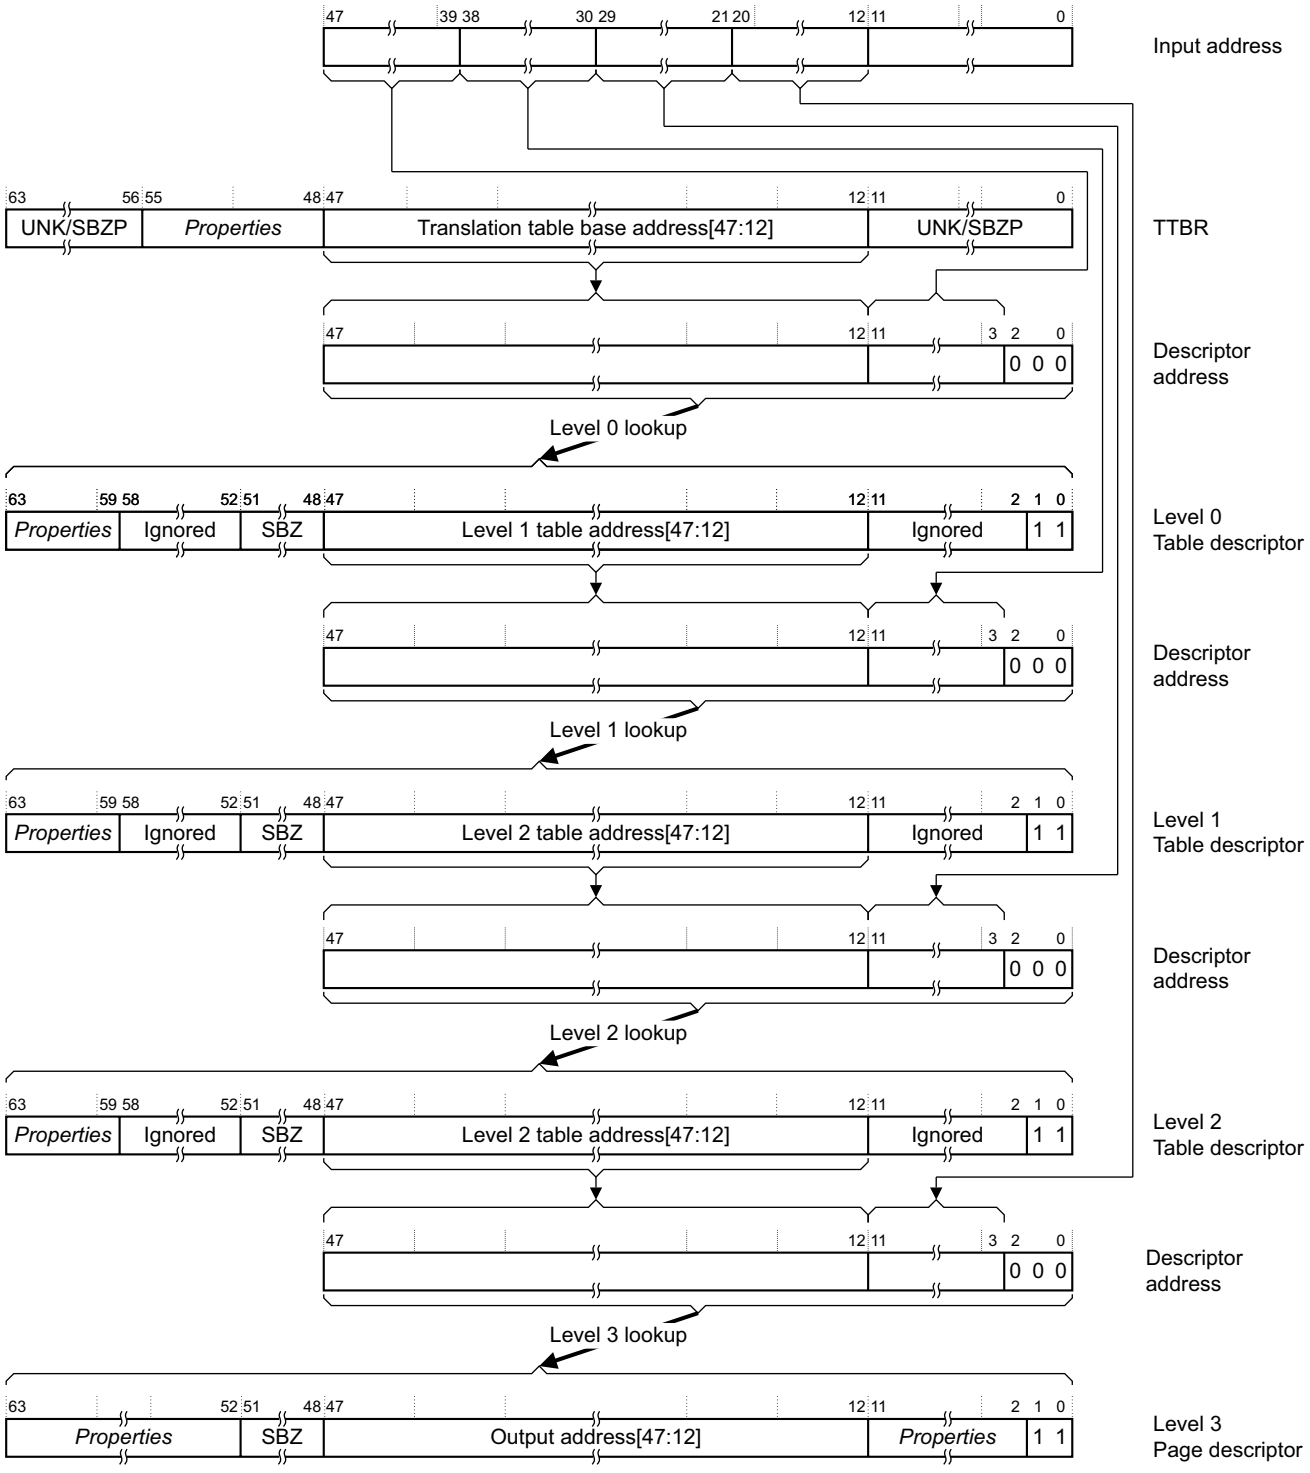


Figure D4-24 Complete stage 1 translation of a 48-bit address using the 4KB translation granule

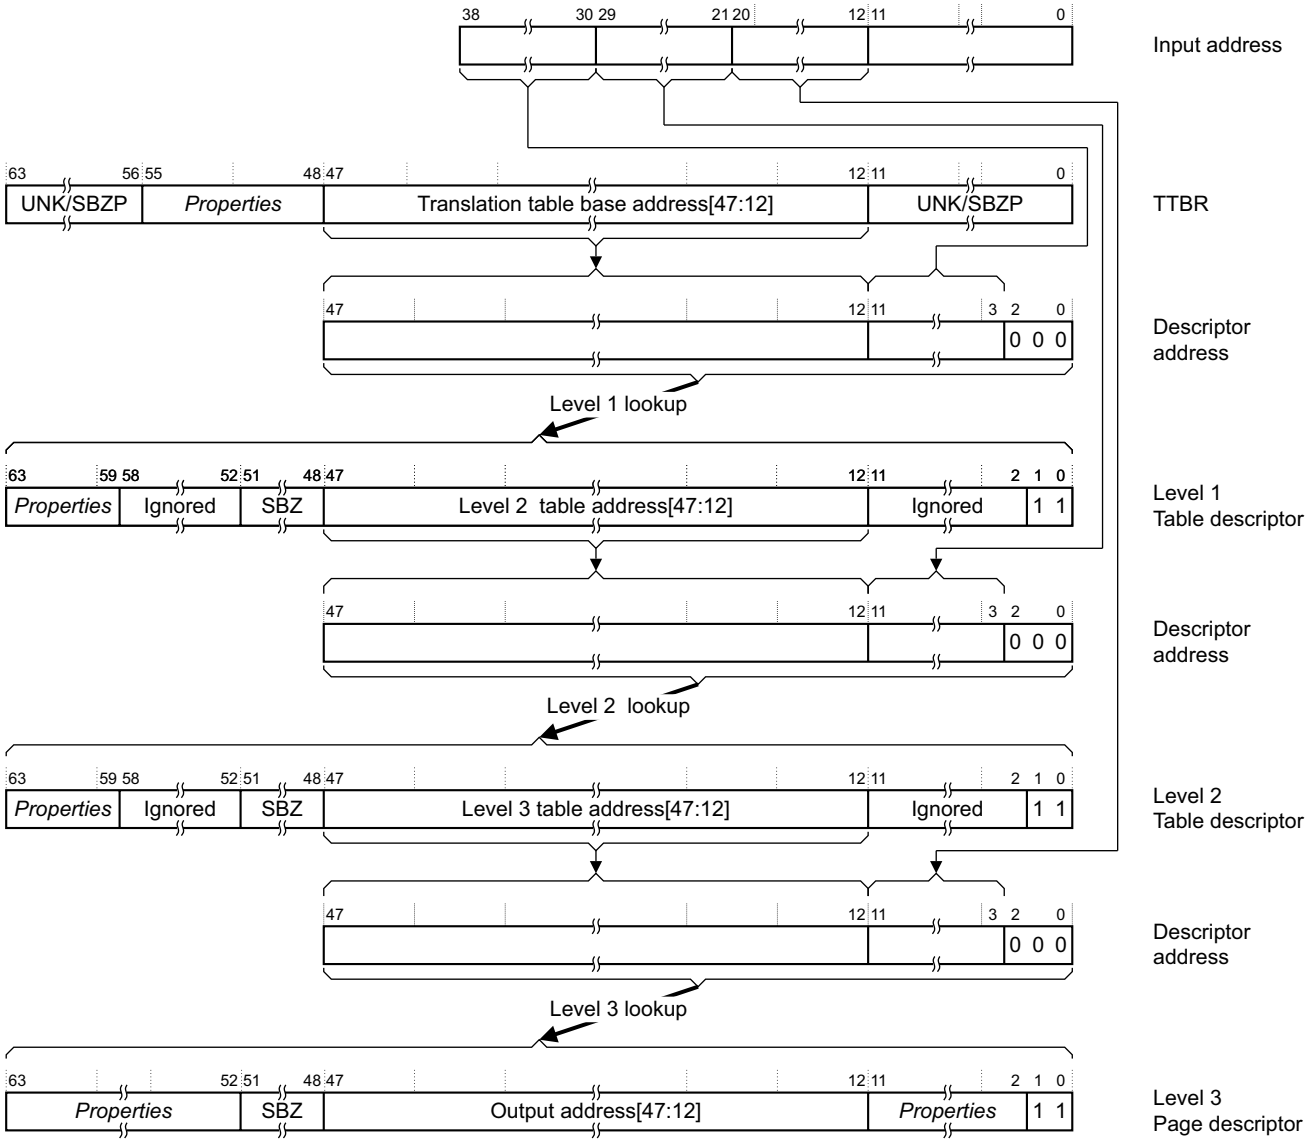
If the level 1 lookup or level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure D4-24 on page D4-1694 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Full translation flow using the 4KB granule and starting at level 1

Figure D4-25 shows the complete translation flow for a stage 1 translation table walk for a 39-bit input address. This lookup must start with a level 1 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page D4-1693.



For details of *Properties* fields, see the register or descriptor description.

Figure D4-25 Complete stage 1 translation of a 39-bit address using the 4KB translation granule

If the level 1 lookup or the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure D4-25 on page D4-1695 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure D4-24 on page D4-1694, shows how the translation for the 42-bit address start the same lookup process one stage later.

Full translation flow using the 64KB granule and starting at level 1

Figure D4-24 on page D4-1694 shows the complete translation flow for a stage 1 translation table walk for a 48-bit input address. This lookup must start with a level 0 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page D4-1693.

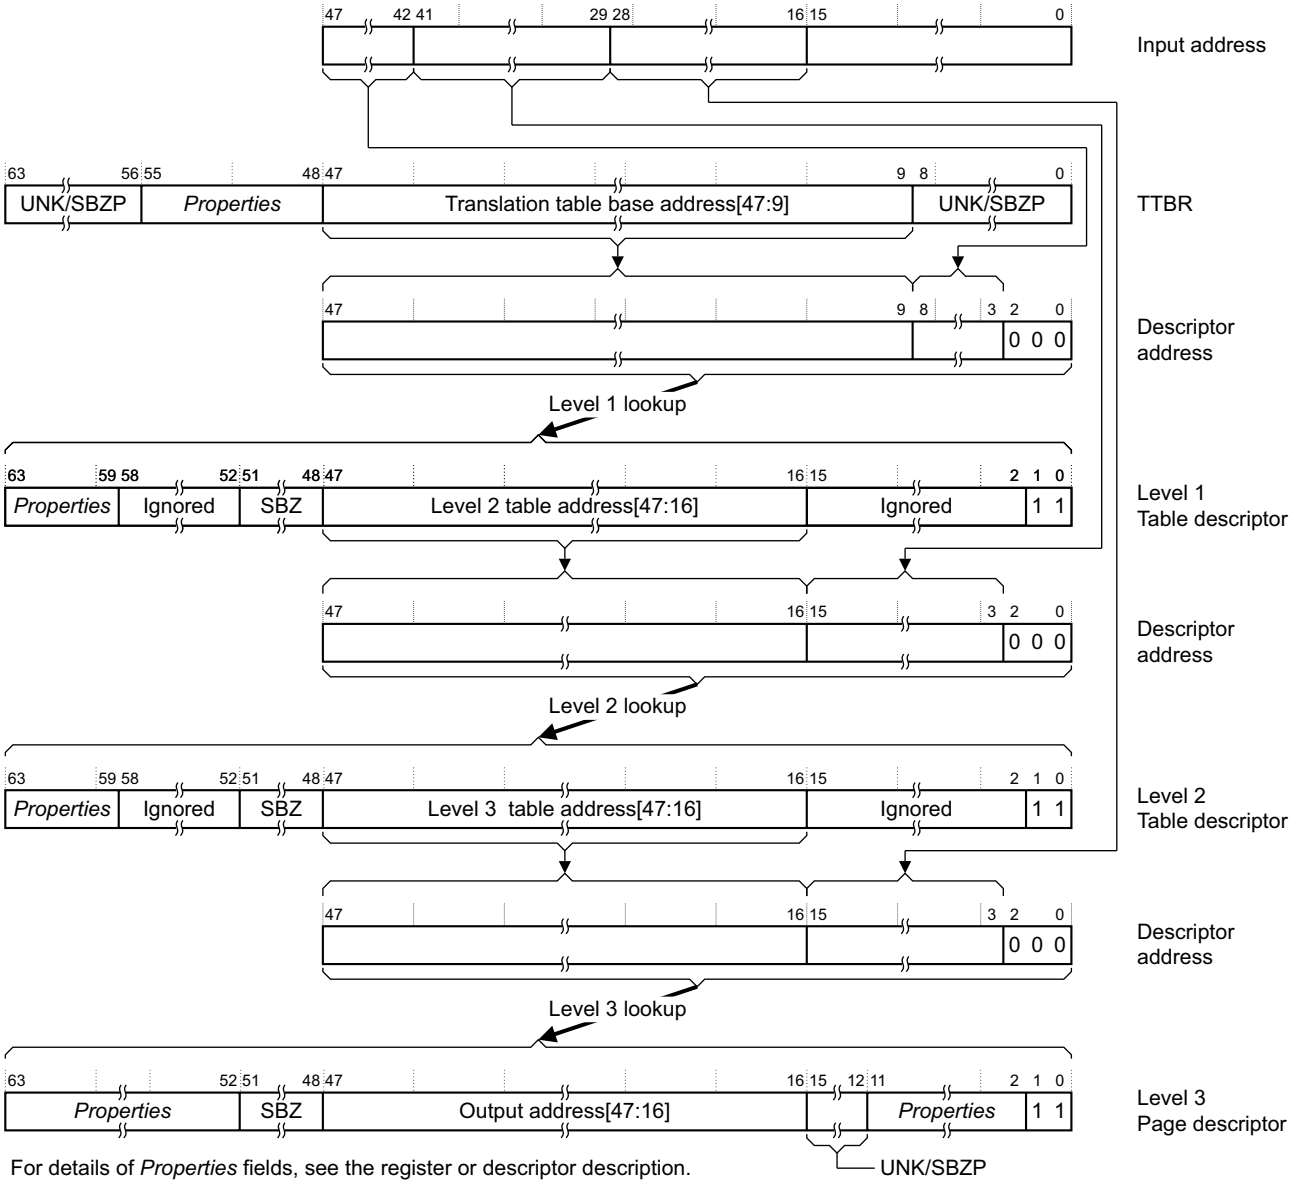


Figure D4-26 Complete stage 1 translation of a 48-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure D4-26 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

The level 1 lookup resolves only 6 bits of the input address. As described in *Performing the initial lookup using the 64KB translation granule* on page D4-1690, this means:

- The translation table size for this level is only 512 bytes.
- The required translation table alignment for this level is 512 bytes.
- The Base address field in the TTBR is extended, at the low-order end, to be bits[47:9].

Full translation flow using the 64KB granule and starting at level 2

Figure D4-25 on page D4-1695 shows the complete translation flow for a stage 1 translation table walk for a 42-bit input address. This lookup must start with a level 2 lookup. For more information about the fields shown in the figure see *The address and properties fields shown in the translation flows* on page D4-1693.

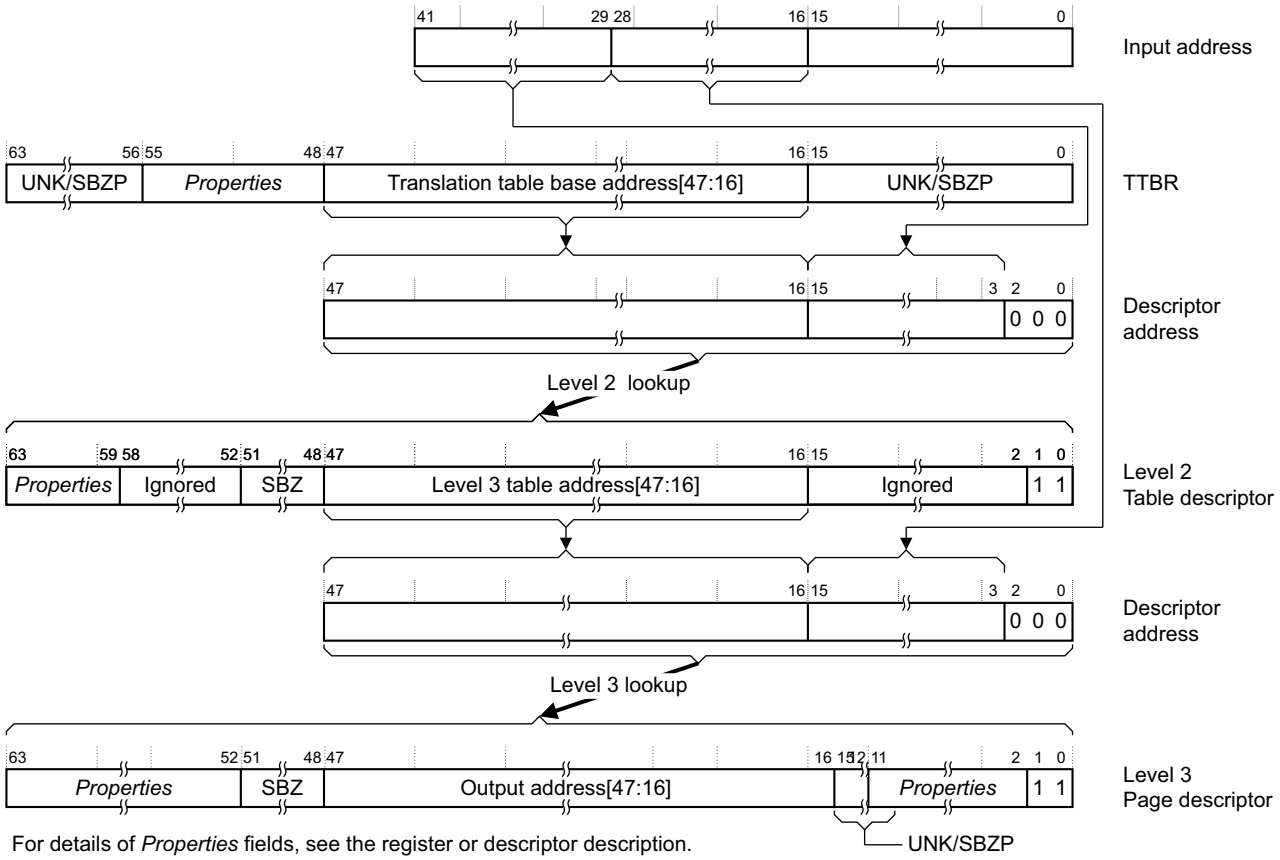

Figure D4-27 Complete stage 1 translation of a 42-bit address using the 64KB translation granule

If the level 2 lookup returns a block descriptor then the translation table walk completes at that level.

Figure D4-27 shows a stage 1 translation. The only difference for a stage 2 translation is that bits[63:58] of the Table descriptors are SBZ.

Comparing this translation with the translation for a 48-bit address, shown in Figure D4-26 on page D4-1696, shows:

- The translation for the 42-bit address starts the same lookup process one stage later.
- Because the initial lookup resolves 13 bits of address:
  - The translation table size for this level is 64KB.
  - The required translation table alignment for this level is 64KB.
  - The Base address field in the TTBR is bits[47:16].

D4.4 VMSAv8-64 translation table format descriptors

In general, a descriptor is one of:

- An invalid or fault entry.
- A table entry, that points to the next-level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the ARMv8 translation table descriptor formats:

- *VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats*.
- *ARMv8 translation table level 3 descriptor formats* on page D4-1701.

Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-1702 then gives more information about the descriptor attribute fields, and *Control of Secure or Non-secure memory access* on page D4-1705 describe how the NS and NSTable together control whether a memory access from Secure state accesses the Secure memory map or the Non-secure memory map.

D4.4.1 VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats

In the VMSAv8-64 translation table format, the difference in the formats of the level 0, level 1 and level 2 descriptors is:

- Whether a block entry is permitted.
- If a block entry is permitted, the size of the memory region described by that entry.

These differences depend on the translation granule, as follows:

4KB granule A level 0 descriptor does not support block translation.

A block entry:

- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

16KB granule Level 0 and level 1 descriptors do not support block translation.

A block entry in a level 2 table describes the mapping of the associated 32MB input address range.

64KB granule Level 0 lookup is not supported.

A level 1 descriptor does not support block translation.

A block entry in a level 2 table describes the mapping of the associated 512MB input address range.

Figure D4-28 on page D4-1699 shows the ARMv8 level 0, level 1 and level 2 descriptor formats:

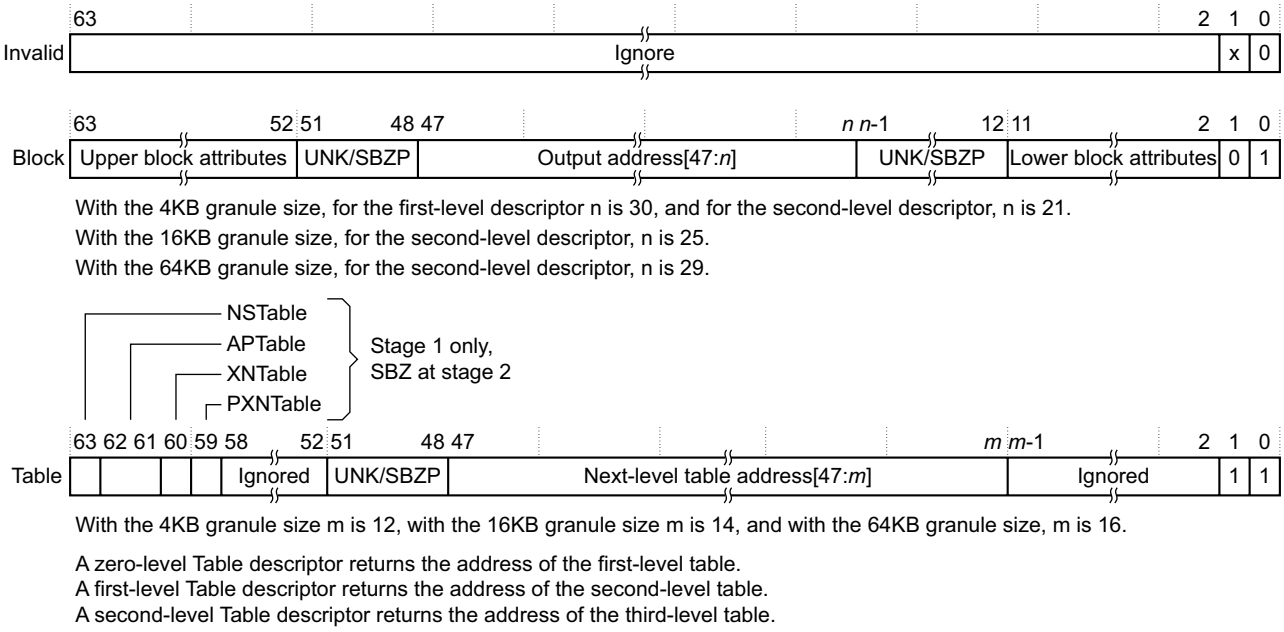

Figure D4-28 VMSAv8-64 level 0, level 1, and level 2 descriptor formats

Descriptor encodings, ARMv8 level 0, level 1, and level 2 formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

0, Block The descriptor gives the base address of a block of memory, and the attributes for that memory region.

1, Table The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

Block descriptor

Gives the base address and attributes of a block of memory, as follows:

4KB translation granule

- For a level 1 Block descriptor, bits[47:30] are bits[47:30] of the output address. This output address specifies a 1GB block of memory.
- For a level 2 descriptor, bits[47:21] are bits[47:21] of the output address.This output address specifies a 2MB block of memory.

16KB translation granule

For a level 2 Block descriptor, bits[47:25] are bits[47:25] of the output address.This output address specifies a 32MB block of memory.

64KB translation granule

For a level 2 Block descriptor, bits[47:29] are bits[47:29] of the output address.This output address specifies a 512MB block of memory.

Bits[63:52, 11:2] provide attributes for the target memory block, see *Memory attribute fields in the VMSAv8-64 translation table format descriptors* on page D4-1702. The position and contents of these bits are identical in the level 2 block descriptor and in the level 3 page descriptor.

Table descriptor

Gives the translation table address for the next-level lookup, as follows:

4KB translation granule

- Bits[47:12] are bits[47:12] of the address of the required next-level table, which is:
  - For a level 0 Table descriptor, the address of a level 1 table.
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[11:0] of the table address are zero.

16KB translation granule

- Bits[47:14] are bits[47:14] of the address of the required next-level table, which is:
  - For a level 0 Table descriptor, the address of a level 1 table.
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[13:0] of the table address are zero.

64KB translation granule

- Bits[47:16] are bits[47:16] of the address of the required next-level table, which is:
  - For a level 1 Table descriptor, the address of a level 2 table.
  - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[15:0] of the table address are zero.

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see *Memory attribute fields in the VMSAv8-64 translation table format descriptors* on page D4-1702.

If the translation table defines the Non-secure EL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target block or table. Otherwise, it is the PA of the target block or table.

D4.4.2 ARMv8 translation table level 3 descriptor formats

For the 4KB granule size, each entry in a level 3 table describes the mapping of the associated 4KB input address range.

For the 16KB granule size, each entry in a level 3 table describes the mapping of the associated 16KB input address range.

For the 64KB granule size, each entry in a level 3 table describes the mapping of the associated 64KB input address range.

Figure D4-29 shows the ARMv8 level 3 descriptor formats.

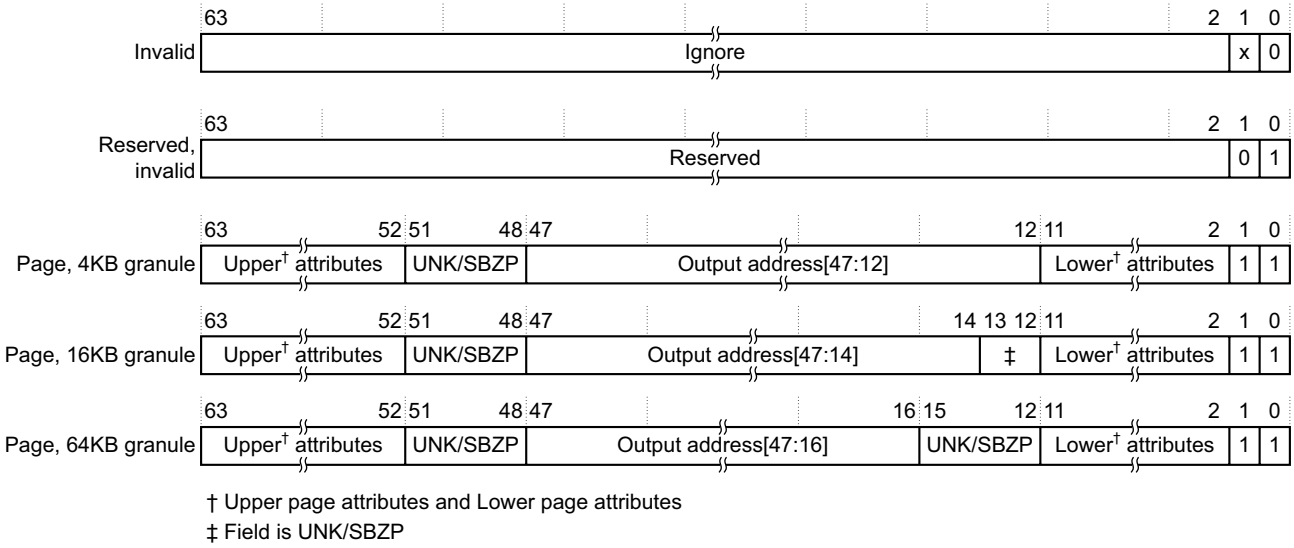

Figure D4-29 VMSAv8-64 level 3 descriptor format

Descriptor bits[1:0] identify whether the descriptor is valid, and the descriptor type of a valid descriptor, encoded as:

`0bx0`**, Invalid** If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

`0b01`**, Reserved, invalid**

Behaves identically to encodings of `0bx0`.

This encoding must not be used in level 3 translation tables.

`0b11`**, Page** Gives the address and attributes of a 4KB, 16KB, or 64KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

Page descriptor

Gives the output address of a page of memory, as follows:

4KB translation granule

Bits[47:12] are bits[47:12] of the output address for a page of memory.

16KB translation granule

Bits[47:14] are bits[47:14] of the output address for a page of memory.

64KB translation granule

Bits[47:16] are bits[47:16] of the output address for a page of memory.

Bits[63:52, 11:2] provide attributes for the target memory page, see *Memory attribute fields in the VMSAv8-64 translation table format descriptors* on page D4-1702.

Note

The position and contents of bits[63:52, 11:2] are identical to bits[63:52, 11:2] in the level 0, level 1, and level 2 block descriptors.

For the Non-secure EL1&0 stage 1 translations, the output address in the descriptor is the IPA of the target page. Otherwise, it is the PA of the target page.

D4.4.3 Memory attribute fields in the VMSAv8-64 translation table format descriptors

Memory region attributes on page D4-1714 describes the region attribute fields. The following subsections summarize the descriptor attributes as follows:

Table descriptor

Table descriptors for stage 2 translations do not include any attribute field. For a summary of the attribute fields in a stage 1 table descriptor, that define the attributes for the next lookup level, see *Next-level attributes in stage 1 VMSAv8-64 Table descriptors*.

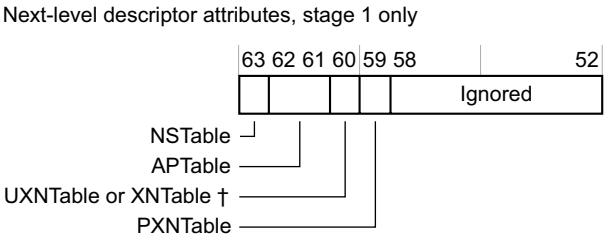
Block and page descriptors

These descriptors define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:

- *Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors* on page D4-1703
- *Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors* on page D4-1704.

Next-level attributes in stage 1 VMSAv8-64 Table descriptors

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the attributes for the next-level translation table access, and bits[58:52] are ignored:



These attributes are:

NSTable, bit[63]

For memory accesses from Secure state, specifies the security level for subsequent levels of lookup, see *Hierarchical control of Secure or Non-secure memory accesses* on page D4-1706.

For memory accesses from Non-secure state, this bit is ignored.

APTable, bits[62:61]

Access permissions limit for subsequent levels of lookup, see *Hierarchical control of data access permissions* on page D4-1709.

APTable[0] is reserved, SBZ:

- In the EL2 translation regime.
- In the EL3 translation regime.

UXNTable or XNTable, bit[60]

XN limit for subsequent levels of lookup, see *Hierarchical control of instruction fetching* on page D4-1712.

This bit is called UXNTable in the EL1&0 translation regime, where it only determines whether execution at EL0 of instructions fetched from the region identified at a lower level of lookup permitted. In the other translation regimes the bit is called XNTable.

PXNTable, bit[59]

PXN limit for subsequent levels of lookup, see *Hierarchical control of instruction fetching* on page D4-1712.

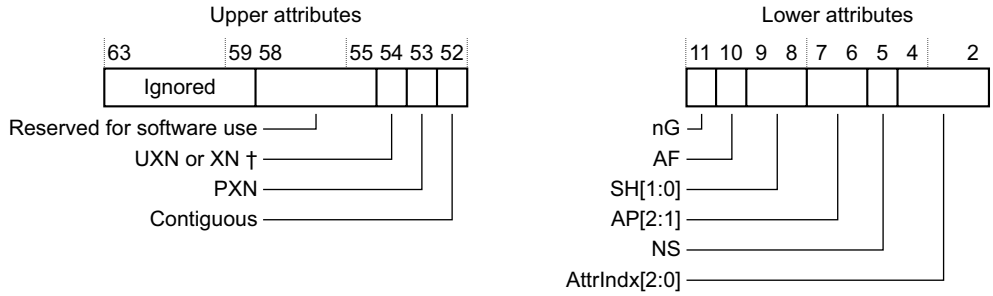
This bit is reserved, SBZ:

- In the EL2 translation regime.
- In the EL3 translation regime.

Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 1
translation:

Attribute fields for VMSAv8-64 stage 1 Block and Page descriptors



† UXN for the EL1&0 translation regime, XN for the other regimes.

For a stage 1 descriptor, the attributes are:

UXN or XN, bit[54]

The Execute-never bit. Determines whether the region is executable, see *Access permissions for instruction execution* on page D4-1710.

This bit is called UXN in the EL1&0 translation regime, where it only determines whether execution at EL0 of instructions fetched from the region is permitted. In the other translation regimes the bit is called XN.

PXN, bit[53] The Privileged execute-never bit. Determines whether the region is executable at EL1, see *Access permissions for instruction execution* on page D4-1710.

This bit is reserved, SBZ, in the EL2 and EL3 translation regimes.

Contiguous, bit[52]

A hint bit indicating that the translation table entry is one of a contiguous set or entries, that might be cached in a single TLB entry, see *The Contiguous bit* on page D4-1718.

nG, bit[11] The not global bit. Determines whether the TLB entry applies to all ASID values, or only to the current ASID value, see *Global and process-specific translation table entries* on page D4-1731.

Valid only to the EL1&0 translation regime. This bit is reserved, SBZ, in all other translation regimes.

AF, bit[10] The Access flag, see *The Access flag* on page D4-1714.

SH, bits[9:8] Shareability field, see *Memory region attributes* on page D4-1714.

AP[2:1], bits[7:6]

Data Access Permissions bits, see *Memory access control* on page D4-1707.

Note

The ARMv8 translation table descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.

AP[1] is reserved, SBO, in the Non-secure EL2 translation regime.

NS, bit[5] Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in the Secure or Non-secure address map, see *Control of Secure or Non-secure memory access* on page D4-1705.

For memory accesses from Non-secure state, this bit is ignored.

AttrIndx[2:0], bits[4:2]

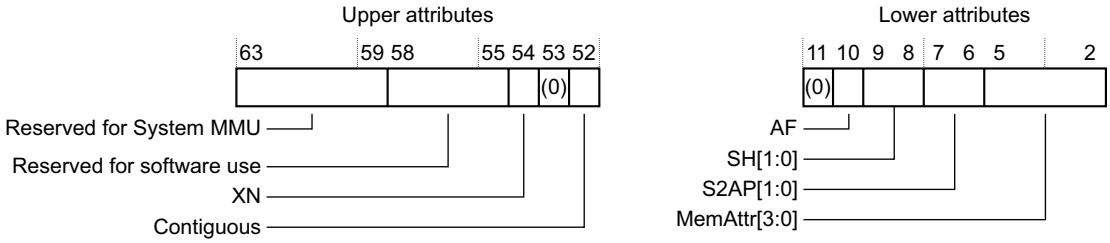
Stage 1 memory attributes index field, for the MAIR_ELx, see *Memory region type and attributes, for stage 1 translations* on page D4-1715.

In the upper attributes block, the architecture guarantees that PE makes no use of the fields marked as *Ignored* and *Reserved for software use*. For more information see *Other fields in the VMSAv8-64 translation table format descriptors* on page D4-1717.

Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 2 translation:

Attribute fields for VMSAv8-64 stage 2 Block and Page descriptors



For a stage 2 descriptor, the attributes are:

XN, bit[54] The Execute-never bit. Determines whether the region is executable, see *Access permissions for instruction execution* on page D4-1710.

Contiguous, bit[52]

A hint bit indicating that the translation table entry is one of a contiguous set or entries, that might be cached in a single TLB entry, see *The Contiguous bit* on page D4-1718.

AF, bit[10] The Access flag, see *The Access flag* on page D4-1714.

SH, bits[9:8] Shareability field, see *The memory region attributes for stage 2 translations, EL1&0 translation regime* on page D4-1716.

S2AP, bits[7:6]

Stage 2 data Access Permissions bits, see *The S2AP data access permissions, Non-secure EL1&0 translation regime* on page D4-1709.

Note

In the original VMSAv7-32 Long-descriptor attribute definition, this field was called HAP[2:1], for consistency with the AP[2:1] field in the stage 1 descriptors and despite there being no HAP[0] bit. ARMv8 renames the field for greater clarity.

MemAttr, bits[5:2]

Stage 2 memory attributes, see *The memory region attributes for stage 2 translations, EL1&0 translation regime* on page D4-1716.

In the upper attributes block:

- The field marked as *Reserved for System MMU use* must be ignored by the PE.
- The architecture guarantees that the PE makes no use of the fields marked as *Reserved for System MMU* and *Reserved for software use*.

For more information see *Other fields in the VMSAv8-64 translation table format descriptors* on page D4-1717.

D4.4.4 Control of Secure or Non-secure memory access

As this section describes, the NS bit in the translation table entries:

- For accesses from Secure state, if the translation table entry was held in secure memory, determines whether the access is to Secure or Non-secure memory.
- Is ignored by:
  - Accesses from Non-secure state.
  - Accesses from Secure state if the translation table entry was held in Non-secure memory.

In the VMSAv8-64 translation table format:

- The NS bit relates only to the memory block or page at the output address defined by the descriptor.
- The descriptors also include an NSTable bit, that affects accesses at lower levels of lookup, see *Hierarchical control of Secure or Non-secure memory accesses* on page D4-1706.

The NS and NSTable bits are valid only for memory accesses from Secure state described by translation table descriptors that are fetched from Secure memory, and:

- In the translation table descriptors in a Non-secure translation table, the NS and NSTable bits are SBZ.
- Memory accesses from Non-secure state, including all accesses from EL2, ignore the values of these bits.

In the Secure translation regimes, for translation table descriptors that are fetched from Secure memory, the NS bit in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map, as follows:

NS == 0 Access the Secure physical address space.

NS == 1 Access the Non-secure physical address space.

For Non-secure translation regimes, and for translation table descriptors fetched from Non-secure memory, the corresponding bit is SBZ and is ignored by the PE. The access is made to Non-secure memory, regardless of the value of the bit.

Hierarchical control of Secure or Non-secure memory accesses

For VMSAv8-64 table descriptors for stage 1 translations, the descriptor includes an NSTable bit, that indicates whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state, the meaning of the NSTable bit is:

NSTable == 0 The defined table address is in the Secure physical address space. In the descriptors in that translation table, NS bits and NSTable bits have their defined meanings.

NSTable == 1 The defined table address is in the Non-secure physical address space. Because this table is fetched from the Non-secure address space, the NS and NSTable bits in the descriptors in this table must be ignored. This means that, for this table:

- The value of the NS bit in any block or page descriptor is ignored. The block or page address refers to Non-secure memory.
- The value of the NSTable bit in any table descriptor is ignored, and the table address refers to Non-secure memory. When this table is accessed, the NS bit in any block or page descriptor is ignored, and all descriptors in the table refer to Non-secure memory.

In addition, an entry fetched in Secure state is treated as non-global if either:

- NSTable is set to 1.
- The fetch ignores the values of NS and NSTable, because of a higher-level fetch with NSTable set to 1.

That is, these entries must be treated as if nG==1, regardless of the value of the nG bit. For more information about the nG bit, see *Global and process-specific translation table entries* on page D4-1731.

D4.5 Access controls and memory region attributes

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of the target memory region. These fields can be classified as address map control, access control, and region attribute fields. *Control of Secure or Non-secure memory access* on page D4-1705 describes the address map control, and the following sections describe the other fields:

- *Memory access control*.
- *Memory region attributes* on page D4-1714.
- *Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime* on page D4-1719.

Note

This section describes the access controls and memory region attributes for each of the translation regimes, and for both stages of translation in the Non-secure EL1&0 translation regime. In general, attribute assignment is simpler in the EL2 and EL3 translation regimes, and in these regimes behavior is consistent fields in the translation tables being treated as follows:

- APTable[0] is ignored by hardware and is treated as if it is 0.
- AP[1] is ignored by hardware and is treated as if it is 1.
- the PXNTable bit is ignored by hardware and is treated as if it is 0.
- the PXN field is ignored by hardware and is treated as if it is 0.

D4.5.1 Memory access control

The access control fields in the translation table descriptors determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the translation table descriptor. If a translation stage does not permit the access then an MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

- *About the access permissions*.
- *The data access permission controls* on page D4-1708.
- *Access permissions for instruction execution* on page D4-1710.
- *The Access flag* on page D4-1714.

About the access permissions

Note

This section gives a general description of memory access permissions. In an implementation that includes EL2, software executing at EL1 in Non-secure state can see only the access permissions defined by the Non-secure EL1&0 stage 1 translations. However, software executing at EL2 can modify these permissions. This modification is invisible to the Non-secure software executing at EL1 or EL0.

The access permission bits control access to the corresponding memory region. The VMSAv8-64 translation table format:

- In stage 1 translations, uses AP[2:1] to define the data access permissions, see *The AP[2:1] data access permissions, for stage 1 translations* on page D4-1708.

  Note

  The description of the access permission field as AP[2:1] is for consistency with the VMSAv8-32 Short-descriptor translation table format, see *The VMSAv8-32 Short-descriptor translation table format* on page G4-3634. The VMSAv8-64 translation table format does not define an AP[0] bit.

- In stage 2 translations, uses S2AP[1:0] to define the data access permissions, see *The S2AP data access permissions, Non-secure EL1&0 translation regime* on page D4-1709.
- Uses the UXN, XN and PXN bits to define access controls for instruction fetches, see *Access permissions for instruction execution* on page D4-1710.

An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation.

Note

In an implementation that includes EL2, each stage of the translation of a memory access made from Non-secure EL1 or EL0 has its own, independent, permission check.

The data access permission controls

The following subsubsections describe the data access permission controls:

- *The AP[2:1] data access permissions, for stage 1 translations*.
- *The S2AP data access permissions, Non-secure EL1&0 translation regime* on page D4-1709.
- *Hierarchical control of data access permissions* on page D4-1709.

The AP[2:1] data access permissions, for stage 1 translations

For the VMSAv8-64 EL1&0 translation regime, the AP[2:1] bits control the stage 1 data access permissions, and:

AP[2] Selects between read-only and read/write access.

AP[1] Selects between Application level (EL0) and System level (EL1) control.

This provides four permission settings for data accesses:

- Read-only at all levels.
- Read/write at all levels.
- Read-only at EL1, no access by software executing at EL0.
- Read/write at EL1, no access by software executing at EL0.

For translation regimes other than the EL1&0 translation regimes, AP[2] determines the stage 1 data access permissions, and AP[1] is:

- SBO.
- Ignored by hardware and is treated as if it is 1.

Table D4-27 shows the effect of the data access permission bits for stage 1 of the EL1&0 translation regime. In this table, an entry of None indicates that any access from that Exception level faults.

Table D4-27 Data access permissions for stage 1 of the EL1&0 translation regime,

AP[2:1]	Access from EL1	Access from EL0
00	Read/write	None
01	Read/write	Read/write
10	Read-only	None
11	Read-only	Read-only

For the Non-secure EL1&0 translation regime:

- The stage 2 translation also defines data access permissions, see *The S2AP data access permissions, Non-secure EL1&0 translation regime* on page D4-1709.
- When both stages of translation are enabled, *Combining the stage 1 and stage 2 data access permissions* on page D4-1719 describes how these permissions are combined.

Table D4-28 shows the effect of the AP[2] data access permission bit for the EL2 and EL3 translation regimes:

Table D4-28 Data access permissions for the EL2 or EL3 translation regime

AP[2]	Access from EL2 or EL3
0	Read/write
1	Read-only

The S2AP data access permissions, Non-secure EL1&0 translation regime

In the Non-secure EL1&0 translation regime, when stage 2 address translation is enabled, the S2AP field in the stage 2 translation table descriptors define the data access permissions as Table D4-29 shows. In this table, an entry of None indicates that any access generates a permission fault:

Table D4-29 Data access permissions for stage 2 of the Non-secure EL1&0 translation regime,

S2AP	Access from Non-secure EL1 or Non-secure EL0
00	None
01	Read-only
10	Write-only
11	Read/write

The S2AP access permissions make no distinction between Non-secure accesses from EL1 and Non-secure accesses from EL0. However, when both stages of address translation are enabled, these permissions are combined with the stage 1 access permissions defined by AP[2:1], see *Combining the stage 1 and stage 2 data access permissions* on page D4-1719.

Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime on page D4-1719 gives more information about the use of the stage 1 and stage 2 access permissions in an implementation of virtualization.

Hierarchical control of data access permissions

The VMSAv8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the data access permissions.

Note

Similar hierarchical controls apply to instruction fetching, see *Hierarchical control of instruction fetching* on page D4-1712.

The restrictions apply only to subsequent levels of lookup for the same stage of translation. The APTable[1:0] field restricts the access permissions, as Table D4-30 shows.

As stated in the table footnote, for the EL2 translation regime, APTable[0] is reserved, SBZ, and is ignored by the hardware.

Table D4-30 Effect of APTable[1:0] on subsequent levels of lookup

APTable[1:0]	Effect
00	No effect on permissions in subsequent levels of lookup.
01[a]	Access at EL0 not permitted, regardless of permissions in subsequent levels of lookup.
10	Write access not permitted, at any Exception level, regardless of permissions in subsequent levels of lookup.

Table D4-30 Effect of APTable[1:0] on subsequent levels of lookup (continued)

APTable[1:0]	Effect
11[a]	Regardless of permissions in subsequent levels of lookup: • Write access not permitted, at any Exception level. • Read access not permitted at EL0.

a. Not valid for the EL2 and EL3 translation regime. In the translation tables for that regime, APTable[0] is SBZ and is ignored by hardware.

Note

The APTable[1:0] settings are combined with the translation table access permissions in the translation tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The VMSAv8-64 provides APTable[1:0] control only for the stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

When APTable[1:0] is not set to `0b00`, its effects might be held in one or more TLB entries. Therefore, a change to APTable[1:0] might require coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

Access permissions for instruction execution

Execute-never (XN) controls determine whether an instruction fetched from the memory region can be executed. These controls are:

UXN, Unprivileged Execute never

Defined only for stage 1 of the EL1&0 translation regime.

PXN, Privileged execute never

Used only for stage 1 of the EL1&0 translation regime:

- For the EL2 and EL3 translation regimes, the descriptors define a PXN bit that is reserved, SBZ, and is ignored by hardware.
- For stage 2 of the Non-secure EL1&0 translation regime, the corresponding bit position is reserved, SBZ, and is ignored by hardware.

XN, Unprivileged Execute never

Defined only for stage 1 of the EL2 and EL3 translation regimes.

Each of theses bits is set to 1 to indicate that instructions cannot be executed from the target memory region. In addition:

- For the EL1&0 translation regime, if the value of the AP[2:1] bits is `0b01`, permitting write access from EL0, then the PXN bit is treated as if it has the value 1, regardless of its actual value.
- For each translation regime, if the value of the corresponding SCTLR_ELx.WXN bit is 1 then any memory region that is writable is treated as XN, regardless of the value of the corresponding UXN, XN, or PXN bit. For more information see *Preventing execution from writable locations* on page D4-1713.
- The SCR_EL3.SIF bit prevents execution in Secure state of any instruction fetched from Non-secure memory, see *Restriction on Secure instruction fetch* on page D4-1714.

The execute-never controls apply to speculative instruction fetching, meaning speculative instruction fetch from a memory region that is execute-never at the current Exception level is prohibited.

Note

- Although the execute-never controls apply to speculative fetching, on a speculative instruction fetch from an execute-never location, no Permission fault is generated unless the PE attempts to execute the instruction fetched from that location. This means that, if a speculative fetch from an execute-never location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.
- The software that defines a translation table must mark any region of memory that is read-sensitive as execute-never, to avoid the possibility of a speculative fetch accessing the memory region. This means it must mark any memory region that corresponds to a read-sensitive peripheral as execute-never.
- When no stage of address translation for the translation regime is enabled, memory regions cannot have UXN, XN, or PXN attributes assigned. *Behavior of instruction fetches when all associated stages of translation are disabled* on page D4-1671 describes how disabling all stages of address translation affects instruction fetching.

The following subsubsections describe the data access permission controls:

- *Instruction execution permissions for stage 1 translations*.
- *Instruction execution permissions for stage 2 translations* on page D4-1712.
- *Hierarchical control of instruction fetching* on page D4-1712.
- *Preventing execution from writable locations* on page D4-1713.
- *Restriction on Secure instruction fetch* on page D4-1714.

Instruction execution permissions for stage 1 translations

Table D4-31 shows the access permissions for instruction execution for stage 1 of the EL1&0 translation regime.

Table D4-31 Access permissions for instruction execution for stage 1 of the EL1&0 translation regime

UXN	PXN	AP[2:1][a]	SCTLR_EL1.WXN	Access from EL1	Access from EL0
0	0	00	0	Executable	Executable
			1	Not executable[b]	Executable
		01	0	Not executable[c]	Executable
			1	Not executable	Not executable[d]
		1x	x	Executable	Executable
0	1	00	x	Not executable	Executable
		01	0	Not executable	Executable
			1	Not executable	Not executable[d]
		1x	x	Not executable	Executable
1	0	00	0	Executable	Not executable
			1	Not executable[b]	Not executable
		01	x	Not executable[c]	Not executable
		1x	x	Executable	Not executable
	1	xx	x	Not executable	Not executable

a. See Table D4-27 on page D4-1708. `0b00` indicates writable from EL1 only, `0b01` indicates writable from EL1 and EL0, `0b1x` indicates not writable from EL1 or EL0.

b. Not executable because of SCTLR_EL1.WXN control, because region is writable at EL1.
c. Not executable, because AArch64 execution treats all regions writable at EL0 as being PXN.
d. Not executable because of SCTLR_EL1.WXN control, because region is writable at EL0.

Table D4-32 shows the access permissions for instruction execution for the EL2 and EL3 translation regimes:

Table D4-32 Access permissions for instruction execution, EL2 and EL3 translation regimes

XN	AP[2][a]	SCTLR_EL2.WXN or[b] SCTLR_EL3.WXN	Access from EL2 or EL3
0	0	0	Executable
		1	Not executable[c]
	1	0	Executable
1	x	x	Not executable

a. See Table D4-28 on page D4-1709. 0 indicates writable from this Exception level, and 1 indicates not writable.
b. SCTLR_EL2 for the EL2 translation regime, SCTLR_EL3 for the EL3 translation regime.
c. Not executable because of the SCTLR_ELx.WXN control, because region is writable at this Exception level.

Instruction execution permissions for stage 2 translations

For the Non-secure EL1&0 stage 2 translation, the XN bit in the stage 2 translation table descriptors controls the execution permission, and this control is completely independent of the S2AP access permissions.

Table D4-33 Access permissions for instruction execution for stage 2 of the Non-secure EL1&0 translation regime,

XN	Access from Non-secure EL1or Non-secure EL0
0	Executable
1	Not executable

The stage 2 XN access permissions make no distinction between Non-secure accesses from EL1 and Non-secure accesses from EL0. However, when both stages of address translation are enabled, these permissions are combined with the stage 1 access permissions defined at stage 1 of the translation, see *Combining the stage 1 and stage 2 instruction execution permissions* on page D4-1719.

Hierarchical control of instruction fetching

The VMSAv8-64 translation table format includes mechanisms by which entries at one level of table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the data access permissions.

The VMSAv8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the instruction fetching controls.

Note

Similar hierarchical controls apply to data accesses, see *Hierarchical control of data access permissions* on page D4-1709.

The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

- UXNTable or XNTable restricts the XN control:
  - When the value of the XNTable bit is 1, the XN bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
  - When the value of the UXNtable bit is 1, the UXN bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
  - When the value of a UXNtable or XNTable bit is 0 the bit has no effect.
- For the EL1&0 translation regime, PXNTable restricts the PXN control:
  - When PXNTable is set to 1, the PXN bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
  - When PXNTable is set to 0 it has no effect.

Note

The UXNtable, XNTable and PXNTable settings are combined with the UXN, XN and PXN bits in the translation table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The UXNtable, XNTable and PXNTable controls are provided only for stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

When the value of UXNtable, XNTable, or PXNTable, is 1, its effects might be held in one or more TLB entries. Therefore, a change to UXNtable, XNTable or PXNTable might require coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

Preventing execution from writable locations

ARMv8 provides control bits that, when corresponding stage 1 address translation is enabled, force writable memory to be treated as UXN, PXN, or XN, regardless of the value of the UXN, PXN, or XN bit:

- For the EL1&0 translation regime, when the value of SCTLR_EL1.WXN is 1:
  - All regions that are writable from EL0 at stage 1 of the address translation are treated as UXN.
  - All regions that are writable from EL1 at stage 1 of the address translation are treated as PXN
- For the EL2 translation regime, when the value of SCTLR_EL2.WXN is 1, all regions that are writable at stage 1 of the address translation are treated as XN.
- For the EL3 translation regime, when the value of SCTLR_EL3.WXN is 1, all regions that are writable at stage 1 of the address translation are treated as XN.

Note

- The SCTLR_ELx.WXN controls are intended to be used in systems with very high security requirements.
- Setting a WXN bit to 1 changes the interpretation of the translation table entry, overriding a zero value of a UXN, XN, or PXN field. It does not cause any change to the translation table entry.

For any given virtual machine, ARM expects WXN to remain static in normal operation. In particular, it is IMPLEMENTATION DEFINED whether TLB entries associated with a particular VMID reflect the effect of the values of these bits. This means that any change of these bits without a corresponding change of VMID might require synchronization and TLB invalidation, as described in *TLB maintenance requirements and the TLB maintenance instructions* on page D4-1733.

Restriction on Secure instruction fetch

EL3 provides a Secure instruction fetch bit, SCR_EL3.SIF. When the value of this bit is 1, and execution is using the EL3 translation regime or the Secure EL1 translation regime, any attempt to execute an instruction fetched from Non-secure physical memory causes a Permission fault. TLB entries might reflect the value of this bit, and therefore any change to the value of this bit requires synchronization and TLB invalidation, as described in *TLB maintenance requirements and the TLB maintenance instructions* on page D4-1733.

The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding translation table descriptor was set to 0.

The AF bit in the translation table descriptors is the Access flag.

Software management of the Access flag

ARMv8 requires that software manages the Access flag. This means an Access flag fault is generated whenever an attempt is made to read into the TLB a translation table descriptor entry for which the value of Access flag is 0.

The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.

Note

If a system incorporates a System MMU that implements the ARM SMMUv3 architecture and software shares translation tables between the ARM PE and the SMMUv3, then the software must be aware of the possibility that the System MMU update the access flag in hardware.

In such a system, system software should perform any changes of translation table entries with an Access flag of 0, other than changes to the Access flag value, by using an Load-Exclusive/Store-Exclusive loop, to allow for the possibility of simultaneous updates.

D4.5.2 Memory region attributes

The memory region attribute fields control the memory type, accesses to the caches, and whether the memory region is Shareable and therefore is coherent. This section also describes some additional translation table fields, that this manual groups with the memory region attributes.

In the EL1&0 translation regime, each enabled stage of address translation assigns memory region attributes, as described in this section. When both stages of translation are enabled, *Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime* on page D4-1719 describes how the assignments from the two stages are combined.

Note

In a virtualization implementation, a hypervisor, executing at EL2, might usefully:

- Reduce the permitted cacheability of a region.
- Increase the required shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

The following sections describe these attributes:

- *The memory region attributes for stage 1 translations* on page D4-1715.
- *The memory region attributes for stage 2 translations, EL1&0 translation regime* on page D4-1716.
- *Other fields in the VMSAv8-64 translation table format descriptors* on page D4-1717.

The memory region attributes for stage 1 translations

The description of the memory region attributes in a translation descriptor divides into:

Memory type and attributes

These are described indirectly, by registers referenced by bits in the table descriptor. This is described as *remapping* the memory type and attribute description. *Memory region type and attributes, for stage 1 translations* describes this encoding.

Shareability The SH[1:0] field in the translation table descriptor encodes shareability information. *Shareability for Normal memory, for stage 1 translations* describes this encoding.

Memory region type and attributes, for stage 1 translations

In the VMSAv8-64 translation table format, the AttrIndx[2:0] field in a block or page translation table descriptor for a stage 1 translation indicates the 8-bit field in the MAIR_ELx that specifies the attributes for the corresponding memory region. The required field is Attr*n*, where *n* = AttrIndx[2:0]. For more information about AttrIndx[2:0] see *Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors* on page D4-1703

Note

Each MAIR_ELx is a 64-bit register that is architecturally mapped to a pair of AArch32 registers. See the MAIR_ELx register descriptions for more information.

Each MAIR_ELx.Attr*n* field defines, for the corresponding memory region:

- The memory type, Device or Normal.
- For Device memory, the Device memory type, one of:
  - Device-nGnRnE.
  - Device-nGnRE.
  - Device-nGRE.
  - Device-GRE.
- For Normal memory:
  - The inner and outer cacheability, Non-cacheable, Write-Through, or Write-Back
  - For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is *Allocate* or *Do not allocate*, and the Transient allocation hints.

For more information about the memory type and attributes, see *Memory types and attributes* on page B2-89.

Shareability for Normal memory, for stage 1 translations

When using the VMSAv8-64 translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region. Table D4-34 shows the encoding of this field.

Table D4-34 SH[1:0] field encoding for Normal memory, VMSAv8-64 translation table format

SH[1:0]	Normal memory
00	Non-shareable
01	UNPREDICTABLE
10	Outer Shareable
11	Inner Shareable

Note

The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes

See *Combining the stage 1 and stage 2 shareability attributes for Normal memory* on page D4-1721 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

The memory region attributes for stage 2 translations, EL1&0 translation regime

In the stage 2 translation table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- *Memory region type and attributes for stage 2 translations* describes how the MemAttr[3:0] field defines these attributes.
- The SH[1:0] field in the translation table descriptor encodes shareability information. *Shareability for Normal memory, for stage 2 translations* on page D4-1717 describes this encoding.

The following sections describe how, when both stages of address translation are enabled, the memory region attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

- *Combining the stage 1 and stage 2 memory type attributes* on page D4-1720
- *Combining the stage 1 and stage 2 cacheability attributes for Normal memory* on page D4-1720
- *Combining the stage 1 and stage 2 shareability attributes for Normal memory* on page D4-1721.

Memory region type and attributes for stage 2 translations

Table D4-35 shows how MemAttr[3:2] gives a top-level definition of the memory type, and of the outer cacheability of a Normal memory region:

Table D4-35 VMSAv8-64 MemAttr[3:2] encoding, stage 2 translation

MemAttr[3:2]	Memory type	Outer cacheability
00	Device. MemAttr[1:0] encodes the Device memory type.	Not applicable
01	Normal. MemAttr[1:0] encodes the Inner Cacheability.	Outer Non-cacheable
10		Outer Write-Through Cacheable
11		Outer Write-Back Cacheable

The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

- When MemAttr[3:2]==`0b00`, indicating Device memory, Table D4-36 shows the encoding of MemAttr[1:0]:

Table D4-36 MemAttr[1:0] encoding for Strongly-ordered or Device memory

MemAttr[1:0]	Meaning when MemAttr[3:2] == `0b00`
00	Region is Device-nGnRnE memory
01	Region is Device-nGnRE memory
10	Region is Device-nGRE memory
11	Region is Device-GRE memory

- When MemAttr[3:2]!=0b00, indicating Normal memory, Table D4-37 shows the encoding of MemAttr[1:0]:

Table D4-37 MemAttr[1:0] encoding for Normal memory

MemAttr[1:0]	Meaning when MemAttr[3:2] != 0b00
00	UNPREDICTABLE
01	Inner Non-cacheable
10	Inner Write-Through Cacheable
11	Inner Write-Back Cacheable

Note

The stage 2 translation does not assign any allocation hints.

Note

The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:

- MemAttr[3:2] == 0b11, Normal memory, Outer Write-Back Cacheable
- MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.

Shareability for Normal memory, for stage 2 translations

When using the VMSAv8-64 translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region. Table D4-38 shows the encoding of this field.

Table D4-38 SH[1:0] field encoding for Normal memory, VMSAv8-64 translation table format

SH[1:0]	Normal memory
00	Non-shareable
01	UNPREDICTABLE
10	Outer Shareable
11	Inner Shareable

Note

- This encoding is the same as the shareability encoding described in *Shareability for Normal memory, for stage 1 translations* on page D4-1715.
- The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes

See *Combining the stage 1 and stage 2 shareability attributes for Normal memory* on page D4-1721 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

Other fields in the VMSAv8-64 translation table format descriptors

The following subsections describe the other fields in the translation table block and page descriptors:

- *The Contiguous bit* on page D4-1718
- *Field reserved for software use* on page D4-1718

- *Ignored fields* on page D4-1719.

The Contiguous bit

When the value of the Contiguous bit is 1, it indicates that the entry is one of a number of adjacent translation table entries that point to a *contiguous output address range*. The required number of adjacent entries depends on the current translation granule size, as follows:

4KB granule 16 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 16 entries must be aligned in the translation table. If accessing a full-sized 4KB translation table, this means that the top 5 of the 9 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

16KB granule This bit indicates that adjacent translation table entries point to contiguous output address range that has the same permissions and attributes. With the 16KB granule, the number of contiguous entries indicated by setting this bit to 1 depends on the lookup level of the translation table:

Level 2 lookup The bit indicates 32 contiguous entries, giving a 1GB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 6 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.

Level 3 lookup The bit indicates 128 contiguous entries, giving a 2MB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 4 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 128 translation table entries at the same translation table level.

64KB granule 32 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 32 entries must be aligned in the translation table. If accessing a full-sized 64KB translation table, this means that the top 8 of the 13 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.

Setting this bit to 1 means that the TLB can cache a single entry to cover the contiguous translation table entries.

This section defines the requirements for programming the contiguous bit. *Possible translation table registers programming errors* on page D4-1665 describes the effect of not meeting these requirements.

The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of the contiguous bit.

TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues.

Field reserved for software use

The architecture reserves a 4-bit field in the Block and Page table descriptors for software use. The architecture guarantees that hardware makes no use of this field.

Note

This means there is no need to invalidate the TLB if these bits are changed.

Ignored fields

For stage 1 translation descriptors, the architecture defines a 4-bit Ignored field in the Block and Page table descriptors, bit[63:59], and guarantees that hardware makes no use of this field. For stage 2 translation descriptors, the corresponding field is reserved for use by a System MMU control, and the ARMv8 architecture requires a PE to ignore this field.

D4.5.3 Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime

The Non-secure EL1&0 translation regime comprises two stage of translation, each of which can be enabled independently:

- Stage 1 translation is configured and controlled from EL1. When enabled, stage 1 translation can define access permissions independently for access from EL0 and for accesses from EL1.

  Stage 1 MMU faults are taken to EL1.

- When stage 2 translation is enabled, the stage 2 access controls defined at EL2:
  - Affect only the Non-secure stage 1 access permissions settings.
  - Take no account of whether the accesses are at EL1 or EL0.
  - Permit software executing at EL2 to assign a write-only attribute to a memory region.

  Stage 2 MMU faults are taken to EL2.

Note

In an implementation of virtualization, the attributes defined in the stage 2 translation tables mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:

- The Guest OS, in the stage 1 translation tables.
- The hypervisor, in the stage 2 translation tables.

The effects of the combination of attributes defined by the Hypervisor are functionally transparent to the Guest OS.

Combining the stage 1 and stage 2 data access permissions

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in *The AP[2:1] data access permissions, for stage 1 translations* on page D4-1708.
- The stage 2 permissions described in *The S2AP data access permissions, Non-secure EL1&0 translation regime* on page D4-1709.

The stage 1 and stage 2 permissions are combined as follows:

1. If an access is not permitted by the stage 1 permissions, then it generates a Stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an access is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a Stage 2 Permission fault.
3. If an access is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.

Combining the stage 1 and stage 2 instruction execution permissions

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in *Instruction execution permissions for stage 1 translations* on page D4-1711.

- The stage 2 permissions described in *Instruction execution permissions for stage 2 translations* on page D4-1712.

The stage 1 and stage 2 permissions are combined as follows:

1. If an instruction fetch is not permitted by the stage 1 permissions, then it generates a Stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an instruction fetch is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a Stage 2 Permission fault.
3. If an instruction fetch is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.

Combining the stage 1 and stage 2 memory type attributes

Table D4-39 shows the rules for combining the stage 1 and stage 2 memory type assignments:

Table D4-39 Combining the stage 1 and stage 2 memory type assignments

Rule	If either stage of translation assigns:	The resultant memory type is:
Device has precedence over Normal	Any Device memory type	A Device memory type
Non-Gathering has precedence over Gathering	A Device-nGxx memory type	A Device-nGxx memory type
Non-Reordering has precedence over Reordering	A Device-nGnRx memory type	A Device-nGnRx memory type
No Early write acknowledge has precedence over Early write acknowledge	The Device-nGnRnE memory type	The Device-nGnRnE memory type

Regardless of any shareability attribute obtained as described in *Combining the stage 1 and stage 2 shareability attributes for Normal memory* on page D4-1721:

- Any location for which the resultant memory type is any type of Device memory is always treated as Outer shareable.
- Any location for which the resultant memory type is Normal Inner Non-cacheable, Outer Non-cacheable is always treated as Outer shareable.

  For information about how the cacheability attribute is obtained from the attributes assigned at each stage of translation see *Combining the stage 1 and stage 2 cacheability attributes for Normal memory*.

The combining of the memory type attributes from the two stages of translation means a translation table walk for a stage 1 translation can be made to Device memory. This is likely to indicate a Guest OS error, and if the value of HCR_EL2.PTW is 1 such an access is trapped to EL2.

Combining the stage 1 and stage 2 cacheability attributes for Normal memory

For a Normal memory region, Table D4-40 shows how the stage 1 and stage 2 cacheability assignments are combined. This combination applies, independently, for the Inner cacheability and Outer cacheability attributes:

Table D4-40 Combining the stage 1 and stage 2 cacheability assignments for Normal memory

Assignment in stage 1	Assignment in stage 2	Resultant cacheability
Non-cacheable	Any	Non-cacheable
Any	Non-cacheable	Non-cacheable

Table D4-40 Combining the stage 1 and stage 2 cacheability assignments for Normal memory (continued)

Assignment in stage 1	Assignment in stage 2	Resultant cacheability
Write-Through Cacheable	Write-Through or Write-Back Cacheable	Write-Through Cacheable
Write-Through or Write-Back Cacheable	Write-Through Cacheable	Write-Through Cacheable
Write-Back Cacheable	Write-Back Cacheable	Write-Back Cacheable

Combining the stage 1 and stage 2 shareability attributes for Normal memory

A memory region is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation, if either:

- The resultant memory type attribute, described in *Combining the stage 1 and stage 2 memory type attributes* on page D4-1720, is any type of Device memory.
- The resultant memory type attribute, described in *Combining the stage 1 and stage 2 memory type attributes* on page D4-1720, is Normal memory, and the resultant cacheability, described in *Combining the stage 1 and stage 2 cacheability attributes for Normal memory* on page D4-1720, is Inner Non-cacheable, Outer Non-cacheable.

For a memory region with a resultant memory type attribute of Normal, that is not Inner Non-cacheable, Outer Non-cacheable, Table D4-41 shows how the stage 1 and stage 2 shareability assignments are combined:

Table D4-41 Combining the stage 1 and stage 2 shareability assignments for Normal memory[a]

Assignment in stage 1	Assignment in stage 2	Resultant shareability
Outer Shareable	Any	Outer Shareable
Inner Shareable	Outer Shareable	Outer Shareable
Inner Shareable	Inner Shareable	Inner Shareable
Inner Shareable	Non-shareable	Inner Shareable
Non-shareable	Outer Shareable	Outer Shareable
Non-shareable	Inner Shareable	Inner Shareable
Non-shareable	Non-shareable	Non-shareable

a. Applies only if the Normal memory is not Inner Non-cacheable, Outer Non-cacheable, see text.

D4.6 MMU faults

In a VMSAv8-64 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

Debug exception An exception caused by the debug configuration, see Chapter D2 *AArch64 Self-hosted Debug*.

Alignment fault An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information see *Alignment support* on page B2-75.

MMU fault An MMU fault is a fault generated by the fault checking sequence for the current translation regime. The remainder of this section describes MMU faults.

External abort Any memory system fault other than a Debug exception, an Alignment fault, or an MMU fault.

Collectively, these mechanisms are called *aborts*.

MMU faults are synchronous exceptions that fall into two categories in AArch64:

- Data Aborts.
- Instruction Aborts

Note

The Instruction Abort exception applies to any synchronous memory abort on an instruction fetch. It is not restricted to speculative instruction fetches.

External aborts can be reported synchronously or asynchronously. In AArch64 state, asynchronous external aborts are reported using the SError interrupt.

An access that causes an abort is said to be aborted, and uses the *Fault Address Registers* (FARs) and *Exception Syndrome Registers* (ESRs) to record context information.

For more information, see *Synchronous exception types, routing and priorities* on page D1-1447.

The Exception level that the MMU fault is taken to depends on the translation regime that generated the fault. The fault context saved in the appropriate ESR_ELx register, where ELx is the Exception level that the fault is taken to, is dependent on whether:

- The MMU fault is due to an Instruction or Data Abort.
- The exception is taken from the same or a lower Exception level.

Software stepping, a debug feature, and a misaligned PC exception are the only exceptions that are higher than an Instruction Abort. Only watchpoints are at a lower priority than Data Aborts in the exception priority hierarchy. For details on the exception model priorities, see *Synchronous exception prioritization* on page D1-1448.

The following sections describe the abort mechanisms:

- *Types of MMU faults* on page D4-1723.
- *The MMU fault-checking sequence* on page D4-1725.
- *Prioritization of synchronous aborts from a single stage of address translation* on page D4-1727.
- *Pseudocode details of the MMU faults* on page D4-1729.

D4.6.1 Types of MMU faults

This section describes the faults that might be detected during one of the fault-checking sequences described in *The MMU fault-checking sequence* on page D4-1725.

The following list includes all the types of exceptions that can occur:

- Alignment fault.
- Permission fault.
- Translation fault.
- Address size fault.
- Synchronous external abort on a translation table walk.
- Access flag fault.
- TLB conflict abort.

When an MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as Device.

The following subsections describe the MMU faults:

- *Permission fault*.
- *Translation fault*.
- *Address size fault* on page D4-1724.
- *External abort on a translation table walk* on page D4-1724.
- *Access flag fault* on page D4-1724.

Permission fault

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See *About the access permissions* on page D4-1707 for information about conditions that cause a Permission fault.

A TLB might hold a translation table entry that cause a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access.

This maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.

Cache maintenance instructions cannot cause a Permission fault, except that:

- A stage 1 translation table walk performed as part of a cache maintenance instruction can generate a stage 2 Permission fault as described in *Stage 2 fault on a stage 1 translation table walk* on page D4-1727.
- A DC IVAC issued in Non-secure state that attempts to update data in a location for which it does not have stage 2 write access can generate a stage 2 Permission fault, as described in *Effects of virtualization and security on the cache maintenance instructions* on page D3-1612.

Translation fault

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a translation table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information see *VMSAv8-64 translation table format descriptors* on page D4-1698.

In addition, a Translation fault is generated if the input address for a translation either does not map on to an address range of a Translation Table Base Register, or the Translation Table Base Register range that it maps on to is disabled. In these cases the fault is reported as a level 0 Translation fault on the translation stage at which the mapping to a region described by a Translation Table Base Register failed.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

A data or unified cache maintenance by VA instruction can generate a Translation fault. Whether an instruction cache invalidate by VA operation can generate a Translation fault is IMPLEMENTATION DEFINED, because it is IMPLEMENTATION DEFINED whether the operation requires an address translation. If the instruction cache invalidate by VA operation requires an address translation then the operation can generate a Translation fault, otherwise it cannot generate a Translation fault.

Address size fault

An Address size fault can be generated at any level of lookup.

An Address size fault is generated if one of the following applies:

- The translation table entries or the TTBR for the stage of translation have address bits above the most significant bit of the specified PA size as non zero.
- The specified output address size is larger than the implemented PA.

The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

For an Address size fault generated because the TTBR used for the translation has non-zero address bits above the most significant bit of the specified PA size the reported fault code indicates a fault at Level 0. Otherwise, the reported fault code indicates the lookup level at which the fault occurred.

For more information on Address size faults, see *Output address size* on page D4-1642.

External abort on a translation table walk

An external abort on a translation table walk can be either synchronous or asynchronous. An external abort on a translation table walk is reported:

- If the external abort is synchronous, using:
  - A synchronous Instruction Abort exception if the translation table walk is for an instruction fetch.
  - A synchronous Data Abort exception if the translation table walk is for a data access.
- If the external abort is asynchronous, using the SError interrupt exception.

Behavior of external aborts on a translation table walk caused by address translation instructions

The address translation instructions summarized in *Address translation instructions, functional group* on page G4-3796 require translation table walks. An external abort can occur in the translation table walk. This is reported as follows:

- If the external abort is synchronous, using a synchronous Data Abort exception.
- If the external abort is asynchronous, using the SError interrupt exception.

For more information, see *Synchronous faults generated by address translation instructions* on page D4-1684.

Access flag fault

An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if a translation table descriptor with the Access flag bit set to 0 is used.

For more information about the Access flag bit, see *VMSAv8-64 translation table format descriptors* on page D4-1698.

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to execute any TLB maintenance instructions to remove the faulting entry.

Whether any cache maintenance by VA instructions can generate Access flag faults is IMPLEMENTATION DEFINED.

For more information, see *The Access flag* on page D4-1714.

D4.6.2 The MMU fault-checking sequence

This section describes the MMU checks made for the memory accesses required for instruction fetches and for explicit memory accesses:

- if an instruction fetch faults it generates an Instruction Abort.
- if an data memory access faults it generates a Data Abort.

MMU fault checking is performed for each stage of address translation.

The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see *About address translation* on page D4-1639.

Note

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in *TLB conflict aborts* on page D4-1733.

Types of MMU faults on page D4-1723 describes the faults that an MMU fault-checking sequence can report.

Figure D4-30 shows the process of fetching a descriptor from the translation table. For the top-level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, if the translation is stage 1 of the Non-secure EL1&0 translation regime, then the descriptor address is in the IPA address space, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.

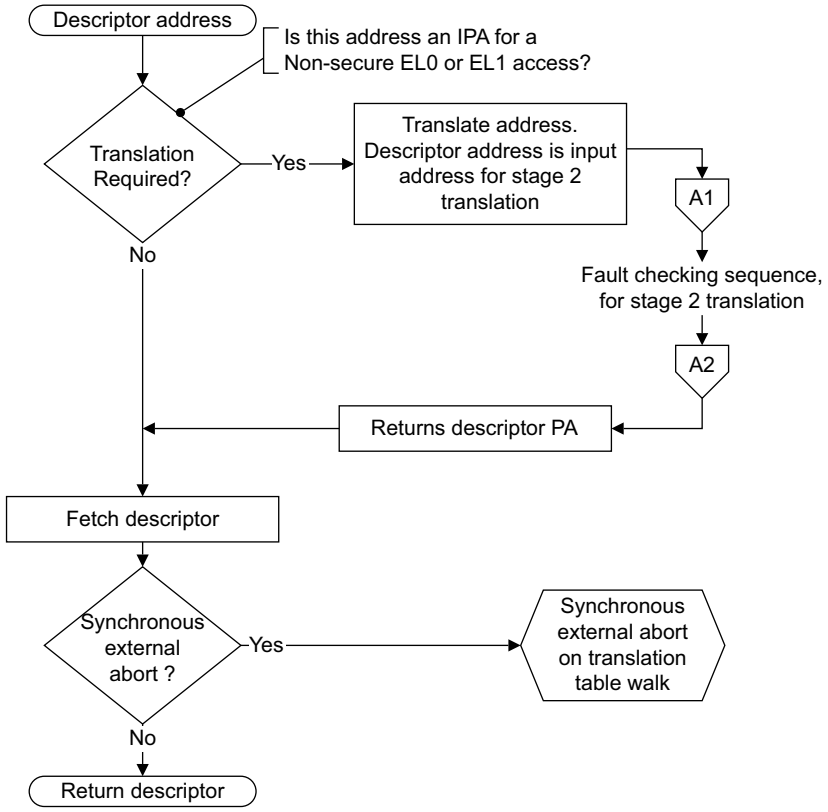


Figure D4-30 Fetching the descriptor in a VMSAv8-64 translation table walk

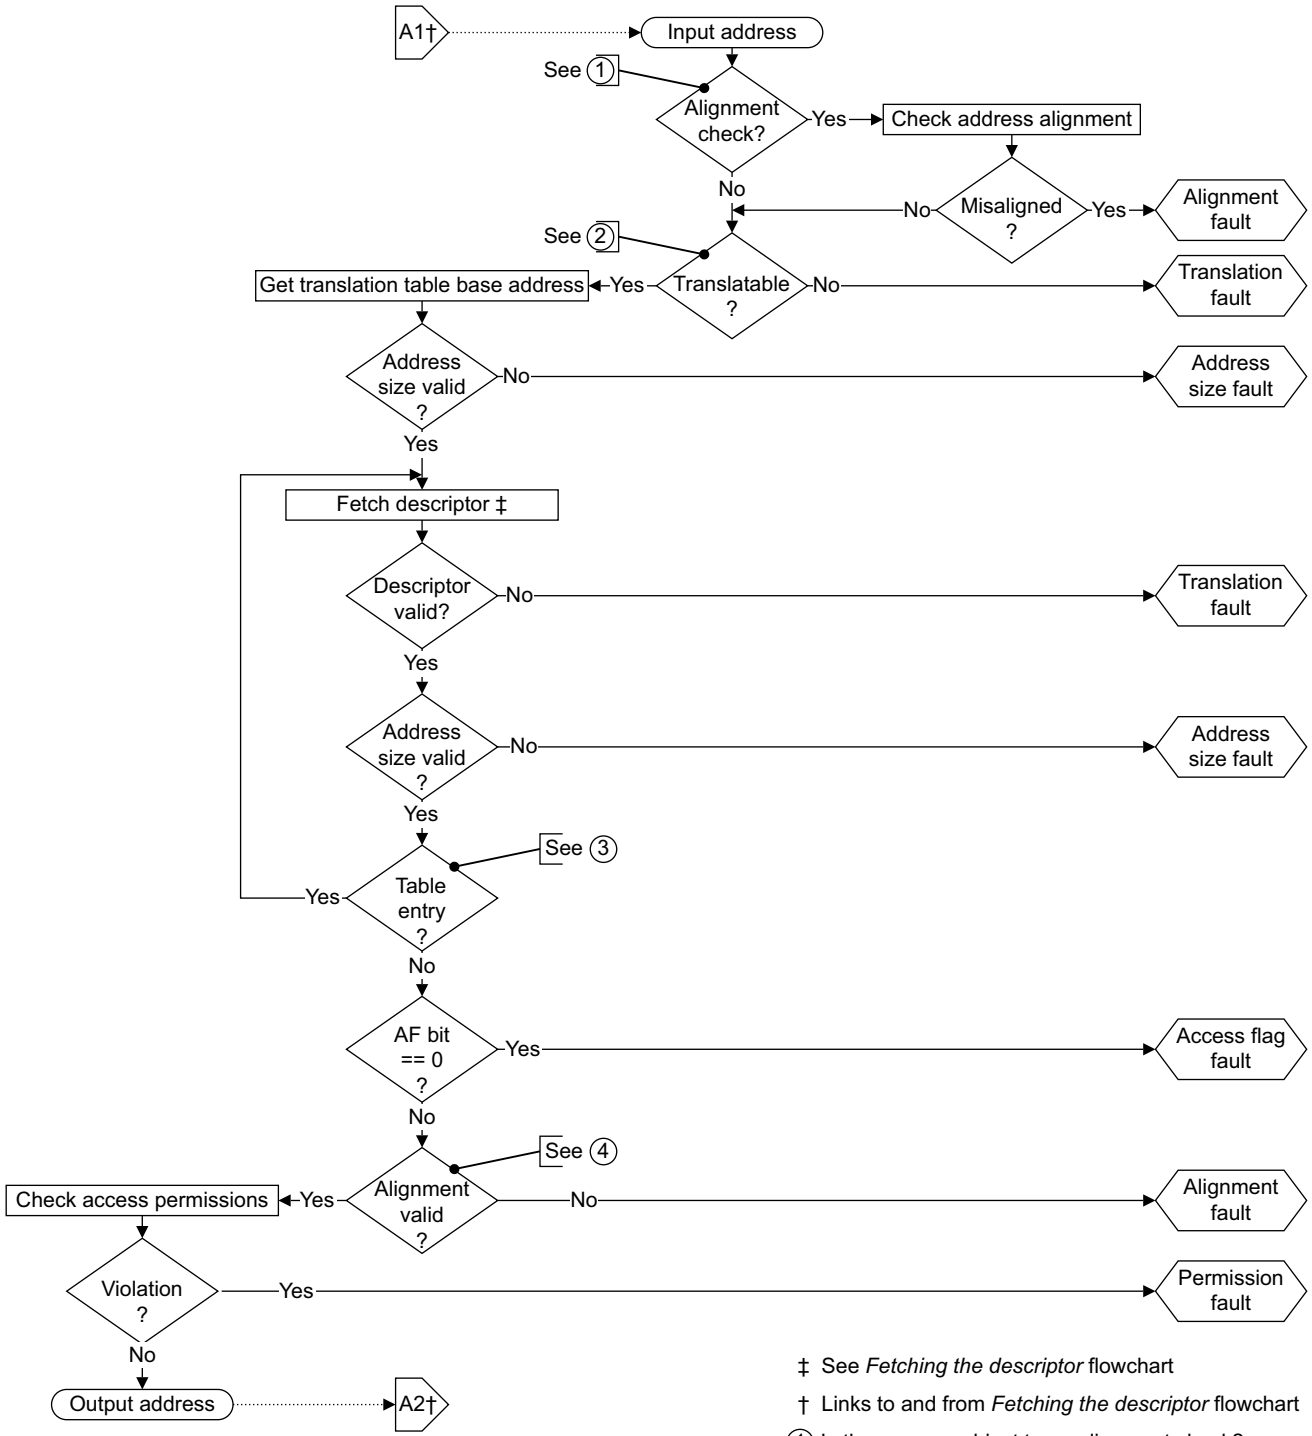
Figure D4-31 on page D4-1726 shows the full VMSA fault checking sequence, including the alignment check on the initial access.



‡ See *Fetching the descriptor* flowchart

† Links to and from *Fetching the descriptor* flowchart

(1) Is the access subject to an alignment check?

(4) Fault any unaligned access to Device memory

Figure D4-31 VMSAv8-64 fault checking sequence

Stage 2 fault on a stage 1 translation table walk

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

- A Translation fault, Access flag fault, or Permission fault.
- A synchronous external abort on the memory access.

If SCR_EL3.EA is set to 1, a synchronous external abort is taken to Secure Monitor mode., Otherwise, these faults are reported as stage 2 memory aborts. ESR_EL2.ISS[7] is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information see *Use of the ESR_EL1, ESR_EL2, and ESR_EL3* on page D1-1426.

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the Device or Strongly-ordered attribute assigned on the stage 2 translation of the address accessed. When the HCR_EL2.PTW bit is set to 1, such an access generates a stage 2 Permission fault.

Note

On most systems, such a mapping to Strongly-ordered or Device memory on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.

A TLB might hold entries that depend on the effect of HCR_EL2.PTW. Therefore, if HCR_EL2.PTW is changed without changing the current VMID, the TLBs must be invalidated before executing in a Non-secure EL1 or EL0 mode. For more information see *Changing HCR_EL2.PTW* on page D4-1743.

A cache maintenance instruction executed at Non-secure EL1 can cause a stage 1 translation table walk that might generate a stage 2 Permission fault, as described in this section. This is an exception to the general rule that a cache maintenance instruction cannot generate a Permission fault.

D4.6.3 Prioritization of synchronous aborts from a single stage of address translation

For a single stage of translation, the priority of the memory management faults on a memory access is as follows, ordered from highest priority to lowest priority. For memory accesses that undergo two stages of translation, the *italic entries show where the faults from second stage translations can occur*. A second stage fault within a second stage translation follows the same priority of faults:

1. Alignment fault not caused by memory type, possible for stage 1 translation only.
2. Translation fault due to the input address being out of the address range to be translated or requiring a TTBR that is disabled. This includes VTCR_EL2.T0SZ being inconsistent with VTCR_EL2.SL0.
3. Address size fault on a TTBR caused by either:
   - The check on TCR_EL1.IPS, TCR_ELx.PS, or VTCR_EL2.PS.
   - The physical address being out of the range implemented.
4. *Second stage abort on a level 0 lookup of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented*. This is second stage abort during a first stage translation table walk.
5. Synchronous parity fault on a level 0 lookup of a translation table walk.
6. Synchronous external abort on a level 0 lookup level of a translation table walk.
7. Translation fault on a level 0 translation table entry.
8. Address Size fault a level 0 lookup translation table entry caused by either:
   - The check on TCR_EL1.IPS, TCR_ELx.PS, or VTCR_EL2.PS.
   - The output address being out of the range implemented.

9. *Second stage abort on a level 1 lookup of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented*. This is second stage abort during a first stage translation table walk.
10. Synchronous parity fault on a level 1 lookup of a translation table walk.
11. Synchronous external abort on a level 1 lookup level of a translation table walk.
12. Translation fault on a level 1 translation table entry.
13. Address size fault on a level 1 lookup translation table entry caused by either:
    - The check on TCR_EL1.IPS, TCR_ELx.PS, or VTCR_EL2.PS.
    - The output address being out of the range implemented.
14. *Second stage abort on a level 2 lookup of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented*. This is second stage abort during a first stage translation table walk.
15. Synchronous parity fault on a level 2 lookup of a translation table walk.
16. Synchronous external abort on a level 2 lookup level of a translation table walk.
17. Translation fault on a level 2 translation table entry.
18. Address size fault on a level 2 lookup translation table entry caused by either:
    - The check on TCR_EL1.IPS, TCR_ELx.PS, or VTCR_EL2.PS.
    - The output address being out of the range implemented.
19. *Second stage abort on a level 3 lookup of a a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented.* This is second stage abort during a first stage translation table walk.
20. Synchronous parity fault on a level 3 lookup of a translation table walk.
21. Synchronous external abort on a level 3 lookup level of a translation table walk.
22. Translation fault on a level 3 translation table entry.
23. Address size fault on a level 3 lookup translation table entry caused by either:
    - The check on TCR_EL1.IPS, TCR_ELx.PS, or VTCR_EL2.PS.
    - The output address being out of the range implemented.
24. Access Flag fault.
25. Alignment fault caused by the memory type.
26. Permission fault.
27. *A fault from the state 2 translation of the memory access. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented*.
28. Synchronous parity fault on the memory access.
29. Synchronous External Abort on the memory access.

Note

The prioritization of TLB Conflict aborts is IMPLEMENTATION DEFINED, as the exact cause of these aborts depends on the form of TLBs implemented.

D4.6.4 Pseudocode details of the MMU faults

The following functions generate fault records that describe MMU faults.

```
FaultRecord AArch64.AlignmentFault(AccType acctype, boolean iswrite, boolean secondstage);

FaultRecord AArch64.TranslationFault(bits(48) ipaddress, integer level,
                                     AccType acctype, boolean iswrite, boolean secondstage,
                                     boolean s2fs1walk);

FaultRecord AArch64.AccessFlagFault(bits(48) ipaddress, integer level,
                                    AccType acctype, boolean iswrite, boolean secondstage,
                                    boolean s2fs1walk);

FaultRecord AArch64.AddressSizeFault(bits(48) ipaddress, integer level,
                                     AccType acctype, boolean iswrite, boolean secondstage,
                                     boolean s2fs1walk);

FaultRecord AArch64.PermissionFault(bits(48) ipaddress, integer level,
                                    AccType acctype, boolean iswrite, boolean secondstage,
                                    boolean s2fs1walk);
```

Abort exceptions on page D3-1628 describes how fault records are used.

D4.7 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and the VMSA provides TLB maintenance instructions for the management of TLB contents.

Note

The ARM architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

To reduce the need for TLB maintenance on context switches, for EL1&0 stage 1 translations the VMSA can distinguish between *Global pages* and *Process-specific pages*. The *Address Space Identifier* (ASID) identifies pages associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures. Similarly, for the Non-secure EL1&0 translation regime, the *virtual machine identifier* (VMID) identifies the current virtual machine, with its own independent ASID space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another, if the virtual machines have different VMIDs.

The following sections describe the architectural requirements for Translation Lookaside Buffers (TLBs) and their maintenance:

- *About ARMv8 Translation Lookaside Buffers (TLBs)*.
- *TLB maintenance requirements and the TLB maintenance instructions* on page D4-1733.

In these descriptions, TLB entries for a translation regime for a particular Exception level are *out of context* when executing at a higher Exception level.

D4.7.1 About ARMv8 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement for every memory access to perform a translation table walk in memory. The ARM architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.
- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.
- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.
- The architecture guarantees that a translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault is not held in the TLB. However a translation table entry that generates a Permission fault might be held in the TLB.
- Any translation table entry that does not generate a Translation or Access flag fault and is not out of context might be allocated to an enabled TLB at any time.

  Note

  An enabled TLB can hold a translation table entry that does not itself generate a Translation fault but that points to a subsequent table in the translation table walk. This is referred to as *intermediate caching* of TLB entries.

- Software can rely on the fact that between disabling and re-enabling a stage of address translation, entries in the TLB relating to that stage of translation have not have been corrupted to give incorrect translations.

The following sections give more information about TLB implementation:

- *Global and process-specific translation table entries* on page D4-1731

- *TLB matching* on page D4-1732
- *TLB behavior at reset* on page D4-1732
- *TLB lockdown* on page D4-1732
- *TLB conflict aborts* on page D4-1733.

See also *TLB maintenance requirements and the TLB maintenance instructions* on page D4-1733.

Global and process-specific translation table entries

In a VMSA implementation, system software can divide the virtual memory map used by memory accesses at EL1 and EL0 into global and non-global regions, indicated by the nG bit in the translation table descriptors:

nG == 0 The translation is global, meaning the region is available for all processes.

nG == 1 The translation is non-global, or process-specific, meaning it relates to the current ASID, as defined in either the TTBR0_EL1 or the TTBR1_EL1.

As indicated by the nG field definitions, each non-global region has an associated *Address Space Identifier* (ASID). These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.

TTBR0_EL1 and TTBR1_EL1 each have an ASID field, and TCR_EL1.A1 determines which of these fields defines the current ASID. See also *ASID size*.

Note

The selected ASID applies to the translation of any address for which the value of the nG bit is 1, regardless of whether the address is translated based on TTBR0_EL1 or on TTBR1_EL1.

For a symmetric multiprocessor cluster where a single operating system is running on the set of processing elements, the ARM architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all processing elements in the system.

The EL2 translation regime and the EL3 translation regime do not support ASIDs, and all descriptors in these regimes are treated as global.

When a PE is using the VMSAv8-64 translation table format, and is in Secure state, a translation must be treated as non-global, regardless of the value of the nG bit, if NSTable is set to 1 at any level of the translation table walk.

For more information see *Control of Secure or Non-secure memory access* on page D4-1705.

ASID size

In VMSAv8-64, the ASID size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits, and ID_AA64MMFR0_EL1.ASID bits identifies the supported size. When an implementation supports a 16 bit ASID, TCR_EL1.AS selects whether the top 8 bits of the ASID are used. When the value of TCR_EL1.AS is 0, ASID[15:8]:

- Are ignored by hardware for every purpose other than reads of ID_AA64MMFR0_EL1.
- Are treated as if they are all zeros when used for allocating and matching entries in the TLB.

Note

VMSAv8-32 uses an 8-bit ASID. For backwards compatibility, when executing using translations controlled from an Exception level that is using AArch32, the ASID size remains at 8 bits. If the implementation supports 16-bit ASIDS, the 8-bit ASID used is zero-extended to 16 bits.

TLB matching

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance instructions described in *TLB maintenance requirements and the TLB maintenance instructions* on page D4-1733 can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular ASID and VMID are changed without suitable invalidation of the TLB. This is an issue regardless of whether the translation table entries are global. In some cases, the TLB can hold two mappings for the same address, and this:

- Might generate a Data abort reported using the TLB Conflict fault code, see *TLB conflict aborts* on page D4-1733.
- Might lead to UNPREDICTABLE behavior. In this case, behavior will be consistent with one of the mappings held in the TLB, or with some amalgamation of the values held in the TLB, but cannot give access to regions of memory with permissions or attributes that could not be assigned by valid translation table entries in the translation regime being used for the access. For more information see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

TLB behavior at reset

The ARM architecture does not require a reset to invalidate the TLBs. The architecture recognizes that an implementation might require caches, including TLBs, to maintain their contents over a system reset. Possible reasons for doing so include power management and debug requirements.

For ARMv8:

- All TLBs are disabled from reset. All stages of address translation are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information see *Controlling address translation stages* on page D4-1640.
- An implementation can require the use of a specific TLB *invalidation routine*, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device.

  ARM recommends that if an invalidation routine is required for this purpose, the routine is based on the TLB maintenance instructions described in *TLB maintenance instructions* on page D4-1735.
- When TLBs that have not been invalidated by some mechanism since reset are enabled, the state of those TLBs is UNPREDICTABLE.

Similar rules apply to cache behavior, see *Behavior of caches at reset* on page D3-1601.

TLB lockdown

The ARM architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

- VMSAv8-64 does not require TLB lockdown support.
- If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.

This means that a region of the system instruction encoding space is reserved for IMPLEMENTATION DEFINED functions, see *Reserved control space for IMPLEMENTATION DEFINED functionality* on page C5-251. An implementation might use some of these encodings to implement TLB lockdown functions. These functions might include:

- Unlock all locked TLB entries.
- Preload into a specific level of TLB. This is beyond the scope of the `PLI` and `PLD` hint instructions.

In an implementation that includes EL2, exceptions generated by problems related to TLB lockdown in a Non-secure EL1 mode, can be routed to either:

- Non-secure EL1, as a Data Abort exception.
- Non-secure EL2, as a Hyp Trap exception.

For more information, see *Traps to EL2 of Non-secure EL1 and EL0 accesses to lockdown, DMA, and TCM operations* on page D1-1474.

TLB conflict aborts

ARMv8 includes the concept of a TLB conflict abort, and defines fault status encodings for such an abort, see *ESR_EL1, Exception Syndrome Register (EL1)* on page D7-1829.

An implementation can generate a TLB conflict abort if it detects that the address being looked up in the TLB hits multiple entries. This can happen if the TLB has been invalidated inappropriately, for example if TLB invalidation required by the architecture has not been performed. If it happens, the resulting behavior is UNPREDICTABLE, but must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Exception level.

In some implementations, multiple hits in the TLB can generate a synchronous Data Abort or Prefetch Abort exception. In any case where this is possible it is IMPLEMENTATION DEFINED whether the abort is a stage 1 abort or a stage 2 abort.

Note

A stage 2 abort cannot be generated if stage 2 of the Non-secure EL1&0 translation regime is disabled.

The priority of the TLB conflict abort is IMPLEMENTATION DEFINED, because it depends on the form of a TLB that can generate the abort.

Note

The TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses.

On a TLB conflict abort, the returned syndrome includes the address that generated the fault. That is, it includes the address that was being looked up in the TLB.

D4.7.2 TLB maintenance requirements and the TLB maintenance instructions

Translation Lookaside Buffers (TLBs) are an implementation mechanism that caches translations or translation table entries. The ARM architecture does not specify the form of any TLB structures, but defines the mechanisms by which TLBs can be maintained.The following sections describe the VMSA TLB maintenance instructions:

- *General TLB maintenance requirements* on page D4-1734.
- *TLB maintenance instructions* on page D4-1735.
- *Maintenance requirements on changing System register values* on page D4-1742.
- *Atomicity of register changes on changing virtual machine* on page D4-1743.

General TLB maintenance requirements

TLB maintenance instructions provide a mechanism for invalidating entries from TLB caching structures to ensure that changes to the translation tables are reflected correctly in those TLB caching structures.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault, provided that the entry does not, itself, cause a Translation fault, an Address size fault, or an Access Flag fault. This means that the entries that can be cached include:

- Entries in translation tables that point to subsequent tables to be used in that stage of translation.
- Stage 2 translation table entries used as part of a stage 1 translation table walk
- Stage 2 translation table entries used to translate the output address of the stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are used during a translation table walk and that are distinct from the data caches in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction of the form of these intermediate TLB caching structures.

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries, and in particular for translation regimes that involve two stages of translation, it is recognized that such caching structures might contain:

- Entries containing information from stage 1 translation table entries, at any level of the translation table walk.
- Entries containing information from stage 2 translation table entries, at any level of the translation table walk.
- Entries that combine information from stage 1 and stage 2 translation table entries, at any level of the translation table walk.

Where a TLB maintenance instruction is:

- Required to apply to stage 1 entries, then it must apply to any cached entries in caching structures that include any stage 1 information that are used to translate the address being invalidated.

  Note

  ARM expects that, in at least some implementations, cached copies of levels of the translation table walk other than the last level are tagged with their ASID, regardless of whether the final level is global. This means that TLB invalidations that involve the ASID require the ASID to match such entries to perform the required invalidation.

- Required to apply to stage 2 entries only, then:
  - It is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
  - It must apply to caching structures that contain information only from stage 2 translation table entries.
- Required to apply to both stage 1 and stage 2 entries, then it must apply to any entry in the caching structures that includes information from either a stage 1 translation table entry or a stage 2 translation table entry, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Whenever translation tables entries associated with a particular VMID or ASID are changed, the corresponding entries must be invalidated from the TLB to ensure that these changes are visible to subsequent execution, including speculative execution, that uses the changed translation table entries.

Some system register bit descriptions state that the effect of the bit is permitted to be cached in a TLB. This means that all TLB entries that might be affected by a change in one of these bits must be invalidated whenever that bit is changed, to ensure that the effect of the change of that control bit is visible to subsequent execution including speculative execution, that uses those control bits. This invalidation is required in addition to, and after, the normal synchronization of the system registers described in *Synchronization requirements for System registers* on page D7-1794, and applies to any stage of address translation that is implemented for the translation regime, and VMID if appropriate, that is affected by that control bit.

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory, software must ensure that any cached copies of affected locations are removed from the caches. For more information see *Cache maintenance requirement created by changing translation table attributes* on page D4-1746.

TLB maintenance instructions

The architecture defines TLB maintenance instructions, that provide the following:

- Invalidate all entries in the TLB.
- Invalidate a single TLB entry by ASID for a non-global entry.
- Invalidate all TLB entries that match a specified ASID.
- Invalidate all TLB entries that match a specified VA, regardless of the ASID.

Each instruction can be specified as applying only to the PE that executes the instruction, or as applying to all PEs in the same Inner Shareable shareability domain as the PE that executes the instruction.

The following subsubsections describe these instructions:

- *TLB maintenance instruction syntax*.
- *Operation of the TLB maintenance instructions* on page D4-1737.
- *Scope of the TLB maintenance instructions* on page D4-1738.
- *Broadcast TLB maintenance between AArch32 and AArch64* on page D4-1739.
- *TLB maintenance with different translation granule sizes* on page D4-1740.
- *Ordering and completion of TLB maintenance instructions* on page D4-1741.
- *TLB maintenance in the event of TLB conflict* on page D4-1741.
- *The interaction of TLB lockdown with TLB maintenance instructions* on page D4-1742.

TLB maintenance instructions on page C5-240 describes the encoding of the TLB maintenance instructions.

TLB maintenance instruction syntax

The A64 syntax for TLB maintenance instructions is:

```
TLBI <operation>{, <Xt>}
```

Where:

`<operation>` Is one of `VMALLE1`, `VA{L}E1`, `ASIDE1`, `VAA{L}E1`, `VMALLE1IS`, `VA{L}E1IS`, `ASIDE1IS`, `VAA{L}E1IS`, `VA{L}E2`, `VA{L}E2IS`, `VA{L}E3`, `VA{L}E3IS`, `ALLE1`, `ALLE1IS`, `ALLE2`, `ALLE2IS`, `ALLE3`, `ALLE3IS`, `VMALLS12E1`, `VMALLS12E1IS`, `IPAS2{L}E1`, or `IPAS2{L}E1IS`.

`<operation>` has a structure of `<type>{L}<level>{,IS}` where:

`<type>` Is one of:

- `ALL` All translations used at `<level>`. For `level` == E1, for translations to which a VMID applies, `ALL` applies for any VMID.
- `VMALL` All stage 1 translations used at <level>. For translations to which a VMID applies, `VMALL` applies only to translations with the current VMID.
- `VMALLS12` All stage 1 and stage 2 translations used at EL1. For translations to which a VMID applies, `VMALLS12` applies only to translations with the current VMID.
  `VMALLS12` is only valid when `level` == E1.
- `ASID` All translations used at EL1 with the supplied ASID. For translations to which a VMID applies, `ASID` applies only to translations with the current VMID.
  `ASID` is only valid when `level` == E1.
- `VA{L}` Translations used at `<level>` for the specified address and ASID, if appropriate, and the current VMID, if appropriate.
- `VAA{L}` Translations used at `<level>` for the specified address and for all ASID values, if appropriate, and the current VMID, if appropriate.
- `IPAS2{L}` Translations used at `<level>` for the specified IPA for the current VMID, if appropriate, held in stage 2 only caching structures.

In the VA{L}, VAA{L}, and IPAS2{L} types:

L — Indicates that the invalidation only applies to caching of entries returned from the last level of translation table walk of the stage 1 translation. See *Scope of the TLB maintenance instructions* on page D4-1738. L is an optional parameter for the VA, VAA, and IPAS2 types.

<level> — Defines the Exception level of the translation regime that the invalidation applies to. Is one of:

- E1 — EL1.
- E2 — EL2.
- E3 — EL3.

An instruction that apples to the translation regime of an Exception level other than the Exception level at which the instruction is executed is UNDEFINED.

TLBI ALLE1{IS}, TLBI IPAS2{L}E1{IS} and TLBI VMALLS12E1{IS} are UNDEFINED at EL1.

Note

All TLB maintenance instructions are UNDEFINED at EL0.

IS — When present, it indicates that the function applies to all TLBs in the Inner Shareable domain.

<Xt> — Passes one or both of an address and an ASID as an argument, where required. <Xt> is required for the TLB ASID, TLB VA{L}, TLB VAA{L}, and TLB IPAS2{L} instructions.

If EL2 is not implemented, the TLBI VA{L}E2, TLBI VA{L}E2IS, TLBI ALLE2, and TLBI ALLE2IS instructions are UNDEFINED.

In VMSAv8-64, the TLB instructions that take a register argument that holds a virtual address, an ASID, or both, use the following register argument format:

Bits[63:48] ASID. However, these bits are RES0 if the instruction does not require an ASID argument.

Bits[47:44] RES0.

Bits[43:0] VA[55:12]. For an instruction that requires a VA argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:

- **4KB granule size** — All bits are valid and used for the invalidation.
- **16KB granule size** — Bits[1:0] RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- **64KB granule size** — Bits[3:0] are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

These bits are RES0 if the instruction does not require a VA argument.

For TLB maintenance instructions that take an address, the maintenance of VA[63:56] is interpreted as being the same as the maintenance of VA[55].

If a TLB maintenance instruction targets a translation regime that is using AArch32, meaning the VA is only 32-bit, then software must treat VA[55:32] as RES0, and these bits are ignored when the instruction is executed.

If the implementation supports 16 bits of ASID then the upper 8 bits of the ASID are RES0 when the context being invalidated only uses 8 bits.

In VMSAv8-64, the TLB instructions that take a register argument that holds an IPA, use the following register argument format:

Bits[63:36] RES0.

Bits[35:0] IPA[47:12]. For an instruction that requires a VA argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:

- **4KB granule size** — All bits are valid and used for the invalidation.

16KB granule size	Bits[1:0] RES0 and ignored when the instruction is executed, because IPA[13:12] have no effect on the operation of the instruction.
64KB granule size	Bits[3:0] are RES0 and ignored when the instruction is executed, because IPA[15:12] have no effect on the operation of the instruction.

Operation of the TLB maintenance instructions

Any TLB maintenance instruction can affect any TLB entries that are not locked down.

The TLB maintenance instructions specify the Exception level of the translation regime to which they apply.

Note

Because there is no guarantee that an unlocked TLB entry remains in the cache, architecturally it is not possible to tell whether a TLB maintenance instruction has affected any TLB entries that were not specified by the instruction.

If a TLB maintenance instruction specifies a VA, and a data or instruction access to that VA would generate an MMU abort, the TLB maintenance instruction does not generate an abort. VAs for which a TLB maintenance instruction does not generate an abort include VAs that are not in the range of VAs that can be translated.

When EL3 is implemented:

- The TLB maintenance instructions that apply to the EL1&0 translation regime take account of the current Security state, as part of the address translation required for the TLB operation.
- SCR_EL3.NS modifies the effect of the TLB maintenance instructions as follows:
  - For instructions that apply to the EL1&0 translation regime, the SCR_EL3.NS bit identifies whether the maintenance instructions apply to the Secure or Non-secure EL1&0 translation regime.

    Note

    If EL3 is not implemented, then there is only a single EL1&0 translation regime.

  - For instructions that apply to the EL2 translation regime, the SCR_EL3.NS bit must be 1 or the instruction is UNDEFINED.
  - For instructions that apply to the EL3 translation regime, the SCR_EL3.NS bit has no effect.

Note

- An address-based TLB maintenance instruction that applies to the Inner Shareable domain does so regardless of the Shareability attributes of the address supplied as an argument to the operation.
- Previous versions of the ARM architecture included TLB maintenance instructions that operated only on instruction TLBs, or only on data TLBs. From the introduction of ARMv7, ARM deprecated any use of these instructions. In ARMv8:
  - AArch64 state does not include any of these instructions.
  - AArch32 state includes some of these instructions, but ARM deprecates their use.

The ARM architecture does not dictate the form in which the TLB stores translation table entries. However, when a TLB maintenance instruction is executed, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

Note

The Contiguous bit does not affect the minimum size of entry that must be invalidated from the TLB

Scope of the TLB maintenance instructions

The TLB invalidation instruction <type> affects the different possible levels of caching in the TLB as follows:

VAL, VAAL — The invalidation applies to all cached copies of the final level of translation table walk of stage 1 translation that would be used with the Security state specified by SCR_EL3.NS, current VMID (for the Non-secure EL1&0 translation regime), and, if appropriate, the specified ASID, during a translation table walk to translate the address specified in the invalidation instruction at the specified Exception Level.

VA, VAA — The invalidation applies to all cached copies of the stage 1 translation table entries, at any table level that would be used with the state specified by SCR_EL3.NS, current VMID (for the Non-secure EL1&0 translation regime), and, if appropriate, the specified ASID, during a translation table walk to translate the address specified in the invalidation instruction at the specified Exception Level.

ASID — The invalidation applies to all cached copies of the stage 1 translation table entries, at any table level that would be used with the state specified by SCR_EL3.NS, current VMID (for the Non-secure EL1&0 translation regime), and the specified ASID during a translation table walk to translate any address at the specified Exception Level.

VMALL — The invalidation applies to all cached copies of the stage 1 translation table entries, at any table level, that would be used with the state specified by SCR_EL3.NS and current VMID (for the Non-secure EL1&0 translation regime) during a translation table walk to translate any address at the specified Exception Level.

VMALLS12 — The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries, at any table level, that would be used with the state specified by SCR_EL3.NS and current VMID (for the Non-secure EL1&0 translation regime) during a translation table walk to translate any address at the specified Exception Level.

Note

If EL2 is not implemented, or if the TLBI VMALLS12 instruction is executed with SCR_EL3.NS==0, the instruction is not UNDEFINED but it has the same effect as TLBI VMALL. This is because there are no stage 2 translations to invalidate.

IPAS2 — The invalidation applies to cached copies of the stage 2 translation table entries held in TLB caching structures holding stage 2 only entries, at any table level, that would be used with the current VMID during a translation table walk to translate any address at the specified Exception Level. It is not required that this instruction invalidates TLB caching structures holding stage 1 and stage 2 entries combined.

The only translation regime to which this instruction can apply is the Non-secure EL1&0 translation regime.

When executed with the SCR_EL3.NS==0, or in an implementation that does not implement EL2, this instruction is a NOP.

The architectural requirements of this instruction are that:

1. The following code is sufficient to invalidate all cached copies of the stage 2 translation of the IPA held in Xt for the current VMID, with the corresponding requirement for the broadcast versions of the instructions:

```
TLBI IPAS2E1, Xt
DSB
TLBI VMALLE1
```

2. The following code is sufficient to invalidate all cached copies of the stage 2 translations of the IPA held in Xt used to translate the virtual address VA (and ASID when executing TLBI VAE1) held in Xt2, with the corresponding requirement for the broadcast versions of the instructions:

```
TLBI IPAS2E1, Xt
DSB
TLBI VAE1, Xt2     ; or TLBI VAAE1, Xt2
```

3. The following code is sufficient to invalidate all cached copies of the stage 2 translations of the IPA held in `Xt` used to translate the IPA produced by the last level of stage 1 translation table lookup for the virtual address VA (and ASID when executing `TLBI VALE1`) held in `Xt2`, with the corresponding requirement for the broadcast versions of the instructions:

```
TLBI IPAS2E1, Xt
DSB
TLBI VALE1, Xt2    ; or TLBI VAALE1, Xt2
```

`IPAS2L` The invalidation applies to cached copies of the stage 2 translation table entries held in TLB caching structures holding stage 2 only entries, at the final level of the stage 2 translation table walk, that would be used with the current VMID during a translation table walk to translate any address at the specified Exception Level. It is not required that this instruction invalidates TLB caching structures holding combined (stage 1 and stage 2) entries.

The only translation regime to which this instruction can apply is the Non-secure EL1&0 translation regime.

When executed with the SCR_EL3.NS==0, or in an implementation that does not implement EL2, this instruction is a `NOP`.

The architecture requirements for `TLBI IPAS2L` instructions correspond to those for the `TLVI IPAS2` instructions, but only for cached copies of the final level of the stage 2 translation.

`ALL` The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries, at any table level, that would be used with the state specified by SCR_EL3.NS, and any VMID during a translation table walk to translate any address at the specified Exception Level.

The entries that the invalidations apply to are not affected by the state of any other control bits involved in the translation process. Therefore, the following is a non-exhaustive list of control bits that do not affect how a TLB maintenance instruction updates the TLB entries:

In AArch64 SCTLR_EL1.M, SCTLR_EL2.M, SCTLR_EL3.{M, RW], HCR_EL2.{VM, RW}, TCR_EL1.{TG1, EPD1, T1SZ, TG0, EPD0, T0SZ, AS, A1}, TCR_EL2.{TG0, T0SZ}, TCR_EL3.{TG0, T0SZ}, VTCR_EL2.{SL0, T0SZ}, TTBR0_EL1.ASID, TTBR1_EL1.ASID.

In AArch32 SCTLR.M, HCR.VM, TTBCR.{EAE, PD1, PD0, N, EPD1, T1SZ, EPD0, T0SZ, A1}, HTCR.T0SZ, VTCR.{SL0, T0SZ}, TTBR0.ASID, TTBR1.ASID, CONTEXTIDR.ASID.

Note

- ARM expects most TLB maintenance performed by an operating system to occur to the last level entries of the stage 1 translation table walks, and the purpose of the address-based TLB invalidation instructions where the invalidation need only apply to caching of entries returned from the last level of translation table walk of stage 1 translation is to avoid unnecessary loss of the intermediate caching of the translation table entries. Similarly, for stage 2 translations ARM expects that most TLB maintenance performed by a hypervisor for a given Guest operation system will affect only the last level entries of the stage 2 translations. Therefore, similar capability is provided for instructions that invalidate single stage 2 entries.
- The architecture permits the invalidation of entries in TLB caching structures at any time, so for each of these instructions the definition is in terms of the minimum set of entries that must be invalidated from TLB caching structures, and an implementation might choose to invalidate more entries. In general, for best performance, ARM recommends not invalidating entries that are not required to be invalidated.
- Dependencies on the VMID for the Non-secure EL1&0 translation regime apply even when HCR_EL2.VM is set to 0. Because the architecture does not require the VTTBR_EL2.VMID field to be reset in hardware, the reset routine of each active PE must initialize VTTBR_EL2.VMID[7:0] to a common value such as 0, even if stage 2 translation is not in use.

Broadcast TLB maintenance between AArch32 and AArch64

In most cases, the TLB maintenance instructions affecting the Inner Shareable domain executed by a PE in an Exception level that is using AArch64 also affects another PE in the same Inner Shareable domain that is executing at the same Exception level and is using AArch32, provided that the virtual address, ASID, and VMID match.

Note

The requirement to match means that the invalidation only occurs on the PE that is using AArch32 if, for the PE that executed the TLB maintenance instruction at an Exception level that is using AArch64, both of the following apply:

- The VA is in the bottom 4GB.
- If it uses a 16-bit ASID, then the top 8 bits of the ASID are zero.

Except for the cases identified here, the TLB maintenance instructions affecting the Inner Shareable domain executed by a PE in an Exception level that is using AArch32 also affects another PE in the same Inner Shareable domain that is executing at the same Exception level and is using AArch64, provided that the virtual address, ASID, and VMID match. The virtual address from the instruction executed in AArch32 state is zero-extended, and the ASID is zero-extended if the PE executing in AArch64 state is using a 16-bit ASID. The exceptions to this general rule are as follows:

1. An ARMv7 PE in the same Inner Shareable domain is treated in the same way as an ARMv8 PE for which EL3 is using AArch32, except that if an ARMv8 PE issues an instruction that does not exist in ARMv7, then that instruction is not required to have an effect on the TLBs of the ARMv7 PE. The instructions that do not exist in ARMv7 include the following TLB maintenance instructions that ARMv8 adds to the T32 and A32 instruction sets:
   - The following instructions that operate on TLB entries for the final level of translation table walk for stage 1 translations:

     `TLBIMVALIS`, `TLBIMVAALIS`, `TLBIMVALHIS`, `TLBIMVAL`, `TLBIMVAAL`, and `TLBIMVALH`.
   - The following instructions that operate by IPA on TLB entries for stage 2 translations:

     `TLBIIPAS2IS`, `TLBIIPAS2LIS`, `TLBIIPAS2`, and `TLBIIPAS2L`.
2. The number of Exception levels in Secure state depends on whether EL3 is using AArch32 or EL3 is using AArch64. This means that, within the Inner Sharable domain, there might be PEs with different numbers of Exception levels in Secure state. Therefore, the following exceptions are made to this principle:
   - If a PE that has EL3 using AArch32 issues an AArch32 TLB maintenance instruction affecting Secure entries, and the Inner Shareable domain also contains PEs with EL3 using AArch64, then the architecture does not require that the AArch32 TLB maintenance instruction has any effect on either:
     - The EL3 translation regime of the PEs with EL3 using AArch64.
     - The Secure EL1 translation regime of the PEs with EL3 using AArch64, regardless of whether the Secure EL1 translation regime is using AArch64 or AArch32.
   - If a PE that has EL3 using AArch64 issues an AArch64 TLB maintenance instruction affecting EL3 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32, then the architecture does not require that the AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.
   - If a PE that has EL3 using AArch64 issues an AArch64 TLB maintenance instruction affecting Secure EL1 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32 then the architecture does not require that the AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.

Note

While the architecture does not require such an effect, the architecture also does not require that entries in the TLB remain in the TLB at any time, and so it is permissible that such instructions affect these translation regimes.

TLB maintenance with different translation granule sizes

If a TLB maintenance instruction specifying a virtual address affecting the EL2 translation regime or the EL3 translation regime is broadcast from a PE using one translation granule size for that translation regime to a PE using a different translation granule size for that same translation regime, the TLB maintenance instruction is not required to perform any invalidation on the recipient PE.

If a TLB maintenance instruction specifying a virtual address affecting the EL1 translation regime is broadcast from a PE using one translation granule size for that translation regime for a particular ASID, VMID (if applicable), and Security state, to a PE where EL1 for the same ASID, VMID (if applicable), and Security state, is using a different translation granule size, the TLB maintenance instruction is not required to perform any invalidation on the recipient PE.

Ordering and completion of TLB maintenance instructions

For AArch64 execution, a TLB maintenance instruction can be executed in any order relative to:

- Loads and stores, unless a `DSB` is executed between the instructions.

  Note

  In the ARM architecture, a translation table walk is considered to be a separate observer, and a store to translation tables can be observed by that separate observer at any time after the instruction has been executed, but is only guaranteed to be observable after the execution of a `DSB` instruction by the PE that executed the TLB maintenance instruction.

- Another TLB maintenance instruction, unless a `DSB` is executed between the instructions.
- A data or instruction cache maintenance instruction, unless a `DSB` is executed between the instructions.

For AArch64 execution, the completion rules are:

- A TLB maintenance instruction is complete when all memory accesses using the TLB entries that have been invalidated have been observed by all observers to the extent that those accesses are required to be observed, as determined by the shareability and cacheability of the memory locations accessed by the accesses. In addition, after the TLB invalidate instruction is complete, no new memory accesses that can be observed by those observers using those TLB entries are performed.

  Note

  For TLB maintenance instructions that affect other PEs, the memory accesses from those PEs that used the TLB entries that have been invalidated are included in the set of memory accesses that must have been observed when the TLB maintenance instruction is complete.

- A TLB maintenance instruction can complete at any time after it is issued, but is only guaranteed to be complete after the execution of `DSB` by the PE that executed the TLB maintenance instruction.
- A completed TLB maintenance instruction is only guaranteed to have its effects visible on the PE that executed the instruction after the execution of an `ISB` instruction by the PE that executed the TLB maintenance instruction.

Note

In all cases in this section, where a `DMB` or `DSB` is referred to, it refers to a `DMB` or `DSB` whose required access type is both loads and stores.

TLB maintenance in the event of TLB conflict

In the event of a TLB conflict abort, which indicates that multiple entries in the TLB are being used to translate the same address, the TLB invalidation of the address (including ASID, VMID and Security state, as appropriate) for the translation regime that gave rise to the fault is required to clear the conflict.

In some implementations with complex caching structures, to clear the conflict might require more extensive invalidation of the TLB, by using the `ALL` or `VMALL` types for the affected translation regimes. The need for such requirements is IMPLEMENTATION DEFINED.

The interaction of TLB lockdown with TLB maintenance instructions

The precise interaction of TLB lockdown with the TLB maintenance instructions is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance instructions must comply with these rules:

- The effect on a locked TLB entry of a TLB invalidate all operation that would invalidate that entry if the entry was not locked is IMPLEMENTATION DEFINED. However, the operation must implement one of the following options:
  - The operation has no effect on entries that are locked down.
  - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down.

    Any such exceptions taken from Non-secure EL1 can be trapped to EL2, see *Traps to EL2 of Non-secure EL1 and EL0 accesses to lockdown, DMA, and TCM operations* on page D1-1474.

  This permits a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.
- The effect on a locked TLB entry of a TLB invalidate by VA or invalidate by ASID match operation that would invalidate that entry if the entry was not locked is IMPLEMENTATION DEFINED. However, the operation must implement one of the following options:
  - The locked entry is invalidated in the TLB.
  - The operation has no effect on any locked entry in the TLB. In the case of an invalidate single entry by VA, this means the PE treats the operation as a `NOP`.
  - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down.

The exception syndrome definitions include a fault code for cache and TLB lockdown faults, see *ESR_EL1, Exception Syndrome Register (EL1)* on page D7-1829.

Note

Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other specified alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined operations. This minimizes the number of customized operations required.

In addition, an implementation that uses an abort mechanism for handling the effect of TLB maintenance instructions on entries that can be locked down but are not actually locked down must also must provide a mechanism that ensures that no TLB entries are locked.

Similar rules apply to cache lockdown, see *The interaction of cache lockdown with cache maintenance instructions* on page D3-1616.

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side-effect of any TLB maintenance instruction, any unlocked entry in the TLB might be invalidated.

Maintenance requirements on changing System register values

The TLB contents can be influenced by control bits in a number of system control registers. This means the TLB must be invalidated after any changes to these bits, unless the changes are accompanied by a change to the VMID or ASID that defines the context to which the bits apply. The general form of the required invalidation sequence is as follows:

```
; Change control bits in system control registers
ISB        ; Synchronize changes to the control bits
; Perform TLB invalidation of all entries that might be affected by the changed control bits
```

The system control register changes that this applies to are:

- Any change to the MAIR_EL1, MAIR_EL2, or MAIR_EL3 registers.
- Any change to the AMAIR_EL1, AMAIR_EL2, or AMAIR_EL3 registers.
- Any change to SCTLR_EL1.EE, SCTLR_EL2.EE, or SCTLR_EL3.EE.
- Any change to SCTLR_EL1.WXN, SCTLR_EL2.WXN, or SCTLR_EL3.WXN.
- Any change to any of the SCR_EL3.{RW, SIF} bits.
- Any change to any of the HCR_EL2.{RW, DC, PTW, VM} bits. See also *Changing HCR_EL2.PTW*.
- Any changes to the registers that control address translation:
  - Any change to any of the TCR_EL1, TCR_EL2, TCR_EL3, or VTCR_EL2 registers.
  - Any change to the TTBR0_EL1, TTBR1_EL1, TTBR0_EL2, TTBR0_EL3, or VTTBR_EL2 registers.

Changing HCR_EL2.PTW

When the value of the Protected table walk bit, HCR_EL2.PTW, is 1, a stage 1 translation table access in the Non-secure EL1&0 translation regime, to an address that is mapped to any type of Device memory by its stage 2 translation, generates a stage 2 Permission fault. A TLB associated with a particular VMID might hold entries that depend on the effect of HCR_EL2.PTW. Therefore, if the value of HCR_EL2.PTW is changed without a change to the VMID value, all TLB entries associated with the current VMID must be invalidated before executing software at Non-secure EL1 or EL0. If this is not done, behavior is UNPREDICTABLE.

Atomicity of register changes on changing virtual machine

From the viewpoint of software executing at Non-secure EL1 or EL0, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for the Non-secure EL1&0 translation regime. This means that all of the following register must change atomically:

- The registers associated with the stage 1 translations:
  - MAIR_EL1 and AMAIR_EL1.
  - TTBR0_EL1, TTBR1_EL1, TCR_EL1, and CONTEXTIDR_EL1.
  - SCTLR_EL1.
- The registers associated with the stage 2 translations:
  - VTTBR_EL2 and VTCR_EL2.
  - MAIR_EL2 and AMAIR_EL2.
  - SCTLR_EL2.

Note

Only some bits of SCTLR_EL1 affect the stage1 translation, and only some bits of SCTLR_EL2 affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution using the Non-secure EL1&0 translation regime. However, when updated as part of a switch of virtual machines they are updated by software executing at EL2. This means the registers are *out of context* when they are updated, and no synchronization precautions are required.

The architecture requires that, when executing at EL3, EL2, or Secure EL1, an implementation must not use the registers associated with the Non-secure EL1&0 translation regime for speculative memory accesses.

D4.8 Caches in a VMSA implementation

The ARM architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

In particular, maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

- Summarizes the architectural requirements for the interaction between caches and address translation.
- Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

- *Data and unified caches*
- *Instruction caches*

In addition, *Cache maintenance requirement created by changing translation table attributes* on page D4-1746 describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance see *Cache maintenance instructions* on page D3-1608, that describes the cache maintenance instructions in the A64 instruction set.

D4.8.1 Data and unified caches

For data and unified caches, the use of address translation is entirely transparent to any data access that is not UNPREDICTABLE.

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

- Two writes to the same PA occur in program order.
- A read of a PA returns the value of the last successful write to that PA.
- A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance instructions.

In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses as *Physically-indexed, physically-tagged* (PIPT) caches.

D4.8.2 Instruction caches

In the ARM architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The ARM architecture supports three different behaviors for instruction caches. For ease of reference and description these are identified by descriptions of the associated expected implementation, as follows:

- PIPT instruction caches
- *Virtually-indexed, physically-tagged* (VIPT) instruction caches
- ASID and VMID tagged *Virtually-indexed, virtually-tagged* (VIVT) instruction caches.

The CTR_EL0.L1Ip field identifies the form of the instruction caches.

The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of address translation transparent to the instruction cache:

- *PIPT instruction caches*.
- *VIPT instruction caches*.
- *ASID and VMID tagged VIVT instruction caches*.
- *The IVIPT Extension* on page D4-1746.

Note

For software to be portable between implementations that might use any of PIPT instruction caches, VIPT instruction caches, or ASID and VMID tagged VIVT instruction caches, the software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

PIPT instruction caches

For PIPT instruction caches, the use of memory address translation is entirely transparent to all instruction fetches that are not UNPREDICTABLE.

If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IVIPT Extension, see *The IVIPT Extension* on page D4-1746.

VIPT instruction caches

For VIPT instruction caches, the use of memory address translation is transparent to all instruction fetches that are not UNPREDICTABLE, except for the effect of memory address translation on instruction cache invalidate by address operations.

Note

Cache invalidation is the only cache maintenance that can be performed on an instruction cache.

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the virtual address supplied with the operation. The effect of the invalidation might not be visible to any other aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a physical address from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IVIPT Extension, see *The IVIPT Extension* on page D4-1746.

ASID and VMID tagged VIVT instruction caches

For ASID and VMID tagged VIVT instruction caches, if the instructions at any virtual address change, for a given translation regime and a given ASID and VMID, as appropriate, then instruction cache maintenance is required to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

- Enabling or disabling the stage of address translation.
- Writing new mappings to the translation tables.

- Any change to the TCR or TTBR for the current translation regime:
  - For a change to the Secure EL1&0 translation regime, a change to the ContextID.
  - For a change to the stage 1 translations of the Non-secure EL1&0 translation regime, a change to the ContextID or VMID.
  - For a change to the stage 2 translations of the Non-secure EL1&0 translation regime, a change to the VMID.

Note

For ASID and VMID tagged VIVT instruction caches only, invalidation is not required if the changes to the translations are such that the instructions associated with the non-faulting translations of a virtual address, for a given translation regime and a given ASID and VMID, as appropriate, remain unchanged, through the sequence of changes to the translations. Examples of translation changes to which this applies are:

- Changing a valid translation to a translation that generates a stage of address translation fault.
- Changing a translation that generates a stage of address translation fault to a valid translation.

This does not apply for VIPT or PIPT instruction caches.

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the virtual address supplied with the operation. The effect of the invalidation might not be visible to any other aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a physical address from an ASID and VMID tagged VIVT instruction cache is to invalidate the entire instruction cache.

The IVIPT Extension

An implementation in which the instruction cache exhibits the behaviors described in *PIPT instruction caches* on page D4-1745, or those described in *VIPT instruction caches* on page D4-1745, is said to implement the *IVIPT Extension* to the ARM architecture.

The formal definition of the IVIPT Extension to the ARM architecture is that it reduces the instruction cache maintenance requirement to the following condition:

- Instruction cache maintenance is required only after writing new data to a physical address that holds an instruction.

D4.8.3 Cache maintenance requirement created by changing translation table attributes

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in *General TLB maintenance requirements* on page D4-1734. If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:

- Write-Back to Write-Through
- Write-Back to Non-cacheable
- Write-Through to Non-cacheable
- Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.

Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from them cache.
3. Change the shareability attributes to the required new values.

Chapter D5
The Performance Monitors Extension

This chapter describes the ARMv8 implementation of the ARM Performance Monitors, that are an optional non-invasive debug component. It describes version 3 of the *Performance Monitor Unit* (PMU) architecture, PMUv3. It contains the following sections:

Note

Table J-1 on page AppxJ-5170 disambiguates the general register references used in this chapter.

D5.1 About the Performance Monitors

In ARMv8-A, the Performance Monitors Extension is an OPTIONAL feature of an implementation, but ARM strongly recommends that ARMv8-A implementations include version 3 of the Performance Monitors Extension, PMUv3.

Note

No previous versions of the Performance Monitor Extension can be implemented in ARMv8.

The basic form of the Performance Monitors is:

- A 64-bit cycle counter.
- A number of 32-bit event counters. The event counted by each counter is programmable. ARMv8 provides space for up to 31 counters. The actual number of counters is IMPLEMENTATION DEFINED, and the specification includes an identification mechanism.

  Note

  ARM recommends that at least two counters are implemented, and that hypervisors provide at least this many counters to guest operating systems.

- Controls for:
  - Enabling and resetting counters.
  - Flagging overflows.
  - Enabling interrupts on overflow.

  Monitoring software can enable the cycle counter independently of the event counters.

The events that can be monitored split into:

- Architectural and microarchitectural events that are likely to be consistent across many microarchitectures.
- Implementation-specific events.

The PMU architecture uses event numbers to identify an event. It:

- Defines event numbers for common events, for use across many architectures and microarchitectures.

  Note

  Implementations that include PMUv3 must, as a minimum requirement, implement a subset of the common events. See *Common event numbers* on page D5-1765.

- Reserves a large event number space for IMPLEMENTATION DEFINED events.

The full set of events for an implementation is IMPLEMENTATION DEFINED. ARM recommends that implementations include all of the events that are appropriate to the architecture profile and microarchitecture of the implementation.

The event numbers of the common events are reserved for the specified events. Each of these event numbers must either:

- Be used for its assigned event.
- Not be used.

When a implementation supports monitoring of an event that is assigned a common event number, ARM strongly recommends that it uses that number for the event. However, software might encounter implementations where an event assigned a number in this range is monitored using an event number from the IMPLEMENTATION DEFINED range.

Note

ARM might define other common event numbers. This is one reason why software must not assume that an event with an assigned common event number is never monitored using an event number from the IMPLEMENTATION DEFINED range.

When an implementation includes the Performance Monitors Extension, ARMv8 defines the following possible interfaces to the Performance Monitors Extension registers:

- A system register interface. This interface is mandatory.
- An external debug interface which optionally supports memory-mapped accesses. This interface is OPTIONAL. See Chapter I2 *Recommended Memory-mapped Interfaces to the Performance Monitors*

An operating system can use the System registers to access the counters. This supports a number of uses, including:

- Dynamic compilation techniques.
- Energy management.

Also, if required, the operating system can enable application software to access the counters. This enables an application to monitor its own performance with fine-grain control without requiring operating system support. For example, an application might implement per-function performance monitoring.

There are many situations where performance monitoring features integrated into the implementation are valuable for applications and for application development. When an operating system does not use the Performance Monitors itself, ARM recommends that the operating system enables application software to access the Performance Monitors.

A hypervisor running on the PE can limit the access of a Non-secure operating system to the Performance Monitors.

To enable interaction with external monitoring, an implementation might consider additional enhancements, such as providing:

- A set of events, from which a selection can be exported onto a bus for use as external events.
- The ability to count external events. This enhancement requires the implementation to include a set of external event input signals.

The Performance Monitors Extension is common to AArch64 operation and AArch32 operation. This means the ARMv8 architecture defines both AArch64 and AArch32 system registers to access the Performance Monitors. For example, the Performance Monitors Cycle Count Register is accessible as:

- When executing in AArch64 state, PMCCNTR_EL0, see *PMCCNTR_EL0, Performance Monitors Cycle Count Register* on page D7-2048.
- When executing in AArch32 state, PMCCNTR, see *PMCCNTR, Performance Monitors Cycle Count Register* on page G5-4234.

D5.1.1 Interaction with trace

It is IMPLEMENTATION DEFINED whether the implementation exports counter events to a Trace extension, or other external monitoring agent, to provide triggering information. The form of any exporting is also IMPLEMENTATION DEFINED. If implemented, this exporting might be enabled as part of the performance monitoring control functionality.

ARM recommends system designers include a mechanism for importing a set of external events to be counted, but such a feature is IMPLEMENTATION DEFINED. When implemented, this feature enables the Trace extension to pass in events to be counted.

D5.1.2 Interaction with power saving operations

All counters are subject to any changes in clock frequency, including clock stopping caused by the `WFI` and `WFE` instructions.

D5.2 Accuracy of the Performance Monitors

The Performance Monitors:

- Are a non-invasive debug component. See *Non-invasive behavior*.
- Must provide approximately accurate count information.

However, the Performance Monitors allow for:

- A reasonable degree of inaccuracy in the counts to keep the implementation and validation cost low. See *A reasonable degree of inaccuracy*.
- A IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to put the PE in an operating state that might do one or both of the following;
  - Change the level of non-invasiveness of the Performance Monitors so that enabling an event counter can impact the performance or behavior of the PE.
  - Allow inaccurate counts. This includes, but is not limited to, cycle counts.

D5.2.1 Non-invasive behavior

The Performance Monitors are a non-invasive debug component. A non-invasive feature permits the observation of data and program flow.

Enabling an event counter must not severely alter the performance or behavior of the PE. Otherwise, the usefulness of event counters for performance measurement and profiling is reduced.

Because there is a software overhead to include use of the Performance Monitors, the overall performance is changed. As such, a small variation in performance from enabling an event counter is permissible. ARM recommends that such a variation is kept within 5% of normal operating performance, when averaged across a suite of code representative of the application workload, not including the software overhead.

If an implementation requires more performance-invasive techniques to count an event, ARM recommends that the implementer defines an IMPLEMENTATION DEFINED event, and documents the impact on behavior accordingly.

D5.2.2 A reasonable degree of inaccuracy

The Performance Monitors provide approximately accurate count information. To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the counts is acceptable. ARM does not define a *reasonable degree of inaccuracy* but recommends the following guidelines:

- Under normal operating conditions, the counters must present an accurate value of the count.
- In exceptional circumstances, such as a change in Security state or other boundary condition, it is acceptable for the count to be inaccurate.
- Under very unusual non-repeating pathological cases the counts can be inaccurate. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in the count is very unlikely.

Note

An implementation must not introduce inaccuracies that can be triggered systematically by the execution of normal pieces of software. For example, dropping a branch count in a loop due to the structure of the loop gives a systematic error that makes the count of branch behavior very inaccurate, and this is not reasonable. However, dropping a single branch count as the result of a rare interaction with an interrupt is acceptable.

The permitted inaccuracy limits the possible uses of the Performance Monitors. In particular, the architecture does not define the point in a pipeline where the event counter is incremented, relative to the point where a read of the event counters is made. This means that pipelining effects can cause some imprecision.

A change of Security state can affect the accuracy of the Performance Monitors, see *Interaction with EL3* on page D5-1755.

Entry to and exit from Debug state can also disturb the normal running of the PE, causing additional inaccuracy in the Performance Monitors. Disabling the counters while in Debug state limits the extent of this inaccuracy. An implementation can limit this inaccuracy to a greater extent, for example by disabling the counters as soon as possible during the Debug state entry sequence.

An implementation must document any particular scenarios where significant inaccuracies are expected.

D5.3 Behavior on overflow

All events are counted in 32-bit wrapping counters, that overflow when they wrap. The cycle counter, PMCCNTR, is a 64-bit wrapping counter, that is configured by PMCR.LC to either:

- Signal an overflow when bit PMCCNTR[63] overflows.
- Signal an overflow when bit PMCCNTR[31] overflows into bit PMCCNTR[32].

On a Performance Monitors counter overflow:

- An overflow status bit is set to 1. See PMOVSCLR.
- An interrupt request is generated if the PE is configured to generate counter overflow interrupts. For more information, see *Generating overflow interrupt requests*.
- The counter continues counting events.

D5.3.1 Generating overflow interrupt requests

Software can program the Performance Monitors so that an overflow interrupt request is generated when a counter overflows. See *PMINTENSET* on page AppxJ-5172 and *PMINTENCLR* on page AppxJ-5172.

The overflow interrupt request is a level-sensitive request.

Note

- The mechanism by which an interrupt request from the Performance Monitors generates an FIQ or IRQ exception is IMPLEMENTATION DEFINED.
- ARM recommends that the overflow interrupt requests:
  - Translate on to the **PMUIRQ** bus, so that they are observable to external devices.
  - Connect to inputs on an IMPLEMENTATION DEFINED generic interrupt controller of type, *Private Peripheral Interrupt* (PPI). See the *ARM Generic Interrupt Controller Architecture Specification* for information about PPIs.
  - Connect to a *Cross Trigger Interface* (CTI), see Chapter H5 *The Embedded Cross Trigger Interface*.

Counters overflow when counting one or more events generates an unsigned carry out. Software can write to the counters to control the frequency at which interrupt requests occur. For counters other than the cycle counter, the counter is always a 32-bit unsigned wrapping value. For example, software might set a counter to `0xFFFF0000`, to generate another counter overflow after 65536 increments, and reset it to this value every time an overflow interrupt occurs.

Note

If an event can occur multiple times in a single clock cycle then counter overflow can occur without the counter registering a value of zero.

For the cycle counter, software can program PMCR.LC to treat the counter as either a 64-bit or a 32-bit unsigned value.

The PE signals a request for:

- Any given PMN*x* counter, when the value of PMOVSSET[*x*] is 1, the value of PMINTENSET[*x*] is 1, and one of the following is true:
  - EL2 is not implemented and the value of PMCR.E is 1.
  - EL2 is implemented, x is less than the value of HDCR.HPMN, and the value of PMCR.E is 1.
  - EL2 is implemented, x is greater than or equal to the value of HDCR.HPMN, and the value of HDCR.HPME is 1.
- The cycle counter, when the values of PMOVSSET[31], PMINTENSET[31], and PMCR.E are all 1.

The overflow interrupt request is active in both Secure and Non-secure states. In particular, if EL3 and EL2 are implemented, overflow events from PMN*x* where *x* is greater than or equal to the value of HDCR.HPMN can be signaled from all modes and states but only if the value of HDCR.HPME is 1.

The interrupt handler for the counter overflow request must cancel the interrupt request, by writing to PMOVSCLR_EL0[*x*] to clear the overflow bit to 0.

D5.3.2 Pseudocode details overflow interrupt requests

The `CheckForPMUOverflow()` pseudocode function signals PMU overflow interrupt requests to an interrupt controller and PMU overflow trigger events to the cross-trigger interface. In AArch64 state, the pseudocode function is as follows:

```
// AArch64.CheckForPMUOverflow()
// =============================
// Signal Performance Monitors overflow IRQ and CTI overflow events

boolean AArch64.CheckForPMUOverflow()

    pmuirq = (PMCR_EL0.E == '1' && PMINTENSET_EL1<31> == '1' && PMOVSSET_EL0<31> == '1');
    for n = 0 to UInt(PMCR_EL0.N) - 1
        if HaveEL(EL2) then
            E = (if n < UInt(MDCR_EL2.HPMN) then PMCR_EL0.E else MDCR_EL2.HPME);
        else
            E = PMCR_EL0.E;
        if E == '1' && PMINTENSET_EL1<n> == '1' && PMOVSSET_EL0<n> == '1' then pmuirq = TRUE;

    SetInterruptRequestLevel(InterruptID_PMUIRQ, if pmuirq then HIGH else LOW);

    CTI_SetEventLevel(CrossTriggerIn_PMUOverflow, if pmuirq then HIGH else LOW);

    // The request remains set until the condition is cleared. (For example, an interrupt handler
    // or cross-triggered event handler clears the overflow status flag by writing to PMOVSCLR_EL0.)

    return pmuirq;
```

In AArch32 state, the function is as follows:

```
// AArch32.CheckForPMUOverflow()
// =============================
// Signal Performance Monitors overflow IRQ and CTI overflow events

boolean AArch32.CheckForPMUOverflow()

    if !ELUsingAArch32(EL1) then return AArch64.CheckForPMUOverflow();

    pmuirq = (PMCR.E == '1' && PMINTENSET<31> == '1' && PMOVSSET<31> == '1');
    for n = 0 to UInt(PMCR.N) - 1
        if HaveEL(EL2) then
            hpmn = if !ELUsingAArch32(EL2) then MDCR_EL2.HPMN else HDCR.HPMN;
            hpme = if !ELUsingAArch32(EL2) then MDCR_EL2.HPME else HDCR.HPME;
            E = (if n < UInt(hpmn) then PMCR.E else hpme);
        else
            E = PMCR.E;
        if E == '1' && PMINTENSET<n> == '1' && PMOVSSET<n> == '1' then pmuirq = TRUE;

    SetInterruptRequestLevel(InterruptID_PMUIRQ, if pmuirq then HIGH else LOW);

    CTI_SetEventLevel(CrossTriggerIn_PMUOverflow, if pmuirq then HIGH else LOW);

    // The request remains set until the condition is cleared. (For example, an interrupt handler
    // or cross-triggered event handler clears the overflow status flag by writing to PMOVSCLR_EL0.)

    return pmuirq;
```

D5.4 Attributability

An event caused by the PE counting the event is Attributable. If an agent other than the PE that is counting the events causes an event, these events are Unattributable.

An event is defined as being either Attributable or Unattributable. If the event is Attributable, it is further defined whether it is Attributable to:

- The current Security state of the PE.
- The current Exception level of the processor.
- When the PE is in Debug state, operations issued to the PE by the debugger through the external debug interface.

An event can be defined as the combination of multiple subevents, which can be either Attributable or Unattributable.

All architecturally defined events are Attributable.

Unattributable events might be counted when Attributable events are not counted. See:

- *Interaction with EL3* on page D5-1755.
- *Event filtering* on page D5-1757.
- *Performance Monitors and Debug state* on page D5-1758.

Table D5-1 Counting events

				Event type		
Counter and PMU enabled	**State**	**Allowed or prohibited**	**Filtered**	**If Attributable to:**	**Then**	**Else**
Yes	Non-debug	Allowed	Not filtered	X	Count	Count
			Filtered	Current EL	Do not count	IMPLEMENTATION DEFINED
		Prohibited	X	Current state	Do not count	IMPLEMENTATION DEFINED
	Debug	X	X	Debugger operations or raw cycles	Do not count	IMPLEMENTATION DEFINED
No	X	X	X	X	Do not count	Do not count

D5.5 Effect of EL3 and EL2

This section describes the effects of implementing EL3 and EL2 on the Performance Monitors. It contains the following subsections:

- *Interaction with EL3*.
- *Interaction with EL2* on page D5-1756.

D5.5.1 Interaction with EL3

Counting events is never prohibited in Non-secure state. From reset, counting Attributable events is prohibited in Secure state. Software can set SDCR.SPME to 1 to permit event counting in Secure state. This enables a Secure Monitor to permit profiling within Secure state without having to configure a debug authentication interface.

The system can use the external authentication interface to override SPME. For example, if **SPNIDEN** and **NIDEN** are HIGH then this permits event counting in Secure state, irrespective of the value in SDCR.SPME.

If EL3 is not implemented, the behavior is as if the value of SDCR.SPME is 1.

In summary, counting Attributable events in Secure state is prohibited unless any one of the following is true:

- EL3 is not implemented.
- EL3 is implemented and SDCR.SPME == 1.
- EL3 is implemented, EL3 or EL1 is using AArch32, executing at EL0, and the value of SDER.SUNIDEN is 1.
- EL3 is implemented, and counting is permitted by an IMPLEMENTATION DEFINED authentication interface, `ExternalSecureNoninvasiveDebugEnabled()` == TRUE.

  Note

  Software can read the Authentication Status register, DBGAUTHSTATUS, to determine the state of an IMPLEMENTATION DEFINED authentication interface.

The cycle counter, PMCCNTR, counts even when event counting is prohibited, unless PMCR.DP is set to 1 or the PE is in Debug state.

For each Unattributable event it is IMPLEMENTATION DEFINED whether it is counted when counting Attributable events is prohibited.

Note

- Additional controls in PMCR, HDCR, PMCNTENSET, and PMINTENCLR can also disable the event counters and the cycle counter.
- Controls in PMEVTYPER<n> and PMCCFILTR can filter out events based on Exception level and Security state.

This disabling of counters or filtering of events takes precedence over the authentication controls.

See `ProfilingProhibited()` and `CountEvents()` in the *Pseudocode details* on page D5-1780 for more details.

In AArch32 state, the Performance Monitors registers are Common registers, see *Classification of System registers* on page G4-3748.

The Performance Monitors registers are always accessible regardless of the values of the authentication signals and the SDER.SUNIDEN bit. Authentication controls whether the counters count events, it does not control access to the Performance Monitors registers.

The Performance Monitors are not intended to be completely accurate, see *Accuracy of the Performance Monitors* on page D5-1750. In particular, some inaccuracy is permitted at the point of changing Security state. However, to avoid the leaking of information from the Secure state, the permitted inaccuracy is that transactions that are not prohibited can be uncounted. Where possible, prohibited transactions must not be counted, but if they are counted, then that counting must not degrade security.

D5.5.2 Interaction with EL2

In an implementation that includes EL2, Non-secure software executing at EL2 can:

- Trap any attempt by the Guest OS to access the PMU. This means the hypervisor can identify which Guest OSs are using the PMU and intelligently employ switching of the PMU state.
- Trap accesses to the PMCR, so that it can fully virtualize the PMU identity registers, PMCR.IMP and PMCR.IDCODE.
- Reserve the highest-numbered counters for its own use by overriding the value of PMCR.N seen by the Guest OS. The implementation must not permit a Guest OS to access the reserved counters.

HDCR controls Performance Monitors virtualization.

For more information see:

- *Counter enables* on page D5-1759.
- *Counter access* on page D5-1760.

D5.6 Event filtering

The PMU can filter events by various combination of Exception level and Security state. This gives software more flexibility for counting events across multiple processes.

D5.6.1 Filtering by Exception level and state

For each event counter PMEVTYPER<n> specifies the Exception levels in which the counter counts Attributable events.

PMCCFILTR specifies the Exception levels in which the cycle counter counts.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether the filtering applies.

For more information, see the individual register descriptions.

D5.6.2 Accuracy of event filtering

The PMU architecture does not require event filtering to be accurate.

For most events, it is acceptable that, during a transition between states, events generated by instructions executed in one state are counted in the other state. The following sections describe the cases where event counts must not be counted in the wrong state:

- *Exception-related events*.
- *Software increment events*.

Exception-related events

The PMU must filter events related to exceptions and exception handling according to the Exception level from which the exception was taken. These events are:

- Exception taken.
- Instruction architecturally executed, condition code check pass, exception return.
- Instruction architecturally executed, condition code check pass, write to CONTEXTIDR.
- Instruction architecturally executed, condition code check pass, write to translation table base.

The PMU must not count an exception after it has been taken because this could systematically report a result of zero exceptions at EL0. Similarly, it is not acceptable for the PMU to count exception returns or writes to CONTEXTIDR after the return from the exception.

Note

Unprivileged software cannot write to CONTEXTIDR.

Software increment events

The PMU must filter software increment events according to the Exception level in which the software increment occurred. Software increment counting must also be precise, meaning the PMU must count every architecturally executed software increment event, and must not count any speculatively executed software increment.

Software increment events must also be counted without the need for explicit synchronization. For example, two software increments executed without an intervening context synchronization operation must increment the event counter twice.

Pseudocode details of event filtering

The pseudocode for the `CountEvents()` function can be found in *Pseudocode details* on page D5-1780.

D5.7 Performance Monitors and Debug state

Attributable events are not counted in Debug state.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when the counting processor is in Debug state. If the event might be counted, then the rules in *Filtering by Exception level and state* on page D5-1757 apply for the current Security state in Debug state.

D5.8 Counter enables

Table D5-2 shows an implementation that does not include EL2, and where the PMCR.E bit is a global counter enable bit, and PMCNTENSET provides an enable bit for each counter.

Table D5-2 Event counter enables when an implementation does not include EL2

PMCR.E	PMCNTENSET[x] == 0	PMCNTENSET[x] == 1
0	PMN*x* disabled	PMN*x* disabled
1	PMN*x* disabled	PMN*x* enabled

If the implementation includes EL2, then in addition to the PMCR.E and PMCNTENSET enable bits:

- HDCR.HPME overrides the value of PMCR.E for counters configured for access in Hyp mode.
- HDCR.HPMN specifies the number of performance counters that the Guest OS can access. The minimum permitted value of HDCR.HPMN is 1, meaning there must be at least one counter that the Guest OS can access.

Table D5-3 shows the combined effect of all the counter enable controls.

Table D5-3 Event counter enables when an implementation includes EL2

HDCR.HPME	PMCR.E	PMCNTENSET[x] == 0	PMCNTENSET[x] == 1	
			x < HDCR.HPMN	x ≥ HDCR.HPMN
0	0	PMN*x* disabled	PMN*x* disabled	PMN*x* disabled
0	1	PMN*x* disabled	PMN*x* enabled	PMN*x* disabled
1	0	PMN*x* disabled	PMN*x* disabled	PMN*x* enabled
1	1	PMN*x* disabled	PMN*x* enabled	PMN*x* enabled

Note

The effect of HDCR.{HPME, HPMN} on the counter enables applies in both Security states. However, in Secure state the value returned for PMCR.N is not affected by HDCR.HPMN.

EL2 does not affect the enabling of PMCCNTR. Table D5-4 shows the PMCCNTR enables, for all implementations.

Table D5-4 Cycle counter enables

PMCR.E	PMCNTENSET[31] == 0	PMCNTENSET[31] == 1
0	PMCCNTR disabled	PMCCNTR disabled
1	PMCCNTR disabled	PMCCNTR enabled

D5.9 Counter access

Counters are accessible in EL3, Secure EL1 and EL2. If software executing at EL2 uses HDCR.HPMN to reserve an event counter, software cannot access that counter from Non-secure EL1 modes or from Non-secure EL0.

Note

This section describes a counter as being accessible from a particular Exception level and state. However, access to the registers are subject to the access permissions described in *Access permissions* on page D5-1777. In particular, accesses from EL0 might be UNDEFINED and accesses from Non-secure EL1 and EL0 might be trapped to EL2.

D5.9.1 Access at EL0

Software can use PMUSERENR.{EN, ER, CR, SW} to enable code executing at EL0 to use the Performance Monitors. For more information, see *Traps to EL1 of EL0 accesses to Performance Monitors registers* on page D1-1466.

D5.9.2 PMN*x* event counters

For an implementation that includes EL2 and EL3, Table D5-5 shows how the values of the HDCR.HPMN field control the behavior of accesses to the PMN*x* event counter registers.

Note

Access to the Performance Monitors registers is also subject to the access permissions described in *Access permissions* on page D5-1777. In particular, accesses might be trapped to EL1 or EL2.

Table D5-5 Result of PMN*x* event counter accesses

Condition	Secure state			Non-secure state		
	EL3	EL1	EL0	EL2	EL1	EL0
x < HDCR.HPM	Succeeds	Succeeds	Succeeds	Succeeds	Succeeds	Succeeds
x ≥ HDCR.HPM	Succeeds	Succeeds	Succeeds	Succeeds	No access	No access

Where Table D5-5 shows no access:

- If PMSELR.SEL is *x* then:
  - A direct read of PMXEVTYPER or PMXEVCNTR is CONSTRAINED UNPREDICTABLE.
  - A direct write to PMXEVTYPER or PMXEVCNTR is CONSTRAINED UNPREDICTABLE.
- A direct read of PMEVTYPER<n> or PMEVCNTR<n> is CONSTRAINED UNPREDICTABLE.
- A direct write of PMEVTYPER<n> or PMEVCNTR<n> is CONSTRAINED UNPREDICTABLE.
- For direct reads and direct writes, PMOVSCLR[*x*], PMOVSSET[*x*], PMCNTENSET[*x*], PMCNTENCLR[*x*], PMINTENSET[*x*], and PMINTENCLR[*x*] are RAZ/WI
- Direct writes to PMSWINC[*x*] are ignored.
- A direct write of 1 to PMCR.P does not reset PMN*x*.

Note

In Secure state, and in the Non-secure EL2 mode, the value of HDCR2.HPMN does not affect the value returned for PMCR.N.

D5.9.3 CCNT cycle counter

The PMU does not provide any control that a hypervisor can use to reserve the cycle counter for its own use. The only control over the cycle counter is an access permission control for EL0. See *Access permissions* on page D5-1777.

D5.10 Event numbers and mnemonics

The following sections describe the event numbers, and the mnemonics for the events:

- *Definition of terms*.
- *Common event numbers* on page D5-1765.
- *Common architectural event numbers* on page D5-1766.
- *Common microarchitectural event numbers* on page D5-1769.
- *Required events* on page D5-1774.
- *IMPLEMENTATION DEFINED event numbers* on page D5-1775.

D5.10.1 Definition of terms

Speculatively executed

Many events relate to speculatively executed operations. Here, speculatively executed means the PE did some work associated with one or more instructions but the instructions were not necessarily architecturally executed.

An instruction might create one or more *microarchitectural operations* (µ-ops) at any point in the execution pipeline. For the purpose of event counting, the µ-ops are counted. The definition of a µ-op is implementation specific. An architecture instruction might create more than one µ-op for each instruction. µ-ops might also be removed or merged in the execution stream, so an architecture instruction might create no µ-ops for an instruction. Any arbitrary translation of instructions to an equivalent sequence of µ-ops is permitted.

This means there is no architecturally guaranteed relationship between a speculatively executed µ-op and an architecturally executed instruction. The results of such an operation can also be discarded, if it transpires that the operation was not required, such as a mispredicted branch. Therefore, ARMv8-A defines these events as *operation speculatively executed*, where appropriate.

The counting of operations can indicate the workload on the PE. However, there is no requirement for operations to represent similar amounts of work, and direct comparisons between different microarchitectures are not meaningful.

For example, an implementation might split an A32 or T32 `LDM` instruction of six registers into six µ-ops, one for each load, and a seventh address-generation operation to determine the base address or writeback address. Also, for doubleword alignment, the six load µ-ops might combine into four operations, that is, a word load, two doubleword loads, and a second word load. This single instruction can then be counted as five, or possibly six, events:

- Four (Operation speculatively executed - Load) events.
- One (Operation speculatively executed - Integer data processing) event.
- One (Operation speculatively executed - Software change of the PC) event, if the PC was one of the six registers in the `LDM` instruction.

Different groups of events can have different IMPLEMENTATION DEFINED definitions of speculatively executed. Such groups share a common base type, which the event name denotes. Each of the events in the previous example are of the base type, operation speculatively executed.

For groups of events with a common base type, speculatively executed operations are all counted on the same basis, which normally means at the same point in the pipeline. It is possible to compare the counts and make meaningful observations about the program being profiled.

Within these groups, events are commonly defined with reference to a particular architecture instruction or group of instructions. In the case of speculatively executed operations this means operations with semantics that map to that type of instruction.

Instruction memory access

A PE acquires instructions for execution through instruction fetches. Instruction fetches might be due to:

- Fetching instructions that are architecturally executed.
- The result of the execution of an instruction preload instruction, `PLI`.
- Speculation that a particular instruction might be executed in the future.

The relationship between the fetch of an individual instruction and an instruction memory access is IMPLEMENTATION DEFINED. For example, an implementation might fetch many instructions including a non-integer number of instructions in a single instruction memory access.

Memory-read operations

A PE accesses memory through memory-read and memory-write operations. A memory-read operation might be due to:

- The result of an architecturally executed memory-reading instructions.
- The result of a speculatively executed memory-reading instructions.
- A translation table walk.

For levels of cache hierarchy beyond the Level 1 caches, memory-read operations also include accesses made as part of a refill of another cache closer to the PE. Such refills might be due to:

- Memory-read operations or memory-write operations that miss in the cache
- The execution of a data preload instruction.
- The execution of an instruction preload instruction on a unified cache.
- The execution of a cache maintenance instruction.

  Note

  A preload instruction or cache maintenance instruction is not, in itself, an access to that cache. However, it might generate cache refills which are then treated as memory-read operations beyond that cache.

- Speculation that a future instruction might access the memory location.

This list is not exhaustive.

The relationship between memory-read instructions and memory-read operations is IMPLEMENTATION DEFINED. For example, for some implementations an `LDP` instruction that reads two 64-bit registers might generate one memory-read operation if the address is quadword-aligned, but for other addresses it generates two or more memory-read operations.

Memory-write operations

Memory-write operations might be due to:

- The result of an architecturally executed memory-writing instructions.
- The result of a speculatively executed memory-writing instructions.

Note

Speculatively executed memory-writing instructions that do not become architecturally executed must not alter the architecturally defined view of memory. They can, however, generate a memory-write operation that is later undone in some implementation specific way.

For levels of cache hierarchy beyond the Level 1 caches, memory-write operations also include accesses made as part of a write-back from another cache closer to the PE. Such write-backs might be due to:

- Evicting a dirty line from the cache, to allocate a cache line for a cache refill, see memory-read operations.
- The execution of a cache maintenance instruction.

  Note

  A cache maintenance instruction is not in itself an access to that cache. However, it might generate write-backs which are then treated as memory-write operations beyond that cache.

- The result of a coherency request from another PE.

This list is not exhaustive.

The relationship between memory-writing instructions and memory-write operations is IMPLEMENTATION DEFINED. For example, for some implementations an STP instruction that writes two 64-bit registers might generate one memory-write operation if the address is quadword-aligned, but for other addresses it generates two or more memory-write operations. In some implementations, the result of two STR instructions that write to adjacent memory might be merged into a single memory-write operation.

Note

The data written back from a cache that is shared with other PEs might not be data that was written by the PE that performs the operation that leads to the write-back. Nevertheless, the event is counted as a write-back event for that PE.

Instruction architecturally executed

Instruction architecturally executed is a class of event that counts for each instruction of the specified type. Architecturally executed means that the program flow is such that the counted instruction would be executed in a sequential execution of the program. Therefore an instruction that has been executed and retired is defined to be *architecturally executed*. When a PE can perform speculative execution, an instruction is not architecturally executed if the PE discards the results of the speculative execution.

Each architecturally executed instruction is counted once, even if the implementation splits the instruction into multiple operations.Instructions that have no visible effect on the architectural state of the PE are architecturally executed if they form part of the architecturally executed program flow. The point where such instructions are retired is IMPLEMENTATION DEFINED.

Examples of instructions that have no visible effect are:

- A NOP.
- A conditional instruction that fails its condition code check.
- A Compare and Branch on Zero, CBZ, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.

The point at which an event causes an event counter to be updated is not defined.

Unless otherwise stated, all instructions of the specified type are counted even if they have no visible effect on the architectural state of the PE. This includes a conditional instruction that fails its condition code check.

For events that count only the execution of instructions that update context state, such as writes to the CONTEXTIDR, if such an instruction is executed twice without an intervening context synchronization operation, it is CONSTRAINED UNPREDICTABLE whether the first instruction is counted.

Note

See *Context synchronization operation* for the definition of this term.

Instruction architecturally executed, condition code check pass

Instruction architecturally executed, condition code check pass is a class of events that explicitly do not occur for:

- A conditional instruction that fails its condition code check.
- A Compare and Branch on Zero, CBZ, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.
- A Test and Branch on Zero, TBZ, instruction that does not branch.
- A Test and Branch on Nonzero, TBNZ, instruction that does not branch.
- A Store-Exclusive instruction that does not write to memory.

Otherwise, the definition of architecturally executed is the same as for *Instruction architecturally executed*.

D5.10.2 Common event numbers

Table D5-6 lists the PMU architectural and microarchitectural event numbers in event number order.

Table D5-6 PMU event numbers

Event number	Event type	Event mnemonic	Description
0x000	Architectural	SW_INCR	Instruction architecturally executed, condition code check pass, software increment
0x001	Microarchitectural	L1I_CACHE_REFILL	Level 1 instruction cache refill
0x002	Microarchitectural	L1I_TLB_REFILL	Level 1 instruction TLB refill
0x003	Microarchitectural	L1D_CACHE_REFILL	Level 1 data cache refill
0x004	Microarchitectural	L1D_CACHE	Level 1 data cache access
0x005	Microarchitectural	L1D_TLB_REFILL	Level 1 data TLB refill
0x006	Architectural	LD_RETIRED	Instruction architecturally executed, condition code check pass, load
0x007	Architectural	ST_RETIRED	Instruction architecturally executed, condition code check pass, store
0x008	Architectural	INST_RETIRED	Instruction architecturally executed
0x009	Architectural	EXC_TAKEN	Exception taken
0x00A	Architectural	EXC_RETURN	Instruction architecturally executed, condition code check pass, exception return
0x00B	Architectural	CID_WRITE_RETIRED	Instruction architecturally executed, condition code check pass, write to CONTEXTIDR
0x00C	Architectural	PC_WRITE_RETIRED	Instruction architecturally executed, condition code check pass, software change of the PC
0x00D	Architectural	BR_IMMED_RETIRED	Instruction architecturally executed, immediate branch
0x00E	Architectural	BR_RETURN_RETIRED	Instruction architecturally executed, condition code check pass, procedure return
0x00F	Architectural	UNALIGNED_LDST_RETIRED	Instruction architecturally executed, condition code check pass, unaligned load or store
0x010	Microarchitectural	BR_MIS_PRED	Mispredicted or not predicted branch speculatively executed
0x011	Microarchitectural	CPU_CYCLES	Cycle
0x012	Microarchitectural	BR_PRED	Predictable branch speculatively executed
0x013	Microarchitectural	MEM_ACCESS	Data memory access
0x014	Microarchitectural	L1I_CACHE	Level 1 instruction cache access
0x015	Microarchitectural	L1D_CACHE_WB	Level 1 data cache write-back
0x016	Microarchitectural	L2D_CACHE	Level 2 data cache access
0x017	Microarchitectural	L2D_CACHE_REFILL	Level 2 data cache refill
0x018	Microarchitectural	L2D_CACHE_WB	Level 2 data cache write-back

Table D5-6 PMU event numbers (continued)

Event number	Event type	Event mnemonic	Description
0x019	Microarchitectural	BUS_ACCESS	Bus access
0x01A	Microarchitectural	MEMORY_ERROR	Local memory error
0x01B	Microarchitectural	INST_SPEC	Operation speculatively executed
0x01C	Architectural	TTBR_WRITE_RETIRED	Instruction architecturally executed, condition code check pass, write to TTBR
0x01D	Microarchitectural	BUS_CYCLES	Bus cycle
0x01E	Architectural	CHAIN	For odd-numbered counters, increments the count by one for each overflow of the preceding even-numbered counter. For even-numbered counters there is no increment.
0x01F	Microarchitectural	L1D_CACHE_ALLOCATE	Level 1 data cache allocation without refill
0x020	Microarchitectural	L2D_CACHE_ALLOCATE	Level 2 data cache allocation without refill

D5.10.3 Common architectural event numbers

This section describes the defined common architectural event numbers.

For the common features, normally the counters must increment only once for each event. The event descriptions include any exceptions to this rule.

In these definitions, the term *architecturally executed* means that the instruction flow is such that the counted instruction would have been executed in a simple sequential execution model.

The common architectural event numbers are:

0x000, Instruction architecturally executed, condition code check pass, software increment

The counter increments on writes to the PMSWINC register.

If the PE performs two architecturally executed writes to the PMSWINC register without an intervening context synchronization operation, then the event is counted twice.

0x006, Instruction architecturally executed, condition code check pass, load

The counter increments for every executed memory-reading instruction.

Note

Event 0x006 does not count the return status value of a Store-Exclusive instruction.

Whether the preload instructions PRFM, PLD, PLDW, PLI, count as memory-reading instructions is IMPLEMENTATION DEFINED. ARM recommends that if the instruction is not implemented as a NOP then it is counted as a memory-reading instruction.

0x007, Instruction architecturally executed, condition code check pass, store

The counter increments for every executed memory-writing instruction.

DC ZVA is counted as a store.

The counter does not increment for a Store-Exclusive instruction that fails.

0x008, Instruction architecturally executed

The counter increments for every architecturally executed instruction.

0x009, Exception taken

The counter increments for each exception taken. See *Exception-related events* on page D5-1757.

Note

The counter counts the PE exceptions described in:

- For exceptions taken to an Exception level using AArch64, *Exception entry* on page D1-1422.
- For exceptions taken to an Exception level using AArch32, *AArch32 state exception descriptions* on page G1-3428.

0x00A, Instruction architecturally executed, condition code check pass, exception return

The counter increments for each executed exception return instruction. See also *Exception-related events* on page D5-1757.The following sections define the counted instructions:

- For an exception return to an Exception level using AArch64, *Exception return* on page D1-1437.
- For an exception return to an Exception level using AArch32, *Exception return to an Exception level using AArch32* on page G1-3412.

0x00B, Instruction architecturally executed, condition code check pass, write to CONTEXTIDR

The counter increments for every write to CONTEXTIDR. See *Exception-related events* on page D5-1757.

In an AArch32 state translation regime, if TTBCR.EAE is 0, every write to CONTEXTIDR updates the ASID field. Therefore, this event can count the ASID field.

Note

The value of the TTBCR.EAE bit has no effect on this event.

If the PE performs two architecturally-executed writes to CONTEXTIDR without an intervening context synchronization operation, it is CONSTRAINED UNPREDICTABLE whether the first write is counted.

0x00C, Instruction architecturally executed, condition code check pass, software change of the PC

The counter increments for every software change of the PC. This includes all:

- Branch instructions.
- Memory-reading instructions that explicitly write to the PC.
- Data processing instructions that explicitly write to the PC.
- Exception return instructions, ERET and RET.

It is IMPLEMENTATION DEFINED whether the counter increments for any or all of:

- BRK and BKPT instructions.
- Undefined Instruction exceptions.
- The exception-generating instructions, SVC, HVC and SMC.

It is IMPLEMENTATION DEFINED whether an ISB is counted as a software change of the PC.

The counter does not increment for exceptions other than those explicitly identified in these lists.

Note

Conditional branches are only counted if the branch is taken.

0x00D, Instruction architecturally executed, immediate branch

The counter counts all immediate branch instructions that are architecturally executed.

In AArch32 state, the counter increments each time the PE executes one of the following instructions:

- `B <label>`.
- `BL <label>`.
- `BLX <label>`.
- `CBZ <Rn>, <label>`.
- `CBNZ <label>`.

In AArch64 state, the counter increments each time the PE executes an immediate branch instructions:

- `B <label>`.
- `B.cond <label>`.
- `BL <label>`.
- `CBZ <Rn>, <label>`.
- `CBNZ <Rn>, <label>`.
- `TBZ <Rn>, <label>`.
- `TBNZ <Rn>, <label>`.

Note

Conditional branches are always counted, regardless of whether the branch is taken.

If an `ISB` is counted as a software change of the PC instruction then it is IMPLEMENTATION DEFINED whether an `ISB` is counted as an immediate branch instruction.

`0x00E`, Instruction architecturally executed, condition code check pass, procedure return

In AArch 32 state, the counter counts the following procedure return instructions:

- `BX R14`.
- `MOV PC, LR`.
- `POP {…, PC}`.
- `LDR PC, [SP], #offset`.

Note

The counter counts only the listed instructions as procedure returns. For example, it does not count the following as procedure return instructions:

- `BX R0`, because Rm != R14.
- `MOV PC, R0`, because Rm != R14.
- `LDM SP, {…, PC}`, because writeback is not specified.
- `LDR PC, [SP, #offset]`, because this specifies the wrong addressing mode.

In AArch64 state, the counter counts all architecturally executed `RET` instructions.

`0x00F`, Instruction architecturally executed, condition code check pass, unaligned load or store

The counter counts each memory-reading instruction or memory-writing instruction that accesses an unaligned address. It is IMPLEMENTATION DEFINED whether this event also counts each Alignment fault Data Abort exception.

See *Unaligned data access* on page E2-2256 for more information.

`0x01C`, Instruction architecturally executed, condition code check pass, write to TTBR

The counter counts writes to TTBR0_EL1 and TTBR1_EL1 in AArch64 state and TTBR0 and TTBR1 in AArch32 state. See *Exception-related events* on page D5-1757.

In an AArch32 state translation regime, if the TTBCR.EAE bit is 1, this count includes all updates to the ASID field in the CONTEXTIDR.

Note

The value of the TTBCR.EAE bit has no effect on this event. If a count of the number of ASID updates is required, then this event and the Instruction architecturally executed condition code check pass, write to CONTEXTIDR event must be counted. Software can choose which event to monitor.

If the PE executes two writes to a TTBR, without an intervening context synchronization operation, it is CONSTRAINED UNPREDICTABLE whether the first write to the TTBR, is counted.

If EL3 is implemented and using AArch64, the counter does not count writes to TTBR0_EL3.

If EL3 is implemented and using AArch32, the counter counts writes to both Banked copies of TTBR0.

If EL2 is implemented and using AArch64, the counter does not count writes to TTBR0_EL2 and to VTTBR_EL2.

If EL 2 implemented and using AArch32, the counter does not count writes to HTTBR and to VTTBR.

`0x01E`**, Chain**

An odd-numbered counter increments when an overflow occurs on the preceding even-numbered counter. This event no effect on the count of an even-numbered counter.

The CHAIN event enables a system to provide either *N* 32-bit counters or *N*/2 64-bit counters. There is no atomic access to a pair of counters, so if software reads a counter-pair that is enabled, it must use a high-low-high read sequence or employ reasonable heuristics, to avoid tearing.

D5.10.4 Common microarchitectural event numbers

This section describes the defined common microarchitectural event numbers.

The common microarchitectural events are features that are likely to be implemented across a wide range of implementations. Unlike the common architectural events, there can be some IMPLEMENTATION DEFINED variation between definitions on different implementations.

Unless otherwise stated, the common microarchitectural features relate only to events resulting from the operation of the PE counting the events. Events resulting from the operation of other PEs that might share a resource must not be counted. Where a resource can be subject to events that do not result from the operation of any of the PEs that share it, ARM recommends that the resource implements its own event counters. An example of a resource that might require its own event counters is a shared Level 2 cache that is subject to accesses from a system coherency port on that cache.

The event definitions relating to Level 2 caches generally assume the Level 2 cache is shared. The event definitions relating to Level 1 caches generally assume the Level 1 cache is not shared.

The common microarchitectural event numbers are:

`0x001`**, Level 1 instruction cache refill**

The counter counts instruction memory accesses that cause a refill of at least the Level 1 instruction or unified cache. This includes each instruction memory access that causes a refill from outside the cache. It excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

CP15 cache maintenance instructions do not count as events.

0x002, Level 1 instruction TLB refill

The counter counts instruction memory accesses that cause a TLB refill of at least the Level 1 instruction TLB. This includes each instruction memory access that causes an access to a level of memory system due to a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- CP15 TLB maintenance instructions.

0x003, Level 1 data cache refill

The counter counts each memory-read operation or memory-write operation that causes a refill of at least the Level 1 data or unified cache from outside the Level 1 cache. Each access to a cache line that causes a new linefill is counted, including those from instructions that generate multiple accesses, such as load or store multiples, and PUSH and POP instructions. In particular, the counter counts accesses to the Level 1 cache that cause a refill that is satisfied by another Level 1 data or unified cache, or a Level 2 cache, or memory.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count:

- Accesses that do not cause a new Level 1 cache refill but are satisfied from refilling data of a previous miss.
- Accesses to a cache line that generate a memory access but not a new linefill, such as write-through writes that hit in the cache.
- CP15 cache maintenance instructions.
- A write that writes an entire line to the cache and does not fetch any data from outside the Level 1 cache, for example:
  - A write of a full cache line from a coalescing buffer.
  - A DC ZVA operation.
- A write that misses in the cache, and writes through the cache without allocating a line.

0x004, Level 1 data cache access

The counter counts each memory-read operation or memory-write operation that causes a cache access to at least the Level 1 data or unified cache. Each access to a cache line is counted including the multiple accesses of instructions, such as LDM or STM. Each access to other Level 1 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

CP15 cache maintenance instructions do not count as events.

0x005, Level 1 data TLB refill

The counter counts each memory-read operation or memory-write operation that causes a TLB refill of at least the Level 1 data or unified TLB. It counts each read or write that causes a refill, in the form of a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- CP15 TLB maintenance instructions.

0x010, Mispredicted or not predicted branch speculatively executed

The counter counts each correction to the predicted program flow that occurs because of a misprediction from, or no prediction from, the branch prediction resources and that relates to instructions that the branch prediction resources are capable of predicting.

If no program-flow prediction resources are implemented, ARM recommends that the counter counts all branches that are not taken.

0x011, Cycle The counter increments on every cycle.

All counters are subject to changes in clock frequency, including when a WFI or WFE instruction stops the clock. This means that it is CONSTRAINED UNPREDICTABLE whether or not CPU_CYCLES continues to increment when the clocks are stopped by WFI and WFE instructions.

Note

Unlike PMCCNTR, this count is not affected by PMCR.DP, PMCR.D, or PMCR.C:

- The counter is not incremented in prohibited regions, so is not affected by PMCR.DP.
- The counter increments on every cycle, regardless of the setting of PMCR.D.
- The counter is reset when event counters are reset by PMCR.P, never by PMCR.C.

0x012, Predictable branch speculatively executed

The counter counts every branch or other change in the program flow that the branch prediction resources are capable of predicting.

If all branches are subject to prediction, for example a BTB or BTAC, then all branches are predictable branches.

If branches are decoded before the predictor, so that the branch prediction logic dynamically predicts only some branches, for example conditional and indirect branches, then it is IMPLEMENTATION DEFINED whether other branches are counted as predictable branches. ARM recommends that all branches are counted.

An implementation might include other structures that predict branches, such as a loop buffer that predicts short backwards direct branches as taken. Each execution of such a branch is a predictable branch. Terminating the loop might generate a misprediction event that is counted by BR_MIS_PRED.

If no program-flow prediction resources are implemented, ARM recommends that BR_PRED counts all branches.

0x013, Data memory access

The counter counts memory-read or memory-write operations that the PE made. The counter increments whether the access results in an access to a Level 1 data or unified cache, a Level 2 data or unified cache, or neither of these.

The counter does not increment as a result of:

- Instruction memory accesses, see *Definition of terms* on page D5-1762.
- Translation table walks.
- CP15 cache maintenance instructions.
- Write-back from any cache.
- Refilling of any cache.

0x014, Level 1 instruction cache access

The counter counts instruction memory accesses that access at least the Level 1 instruction or unified cache. Each access to other Level 1 instruction memory structures, such as refill buffers, is also counted.

`0x015`**, Level 1 data cache write-back**

The counter counts every write-back of data from the Level 1 data or unified cache. The counter counts each write-back that causes data to be written from the Level 1 cache to outside of the Level 1 cache. For example, the counter counts the following cases:

- A write-back that causes data to be written to a Level 2 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 1 cache.
- Transfer of data from the Level 1 cache to outside of this cache made as a result of a coherency request. The conditions determining which of these are counted for transfers to other Level 1 caches within the same multiprocessor cluster are IMPLEMENTATION DEFINED.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

Whether this also includes write-backs made as a result of CP15 cache maintenance instructions is IMPLEMENTATION DEFINED.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 2 cache or memory.
- Writes from the PE that write through the Level 1 cache to outside of the Level 1 cache.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back.

If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted. See *Attributability* on page D5-1754.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a `DC ZVA` operation.

`0x016`**, Level 2 data cache access**

The counter counts memory-read or memory-write operations, that the PE made, that access at least the Level 2 data or unified cache. Each access to a cache line is counted including refills of and write-backs from the Level 1 data, instruction, or unified caches. Each access to other Level 2 data or unified memory structures, such as refill buffers, write buffers, and write-back buffers, is also counted.

The counter does not count:

- Operations made by other PEs that share this cache.
- CP15 cache maintenance instructions.

`0x017`**, Level 2 data cache refill**

The counter counts memory-read or memory-write operations, that the PE made, that access at least the Level 2 data or unified cache and cause a refill of a Level 1 data, instruction, or unified cache or of the Level 2 data or unified cache. Each read from or write to the cache that causes a refill from outside the Level 1 and Level 2 caches is counted.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 2 cache that cause a refill that is satisfied by another Level 2 cache, a Level 3 cache, or memory.
- Refills of and write-backs from any Level 1 data, instruction or unified cache that cause a refill from outside the Level 1 and Level 2 caches.
- Accesses to the Level 2 cache that cause a refill of a Level 1 cache from outside of the Level 1 and Level 2 caches, even if there is no refill of the Level 2 cache.

The counter does not count:

- Accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

- Accesses to the Level 2 cache that generate a memory access but not a new linefill, such as write-through writes that hit in the Level 2 cache.
- Accesses to the Level 2 cache that are part of a Level 1 cache refill or write-back that hit in the Level 2 cache so do not cause a refill from outside of the Level 1 and Level 2 caches.
- Operations made by other PEs that share this cache, as events on this PE.
- CP15 cache maintenance instructions.
- A write that writes an entire line to the cache and does not fetch any data from outside the Level 1 and Level 2 caches, for example:
  — A write-back from a Level 1 cache to a Level 2 cache.
  — A write from a coalescing buffer of a full cache line.
  — A `DC ZVA` operation.
- A write that misses in the cache, and writes through the cache without allocating a line.

`0x018`**, Level 2 data cache write-back**

The counter counts every write-back of data from the Level 2 data or unified cache that occurs as a result of an operation by this PE. It counts each write-back that causes data to be written from the Level 2 cache to outside the Level 1 and Level 2 caches. For example, the counter counts:

- A write-back that causes data to be written to a Level 3 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 2 cache.

Each write-back is counted once, even if it requires multiple accesses to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of data from the Level 2 cache to outside the Level 1 and Level 2 cache made as a result of a coherency request, but:
  — If the Level 2 cache is shared then the transfer is not counted because it is not caused by an operation by this PE.
  — If the Level 2 cache is not shared then the conditions that determine which of these transfers are counted, for transfers to other Level 2 caches within the same multiprocessor cluster, are IMPLEMENTATION DEFINED.
- Write-backs made as a result of CP15 cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 3 cache or memory.
- Writes from the PE or Level 1 data or unified cache that write through the Level 2 cache to outside the Level 1 and Level 2 caches.
- Transfers of data from the Level 2 cache to a Level 1 cache, to satisfy a Level 1 cache refill.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back.

If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted. See *Attributability* on page D5-1754.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a `DC ZVA` operation.

`0x019`**, Bus access**

The counter counts memory-read or memory-write operations that access outside of the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED. It must count accesses beyond the cache furthest from the PE for which accesses can be counted.

This means that:

- If Level 2 cache access events are implemented and no IMPLEMENTATION DEFINED events can count accesses for any caches outside a Level 2 cache, this counter increments for an access beyond the Level 2 cache.

- If Level 2 cache access events are not implemented and Level 1 cache access events are implemented, this counter increments for an access beyond the Level 1 cache.
- If neither Level 1 or Level 2 cache access events are implemented, this counter increments for all data accesses that the PE made.

The definition of a bus access is IMPLEMENTATION DEFINED but physically is a single beat rather than a burst. That is, for each bus cycle for which the bus is active.

Bus accesses include refills of and write-backs from Level 1 and Level 2 data, instruction, and unified caches. Whether bus accesses include operations that do use the bus but not explicitly transfer data, such as barrier operations, is IMPLEMENTATION DEFINED.

Where an implementation has multiple external buses, this event counts the sum of accesses across all buses.

If a bus supports multiple accesses per cycle, for example through multiple channels, the counter increments once for each channel that is active on a cycle, and so it might increment by more than one in any given cycle.

`0x01A`**, Local memory error**

The counter counts every occurrence of a memory error signaled by a memory closely coupled to this PE. The definition of local memories is IMPLEMENTATION DEFINED but includes caches, tightly-coupled memories, and TLB arrays.

Memory error refers to a physical error detected by the hardware, such as a parity error. It includes errors that are correctable and those that are not. It does not include errors as defined in the architecture, such as MMU faults.

`0x01B`**, Operation speculatively executed**

The counter counts instructions that are speculatively executed by the PE. This includes instructions that are subsequently not architecturally executed. As a result, this event counts a larger number of instructions than the number of instructions architecturally executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

`0x01D`**, Bus cycle**

The counter increments on every cycle of the external memory interface of the PE.

Note

If the implementation clocks the external memory interface at the same rate as the processor hardware, the counter counts every cycle.

`0x01F`**, Level 1 data cache allocation without refill**

The counter increments on every writes that writes an entire line into the Level 1 cache without fetching from outside the cache, for example:

- A write from a coalescing buffer of a full cache line.
- A `DC ZVA` operation.

`0x020`**, Level 2 data cache allocation without refill**

The counter increments on every writes that writes an entire line into the Level 2 cache without fetching from outside the Level 1 or Level 2 caches, for example:

- A write-back from a Level 1 to Level 2 cache.
- A write from a coalescing buffer of a full cache line.
- A `DC ZVA` operation.

D5.10.5 Required events

A implementation that includes PMUv3 must implement the following common events:

- `0x000`, Instruction architecturally executed, condition code check pass, software increment
- `0x003`, Level 1 data cache refill.

Note

Event 0x003 is only required if the implementation includes a Level 1 data or unified cache.

- 0x004, Level 1 data cache access.

Note

Event 0x004 is only required if the implementation includes a Level 1 data or unified cache.

- 0x010, Mispredicted or not predicted branch speculatively executed.

Note

Event 0x010 is only required if the implementation includes program-flow prediction.

- 0x011, Cycle.
- 0x012, Predictable branch speculatively executed.

Note

Event 0x012 is only required if the implementation includes program-flow prediction.

- At least one of:
  - 0x008, Instruction architecturally executed.
  - 0x01B, Operation speculatively executed.

Note

ARM recommends that events 0x008 and 0x01B are implemented.

D5.10.6 IMPLEMENTATION DEFINED event numbers

For IMPLEMENTATION DEFINED event numbers, each counter is defined, independently, to either:

- Increment only once for each event.
- Count the duration for which an event occurs.

ARM recommends that implementers establish a standardized numbering scheme for their IMPLEMENTATION DEFINED events, with common definitions, and common count numbers, applied to all of their implementations. In general, the recommended approach is for standardization across implementations with common features. However, ARM recognizes that attempting to standardize the encoding of microarchitectural features across too wide a range of implementations is not productive.

ARM strongly recommends that at least the following classes of event are identified in the IMPLEMENTATION DEFINED events:

- Cumulative duration of stalls resulting from the holes in the instruction availability, separating out counts for key buffering points that might exist.
- Cumulative duration data-dependent stalls, separating out counts for key dependency classes that might exist.
- Cumulative duration of stalls due to unavailability of execution resources, including, for example, write buffers, separating out counts for key resources that might exist.
- Missed superscalar issue opportunities, if relevant, separating out counts for key classes of issue that might exist.
- Miss rates for different levels of caches and TLBs.
- Any external events passed to the PE through an IMPLEMENTATION DEFINED mechanism.
- Cumulative durations:
  - For which the CPSR.I and CPSR.F interrupt mask bits are set to 1, in AArch32 state.

  - For which the PSTATE.I and PSTATE.F interrupt mask bits are set to 1, in AArch64 state.

- Any other microarchitectural features that the implementer considers are valuable to count.

The IMPLEMENTATION DEFINED event numbers are `0x040` to `0x3FF`. Appendix C *Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events* lists the ARM recommended standardized numbering scheme for these events.

D5.11 Performance Monitors Extension registers

The following section describes the Performance Monitors Extension registers.

The following subsections give general information about the Performance Monitors Extension registers, that apply for both Execution states:

- *Relationship between AArch32 and AArch64 Performance Monitors registers*.
- *Access permissions*.

Performance Monitors Extension registers, functional group on page G4-3798 summarizes the Performance Monitors Extension registers in AArch32 state, and shows the CP15 encodings of these registers.

Op0==0b11, Moves to and from non-debug System registers and special-purpose registers on page C5-243 summarized the Performance Monitors Extension in AArch64 state.

D5.11.1 Relationship between AArch32 and AArch64 Performance Monitors registers

Table J-2 on page AppxJ-5172 lists the Performance Monitors register names for AArch32 and AArch64 states.

D5.11.2 Access permissions

Each Exception level is able to control the system register accesses, to the Performance Monitors registers, at lower Exception levels. The access control flow is:

1. If at EL0:
   - Writes to PMUSERENR are unallocated.
   - Reads and writes of PMINTENSET and PMINTENCLR are unallocated.
   - PMUSERENR.EN == 0:
     - If PMUSERENR.SW == 0 then writes to PMSWINC are trapped to EL1.
     - If PMUSERENR.CR == 0 then reads of PMCCNTR are trapped to EL1.
     - If PMUSERENR.ER == 0 then reads of PMEVCNTR<n> and PMXEVCNTR, and reads and writes of PMSELR, are trapped to EL1.
     - Otherwise, for all other Performance Monitors registers, other than reads of PMUSERENR, reads and writes are trapped to EL1.

   Note

   If HCR.TGE==1, then all exceptions that would be taken to EL1 are instead taken to EL2.

2. Otherwise, at EL1 and EL0 in Non-secure state, if EL2 is implemented:
   - If HDCR.TPMCR == 1 then accesses to PMCR are trapped to EL2.
   - If HDCR.TPM == 1 then accesses to all Performance Monitors registers, including PMCR, are trapped to EL2.
3. Otherwise, at EL2, EL1 and EL0, if EL3 is implemented and using AArch64, and if MDCR_EL3.TPM == 1 then accesses to all Performance Monitors registers are trapped to EL3.

   Note

   These traps are not possible if EL3 is using AArch32.

4. Otherwise, the access is permitted.

Note

These traps and enables only apply to System register accesses using system register access instructions. For accesses through the optional memory-mapped or external debug interfaces, see *Access permissions for memory-mapped views of the Performance Monitors* on page I2-4684.

For details of the headings used in Table D5-7, see *Controls at higher Exception levels* on page D1-1459. In addition. the following terms are used:

Instruction This shows the access instruction, read (`MRS`), write (`MSR`), or both (-). In AArch32 state, the equivalent instructions are `MRC` and `MCR`.

Default access

If the *Default access* is - then the access is trapped from EL0 to EL1 unless the PMUSERENR *enables* are set to 1.

Resultant access permission

This indicates the resulting access permission provided the enables at EL0 are enabled and the traps to EL2 or EL3 are disabled.

Table D5-7 shows the access permissions for system register accesses to the Performance Monitor registers.

Table D5-7 Access permissions for the Performance Monitors system registers

Register	Instruction	At EL0:		Traps from below to:		Resultant access permission
		Default access	PMUSERENR enables	EL2	EL3[a]	
PMCR	-	-	EN	TPMCR or TPM	TPM	RW
PMCNTENSET	-	-	EN	TPM	TPM	RW
PMCNTENCLR	-	-	EN	TPM	TPM	RW
PMOVSCLR	-	-	EN	TPM	TPM	RW
PMSWINC	-	-	EN or SW	TPM	TPM	WO
PMSELR	-	-	EN or ER	TPM	TPM	RW
PMCEID0	-	-	EN	TPM	TPM	RO
PMCEID1	-	-	EN	TPM	TPM	RO
PMCCNTR	Read	-	EN or CR	TPM	TPM	RW
	Write	-	EN			
PMXEVTYPER	-	-	EN	TPM	TPM	RW
PMXEVCNTR	Read	-	EN or ER	TPM	TPM	RW
	Write	-	EN			
PMUSERENR	Read	RO	-	TPM	TPM	RW
	Write	UND				
PMINTENSET	-	UND	-	TPM	TPM	RW
PMINTENCLR	-	UND	-	TPM	TPM	RW
PMOVSSET	-	-	EN	TPM	TPM	RW

Table D5-7 Access permissions for the Performance Monitors system registers (continued)

Register	Instruction	At EL0: Default access	At EL0: PMUSERENR enables	Traps from below to: EL2	Traps from below to: EL3[a]	Resultant access permission
PMEVCNTR<n>	Read	-	EN or ER	TPM	TPM	RW
	Write	-	EN			
PMEVTYPER<n>	-	-	EN	TPM	TPM	RW
PMCCFILTR	-	-	EN	TPM	TPM	RW

a. Only if EL3 is using AArch64.

D5.12 Pseudocode details

In AArch64 state, the pseudocode function for ProfilingProhibited()is as follows:

```
// AArch64.ProfilingProhibited()
// =============================
// Determine whether Performance Monitors counting is prohibited in the current state.

boolean AArch64.ProfilingProhibited(boolean secure, bits(2) el)

    // Events are always counted in Non-secure state.
    if !secure then return FALSE;

    // Counting events in Secure state is prohibited unless any one of:
    // * EL3 is not implemented
    if !HaveEL(EL3) then return FALSE;

    // * EL3 is using AArch64 and MDCR_EL3.SPME == 1
    if MDCR_EL3.SPME == '1' then return FALSE;

    // * Allowed by the IMPLEMENTATION DEFINED authentication interface
    if ExternalSecureNoninvasiveDebugEnabled() then return FALSE;

    return TRUE;
```

In AArch32 state, the function is as follows:

```
// AArch32.ProfilingProhibited()
// =============================
// Determine whether Performance Monitors counting is prohibited in the current state.

boolean AArch32.ProfilingProhibited(boolean secure, bits(2) el)

    if (el == EL0 && !ELUsingAArch32(EL1)) || !ELUsingAArch32(el) then
        return AArch64.ProfilingProhibited(secure, el);

    // Events are always counted in Non-secure state.
    if !secure then return FALSE;

    // Counting events in Secure state is prohibited unless any one of:
    // * EL3 is not implemented
    if !HaveEL(EL3) then return FALSE;

    // * EL3 is using AArch64 and MDCR_EL3.SPME == 1
    // * EL3 is using AArch32 and SDCR.SPME == 1
    spme = (if ELUsingAArch32(EL3) then SDCR.SPME else MDCR_EL3.SPME);
    if spme == '1' then return FALSE;

    // * Allowed by the IMPLEMENTATION DEFINED authentication interface
    if ExternalSecureNoninvasiveDebugEnabled() then return FALSE;

    // * EL3 or EL1 is using AArch32, executing at EL0, and SDER.SUNIDEN == 1.
    if el == EL0 && ELUsingAArch32(EL1) && SDER.SUNIDEN == '1' then return FALSE;

    return TRUE;
```

The CountEvents() function returns TRUE if PMN*x* counts events in the current mode and state. In AArch64 state, the pseudocode function is as follows:

```
// AArch64.CountEvents()
// =====================

boolean AArch64.CountEvents(integer n)
    assert(n == 31 || n < UInt(PMCR_EL0.N));

    filter = (if n == 31 then PMCCFILTR_EL0<31:26> else PMEVTYPER_EL0[n]<31:26>);
```

```
    M = if !HaveEL(EL3) then '0' else (filter<5> EOR filter<0>);
    H = if !HaveEL(EL2) then '0' else filter<1>;
    P = filter<5>;  U = filter<4>;
    if !IsSecure() && HaveEL(EL3) then
        P = P EOR filter<3>;  U = U EOR filter<2>;

    prohibited = AArch64.ProfilingProhibited(TRUE, PSTATE.EL);
    if prohibited && n == 31 && PMCR_EL0.DP == '0' then prohibited = FALSE;

    if HaveEL(EL2) then
        E = (if n < UInt(MDCR_EL2.HPMN) then PMCR_EL0.E else MDCR_EL2.HPME);
    else
        E = PMCR_EL0.E;
    enabled = (E == '1' && PMCNTENSET_EL0<n> == '1');

    case PSTATE.EL of
        when EL0  filtered = U == '1';
        when EL1  filtered = P == '1';
        when EL2  filtered = H == '0';
        when EL3  filtered = M == '1';

    return !prohibited && !filtered && enabled && !Halted();
```

In AArch32 state, the function is as follows:

```
// AArch32.CountEvents()
// =====================

boolean AArch32.CountEvents(integer n)
    assert(n == 31 || n < UInt(PMCR.N));

    if !ELUsingAArch32(EL1) then return AArch64.CountEvents(n);

    filter = (if n == 31 then PMCCFILTR<31:26> else PMEVTYPER[n]<31:26>);

    M = if !HaveEL(EL3) then '0' else (filter<5> EOR filter<0>);
    H = if !HaveEL(EL2) then '0' else filter<1>;
    P = filter<5>;  U = filter<4>;
    if !IsSecure() && HaveEL(EL3) then
        P = P EOR filter<3>;  U = U EOR filter<2>;

    prohibited = AArch32.ProfilingProhibited(TRUE, PSTATE.EL);
    if prohibited && n == 31 && PMCR_EL0.DP == '0' then prohibited = FALSE;

    if HaveEL(EL2) then
        hpmn = if !ELUsingAArch32(EL2) then MDCR_EL2.HPMN else HDCR.HPMN;
        hpme = if !ELUsingAArch32(EL2) then MDCR_EL2.HPME else HDCR.HPME;
        E = (if n < UInt(hpmn) then PMCR.E else hpme);
    else
        E = PMCR.E;
    enabled = (E == '1' && PMCNTENSET<n> == '1');

    case PSTATE.EL of
        when EL0  filtered = U == '1';
        when EL1  filtered = P == '1';
        when EL2  filtered = H == '0';
        when EL3  filtered = M == '1';

    return !prohibited && !filtered && enabled && !Halted();
```

Chapter D6
The Generic Timer

This chapter describes the implementation of the ARM Generic Timer as an extension to an ARMv8 implementation. It includes the definition of the system control register interface to an ARM Generic Timer.

It contains the following sections:

- *About the Generic Timer* on page D6-1784.
- *About the Generic Timer registers* on page D6-1791.

Chapter I1 *System Level Implementation of the Generic Timer* describes the system level implementation of the Generic Timer.

D6.1 About the Generic Timer

Figure D6-1 shows an example system-on-chip that uses the Generic Timer as a system timer. In this figure:

- This manual defines the architecture of the individual PEs in the multiprocessor blocks.
- The *ARM Generic Interrupt Controller Architecture Specification* defines a possible architecture for the GICs.
- Generic Timer functionality is distributed across multiple components.

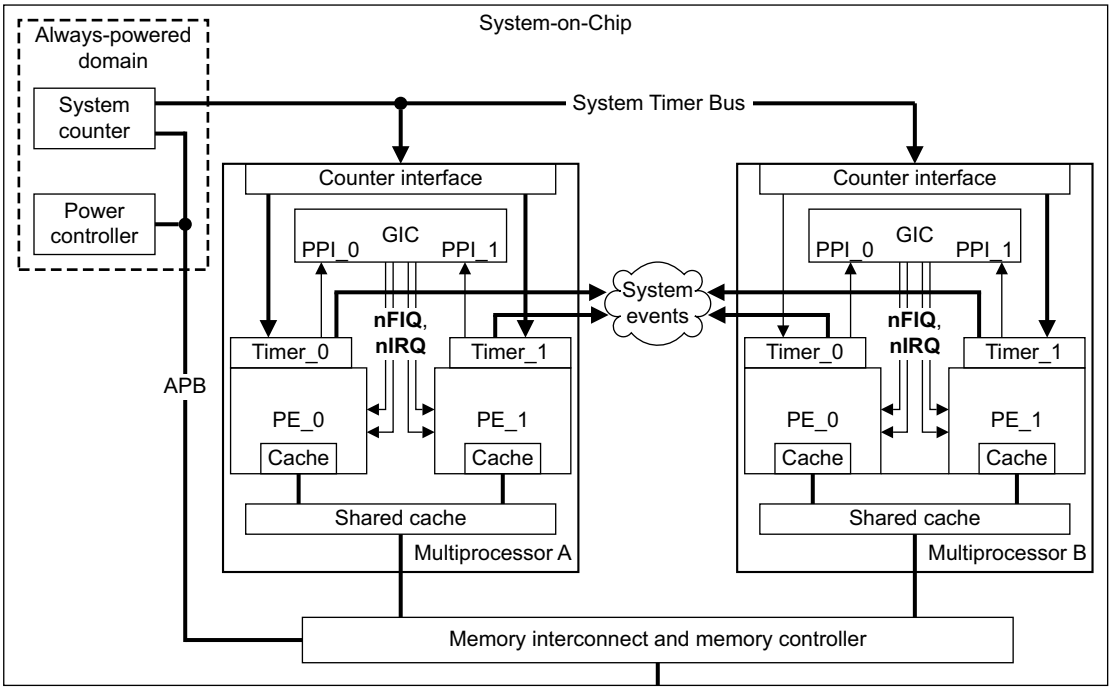

Figure D6-1 Generic Timer example

This chapter:

- Gives a general description of the Generic Timer.
- Defines the system control register interface to the Generic Timer. Each PE shown in Figure D6-1 includes an implementation of this interface.

The Generic Timer:

- Provides a system counter, that measures the passing of time in real-time.
- Supports *virtual counters* that measure the passing of virtual-time. That is, a virtual counter can measure the passing of time on a particular virtual machine.
- Timers, that can trigger events after a period of time has passed. The timers:
  - Can be used as count-up or as count-down timers.
  - Can operate in real-time or in virtual-time.

D6.1.1 System counter

The Generic Timer provides a system counter with the following specification:

Width At least 56 bits wide.
The value returned by any 64-bit read of the counter is zero-extended to 64 bits.

Frequency Increments at a fixed frequency, typically in the range 1-50MHz.
Can support one or more alternative operating modes in which it increments by larger amounts at a lower frequency, typically for power-saving.

Roll-over Roll-over time of not less than 40 years.

Accuracy ARM does not specify a required accuracy, but recommends that the counter does not gain or lose more than ten seconds in a 24-hour period.
Use of lower-frequency modes must not affect the implemented accuracy.

Start-up Starts operating from zero.

The system counter must provide a uniform view of system time. More precisely, it must be impossible for the following sequence of events to show system time going backwards:

1. Device A reads the time from the system counter.
2. Device A communicates with another agent in the system, Device B.
3. After recognizing the communication from Device A, Device B reads the time from the system counter.

The system counter must be implemented in an always-on power domain.

To support lower-power operating modes, the counter can increment by larger amounts at a lower frequency. For example, a 10MHz system counter might either increment either:

- By 1 at 10MHz.
- By 500 at 20KHz, when the system lowers the clock frequency, to reduce power consumption.

In this case, the counter must support transitions between high-frequency, high-precision operation, and lower-frequency, lower-precision operation, without any impact on the required accuracy of the counter.

Software can access the CNTFRQ register to read or modify the clock frequency of the system counter, see *Initializing and reading the system counter frequency*.

The mechanism by which the count from the system counter is distributed to system components is IMPLEMENTATION DEFINED, but each PE with a system control register interface to the system counter must have a counter input that can capture each increment of the counter.

Note

So that the system counter can be clocked independently from the PE hardware, the count value might be distributed using a Gray code sequence. *Gray-count scheme for timer distribution scheme* on page I1-4682 gives more information about this possibility.

Initializing and reading the system counter frequency

Typically, the system counter frequency is set, using the system control register interface, only during the system boot process. It is set by writing the system counter frequency to the CNTFRQ register. Only software executing at the highest Exception level implemented can write to CNTFRQ.

Note

The CNTFRQ register is UNKNOWN at reset, and therefore the counter frequency must be set as part of the system boot process.

Software can read the CNTFRQ register, to determine the current system counter frequency, in the following states and modes:

- Non-secure EL2 mode.
- Secure and Non-secure EL1 modes.
- When CNTKCTL.EL0PCTEN is set to 1, Secure and Non-secure EL0 modes.

Memory-mapped controls of the system counter

Some system counter controls are accessible only through the memory-mapped interface to the system counter. These controls are:

- Enabling and disabling the counter.
- Setting the counter value.
- Changing the operating mode, to change the update frequency and increment value.
- Enabling Halt-on-debug, that a debugger can then use to suspend counting.

For descriptions of these controls, see Chapter I1 *System Level Implementation of the Generic Timer*.

D6.1.2 The physical counter

The PE includes a physical counter that contains the count value of the system counter. The CNTPCT register holds the current physical counter value.

Accessing the physical counter

Software with sufficient privilege can read CNTPCT using a 64-bit system control register read.

In all implementations, CNTPCT:

- Is always accessible from Secure EL1 modes, and from Non-secure Hyp mode.
- Is accessible from Non-secure EL1 modes only when CNTHCTL.EL1PCTEN is set to 1. When CNTHCTL.EL1PCTEN is set to 0, any attempt to access CNTPCT from Non-secure EL1generates a Hyp Trap exception, see *Hyp Trap exception* on page G1-3430.

In addition, when CNTKCTL.EL0PCTEN is set to 1, if CNTPCT is accessible from EL1 in the current Security state then it is also accessible from EL0 in that Security state.

When CNTKCTL.EL0PCTEN is set to 0, any attempt to access CNTPCT from EL0is UNDEFINED.

In all implementations:

- The CNTKCTL control has priority over the CNTHCTL control. When both of the following apply, this means that an attempt to access CNTPCT from Non-secure EL0 is UNDEFINED:
  - CNTHCTL.EL1PCTEN is set to 0, to disable accesses from Non-secure EL1.
  - CNTKCTL.EL0PCTEN is set to 0, to disable accesses from EL0.
- When EL0 accesses are enabled, the CNTHCTL applies to Non-secure EL0 accesses. When both of the following apply, this means that an attempt to access CNTPCT from Non-secure EL0 generates a Hyp Trap exception:
  - CNTHCTL.EL1PCTEN is set to 0, to disable accesses from Non-secure EL1.
  - CNTKCTL.EL0PCTEN is set to 1, to enable accesses from EL0.

Reads of CNTPCT can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that CNTPCT must be read, an `ISB` must be used to ensure that the read of CNTPCT occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
    LDR R1, [R2]
    CMP R1, #1
```

```
    BNE loop
    ISB             ; without this, the CNTPCT could be read before the memory location in [R2]
                    ; has had the value 1 written to it
    MRS R1, CNTPCT
```

D6.1.3 The virtual counter

An implementation of the Generic Timer always includes a virtual counter, that indicates virtual time:

The virtual counter contains the value of the physical counter minus a 64-bit virtual offset. When executing in a Non-secure EL1 or EL0 mode, the virtual offset value relates to the current virtual machine.

The CNTVOFF register contains the virtual offset. CNTVOFF is only accessible from EL2, or from EL3 when SCR.NS is set to 1. See *Status of the CNTVOFF register* on page D6-1791 for more information.

The CNTVCT register holds the current virtual counter value.

Accessing the virtual counter

Software with sufficient privilege can read CNTVCT using a 64-bit system control register read.

CNTVCT is always accessible from Secure EL3, from Secure EL1 when EL3 is using AArch64, and from Non-secure EL1 and EL2.

In addition, when CNTKCTL.EL0VCTEN is set to 1, CNTVCT is accessible from EL0.

When CNTKCTL.EL0VCTEN is set to 0, any attempt to access CNTVCT from EL0 is UNDEFINED.

Reads of CNTVCT can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that CNTVCT must be read, an ISB must be used to ensure that the read of CNTVCT occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
    LDR R1, [R2]
    CMP R1, #1
    BNE loop
    ISB             ; without this, the CNTVCT could be read before the memory location in [R2]
                    ; has had the value 1 written to it
    MRS R1, CNTVCT
```

D6.1.4 Event streams

An implementation that includes the Generic Timer can use the system counter to generate one or more *event streams*, to generate periodic wake-up events as part of the mechanism described in *Wait for Event mechanism and Send event* on page D1-1503.

Note

An event stream might be used:

- To impose a time-out on a Wait For Event polling loop.
- To safeguard against any programming error that means an expected event is not generated.

An event stream is configured by:

- Selecting which bit, from the bottom 16 bits of a counter, triggers the event. This determines the frequency of the events in the stream.
- Selecting whether the event is generated on each 0 to 1 transition, or each 1 to 0 transition, of the selected counter bit.

The CNTKCTL.{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the virtual counter.

In all implementations the CNTHCTL.{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the physical counter.

The operation of an event stream is as follows:

- The pseudocode variables PreviousCNTVCT and PreviousCNTPCT are initialized as:

```
// Variables used for generation of the timer event stream.
bits(64) PreviousCNTVCT = bits(64) UNKNOWN;
bits(64) PreviousCNTPCT = bits(64) UNKNOWN;
```

- The pseudocode functions TestEventCNTV() and TestEventCNTP() are called on each cycle of the PE clock.
- The TestEventCNTx() pseudocode template defines the functions TestEventCNTV() and TestEventCNTP():

```
// TestEventCNTx()
// ===============

// Template for the TestEventCNTV() and TestEventCNTP() functions:
//   CNTxCT         is  CNTVCT          or  CNTPCT          64-bit count value
//   CNTxCTL        is  CNTVCTL         or  CNTPCTL         Control register
//   PreviousCNTxCT is  PreviousCNTVCT  or  PreviousCNTPCT

TestEventCNTx()
    if CNTxCTL.EVNTEN == '1' then
        n = UInt(CNTxCTL.EVNTI);
        SampleBit   = CNTxCT<n>;
        PreviousBit = PreviousCNTxCT<n>;

        if CNTxCTL.EVNTDIR == '0' then
            if PreviousBit == '0' && SampleBit == '1' then EventRegisterSet();
        else
            if PreviousBit == '1' && SampleBit == '0' then EventRegisterSet();

    PreviousCNTxCT = CNTxCT;

    return;
```

D6.1.5 Timers

The following timers are provided by an implementation of the Generic Timer Extension:

- A Non-secure EL1 physical timer.
- A Secure EL1 physical timer.
- A Non-secure EL2 physical timer.
- A virtual timer.

The output of each implemented timer:

- Provides an output signal to the system.
- If the PE interfaces to a *Generic Interrupt Controller* (GIC), signals a *Private Peripheral Interrupt* (PPI) to that GIC. In a multiprocessor implementation, each PE must use the same interrupt number for each timer.

Each timer is implemented as three registers:

- A 64-bit CompareValue register, that provides a 64-bit unsigned upcounter.
- A 32-bit TimerValue register, that provides a 32-bit signed downcounter.
- A 32-bit Control register.

In all implementations, the registers for the EL1 physical timer are Banked, to provide the Secure and Non-secure implementations of the timer. Table D6-1 shows the Timer registers.

Table D6-1 Timer registers summary for the Generic Timer

	EL1 physical timer[a]	EL2 physical timer	Virtual timer
CompareValue register	CNTP_CVAL	CNTHP_CVAL	CNTV_CVAL
TimerValue register	CNTP_TVAL	CNTHP_TVAL	CNTV_TVAL
Control register	CNTP_CTL	CNTHP_CTL	CNTV_CTL

a. In AArch32 state, the registers are Banked.

Table J-3 on page AppxJ-5172 disambiguates these general names to the AArch64 and AArch32 descriptions of these registers.

The following sections describe:

- *Accessing the timer registers*
- *Operation of the CompareValue views of the timers* on page D6-1790
- *Operation of the TimerValue views of the timers* on page D6-1790.

Accessing the timer registers

For each timer, all timer registers have the same access permissions, as follows:

EL1 physical timer Accessible from EL1 modes, except that Non-secure software executing at EL2 controls access from Non-secure EL1 modes.

When access from EL1 modes is permitted, CNTKCTL.EL0PTEN determines whether the registers are accessible from EL0 modes. If an access is not permitted because CNTKCTL.EL0PTEN is set to 0, an attempted access from EL0 is UNDEFINED.

In all implementations:

- Except for accesses from Monitor mode, accesses are to the registers for the current Security state.
- For accesses from Monitor mode, the value of SCR_EL3.NS determines whether accesses are to the Secure or the Non-secure registers.
- The Non-secure registers are accessible from Hyp mode.
- CNTHCTL.NSEL1TPEN determines whether the Non-secure registers are accessible from Non-secure EL1 modes. If this bit is set to 1, to enable access from Non-secure EL1 modes, CNTKCTL.EL0PTEN determines whether the registers are accessible from Non-secure EL0 modes.

  If an access is not permitted because CNTHCTL.NSEL1TPEN is set to 0, an attempted access from a Non-secure EL1 or EL0 mode generates a Hyp Trap exception. However, if CNTKCTL.EL0PTEN is set to 0, this control takes priority, and an attempted access from EL0 is UNDEFINED.

Virtual timer Accessible from Secure and Non-secure EL1 modes, and from Hyp mode.

CNTKCTL.EL0VTEN determines whether the registers are accessible from EL0 modes. If an access is not permitted because CNTKCTL.EL0VTEN is set to 0, an attempted access from an EL0 is UNDEFINED.

EL2 physical timer Accessible from Non-secure Hyp mode, and from Secure Monitor mode when SCR_EL3.NS is set to 1.

Operation of the CompareValue views of the timers

The CompareValue view of a timer operates as a 64-bit upcounter. The timer triggers when the appropriate counter reaches the value programmed into a CompareValue register. When the timer triggers, it generates an interrupt if the interrupt is enabled in the corresponding timer control register, CNTP_CTL, CNTHP_CTL, or CNTV_CTL.

The operation of this view of a timer is:

```
EventTriggered = (((Counter[63:0] - Offset[63:0])[63:0] - CompareValue[63:0]) >= 0)
```

Where:

`EventTriggered` Is TRUE if the event for this timer must be triggered, and FALSE otherwise.

`Counter` The physical counter value, that can be read from the CNTPCT register.

Note

The virtual counter value, that can be read from the CNTVCT register, is the value:

```
(Counter - Offset)
```

`Offset` For a physical timer it is zero, and for the virtual timer it is the virtual offset, held in the CNTVOFF register.

`CompareValue` The value of the appropriate CompareValue register, CNTP_CVAL, CNTHP_CTL, or CNTV_CVAL.

In this view of a timer, `Counter`, `Offset`, and `CompareValue` are all 64-bit unsigned values.

Note

This means that a timer with a `CompareValue` of, or close to, `0xFFFF_FFFF_FFFF_FFFF` might never trigger. However, there is no practical requirement to use values close to the counter wrap value.

Operation of the TimerValue views of the timers

The TimerValue view of a timer operates as a signed 32-bit downcounter. A TimerValue register is programmed with a count value. This value decrements on each increment of the appropriate counter, and the timer triggers when the value reaches zero. When the timer triggers, it generates an interrupt if the interrupt is enabled in the corresponding timer control register, CNTP_CTL, CNTHP_CTL, or CNTV_CTL.

This view of a timer depends on the following behavior of accesses to TimerValue registers:

Reads `TimerValue = (CompareValue - (Counter - Offset))[31:0]`

Writes `CompareValue = ((Counter - Offset)[63:0] + SignExtend(TimerValue))[63:0]`

Where the arguments have the definitions used in *Operation of the CompareValue views of the timers*, and in addition:

`TimerValue` The value of a TimerValue register, CNTP_TVAL, CNTHP_TVAL, or CNTV_TVAL.

The operation of this view of a timer is, effectively:

```
EventTriggered = (TimerValue ≤ 0)
```

In this view of a timer, all values are signed, in standard two's complement form.

After an event has triggered, a read of a TimerValue register indicates the time since the event triggered.

Note

Programming TimerValue to a negative number with magnitude greater than (Counter−Offset) can lead to an arithmetic overflow that causes the CompareValue to be an extremely large positive value. This potentially delays the resultant interrupt for an extremely long period of time.

D6.2 About the Generic Timer registers

This chapter uses general names to refer to the Generic Timer registers. Table J-3 on page AppxJ-5172 disambiguates these general names to either the AArch64 System registers or the AArch32 System registers.

D6.2.1 Status of the CNTVOFF register

All implementations of the Generic Timer extension include the virtual counter. Therefore, conceptually, all implementations include the CNTVOFF register that defines the *virtual offset* between the physical count and the virtual count. CNTVOFF is only accessible at EL2 or above. If EL2 is not implemented, the virtual counter uses a fixed virtual offset of zero.

Chapter D7
AArch64 System Register Descriptions

This chapter defines the AArch64 System registers. It contains the following sections:

D7.1 About the AArch64 System registers

This section describes common features of the AArch64 registers.

D7.1.1 Fixed values in the System register descriptions

See *Fixed values in instruction and register descriptions* on page C5-232. This section defines how the glossary terms RAZ, RES0, RAO, and RES1 can be represented in the System register descriptions,

D7.1.2 General behavior of accesses to the System registers

This section gives general information about the behavior of accesses to the System registers.

Synchronization requirements for System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that any data dependencies between the instructions are respected.

Note

In particular, system registers that hold self-incrementing counts such as the performance counters or the Generic Timer counter or timers, can be read early. For example, where a memory access is used to communicate a read of such counters, an `ISB` must be inserted between the read of the memory location and the read of the Generic Timer counter, where it is necessary that the Generic Timer counter returns a count value after the memory communication.

Direct writes using the instructions in Table C5-6 on page C5-244 require synchronization before software can rely on the effects of changes to the system registers to affect instructions appearing in program order after the direct write to the system register. Direct writes to these registers are not allowed to affect any instructions appearing in program order before the direct write. The only exceptions are:

- All direct writes to the same register, that use the same encoding for that register, are guaranteed to occur in program order relative to each other
- All direct writes to a register occur in program order with respect to all direct reads to the same register using the same encoding.

Explicit synchronization occurs as a result a *Context synchronization operation*, which is of one of the following events:

- Execution of an `ISB` instruction.
- Exception entry.
- Exception return.
- Execution of a `DCPS` instruction in Debug state.
- Execution of a `DRPS` instruction in Debug state.
- Exit from Debug state.

Note

The `ISB`, exception entry, or exception return events are applicable either in Debug state or not in Debug state.

Conceptually, explicit synchronization occurs as the first step of each of these events, so that if the event uses state that has previously been changed but was not synchronized by the time of the event, the event is guaranteed to use the state as if it had been synchronized.

Note

This explicit synchronization applies as the first step of the execution of the events, and does not apply to any effect of system registers that apply to the fetch and decode of the instructions that cause these events, such as breakpoints or changes to the translation table.

In addition, any system instructions that cause a write to a system register must be synchronized before the result is guaranteed to be visible to subsequent direct reads of that system register.

Direct reads to any one of the following registers, using the same encoding, occur in program order relative to each other:

- ISR_EL1
- The Generic Timer registers, that is, CNTPCT_EL0 and CNTVCT_EL0, and the Counter registers CNTP_TVAL_EL0, CNTV_TVAL_EL0, CNTHP_TVAL_EL2, and CNTPS_TVAL_EL1.
- DBGCLAIMCLR_EL1.
- The PMU Counters, that is, PMCCNTR_EL0, PMEVCNTR<n>_EL0, PMXEVCNTR_EL0, PMOVSCLR_EL0, and PMOVSSET_EL0.
- The Debug Communications Channel registers, that is, DBGDTRTX_EL0, DBGDTRRX_EL0, DBGDTR_EL0, MDCCSR_EL0 or EDSCR.

All other direct reads of system registers can occur in any order if synchronization has not been performed.

Table D7-1 describes the synchronization requirements between two successive read/write accesses to the same register, where the ordering of the read/write is:

1. Program order, in the event that the read or write is caused by an instruction executed on this PE, other than one caused by a memory access by this PE.
2. The order of arrival of asynchronous reads and writes by the PE relative to the execution of instructions.

Table D7-1 Synchronization requirements

First read-write	Second read-write	Synchronization requirement
Direct read	Direct read	None
	Direct write	None
	Indirect read	None
	Indirect write	None, see *Notes* on page D7-1796
Direct write	Direct read	None
	Direct write	None
	Indirect read	Required
	Indirect write	None, see *Notes* on page D7-1796
Indirect read	Direct read	None
	Direct write	None
	Indirect read	None
	Indirect write	None
Indirect write	Direct read	Required, see *Notes* on page D7-1796
	Direct write	None, see *Notes* on page D7-1796
	Indirect read	Required, see *Notes* on page D7-1796
	Indirect write	None, see *Notes* on page D7-1796

Notes

In Table D7-1 on page D7-1795:

Direct read Where software uses a system register access instruction to read the register, see *Instructions for accessing non-debug System registers* on page C5-243. Where a direct read of a register has a side-effect that changes the contents of a register, the effect of a direct read on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to have occurred, and be visible to subsequent direct or indirect reads or writes, if synchronization is performed after the direct read.

Direct write Where software uses a system register access instruction to write to the register, see *Instructions for accessing non-debug System registers* on page C5-243. Where a direct write to a register has an effect on the register that means that the value in the register is not always the last value that is written (as is the case with set and clear registers), the effect of a direct write on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Indirect read Where an instruction uses a system register to establish operating conditions, for example, translation table base register addresses or whether the cache is enabled, for the instruction. This includes situations where the contents of one system register selects what value is read using a different register. Indirect reads also include reads of the system register by external agents such as debuggers. Where an indirect read of a register has a side-effect that changes the contents of that register, that is defined to be an indirect write.

Indirect write Where a system register is written as the consequence of some other instruction, exception, operation, or by the asynchronous operation of such some external agent, including the passage of time as seen in counters, timers, or performance counters, the assertion of interrupts, or writes from an external debugger.

Note

Since an exception is context synchronizing, registers such as the Exception Syndrome registers that are indirectly written as part of exception entry do not require additional synchronization.

Where a direct read or write to a register is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two accesses.

Where an indirect write caused by a direct write is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two indirect accesses.

Where a direct read to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated, the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct read and before the subsequent direct or indirect reads or writes.

Where a direct write to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated as a side-effect of that direct write (as opposed to simply being a direct write to the different encoding), the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Where indirect writes are caused by the actions of external agents such as debuggers, or by memory-mapped reads or writes by the PE, then an indirect write by that agent and mechanism to a register, followed by an indirect read by that agent and mechanism to the same register using the same address, does not require synchronization.

Indirect writes to the following registers caused by external agents, autonomous asynchronous events, or as a result of memory-mapped writes, are required to be observable to:

- Direct reads in finite time without explicit synchronization.
- Subsequent indirect reads without explicit synchronization:
  - ISR_EL1.
  - The Generic Timer registers, that is, CNTPCT_EL0 and CNTVCT_EL0, and the Counter registers CNTP_TVAL_EL0, CNTV_TVAL_EL0, CNTHP_TVAL_EL2, and CNTPS_TVAL_EL1.
  - The debug claim registers, DBGCLAIMCLR_EL1 and DBGCLAIMSET_EL1.
  - The PMU Counters, that is, PMCCNTR_EL0, PMEVCNTR<n>_EL0, PMXEVCNTR_EL0, PMOVSCLR_EL0, and PMOVSSET_EL0.
  - The Debug Communications Channel registers, that is, DBGDTRTX_EL0, DBGDTRRX_EL0, DBGDTR_EL0, MDCCSR_EL0 or EDSCR.

Note

- The provision of explicit synchronization requirements to system registers is provided to allow the direct access to these registers to be implemented in a small number of cycles, and that updates to multiple registers can be performed quickly with the synchronization penalty being paid only when the updates have occurred.
- Since toolkits might use registers such as the thread-local storage registers within compiled code, it is recommended that access to these registers is implemented to take a small number of cycles.
- While no synchronization is required between a direct write and a direct read, or between a direct read and an indirect write, this does not imply that a direct read causes synchronization of a previous direct write. That is, the sequence direct write → direct read → indirect read, with no intervening context synchronization, does not guarantee that the indirect read observes the result of the direct write.

D7.2 General system control registers

This section lists the system control registers in AArch64 that are not part of one of the other listed groups.

D7.2.1 ACTLR_EL1, Auxiliary Control Register (EL1)

The ACTLR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for EL1.

This register is part of:

- the Other system control registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

ACTLR_EL1 is architecturally mapped to AArch32 register ACTLR (NS).

Attributes

ACTLR_EL1 is a 32-bit register.

Field descriptions

The ACTLR_EL1 bit assignments are:

Accessing the ACTLR_EL1

To access the ACTLR_EL1:

```
MRS <Xt>, ACTLR_EL1 ; Read ACTLR_EL1 into Xt
MSR ACTLR_EL1, <Xt> ; Write Xt to ACTLR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0001	0000	001

D7.2.2 ACTLR_EL2, Auxiliary Control Register (EL2)

The ACTLR_EL2 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for EL2.

This register is part of:

- the Virtualization registers functional group
- the Other system control registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

ACTLR_EL2 is architecturally mapped to AArch32 register HACTLR.

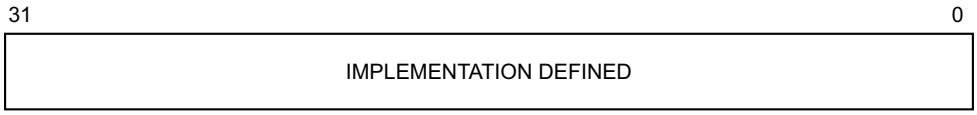
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

ACTLR_EL2 is a 32-bit register.

Field descriptions

The ACTLR_EL2 bit assignments are:



Accessing the ACTLR_EL2

To access the ACTLR_EL2:

```
MRS <Xt>, ACTLR_EL2 ; Read ACTLR_EL2 into Xt
MSR ACTLR_EL2, <Xt> ; Write Xt to ACTLR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0001	0000	001

D7.2.3 ACTLR_EL3, Auxiliary Control Register (EL3)

The ACTLR_EL3 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for EL3.

This register is part of:

- the Other system control registers functional group
- the Security registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

ACTLR_EL3 can be mapped to AArch32 register ACTLR (S), but this is not architecturally mandated.

Attributes

ACTLR_EL3 is a 32-bit register.

Field descriptions

The ACTLR_EL3 bit assignments are:

Accessing the ACTLR_EL3

To access the ACTLR_EL3:

```
MRS <Xt>, ACTLR_EL3 ; Read ACTLR_EL3 into Xt
MSR ACTLR_EL3, <Xt> ; Write Xt to ACTLR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0001	0000	001

D7.2.4 AFSR0_EL1, Auxiliary Fault Status Register 0 (EL1)

The AFSR0_EL1 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

This register is part of:

- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

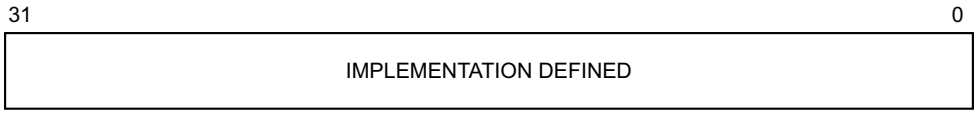
AFSR0_EL1 is architecturally mapped to AArch32 register ADFSR (NS).

Attributes

AFSR0_EL1 is a 32-bit register.

Field descriptions

The AFSR0_EL1 bit assignments are:



Accessing the AFSR0_EL1

To access the AFSR0_EL1:

```
MRS <Xt>, AFSR0_EL1 ; Read AFSR0_EL1 into Xt
MSR AFSR0_EL1, <Xt> ; Write Xt to AFSR0_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0101	0001	000

D7.2.5 AFSR0_EL2, Auxiliary Fault Status Register 0 (EL2)

The AFSR0_EL2 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

AFSR0_EL2 is architecturally mapped to AArch32 register HADFSR.

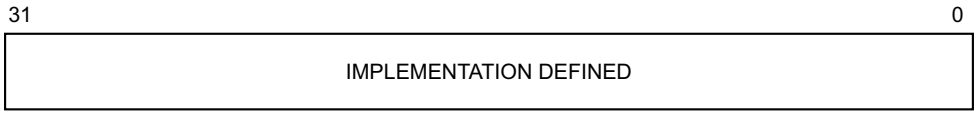
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

AFSR0_EL2 is a 32-bit register.

Field descriptions

The AFSR0_EL2 bit assignments are:



Accessing the AFSR0_EL2

To access the AFSR0_EL2:

```
MRS <Xt>, AFSR0_EL2 ; Read AFSR0_EL2 into Xt
MSR AFSR0_EL2, <Xt> ; Write Xt to AFSR0_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0101	0001	000

D7.2.6 AFSR0_EL3, Auxiliary Fault Status Register 0 (EL3)

The AFSR0_EL3 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL3.

This register is part of:

- the Exception and fault handling registers functional group
- the Security registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

AFSR0_EL3 can be mapped to AArch32 register ADFSR (S), but this is not architecturally mandated.

Attributes

AFSR0_EL3 is a 32-bit register.

Field descriptions

The AFSR0_EL3 bit assignments are:

Accessing the AFSR0_EL3

To access the AFSR0_EL3:

```
MRS <Xt>, AFSR0_EL3 ; Read AFSR0_EL3 into Xt
MSR AFSR0_EL3, <Xt> ; Write Xt to AFSR0_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0101	0001	000

D7.2.7 AFSR1_EL1, Auxiliary Fault Status Register 1 (EL1)

The AFSR1_EL1 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

This register is part of:

- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

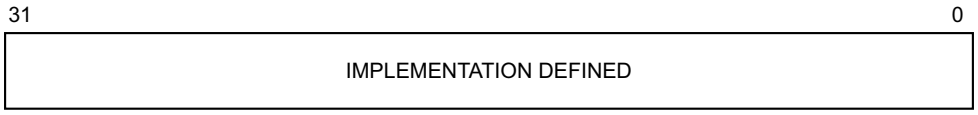
AFSR1_EL1 is architecturally mapped to AArch32 register AIFSR (NS).

Attributes

AFSR1_EL1 is a 32-bit register.

Field descriptions

The AFSR1_EL1 bit assignments are:



Accessing the AFSR1_EL1

To access the AFSR1_EL1:

```
MRS <Xt>, AFSR1_EL1 ; Read AFSR1_EL1 into Xt
MSR AFSR1_EL1, <Xt> ; Write Xt to AFSR1_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0101	0001	001

D7.2.8 AFSR1_EL2, Auxiliary Fault Status Register 1 (EL2)

The AFSR1_EL2 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

AFSR1_EL2 is architecturally mapped to AArch32 register HAIFSR.

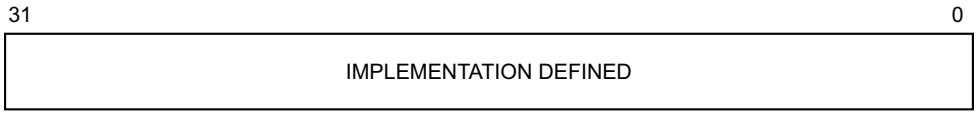
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

AFSR1_EL2 is a 32-bit register.

Field descriptions

The AFSR1_EL2 bit assignments are:



Accessing the AFSR1_EL2

To access the AFSR1_EL2:

```
MRS <Xt>, AFSR1_EL2 ; Read AFSR1_EL2 into Xt
MSR AFSR1_EL2, <Xt> ; Write Xt to AFSR1_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0101	0001	001

D7.2.9 AFSR1_EL3, Auxiliary Fault Status Register 1 (EL3)

The AFSR1_EL3 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL3.

This register is part of:

- the Exception and fault handling registers functional group
- the Security registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

AFSR1_EL3 can be mapped to AArch32 register AIFSR (S), but this is not architecturally mandated.

Attributes

AFSR1_EL3 is a 32-bit register.

Field descriptions

The AFSR1_EL3 bit assignments are:

Accessing the AFSR1_EL3

To access the AFSR1_EL3:

```
MRS <Xt>, AFSR1_EL3 ; Read AFSR1_EL3 into Xt
MSR AFSR1_EL3, <Xt> ; Write Xt to AFSR1_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0101	0001	001

D7.2.10 AIDR_EL1, Auxiliary ID Register

The AIDR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED identification information.

This register is part of:

- the Identification registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

The value of this register must be interpreted in conjunction with the value of MIDR_EL1.

Configurations

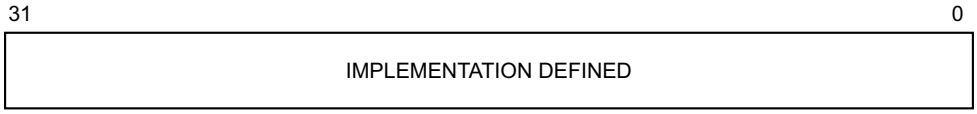
AIDR_EL1 is architecturally mapped to AArch32 register AIDR.

Attributes

AIDR_EL1 is a 32-bit register.

Field descriptions

The AIDR_EL1 bit assignments are:



Bits [31:0]

IMPLEMENTATION DEFINED

Accessing the AIDR_EL1

To access the AIDR_EL1:

```
MRS <Xt>, AIDR_EL1 ; Read AIDR_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	001	0000	0000	111

D7.2.11 AMAIR_EL1, Auxiliary Memory Attribute Indirection Register (EL1)

The AMAIR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL1.

This register is part of:

- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

AMAIR_EL1 is permitted to be cached in a TLB.

Configurations

AMAIR_EL1[31:0] is architecturally mapped to AArch32 register AMAIR0 (NS).

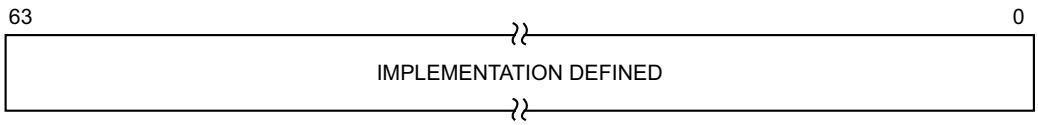
AMAIR_EL1[63:32] is architecturally mapped to AArch32 register AMAIR1 (NS).

Attributes

AMAIR_EL1 is a 64-bit register.

Field descriptions

The AMAIR_EL1 bit assignments are:



Accessing the AMAIR_EL1

To access the AMAIR_EL1:

```
MRS <Xt>, AMAIR_EL1 ; Read AMAIR_EL1 into Xt
MSR AMAIR_EL1, <Xt> ; Write Xt to AMAIR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1010	0011	000

D7.2.12 AMAIR_EL2, Auxiliary Memory Attribute Indirection Register (EL2)

The AMAIR_EL2 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL2.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

AMAIR_EL2 is permitted to be cached in a TLB.

Configurations

AMAIR_EL2[31:0] is architecturally mapped to AArch32 register HAMAIR0.

AMAIR_EL2[63:32] is architecturally mapped to AArch32 register HAMAIR1.

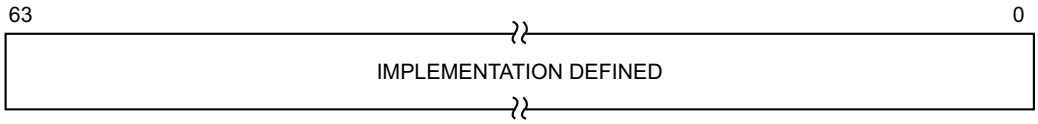
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

AMAIR_EL2 is a 64-bit register.

Field descriptions

The AMAIR_EL2 bit assignments are:



Accessing the AMAIR_EL2

To access the AMAIR_EL2:

```
MRS <Xt>, AMAIR_EL2 ; Read AMAIR_EL2 into Xt
MSR AMAIR_EL2, <Xt> ; Write Xt to AMAIR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1010	0011	000

D7.2.13 AMAIR_EL3, Auxiliary Memory Attribute Indirection Register (EL3)

The AMAIR_EL3 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL3.

This register is part of:

- the Virtual memory control registers functional group
- the Security registers functional group
- the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

AMAIR_EL3 is permitted to be cached in a TLB.

Configurations

AMAIR_EL3[31:0] can be mapped to AArch32 register AMAIR0 (S), but this is not architecturally mandated.

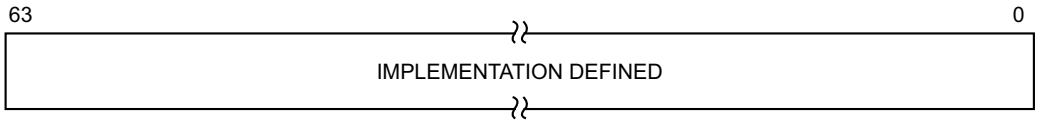
AMAIR_EL3[63:32] can be mapped to AArch32 register AMAIR1 (S), but this is not architecturally mandated.

Attributes

AMAIR_EL3 is a 64-bit register.

Field descriptions

The AMAIR_EL3 bit assignments are:



Accessing the AMAIR_EL3

To access the AMAIR_EL3:

```
MRS <Xt>, AMAIR_EL3 ; Read AMAIR_EL3 into Xt
MSR AMAIR_EL3, <Xt> ; Write Xt to AMAIR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	1010	0011	000

D7.2.14 CCSIDR_EL1, Current Cache Size ID Register

The CCSIDR_EL1 characteristics are:

Purpose

Provides information about the architecture of the currently selected cache.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

CCSIDR_EL1 is architecturally mapped to AArch32 register CCSIDR.

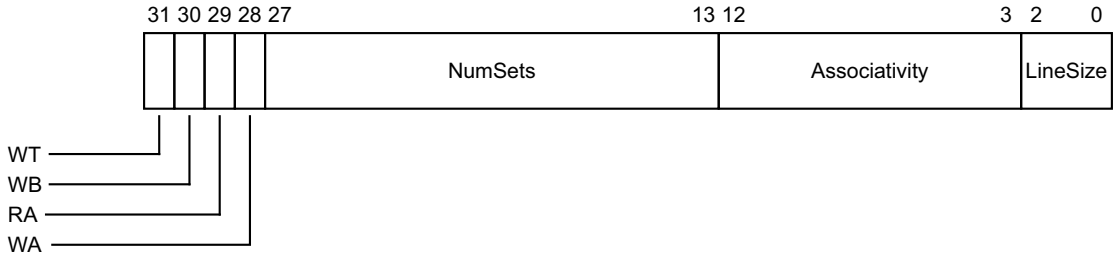
The implementation includes one CCSIDR_EL1 for each cache that it can access. CSSELR_EL1 selects which Cache Size ID Register is accessible.

Attributes

CCSIDR_EL1 is a 32-bit register.

Field descriptions

The CCSIDR_EL1 bit assignments are:



WT, bit [31]

Indicates whether the selected cache level supports write-through. Permitted values are:

`0` Write-through not supported.

`1` Write-through supported.

WB, bit [30]

Indicates whether the selected cache level supports write-back. Permitted values are:

`0` Write-back not supported.

`1` Write-back supported.

RA, bit [29]

Indicates whether the selected cache level supports read-allocation. Permitted values are:

`0` Read-allocation not supported.

`1` Read-allocation supported.

WA, bit [28]

Indicates whether the selected cache level supports write-allocation. Permitted values are:

`0` Write-allocation not supported.

`1` Write-allocation supported.

NumSets, bits [27:13]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Associativity, bits [12:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]

(Log_2(Number of bytes in cache line)) - 4. For example:

For a line length of 16 bytes: $Log_2(16) = 4$, LineSize entry = 0. This is the minimum line length.

For a line length of 32 bytes: $Log_2(32) = 5$, LineSize entry = 1.

Accessing the CCSIDR_EL1

To access the CCSIDR_EL1:

```
MRS <Xt>, CCSIDR_EL1 ; Read CCSIDR_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	001	0000	0000	000

D7.2.15 CLIDR_EL1, Cache Level ID Register

The CLIDR_EL1 characteristics are:

Purpose

Identifies the type of cache, or caches, implemented at each level, up to a maximum of seven levels. Also identifies the Level of Coherency and Level of Unification for the cache hierarchy.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

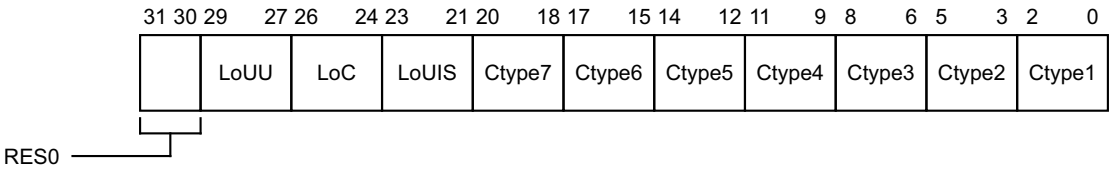
CLIDR_EL1 is architecturally mapped to AArch32 register CLIDR.

Attributes

CLIDR_EL1 is a 32-bit register.

Field descriptions

The CLIDR_EL1 bit assignments are:



Bits [31:30]

Reserved, RES0.

LoUU, bits [29:27]

Level of Unification Uniprocessor for the cache hierarchy.

LoC, bits [26:24]

Level of Coherency for the cache hierarchy.

LoUIS, bits [23:21]

Level of Unification Inner Shareable for the cache hierarchy.

Ctype<n>, bits [3(n-1)+2:3(n-1)], for 3(n-1)+2:3(n-1) = 1 to 7

Cache Type fields. Indicate the type of cache implemented at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

`000` No cache.

`001` Instruction cache only.

`010` Data cache only.

`011` Separate instruction and data caches.

`100` Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of `000`, no caches exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of `000`, the values of Ctype4 to Ctype7 must be ignored.

Accessing the CLIDR_EL1

To access the CLIDR_EL1:

```
MRS <Xt>, CLIDR_EL1 ; Read CLIDR_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	001	0000	0000	001

D7.2.16 CONTEXTIDR_EL1, Context ID Register

The CONTEXTIDR_EL1 characteristics are:

Purpose

Identifies the current Process Identifier.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

Configurations

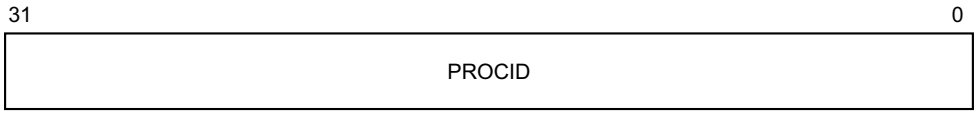
CONTEXTIDR_EL1 is architecturally mapped to AArch32 register CONTEXTIDR (NS).

Attributes

CONTEXTIDR_EL1 is a 32-bit register.

Field descriptions

The CONTEXTIDR_EL1 bit assignments are:



PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process. The bottom 8 bits of this register are not used to hold the ASID.

Accessing the CONTEXTIDR_EL1

To access the CONTEXTIDR_EL1:

```
MRS <Xt>, CONTEXTIDR_EL1 ; Read CONTEXTIDR_EL1 into Xt
MSR CONTEXTIDR_EL1, <Xt> ; Write Xt to CONTEXTIDR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1101	0000	001

D7.2.17 CPACR_EL1, Architectural Feature Access Control Register

The CPACR_EL1 characteristics are:

Purpose

Controls access to Trace, Floating-point, and Advanced SIMD functionality.

This register is part of the Other system control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

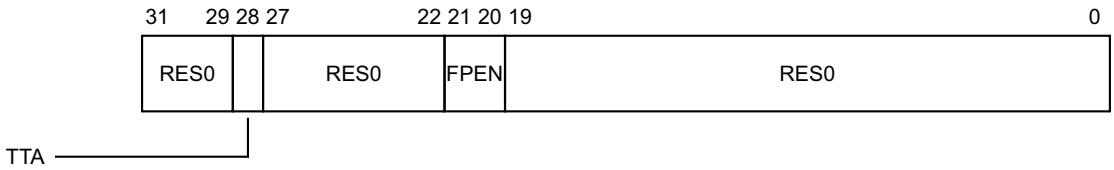
CPACR_EL1 is architecturally mapped to AArch32 register CPACR.

Attributes

CPACR_EL1 is a 32-bit register.

Field descriptions

The CPACR_EL1 bit assignments are:



Bits [31:29]

Reserved, RES0.

TTA, bit [28]

Causes access to the Trace functionality to trap to EL1 when executed from EL0 or EL1.

0 Does not cause System register access to the Trace functionality to be trapped.

1 Causes System register access to the Trace functionality to be trapped.

If system register access to trace functionality is not implemented, this bit is RES0.

Bits [27:22]

Reserved, RES0.

FPEN, bits [21:20]

Causes instructions that access the registers associated with Floating Point and Advanced SIMD execution to trap to EL1 when executed from EL0 or EL1.

00 Causes any instructions in EL0 or EL1 that use the registers associated with Floating Point and Advanced SIMD execution to be trapped.

01 Causes any instructions in EL0 that use the registers associated with Floating Point and Advanced SIMD execution to be trapped, but does not cause any instruction in EL1 to be trapped.

10	Causes any instructions in EL0 or EL1 that use the registers associated with Floating Point and Advanced SIMD execution to be trapped.
11	Does not cause any instruction to be trapped.

Bits [19:0]

Reserved, RES0.

Accessing the CPACR_EL1

To access the CPACR_EL1:

```
MRS <Xt>, CPACR_EL1 ; Read CPACR_EL1 into Xt
MSR CPACR_EL1, <Xt> ; Write Xt to CPACR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0001	0000	010

D7.2.18 CPTR_EL2, Architectural Feature Trap Register (EL2)

The CPTR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of access to CPACR, CPACR_EL1, Trace functionality and registers associated with Floating Point and Advanced SIMD execution. Also controls EL2 access to this functionality.

This register is part of the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

CPTR_EL2 is architecturally mapped to AArch32 register HCPTR.

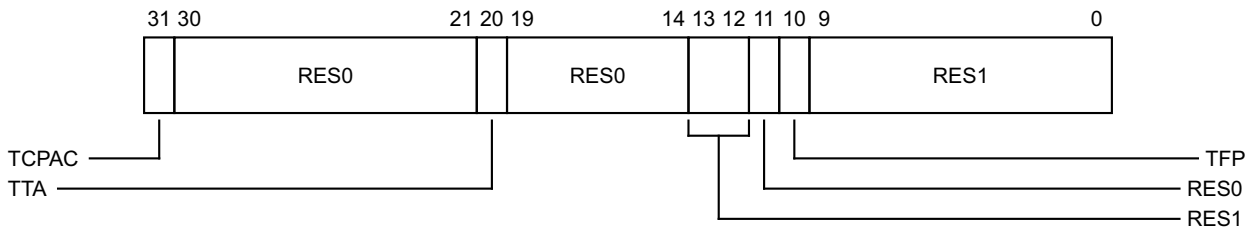
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

CPTR_EL2 is a 32-bit register.

Field descriptions

The CPTR_EL2 bit assignments are:



TCPAC, bit [31]

This causes a direct access to CPACR or CPACR_EL1 from EL1 to trap to EL2. Possible values of this bit are:

`0` Does not cause access to CPACR or CPACR_EL1 to be trapped.

`1` Causes access to CPACR or CPACR_EL1 to be trapped.

Bits [30:21]

Reserved, RES0.

TTA, bit [20]

This causes access to the Trace functionality to trap to EL2 when executed from EL0, EL1, or EL2, unless already trapped to EL1. Possible values of this bit are:

`0` Does not cause System register access to the Trace Functionality to be trapped.

`1` Causes System register access to the Trace Functionality to be trapped.

If system register access to trace functionality is not supported, this bit is RES0.

Bits [19:14]

Reserved, RES0.

Bits [13:12]

Reserved, RES1.

Bit [11]

Reserved, RES0.

TFP, bit [10]

This causes instructions that access the registers associated with Floating Point and Advanced SIMD execution to trap to EL2 when executed from EL0, EL1, or EL2, unless trapped to EL1. Possible values of this bit are:

`0` Does not cause any instruction to be trapped.

`1` Causes any instructions that use the registers associated with Floating Point and Advanced SIMD execution to be trapped.

Bits [9:0]

Reserved, RES1.

Accessing the CPTR_EL2

To access the CPTR_EL2:

```
MRS <Xt>, CPTR_EL2 ; Read CPTR_EL2 into Xt
MSR CPTR_EL2, <Xt> ; Write Xt to CPTR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0001	0001	010

D7.2.19 CPTR_EL3, Architectural Feature Trap Register (EL3)

The CPTR_EL3 characteristics are:

Purpose

Controls trapping to EL3 of access to CPACR_EL1, Trace functionality and registers associated with Floating Point and Advanced SIMD execution. Also controls EL3 access to this functionality.

This register is part of the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

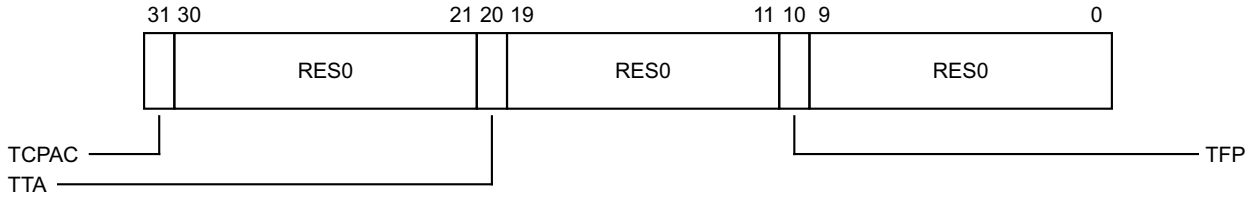
There are no configuration notes.

Attributes

CPTR_EL3 is a 32-bit register.

Field descriptions

The CPTR_EL3 bit assignments are:



TCPAC, bit [31]

This causes a direct access to the CPACR_EL1 from EL1 or the CPTR_EL2 from EL2 to trap to EL3 unless it is trapped at EL2. Possible values of this bit are:

`0` Does not cause access to the CPACR_EL1 or CPTR_EL2 to be trapped.

`1` Causes access to the CPACR_EL1 or CPTR_EL2 to be trapped.

Bits [30:21]

Reserved, RES0.

TTA, bit [20]

This causes access to the Trace functionality to trap to EL3 when executed from EL0, EL1, EL2, or EL3, unless already trapped to EL1 or EL2. Possible values of this bit are:

`0` Does not cause System register access to the Trace Functionality to be trapped.

`1` Causes System register access to the Trace Functionality to be trapped.

If system register access to trace functionality is not supported, this bit is RES0.

Bits [19:11]

Reserved, RES0.

TFP, bit [10]

This causes instructions that access the registers associated with Floating Point and Advanced SIMD execution to trap to EL3 when executed from any exception level, unless trapped to EL1 or EL2. Possible values of this bit are:

`0` Does not cause any instruction to be trapped.

`1` Causes any instructions that use the registers associated with Floating Point and Advanced SIMD execution to be trapped.

Bits [9:0]

Reserved, RES0.

Accessing the CPTR_EL3

To access the CPTR_EL3:

```
MRS <Xt>, CPTR_EL3 ; Read CPTR_EL3 into Xt
MSR CPTR_EL3, <Xt> ; Write Xt to CPTR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0001	0001	010

D7.2.20 CSSELR_EL1, Cache Size Selection Register

The CSSELR_EL1 characteristics are:

Purpose

Selects the current Cache Size ID Register, CCSIDR_EL1, by specifying the required cache level and the cache type (either instruction or data cache).

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

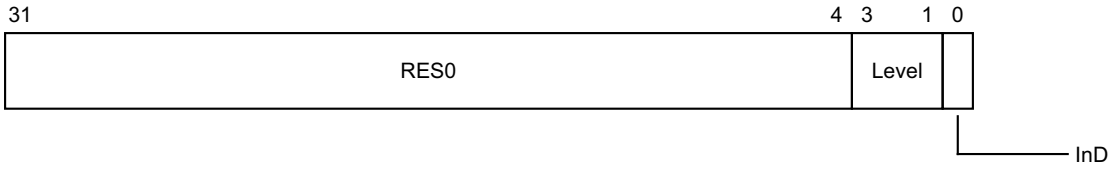
CSSELR_EL1 is architecturally mapped to AArch32 register CSSELR (NS).

Attributes

CSSELR_EL1 is a 32-bit register.

Field descriptions

The CSSELR_EL1 bit assignments are:



Bits [31:4]

Reserved, RES0.

Level, bits [3:1]

Cache level of required cache. Permitted values are from `0b000`, indicating Level 1 cache, to `0b110` indicating Level 7 cache.

InD, bit [0]

Instruction not Data bit. Permitted values are:

`0` Data or unified cache.

`1` Instruction cache.

Accessing the CSSELR_EL1

To access the CSSELR_EL1:

```
MRS <Xt>, CSSELR_EL1 ; Read CSSELR_EL1 into Xt
MSR CSSELR_EL1, <Xt> ; Write Xt to CSSELR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	010	0000	0000	000

D7.2.21 CTR_EL0, Cache Type Register

The CTR_EL0 characteristics are:

Purpose

Provides information about the architecture of the caches.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 when SCTLR_EL1.UCT is set to 1.

Configurations

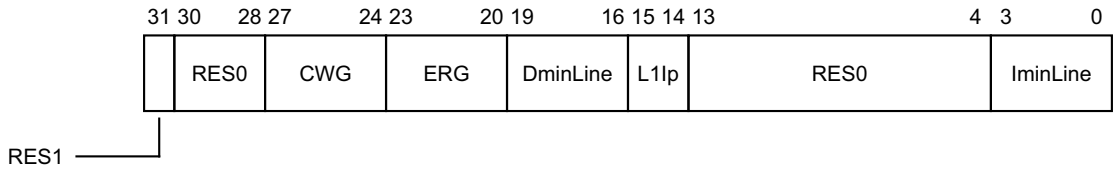
CTR_EL0 is architecturally mapped to AArch32 register CTR.

Attributes

CTR_EL0 is a 32-bit register.

Field descriptions

The CTR_EL0 bit assignments are:



Bit [31]

Reserved, RES1.

Bits [30:28]

Reserved, RES0.

CWG, bits [27:24]

Cache Writeback Granule. Log_2 of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

A value of `0b0000` indicates that this register does not provide Cache Writeback Granule information and either:

- The architectural maximum of 512 words (2KB) must be assumed.
- The Cache Writeback Granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than `0b1001` are reserved.

ERG, bits [23:20]

Exclusives Reservation Granule. Log_2 of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

A value of `0b0000` indicates that this register does not provide Exclusives Reservation Granule information and the architectural maximum of 512 words (2KB) must be assumed.

Values greater than `0b1001` are reserved.

DminLine, bits [19:16]

Log_2 of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the processor.

L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:

`01` ASID-tagged Virtual Index, Virtual Tag (AIVIVT)

`10` Virtual Index, Physical Tag (VIPT)

`11` Physical Index, Physical Tag (PIPT)

Other values are reserved.

Bits [13:4]

Reserved, RES0.

IminLine, bits [3:0]

Log_2 of the number of words in the smallest cache line of all the instruction caches that are controlled by the processor.

Accessing the CTR_EL0

To access the CTR_EL0:

```
MRS <Xt>, CTR_EL0 ; Read CTR_EL0 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	0000	0000	001

D7.2.22 DACR32_EL2, Domain Access Control Register

The DACR32_EL2 characteristics are:

Purpose

Allows access to the AArch32 DACR register from AArch64 state only. Its value has no effect on execution in AArch64 state.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

DACR32_EL2 is architecturally mapped to AArch32 register DACR (NS).

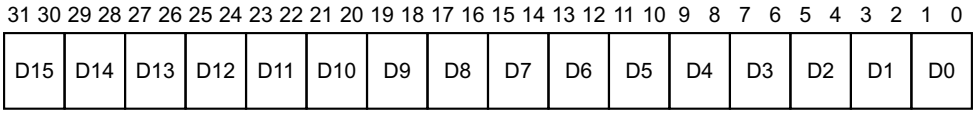
If EL1 is AArch64 only, this register is UNDEFINED.

Attributes

DACR32_EL2 is a 32-bit register.

Field descriptions

The DACR32_EL2 bit assignments are:



D<n>, bits [2n+1:2n], for 2n+1:2n = 0 to 15

Domain n access permission, where n = 0 to 15. Permitted values are:

`00` No access. Any access to the domain generates a Domain fault.

`01` Client. Accesses are checked against the permission bits in the translation tables.

`11` Manager. Accesses are not checked against the permission bits in the translation tables.

The value `10` is reserved.

Accessing the DACR32_EL2

To access the DACR32_EL2:

```
MRS <Xt>, DACR32_EL2 ; Read DACR32_EL2 into Xt
MSR DACR32_EL2, <Xt> ; Write Xt to DACR32_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0011	0000	000

D7.2.23 DCZID_EL0, Data Cache Zero ID register

The DCZID_EL0 characteristics are:

Purpose

Indicates the block size that is written with byte values of 0 by the DC ZVA (Data Cache Zero by Virtual Address) system instruction.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RO	RO	RO	RO	RO	RO

Configurations

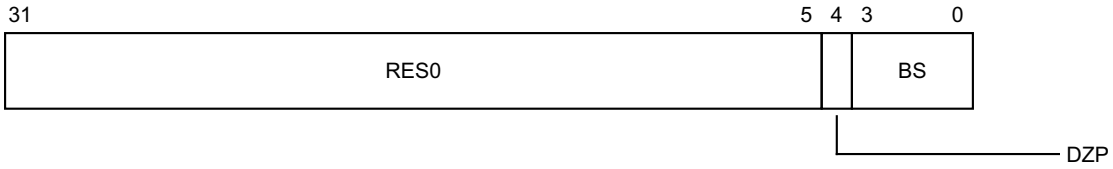
There are no configuration notes.

Attributes

DCZID_EL0 is a 32-bit register.

Field descriptions

The DCZID_EL0 bit assignments are:



Bits [31:5]

Reserved, RES0.

DZP, bit [4]

Data Zero prohibited. Permitted values are:

`0` DC ZVA instruction is permitted.

`1` DC ZVA instruction is prohibited.

The value read from this field is governed by the access state and the values of the HCR_EL2.TDZ and SCTLR_EL1.DZE bits.

BS, bits [3:0]

Log_2 of the block size in words. The maximum size supported is 2 KB (value == 9).

Accessing the DCZID_EL0

To access the DCZID_EL0:

```
MRS <Xt>, DCZID_EL0 ; Read DCZID_EL0 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	0000	0000	111

D7.2.24 ESR_EL1, Exception Syndrome Register (EL1)

The ESR_EL1 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL1.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL1, the value of ESR_EL1 is UNKNOWN. The value written to ESR_EL1 must be consistent with a value that could be created as a result of an exception from the same exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that exception level, in order to avoid the possibility of a privilege violation.

Configurations

ESR_EL1 is architecturally mapped to AArch32 register DFSR (NS).

Attributes

ESR_EL1 is a 32-bit register.

Field descriptions

See *ESR_ELx, Exception Syndrome Register* on page D7-1832.

Accessing the ESR_EL1

To access the ESR_EL1:

```
MRS <Xt>, ESR_EL1 ; Read ESR_EL1 into Xt
MSR ESR_EL1, <Xt> ; Write Xt to ESR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0101	0010	000

D7.2.25 ESR_EL2, Exception Syndrome Register (EL2)

The ESR_EL2 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL2.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of ESR_EL2 is UNKNOWN. The value written to ESR_EL2 must be consistent with a value that could be created as a result of an exception from the same exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that exception level, in order to avoid the possibility of a privilege violation.

Configurations

ESR_EL2 is architecturally mapped to AArch32 register HSR.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

ESR_EL2 is a 32-bit register.

Field descriptions

See *ESR_ELx, Exception Syndrome Register* on page D7-1832.

Accessing the ESR_EL2

To access the ESR_EL2:

```
MRS <Xt>, ESR_EL2 ; Read ESR_EL2 into Xt
MSR ESR_EL2, <Xt> ; Write Xt to ESR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0101	0010	000

D7.2.26 ESR_EL3, Exception Syndrome Register (EL3)

The ESR_EL3 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL3.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL3, the value of ESR_EL3 is UNKNOWN. The value written to ESR_EL3 must be consistent with a value that could be created as a result of an exception from the same exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that exception level, in order to avoid the possibility of a privilege violation.

Configurations

ESR_EL3 can be mapped to AArch32 register DFSR (S), but this is not architecturally mandated.

Attributes

ESR_EL3 is a 32-bit register.

Field descriptions

See *ESR_ELx, Exception Syndrome Register* on page D7-1832.

Accessing the ESR_EL3

To access the ESR_EL3:

```
MRS <Xt>, ESR_EL3 ; Read ESR_EL3 into Xt
MSR ESR_EL3, <Xt> ; Write Xt to ESR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0101	0010	000

D7.2.27 ESR_ELx, Exception Syndrome Register

This page describes ESR_EL1, ESR_EL2, and ESR_EL3.

The ESR_ELx characteristics are:

Purpose

Holds syndrome information for an exception taken to ELx.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to ELx, the value of ESR_ELx is UNKNOWN. The value written to ESR_ELx must be consistent with a value that could be created as a result of an exception from the same exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that exception level, in order to avoid the possibility of a privilege violation.

Configurations

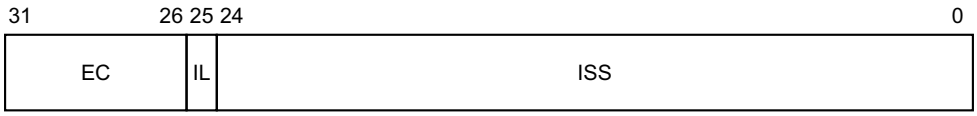
If EL2 is not implemented, ESR_EL2 is RES0 from EL3.

Attributes

The ESR_ELx registers are 32-bit registers.

Field descriptions

The ESR_ELx bit assignments are:



EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about. Possible values of this field are:

EC == 000000

(This value is valid for all described registers)

Unknown or Uncategorized Reason - generally used for exceptions as a result of erroneous execution.

See *ISS encoding for an exception with an unknown reason* on page D7-1837.

EC == 000001

(This value is valid for all described registers)

Exceptions from WFE/WFI from either AArch32 or AArch64 as a result of configurable traps, enables, or disables.

Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

See *ISS encoding for an exception from a WFI or WFE instruction* on page D7-1837.

EC == 000011

(This value is valid for all described registers)

Exceptions from MCR/MRC to CP15 from AArch32 as a result of configurable traps, enables, or disables that do not use code `0b000000`.

See *ISS encoding for an exception from an MCR or MRC access from AArch32 state* on page D7-1839

EC == 000100

(This value is valid for all described registers)

Exceptions from MCRR/MRRC to CP15 from AArch32 as a result of configurable traps, enables, or disables that do not use code `0b000000`.

See *ISS encoding for an exception from an MCRR or MRRC access from AArch32 state* on page D7-1840.

EC == 000101

(This value is valid for all described registers)

Exceptions from MCR/MRC to CP14 from AArch32 as a result of configurable traps, enables, or disables that do not use code `0b000000`.

See *ISS encoding for an exception from an MCR or MRC access from AArch32 state* on page D7-1839.

EC == 000110

(This value is valid for all described registers)

Exceptions from LDC/STC to CP14 from AArch32 as a result of configurable traps, enables, or disables.

Note

The only architected uses of these instructions to access CP14 are:

- An STC to write to DBGDTRRX_EL0 or DBGDTRRXint.
- An LDC to read from DBGDTRTX_EL0 or DBGDTRTXint.

See *ISS encoding for an exception from an LDC or STC access to CP14 from AArch32 state* on page D7-1842.

EC == 000111

(This value is valid for all described registers)

Exceptions from access to Advanced SIMD or Floating Point as a result of configurable traps, enables, or disables.

See *ISS encoding for an exception from an access to a SIMD or floating-point register* on page D7-1844.

EC == 001000

(This value is valid for ESR_EL2)

Exceptions from MRC (or VMRS) to CP10 for MVFR0, MVFR1, MVFR2, or FPSID of ID Group traps from AArch32 unless reported using code `0b000111`.

See *ISS encoding for an exception from an MCR or MRC access from AArch32 state* on page D7-1839.

EC == 001100

(This value is valid for all described registers)

Exceptions from MCRR/MRRC to CP14 from AArch32 as a result of configurable traps, enables, or disables.

See *ISS encoding for an exception from an MCRR or MRRC access from AArch32 state* on page D7-1840.

EC == 001110

(This value is valid for all described registers)

Exceptions that occur because the value of PSTATE.IL is 1.

See *ISS encoding for an exception from an Illegal Execution state, PC alignment fault, or SP alignment fault* on page D7-1845.

EC == 010001

(This value is valid for ESR_EL1 and ESR_EL2)

SVC executed in AArch32.

See *ISS encoding for an exception from HVC or SVC instruction execution* on page D7-1845.

EC == 010010

(This value is valid for ESR_EL2)

HVC that is not disabled executed in AArch32.

See *ISS encoding for an exception from HVC or SVC instruction execution* on page D7-1845.

EC == 010011

(This value is valid for ESR_EL2 and ESR_EL3)

SMC that is not disabled executed in AArch32.

See *ISS encoding for an exception from SMC instruction execution in AArch32 state* on page D7-1846.

EC == 010101

(This value is valid for all described registers)

SVC executed in AArch64.

See *ISS encoding for an exception from HVC or SVC instruction execution* on page D7-1845.

EC == 010110

(This value is valid for ESR_EL2 and ESR_EL3)

HVC that is not disabled executed in AArch64.

See *ISS encoding for an exception from HVC or SVC instruction execution* on page D7-1845.

EC == 010111

(This value is valid for ESR_EL2 and ESR_EL3)

SMC that is not disabled executed in AArch64.

See *ISS encoding for an exception from SMC instruction execution in AArch64 state* on page D7-1846.

EC == 011000

(This value is valid for all described registers)

Exceptions as a result of MSR, MRS, or System AArch64 instructions as a result of configurable traps, enables, or disables, except those using codes `0b000000`, `0b000001`, or `0b000111`.

See *ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state* on page D7-1847.

EC == 100000

(This value is valid for all described registers)

Instruction Abort that caused entry from a lower exception level (AArch32 or AArch64). Used for instruction access generated MMU faults and synchronous external aborts, including synchronous parity errors. Not used for debug related exceptions.

See *ISS encoding for an exception from an Instruction abort exception* on page D7-1848.

EC == 100001

(This value is valid for all described registers)

Instruction Abort that caused entry from a current exception level (AArch64). Used for instruction access generated MMU faults and synchronous external aborts, including synchronous parity errors. Not used for debug related exceptions.

See *ISS encoding for an exception from an Instruction abort exception* on page D7-1848.

EC == 100010

(This value is valid for all described registers)

PC Alignment Exception.

See *ISS encoding for an exception from an Illegal Execution state, PC alignment fault, or SP alignment fault* on page D7-1845.

EC == 100100

(This value is valid for all described registers)

Data Abort that caused entry from a lower exception level (AArch32 or AArch64). Used for data access generated MMU faults, alignment faults other than those caused by the Stack Pointer misalignment, and synchronous external aborts, including synchronous parity errors. Not used for debug related exceptions.

See *ISS encoding for an exception from a Data abort exception* on page D7-1849.

EC == 100101

(This value is valid for all described registers)

Data Abort that caused entry from a current exception level (AArch64). Used for data access generated MMU faults, alignment faults other than those caused by the Stack Pointer misalignment, and synchronous external aborts, including synchronous parity errors. Not used for debug related exceptions.

See *ISS encoding for an exception from a Data abort exception* on page D7-1849.

EC == 100110

(This value is valid for all described registers)

Stack Pointer Alignment Exception.

See *ISS encoding for an exception from an Illegal Execution state, PC alignment fault, or SP alignment fault* on page D7-1845.

EC == 101000

(This value is valid for ESR_EL1 and ESR_EL2)

Exceptions as a result of Floating-point exception (optional feature) from AArch32.

See *ISS encoding for an exception from a floating-point exception* on page D7-1852.

EC == 101100

(This value is valid for all described registers)

Exceptions as a result of Floating-point exception from AArch64.

See *ISS encoding for an exception from a floating-point exception* on page D7-1852.

EC == 101111

(This value is valid for all described registers)

SError Interrupt.

See *ISS encoding for an SError interrupt* on page D7-1854.

EC == 110000

(This value is valid for ESR_EL1 and ESR_EL2)

Breakpoint debug event that caused entry from a lower exception level.

See *ISS encoding for a Breakpoint exception or Vector Catch exception* on page D7-1854.

EC == 110001

(This value is valid for ESR_EL1 and ESR_EL2)

Breakpoint debug event that caused entry from a current exception level.

See *ISS encoding for a Breakpoint exception or Vector Catch exception* on page D7-1854.

EC == 110010

(This value is valid for ESR_EL1 and ESR_EL2)

Software step debug event that caused entry from a lower exception level.

See *ISS encoding for Software Step exception* on page D7-1857.

EC == 110011

(This value is valid for ESR_EL1 and ESR_EL2)

Software step debug event that caused entry from a current exception level.

See *ISS encoding for Software Step exception* on page D7-1857.

EC == 110100

(This value is valid for ESR_EL1 and ESR_EL2)

Watchpoint debug event that caused entry from a lower exception level.

See *ISS encoding for a Watchpoint exception* on page D7-1855.

EC == 110101

(This value is valid for ESR_EL1 and ESR_EL2)

Watchpoint debug event that caused entry from a current exception level.

See *ISS encoding for a Watchpoint exception* on page D7-1855.

EC == 111000

(This value is valid for ESR_EL1 and ESR_EL2)

BKPT instruction executed in AArch32 state.

See *ISS encoding for a Software Breakpoint Instruction exception* on page D7-1858.

EC == 111010

(This value is valid for ESR_EL2)

AArch32 state Vector catch debug event.

See *ISS encoding for a Breakpoint exception or Vector Catch exception* on page D7-1854.

EC == 111100

(This value is valid for all described registers)

BRK instruction executed in AArch64 state.

See *ISS encoding for a Software Breakpoint Instruction exception* on page D7-1858.

Other values are reserved.

IL, bit [25]

Instruction Length for synchronous exceptions. Possible values of this bit are:

`0` 16-bit instruction trapped.

`1` 32-bit instruction trapped. This value also applies to the following exceptions:

- An SError interrupt.
- An Instruction Abort exception.
- A Misaligned PC exception.
- A Misaligned Stack Pointer exception.
- A Data Abort for which the value of the ISV bit is 0.
- An Illegal Execution State exception.

- Any debug exception except for Software Breakpoint Instruction exceptions. For Software Breakpoint Instruction exceptions, this bit has its standard meaning:

  `0` 16-bit T32 BKPT instruction.

  1 32-bit A32 BKPT instruction or A64 BRK instruction.
- An exception reported using EC value `0b000000`.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number, even if the reported exception was taken from AArch32 state. If the register number is AArch32 register R15, then:

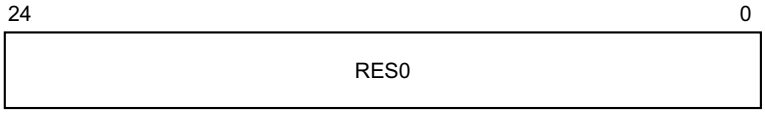
- If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value `0b11111`.
- If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
  - The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
  - The value `0b11111`.

When the EC field is `0b000000`, indicating an exception with an unknown reason, the ISS field is not valid, RES0.

The following subsubsections describe each of the ISS formats.

ISS encoding for an exception with an unknown reason

These are the exceptions reported with an EC value of `0b000000`. The ISS encoding for these exceptions is:



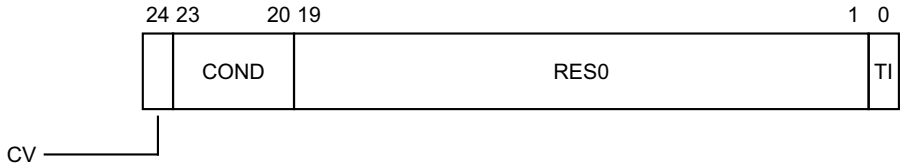
Bits [24:0]

Reserved, RES0.

See *Exceptions with an unknown reason* on page D1-1429 for more information about these exceptions.

ISS encoding for an exception from a WFI or WFE instruction

This is the exception syndrome with EC value `0b000001`. It reports exceptions from `WFI` or `WFE` instructions executed in either Execution state that result from configurable traps, enables, or disables. The ISS encoding for these exceptions is:



CV, bit [24]

Condition code valid. Possible values of this bit are:

`0` The COND field is not valid.

1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only when CV is set to 1.

For exceptions taken from AArch64, this field is set to `0b1110`.

For exceptions taken from AArch32:

- When an A32 instruction is trapped:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

Bits [19:1]

Reserved, RES0.

TI, bit [0]

Trapped instruction. Possible values of this bit are:

`0` WFI trapped.

`1` WFE trapped.

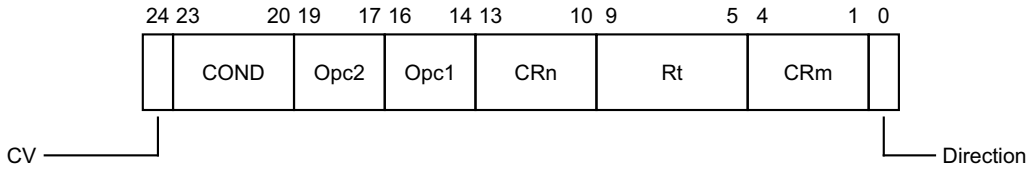
See *Exception from a WFI or WFE instruction, from AArch32 or AArch64 state* on page D1-1430 for more information about these exceptions.

ISS encoding for an exception from an MCR or MRC access from AArch32 state

These are the exception syndromes with the following EC values:

- `0b000011`, `MRC` or `MCR` access to CP15.
- `0b000101`, `MRC` or `MCR` access to CP14.
- `0b001000`, `MRC` or `VMRS` access to CP10.

These report exceptions from `MRC`, `MCR`, or `VMRS` instructions executed in AArch32 state that result from configurable traps, enables, or disables and are not reported using the EC code of `0b000000`. The ISS encoding for these exceptions is:



CV, bit [24]

Condition code valid. Possible values of this bit are:

`0` The COND field is not valid.

`1` The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only when CV is set to 1.

For exceptions taken from AArch64, this field is set to `0b1110`.

For exceptions taken from AArch32:

- When an A32 instruction is trapped:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value `0b000`.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value `0b111`.

CRn, bits [13:10]

The CRn value from the issued instruction, the coprocessor primary register value.

For a trapped VMRS access, holds the reg_field from the VMRS instruction encoding.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

CRm, bits [4:1]

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value `0b0000`.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

`0` Write to coprocessor. MCR instruction.

`1` Read from coprocessor. MRC or VMRS instruction.

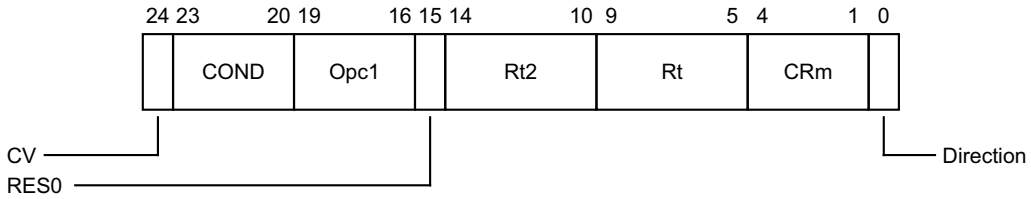
See *Exception from an MCR or MRC access from AArch32 state* on page D1-1430 for more information about these exceptions.

ISS encoding for an exception from an MCRR or MRRC access from AArch32 state

These are the exception syndromes with the following EC values:

- `0b000100`, `MRRC` or `MCRR` access to CP15.
- `0b001100`, `MRRC` access to CP14.

These report exceptions from `MCRR`, or `MRRC` instructions executed in AArch32 state that result from configurable traps, enables, or disables and are not reported using the EC code of `0b000000`. The ISS encoding for these exceptions is:



CV, bit [24]

Condition code valid. Possible values of this bit are:

`0` The COND field is not valid.

`1` The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.

— CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only when CV is set to 1.

For exceptions taken from AArch64, this field is set to `0b1110`.

For exceptions taken from AArch32:

- When an A32 instruction is trapped:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

Opc1, bits [19:16]

The Opc1 value from the issued instruction.

Bit [15]

Reserved, RES0.

Rt2, bits [14:10]

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

CRm, bits [4:1]

The CRm value from the issued instruction.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

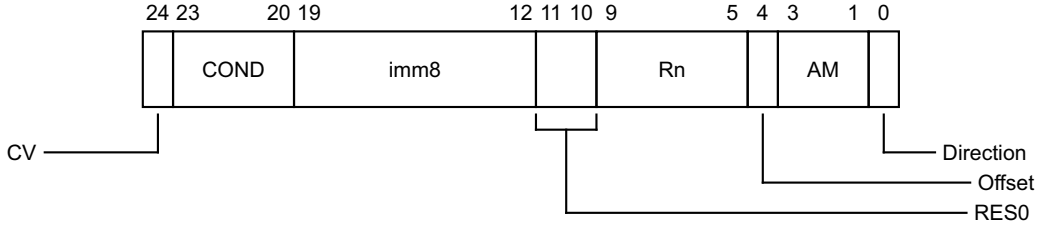
`0` Write to coprocessor. MCRR instruction.

`1` Read from coprocessor. MRRC instruction.

See *Exception from an MCRR or MRRC access from AArch32 state* on page D1-1431 for more information about these exceptions.

ISS encoding for an exception from an LDC or STC access to CP14 from AArch32 state

This is the exception syndrome with EC value `0b000110`. This reports exceptions from `LDC`, or `STC` instructions executed in AArch32 state that result from configurable traps, enables, or disables. The ISS encoding for these exceptions is:



CV, bit [24]

Condition code valid. Possible values of this bit are:

`0` The COND field is not valid.

`1` The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only when CV is set to 1.

For exceptions taken from AArch64, this field is set to `0b1110`.

For exceptions taken from AArch32:

- When an A32 instruction is trapped:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

imm8, bits [19:12]

The immediate value from the issued instruction.

Bits [11:10]

Reserved, RES0.

Rn, bits [9:5]

The Rn value from the issued instruction. Valid only when the Direction field is 0, indicating a trapped STC instruction.

When the Direction field is 1, indicating a trapped LDC instruction, this field is RES0.

Offset, bit [4]

Indicates whether the offset is added or subtracted:

`0` Subtract offset.

`1` Add offset.

This bit corresponds to the U bit in the instruction encoding.

AM, bits [3:1]

Addressing mode. The permitted values of this field are:

`000` Immediate unindexed.

`001` Immediate post-indexed.

`010` Immediate offset.

`011` Immediate pre-indexed.

`100` Literal unindexed.
A32 instruction set only.
For a trapped LDC or STC T32 instruction, this encoding is reserved.

`110` Literal offset.
For the STC instruction, valid only in the A32 instruction set.
For a trapped STC T32 instruction, this encoding is reserved.

The values `0b101` and `0b111` are reserved.

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

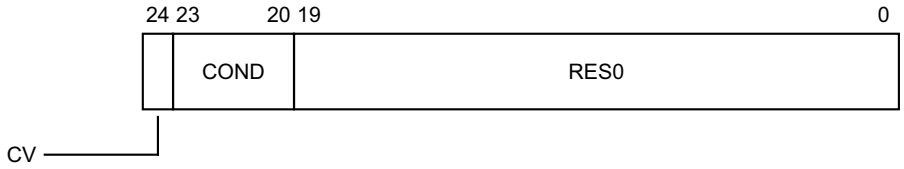
`0` Write to coprocessor. STC instruction.

`1` Read from coprocessor. LDC instruction.

See *Exception from an LDC or STC access to CP14 from AArch32 state* on page D1-1432 for more information about these exceptions.

ISS encoding for an exception from an access to a SIMD or floating-point register

This is the exception syndrome with EC value `0b000111`. This reports exceptions from accesses to the SIMD and floating-point register bank, or to SIMD and floating-point System registers, from either Execution state, that result from configurable traps, enables, other than exceptions that occur because the value of HCR_EL2.TGE is 1. The ISS encoding for these exceptions is:



CV, bit [24]

Condition code valid. Possible values of this bit are:

`0` The COND field is not valid.

`1` The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only when CV is set to 1.

For exceptions taken from AArch64, this field is set to `0b1110`.

For exceptions taken from AArch32:

- When an A32 instruction is trapped:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition of a T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

Bits [19:0]

Reserved, RES0.

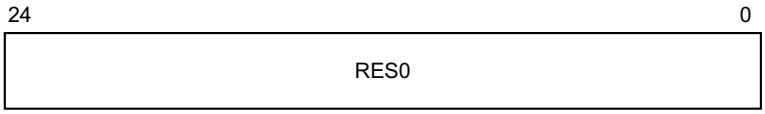
See *Exception from an access to SIMD or floating-point registers, from AArch32 or AArch64* on page D1-1432 for more information about these exceptions.

ISS encoding for an exception from an Illegal Execution state, PC alignment fault, or SP alignment fault

These are the exception syndromes with the following EC values:

- `0b001110`, Illegal Execution State.
- `0b100010`, Misaligned PC.
- `0b100110`, Misaligned stack pointer.

The ISS encoding for these exceptions is:



Bits [24:0]

Reserved, RES0.

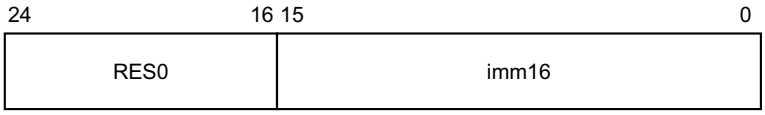
See *Exception from an illegal Execution State, misaligned PC, or misaligned stack pointer* on page D1-1432 for more information about these exceptions.

ISS encoding for an exception from HVC or SVC instruction execution

These are the exception syndromes with the following EC values:

- `0b010001`, `SVC` instruction executed in AArch32 state.
- `0b010010`, `HVC` instruction executed, when not disabled, in AArch32 state.
- `0b010101`, `SVC` instruction executed in AArch64 state.
- `0b010110`, `HVC` instruction executed, when not disabled, in AArch64 state.

The ISS encoding for these exceptions is:



Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction this is the value of the imm16 field of the issued instruction.

For an SVC instruction:

- If the instruction is unconditional, then:
  - For the 16-bit T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The HVC instruction is unconditional, and a conditional SVC instruction generates a Supervisor Call exception that is routed to Hyp mode only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not include conditionality information.

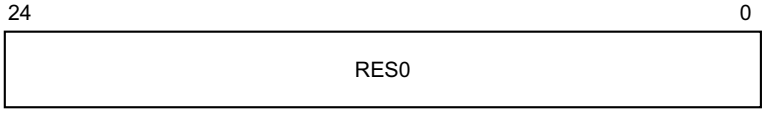
Note

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not include conditionality information.

See *Exception from HVC or SVC instruction execution* on page D1-1432 for more information about these exceptions.

ISS encoding for an exception from SMC instruction execution in AArch32 state

This is the exception syndrome with EC value 0b010011. This reports the exception from an SMC that is not disabled and is executed in AArch32 state. The ISS encoding for these exceptions is:



Bits [24:0]

Reserved, RES0.

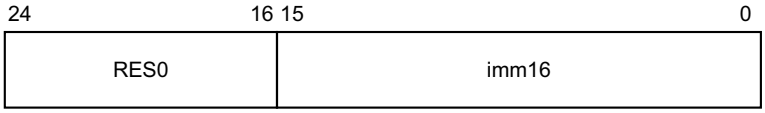
Note

- An SMC instruction that fails its condition code check cannot generate this exception. Therefore, the syndrome information does not include conditionality information.
- The value of ISS[24:0] described here is used both:
  - When an SMC instruction is trapped from Non-secure EL1 modes.
  - When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

See *Exception from SMC instruction execution in AArch32 state* on page D1-1433 for more information about these exceptions.

ISS encoding for an exception from SMC instruction execution in AArch64 state

This is the exception syndrome with EC value 0b010111. This reports the exception from an SMC that is not disabled and is executed in AArch64 state. The ISS encoding for these exceptions is:



Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the issued SMC instruction.

Note

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from Non-secure EL1.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

See *Exception from SMC instruction execution in AArch64 state* on page D1-1433 for more information about these exceptions.

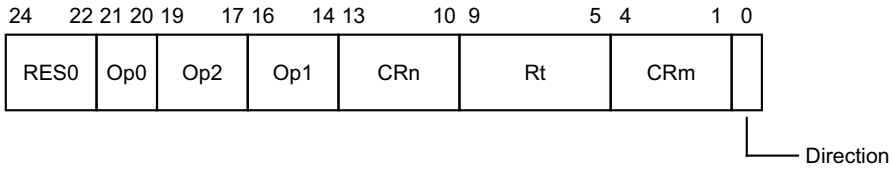
ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

This is the exception syndrome with the EC value `0b011000`. This reports exceptions from `MSR`, `MRS`, or System instructions executed in AArch64 state that result from configurable traps, enables, or disables and are not reported using the EC codes of `0b000000`, `0b000001`, or `0b000111`.

Note

The System instruction class encoding space on page C5-233 identifies the System instructions referred to in this description.

The ISS encoding for these exceptions is:



Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

Op2, bits [19:17]

The Op2 value from the issued instruction.

Op1, bits [16:14]

The Op1 value from the issued instruction.

CRn, bits [13:10]

The CRn value from the issued instruction, the coprocessor primary register value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

CRm, bits [4:1]

The CRm value from the issued instruction.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

`0` Write access, including MSR instructions.

`1` Read access, including MRS instructions.

For exceptions caused by System instructions, see *System* on page C4-176 for the instruction arguments returned in the syndrome.

See *Exception from MSR, MRS, or System instruction execution in AArch64 state* on page D1-1433 for more information about these exceptions.

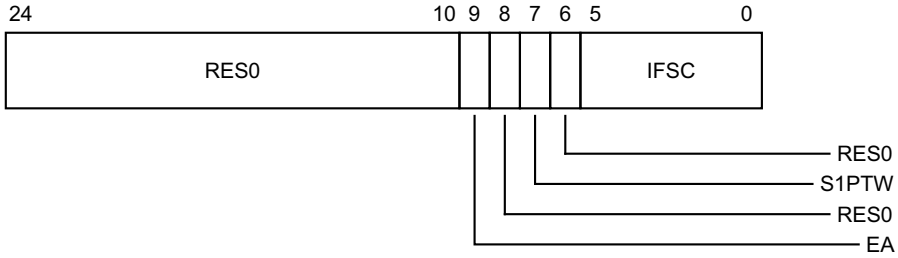
ISS encoding for an exception from an Instruction abort exception

These are the exception syndromes with the following EC values:

- `0b100000`, for an Instruction abort exception taken from a lower Exception level, that could be using AArch64 or AArch32.
- `0b100001`, for an Instruction abort exception taken without a change in Exception level, meaning it is taken from an Exception level that is using AArch64.

These EC values are not used for Debug exceptions.

The ISS encoding for these exceptions is:



Bits [24:10]

Reserved, RES0.

EA, bit [9]

External abort type. This bit can be provide an IMPLEMENTATION DEFINED classification of external aborts.

For any abort other than an External abort this bit returns a value of 0.

Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:

`0` Fault not on a stage 2 translation for a stage 1 translation table walk.

`1` Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For a stage 1 fault, this bit is RES0.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code. Possible values of this field are:

`000000` Address size fault, zeroth level of translation or translation table base register

`000001` Address size fault, first level

`000010` Address size fault, second level

`000011` Address size fault, third level

`000100` Translation fault, zeroth level

`000101` Translation fault, first level

`000110` Translation fault, second level

`000111` Translation fault, third level

`001001` Access flag fault, first level

001010	Access flag fault, second level
001011	Access flag fault, third level
001101	Permission fault, first level
001110	Permission fault, second level
001111	Permission fault, third level
010000	Synchronous external abort
011000	Synchronous parity error on memory access
010100	Synchronous external abort on translation table walk, zeroth level
010101	Synchronous external abort on translation table walk, first level
010110	Synchronous external abort on translation table walk, second level
010111	Synchronous external abort on translation table walk, third level
011100	Synchronous parity error on memory access on translation table walk, zeroth level
011101	Synchronous parity error on memory access on translation table walk, first level
011110	Synchronous parity error on memory access on translation table walk, second level
011111	Synchronous parity error on memory access on translation table walk, third level
100001	Alignment fault
100010	Debug event
110000	TLB conflict abort
110100	IMPLEMENTATION DEFINED fault (Lockdown fault)

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 0 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault cased by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

See *Exception from an Instruction abort* on page D1-1434 for more information about these exceptions.

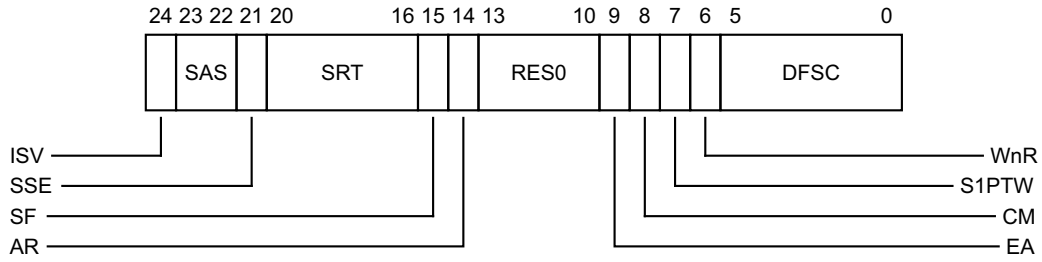
ISS encoding for an exception from a Data abort exception

These are the exception syndromes with the following EC values:

- 0x24, for a Data abort exception taken from a lower Exception level, that could be using AArch64 or AArch32.
- 0x25, for a Data abort exception taken without a change in Exception level, meaning it is taken from an Exception level that is using AArch64.

These EC values are not used for Debug exceptions.

The ISS encoding for these exceptions is:



ISV, bit [24]

Instruction syndrome valid. Indicates whether the rest of the syndrome information in this register is valid.

0 No valid instruction syndrome. ISS[23:16] are RES0.

1 ISS[24:16] hold a valid instruction syndrome.

SAS, bits [23:22]

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

00 Byte

01 Halfword

10 Word

11 Doubleword

SSE, bit [21]

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

0 Sign-extension not required.

1 Data item must be sign-extended.

For all other operations this bit is 0.

SRT, bits [20:16]

Syndrome Register transfer. The register number of the Rt operand of the faulting instruction.

SF, bit [15]

Width of the register accessed by the instruction is Sixty-Four. Possible values of this bit are:

0 Instruction loads/stores a 32-bit wide register.

1 Instruction loads/stores a 64-bit wide register.

AR, bit [14]

Acquire/Release. Possible values of this bit are:

0 Instruction did not have acquire/release semantics.

1 Instruction did have acquire/release semantics.

Bits [13:10]

Reserved, RES0.

EA, bit [9]

External abort type. This bit can be provide an IMPLEMENTATION DEFINED classification of external aborts.

For any abort other than an External abort this bit returns a value of 0.

CM, bit [8]

Indicates the data fault came from a Cache Maintenance Instruction, other than DC ZVA instruction, or VA to PA instructions for synchronous faults only.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a fault on the stage 2 translation of an address accessed during a stage 1 translation table walk:

`0` Fault not on a stage 2 translation for a stage 1 translation table walk.

`1` Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For a stage 1 fault, this bit is RES0.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by a write or a read operation. The possible values of this bit are:

`0` Abort caused by a read operation.

`1` Abort caused by a write operation.

For faults on cache maintenance and address translation operations, this bit always returns a value of 1.

DFSC, bits [5:0]

Data Fault Status Code. Possible values of this field are:

`000000` Address size fault, zeroth level of translation or translation table base register

`000001` Address size fault, first level

`000010` Address size fault, second level

`000011` Address size fault, third level

`000100` Translation fault, zeroth level

`000101` Translation fault, first level

`000110` Translation fault, second level

`000111` Translation fault, third level

`001001` Access flag fault, first level

`001010` Access flag fault, second level

`001011` Access flag fault, third level

`001101` Permission fault, first level

`001110` Permission fault, second level

`001111` Permission fault, third level

`010000` Synchronous external abort

`011000` Synchronous parity error on memory access

`010001` Asynchronous external abort

`011001` Asynchronous parity error on memory access

`010100` Synchronous external abort on translation table walk, zeroth level

`010101` Synchronous external abort on translation table walk, first level

`010110` Synchronous external abort on translation table walk, second level

`010111` Synchronous external abort on translation table walk, third level

`011100` Synchronous parity error on memory access on translation table walk, zeroth level

`011101` Synchronous parity error on memory access on translation table walk, first level

`011110` Synchronous parity error on memory access on translation table walk, second level

`011111` Synchronous parity error on memory access on translation table walk, third level

100001	Alignment fault
100010	Debug event
110000	TLB conflict abort
110100	IMPLEMENTATION DEFINED fault (Lockdown fault)
110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
111101	Section Domain Fault, used only for faults reported in the PAR_EL1
111110	Page Domain Fault, used only for faults reported in the PAR_EL1

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 0 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault cased by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

See *Exception from a Data abort* on page D1-1434 for more information about these exceptions.

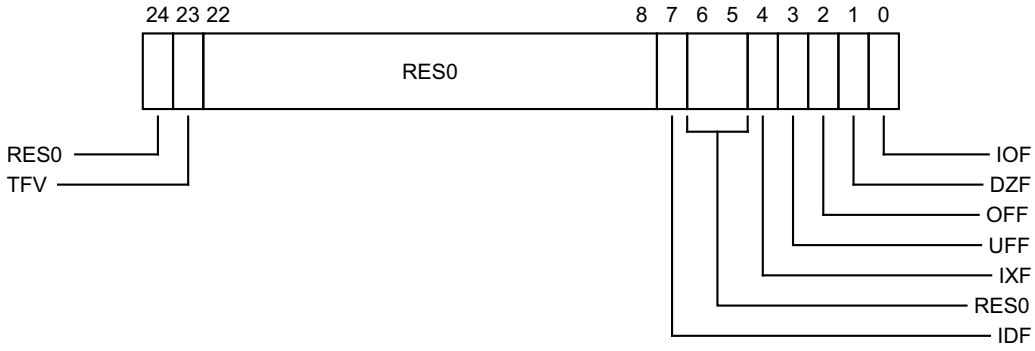
ISS encoding for an exception from a floating-point exception

These are the exception syndromes with the following EC values:

- `0b101000`, trapped floating-point exception from AArch32.
- `0b101100`, trapped floating-point exception from AArch64.

These EC values are used to report the floating-point exceptions defined by IEE 754, and input denormal. In an implementation that does not support the trapping of these floating-point exceptions, the `0b101000` and `0b101100` EC codes are reserved.

The ISS encoding for these exceptions is:



Bit [24]

Reserved, RES0.

TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about a trapped fault. The possible values of this bit are:

0 The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about a trapped fault and are UNKNOWN.

1 The IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about one or more trapped faults. All floating-point exceptions indicated by these bits have occurred since the bits were last cleared to 0.

Bits [22:8]

Reserved, RES0.

IDF, bit [7]

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0 Input denormal floating-point exception has not occurred.

1 Input denormal floating-point exception has occurred since the bit was last set to 0.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0 Inexact floating-point exception has not occurred.

1 Inexact floating-point exception has occurred since the bit was last set to 0.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0 Underflow floating-point exception has not occurred.

1 Underflow floating-point exception has occurred since the bit was last set to 0.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0 Overflow floating-point exception has not occurred.

1 Overflow floating-point exception has occurred since the bit was last set to 0.

DZF, bit [1]

Divide-by-zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

0 Divide-by-zero floating-point exception has not occurred.

1 Divide-by-zero floating-point exception has occurred since the bit was last set to 0.

IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

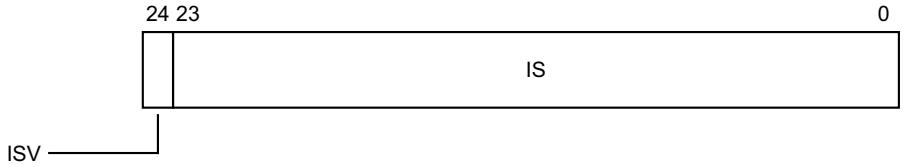
0 Invalid Operation floating-point exception has not occurred.

1 Invalid Operation floating-point exception has occurred since the bit was last set to 0.

See *Floating-point exceptions* on page D1-1435 for more information about these exceptions.

ISS encoding for an SError interrupt

This is the exception syndrome with EC value `0b101111`. It is used to report the exception caused by an SError interrupt. The ISS encoding for these exceptions is:



ISV, bit [24]

Instruction syndrome valid. Indicates whether the rest of the syndrome information in this register is valid.

`0` No valid instruction syndrome. ISS[23:0] are RES0.

`1` ISS[23:0] hold a valid instruction syndrome.

IS, bits [23:0]

Implementation specific syndrome information that can be used to provide additional implementation specific information. Only valid if bit[24] of this register is 1. If bit[24] is 0, this field is RES0.

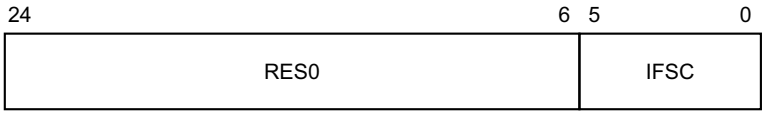
See also *SError interrupt* on page D1-1435.

ISS encoding for a Breakpoint exception or Vector Catch exception

These are the exception syndromes with the following EC values:

- `0b110000`, Breakpoint exception taken from a lower Exception level.
- `0b110001`, Breakpoint exception taken without a change of Exception level.
- `0b111010`, AArch32 Vector Catch exception.

The ISS encoding for these exceptions is:



Bits [24:6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code. Possible values of this field are:

`000000` Address size fault, zeroth level of translation or translation table base register

`000001` Address size fault, first level

`000010` Address size fault, second level

`000011` Address size fault, third level

`000100` Translation fault, zeroth level

`000101` Translation fault, first level

`000110` Translation fault, second level

`000111` Translation fault, third level

`001001` Access flag fault, first level

`001010` Access flag fault, second level

`001011` Access flag fault, third level

`001101` Permission fault, first level

001110	Permission fault, second level
001111	Permission fault, third level
010000	Synchronous external abort
011000	Synchronous parity error on memory access
010100	Synchronous external abort on translation table walk, zeroth level
010101	Synchronous external abort on translation table walk, first level
010110	Synchronous external abort on translation table walk, second level
010111	Synchronous external abort on translation table walk, third level
011100	Synchronous parity error on memory access on translation table walk, zeroth level
011101	Synchronous parity error on memory access on translation table walk, first level
011110	Synchronous parity error on memory access on translation table walk, second level
011111	Synchronous parity error on memory access on translation table walk, third level
100001	Alignment fault
100010	Debug event
110000	TLB conflict abort
110100	IMPLEMENTATION DEFINED fault (Lockdown fault)

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 0 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault cased by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

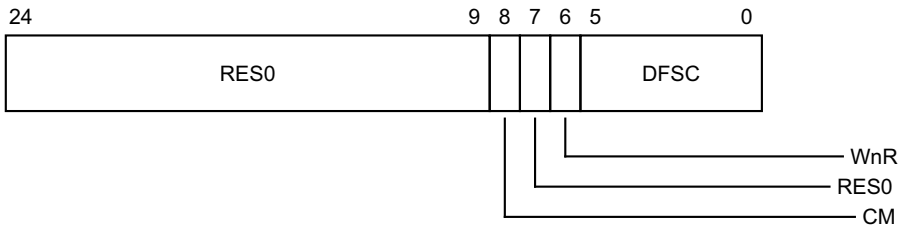
See *Breakpoint exception or Vector Catch exception* on page D1-1435 for more information about these exceptions.

ISS encoding for a Watchpoint exception

These are the exception syndromes with the following EC values:

- 0b110100, Watchpoint exception taken from a lower Exception level.
- 0b110101, Watchpoint exception taken without a change of Exception level.

The ISS encoding for these exceptions is:



Bits [24:9]

Reserved, RES0.

CM, bit [8]

Indicates the data fault came from a Cache Maintenance Instruction, other than DC ZVA instruction, or VA to PA instructions for synchronous faults only.

Bit [7]

Reserved, RES0.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by a write or a read operation. The possible values of this bit are:

0 Abort caused by a read operation.

1 Abort caused by a write operation.

For faults on cache maintenance and address translation operations, this bit always returns a value of 1.

DFSC, bits [5:0]

Data Fault Status Code. Possible values of this field are:

000000 Address size fault, zeroth level of translation or translation table base register

000001 Address size fault, first level

000010 Address size fault, second level

000011 Address size fault, third level

000100 Translation fault, zeroth level

000101 Translation fault, first level

000110 Translation fault, second level

000111 Translation fault, third level

001001 Access flag fault, first level

001010 Access flag fault, second level

001011 Access flag fault, third level

001101 Permission fault, first level

001110 Permission fault, second level

001111 Permission fault, third level

010000 Synchronous external abort

011000 Synchronous parity error on memory access

010001 Asynchronous external abort

011001 Asynchronous parity error on memory access

010100 Synchronous external abort on translation table walk, zeroth level

010101 Synchronous external abort on translation table walk, first level

010110 Synchronous external abort on translation table walk, second level

010111 Synchronous external abort on translation table walk, third level

011100 Synchronous parity error on memory access on translation table walk, zeroth level

011101 Synchronous parity error on memory access on translation table walk, first level

011110 Synchronous parity error on memory access on translation table walk, second level

011111 Synchronous parity error on memory access on translation table walk, third level

100001 Alignment fault

100010 Debug event

110000 TLB conflict abort

110100 IMPLEMENTATION DEFINED fault (Lockdown fault)

110101 IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)

111101 Section Domain Fault, used only for faults reported in the PAR_EL1

111110 Page Domain Fault, used only for faults reported in the PAR_EL1

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 0 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault cased by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

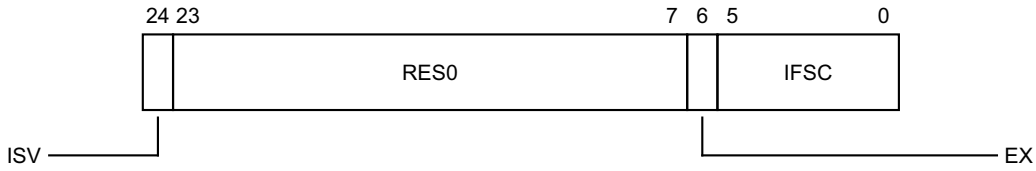
See *Watchpoint exception* on page D1-1435 for more information about these exceptions.

ISS encoding for Software Step exception

These are the exception syndromes with the following EC values:

- `0b110010`, Software Step exception taken from a lower Exception level.
- `00b110011`, Software Step exception taken without a change of Exception level.

The ISS encoding for these exceptions is:



ISV, bit [24]

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

`0` EX bit is RES0.

`1` EX bit is valid.

See the ISS[6] description for more information.

Bits [23:7]

Reserved, RES0.

EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

`0` An instruction other than a Load-Exclusive instruction was stepped.

`1` A Load-Exclusive instruction was stepped.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

IFSC, bits [5:0]

Instruction Fault Status Code. Possible values of this field are:

`000000` Address size fault, zeroth level of translation or translation table base register

`000001` Address size fault, first level

`000010` Address size fault, second level

`000011` Address size fault, third level

`000100` Translation fault, zeroth level

`000101` Translation fault, first level

`000110` Translation fault, second level

000111	Translation fault, third level
001001	Access flag fault, first level
001010	Access flag fault, second level
001011	Access flag fault, third level
001101	Permission fault, first level
001110	Permission fault, second level
001111	Permission fault, third level
010000	Synchronous external abort
011000	Synchronous parity error on memory access
010100	Synchronous external abort on translation table walk, zeroth level
010101	Synchronous external abort on translation table walk, first level
010110	Synchronous external abort on translation table walk, second level
010111	Synchronous external abort on translation table walk, third level
011100	Synchronous parity error on memory access on translation table walk, zeroth level
011101	Synchronous parity error on memory access on translation table walk, first level
011110	Synchronous parity error on memory access on translation table walk, second level
011111	Synchronous parity error on memory access on translation table walk, third level
100001	Alignment fault
100010	Debug event
110000	TLB conflict abort
110100	IMPLEMENTATION DEFINED fault (Lockdown fault)

All other values are reserved.

The lookup level associated with a fault is:

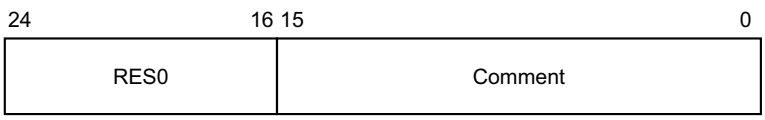
- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 0 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault cased by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

See *Software Step exception* on page D1-1436 for more information about these exceptions.

ISS encoding for a Software Breakpoint Instruction exception

These are the exception syndromes with the following EC values:

- 0b111000, BKPT instruction executed in AArch32 state.
- 0b111100, BRK instruction executed in AArch64 state.



Bits [24:16]

Reserved, RES0.

Comment, bits [15:0]

Set to the instruction comment field value, zero extended as necessary.

See *Software Breakpoint Instruction exception* on page D1-1436 for more information about these exceptions.

D7.2.28 FAR_EL1, Fault Address Register (EL1)

The FAR_EL1 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous instruction or data aborts, or exceptions from a misaligned PC or a Watchpoint debug event, taken to EL1.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

FAR_EL1[31:0] is architecturally mapped to AArch32 register DFAR (NS).

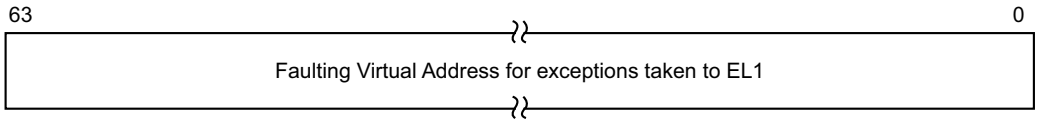
FAR_EL1[63:32] is architecturally mapped to AArch32 register IFAR (NS).

Attributes

FAR_EL1 is a 64-bit register.

Field descriptions

The FAR_EL1 bit assignments are:



Bits [63:0]

Faulting Virtual Address for exceptions taken to EL1. Exceptions that set the FAR_EL1 are all synchronous instruction aborts or data aborts, an exception from a misaligned PC, or a Watchpoint debug event.

If a memory fault that sets FAR_EL1 is generated from one of the data cache instructions, this field holds the address specified in the register argument of the instruction.

Accessing the FAR_EL1

To access the FAR_EL1:

```
MRS <Xt>, FAR_EL1 ; Read FAR_EL1 into Xt
MSR FAR_EL1, <Xt> ; Write Xt to FAR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0110	0000	000

D7.2.29 FAR_EL2, Fault Address Register (EL2)

The FAR_EL2 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous instruction or data aborts, or exceptions from a misaligned PC or a Watchpoint debug event, taken to EL2.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

FAR_EL2[31:0] is architecturally mapped to AArch32 register HDFAR.

FAR_EL2[63:32] is architecturally mapped to AArch32 register HIFAR.

FAR_EL2[31:0] is architecturally mapped to AArch32 register DFAR (S) when EL2 is implemented.

FAR_EL2[63:32] is architecturally mapped to AArch32 register IFAR (S) when EL2 is implemented.

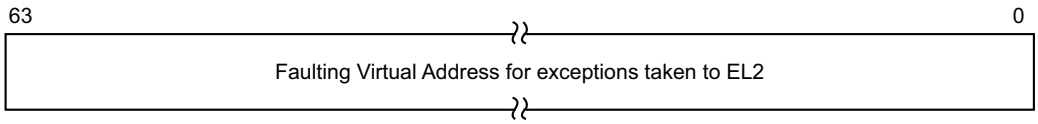
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

FAR_EL2 is a 64-bit register.

Field descriptions

The FAR_EL2 bit assignments are:



Bits [63:0]

Faulting Virtual Address for exceptions taken to EL2. Exceptions that set the FAR_EL2 are all synchronous instruction aborts or data aborts, an exception from a misaligned PC, or a Watchpoint debug event.

If a memory fault that sets FAR_EL2 is generated from one of the data cache instructions, this field holds the address specified in the register argument of the instruction.

Accessing the FAR_EL2

To access the FAR_EL2:

```
MRS <Xt>, FAR_EL2 ; Read FAR_EL2 into Xt
MSR FAR_EL2, <Xt> ; Write Xt to FAR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0110	0000	000

D7.2.30 FAR_EL3, Fault Address Register (EL3)

The FAR_EL3 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous instruction or data aborts, or exceptions from a misaligned PC, taken to EL3.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

FAR_EL3[31:0] can be mapped to AArch32 register DFAR (S) when EL2 is not implemented, but this is not architecturally mandated.

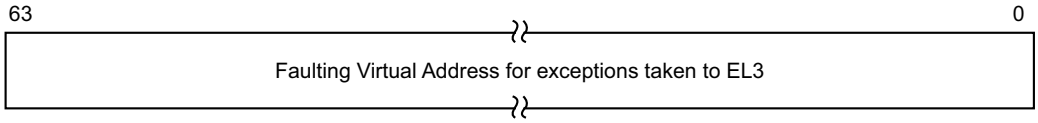
FAR_EL3[63:32] can be mapped to AArch32 register IFAR (S) when EL2 is not implemented, but this is not architecturally mandated.

Attributes

FAR_EL3 is a 64-bit register.

Field descriptions

The FAR_EL3 bit assignments are:



Bits [63:0]

Faulting Virtual Address for exceptions taken to EL3. Exceptions that set the FAR_EL3 are all synchronous instruction aborts or data aborts, or an exception from a misaligned PC.

If a memory fault that sets FAR_EL3 is generated from one of the data cache instructions, this field holds the address specified in the register argument of the instruction.

Accessing the FAR_EL3

To access the FAR_EL3:

```
MRS <Xt>, FAR_EL3 ; Read FAR_EL3 into Xt
MSR FAR_EL3, <Xt> ; Write Xt to FAR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0110	0000	000

D7.2.31 FPEXC32_EL2, Floating-point Exception Control register

The FPEXC32_EL2 characteristics are:

Purpose

Allows access to the AArch32 register FPEXC from AArch64 state only. Its value has no effect on execution in AArch64 state.

This register is part of the Floating-point registers functional group.

Usage constraints

This register is accessible as FPEXC32_EL2 shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Note

This register is accessible from EL1 using AArch32 as FPEXC.

If EL1 only supports AArch64 execution, this register is UNDEFINED.

Configurations

FPEXC32_EL2 is architecturally mapped to AArch32 register FPEXC.

Attributes

FPEXC32_EL2 is a 32-bit register.

For more information, see *FPEXC, Floating-Point Exception Control register* on page G5-3894.

Accessing the FPEXC32_EL2:

To access the FPEXC32_EL2:

```
MRS <Xt>, FPEXC32_EL2 ; Read FPEXC32_EL2 into Xt
MSR FPEXC32_EL2, <Xt> ; Write Xt to FPEXC32_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0101	0011	000

D7.2.32 HACR_EL2, Hypervisor Auxiliary Control Register

The HACR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of IMPLEMENTATION DEFINED aspects of Non-secure EL1 or EL0 operation.

This register is part of the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

HACR_EL2 is architecturally mapped to AArch32 register HACR.

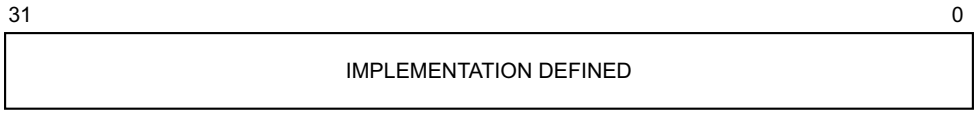
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HACR_EL2 is a 32-bit register.

Field descriptions

The HACR_EL2 bit assignments are:



Accessing the HACR_EL2

To access the HACR_EL2:

```
MRS <Xt>, HACR_EL2 ; Read HACR_EL2 into Xt
MSR HACR_EL2, <Xt> ; Write Xt to HACR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0001	0001	111

D7.2.33 HCR_EL2, Hypervisor Configuration Register

The HCR_EL2 characteristics are:

Purpose

Provides configuration controls for virtualization, including defining whether various Non-secure operations are trapped to EL2.

This register is part of the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

HCR_EL2[31:0] is architecturally mapped to AArch32 register HCR.

HCR_EL2[63:32] is architecturally mapped to AArch32 register HCR2.

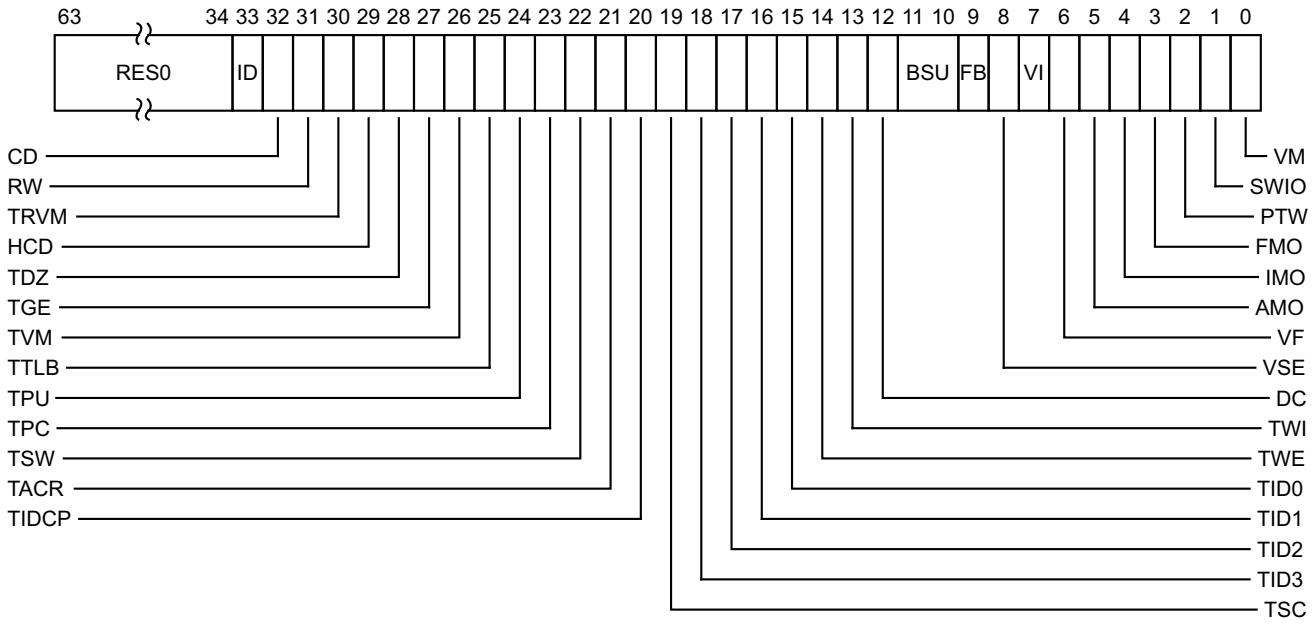
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HCR_EL2 is a 64-bit register.

Field descriptions

The HCR_EL2 bit assignments are:



Bits [63:34]

Reserved, RES0.

ID, bit [33]

Stage 2 Instruction cache disable. When HCR_EL2.VM==1, this forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable for the EL1&0 translation regime.

0 No effect on the stage 2 of the EL1&0 translation regime for instruction accesses.

1 Forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable for the EL1&0 translation regime.

This bit has no effect on the EL2 or EL3 translation regimes.

CD, bit [32]

Stage 2 Data cache disable. When HCR_EL2.VM==1, this forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the EL1&0 translation regime.

0 No effect on the stage 2 of the EL1&0 translation regime for data accesses and translation table walks.

1 Forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the EL1&0 translation regime.

This bit has no effect on the EL2 or EL3 translation regimes.

RW, bit [31]

Execution state control for lower exception levels:

0 Lower levels are all AArch32.

1 EL1 is AArch64. EL0 is determined by the Execution state described in the current process state when executing at EL0.

When SCR_EL3.NS==0, this bit behaves as if it has the same value as the SCR_EL3.RW bit except for the value read back.

The RW bit is permitted to be cached in a TLB.

TRVM, bit [30]

Trap Read of Virtual Memory controls. When this bit is set to 1, this causes Reads to the EL1 virtual memory control registers from EL1 to be trapped to EL2. This covers the following registers:

AArch32: SCTLR, TTBR0, TTBR1, TTBCR, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR/MAIR0, NMRR/MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

AArch64: SCTLR_EL1, TTBR0_EL1, TTBR1_EL1, TCR_EL1, ESR_EL1, FAR_EL1, AFSR0_EL1, AFSR1_EL1, MAIR_EL1, AMAIR_EL1, CONTEXTIDR_EL1.

HCD, bit [29]

Hypervisor Call Disable, if EL3 is not implemented:

0 HVC instruction is enabled at EL1 or EL2.

1 HVC instruction is UNDEFINED at all exception levels.

If EL3 is implemented, this bit is RES0.

TDZ, bit [28]

Trap DC ZVA instruction:

0 The instruction is not trapped.

1 The instruction is trapped to EL2 when executed in Non-secure EL1 or EL0.

This bit also has an effect on the value read from the DCZID_EL0 register. If this bit is 1, then reading DCZID_EL0.DZP from Non-secure EL1 or EL0 will return 1 to indicate that DC ZVA is prohibited.

TGE, bit [27]

Trap General Exceptions. If this bit is set to 1, and SCR_EL3.NS is set to 1, then:

- All exceptions that would be routed to EL1 are routed to EL2.

- The SCTLR_EL1.M bit is treated as being 0 regardless of its actual state (for EL1 using AArch32 or AArch64) other than for the purpose of reading the bit.
- The HCR_EL2.FMO, IMO and AMO bits are treated as being 1 regardless of their actual state other than for the purpose of reading the bits.
- All virtual interrupts are disabled.
- Any implementation defined mechanisms for signalling virtual interrupts are disabled.
- An exception return to EL1 is treated as an illegal exception return.

Additionally, if HCR_EL2.TGE == 1, the MDCR_EL2.{TDRA,TDOSA,TDA} bits are ignored and the processor behaves as if they are set to 1, other than for the value read back from MDCR_EL2.

TVM, bit [26]

Trap Virtual Memory controls. When this bit is set to 1, this causes Writes to the EL1 virtual memory control registers from EL1 to be trapped to EL2. This covers the following registers:

AArch32: SCTLR, TTBR0, TTBR1, TTBCR, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR/MAIR0, NMRR/MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

AArch64: SCTLR_EL1, TTBR0_EL1, TTBR1_EL1, TCR_EL1, ESR_EL1, FAR_EL1, AFSR0_EL1, AFSR1_EL1, MAIR_EL1, AMAIR_EL1, CONTEXTIDR_EL1

TTLB, bit [25]

Trap TLB maintenance instructions. When this bit is set to 1, this causes TLB maintenance instructions executed from EL1 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

AArch32: TLBIALLIS, TLBIMVAIS, TLBIASIDIS, TLBIMVAAIS, TLBIALL, TLBIMVA, TLBIASID, DTLBIALL, DTLBIMVA, DTLBIASID, ITLBIALL, ITLBIMVA, ITLBIASID, TLBIMVAA, TLBIMVALIS, TLBIMVAALIS, TLBIMVAL, TLBIMVAAL

AArch64: TLBI VMALLE1, TLBI VAE1, TLBI ASIDE1, TLBI VAAE1, TLBI VALE1, TLBI VAALE1, TLBI VMALLE1IS, TLBI VAE1IS, TLBI ASIDE1IS, TLBI VAAE1IS, TLBI VALE1IS, TLBI VAALE1IS

TPU, bit [24]

Trap Cache maintenance instructions to Point of Unification. When this bit is set to 1, this causes Cache maintenance instructions to the point of unification executed from EL1 or EL0 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

AArch32: ICIMVAU, ICIALLU, ICIALLUIS, DCCMVAU.

AArch64: IC IVAU, IC IALLU, IC IALLUIS, DC CVAU.

TPC, bit [23]

Trap Data/Unified Cache maintenance operations to Point of Coherency. When this bit is set to 1, this causes Data or Unified Cache maintenance instructions by address to the point of coherency executed from EL1 or EL0 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

AArch32: DCIMVAC, DCCIMVAC, DCCMVAC.

AArch64: DC IVAC, DC CIVAC, DC CVAC.

TSW, bit [22]

Trap Data/Unified Cache maintenance operations by Set/Way. When this bit is set to 1, this causes Data or Unified Cache maintenance instructions by set/way executed from EL1 which are not UNDEFINED to be trapped to EL2. This covers the following instructions:

AArch32: DCISW, DCCSW, DCCISW.

AArch64: DC ISW, DC CSW, DC CISW.

TACR, bit [21]

Trap Auxiliary Control Register. When this bit is set to 1, this causes accesses to the following registers executed from EL1 to be trapped to EL2:

AArch32: ACTLR.

AArch64: ACTLR_EL1.

TIDCP, bit [20]

Trap Implementation Dependent functionality. When this bit is set to 1, this causes accesses to the following instruction set space executed from EL1 to be trapped to EL2.

AArch32: MCR and MRC instructions as follows:

- All CP15, CRn==9, Opcode1 = {0-7}, CRm == {c0-c2, c5-c8}, opcode2 == {0-7}.
- All CP15, CRn==10, Opcode1 =={0-7}, CRm == {c0, c1, c4, c8}, opcode2 == {0-7}.
- All CP15, CRn==11, Opcode1=={0-7}, CRm == {c0-c8, c15}, opcode2 == {0-7}.

AArch64: All encoding space reserved for IMPLEMENTATION DEFINED system operations (S1 <op1> <cn> <cm> <op2>) and system registers (S3_<op1>_<Cn>_<Cm>_<op2>).

It is IMPLEMENTATION DEFINED whether any of this functionality accessed from EL0 is trapped to EL2 when the HCR_EL2.TIDCP bit is set. If it is not trapped to EL2, it results in an Undefined exception taken to EL1.

TSC, bit [19]

Trap SMC. When this bit is set to 1, this causes the following instructions executed from EL1 to be trapped to EL2:

AArch32: SMC.

AArch64: SMC.

If EL3 is not implemented, this bit is RES0.

TID3, bit [18]

Trap ID Group 3. When this bit is set to 1, this causes reads to the following registers executed from EL1 to be trapped to EL2:

AArch32: ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0, ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5, MVFR0, MVFR1, MVFR2. Also MRC to any of the following encodings:

- CP15, CRn == 0, Opc1 == 0, CRm == {3-7}, Opc2 == {0,1}.
- CP15, CRn == 0, Opc1 == 0, CRm == 3, Opc2 == 2.
- CP15, CRn == 0, Opc1 == 0, CRm == 5, Opc2 == {4,5}.

AArch64: ID_PFR0_EL1, ID_PFR1_EL1, ID_DFR0_EL1, ID_AFR0_EL1, ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1, ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, ID_ISAR5_EL1, MVFR0_EL1, MVFR1_EL1, MVFR2_EL1, ID_AA64PFR0_EL1, ID_AA64PFR1_EL1, ID_AA64DFR0_EL1, ID_AA64DFR1_EL1, ID_AA64ISAR0_EL1, ID_AA64ISAR1_EL1, ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1, ID_AA64AFR0_EL1, ID_AA64AFR1_EL1.

TID2, bit [17]

Trap ID Group 2. When this bit is set to 1, this causes reads (or writes to CSSELR/CSSELR_EL1) to the following registers executed from EL1 or EL0 if not UNDEFINED to be trapped to EL2:

AArch32: CTR, CCSIDR, CLIDR, CSSELR.

AArch64: CTR_EL0, CCSIDR_EL1, CLIDR_EL1, CSSELR_EL1.

TID1, bit [16]

Trap ID Group 1. When this bit is set to 1, this causes reads to the following registers executed from EL1 to be trapped to EL2:

AArch32: TCMTR, TLBTR, AIDR, REVIDR.

AArch64: AIDR_EL1, REVIDR_EL1.

TID0, bit [15]

Trap ID Group 0. When this bit is set to 1, this causes reads to the following registers executed from EL1 or EL0 if not UNDEFINED to be trapped to EL2:

AArch32: FPSID, JIDR.

AArch64: None.

TWE, bit [14]

Trap WFE. When this bit is set to 1, this causes the following instructions executed from EL1 or EL0 to be trapped to EL2 if the instruction would otherwise cause suspension of execution (i.e. if the event register is not set):

AArch32: WFE.

AArch64: WFE.

Conditional WFE instructions that fail their condition are not trapped if this bit is set to 1.

TWI, bit [13]

Trap WFI. When this bit is set to 1, this causes the following instructions executed from EL1 or EL0 to be trapped to EL2 if the instruction would otherwise cause suspension of execution (i.e. if there is not a pending WFI wakeup event):

AArch32: WFI.

AArch64: WFI.

Conditional WFI instructions that fail their condition are not trapped if this bit is set to 1.

DC, bit [12]

Default Cacheable. When this bit is set to 1, this causes:

- The SCTLR_EL1.M bit to behave as 0 when in the Non-secure state for all purposes other than reading the value of the bit.
- The HCR_EL2.VM bit to behave as 1 when in the Non-secure state for all purposes other than reading the value of the bit.

The memory type produced by the first stage of translation used by EL1 and EL0 is Normal Non-Shareable, Inner WriteBack Read-WriteAllocate, Outer WriteBack Read-WriteAllocate.

When this bit is 0 and the stage 1 MMU is disabled, the default memory attribute for Data accesses is Device-nGnRnE.

This bit is permitted to be cached in a TLB.

BSU, bits [11:10]

Barrier Shareability upgrade. The value in this field determines the minimum shareability domain that is applied to any barrier executed from EL1 or EL0:

00	No effect
01	Inner Shareable
10	Outer Shareable
11	Full system

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

FB, bit [9]

Force broadcast. When this bit is set to 1, this causes the following instructions to be broadcast within the Inner Shareable domain when executed from Non-secure EL1:

AArch32: BPIALL, TLBIALL, TLBIMVA, TLBIASID, DTLBIALL, DTLBIMVA, DTLBIASID, ITLBIALL, ITLBIMVA, ITLBIASID, TLBIMVAA, ICIALLU, TLBIMVAL, TLBIMVAAL.

AArch64: TLBI VMALLE1, TLBI VAE1, TLBI ASIDE1, TLBI VAAE1, TLBI VALE1, TLBI VAALE1, IC IALLU.

VSE, bit [8]

Virtual System Error/Asynchronous Abort.

0 Virtual System Error/Asynchronous Abort is not pending by this mechanism.

1 Virtual System Error/Asynchronous Abort is pending by this mechanism.

The virtual System Error/Asynchronous Abort is only enabled when the HCR_EL2.AMO bit is set.

VI, bit [7]

Virtual IRQ Interrupt.

0 Virtual IRQ is not pending by this mechanism.

1 Virtual IRQ is pending by this mechanism.

The virtual IRQ is only enabled when the HCR_EL2.IMO bit is set.

VF, bit [6]

Virtual FIQ Interrupt.

0 Virtual FIQ is not pending by this mechanism.

1 Virtual FIQ is pending by this mechanism.

The virtual FIQ is only enabled when the HCR_EL2.FMO bit is set.

AMO, bit [5]

Asynchronous abort and error interrupt routing.

0 Asynchronous External Aborts and SError Interrupts while executing at exception levels lower than EL2 are not taken in EL2. Virtual System Error/Asynchronous Abort is disabled.

1 Asynchronous External Aborts and SError Interrupts while executing at EL2 or lower are taken in EL2 unless routed by the SCR_EL3.EA bit to EL3. Virtual System Error/Asynchronous Abort is enabled.

IMO, bit [4]

Physical IRQ Routing.

0 Physical IRQ while executing at exception levels lower than EL2 are not taken in EL2. Virtual IRQ Interrupt is disabled.

1 Physical IRQ while executing at EL2 or lower are taken in EL2 unless routed by the SCR_EL3.IRQ bit to EL3. Virtual IRQ Interrupt is enabled.

FMO, bit [3]

Physical FIQ Routing.

0 Physical FIQ while executing at exception levels lower than EL2 are not taken in EL2. Virtual FIQ Interrupt is disabled.

1 Physical FIQ while executing at EL2 or lower are taken in EL2 unless routed by the SCR_EL3.FIQ bit to EL3. Virtual FIQ Interrupt is enabled.

PTW, bit [2]

Protected Table Walk. When this bit is set to 1, if the stage 2 translation of a translation table access made as part of a stage 1 translation table walk at EL0 or EL1 maps that translation table access to Strongly-ordered or Device memory, the access is faulted as a stage 2 Permission fault.

This bit is permitted to be cached in a TLB.

SWIO, bit [1]

Set/Way Invalidation Override. When this bit is set to 1, this causes EL1 execution of the data cache invalidate by set/way instruction to be treated as data cache clean and invalidate by set/way. That is:

AArch32: DCISW is executed as DCCISW.

AArch64: DC ISW is executed as DC CISW.

As a result of changes to the behavior of DCISW, this bit is redundant in v8-A. It is permissible that an implementation makes this bit RES1.

VM, bit [0]

Virtualization MMU enable for EL1 and EL0 stage 2 address translation. Possible values of this bit are:

0 EL1 and EL0 stage 2 address translation disabled.

1 EL1 and EL0 stage 2 address translation enabled.

This bit is permitted to be cached in a TLB.

Accessing the HCR_EL2

To access the HCR_EL2:

```
MRS <Xt>, HCR_EL2 ; Read HCR_EL2 into Xt
MSR HCR_EL2, <Xt> ; Write Xt to HCR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0001	0001	000

D7.2.34 HPFAR_EL2, Hypervisor IPA Fault Address Register

The HPFAR_EL2 characteristics are:

Purpose

Holds the faulting IPA for some aborts on a stage 2 translation taken to EL2.

This register is part of:

- the Exception and fault handling registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

HPFAR_EL2[31:0] is architecturally mapped to AArch32 register HPFAR.

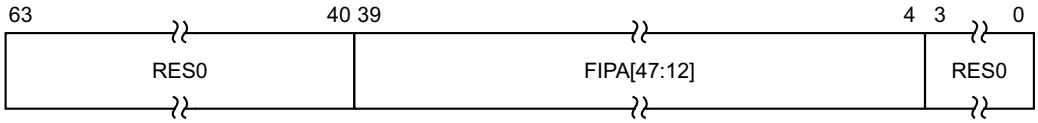
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HPFAR_EL2 is a 64-bit register.

Field descriptions

The HPFAR_EL2 bit assignments are:



Bits [63:40]

Reserved, RES0.

FIPA[47:12], bits [39:4]

Bits [47:12] of the faulting intermediate physical address. For implementations with fewer than 48 physical address bits, the equivalent upper bits in this field are RES0.

Bits [3:0]

Reserved, RES0.

Accessing the HPFAR_EL2

To access the HPFAR_EL2:

```
MRS <Xt>, HPFAR_EL2 ; Read HPFAR_EL2 into Xt
MSR HPFAR_EL2, <Xt> ; Write Xt to HPFAR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0110	0000	100

D7.2.35 HSTR_EL2, Hypervisor System Trap Register

The HSTR_EL2 characteristics are:

Purpose

Controls access to coprocessor registers at lower exception levels in AArch32.

This register is part of the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

HSTR_EL2 is architecturally mapped to AArch32 register HSTR.

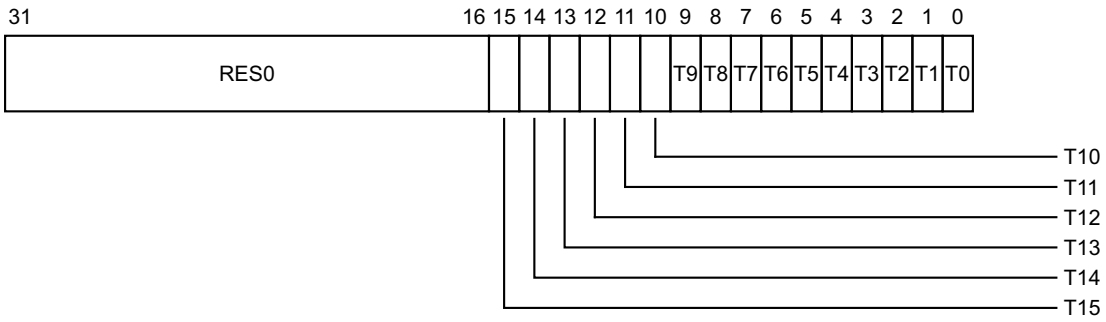
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

HSTR_EL2 is a 32-bit register.

Field descriptions

The HSTR_EL2 bit assignments are:



Bits [31:16]

Reserved, RES0.

T<n>, bit [n], for n = 0 to 15

Trap coprocessor primary register. For each field T<n>, the possible values of this bit are:

`0` Has no effect on Non-secure accesses to CP15 coprocessor registers.

`1` Trap valid Non-secure accesses to coprocessor primary register c<n> to Hyp mode.

When T<n> is set to 1, any valid Non-secure access to CP15 primary coprocessor register c<n> is trapped to Hyp mode. For example, when T7 is set to 1:

- Any valid Non-secure 32-bit CP15 accesses, using MRC or MCR instructions with CRn==c7, are trapped to Hyp mode.
- Any valid Non-secure 64-bit CP15 accesses, using MRRC or MCRR instructions with CRm==c7, are trapped to Hyp mode.

Fields T14 and T4 are RES0.

Accessing the HSTR_EL2

To access the HSTR_EL2:

```
MRS <Xt>, HSTR_EL2 ; Read HSTR_EL2 into Xt
MSR HSTR_EL2, <Xt> ; Write Xt to HSTR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0001	0001	011

D7.2.36 ID_AA64AFR0_EL1, AArch64 Auxiliary Feature Register 0

The ID_AA64AFR0_EL1 characteristics are:

Purpose

Provides information about the IMPLEMENTATION DEFINED features of the processor in AArch64 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

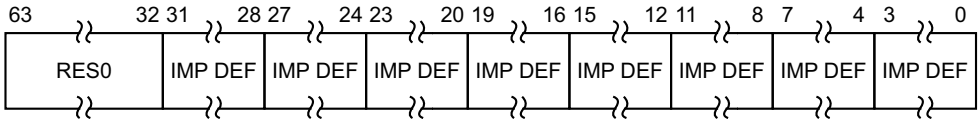
There are no configuration notes.

Attributes

ID_AA64AFR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64AFR0_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

Bits [31:0]

IMPLEMENTATION DEFINED

Accessing the ID_AA64AFR0_EL1

To access the ID_AA64AFR0_EL1:

```
MRS <Xt>, ID_AA64AFR0_EL1 ; Read ID_AA64AFR0_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0101	100

D7.2.37 ID_AA64AFR1_EL1, AArch64 Auxiliary Feature Register 1

The ID_AA64AFR1_EL1 characteristics are:

Purpose

Reserved for future expansion of information about the IMPLEMENTATION DEFINED features of the processor in AArch64 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

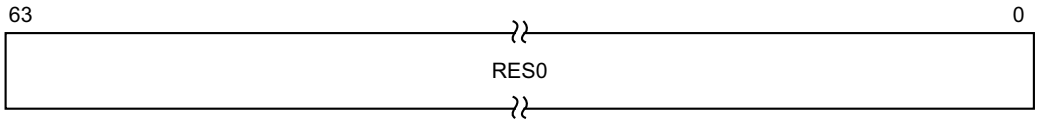
There are no configuration notes.

Attributes

ID_AA64AFR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64AFR1_EL1 bit assignments are:



Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64AFR1_EL1

To access the ID_AA64AFR1_EL1:

```
MRS <Xt>, ID_AA64AFR1_EL1 ; Read ID_AA64AFR1_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0101	101

D7.2.38 ID_AA64DFR0_EL1, AArch64 Debug Feature Register 0

The ID_AA64DFR0_EL1 characteristics are:

Purpose

Provides top level information about the debug system in AArch64 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

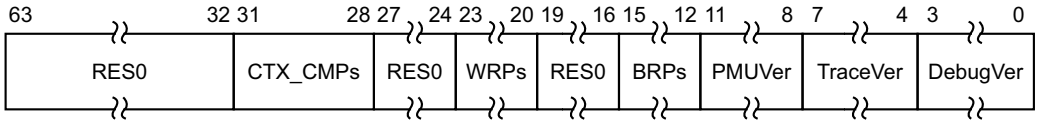
ID_AA64DFR0_EL1 is architecturally mapped to external register ID_AA64DFR0_EL1.

Attributes

ID_AA64DFR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64DFR0_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

CTX_CMPs, bits [31:28]

Number of breakpoints that are context-aware, minus 1. These are the highest numbered breakpoints.

Bits [27:24]

Reserved, RES0.

WRPs, bits [23:20]

Number of watchpoints, minus 1. The value of `0b0000` is reserved.

Bits [19:16]

Reserved, RES0.

BRPs, bits [15:12]

Number of breakpoints, minus 1. The value of `0b0000` is reserved.

PMUVer, bits [11:8]

Performance Monitors extension version. Indicates whether system register interface to Performance Monitors extension is implemented. Permitted values are:

`0000` Performance Monitors extension system registers not implemented.

`0001` Performance Monitors extension system registers implemented, PMUv3.

1111 IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported.

All other values are reserved.

TraceVer, bits [7:4]

Trace extension. Indicates whether system register interface to Trace extension is implemented. Permitted values are:

0000 Trace extension system registers not implemented.

0001 Trace extension system registers implemented.

All other values are reserved.

A value of 0000 only indicates that no system register interface to the trace extension is implemented. A trace extension might nevertheless be implemented without a system register interface.

DebugVer, bits [3:0]

Debug architecture version. Indicates the presence of the ARMv8-A debug architecture.

0110 ARMv8-A debug architecture.

All other values are reserved.

Accessing the ID_AA64DFR0_EL1

To access the ID_AA64DFR0_EL1:

```
MRS <Xt>, ID_AA64DFR0_EL1 ; Read ID_AA64DFR0_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0101	000

D7.2.39 ID_AA64DFR1_EL1, AArch64 Debug Feature Register 1

The ID_AA64DFR1_EL1 characteristics are:

Purpose

Reserved for future expansion of top level information about the debug system in AArch64 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

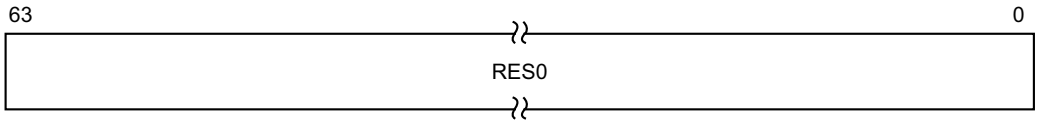
ID_AA64DFR1_EL1 is architecturally mapped to external register ID_AA64DFR1_EL1.

Attributes

ID_AA64DFR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64DFR1_EL1 bit assignments are:



Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64DFR1_EL1

To access the ID_AA64DFR1_EL1:

```
MRS <Xt>, ID_AA64DFR1_EL1 ; Read ID_AA64DFR1_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0101	001

D7.2.40 ID_AA64ISAR0_EL1, AArch64 Instruction Set Attribute Register 0

The ID_AA64ISAR0_EL1 characteristics are:

Purpose

Provides information about the instructions implemented by the processor in AArch64 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

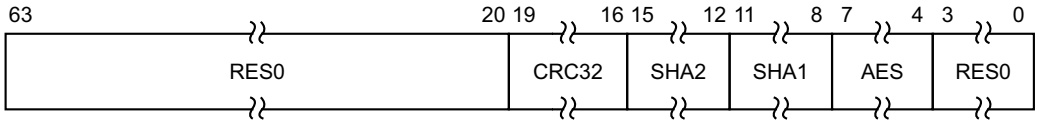
ID_AA64ISAR0_EL1 is architecturally mapped to external register ID_AA64ISAR0_EL1.

Attributes

ID_AA64ISAR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64ISAR0_EL1 bit assignments are:



Bits [63:20]

Reserved, RES0.

CRC32, bits [19:16]

CRC32 instructions in AArch64 state. Possible values of this field are:

0000 No CRC32 instructions implemented.

0001 CRC32B, CRC32H, CRC32W, CRC32X, CRC32CB, CRC32CH, CRC32CW, and CRC32CX instructions implemented.

All other values are reserved.

This field must have the same value as ID_ISAR5.CRC32. The architecture requires that if CRC32 is supported in one Execution state, it must be supported in both Execution states.

SHA2, bits [15:12]

SHA2 instructions in AArch64 state. Possible values of this field are:

0000 No SHA2 instructions implemented.

0001 SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 instructions implemented.

All other values are reserved.

SHA1, bits [11:8]

SHA1 instructions in AArch64 state. Possible values of this field are:

0000 No SHA1 instructions implemented.

`0001` SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 instructions implemented.

All other values are reserved.

AES, bits [7:4]

AES instructions in AArch64 state. Possible values of this field are:

`0000` No AES instructions implemented.

`0001` AESE, AESD, AESMC, and AESIMC instructions implemented.

`0010` The same instructions as for the value `0001`, with the addition of PMULL/PMULL2 instructions operating on 64-bit data quantities.

Bits [3:0]

Reserved, RES0.

Accessing the ID_AA64ISAR0_EL1

To access the ID_AA64ISAR0_EL1:

```
MRS <Xt>, ID_AA64ISAR0_EL1 ; Read ID_AA64ISAR0_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0110	000

D7.2.41 ID_AA64ISAR1_EL1, AArch64 Instruction Set Attribute Register 1

The ID_AA64ISAR1_EL1 characteristics are:

Purpose

Reserved for future expansion of the information about the instruction sets implemented by the processor in AArch64 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

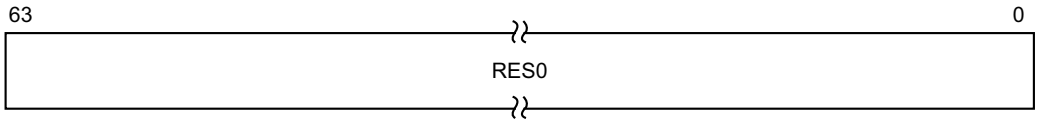
ID_AA64ISAR1_EL1 is architecturally mapped to external register ID_AA64ISAR1_EL1.

Attributes

ID_AA64ISAR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64ISAR1_EL1 bit assignments are:



Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64ISAR1_EL1

To access the ID_AA64ISAR1_EL1:

```
MRS <Xt>, ID_AA64ISAR1_EL1 ; Read ID_AA64ISAR1_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0110	001

D7.2.42 ID_AA64MMFR0_EL1, AArch64 Memory Model Feature Register 0

The ID_AA64MMFR0_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

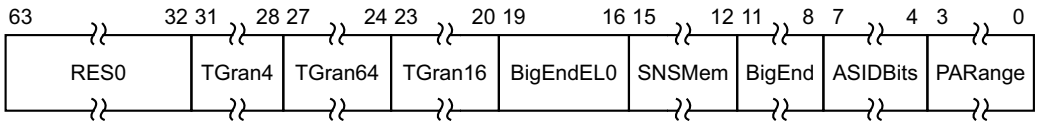
ID_AA64MMFR0_EL1 is architecturally mapped to external register ID_AA64MMFR0_EL1.

Attributes

ID_AA64MMFR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64MMFR0_EL1 bit assignments are:



Bits [63:32]

Reserved, RES0.

TGran4, bits [31:28]

Support for 4 KB memory translation granule size. Permitted values are:

0000 4 KB granule supported.

1111 4 KB granule not supported.

All other values are reserved.

TGran64, bits [27:24]

Support for 64 KB memory translation granule size. Permitted values are:

0000 64 KB granule supported.

1111 64 KB granule not supported.

All other values are reserved.

TGran16, bits [23:20]

Support for 16 KB memory translation granule size. Permitted values are:

0000 16 KB granule not supported.

0001 16 KB granule supported.

All other values are reserved.

BigEndEL0, bits [19:16]

Mixed-endian support at EL0 only. Permitted values are:

`0000` No mixed-endian support at EL0. The SCTLR_EL1.E0E bit has a fixed value.

`0001` Mixed-endian support at EL0. The SCTLR_EL1.E0E bit can be configured.

All other values are reserved.

This field is invalid and is RES0 if the BigEnd field, bits [11:8], is not `0000`.

SNSMem, bits [15:12]

Secure versus Non-secure Memory distinction. Permitted values are:

`0000` No support for a distinction between Secure and Non-secure Memory.

`0001` Support for a distinction between Secure and Non-secure Memory.

All other values are reserved.

BigEnd, bits [11:8]

Mixed-endian configuration support. Permitted values are:

`0000` No mixed-endian support. The SCTLR.EE bits have a fixed value. See the BigEndEL0 field, bits[19:16], for whether EL0 supports mixed-endian.

`0001` Mixed-endian support. The SCTLR.EE and SCTLR.E0E bits can be configured.

All other values are reserved.

ASIDBits, bits [7:4]

Number of ASID bits. Permitted values are:

`0000` 8 bits.

`0010` 16 bits.

All other values are reserved.

PARange, bits [3:0]

Physical Address range supported. Permitted values are:

`0000` 32 bits, 4 GB.

`0001` 36 bits, 64 GB.

`0010` 40 bits, 1 TB.

`0011` 42 bits, 4 TB.

`0100` 44 bits, 16 TB.

`0101` 48 bits, 256 TB.

All other values are reserved.

Accessing the ID_AA64MMFR0_EL1

To access the ID_AA64MMFR0_EL1:

```
MRS <Xt>, ID_AA64MMFR0_EL1 ; Read ID_AA64MMFR0_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0111	000

D7.2.43 ID_AA64MMFR1_EL1, AArch64 Memory Model Feature Register 1

The ID_AA64MMFR1_EL1 characteristics are:

Purpose

Reserved for future expansion of the information about the implemented memory model and memory management support in AArch64 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

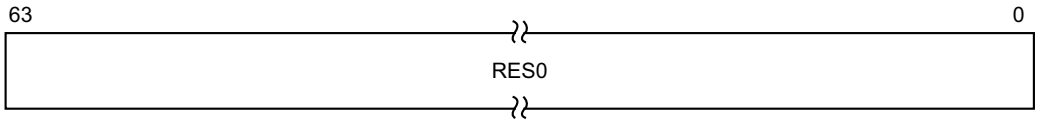
ID_AA64MMFR1_EL1 is architecturally mapped to external register ID_AA64MMFR1_EL1.

Attributes

ID_AA64MMFR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64MMFR1_EL1 bit assignments are:



Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64MMFR1_EL1

To access the ID_AA64MMFR1_EL1:

```
MRS <Xt>, ID_AA64MMFR1_EL1 ; Read ID_AA64MMFR1_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0111	001

D7.2.44 ID_AA64PFR0_EL1, AArch64 Processor Feature Register 0

The ID_AA64PFR0_EL1 characteristics are:

Purpose

Provides additional information about implemented processor features in AArch64 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

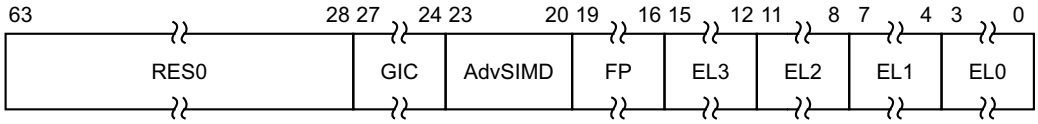
ID_AA64PFR0_EL1 is architecturally mapped to external register ID_AA64PFR0_EL1.

Attributes

ID_AA64PFR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64PFR0_EL1 bit assignments are:



Bits [63:28]

Reserved, RES0.

GIC, bits [27:24]

GIC system register interface. Permitted values are:

0000 No GIC system registers are supported.

0001 GICv3 system registers are supported.

All other values are reserved.

AdvSIMD, bits [23:20]

Advanced SIMD. Permitted values are:

0000 Advanced SIMD is implemented.

1111 Advanced SIMD is not implemented.

All other values are reserved.

FP, bits [19:16]

Floating-point. Permitted values are:

0000 Floating-point is implemented.

1111 Floating-point is not implemented.

All other values are reserved.

EL3, bits [15:12]

EL3 exception level handling. Permitted values are:

0000 EL3 is not implemented.

0001 EL3 can be executed in AArch64 state only.

0010 EL3 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

EL2, bits [11:8]

EL2 exception level handling. Permitted values are:

0000 EL2 is not implemented.

0001 EL2 can be executed in AArch64 state only.

0010 EL2 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

EL1, bits [7:4]

EL1 exception level handling. Permitted values are:

0000 EL1 is not implemented.

0001 EL1 can be executed in AArch64 state only.

0010 EL1 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

EL0, bits [3:0]

EL0 exception level handling. Permitted values are:

0000 EL0 is not implemented.

0001 EL0 can be executed in AArch64 state only.

0010 EL0 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

Accessing the ID_AA64PFR0_EL1

To access the ID_AA64PFR0_EL1:

```
MRS <Xt>, ID_AA64PFR0_EL1 ; Read ID_AA64PFR0_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0100	000

D7.2.45 ID_AA64PFR1_EL1, AArch64 Processor Feature Register 1

The ID_AA64PFR1_EL1 characteristics are:

Purpose

Reserved for future expansion of information about implemented processor features in AArch64 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

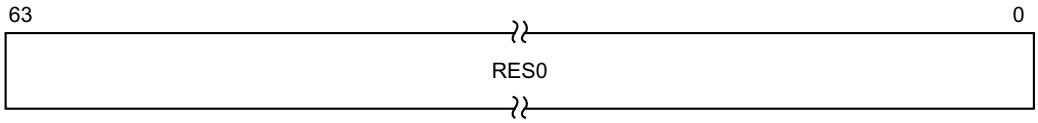
ID_AA64PFR1_EL1 is architecturally mapped to external register ID_AA64PFR1_EL1.

Attributes

ID_AA64PFR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64PFR1_EL1 bit assignments are:



Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64PFR1_EL1

To access the ID_AA64PFR1_EL1:

```
MRS <Xt>, ID_AA64PFR1_EL1 ; Read ID_AA64PFR1_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0100	001

D7.2.46 ID_AFR0_EL1, AArch32 Auxiliary Feature Register 0

The ID_AFR0_EL1 characteristics are:

Purpose

Provides information about the IMPLEMENTATION DEFINED features of the processor in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_AFR0_EL1 is architecturally mapped to AArch32 register ID_AFR0.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_AFR0_EL1 is a 32-bit register.

For more information, see *ID_AFR0, Auxiliary Feature Register 0* on page G5-3965.

Accessing the ID_AFR0_EL1:

To access the ID_AFR0_EL1:

```
MRS <Xt>, ID_AFR0_EL1 ; Read ID_AFR0_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0001	011

D7.2.47 ID_DFR0_EL1, AArch32 Debug Feature Register 0

The ID_DFR0_EL1 characteristics are:

Purpose

Provides top level information about the debug system in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_DFR0_EL1 is architecturally mapped to AArch32 register ID_DFR0.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_DFR0_EL1 is a 32-bit register.

For more information, see *ID_DFR0, Debug Feature Register 0* on page G5-3966.

Accessing the ID_DFR0_EL1:

To access the ID_DFR0_EL1:

```
MRS <Xt>, ID_DFR0_EL1 ; Read ID_DFR0_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0001	010

D7.2.48 ID_ISAR0_EL1, AArch32 Instruction Set Attribute Register 0

The ID_ISAR0_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the processor in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_ISAR0_EL1 is architecturally mapped to AArch32 register ID_ISAR0.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_ISAR0_EL1 is a 32-bit register.

For more information, see *ID_ISAR0, Instruction Set Attribute Register 0* on page G5-3969.

Accessing the ID_ISAR0_EL1:

To access the ID_ISAR0_EL1:

```
MRS <Xt>, ID_ISAR0_EL1 ; Read ID_ISAR0_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0010	000

D7.2.49 ID_ISAR1_EL1, AArch32 Instruction Set Attribute Register 1

The ID_ISAR1_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the processor in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_ISAR1_EL1 is architecturally mapped to AArch32 register ID_ISAR1.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_ISAR1_EL1 is a 32-bit register.

For more information, see *ID_ISAR1, Instruction Set Attribute Register 1* on page G5-3971.

Accessing the ID_ISAR1_EL1:

To access the ID_ISAR1_EL1:

```
MRS <Xt>, ID_ISAR1_EL1 ; Read ID_ISAR1_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0010	001

D7.2.50 ID_ISAR2_EL1, AArch32 Instruction Set Attribute Register 2

The ID_ISAR2_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the processor in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_ISAR2_EL1 is architecturally mapped to AArch32 register ID_ISAR2.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_ISAR2_EL1 is a 32-bit register.

For more information, see *ID_ISAR2, Instruction Set Attribute Register 2* on page G5-3974.

Accessing the ID_ISAR2_EL1:

To access the ID_ISAR2_EL1:

```
MRS <Xt>, ID_ISAR2_EL1 ; Read ID_ISAR2_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0010	010

D7.2.51 ID_ISAR3_EL1, AArch32 Instruction Set Attribute Register 3

The ID_ISAR3_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the processor in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_ISAR3_EL1 is architecturally mapped to AArch32 register ID_ISAR3.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_ISAR3_EL1 is a 32-bit register.

For more information, see *ID_ISAR3, Instruction Set Attribute Register 3* on page G5-3977.

Accessing the ID_ISAR3_EL1:

To access the ID_ISAR3_EL1:

```
MRS <Xt>, ID_ISAR3_EL1 ; Read ID_ISAR3_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0010	011

D7.2.52 ID_ISAR4_EL1, AArch32 Instruction Set Attribute Register 4

The ID_ISAR4_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the processor in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_ISAR4_EL1 is architecturally mapped to AArch32 register ID_ISAR4.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_ISAR4_EL1 is a 32-bit register.

For more information, see *ID_ISAR4, Instruction Set Attribute Register 4* on page G5-3980.

Accessing the ID_ISAR4_EL1:

To access the ID_ISAR4_EL1:

```
MRS <Xt>, ID_ISAR4_EL1 ; Read ID_ISAR4_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0010	100

D7.2.53 ID_ISAR5_EL1, AArch32 Instruction Set Attribute Register 5

The ID_ISAR5_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the processor in AArch32.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_ISAR5_EL1 is architecturally mapped to AArch32 register ID_ISAR5.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_ISAR5_EL1 is a 32-bit register.

For more information, see *ID_ISAR5, Instruction Set Attribute Register 5* on page G5-3983.

Accessing the ID_ISAR5_EL1:

To access the ID_ISAR5_EL1:

```
MRS <Xt>, ID_ISAR5_EL1 ; Read ID_ISAR5_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0010	101

D7.2.54 ID_MMFR0_EL1, AArch32 Memory Model Feature Register 0

The ID_MMFR0_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_MMFR0_EL1 is architecturally mapped to AArch32 register ID_MMFR0.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_MMFR0_EL1 is a 32-bit register.

For more information, see *ID_MMFR0, Memory Model Feature Register 0* on page G5-3985.

Accessing the ID_MMFR0_EL1:

To access the ID_MMFR0_EL1:

```
MRS <Xt>, ID_MMFR0_EL1 ; Read ID_MMFR0_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0001	100

D7.2.55 ID_MMFR1_EL1, AArch32 Memory Model Feature Register 1

The ID_MMFR1_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_MMFR1_EL1 is architecturally mapped to AArch32 register ID_MMFR1.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_MMFR1_EL1 is a 32-bit register.

For more information, see *ID_MMFR1, Memory Model Feature Register 1* on page G5-3988.

Accessing the ID_MMFR1_EL1:

To access the ID_MMFR1_EL1:

```
MRS <Xt>, ID_MMFR1_EL1 ; Read ID_MMFR1_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0001	101

D7.2.56 ID_MMFR2_EL1, AArch32 Memory Model Feature Register 2

The ID_MMFR2_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_MMFR2_EL1 is architecturally mapped to AArch32 register ID_MMFR2.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_MMFR2_EL1 is a 32-bit register.

For more information, see *ID_MMFR2, Memory Model Feature Register 2* on page G5-3993.

Accessing the ID_MMFR2_EL1:

To access the ID_MMFR2_EL1:

```
MRS <Xt>, ID_MMFR2_EL1 ; Read ID_MMFR2_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0001	110

D7.2.57 ID_MMFR3_EL1, AArch32 Memory Model Feature Register 3

The ID_MMFR3_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_MMFR3_EL1 is architecturally mapped to AArch32 register ID_MMFR3.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_MMFR3_EL1 is a 32-bit register.

For more information, see *ID_MMFR3, Memory Model Feature Register 3* on page G5-3997.

Accessing the ID_MMFR3_EL1:

To access the ID_MMFR3_EL1:

```
MRS <Xt>, ID_MMFR3_EL1 ; Read ID_MMFR3_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0001	111

D7.2.58 ID_PFR0_EL1, AArch32 Processor Feature Register 0

The ID_PFR0_EL1 characteristics are:

Purpose

Gives top-level information about the instruction sets supported by the processor in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_PFR0_EL1 is architecturally mapped to AArch32 register ID_PFR0.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_PFR0_EL1 is a 32-bit register.

For more information, see *ID_PFR0, Processor Feature Register 0* on page G5-4000.

Accessing the ID_PFR0_EL1:

To access the ID_PFR0_EL1:

```
MRS <Xt>, ID_PFR0_EL1 ; Read ID_PFR0_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0001	000

D7.2.59 ID_PFR1_EL1, AArch32 Processor Feature Register 1

The ID_PFR1_EL1 characteristics are:

Purpose

Gives information about the programmers' model and extensions support in AArch32 state.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ID_PFR1_EL1 is architecturally mapped to AArch32 register ID_PFR1.

In an AArch64-only implementation, this register is RES0.

Attributes

ID_PFR1_EL1 is a 32-bit register.

For more information, see *ID_PFR1, Processor Feature Register 1* on page G5-4002.

Accessing the ID_PFR1_EL1:

To access the ID_PFR1_EL1:

```
MRS <Xt>, ID_PFR1_EL1 ; Read ID_PFR1_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0001	001

D7.2.60 IFSR32_EL2, Instruction Fault Status Register (EL2)

The IFSR32_EL2 characteristics are:

Purpose

Allows access to the AArch32 IFSR register from AArch64 state only. Its value has no effect on execution in AArch64 state.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

IFSR32_EL2 is architecturally mapped to AArch32 register IFSR (NS).

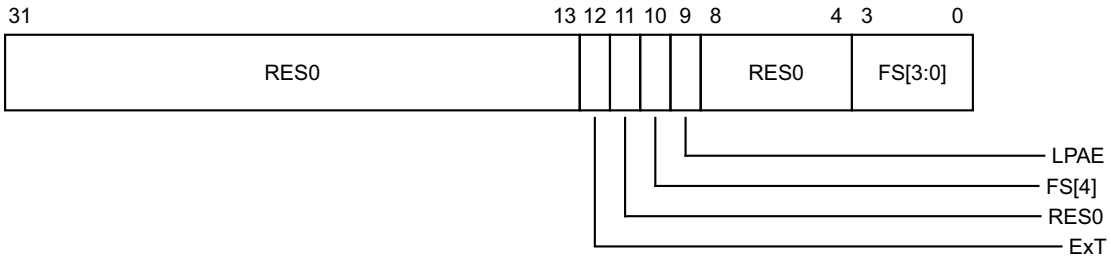
Attributes

IFSR32_EL2 is a 32-bit register.

Field descriptions

The IFSR32_EL2 bit assignments are:

When TTBCR.EAE==0:



Bits [31:13]

Reserved, RES0.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

For aborts other than external aborts this bit always returns 0.

Bit [11]

Reserved, RES0.

FS[4], bit [10]

See below for description of the FS field.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

0 Using the Short-descriptor translation table formats.

1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:4]

Reserved, RES0.

FS[3:0], bits [3:0]

Fault status bits. Interpreted with bit[10]. Possible values of the FS[4:0] field are:

00010 Debug event

00011 Access flag fault, first level

00101 Translation fault, first level

00110 Access flag fault, second level

00111 Translation fault, second level

01000 Synchronous external abort

01001 Domain fault, first level

01011 Domain fault, second level

01100 Synchronous external abort on translation table walk, first level

01101 Permission fault, first level

01110 Synchronous external abort on translation table walk, second level

01111 Permission fault, second level

10000 TLB conflict abort

10100 IMPLEMENTATION DEFINED fault (Lockdown fault)

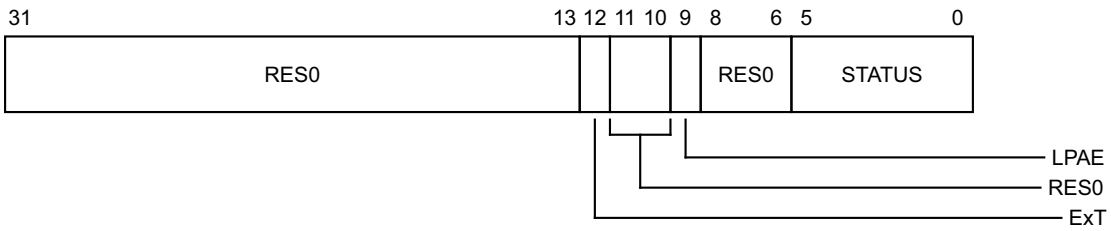
11001 Synchronous parity error on memory access

11100 Synchronous parity error on translation table walk, first level

11110 Synchronous parity error on translation table walk, second level

All other values are reserved.

When TTBCR.EAE==1:



Bits [31:13]

Reserved, RES0.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

For aborts other than external aborts this bit always returns 0.

Bits [11:10]

Reserved, RES0.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

0 Using the Short-descriptor translation table formats.

1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:6]

Reserved, RES0.

STATUS, bits [5:0]

Fault status bits. All encodings not shown below are reserved:

000000 Address size fault in TTBR0 or TTBR1

000001 Address size fault, first level

000010 Address size fault, second level

000011 Address size fault, third level

000101 Translation fault, first level

000110 Translation fault, second level

000111 Translation fault, third level

001001 Access flag fault, first level

001010 Access flag fault, second level

001011 Access flag fault, third level

001101 Permission fault, first level

001110 Permission fault, second level

001111 Permission fault, third level

010000 Synchronous external abort

010101 Synchronous external abort on translation table walk, first level

010110 Synchronous external abort on translation table walk, second level

010111 Synchronous external abort on translation table walk, third level

011000 Synchronous parity error on memory access

011101 Synchronous parity error on memory access on translation table walk, first level

011110 Synchronous parity error on memory access on translation table walk, second level

011111 Synchronous parity error on memory access on translation table walk, third level

100001 Alignment fault

100010 Debug event

110000 TLB conflict abort

110100 IMPLEMENTATION DEFINED fault (Lockdown fault)

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.

- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because an MMU is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a First level fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Accessing the IFSR32_EL2

To access the IFSR32_EL2:

```
MRS <Xt>, IFSR32_EL2 ; Read IFSR32_EL2 into Xt
MSR IFSR32_EL2, <Xt> ; Write Xt to IFSR32_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0101	0000	001

D7.2.61 ISR_EL1, Interrupt Status Register

The ISR_EL1 characteristics are:

Purpose

Shows whether an IRQ, FIQ, or SError interrupt is pending. If EL2 is implemented, an indicated pending interrupt might be a physical interrupt or a virtual interrupt.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

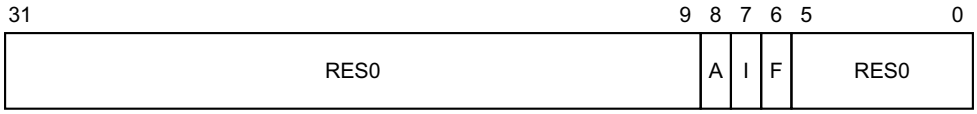
ISR_EL1 is architecturally mapped to AArch32 register ISR.

Attributes

ISR_EL1 is a 32-bit register.

Field descriptions

The ISR_EL1 bit assignments are:



Bits [31:9]

Reserved, RES0.

A, bit [8]

SError pending bit:

0 No pending SError.

1 An SError interrupt is pending.

I, bit [7]

IRQ pending bit. Indicates whether an IRQ interrupt is pending:

0 No pending IRQ.

1 An IRQ interrupt is pending.

F, bit [6]

FIQ pending bit. Indicates whether an FIQ interrupt is pending.

0 No pending FIQ.

1 An FIQ interrupt is pending.

Bits [5:0]

Reserved, RES0.

Accessing the ISR_EL1

To access the ISR_EL1:

```
MRS <Xt>, ISR_EL1 ; Read ISR_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	0001	000

D7.2.62 MAIR_EL1, Memory Attribute Indirection Register (EL1)

The MAIR_EL1 characteristics are:

Purpose

Provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations at EL1.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

MAIR_EL1 is permitted to be cached in a TLB.

Configurations

MAIR_EL1[31:0] is architecturally mapped to AArch32 register PRRR (NS) when TTBCR.EAE==0.

MAIR_EL1[31:0] is architecturally mapped to AArch32 register MAIR0 (NS) when TTBCR.EAE==1.

MAIR_EL1[63:32] is architecturally mapped to AArch32 register NMRR (NS) when TTBCR.EAE==0.

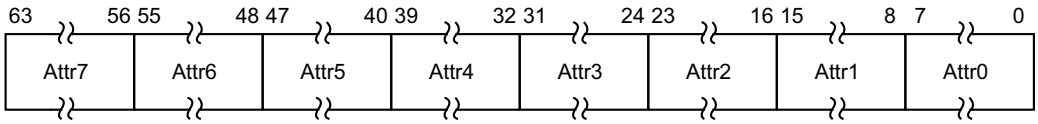
MAIR_EL1[63:32] is architecturally mapped to AArch32 register MAIR1 (NS) when TTBCR.EAE==1.

Attributes

MAIR_EL1 is a 64-bit register.

Field descriptions

The MAIR_EL1 bit assignments are:



Attr<n>, bits [8n+7:8n], for 8n+7:8n = 0 to 7

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where AttrIndx[2:0] gives the value of <n> in Attr<n>.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
`0000`	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
`00RW`, RW not `00`	Normal Memory, Outer Write-through transient
`0100`	Normal Memory, Outer Non-Cacheable

Attr<n>[7:4]	Meaning
01RW, RW not 00	Normal Memory, Outer Write-back transient
10RW	Normal Memory, Outer Write-through non-transient
11RW	Normal Memory, Outer Write-back non-transient

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through transient
0100	Device-nGnRE memory	Normal memory, Inner Non-Cacheable
01RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back transient
1000	Device-nGRE memory	Normal Memory, Inner Write-through non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through non-transient
1100	Device-GRE memory	Normal Memory, Inner Write-back non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back non-transient

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.

ARMv7's Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	Do not allocate
1	Allocate

Accessing the MAIR_EL1

To access the MAIR_EL1:

```
MRS <Xt>, MAIR_EL1 ; Read MAIR_EL1 into Xt
MSR MAIR_EL1, <Xt> ; Write Xt to MAIR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1010	0010	000

D7.2.63 MAIR_EL2, Memory Attribute Indirection Register (EL2)

The MAIR_EL2 characteristics are:

Purpose

Provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations at EL2.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

MAIR_EL2 is permitted to be cached in a TLB.

Configurations

MAIR_EL2[31:0] is architecturally mapped to AArch32 register HMAIR0.

MAIR_EL2[63:32] is architecturally mapped to AArch32 register HMAIR1.

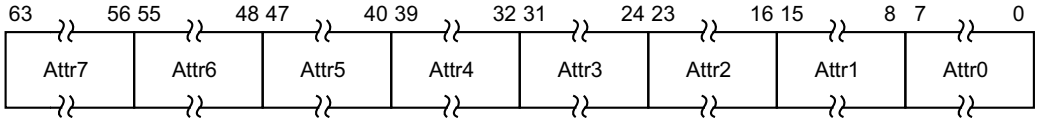
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

MAIR_EL2 is a 64-bit register.

Field descriptions

The MAIR_EL2 bit assignments are:



Attr<n>, bits [8n+7:8n], for 8n+7:8n = 0 to 7

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where AttrIndx[2:0] gives the value of <n> in Attr<n>.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
0000	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
00RW, RW not 00	Normal Memory, Outer Write-through transient
0100	Normal Memory, Outer Non-Cacheable
01RW, RW not 00	Normal Memory, Outer Write-back transient
10RW	Normal Memory, Outer Write-through non-transient
11RW	Normal Memory, Outer Write-back non-transient

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through transient
0100	Device-nGnRE memory	Normal memory, Inner Non-Cacheable
01RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back transient
1000	Device-nGRE memory	Normal Memory, Inner Write-through non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through non-transient
1100	Device-GRE memory	Normal Memory, Inner Write-back non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back non-transient

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.

ARMv7's Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	Do not allocate
1	Allocate

Accessing the MAIR_EL2

To access the MAIR_EL2:

```
MRS <Xt>, MAIR_EL2 ; Read MAIR_EL2 into Xt
MSR MAIR_EL2, <Xt> ; Write Xt to MAIR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1010	0010	000

D7.2.64 MAIR_EL3, Memory Attribute Indirection Register (EL3)

The MAIR_EL3 characteristics are:

Purpose

Provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations at EL3.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

MAIR_EL3 is permitted to be cached in a TLB.

Configurations

MAIR_EL3[31:0] can be mapped to AArch32 register PRRR (S) when TTBCR.EAE==0, but this is not architecturally mandated.

MAIR_EL3[31:0] can be mapped to AArch32 register MAIR0 (S) when TTBCR.EAE==1, but this is not architecturally mandated.

MAIR_EL3[63:32] can be mapped to AArch32 register NMRR (S) when TTBCR.EAE==0, but this is not architecturally mandated.

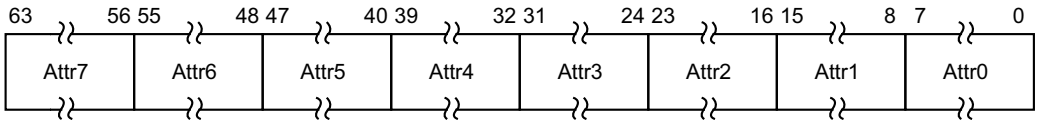
MAIR_EL3[63:32] can be mapped to AArch32 register MAIR1 (S) when TTBCR.EAE==1, but this is not architecturally mandated.

Attributes

MAIR_EL3 is a 64-bit register.

Field descriptions

The MAIR_EL3 bit assignments are:



Attr<n>, bits [8n+7:8n], for 8n+7:8n = 0 to 7

The memory attribute encoding for an AttrIndx[2:0] entry in a Long descriptor format translation table entry, where AttrIndx[2:0] gives the value of <n> in Attr<n>.

Bits [7:4] are encoded as follows:

Attr<n>[7:4]	Meaning
`0000`	Device memory. See encoding of Attr<n>[3:0] for the type of Device memory.
`00RW`, RW not `00`	Normal Memory, Outer Write-through transient
`0100`	Normal Memory, Outer Non-Cacheable

Attr<n>[7:4]	Meaning
01RW, RW not 00	Normal Memory, Outer Write-back transient
10RW	Normal Memory, Outer Write-through non-transient
11RW	Normal Memory, Outer Write-back non-transient

R = Outer Read Allocate Policy, W = Outer Write Allocate Policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

Attr<n>[3:0]	Meaning when Attr<n>[7:4] is 0000	Meaning when Attr<n>[7:4] is not 0000
0000	Device-nGnRnE memory	UNPREDICTABLE
00RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through transient
0100	Device-nGnRE memory	Normal memory, Inner Non-Cacheable
01RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back transient
1000	Device-nGRE memory	Normal Memory, Inner Write-through non-transient (RW=00)
10RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-through non-transient
1100	Device-GRE memory	Normal Memory, Inner Write-back non-transient (RW=00)
11RW, RW not 00	UNPREDICTABLE	Normal Memory, Inner Write-back non-transient

R = Inner Read Allocate Policy, W = Inner Write Allocate Policy.

ARMv7's Strongly-ordered and Device memory types have been renamed to Device-nGnRnE and Device-nGnRE in ARMv8.

The R and W bits in some Attr<n> fields have the following meanings:

R or W	Meaning
0	Do not allocate
1	Allocate

Accessing the MAIR_EL3

To access the MAIR_EL3:

```
MRS <Xt>, MAIR_EL3 ; Read MAIR_EL3 into Xt
MSR MAIR_EL3, <Xt> ; Write Xt to MAIR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	1010	0010	000

D7.2.65 MIDR_EL1, Main ID Register

The MIDR_EL1 characteristics are:

Purpose

Provides identification information for the processor, including an implementer code for the device and a device ID number.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

If EL2 is implemented, reads of MIDR_EL1 from EL1(NS) return the value from VPIDR_EL2.

Configurations

MIDR_EL1 is architecturally mapped to AArch32 register MIDR.

MIDR_EL1 is architecturally mapped to external register MIDR_EL1.

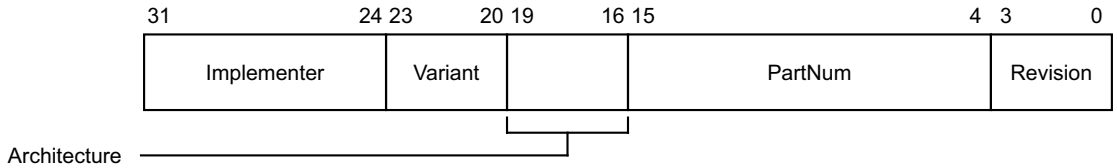
Some fields of MIDR_EL1 are IMPLEMENTATION DEFINED. For details of the values of these fields for a particular ARMv8 implementation, and any implementation-specific significance of these values, see the product documentation.

Attributes

MIDR_EL1 is a 32-bit register.

Field descriptions

The MIDR_EL1 bit assignments are:



Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

Hex representation	ASCII representation	Implementer
0x41	A	ARM Limited
0x42	B	Broadcom Corporation
0x43	C	Cavium Inc.
0x44	D	Digital Equipment Corporation
0x49	I	Infineon Technologies AG

Hex representation	ASCII representation	Implementer
0x4D	M	Motorola or Freescale Semiconductor Inc.
0x4E	N	NVIDIA Corporation
0x50	P	Applied Micro Circuits Corporation
0x51	Q	Qualcomm Inc.
0x56	V	Marvell International Ltd.
0x69	i	Intel Corporation

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

Architecture, bits [19:16]

The permitted values of this field are:

0001 ARMv4

0010 ARMv4T

0011 ARMv5 (obsolete)

0100 ARMv5T

0101 ARMv5TE

0110 ARMv5TEJ

0111 ARMv6

1111 Defined by CPUID scheme

All other values are reserved.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

Accessing the MIDR_EL1

To access the MIDR_EL1:

```
MRS <Xt>, MIDR_EL1 ; Read MIDR_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0000	000

D7.2.66 MPIDR_EL1, Multiprocessor Affinity Register

The MPIDR_EL1 characteristics are:

Purpose

In a multiprocessor system, provides an additional processor identification mechanism for scheduling purposes.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

If EL2 is implemented, reads of MPIDR_EL1 from EL1(NS) return the value from VMPIDR_EL2.

Configurations

MPIDR_EL1 is architecturally mapped to AArch32 register MPIDR.

In a uniprocessor system, ARM recommends that this register returns a value of 0.

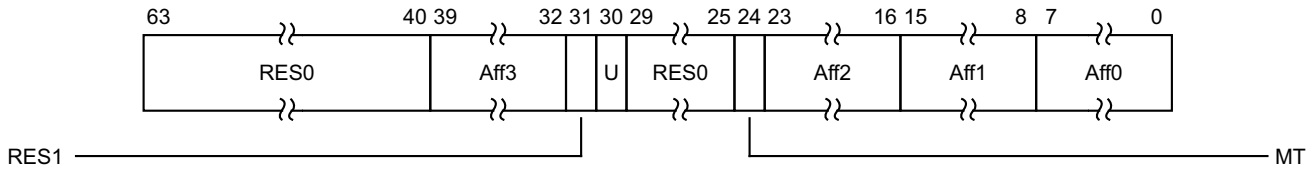
In the system as a whole, the assigned value of all affinity fields in the MPIDR_EL1 for each PE must be unique.

Attributes

MPIDR_EL1 is a 64-bit register.

Field descriptions

The MPIDR_EL1 bit assignments are:



Bits [63:40]

Reserved, RES0.

Aff3, bits [39:32]

Affinity level 3. Highest level affinity field.

Bit [31]

Reserved, RES1.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

`0` PE is part of a multiprocessor system.

`1` PE is part of a uniprocessor system.

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach. The possible values of this bit are:

0 Performance of the PEs at the lowest affinity level is largely independent.

1 Performance of the PEs at the lowest affinity level is very interdependent.

Aff2, bits [23:16]

Affinity level 2. Second highest level affinity field.

Aff1, bits [15:8]

Affinity level 1. Third highest level affinity field.

Aff0, bits [7:0]

Affinity level 0. Lowest level affinity field.

Note

- The interpretation of these fields is IMPLEMENTATION DEFINED, and must be documented as part of the documentation of the multiprocessor system.
- The software mechanism to discover the total number of affinity numbers used at each level is IMPLEMENTATION DEFINED, and is part of the general system identification task.

Multi-threading approach to lowest affinity levels

If MIDR_EL1.MT is set to 1, this indicates that the PEs at affinity level 0 are logical PEs, implemented using a multi-threading type approach. In such an approach, there can be a significant performance impact if a new thread is assigned to the PE with:

- A different affinity level 0 value to some other thread, referred to as the original thread.
- A pair of values for affinity levels 1 and 2 that are the same as the pair of values of the original thread.

In this situation, the performance of the original thread might be significantly reduced.

Note

In this description a thread always refers to a thread or a PE.

Accessing the MPIDR_EL1:

To access the MPIDR_EL1:

```
MRS <Xt>, MPIDR_EL1 ; Read MPIDR_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0000	101

D7.2.67 MVFR0_EL1, AArch32 Media and Floating-point Feature Register 0

The MVFR0_EL1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point functionality.

This register is part of:

- the Floating-point registers functional group
- the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

MVFR0_EL1 is architecturally mapped to AArch32 register MVFR0.

In an AArch64-only implementation, this register is RES0.

Attributes

MVFR0_EL1 is a 32-bit register.

For more information, see *MVFR0, Media and Floating-point Feature Register 0* on page G5-4033.

Accessing the MVFR0_EL1:

To access the MVFR0_EL1:

```
MRS <Xt>, MVFR0_EL1 ; Read MVFR0_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0011	000

D7.2.68 MVFR1_EL1, AArch32 Media and Floating-point Feature Register 1

The MVFR1_EL1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point functionality.

This register is part of:

- the Floating-point registers functional group
- the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

MVFR1_EL1 is architecturally mapped to AArch32 register MVFR1.

In an AArch64-only implementation, this register is RES0.

Attributes

MVFR1_EL1 is a 32-bit register.

For more information, see *MVFR1, Media and Floating-point Feature Register 1* on page G5-4036.

Accessing the MVFR1_EL1:

To access the MVFR1_EL1:

```
MRS <Xt>, MVFR1_EL1 ; Read MVFR1_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0011	001

D7.2.69 MVFR2_EL1, AArch32 Media and Floating-point Feature Register 2

The MVFR2_EL1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point functionality.

This register is part of:

- the Floating-point registers functional group
- the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

MVFR2_EL1 is architecturally mapped to AArch32 register MVFR2.

In an AArch64-only implementation, this register is RES0.

Attributes

MVFR2_EL1 is a 32-bit register.

For more information, see *MVFR2, Media and Floating-point Feature Register 2* on page G5-4039.

Accessing the MVFR2_EL1:

To access the MVFR2_EL1:

```
MRS <Xt>, MVFR2_EL1 ; Read MVFR2_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0011	010

D7.2.70 PAR_EL1, Physical Address Register

The PAR_EL1 characteristics are:

Purpose

Receives the PA from any address translation operation.

This register is part of the Address translation instructions functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

PAR_EL1 is architecturally mapped to AArch32 register PAR (NS).

Attributes

PAR_EL1 is a 64-bit register.

Field descriptions

The PAR_EL1 bit assignments are:

For all register layouts:

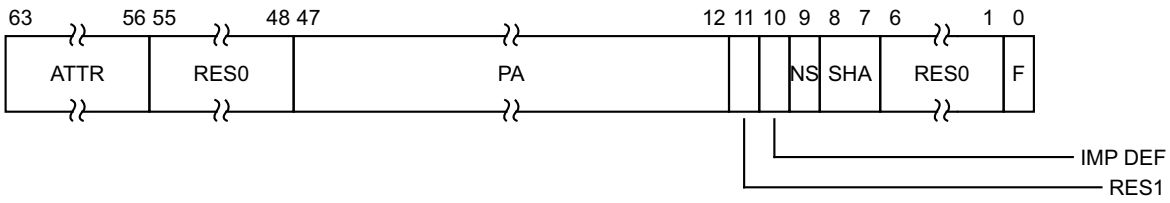
F, bit [0]

Indicates whether the conversion completed successfully.

`0` VA to PA conversion completed successfully.

`1` VA to PA conversion aborted.

When PAR_EL1.F==0:



ATTR, bits [63:56]

Memory attributes for the returned PA, as indicated by the translation table entry. This field uses the same encoding as the Attr<n> fields in MAIR_EL1, MAIR_EL2, and MAIR_EL3.

Bits [55:48]

Reserved, RES0.

PA, bits [47:12]

Physical Address. The physical address corresponding to the supplied virtual address. This field returns address bits[47:12].

Bit [11]

Reserved, RES1.

NS, bit [9]

Non-secure. The NS attribute for a translation table entry read from Secure state.

This bit is UNKNOWN for a translation table entry read from Non-secure state.

SHA, bits [8:7]

Shareability attribute, from the translation table entry for the returned PA. Permitted values are:

`00` Non-shareable.

`10` Outer Shareable.

`11` Inner Shareable.

The value `01` is reserved.

Note: this takes the value `10` for:

- Any type of Device memory.
- Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.

Bits [6:1]

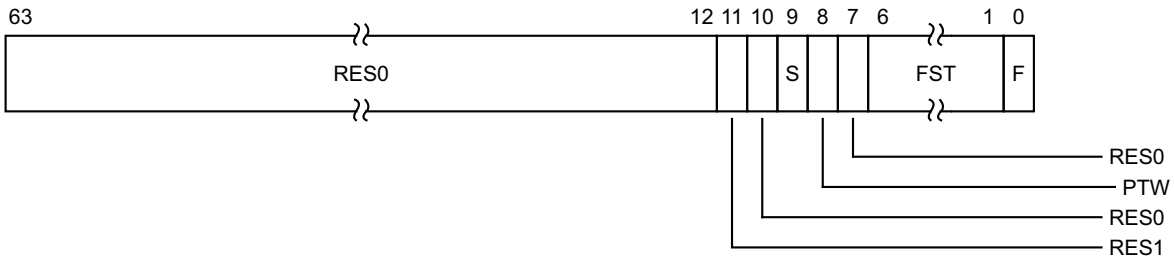
Reserved, RES0.

F, bit [0]

Indicates whether the conversion completed successfully.

`0` VA to PA conversion completed successfully.

When PAR_EL1.F==1:



Bits [63:12]

Reserved, RES0.

Bit [11]

Reserved, RES1.

Bit [10]

Reserved, RES0.

S, bit [9]

Indicates the translation stage at which the translation aborted:

`0` Translation aborted because of a fault in the stage 1 translation.

`1` Translation aborted because of a fault in the stage 2 translation.

PTW, bit [8]

If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.

Bit [7]

Reserved, RES0.

FST, bits [6:1]

Fault status code, as shown in the Data Abort ESR encoding.

F, bit [0]

Indicates whether the conversion completed successfully.

1 VA to PA conversion aborted.

Accessing the PAR_EL1

To access the PAR_EL1:

```
MRS <Xt>, PAR_EL1 ; Read PAR_EL1 into Xt
MSR PAR_EL1, <Xt> ; Write Xt to PAR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0111	0100	000

D7.2.71 REVIDR_EL1, Revision ID Register

The REVIDR_EL1 characteristics are:

Purpose

Provides implementation-specific minor revision information that can only be interpreted in conjunction with the Main ID Register.

This register is part of the Identification registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

REVIDR_EL1 is architecturally mapped to AArch32 register REVIDR.

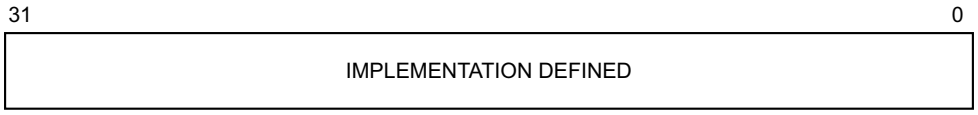
If REVIDR_EL1 has the same value as MIDR_EL1, then its contents has no significance.

Attributes

REVIDR_EL1 is a 32-bit register.

Field descriptions

The REVIDR_EL1 bit assignments are:



Bits [31:0]

IMPLEMENTATION DEFINED

Accessing the REVIDR_EL1

To access the REVIDR_EL1:

```
MRS <Xt>, REVIDR_EL1 ; Read REVIDR_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0000	0000	110

D7.2.72 RMR_EL1, Reset Management Register (if EL2 and EL3 not implemented)

The RMR_EL1 characteristics are:

Purpose

If EL1 is the highest exception level implemented, and is capable of using both AArch32 and AArch64, controls the Execution state that the processor boots into and allows request of a Warm reset.

This register is part of the Reset management registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1
-	RW

Configurations

RMR_EL1 is architecturally mapped to AArch32 register RMR (at EL1).

Only implemented if the highest exception level implemented is EL1 and supports AArch32 and AArch64.

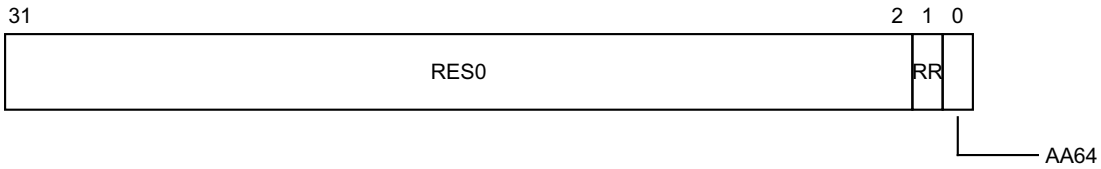
If EL1 is not the highest one implemented, then this register is not implemented and its encoding is UNDEFINED.

Attributes

RMR_EL1 is a 32-bit register.

Field descriptions

The RMR_EL1 bit assignments are:



Bits [31:2]

Reserved, RES0.

RR, bit [1]

When set to 1 this bit requests a Warm reset. The bit is strictly a request.

On Warm reset, the field resets to 0.

AA64, bit [0]

Determines which Execution state the processor boots into after a Warm reset:

0 AArch32.

1 AArch64.

The reset vector address on reset takes a choice between two IMP DEF values, depending on the value in the AA64 bit.

On Cold reset, the field resets to 1.

Accessing the RMR_EL1

To access the RMR_EL1:

```
MRS <Xt>, RMR_EL1 ; Read RMR_EL1 into Xt
MSR RMR_EL1, <Xt> ; Write Xt to RMR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	0000	010

D7.2.73 RMR_EL2, Reset Management Register (if EL3 not implemented)

The RMR_EL2 characteristics are:

Purpose

If EL2 is the highest exception level implemented, and is capable of using both AArch32 and AArch64, controls the Execution state that the processor boots into and allows request of a Warm reset.

This register is part of:

- the Virtualization registers functional group
- the Reset management registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1	EL2
-	-	RW

Configurations

RMR_EL2 is architecturally mapped to AArch32 register HRMR.

Only implemented if the highest exception level implemented is EL2 and supports AArch32 and AArch64.

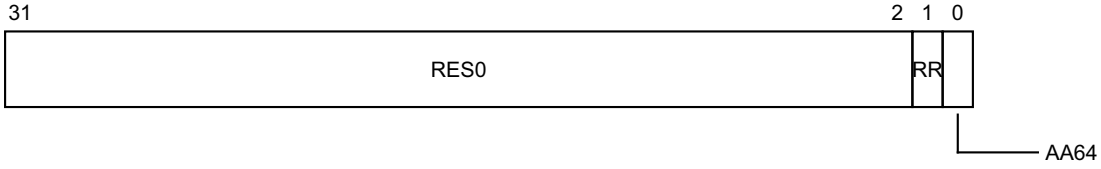
If EL2 is not the highest one implemented, then this register is not implemented and its encoding is UNDEFINED.

Attributes

RMR_EL2 is a 32-bit register.

Field descriptions

The RMR_EL2 bit assignments are:



Bits [31:2]

Reserved, RES0.

RR, bit [1]

When set to 1 this bit requests a Warm reset. The bit is strictly a request.

On Warm reset, the field resets to 0.

AA64, bit [0]

Determines which Execution state the processor boots into after a Warm reset:

`0`. AArch32.

`1`. AArch64.

The reset vector address on reset takes a choice between two IMP DEF values, depending on the value in the AA64 bit.

On Cold reset, the field resets to 1.

Accessing the RMR_EL2

To access the RMR_EL2:

```
MRS <Xt>, RMR_EL2 ; Read RMR_EL2 into Xt
MSR RMR_EL2, <Xt> ; Write Xt to RMR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	0000	010

D7.2.74 RMR_EL3, Reset Management Register (if EL3 implemented)

The RMR_EL3 characteristics are:

Purpose

If EL3 is the highest exception level implemented, and is capable of using both AArch32 and AArch64, controls the Execution state that the processor boots into and allows request of a Warm reset.

This register is part of the Reset management registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

RMR_EL3 is architecturally mapped to AArch32 register RMR (at EL3).

Only implemented if the highest exception level implemented is EL3 and supports AArch32 and AArch64.

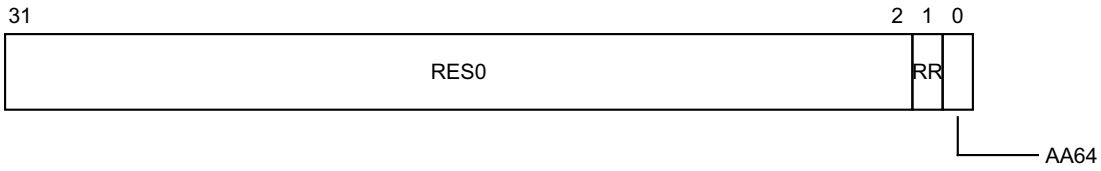
If EL3 is not the highest one implemented, then this register is not implemented and its encoding is UNDEFINED.

Attributes

RMR_EL3 is a 32-bit register.

Field descriptions

The RMR_EL3 bit assignments are:



Bits [31:2]

Reserved, RES0.

RR, bit [1]

When set to 1 this bit requests a Warm reset. The bit is strictly a request.

On Warm reset, the field resets to 0.

AA64, bit [0]

Determines which Execution state the processor boots into after a Warm reset:

0 AArch32.

1 AArch64.

The reset vector address on reset takes a choice between two IMP DEF values, depending on the value in the AA64 bit.

On Cold reset, the field resets to 1.

Accessing the RMR_EL3

To access the RMR_EL3:

```
MRS <Xt>, RMR_EL3 ; Read RMR_EL3 into Xt
MSR RMR_EL3, <Xt> ; Write Xt to RMR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	1100	0000	010

D7.2.75 RVBAR_EL1, Reset Vector Base Address Register (if EL2 and EL3 not implemented)

The RVBAR_EL1 characteristics are:

Purpose

If EL1 is the highest exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

This register is part of the Reset management registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1
-	RO

Configurations

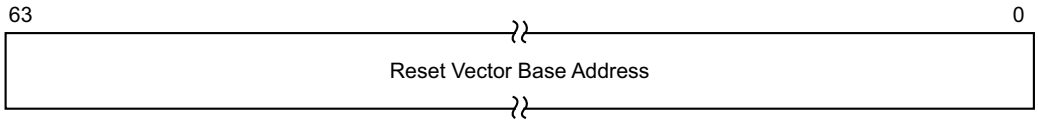
Only implemented if the highest exception level implemented is EL1.

Attributes

RVBAR_EL1 is a 64-bit register.

Field descriptions

The RVBAR_EL1 bit assignments are:



Bits [63:0]

Reset Vector Base Address. If this exception level is the highest one implemented, this field contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the processor.

If this exception level is not the highest one implemented, then this register is not implemented and its encoding is UNDEFINED.

Accessing the RVBAR_EL1

To access the RVBAR_EL1:

```
MRS <Xt>, RVBAR_EL1 ; Read RVBAR_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	0000	001

D7.2.76 RVBAR_EL2, Reset Vector Base Address Register (if EL3 not implemented)

The RVBAR_EL2 characteristics are:

Purpose

If EL2 is the highest exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

This register is part of the Reset management registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1	EL2
-	-	RO

Configurations

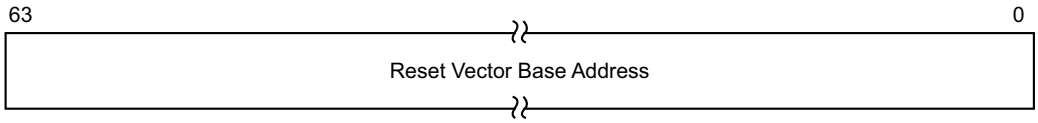
Only implemented if the highest exception level implemented is EL2.

Attributes

RVBAR_EL2 is a 64-bit register.

Field descriptions

The RVBAR_EL2 bit assignments are:



Bits [63:0]

Reset Vector Base Address. If this exception level is the highest one implemented, this field contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the processor.

If this exception level is not the highest one implemented, then this register is not implemented and its encoding is UNDEFINED.

Accessing the RVBAR_EL2

To access the RVBAR_EL2:

```
MRS <Xt>, RVBAR_EL2 ; Read RVBAR_EL2 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	0000	001

D7.2.77 RVBAR_EL3, Reset Vector Base Address Register (if EL3 implemented)

The RVBAR_EL3 characteristics are:

Purpose

If EL3 is the highest exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

This register is part of the Reset management registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RO	RO

Configurations

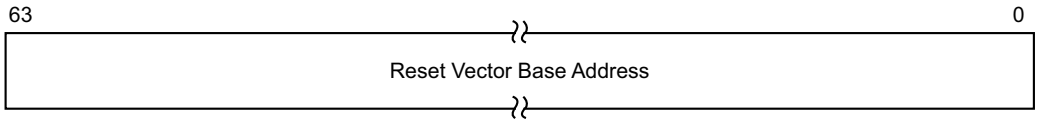
Only implemented if the highest exception level implemented is EL3.

Attributes

RVBAR_EL3 is a 64-bit register.

Field descriptions

The RVBAR_EL3 bit assignments are:



Bits [63:0]

Reset Vector Base Address. If this exception level is the highest one implemented, this field contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the processor.

If this exception level is not the highest one implemented, then this register is not implemented and its encoding is UNDEFINED.

Accessing the RVBAR_EL3

To access the RVBAR_EL3:

```
MRS <Xt>, RVBAR_EL3 ; Read RVBAR_EL3 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	1100	0000	001

D7.2.78 S3_<op1>_<Cn>_<Cm>_<op2>, IMPLEMENTATION DEFINED registers

The S3_<op1>_<Cn>_<Cm>_<op2> characteristics are:

Purpose

This area of the instruction set space is reserved for IMPLEMENTATION DEFINED registers.

This register is part of the IMPLEMENTATION DEFINED functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
IMP DEF	IMP DEF	IMP DEF	IMP DEF	IMP DEF	IMP DEF

The numbers in these register names are encoded in decimal without leading zeroes, and the Cn and Cm fields require a literal C before the number. For example, S3_4_C11_C9_7.

Configurations

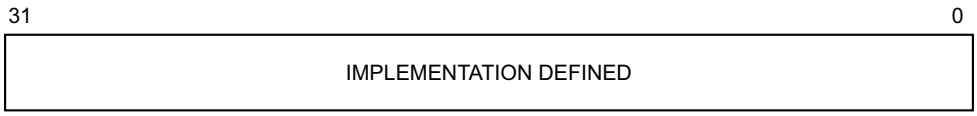
There are no configuration notes.

Attributes

S3_<op1>_<Cn>_<Cm>_<op2> is a 32-bit register.

Field descriptions

The S3_<op1>_<Cn>_<Cm>_<op2> bit assignments are:



Accessing the S3_<op1>_<Cn>_<Cm>_<op2> registers

To access the S3_<op1>_<Cn>_<Cm>_<op2> registers:

```
MRS <Xt>, S3_<op1>_<Cn>_<Cm>_<op2> ; Read S3_<op1>_<Cn>_<Cm>_<op2> into Xt
MSR S3_<op1>_<Cn>_<Cm>_<op2>, <Xt> ; Write Xt to S3_<op1>_<Cn>_<Cm>_<op2>
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	xxx	1x11	xxxx	xxx

D7.2.79 SCR_EL3, Secure Configuration Register

The SCR_EL3 characteristics are:

Purpose

Defines the configuration of the current Security state. It specifies:

- The Security state of EL0 and EL1, either Secure or Non-secure.
- The Execution state at lower exception levels.
- Whether IRQ, FIQ, and External Abort interrupts are taken to EL3.

This register is part of the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

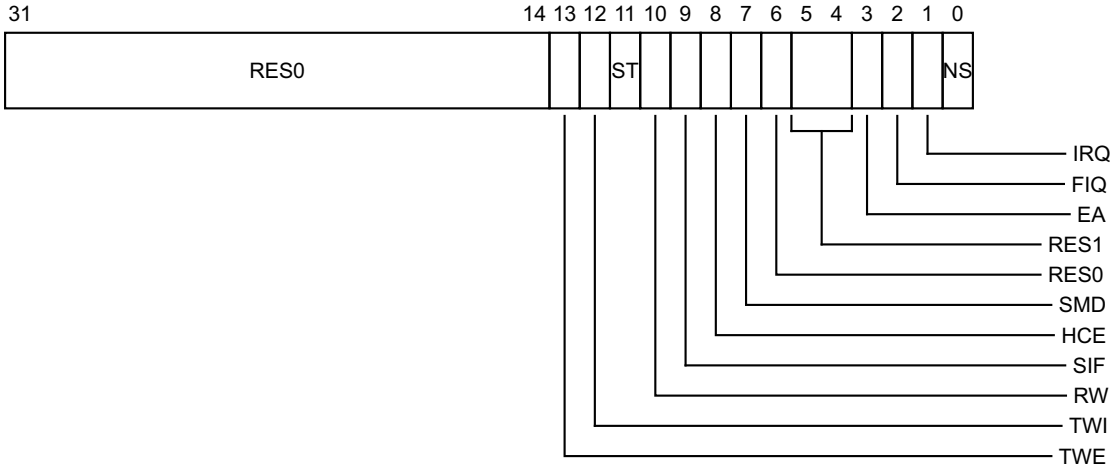
SCR_EL3 can be mapped to AArch32 register SCR, but this is not architecturally mandated.

Attributes

SCR_EL3 is a 32-bit register.

Field descriptions

The SCR_EL3 bit assignments are:



Bits [31:14]

Reserved, RES0.

TWE, bit [13]

Trap WFE. The possible values of this bit are:

0 WFE instructions not trapped.

1 WFE instructions executed in AArch32 or AArch64 at EL2, EL1, or EL0 are trapped to EL3 if the instruction would otherwise cause suspension of execution, i.e. if there is not a pending WFI wakeup event and the instruction does not cause another exception.

TWI, bit [12]

Trap WFI. The possible values of this bit are:

`0` WFI instructions not trapped.

`1` WFI instructions executed in AArch32 or AArch64 at EL2, EL1, or EL0 are trapped to EL3 if the instruction would otherwise cause suspension of execution.

ST, bit [11]

Enables Secure EL1 access to the CNTPS_TVAL_EL1, CNTPS_CTL_EL1, and CNTPS_CVAL_EL1 registers. The possible values of this bit are:

`0` These registers are only accessible in EL3.

`1` These registers are accessible in EL3 and also in EL1 when SCR_EL3.NS==0.

If this bit is 0 and there is a Secure EL1 access to one of the CNTPS registers:

- An exception is taken to EL3.
- The exception class for this exception, as returned in ESR_EL3.EC, is `0x18`.

RW, bit [10]

Execution state control for lower exception levels.

`0` Lower levels are all AArch32.

`1` The next lower level is AArch64.

If EL2 is present:

- EL2 is AArch64.
- EL2 controls EL1 and EL0 behaviors.

If EL2 is not present:

- EL1 is AArch64.
- EL0 is determined by the Execution state described in the current process state when executing at EL0.

This bit is permitted to be cached in a TLB.

SIF, bit [9]

Secure instruction fetch. When the processor is in Secure state, this bit disables instruction fetch from Non-secure memory. The possible values for this bit are:

`0` Secure state instruction fetches from Non-secure memory are permitted.

`1` Secure state instruction fetches from Non-secure memory are not permitted.

This bit is permitted to be cached in a TLB.

HCE, bit [8]

Hypervisor Call enable. This bit enables use of the HVC instruction from Non-secure EL1 modes. The possible values of this bit are:

`0` HVC instruction is UNDEFINED in Non-secure EL1 modes, and either UNDEFINED or a NOP in Hyp mode, depending on the implementation.

`1` HVC instruction is enabled in Non-secure EL1 modes, and performs a Hypervisor Call.

If EL3 is implemented but EL2 is not implemented, this bit is RES0.

SMD, bit [7]

SMC Disable.

`0` SMC is enabled at EL1, EL2, or EL3.

`1` SMC is UNDEFINED at all exception levels. At EL1 in the Non-secure state, the HCR_EL2.TSC bit has priority over this control.

Bit [6]

Reserved, RES0.

Bits [5:4]

Reserved, RES1.

EA, bit [3]

External Abort and SError Interrupt Routing.

0 External Aborts and SError Interrupts while executing at exception levels other than EL3 are not taken in EL3.

1 External Aborts and SError Interrupts while executing at all exception levels are taken in EL3.

FIQ, bit [2]

Physical FIQ Routing.

0 Physical FIQ while executing at exception levels other than EL3 are not taken in EL3.

1 Physical FIQ while executing at all exception levels are taken in EL3.

IRQ, bit [1]

Physical IRQ Routing.

0 Physical IRQ while executing at exception levels other than EL3 are not taken in EL3.

1 Physical IRQ while executing at all exception levels are taken in EL3.

NS, bit [0]

Non-secure bit.

0 Indicates that EL0 and EL1 are in Secure state, and so memory accesses from those exception levels can access Secure memory.

1 Indicates that EL0 and EL1 are in Non-secure state, and so memory accesses from those exception levels cannot access Secure memory.

Accessing the SCR_EL3

To access the SCR_EL3:

```
MRS <Xt>, SCR_EL3 ; Read SCR_EL3 into Xt
MSR SCR_EL3, <Xt> ; Write Xt to SCR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0001	0001	000

D7.2.80 SCTLR_EL1, System Control Register (EL1)

The SCTLR_EL1 characteristics are:

Purpose

Provides top level control of the system, including its memory system, at EL1.

This register is part of the Other system control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

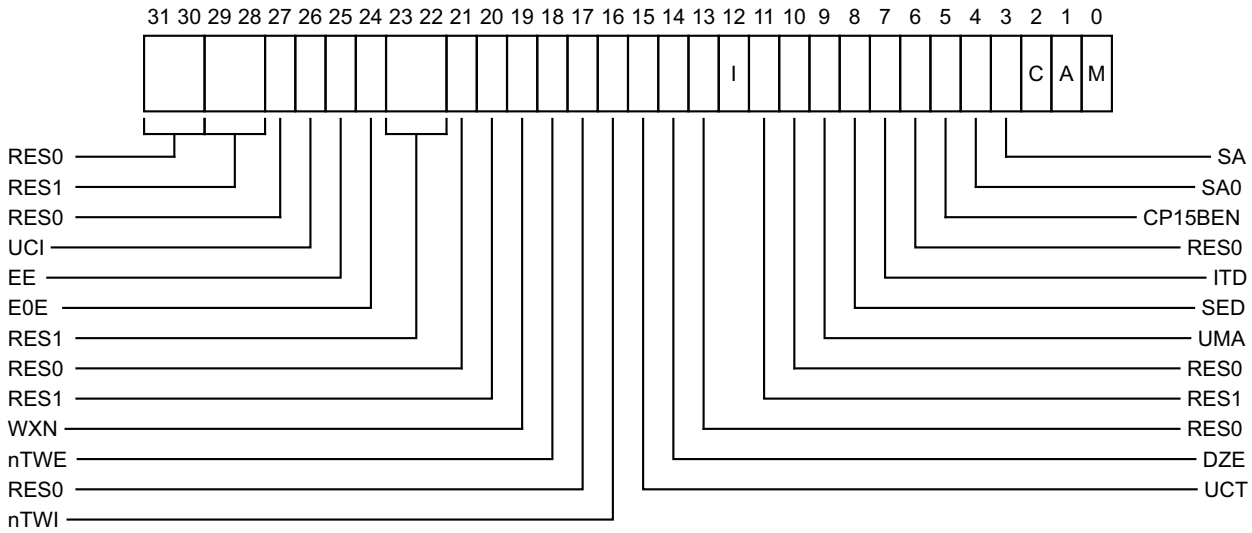
SCTLR_EL1 is architecturally mapped to AArch32 register SCTLR (NS).

Attributes

SCTLR_EL1 is a 32-bit register.

Field descriptions

The SCTLR_EL1 bit assignments are:



Bits [31:30]

Reserved, RES0.

Bits [29:28]

Reserved, RES1.

Bit [27]

Reserved, RES0.

UCI, bit [26]

When set, enables EL0 access in AArch64 for DC CVAU, DC CIVAC, DC CVAC, and IC IVAU instructions.

Reset value is architecturally UNKNOWN.

EE, bit [25]

Exception Endianness. This bit controls the endianness for:

- Explicit data accesses at EL1.
- Stage 1 translation table walks at EL1 and EL0.

The possible values of this bit are:

`0` Little-endian.

`1` Big-endian.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

The EE bit is permitted to be cached in a TLB.

If this register is at the highest exception level implemented, field resets to an IMPLEMENTATION DEFINED value. Otherwise, its reset value is UNKNOWN.

E0E, bit [24]

Endianness of explicit data accesses at EL0. The possible values of this bit are:

`0` Explicit data accesses at EL0 are little-endian.

`1` Explicit data accesses at EL0 are big-endian.

If an implementation only supports Little-endian accesses at EL0 then this bit is RES0.

If an implementation only supports Big-endian accesses at EL0 then this bit is RES1.

This bit has no effect on the endianness of LDTR* and STTR* instructions executed at EL1.

Reset value is architecturally UNKNOWN.

Bits [23:22]

Reserved, RES1.

Bit [21]

Reserved, RES0.

Bit [20]

Reserved, RES1.

WXN, bit [19]

Write permission implies XN (Execute Never). This bit can be used to require all memory regions with write permission to be treated as XN. The possible values of this bit are:

`0` Regions with write permission are not forced to XN.

`1` Regions with write permission are forced to XN.

The WXN bit is permitted to be cached in a TLB.

Reset value is architecturally UNKNOWN.

nTWE, bit [18]

Not trap WFE. Possible values of this bit are:

`0` If a WFE instruction executed at EL0 would cause execution to be suspended, such as if the event register is not set and there is not a pending WFE wakeup event, it is taken as an exception to EL1 using the `0x1` ESR code.

`1` WFE instructions are executed as normal.

Conditional WFE instructions that fail their condition do not cause an exception if this bit is 0.

Reset value is architecturally UNKNOWN.

Bit [17]

Reserved, RES0.

nTWI, bit [16]

Not trap WFI. Possible values of this bit are:

`0` If a WFI instruction executed at EL0 would cause execution to be suspended, such as if there is not a pending WFI wakeup event, it is taken as an exception to EL1 using the `0x1` ESR code.

`1` WFI instructions are executed as normal.

Conditional WFI instructions that fail their condition do not cause an exception if this bit is 0.

Reset value is architecturally UNKNOWN.

UCT, bit [15]

When set, enables EL0 access in AArch64 to the CTR_EL0 register.

Reset value is architecturally UNKNOWN.

DZE, bit [14]

Access to DC ZVA instruction at EL0. The possible values of this bit are:

`0` Execution of the DC ZVA instruction is prohibited at EL0, and it is treated as UNDEFINED at EL0.

`1` Execution of the DC ZVA instruction is allowed at EL0.

Reset value is architecturally UNKNOWN.

Bit [13]

Reserved, RES0.

I, bit [12]

Instruction cache enable. This is an enable bit for instruction caches at EL0 and EL1:

`0` Instruction caches disabled at EL0 and EL1. If SCTLR_EL1.M is set to 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal memory, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.

`1` Instruction caches enabled at EL0 and EL1. If SCTLR_EL1.M is set to 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal memory, Outer Shareable, Inner Write-Through, Outer Write-Through.

When this bit is 0, all EL1 and EL0 Normal memory instruction accesses are Non-cacheable.

If the HCR_EL2.DC bit is set to 1, then the Non-secure stage 1 EL1&0 translation regime is Cacheable regardless of the value of this bit.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

Bit [11]

Reserved, RES1.

Bit [10]

Reserved, RES0.

UMA, bit [9]

User Mask Access. Controls access to interrupt masks from EL0, when EL0 is using AArch64. The possible values of this bit are:

`0` Disable access to the interrupt masks from EL0.

1 Enable access to the interrupt masks from EL0.

Reset value is architecturally UNKNOWN.

SED, bit [8]

SETEND Disable. The possible values of this bit are:

0 The SETEND instruction is available.

1 The SETEND instruction is UNALLOCATED.

If an implementation does not support mixed endian operation, this bit is RES1.

Reset value is architecturally UNKNOWN.

ITD, bit [7]

IT Disable. The possible values of this bit are:

0 The IT instruction functionality is available.

1 It is IMPLEMENTATION DEFINED whether the IT instruction is treated as either:

- A 16-bit instruction, which can only be followed by another 16-bit instruction.
- The first half of a 32-bit instruction.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

All encodings of the IT instruction with hw1[3:0]!=1000 are UNDEFINED and treated as unallocated.

All encodings of the subsequent instruction with the following values for hw1 are UNDEFINED (and treated as unallocated):

`11xxxxxxxxxxxxxx`
All 32-bit instructions, B(2), B(1), Undefined, SVC, Load/Store multiple

`1x11xxxxxxxxxxx`
Miscellaneous 16-bit instructions

`1x100xxxxxxxxxx`
ADD Rd, PC, #imm

`01001xxxxxxxxxx`
LDR Rd, [PC, #imm]

`0100x1xxx1111xxx`
ADD(4),CMP(3), MOV, BX pc, BLX pc

`010001xx1xxxx111`
ADD(4),CMP(3), MOV (Note: this pattern also covers UNPREDICTABLE cases with BLX Rn)

Contrary to the standard treatment of conditional UNDEFINED instructions in the ARM architecture, in this case these instructions are always treated as UNDEFINED, regardless of whether the instruction would pass or fail its condition codes as a result of being in an IT block.

Reset value is architecturally UNKNOWN.

Bit [6]

Reserved, RES0.

CP15BEN, bit [5]

CP15 barrier enable. If implemented, this is an enable bit for the AArch32 CP15 DMB, DSB, and ISB barrier operations:

0 AArch32 CP15 barrier operations disabled. Their encodings are UNDEFINED.

1 AArch32 CP15 barrier operations enabled.

If an implementation does not support the CP15 barrier operations, this bit is RES0.

Reset value is architecturally UNKNOWN.

SA0, bit [4]

Stack Alignment Check Enable for EL0. When set, use of the stack pointer as the base address in a load/store instruction at EL0 must be aligned to a 16-byte boundary, or a Stack Alignment Fault exception will be raised.

Reset value is architecturally UNKNOWN.

SA, bit [3]

Stack Alignment Check Enable. When set, use of the stack pointer as the base address in a load/store instruction at this register's exception level must be aligned to a 16-byte boundary, or a Stack Alignment Fault exception will be raised.

Reset value is architecturally UNKNOWN.

C, bit [2]

Cache enable. This is an enable bit for data and unified caches at EL0 and EL1:

`0` Data and unified caches disabled.

`1` Data and unified caches enabled.

When this bit is 0, all EL0 and EL1 Normal memory data accesses and all accesses to the EL1&0 stage 1 translation tables are Non-cacheable.

If the HCR_EL2.DC bit is set to 1, then the Non-secure stage 1 EL1&0 translation regime is Cacheable regardless of the value of the SCTLR_EL1.C bit.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking:

`0` Alignment fault checking disabled.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

`1` Alignment fault checking enabled.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

Reset value is architecturally UNKNOWN.

M, bit [0]

MMU enable for EL1 and EL0 stage 1 address translation. Possible values of this bit are:

`0` EL1 and EL0 stage 1 address translation disabled.

`1` EL1 and EL0 stage 1 address translation enabled.

If HCR_EL2.DC is set to 1, then in Non-secure state the SCTLR_EL1.M bit behaves as 0 for all purposes other than reading the value of the bit.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

Accessing the SCTLR_EL1

To access the SCTLR_EL1:

```
MRS <Xt>, SCTLR_EL1 ; Read SCTLR_EL1 into Xt
MSR SCTLR_EL1, <Xt> ; Write Xt to SCTLR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0001	0000	000

D7.2.81 SCTLR_EL2, System Control Register (EL2)

The SCTLR_EL2 characteristics are:

Purpose

Provides top level control of the system, including its memory system, at EL2.

This register is part of:

- the Virtualization registers functional group
- the Other system control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

SCTLR_EL2 is architecturally mapped to AArch32 register HSCTLR.

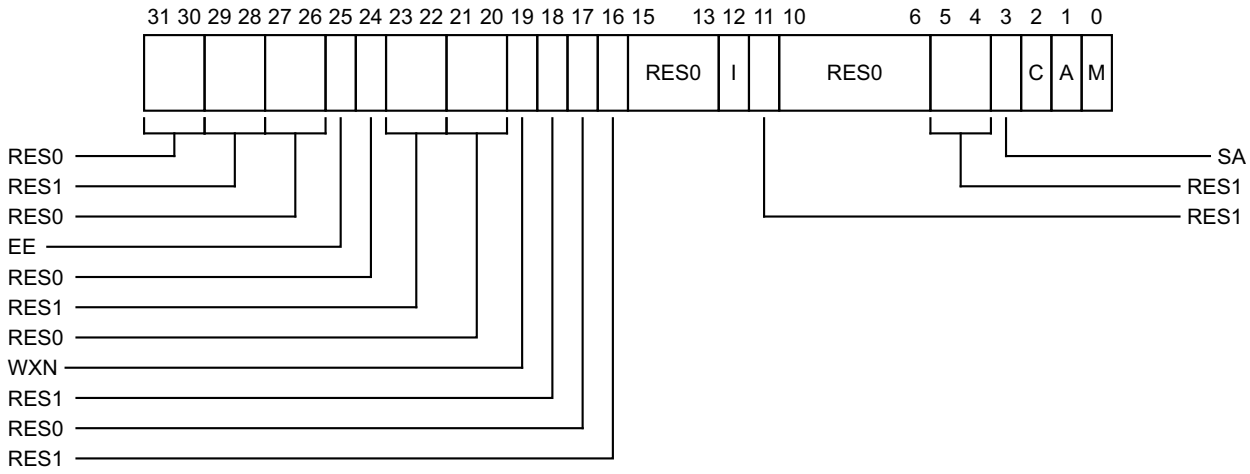
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

SCTLR_EL2 is a 32-bit register.

Field descriptions

The SCTLR_EL2 bit assignments are:



Bits [31:30]

Reserved, RES0.

Bits [29:28]

Reserved, RES1.

Bits [27:26]

Reserved, RES0.

EE, bit [25]

Exception Endianness. This bit controls the endianness for:

- Explicit data accesses at EL2.
- Stage 1 translation table walks at EL2.
- Stage 2 translation table walks at EL1 and EL0.

The possible values of this bit are:

0 Little-endian.

1 Big-endian.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

The EE bit is permitted to be cached in a TLB.

If this register is at the highest exception level implemented, field resets to an IMPLEMENTATION DEFINED value. Otherwise, its reset value is UNKNOWN.

Bit [24]

Reserved, RES0.

Bits [23:22]

Reserved, RES1.

Bits [21:20]

Reserved, RES0.

WXN, bit [19]

Write permission implies XN (Execute Never). This bit can be used to require all memory regions with write permission to be treated as XN. The possible values of this bit are:

0 Regions with write permission are not forced to XN.

1 Regions with write permission are forced to XN.

The WXN bit is permitted to be cached in a TLB.

Reset value is architecturally UNKNOWN.

Bit [18]

Reserved, RES1.

Bit [17]

Reserved, RES0.

Bit [16]

Reserved, RES1.

Bits [15:13]

Reserved, RES0.

I, bit [12]

Instruction cache enable. This is an enable bit for instruction caches at EL2:

0 Instruction caches disabled at EL2. If SCTLR_EL2.M is set to 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal memory, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.

1 Instruction caches enabled at EL2. If SCTLR_EL2.M is set to 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal memory, Outer Shareable, Inner Write-Through, Outer Write-Through.

When this bit is 0, all EL2 Normal memory instruction accesses are Non-cacheable. This bit has no effect on the EL1&0 or EL3 translation regimes.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

Bit [11]

Reserved, RES1.

Bits [10:6]

Reserved, RES0.

Bits [5:4]

Reserved, RES1.

SA, bit [3]

Stack Alignment Check Enable. When set, use of the stack pointer as the base address in a load/store instruction at this register's exception level must be aligned to a 16-byte boundary, or a Stack Alignment Fault exception will be raised.

Reset value is architecturally UNKNOWN.

C, bit [2]

Cache enable. This is an enable bit for data and unified caches at EL2:

0 Data and unified caches disabled at EL2.

1 Data and unified caches enabled at EL2.

When this bit is 0, all EL2 Normal memory data accesses and all accesses to the EL2 translation tables are Non-cacheable. This bit has no effect on the EL1&0 or EL3 translation regimes.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking:

0 Alignment fault checking disabled.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

1 Alignment fault checking enabled.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

Reset value is architecturally UNKNOWN.

M, bit [0]

MMU enable for EL2 stage 1 address translation. Possible values of this bit are:

0 EL2 stage 1 address translation disabled.

1 EL2 stage 1 address translation enabled.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

Accessing the SCTLR_EL2

To access the SCTLR_EL2:

```
MRS <Xt>, SCTLR_EL2 ; Read SCTLR_EL2 into Xt
MSR SCTLR_EL2, <Xt> ; Write Xt to SCTLR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0001	0000	000

D7.2.82 SCTLR_EL3, System Control Register (EL3)

The SCTLR_EL3 characteristics are:

Purpose

Provides top level control of the system, including its memory system, at EL3.

This register is part of the Other system control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

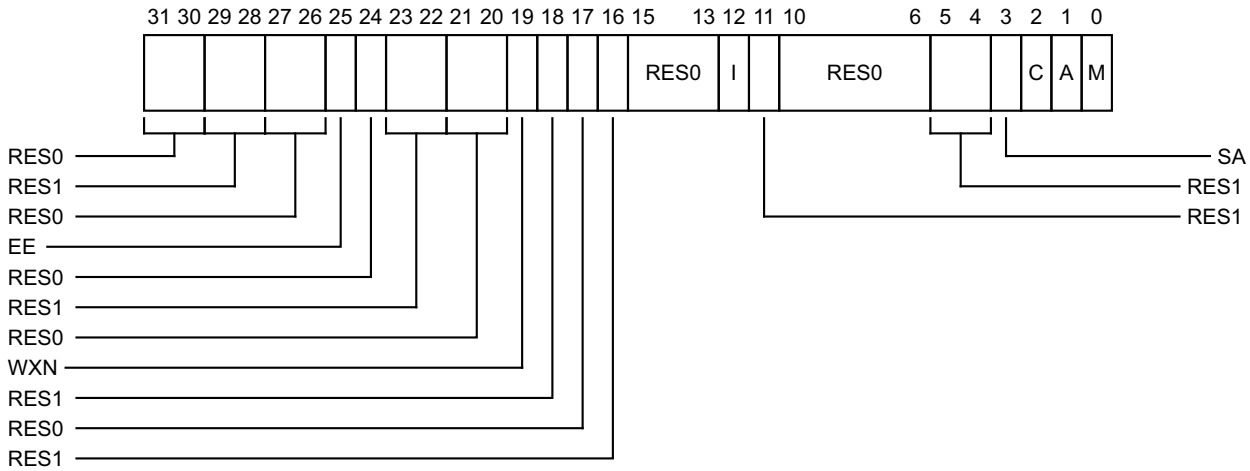
SCTLR_EL3 can be mapped to AArch32 register SCTLR (S), but this is not architecturally mandated.

Attributes

SCTLR_EL3 is a 32-bit register.

Field descriptions

The SCTLR_EL3 bit assignments are:



Bits [31:30]

Reserved, RES0.

Bits [29:28]

Reserved, RES1.

Bits [27:26]

Reserved, RES0.

EE, bit [25]

Exception Endianness. This bit controls the endianness for:

- Explicit data accesses at EL3.

- Stage 1 translation table walks at EL3.

The possible values of this bit are:

0 Little-endian.

1 Big-endian.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

The EE bit is permitted to be cached in a TLB.

If this register is at the highest exception level implemented, field resets to an IMPLEMENTATION DEFINED value. Otherwise, its reset value is UNKNOWN.

Bit [24]

Reserved, RES0.

Bits [23:22]

Reserved, RES1.

Bits [21:20]

Reserved, RES0.

WXN, bit [19]

Write permission implies XN (Execute Never). This bit can be used to require all memory regions with write permission to be treated as XN. The possible values of this bit are:

0 Regions with write permission are not forced to XN.

1 Regions with write permission are forced to XN.

The WXN bit is permitted to be cached in a TLB.

Reset value is architecturally UNKNOWN.

Bit [18]

Reserved, RES1.

Bit [17]

Reserved, RES0.

Bit [16]

Reserved, RES1.

Bits [15:13]

Reserved, RES0.

I, bit [12]

Instruction cache enable. This is an enable bit for instruction caches at EL3:

0 Instruction caches disabled at EL3. If SCTLR_EL3.M is set to 0, instruction accesses from stage 1 of the EL3 translation regime are to Normal memory, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.

1 Instruction caches enabled at EL3. If SCTLR_EL3.M is set to 0, instruction accesses from stage 1 of the EL3 translation regime are to Normal memory, Outer Shareable, Inner Write-Through, Outer Write-Through.

When this bit is 0, all EL3 Normal memory instruction accesses are Non-cacheable. This bit has no effect on the EL1&0 or EL2 translation regimes.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

Bit [11]

Reserved, RES1.

Bits [10:6]

Reserved, RES0.

Bits [5:4]

Reserved, RES1.

SA, bit [3]

Stack Alignment Check Enable. When set, use of the stack pointer as the base address in a load/store instruction at this register's exception level must be aligned to a 16-byte boundary, or a Stack Alignment Fault exception will be raised.

Reset value is architecturally UNKNOWN.

C, bit [2]

Cache enable. This is an enable bit for data and unified caches at EL3:

0 Data and unified caches disabled at EL3.

1 Data and unified caches enabled at EL3.

When this bit is 0, all EL3 Normal memory data accesses and all accesses to the EL3 translation tables are Non-cacheable. This bit has no effect on the EL1&0 or EL2 translation regimes.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking:

0 Alignment fault checking disabled.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

1 Alignment fault checking enabled.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

Reset value is architecturally UNKNOWN.

M, bit [0]

MMU enable for EL3 stage 1 address translation. Possible values of this bit are:

0 EL3 stage 1 address translation disabled.

1 EL3 stage 1 address translation enabled.

If this register is at the highest exception level implemented, field resets to 0. Otherwise, its reset value is UNKNOWN.

Accessing the SCTLR_EL3

To access the SCTLR_EL3:

```
MRS <Xt>, SCTLR_EL3 ; Read SCTLR_EL3 into Xt
MSR SCTLR_EL3, <Xt> ; Write Xt to SCTLR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0001	0000	000

D7.2.83 TCR_EL1, Translation Control Register (EL1)

The TCR_EL1 characteristics are:

Purpose

Determines which of the Translation Table Base Registers defined the base address for a translation table walk required for the stage 1 translation of a memory access from EL0 or EL1. Also controls the translation table format and holds cacheability and shareability information.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Any of the bits in TCR_EL1 are permitted to be cached in a TLB.

Configurations

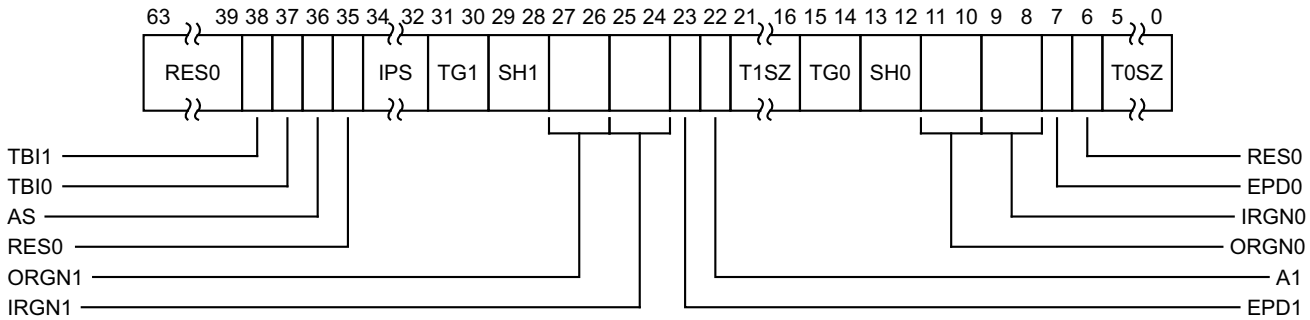
TCR_EL1[31:0] is architecturally mapped to AArch32 register TTBCR (NS).

Attributes

TCR_EL1 is a 64-bit register.

Field descriptions

The TCR_EL1 bit assignments are:



Bits [63:39]

Reserved, RES0.

TBI1, bit [38]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR1_EL1 region, or ignored and used for tagged addresses.

`0` Top Byte used in the address calculation.

`1` Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by TTBR1_EL1. It has an effect whether the EL1&0 translation regime is enabled or not.

Additionally, this affects changes to the program counter, when TBI1 is 1 and bit [55] of the target address is 1, caused by:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

In these cases bits [63:56] of the address are also set to 1 before it is stored in the PC.

TBI0, bit [37]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR0_EL1 region, or ignored and used for tagged addresses.

`0` Top Byte used in the address calculation.

`1` Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL1. It has an effect whether the EL1&0 translation regime is enabled or not.

Additionally, this affects changes to the program counter, when TBI0 is 1 and bit [55] of the target address is 0, caused by:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

In these cases bits [63:56] of the address are also set to 0 before it is stored in the PC.

AS, bit [36]

ASID Size.

`0` 8 bit - the upper 8 bits of TTBR0_EL1 and TTBR1_EL1 are ignored by hardware for every purpose except reading back the register, and are treated as if they are all zeros for when used for allocation and matching entries in the TLB.

`1` 16 bit - the upper 16 bits of TTBR0_EL1 and TTBR1_EL1 are used for allocation and matching in the TLB.

If the implementation has only 8 bits of ASID, this field is RES0.

Bit [35]

Reserved, RES0.

IPS, bits [34:32]

Intermediate Physical Address Size.

`000` 32 bits, 4 GB.

`001` 36 bits, 64 GB.

`010` 40 bits, 1 TB.

`011` 42 bits, 4 TB.

`100` 44 bits, 16 TB.

`101` 48 bits, 256 TB.

Other values are reserved.

The reserved values behave in the same way as the `101` encoding, but software must not rely on this property as the behavior of the RESERVED values might change in a future revision of the architecture.

TG1, bits [31:30]

TTBR1_EL1 Granule size.

`01` 16KByte

10 4KByte

11 64KByte

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

SH1, bits [29:28]

Shareability attribute for memory associated with translation table walks using TTBR1_EL1.

00 Non-shareable

10 Outer Shareable

11 Inner Shareable

Other values are reserved.

ORGN1, bits [27:26]

Outer cacheability attribute for memory associated with translation table walks using TTBR1_EL1.

00 Normal memory, Outer Non-cacheable

01 Normal memory, Outer Write-Back Write-Allocate Cacheable

10 Normal memory, Outer Write-Through Cacheable

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

IRGN1, bits [25:24]

Inner cacheability attribute for memory associated with translation table walks using TTBR1_EL1.

00 Normal memory, Inner Non-cacheable

01 Normal memory, Inner Write-Back Write-Allocate Cacheable

10 Normal memory, Inner Write-Through Cacheable

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

EPD1, bit [23]

Translation table walk disable for translations using TTBR1_EL1. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR1_EL1. The encoding of this bit is:

0 Perform translation table walks using TTBR1_EL1.

1 A TLB miss on an address that is translated using TTBR1_EL1 generates a Translation fault. No translation table walk is performed.

A1, bit [22]

Selects whether TTBR0_EL1 or TTBR1_EL1 defines the ASID. The encoding of this bit is:

0 TTBR0_EL1.ASID defines the ASID.

1 TTBR1_EL1.ASID defines the ASID.

T1SZ, bits [21:16]

The size offset of the memory region addressed by TTBR1_EL1. The region size is $2^{64-T1SZ}$ bytes.

The maximum and minimum possible values for T1SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

TG0, bits [15:14]

Granule size for the corresponding translation table base address register.

00 4KByte

01 64KByte

10 16KByte

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0_EL1.

00 Non-shareable

10 Outer Shareable

11 Inner Shareable

Other values are reserved.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL1.

00 Normal memory, Outer Non-cacheable

01 Normal memory, Outer Write-Back Write-Allocate Cacheable

10 Normal memory, Outer Write-Through Cacheable

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL1.

00 Normal memory, Inner Non-cacheable

01 Normal memory, Inner Write-Back Write-Allocate Cacheable

10 Normal memory, Inner Write-Through Cacheable

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

EPD0, bit [7]

Translation table walk disable for translations using TTBR0. This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using TTBR0. The encoding of this bit is:

0 Perform translation table walks using TTBR0.

1 A TLB miss on an address that is translated using TTBR0 generates a Translation fault. No translation table walk is performed.

Bit [6]

Reserved, RES0.

T0SZ, bits [5:0]

The size offset of the memory region addressed by TTBR0_EL1. The region size is $2^{64-T0SZ}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

Accessing the TCR_EL1

To access the TCR_EL1:

```
MRS <Xt>, TCR_EL1 ; Read TCR_EL1 into Xt
MSR TCR_EL1, <Xt> ; Write Xt to TCR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0010	0000	010

D7.2.84 TCR_EL2, Translation Control Register (EL2)

The TCR_EL2 characteristics are:

Purpose

Controls translation table walks required for the stage 1 translation of memory accesses from EL2, and holds cacheability and shareability information for the accesses.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Any of the bits in TCR_EL2 are permitted to be cached in a TLB.

Configurations

TCR_EL2 is architecturally mapped to AArch32 register HTCR.

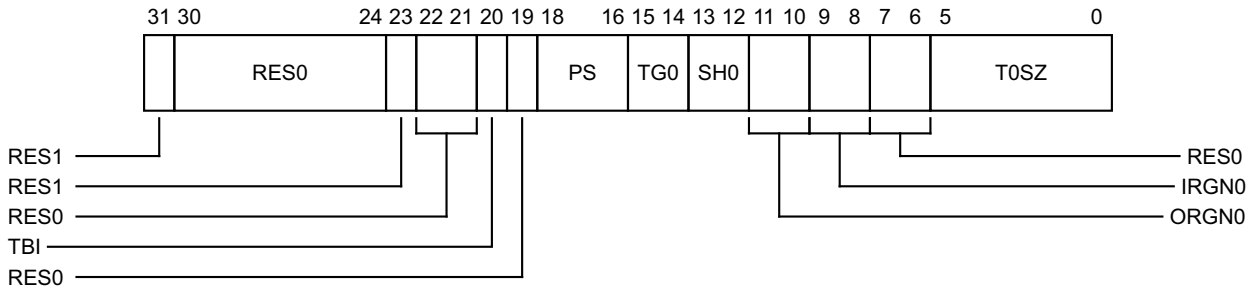
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

TCR_EL2 is a 32-bit register.

Field descriptions

The TCR_EL2 bit assignments are:



Bit [31]

Reserved, RES1.

Bits [30:24]

Reserved, RES0.

Bit [23]

Reserved, RES1.

Bits [22:21]

Reserved, RES0.

TBI, bit [20]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR0_EL2 region, or ignored and used for tagged addresses.

`0` Top Byte used in the address calculation.

`1` Top Byte ignored in the address calculation.

This affects addresses generated in EL2 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL2. It has an effect whether the EL2 translation regime is enabled or not.

Additionally, this affects changes to the program counter, when TBI is 1, caused by:

- A branch or procedure return within EL2.
- An exception taken to EL2.
- An exception return to EL2.

In these cases bits [63:56] of the address are set to 0 before it is stored in the PC.

Bit [19]

Reserved, RES0.

PS, bits [18:16]

Physical Address Size.

`000` 32 bits, 4 GB.

`001` 36 bits, 64 GB.

`010` 40 bits, 1 TB.

`011` 42 bits, 4 TB.

`100` 44 bits, 16 TB.

`101` 48 bits, 256 TB.

Other values are reserved.

The reserved values behave in the same way as the `101` encoding, but software must not rely on this property as the behavior of the RESERVED values might change in a future revision of the architecture.

TG0, bits [15:14]

Granule size for the corresponding translation table base address register.

`00` 4KByte

`01` 64KByte

`10` 16KByte

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0_EL2.

`00` Non-shareable

`10` Outer Shareable

`11` Inner Shareable

Other values are reserved.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL2.

00 Normal memory, Outer Non-cacheable

01 Normal memory, Outer Write-Back Write-Allocate Cacheable

10 Normal memory, Outer Write-Through Cacheable

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL2.

00 Normal memory, Inner Non-cacheable

01 Normal memory, Inner Write-Back Write-Allocate Cacheable

10 Normal memory, Inner Write-Through Cacheable

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

Bits [7:6]

Reserved, RES0.

T0SZ, bits [5:0]

The size offset of the memory region addressed by TTBR0_EL2. The region size is $2^{64-T0SZ}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

Accessing the TCR_EL2

To access the TCR_EL2:

```
MRS <Xt>, TCR_EL2 ; Read TCR_EL2 into Xt
MSR TCR_EL2, <Xt> ; Write Xt to TCR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0010	0000	010

D7.2.85 TCR_EL3, Translation Control Register (EL3)

The TCR_EL3 characteristics are:

Purpose

Controls translation table walks required for the stage 1 translation of memory accesses from EL3, and holds cacheability and shareability information for the accesses.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Any of the bits in TCR_EL3 are permitted to be cached in a TLB.

Configurations

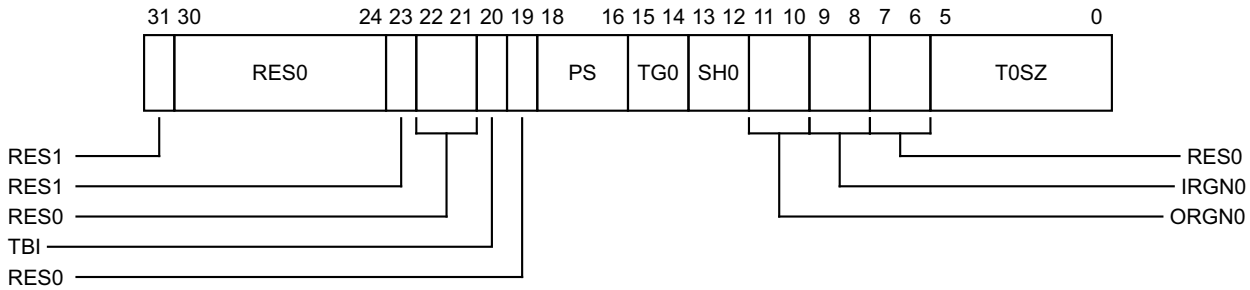
TCR_EL3[31:0] can be mapped to AArch32 register TTBCR (S), but this is not architecturally mandated.

Attributes

TCR_EL3 is a 32-bit register.

Field descriptions

The TCR_EL3 bit assignments are:



Bit [31]

Reserved, RES1.

Bits [30:24]

Reserved, RES0.

Bit [23]

Reserved, RES1.

Bits [22:21]

Reserved, RES0.

TBI, bit [20]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the TTBR0_EL3 region, or ignored and used for tagged addresses.

`0` Top Byte used in the address calculation.

`1` Top Byte ignored in the address calculation.

This affects addresses generated in EL3 using AArch64 where the address would be translated by tables pointed to by TTBR0_EL3. It has an effect whether the EL3 translation regime is enabled or not.

Additionally, this affects changes to the program counter, when TBI is 1, caused by:

- A branch or procedure return within EL3.
- A exception taken to EL3.
- An exception return to EL3.

In these cases bits [63:56] of the address are set to 0 before it is stored in the PC.

Bit [19]

Reserved, RES0.

PS, bits [18:16]

Physical Address Size.

`000` 32 bits, 4 GB.

`001` 36 bits, 64 GB.

`010` 40 bits, 1 TB.

`011` 42 bits, 4 TB.

`100` 44 bits, 16 TB.

`101` 48 bits, 256 TB.

Other values are reserved.

The reserved values behave in the same way as the `101` encoding, but software must not rely on this property as the behavior of the RESERVED values might change in a future revision of the architecture.

TG0, bits [15:14]

Granule size for the corresponding translation table base address register.

`00` 4KByte

`01` 64KByte

`10` 16KByte

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using TTBR0_EL3.

`00` Non-shareable

`10` Outer Shareable

`11` Inner Shareable

Other values are reserved.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using TTBR0_EL3.

00 Normal memory, Outer Non-cacheable

01 Normal memory, Outer Write-Back Write-Allocate Cacheable

10 Normal memory, Outer Write-Through Cacheable

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using TTBR0_EL3.

00 Normal memory, Inner Non-cacheable

01 Normal memory, Inner Write-Back Write-Allocate Cacheable

10 Normal memory, Inner Write-Through Cacheable

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

Bits [7:6]

Reserved, RES0.

T0SZ, bits [5:0]

The size offset of the memory region addressed by TTBR0_EL3. The region size is $2^{64-T0SZ}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

Accessing the TCR_EL3

To access the TCR_EL3:

```
MRS <Xt>, TCR_EL3 ; Read TCR_EL3 into Xt
MSR TCR_EL3, <Xt> ; Write Xt to TCR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0010	0000	010

D7.2.86 TPIDR_EL0, EL0 Read/Write Software Thread ID Register

The TPIDR_EL0 characteristics are:

Purpose

Provides a location where software executing at EL0 can store thread identifying information, for OS management purposes.

This register is part of the Thread and process ID registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW

Configurations

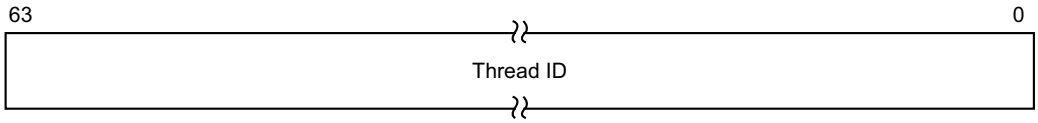
TPIDR_EL0[31:0] is architecturally mapped to AArch32 register TPIDRURW (NS).

Attributes

TPIDR_EL0 is a 64-bit register.

Field descriptions

The TPIDR_EL0 bit assignments are:



Bits [63:0]

Thread ID. Thread identifying information stored by software running at this exception level.

Accessing the TPIDR_EL0

To access the TPIDR_EL0:

```
MRS <Xt>, TPIDR_EL0 ; Read TPIDR_EL0 into Xt
MSR TPIDR_EL0, <Xt> ; Write Xt to TPIDR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1101	0000	010

D7.2.87 TPIDR_EL1, EL1 Software Thread ID Register

The TPIDR_EL1 characteristics are:

Purpose

Provides a location where software executing at EL1 can store thread identifying information, for OS management purposes.

This register is part of the Thread and process ID registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

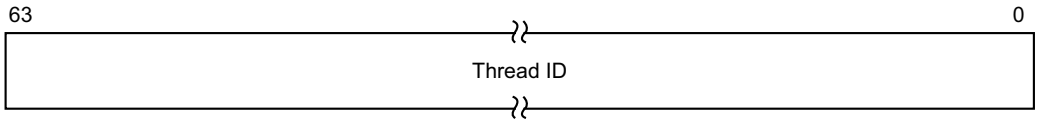
TPIDR_EL1[31:0] is architecturally mapped to AArch32 register TPIDRPRW (NS).

Attributes

TPIDR_EL1 is a 64-bit register.

Field descriptions

The TPIDR_EL1 bit assignments are:



Bits [63:0]

Thread ID. Thread identifying information stored by software running at this exception level.

Accessing the TPIDR_EL1

To access the TPIDR_EL1:

```
MRS <Xt>, TPIDR_EL1 ; Read TPIDR_EL1 into Xt
MSR TPIDR_EL1, <Xt> ; Write Xt to TPIDR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1101	0000	100

D7.2.88 TPIDR_EL2, EL2 Software Thread ID Register

The TPIDR_EL2 characteristics are:

Purpose

Provides a location where software executing at EL2 can store thread identifying information, for OS management purposes.

This register is part of:

- the Virtualization registers functional group
- the Thread and process ID registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

TPIDR_EL2[31:0] is architecturally mapped to AArch32 register HTPIDR.

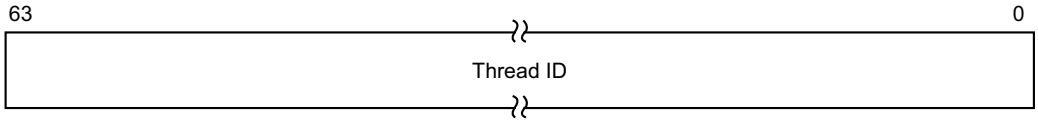
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

TPIDR_EL2 is a 64-bit register.

Field descriptions

The TPIDR_EL2 bit assignments are:



Bits [63:0]

Thread ID. Thread identifying information stored by software running at this exception level.

Accessing the TPIDR_EL2

To access the TPIDR_EL2:

```
MRS <Xt>, TPIDR_EL2 ; Read TPIDR_EL2 into Xt
MSR TPIDR_EL2, <Xt> ; Write Xt to TPIDR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1101	0000	010

D7.2.89 TPIDR_EL3, EL3 Software Thread ID Register

The TPIDR_EL3 characteristics are:

Purpose

Provides a location where software executing at EL3 can store thread identifying information, for OS management purposes.

This register is part of the Thread and process ID registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

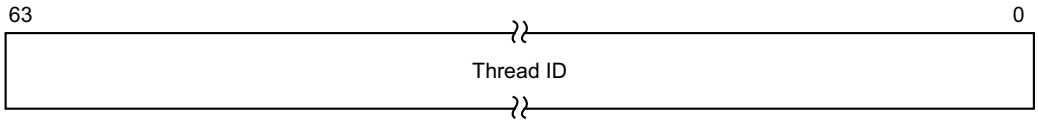
There are no configuration notes.

Attributes

TPIDR_EL3 is a 64-bit register.

Field descriptions

The TPIDR_EL3 bit assignments are:



Bits [63:0]

Thread ID. Thread identifying information stored by software running at this exception level.

Accessing the TPIDR_EL3

To access the TPIDR_EL3:

```
MRS <Xt>, TPIDR_EL3 ; Read TPIDR_EL3 into Xt
MSR TPIDR_EL3, <Xt> ; Write Xt to TPIDR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	1101	0000	010

D7.2.90 TPIDRRO_EL0, EL0 Read-Only Software Thread ID Register

The TPIDRRO_EL0 characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes.

This register is part of the Thread and process ID registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RO	RW	RW	RW	RW	RW

Configurations

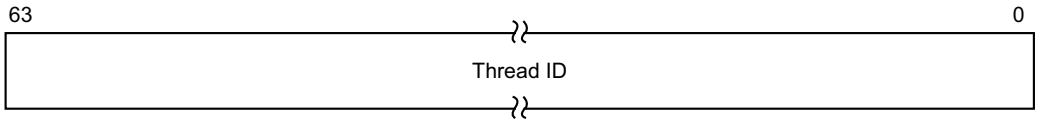
TPIDRRO_EL0[31:0] is architecturally mapped to AArch32 register TPIDRURO (NS).

Attributes

TPIDRRO_EL0 is a 64-bit register.

Field descriptions

The TPIDRRO_EL0 bit assignments are:



Bits [63:0]

Thread ID. Thread identifying information stored by software running at this exception level.

Accessing the TPIDRRO_EL0

To access the TPIDRRO_EL0:

```
MRS <Xt>, TPIDRRO_EL0 ; Read TPIDRRO_EL0 into Xt
MSR TPIDRRO_EL0, <Xt> ; Write Xt to TPIDRRO_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1101	0000	011

D7.2.91 TTBR0_EL1, Translation Table Base Register 0 (EL1)

The TTBR0_EL1 characteristics are:

Purpose

Holds the base address of translation table 0, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses at EL0 and EL1.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Any of the fields in this register are permitted to be cached in a TLB.

Configurations

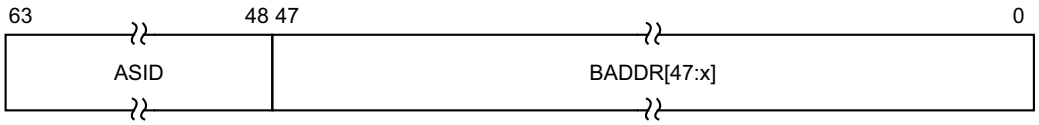
TTBR0_EL1 is architecturally mapped to AArch32 register TTBR0 (NS).

Attributes

TTBR0_EL1 is a 64-bit register.

Field descriptions

The TTBR0_EL1 bit assignments are:



ASID, bits [63:48]

An ASID for the translation table base address. The TCR_EL1.A1 field selects either TTBR0_EL1.ASID or TTBR1_EL1.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

BADDR[47:x], bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of TCR_EL1.T0SZ, the stage of translation, and the memory translation granule size.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated.

The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.

If bits [x-1:0] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

Accessing the TTBR0_EL1

To access the TTBR0_EL1:

```
MRS <Xt>, TTBR0_EL1 ; Read TTBR0_EL1 into Xt
MSR TTBR0_EL1, <Xt> ; Write Xt to TTBR0_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0010	0000	000

D7.2.92 TTBR0_EL2, Translation Table Base Register 0 (EL2)

The TTBR0_EL2 characteristics are:

Purpose

Holds the base address of the translation table for the stage 1 translation of memory accesses from EL2.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Any of the fields in this register are permitted to be cached in a TLB.

Configurations

TTBR0_EL2 is architecturally mapped to AArch32 register HTTBR.

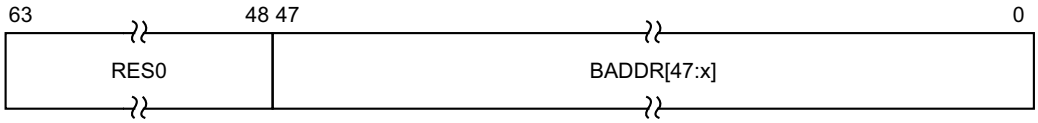
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

TTBR0_EL2 is a 64-bit register.

Field descriptions

The TTBR0_EL2 bit assignments are:



Bits [63:48]

Reserved, RES0.

BADDR[47:x], bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of TCR_EL2.T0SZ, the stage of translation, and the memory translation granule size.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated.

The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.

If bits [x-1:0] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

Accessing the TTBR0_EL2

To access the TTBR0_EL2:

```
MRS <Xt>, TTBR0_EL2 ; Read TTBR0_EL2 into Xt
MSR TTBR0_EL2, <Xt> ; Write Xt to TTBR0_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0010	0000	000

D7.2.93 TTBR0_EL3, Translation Table Base Register 0 (EL3)

The TTBR0_EL3 characteristics are:

Purpose

Holds the base address of the translation table for the stage 1 translation of memory accesses from EL3.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Any of the fields in this register are permitted to be cached in a TLB.

Configurations

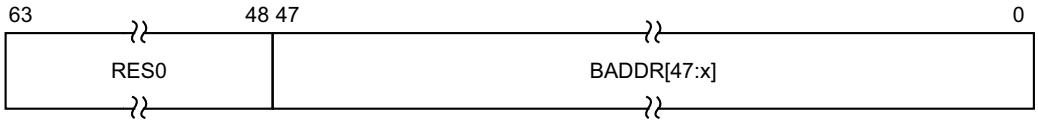
TTBR0_EL3 can be mapped to AArch32 register TTBR0 (S), but this is not architecturally mandated.

Attributes

TTBR0_EL3 is a 64-bit register.

Field descriptions

The TTBR0_EL3 bit assignments are:



Bits [63:48]

Reserved, RES0.

BADDR[47:x], bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of TCR_EL3.T0SZ, the stage of translation, and the memory translation granule size.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated.

The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.

If bits [x-1:0] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

Accessing the TTBR0_EL3

To access the TTBR0_EL3:

```
MRS <Xt>, TTBR0_EL3 ; Read TTBR0_EL3 into Xt
MSR TTBR0_EL3, <Xt> ; Write Xt to TTBR0_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0010	0000	000

D7.2.94 TTBR1_EL1, Translation Table Base Register 1

The TTBR1_EL1 characteristics are:

Purpose

Holds the base address of translation table 1, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses at EL0 and EL1.

This register is part of the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Any of the fields in this register are permitted to be cached in a TLB.

Configurations

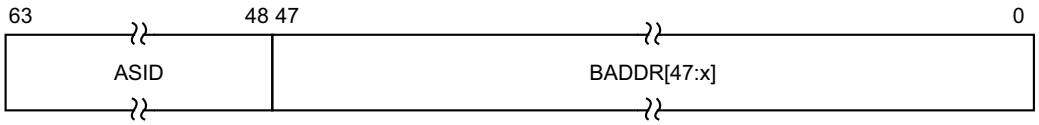
TTBR1_EL1 is architecturally mapped to AArch32 register TTBR1 (NS).

Attributes

TTBR1_EL1 is a 64-bit register.

Field descriptions

The TTBR1_EL1 bit assignments are:



ASID, bits [63:48]

An ASID for the translation table base address. The TCR_EL1.A1 field selects either TTBR0_EL1.ASID or TTBR1_EL1.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

BADDR[47:x], bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of TCR_EL1.T0SZ, the stage of translation, and the memory translation granule size.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated.

The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.

If bits [x-1:0] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.
- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

Accessing the TTBR1_EL1

To access the TTBR1_EL1:

```
MRS <Xt>, TTBR1_EL1 ; Read TTBR1_EL1 into Xt
MSR TTBR1_EL1, <Xt> ; Write Xt to TTBR1_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0010	0000	001

D7.2.95 VBAR_EL1, Vector Base Address Register (EL1)

The VBAR_EL1 characteristics are:

Purpose

Holds the exception base address for any exception that is taken to EL1.

This register is part of the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

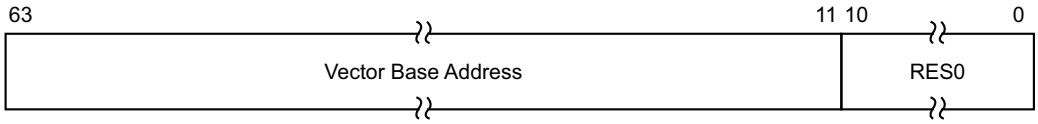
VBAR_EL1[31:0] is architecturally mapped to AArch32 register VBAR (NS).

Attributes

VBAR_EL1 is a 64-bit register.

Field descriptions

The VBAR_EL1 bit assignments are:



Bits [63:11]

Vector Base Address. Base address of the exception vectors for exceptions taken in EL1.

If tagged addresses are being used, bits [55:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

If tagged addresses are not being used, bits [63:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

Bits [10:0]

Reserved, RES0.

Accessing the VBAR_EL1

To access the VBAR_EL1:

```
MRS <Xt>, VBAR_EL1 ; Read VBAR_EL1 into Xt
MSR VBAR_EL1, <Xt> ; Write Xt to VBAR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	0000	000

D7.2.96 VBAR_EL2, Vector Base Address Register (EL2)

The VBAR_EL2 characteristics are:

Purpose

Holds the exception base address for any exception that is taken to EL2.

This register is part of:

- the Virtualization registers functional group
- the Exception and fault handling registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

VBAR_EL2[31:0] is architecturally mapped to AArch32 register HVBAR.

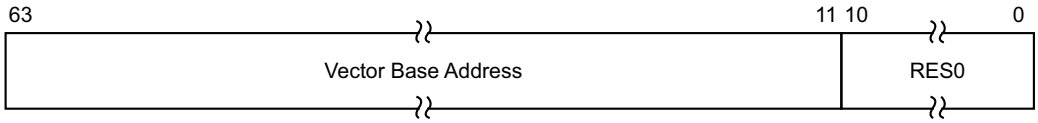
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

VBAR_EL2 is a 64-bit register.

Field descriptions

The VBAR_EL2 bit assignments are:



Bits [63:11]

Vector Base Address. Base address of the exception vectors for exceptions taken in EL2.

If tagged addresses are being used, bits [55:48] of VBAR_EL2 must be 0 or else the use of the vector address will result in a recursive exception.

If tagged addresses are not being used, bits [63:48] of VBAR_EL2 must be 0 or else the use of the vector address will result in a recursive exception.

Bits [10:0]

Reserved, RES0.

Accessing the VBAR_EL2

To access the VBAR_EL2:

```
MRS <Xt>, VBAR_EL2 ; Read VBAR_EL2 into Xt
MSR VBAR_EL2, <Xt> ; Write Xt to VBAR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	0000	000

D7.2.97 VBAR_EL3, Vector Base Address Register (EL3)

The VBAR_EL3 characteristics are:

Purpose

Holds the exception base address for any exception that is taken to EL3.

This register is part of:

- the Exception and fault handling registers functional group
- the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

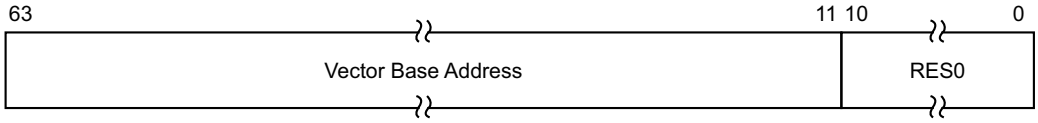
VBAR_EL3[31:0] can be mapped to AArch32 register VBAR (S), but this is not architecturally mandated.

Attributes

VBAR_EL3 is a 64-bit register.

Field descriptions

The VBAR_EL3 bit assignments are:



Bits [63:11]

Vector Base Address. Base address of the exception vectors for exceptions taken in EL3.

If tagged addresses are being used, bits [55:48] of VBAR_EL3 must be 0 or else the use of the vector address will result in a recursive exception.

If tagged addresses are not being used, bits [63:48] of VBAR_EL3 must be 0 or else the use of the vector address will result in a recursive exception.

Bits [10:0]

Reserved, RES0.

Accessing the VBAR_EL3

To access the VBAR_EL3:

```
MRS <Xt>, VBAR_EL3 ; Read VBAR_EL3 into Xt
MSR VBAR_EL3, <Xt> ; Write Xt to VBAR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	1100	0000	000

D7.2.98 VMPIDR_EL2, Virtualization Multiprocessor ID Register

The VMPIDR_EL2 characteristics are:

Purpose

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by Non-secure EL1 reads of MPIDR_EL1.

This register is part of:

- the Identification registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as VMPIDR_EL2 as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Note

This register is accessible from EL1 as MPIDR_EL1.

Configurations

VMPIDR_EL2[31:0] is architecturally mapped to AArch32 register VMPIDR.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

VMPIDR_EL2 is a 64-bit register.

For an interpretation of the values in this register, see MPIDR_EL1.

Accessing the VMPIDR_EL2:

To access the VMPIDR_EL2:

```
MRS <Xt>, VMPIDR_EL2 ; Read VMPIDR_EL2 into Xt
MSR VMPIDR_EL2, <Xt> ; Write Xt to VMPIDR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0000	0000	101

D7.2.99 VPIDR_EL2, Virtualization Processor ID Register

The VPIDR_EL2 characteristics are:

Purpose

Holds the value of the Virtualization Processor ID. This is the value returned by Non-secure EL1 reads of MIDR_EL1.

This register is part of:

- the Virtualization registers functional group
- the Identification registers functional group.

Usage constraints

This register is accessible as VPIDR_EL2 shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Note

This register is accessible from EL1 as MIDR_EL1.

Configurations

VPIDR_EL2 is architecturally mapped to AArch32 register VPIDR.

If EL2 is not implemented, this register is RES0 from EL3.

Attributes

VPIDR_EL2 is a 32-bit register.

For an interpretation of the values in the register, see MIDR_EL1.

Accessing the VPIDR_EL2:

To access the VPIDR_EL2:

```
MRS <Xt>, VPIDR_EL2 ; Read VPIDR_EL2 into Xt
MSR VPIDR_EL2, <Xt> ; Write Xt to VPIDR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0000	0000	000

D7.2.100 VTCR_EL2, Virtualization Translation Control Register

The VTCR_EL2 characteristics are:

Purpose

Controls the translation table walks required for the stage 2 translation of memory accesses from Non-secure EL0 and EL1, and holds cacheability and shareability information for the accesses.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Any of the bits in VTCR_EL2 are permitted to be cached in a TLB.

Configurations

VTCR_EL2 is architecturally mapped to AArch32 register VTCR.

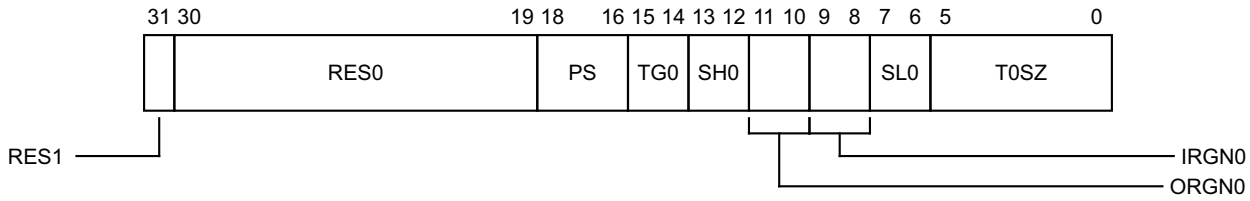
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

VTCR_EL2 is a 32-bit register.

Field descriptions

The VTCR_EL2 bit assignments are:



Bit [31]

Reserved, RES1.

Bits [30:19]

Reserved, RES0.

PS, bits [18:16]

Physical Address Size.

000	32 bits, 4 GB.
001	36 bits, 64 GB.
010	40 bits, 1 TB.
011	42 bits, 4 TB.
100	44 bits, 16 TB.
101	48 bits, 256 TB.

Other values are reserved.

The reserved values behave in the same way as the 101 encoding, but software must not rely on this property as the behavior of the RESERVED values might change in a future revision of the architecture.

TG0, bits [15:14]

Granule size for the corresponding translation table base address register.

00 4KByte

01 64KByte

10 16KByte

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using VTTBR_EL2.

00 Non-shareable

10 Outer Shareable

11 Inner Shareable

Other values are reserved.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using VTTBR_EL2.

00 Normal memory, Outer Non-cacheable

01 Normal memory, Outer Write-Back Write-Allocate Cacheable

10 Normal memory, Outer Write-Through Cacheable

11 Normal memory, Outer Write-Back no Write-Allocate Cacheable

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using VTTBR_EL2.

00 Normal memory, Inner Non-cacheable

01 Normal memory, Inner Write-Back Write-Allocate Cacheable

10 Normal memory, Inner Write-Through Cacheable

11 Normal memory, Inner Write-Back no Write-Allocate Cacheable

SL0, bits [7:6]

Starting level of the VTCR_EL2 addressed region. The meaning of this field depends on the value of VTCR_EL2.TG0 (the granule size).

00 If TG0 is 00 (4KB granule), start at level 2. If TG0 is 10 (16KB granule) or 01 (64KB granule), start at level 3.

01 If TG0 is 00 (4KB granule), start at level 1. If TG0 is 10 (16KB granule) or 01 (64KB granule), start at level 2.

10 If TG0 is 00 (4KB granule), start at level 0. If TG0 is 10 (16KB granule) or 0b01 (64KB granule), start at level 1.

Other values are reserved.

T0SZ, bits [5:0]

The size offset of the memory region addressed by VTTBR_EL2. The region size is $2^{64-T0SZ}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

Accessing the VTCR_EL2

To access the VTCR_EL2:

```
MRS <Xt>, VTCR_EL2 ; Read VTCR_EL2 into Xt
MSR VTCR_EL2, <Xt> ; Write Xt to VTCR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0010	0001	010

D7.2.101 VTTBR_EL2, Virtualization Translation Table Base Register

The VTTBR_EL2 characteristics are:

Purpose

Holds the base address of the translation table for the stage 2 translation of memory accesses from Non-secure EL0 and EL1.

This register is part of:

- the Virtualization registers functional group
- the Virtual memory control registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Any of the fields in this register are permitted to be cached in a TLB.

Configurations

VTTBR_EL2 is architecturally mapped to AArch32 register VTTBR.

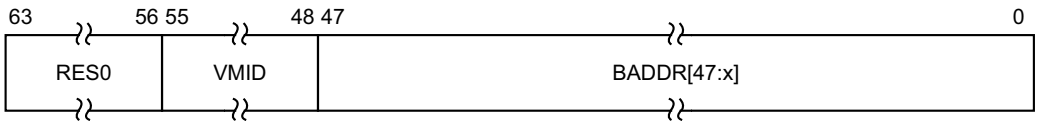
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

VTTBR_EL2 is a 64-bit register.

Field descriptions

The VTTBR_EL2 bit assignments are:



Bits [63:56]

Reserved, RES0.

VMID, bits [55:48]

The VMID for the translation table.

BADDR[47:x], bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0.

x is based on the value of VTCR_EL2.T0SZ, the stage of translation, and the memory translation granule size.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated.

The value of x determines the required alignment of the translation table, which must be aligned to 2^x bytes.

If bits [x-1:0] are not all zero, this is a misaligned Translation Table Base Address. Its effects are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits might be the value written or might be zero.

- The calculation of an address for a translation table walk using this register can be corrupted in those bits that are non-zero.

Accessing the VTTBR_EL2

To access the VTTBR_EL2:

```
MRS <Xt>, VTTBR_EL2 ; Read VTTBR_EL2 into Xt
MSR VTTBR_EL2, <Xt> ; Write Xt to VTTBR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0010	0001	000

D7.3 Debug registers

This section lists the Debug registers in AArch64.

D7.3.1 DBGAUTHSTATUS_EL1, Debug Authentication Status register

The DBGAUTHSTATUS_EL1 characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

DBGAUTHSTATUS_EL1 is architecturally mapped to AArch32 register DBGAUTHSTATUS.

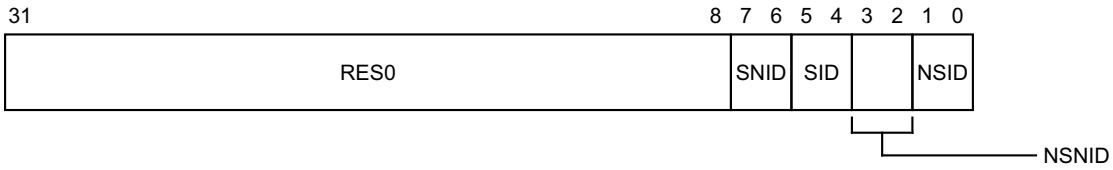
DBGAUTHSTATUS_EL1 is architecturally mapped to external register DBGAUTHSTATUS_EL1.

Attributes

DBGAUTHSTATUS_EL1 is a 32-bit register.

Field descriptions

The DBGAUTHSTATUS_EL1 bit assignments are:



Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Secure non-invasive debug. Possible values of this field are:

`00` Not implemented. EL3 is not implemented and the processor is Non-secure.

`10` Implemented and disabled. ExternalSecureNoninvasiveDebugEnabled() == FALSE.

`11` Implemented and enabled. ExternalSecureNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the processor is Non-secure.

10 Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSNID, bits [3:2]

Non-secure non-invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the processor is Secure.

10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

00 Not implemented. EL3 is not implemented and the processor is Secure.

10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.

11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

Other values are reserved.

Accessing the DBGAUTHSTATUS_EL1

To access the DBGAUTHSTATUS_EL1:

```
MRS <Xt>, DBGAUTHSTATUS_EL1 ; Read DBGAUTHSTATUS_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0111	1110	110

D7.3.2 DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n>_EL1 characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register DBGBVR<n>_EL1, where n is 0 to 15.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

When the E field is zero, all the other fields in the register are ignored.

Configurations

DBGBCR<n>_EL1 is architecturally mapped to AArch32 register DBGBCR<n>.

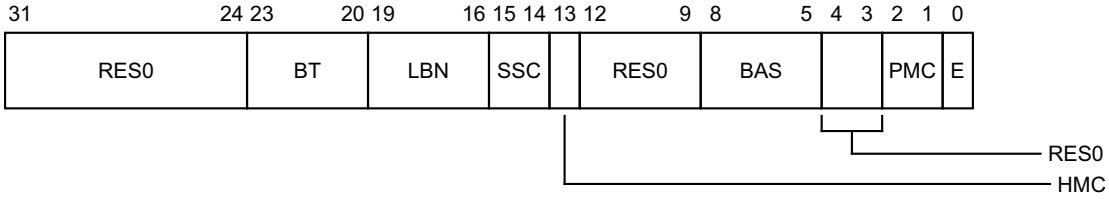
DBGBCR<n>_EL1 is architecturally mapped to external register DBGBCR<n>_EL1.

Attributes

DBGBCR<n>_EL1 is a 32-bit register.

Field descriptions

The DBGBCR<n>_EL1 bit assignments are:



Bits [31:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type. Possible values are:

0000 Unlinked address match.

0001 Linked address match.

0010 Unlinked context ID match.

0011 Linked context ID match

0100 Unlinked address mismatch.

0101 Linked address mismatch.

1000 Unlinked VMID match.

1001 Linked VMID match.

1010 Unlinked VMID and context ID match.

1011 Linked VMID and context ID match.

The field breaks down as follows:

- BT[3:1]: Base type.

  `000` Match address. DBGBVR<n>_EL1 is the address of an instruction.

  `010` Mismatch address. Behaves as type `000` if in an AArch64 translation, or if Halting debug is enabled and halting is allowed. Otherwise, DBGBVR<n>_EL1 is the address of an instruction to be stepped.

  `001` Match context ID. DBGBVR<n>_EL1[31:0] is a context ID.

  `100` Match VMID. DBGBVR<n>_EL1[39:32] is a VMID.

  `101` Match VMID and context ID. DBGBVR<n>_EL1[31:0] is a context ID, and DBGBVR<n>_EL1[39:32] is a VMID.

- BT[0]: Enable linking.

If the breakpoint is not context-aware, BT[3] and BT[1] are RES0. If EL2 is not implemented, BT[3] is RES0. If EL1 using AArch32 is not implemented, BT[2] is RES0.

The values `011x` and `11xx` are reserved, but must behave as if the breakpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

On Cold reset, the field reset value is architecturally UNKNOWN.

LBN, bits [19:16]

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

On Cold reset, the field reset value is architecturally UNKNOWN.

SSC, bits [15:14]

Security state control. Determines the Security states under which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [12:9]

Reserved, RES0.

BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state. In an AArch64-only implementation, this field is reserved, RES1. Otherwise:

- BAS[2] and BAS[0] are read/write.
- BAS[3] and BAS[1] are read-only copies of BAS[2] and BAS[0] respectively.

The values `0011` and `1100` are only supported if AArch32 is supported at any exception level.

The permitted values depend on the breakpoint type.

For Address match breakpoints in either AArch32 or AArch64 state:

BAS	Match instruction at	Constraint for debuggers
0011	DBGBVR<n>_EL1	Use for T32 instructions.
1100	DBGBVR<n>_EL1+2	Use for T32 instructions.
1111	DBGBVR<n>_EL1	Use for A64 and A32 instructions.

0000 is reserved and must behave as if the breakpoint is disabled or map to a permitted value.

For Address mismatch breakpoints in an AArch32 stage 1 translation regime:

BAS	Step instruction at	Constraint for debuggers
0000	-	Use for a match anywhere breakpoint.
0011	DBGBVR<n>_EL1	Use for stepping T32 instructions.
1100	DBGBVR<n>_EL1+2	Use for stepping T32 instructions.
1111	DBGBVR<n>_EL1	Use for stepping A32 instructions.

For Context matching breakpoints, this field is RES1 and ignored.

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the exception level or levels at which a breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

E, bit [0]

Enable breakpoint DBGBVR<n>_EL1. Possible values are:

0 Breakpoint disabled.

1 Breakpoint enabled.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGBCR<n>_EL1

To access the DBGBCR<n>_EL1:

```
MRS <Xt>, DBGBCR<n>_EL1 ; Read DBGBCR<n>_EL1 into Xt, where n is in the range 0 to 15
MSR DBGBCR<n>_EL1, <Xt> ; Write Xt to DBGBCR<n>_EL1, where n is in the range 0 to 15
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0000	n<3:0>	101

D7.3.3 DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n>_EL1 characteristics are:

Purpose

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint n together with control register DBGBCR<n>_EL1, where n is 0 to 15.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

DBGBVR<n>_EL1[31:0] is architecturally mapped to AArch32 register DBGBVR<n>.

DBGBVR<n>_EL1[63:32] is architecturally mapped to AArch32 register DBGBXVR<n>.

DBGBVR<n>_EL1 is architecturally mapped to external register DBGBVR<n>_EL1.

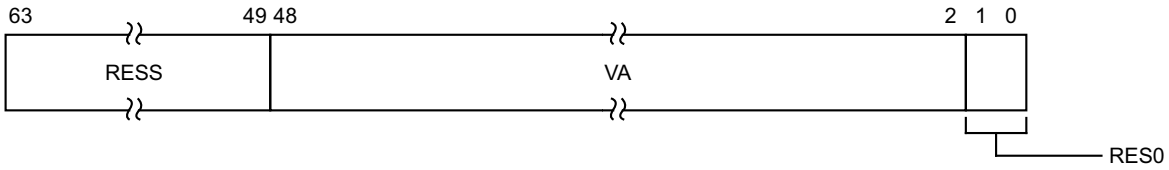
Attributes

DBGBVR<n>_EL1 is a 64-bit register.

Field descriptions

The DBGBVR<n>_EL1 bit assignments are:

When DBGBCR<n>_EL1.BT==0b0x0x:



RESS, bits [63:49]

Reserved, Sign extended. Hardwired to the value of the sign bit, bit [48]. Hardware and software must treat this field as RES0 if bit[48] is 0, and as RES1 if bit[48] is 1.

VA, bits [48:2]

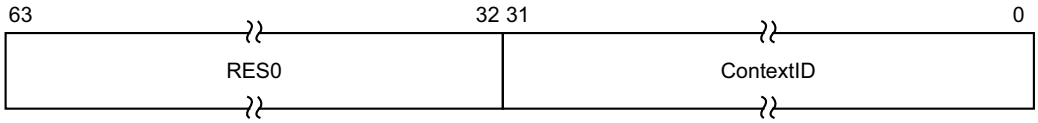
Bits[48:2] of the address value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT==0b0x1x:



Bits [63:32]

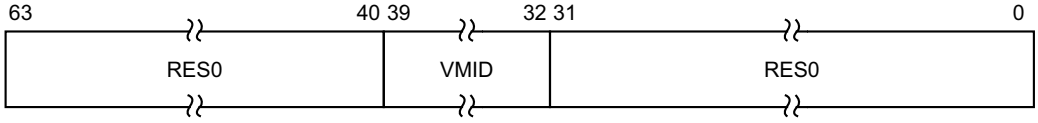
Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

When DBGBCR<n>_EL1.BT==0b1x0x and EL2 implemented:



Bits [63:40]

Reserved, RES0.

VMID, bits [39:32]

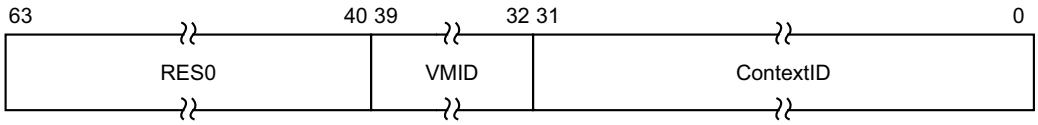
VMID value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [31:0]

Reserved, RES0.

When DBGBCR<n>_EL1.BT==0x1x1x and EL2 implemented:



Bits [63:40]

Reserved, RES0.

VMID, bits [39:32]

VMID value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

ContextID, bits [31:0]

Context ID value for comparison.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGBVR<n>_EL1

To access the DBGBVR<n>_EL1:

```
MRS <Xt>, DBGBVR<n>_EL1 ; Read DBGBVR<n>_EL1 into Xt, where n is in the range 0 to 15
MSR DBGBVR<n>_EL1, <Xt> ; Write Xt to DBGBVR<n>_EL1, where n is in the range 0 to 15
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0000	n<3:0>	100

D7.3.4 DBGCLAIMCLR_EL1, Debug Claim Tag Clear register

The DBGCLAIMCLR_EL1 characteristics are:

Purpose

Used by software to read the values of the CLAIM bits, and to clear these bits to 0.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

DBGCLAIMCLR_EL1 is architecturally mapped to AArch32 register DBGCLAIMCLR.

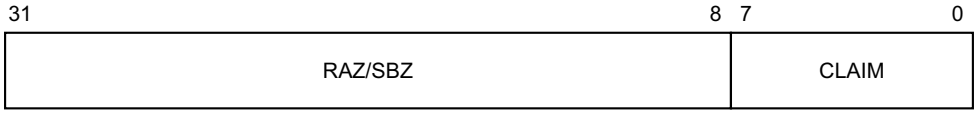
DBGCLAIMCLR_EL1 is architecturally mapped to external register DBGCLAIMCLR_EL1.

Attributes

DBGCLAIMCLR_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMCLR_EL1 bit assignments are:



Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Claim clear bits. Reading this field returns the current value of the CLAIM bits.

Writing a 1 to one of these bits clears the corresponding CLAIM bit to 0. This is an indirect write to the CLAIM bits.

A single write operation can clear multiple bits to 0. Writing 0 to one of these bits has no effect.

On Cold reset, the field resets to 0.

Accessing the DBGCLAIMCLR_EL1

To access the DBGCLAIMCLR_EL1:

```
MRS <Xt>, DBGCLAIMCLR_EL1 ; Read DBGCLAIMCLR_EL1 into Xt
MSR DBGCLAIMCLR_EL1, <Xt> ; Write Xt to DBGCLAIMCLR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0111	1001	110

D7.3.5 DBGCLAIMSET_EL1, Debug Claim Tag Set register

The DBGCLAIMSET_EL1 characteristics are:

Purpose

Used by software to set CLAIM bits to 1.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

DBGCLAIMSET_EL1 is architecturally mapped to AArch32 register DBGCLAIMSET.

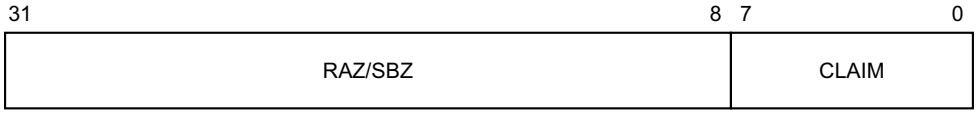
DBGCLAIMSET_EL1 is architecturally mapped to external register DBGCLAIMSET_EL1.

Attributes

DBGCLAIMSET_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMSET_EL1 bit assignments are:



Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Claim set bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM bit to 1. This is an indirect write to the CLAIM bits.

A single write operation can set multiple bits to 1. Writing 0 to one of these bits has no effect.

On Cold reset, the field resets to 0.

Accessing the DBGCLAIMSET_EL1

To access the DBGCLAIMSET_EL1:

```
MRS <Xt>, DBGCLAIMSET_EL1 ; Read DBGCLAIMSET_EL1 into Xt
MSR DBGCLAIMSET_EL1, <Xt> ; Write Xt to DBGCLAIMSET_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0111	1000	110

D7.3.6 DBGDTR_EL0, Debug Data Transfer Register, half-duplex

The DBGDTR_EL0 characteristics are:

Purpose

Transfers 64 bits of data between the processor and an external host. Can transfer both ways using only a single register.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register can be accessed at EL0 when MDSCR_EL1.TDCC is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

If EDSCR.ITE == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Configurations

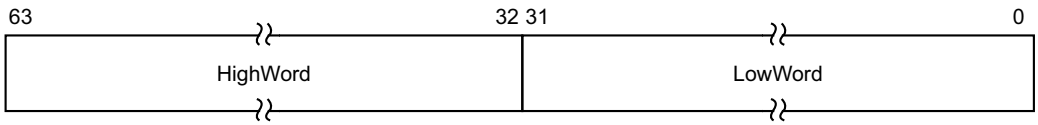
There are no configuration notes.

Attributes

DBGDTR_EL0 is a 64-bit register.

Field descriptions

The DBGDTR_EL0 bit assignments are:



HighWord, bits [63:32]

Writes to this register set DTRRX to the value in this field. Reads from this register return the value of DTRTX.

LowWord, bits [31:0]

Writes to this register set DTRTX to the value in this field. Reads from this register return the value of DTRRX.

Accessing the DBGDTR_EL0

To access the DBGDTR_EL0:

```
MRS <Xt>, DBGDTR_EL0 ; Read DBGDTR_EL0 into Xt
MSR DBGDTR_EL0, <Xt> ; Write Xt to DBGDTR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	011	0000	0100	000

D7.3.7 DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

Purpose

Transfers 32 bits of data from an external host to the processor.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	RO	RO	RO	RO	RO

This register can be read at EL0 when MDSCR_EL1.TDCC is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

If EDSCR.ITE == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Configurations

DBGDTRRX_EL0 is architecturally mapped to AArch32 register DBGDTRRXint.

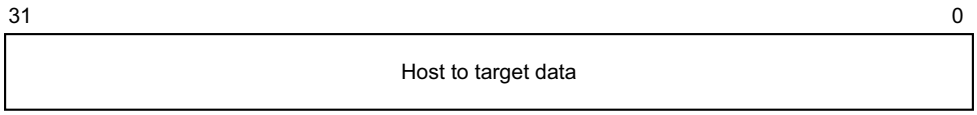
DBGDTRRX_EL0 is architecturally mapped to external register DBGDTRRX_EL0.

Attributes

DBGDTRRX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRRX_EL0 bit assignments are:



Bits [31:0]

Host to target data. One word of data for transfer from the debug host to the debug target.

For the full behavior of the Debug Communications Channel, see The Debug Communication Channel and Instruction Transfer Register.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGDTRRX_EL0

To access the DBGDTRRX_EL0:

```
MRS <Xt>, DBGDTRRX_EL0 ; Read DBGDTRRX_EL0 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	011	0000	0101	000

D7.3.8 DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers 32 bits of data from the processor to an external host.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-WO	WO	WO	WO	WO	WO

This register can be written at EL0 when MDSCR_EL1.TDCC is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

If EDSCR.ITE == 0 when the processor exits Debug state on receiving a Restart request trigger event, the behavior of any operation issued by a DTR access in memory access mode that has not completed execution is CONSTRAINED UNPREDICTABLE, and must do one of the following:

- It must complete execution in Debug state before the processor executes the restart sequence.
- It must complete execution in Non-debug state before the processor executes the restart sequence.
- It must be abandoned. This means that the instruction does not execute. Any registers or memory accessed by the instruction are left in an UNKNOWN state.

Configurations

DBGDTRTX_EL0 is architecturally mapped to AArch32 register DBGDTRTXint.

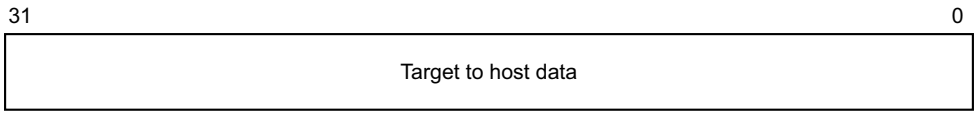
DBGDTRTX_EL0 is architecturally mapped to external register DBGDTRTX_EL0.

Attributes

DBGDTRTX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRTX_EL0 bit assignments are:



Bits [31:0]

Target to host data. One word of data for transfer from the debug target to the debug host.

For the full behavior of the Debug Communications Channel, see The Debug Communication Channel and Instruction Transfer Register.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGDTRTX_EL0

To access the DBGDTRTX_EL0:

```
MSR DBGDTRTX_EL0, <Xt> ; Write Xt to DBGDTRTX_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	011	0000	0101	000

D7.3.9 DBGPRCR_EL1, Debug Power Control Register

The DBGPRCR_EL1 characteristics are:

Purpose

Controls behavior of processor on power-down request.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

DBGPRCR_EL1 is architecturally mapped to AArch32 register DBGPRCR.

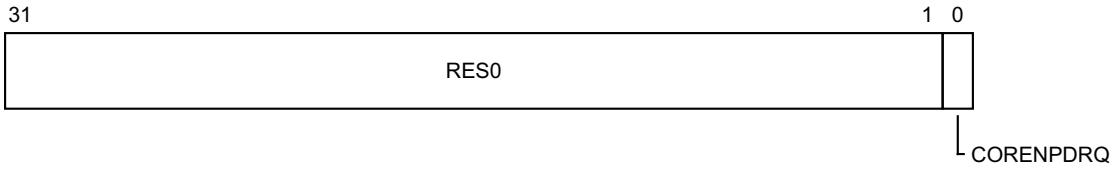
Bit [0] of this register is mapped to EDPRCR.CORENPDRQ, bit [0] of the external view of this register. The other bits in these registers are not mapped to each other.

Attributes

DBGPRCR_EL1 is a 32-bit register.

Field descriptions

The DBGPRCR_EL1 bit assignments are:



Bits [31:1]

Reserved, RES0.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:

`0` On a powerdown request, the system powers down the Core power domain.

`1` On a powerdown request, the system emulates powerdown of the Core power domain. In this emulation mode the Core power domain is not actually powered down.

On Cold reset, the field resets to the value of EDPRCR.COREPURQ.

Accessing the DBGPRCR_EL1

To access the DBGPRCR_EL1:

```
MRS <Xt>, DBGPRCR_EL1 ; Read DBGPRCR_EL1 into Xt
MSR DBGPRCR_EL1, <Xt> ; Write Xt to DBGPRCR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0001	0100	100

D7.3.10 DBGVCR32_EL2, Debug Vector Catch Register

The DBGVCR32_EL2 characteristics are:

Purpose

Allows access to the AArch32 register DBGVCR from AArch64 state only. Its value has no effect on execution in AArch64 state.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

DBGVCR32_EL2 is architecturally mapped to AArch32 register DBGVCR.

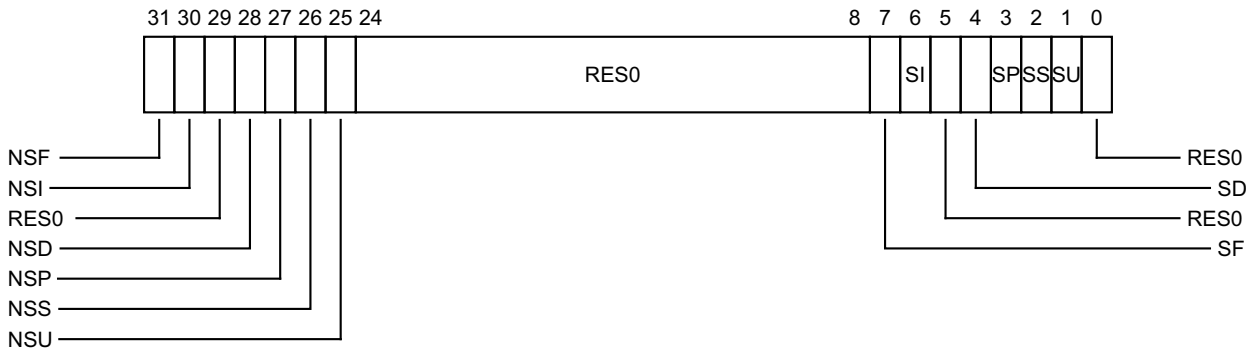
Attributes

DBGVCR32_EL2 is a 32-bit register.

Field descriptions

The DBGVCR32_EL2 bit assignments are:

When EL3 implemented and using AArch64:



NSF, bit [31]

FIQ vector catch enable in Non-secure state.

The exception vector offset is `0x1C`.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSI, bit [30]

IRQ vector catch enable in Non-secure state.

The exception vector offset is `0x18`.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [29]

Reserved, RES0.

NSD, bit [28]

Data Abort vector catch enable in Non-secure state.

The exception vector offset is `0x10`.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSP, bit [27]

Prefetch Abort vector catch enable in Non-secure state.

The exception vector offset is `0x0C`.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSS, bit [26]

Supervisor Call (SVC) vector catch enable in Non-secure state.

The exception vector offset is `0x08`.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSU, bit [25]

Undefined Instruction vector catch enable in Non-secure state.

The exception vector offset is `0x04`.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bits [24:8]

Reserved, RES0.

SF, bit [7]

FIQ vector catch enable in Secure state.

The exception vector offset is `0x1C`.

On Warm reset, the field reset value is architecturally UNKNOWN.

SI, bit [6]

IRQ vector catch enable in Secure state.

The exception vector offset is `0x18`.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

SD, bit [4]

Data Abort vector catch enable in Secure state.

The exception vector offset is `0x10`.

On Warm reset, the field reset value is architecturally UNKNOWN.

SP, bit [3]

Prefetch Abort vector catch enable in Secure state.

The exception vector offset is `0x0C`.

On Warm reset, the field reset value is architecturally UNKNOWN.

SS, bit [2]

Supervisor Call (SVC) vector catch enable in Secure state.

The exception vector offset is `0x08`.

On Warm reset, the field reset value is architecturally UNKNOWN.

SU, bit [1]

Undefined Instruction vector catch enable in Secure state.

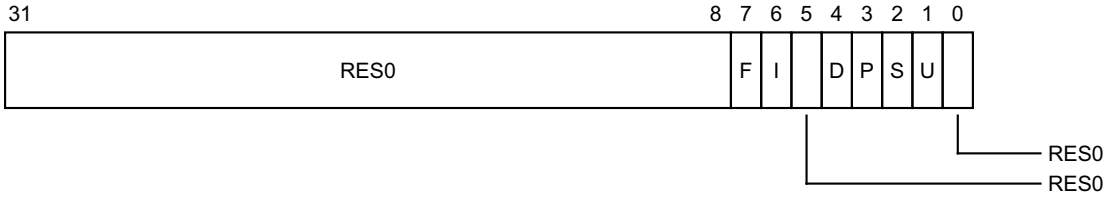
The exception vector offset is `0x04`.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

When EL3 not implemented:



Bits [31:8]

Reserved, RES0.

F, bit [7]

FIQ vector catch enable.

The exception vector offset is `0x1C`.

On Warm reset, the field reset value is architecturally UNKNOWN.

I, bit [6]

IRQ vector catch enable.

The exception vector offset is `0x18`.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

D, bit [4]

Data Abort vector catch enable.

The exception vector offset is `0x10`.

On Warm reset, the field reset value is architecturally UNKNOWN.

P, bit [3]

Prefetch Abort vector catch enable.

The exception vector offset `0x0C`.

On Warm reset, the field reset value is architecturally UNKNOWN.

S, bit [2]

Supervisor Call (SVC) vector catch enable.

The exception vector offset is `0x08`.

On Warm reset, the field reset value is architecturally UNKNOWN.

U, bit [1]

Undefined Instruction vector catch enable.

The exception vector offset is `0x04`.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

Accessing the DBGVCR32_EL2

To access the DBGVCR32_EL2:

```
MRS <Xt>, DBGVCR32_EL2 ; Read DBGVCR32_EL2 into Xt
MSR DBGVCR32_EL2, <Xt> ; Write Xt to DBGVCR32_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	100	0000	0111	000

D7.3.11 DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n>_EL1 characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register DBGWVR<n>_EL1, where n is 0 to 15.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

When the E field is zero, all the other fields in the register are ignored.

Configurations

DBGWCR<n>_EL1 is architecturally mapped to AArch32 register DBGWCR<n>.

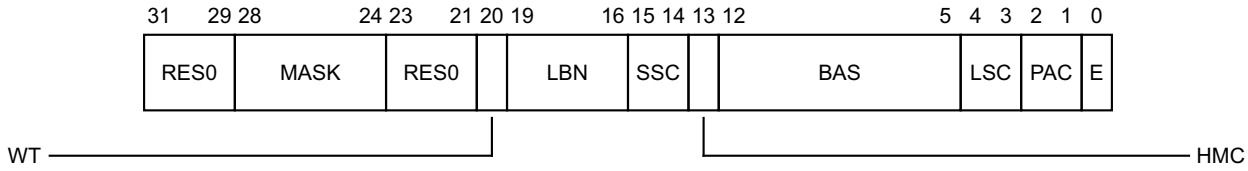
DBGWCR<n>_EL1 is architecturally mapped to external register DBGWCR<n>_EL1.

Attributes

DBGWCR<n>_EL1 is a 32-bit register.

Field descriptions

The DBGWCR<n>_EL1 bit assignments are:



Bits [31:29]

Reserved, RES0.

MASK, bits [28:24]

Address mask. Only objects up to 2GB can be watched using a single mask.

`00000` No mask.

`00001` Reserved.

`00010` Reserved.

Other values mask the corresponding number of address bits, from `0b00011` masking 3 address bits (`0x00000007` mask for address) to `0b11111` masking 31 address bits (`0x7FFFFFFF` mask for address).

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [23:21]

Reserved, RES0.

WT, bit [20]

Watchpoint type. Possible values are:

`0` Unlinked data address match.

`1` Linked data address match.

On Cold reset, the field reset value is architecturally UNKNOWN.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

On Cold reset, the field reset value is architecturally UNKNOWN.

SSC, bits [15:14]

Security state control. Determines the Security states under which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n>_EL1 is being watched.

BAS	Description
xxxxxxx1	Match byte at DBGWVR<n>_EL1
xxxxxx1x	Match byte at DBGWVR<n>_EL1+1
xxxxx1xx	Match byte at DBGWVR<n>_EL1+2
xxxx1xxx	Match byte at DBGWVR<n>_EL1+3

In cases where DBGWVR<n>_EL1 addresses a double-word:

BAS	Description, if DBGWVR<n>_EL1[2] == 0
xxx1xxxx	Match byte at DBGWVR<n>_EL1+4
xx1xxxxx	Match byte at DBGWVR<n>_EL1+5
x1xxxxxx	Match byte at DBGWVR<n>_EL1+6
1xxxxxxx	Match byte at DBGWVR<n>_EL1+7

If DBGWVR<n>_EL1[2] == 1, only BAS[3:0] is used. ARM deprecates setting DBGWVR<n>_EL1 == 1.

The valid values for BAS are `0b0000000`, or a binary number all of whose set bits are contiguous. All other values are reserved and must not be used by software.

If BAS is zero, no bytes are watched by this watchpoint.

Ignored if E is 0.

On Cold reset, the field reset value is architecturally UNKNOWN.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

`01` Match instructions that load from a watchpointed address.

`10` Match instructions that store to a watchpointed address.

`11` Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

Ignored if E is 0.

On Cold reset, the field reset value is architecturally UNKNOWN.

PAC, bits [2:1]

Privilege of access control. Determines the exception level or levels at which a watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and HMC fields.

On Cold reset, the field reset value is architecturally UNKNOWN.

E, bit [0]

Enable watchpoint n. Possible values are:

`0` Watchpoint disabled.

`1` Watchpoint enabled.

On Cold reset, the field reset value is architecturally UNKNOWN.

Accessing the DBGWCR<n>_EL1

To access the DBGWCR<n>_EL1:

```
MRS <Xt>, DBGWCR<n>_EL1 ; Read DBGWCR<n>_EL1 into Xt, where n is in the range 0 to 15
MSR DBGWCR<n>_EL1, <Xt> ; Write Xt to DBGWCR<n>_EL1, where n is in the range 0 to 15
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0000	n<3:0>	111

D7.3.12 DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n>_EL1 characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register DBGWCR<n>_EL1, where n is 0 to 15.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

DBGWVR<n>_EL1[31:0] is architecturally mapped to AArch32 register DBGWVR<n>.

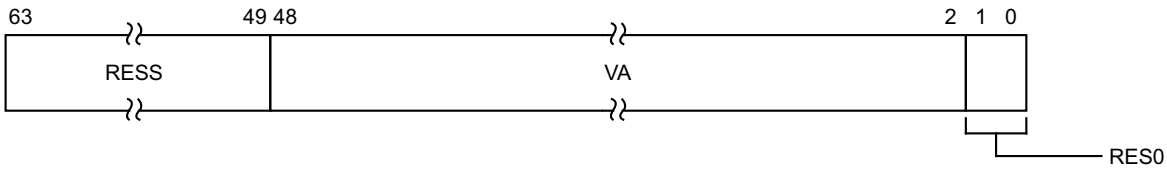
DBGWVR<n>_EL1 is architecturally mapped to external register DBGWVR<n>_EL1.

Attributes

DBGWVR<n>_EL1 is a 64-bit register.

Field descriptions

The DBGWVR<n>_EL1 bit assignments are:



RESS, bits [63:49]

Reserved, Sign extended. Hardwired to the value of the sign bit, bit [48]. Hardware and software must treat this field as RES0 if bit[48] is 0, and as RES1 if bit[48] is 1.

VA, bits [48:2]

Bits[48:2] of the address value for comparison.

ARM deprecates setting DBGWVR<n>_EL1[2] == 1.

On Cold reset, the field reset value is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

Accessing the DBGWVR<n>_EL1

To access the DBGWVR<n>_EL1:

```
MRS <Xt>, DBGWVR<n>_EL1 ; Read DBGWVR<n>_EL1 into Xt, where n is in the range 0 to 15
MSR DBGWVR<n>_EL1, <Xt> ; Write Xt to DBGWVR<n>_EL1, where n is in the range 0 to 15
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0000	n<3:0>	110

D7.3.13 DLR_EL0, Debug Link Register

The DLR_EL0 characteristics are:

Purpose

In Debug state, holds the address to restart from.

This register is part of:

- the Debug registers functional group
- the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW

Access to this register is from Debug state only. During normal execution this register is UNALLOCATED.

Configurations

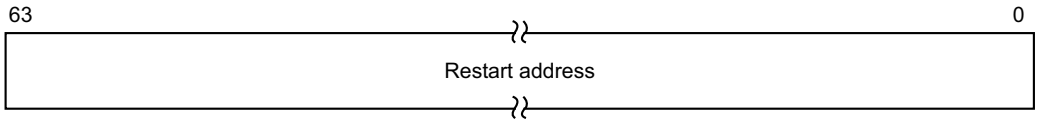
DLR_EL0[31:0] is architecturally mapped to AArch32 register DLR.

Attributes

DLR_EL0 is a 64-bit register.

Field descriptions

The DLR_EL0 bit assignments are:



Bits [63:0]

Restart address.

Accessing the DLR_EL0

To access the DLR_EL0:

```
MRS <Xt>, DLR_EL0 ; Read DLR_EL0 into Xt
MSR DLR_EL0, <Xt> ; Write Xt to DLR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	0100	0101	001

D7.3.14 DSPSR_EL0, Debug Saved Program Status Register

The DSPSR_EL0 characteristics are:

Purpose

Holds the saved processor state on entry to Debug state.

This register is part of:

- the Debug registers functional group
- the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW

Access to this register is from Debug state only. During normal execution this register is UNALLOCATED.

Configurations

DSPSR_EL0 is architecturally mapped to AArch32 register DSPSR.

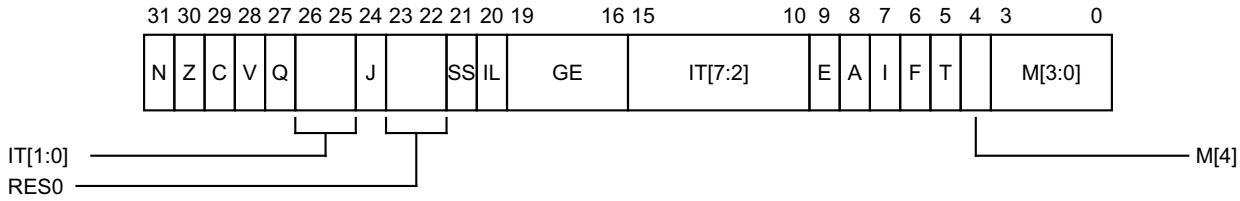
Attributes

DSPSR_EL0 is a 32-bit register.

Field descriptions

The DSPSR_EL0 bit assignments are:

When entering Debug state from AArch32:



N, bit [31]

Set to the value of CPSR.N on entering Debug state, and copied to CPSR.N on exiting Debug state.

Z, bit [30]

Set to the value of CPSR.Z on entering Debug state, and copied to CPSR.Z on exiting Debug state.

C, bit [29]

Set to the value of CPSR.C on entering Debug state, and copied to CPSR.C on exiting Debug state.

V, bit [28]

Set to the value of CPSR.V on entering Debug state, and copied to CPSR.V on exiting Debug state.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:22]

Reserved, RES0.

SS, bit [21]

Software step. Indicates whether software step was enabled when Debug state was entered.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before Debug state was entered.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the Debug state entry was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that Debug state was entered from. Possible values of this bit are:

`1` Exception taken from AArch32.

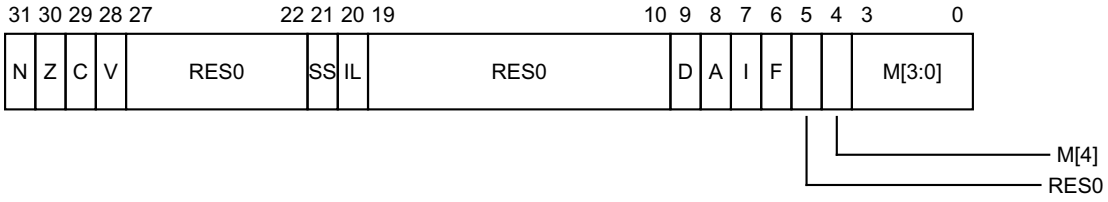
M[3:0], bits [3:0]

Mode that Debug state was entered from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0110`	Monitor
`0b0111`	Abort
`0b1010`	Hyp
`0b1011`	Undefined
`0b1111`	System

Other values are reserved.

When entering Debug state from AArch64:



N, bit [31]

Set to the value of the N condition flag on entering Debug state, and copied to the N condition flag on exiting Debug state.

Z, bit [30]

Set to the value of the Z condition flag on entering Debug state, and copied to the Z condition flag on exiting Debug state.

C, bit [29]

Set to the value of the C condition flag on entering Debug state, and copied to the C condition flag on exiting Debug state.

V, bit [28]

Set to the value of the V condition flag on entering Debug state, and copied to the V condition flag on exiting Debug state.

Bits [27:22]

Reserved, RES0.

SS, bit [21]

Software step. Indicates whether software step was enabled when Debug state was entered.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before Debug state was entered.

Bits [19:10]

Reserved, RES0.

D, bit [9]

Process state D mask. The possible values of this bit are:

`0` Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current exception level are not masked.

`1` Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current exception level are masked.

When the target exception level of the debug exception is not than the current exception level, the exception is not masked by this bit.

A, bit [8]

SError (System Error) mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state that Debug state was entered from. Possible values of this bit are:

`0` Exception taken from AArch64.

M[3:0], bits [3:0]

Mode that Debug state was entered from. For exceptions taken from AArch64, the possible values are:

M[3:0]	Mode
0b0000	EL0t
0b0100	EL1t
0b0101	EL1h
0b1000	EL2t
0b1001	EL2h
0b1100	EL3t
0b1101	EL3h

Other values are reserved.

For exceptions from AArch64:

- M[3:2] holds the Exception Level.
- M[1] is unused, and returning to an exception level that is using AArch64 with this bit set is treated as an illegal exception return.
- M[0] is used to select the SP:
  - 0 means the SP is always SP0.
  - 1 means the exception SP is determined by the EL.

Accessing the DSPSR_EL0

To access the DSPSR_EL0:

```
MRS <Xt>, DSPSR_EL0 ; Read DSPSR_EL0 into Xt
MSR DSPSR_EL0, <Xt> ; Write Xt to DSPSR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	0100	0101	000

D7.3.15 MDCCINT_EL1, Monitor DCC Interrupt Enable Register

The MDCCINT_EL1 characteristics are:

Purpose

Enables interrupt requests to be signaled based on the DCC status flags.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

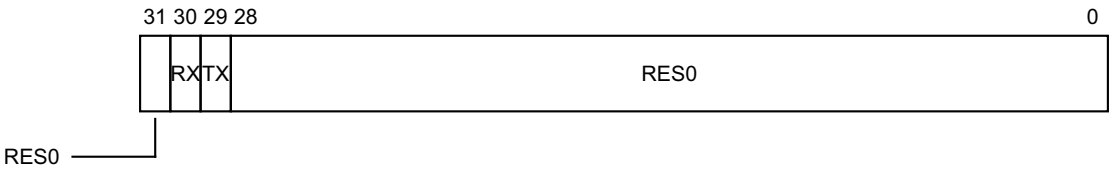
MDCCINT_EL1 is architecturally mapped to AArch32 register DBGDCCINT.

Attributes

MDCCINT_EL1 is a 32-bit register.

Field descriptions

The MDCCINT_EL1 bit assignments are:



Bit [31]

Reserved, RES0.

RX, bit [30]

DCC interrupt request enable control for DTRRX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

0 No interrupt request generated by DTRRX.

1 Interrupt request will be generated on RXfull == 1.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

On Warm reset, the field resets to 0.

TX, bit [29]

DCC interrupt request enable control for DTRTX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

0 No interrupt request generated by DTRTX.

1 Interrupt request will be generated on TXfull == 0.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

On Warm reset, the field resets to 0.

Bits [28:0]

Reserved, RES0.

Accessing the MDCCINT_EL1

To access the MDCCINT_EL1:

```
MRS <Xt>, MDCCINT_EL1 ; Read MDCCINT_EL1 into Xt
MSR MDCCINT_EL1, <Xt> ; Write Xt to MDCCINT_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0000	0010	000

D7.3.16 MDCCSR_EL0, Monitor DCC Status Register

The MDCCSR_EL0 characteristics are:

Purpose

Main control register for the debug implementation, containing flow-control flags for the DCC. This is an internal, read-only view.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	RO	RO	RO	RO	RO

This register can be read at EL0 when MDSCR_EL1.TDCC is set to 0. When it is set to 1, EL0 access to this register is trapped to EL1.

Configurations

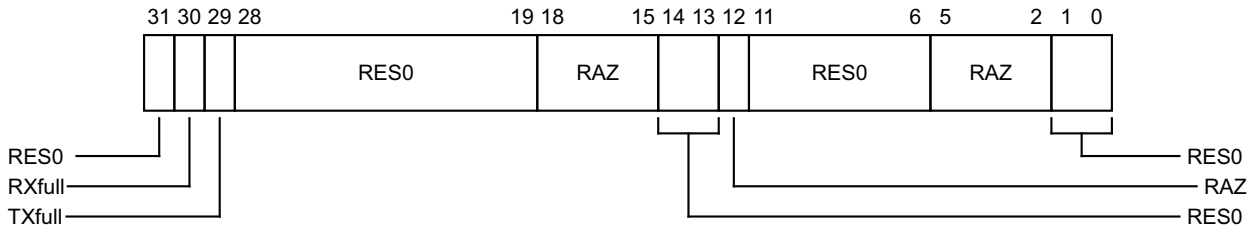
MDCCSR_EL0 is architecturally mapped to AArch32 register DBGDSCRint.

Attributes

MDCCSR_EL0 is a 32-bit register.

Field descriptions

The MDCCSR_EL0 bit assignments are:



Bit [31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. Read-only view of the equivalent bit in the EDSCR.

TXfull, bit [29]

DTRTX full. Read-only view of the equivalent bit in the EDSCR.

Bits [28:19]

Reserved, RES0.

Bits [18:15]

Reserved, RAZ. Hardware must implement this field as RAZ. Software must not rely on this field being RAZ.

Bits [14:13]

Reserved, RES0.

Bit [12]

Reserved, RAZ. Hardware must implement this field as RAZ. Software must not rely on this field being RAZ.

Bits [11:6]

Reserved, RES0.

Bits [5:2]

Reserved, RAZ. Hardware must implement this field as RAZ. Software must not rely on this field being RAZ.

Bits [1:0]

Reserved, RES0.

Accessing the MDCCSR_EL0

To access the MDCCSR_EL0:

```
MRS <Xt>, MDCCSR_EL0 ; Read MDCCSR_EL0 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	011	0000	0001	000

D7.3.17 MDCR_EL2, Monitor Debug Configuration Register (EL2)

The MDCR_EL2 characteristics are:

Purpose

Provides configuration options for the Virtualization extensions to self-hosted debug and the Performance Monitors extension.

This register is part of:

- the Debug registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

MDCR_EL2 is architecturally mapped to AArch32 register HDCR.

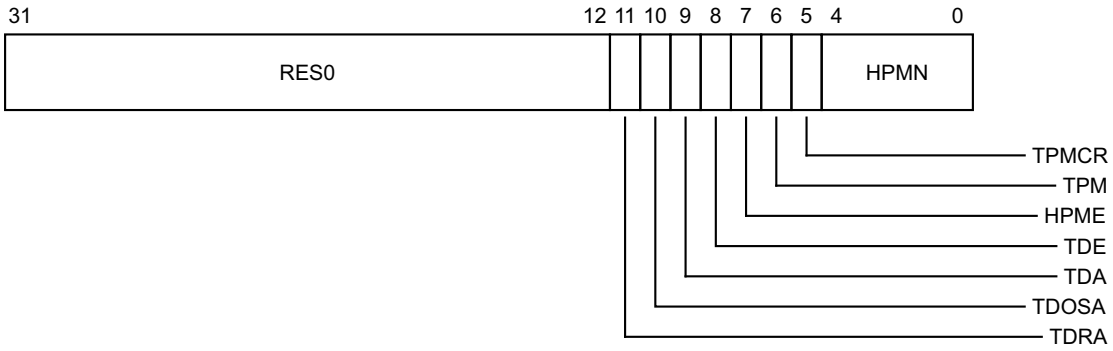
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

MDCR_EL2 is a 32-bit register.

Field descriptions

The MDCR_EL2 bit assignments are:



Bits [31:12]

Reserved, RES0.

TDRA, bit [11]

Trap debug ROM address register access. The possible values of this bit are:

0 Has no effect on accesses to debug ROM address registers from EL1 and EL0.

1 Trap valid EL1 and EL0 access to debug ROM address registers to EL2.

When this bit is set to 1, any access to the following registers from EL1 or EL0 is trapped to EL2:

AArch32: DBGDRAR, DBGDSAR.

AArch64: MDRAR_EL1.

If HCR_EL2.TGE == 1 or MDCR_EL2.TDE == 1, then this bit is ignored and treated as though it is 1 other than for the value read back from MDCR_EL2.

On Warm reset, the field reset value is architecturally UNKNOWN.

TDOSA, bit [10]

Trap debug OS-related register access. The possible values of this bit are:

`0` Has no effect on accesses to OS-related debug registers.

`1` Trap valid accesses to OS-related debug registers to EL2.

When this bit is set to 1, any access to the following registers from EL1 or EL0 is trapped to EL2:

AArch32: DBGOSLAR, DBGOSLSR, DBGOSDLR, DBGPRCR.

AArch64: OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, DBGPRCR_EL1.

If HCR_EL2.TGE == 1 or MDCR_EL2.TDE == 1, then this bit is ignored and treated as though it is 1 other than for the value read back from MDCR_EL2.

On Warm reset, the field reset value is architecturally UNKNOWN.

TDA, bit [9]

Trap debug access. The possible values of this bit are:

`0` Has no effect on accesses to Debug registers.

`1` Trap valid Non-secure accesses to Debug registers to EL2.

When this bit is set to 1, any valid Non-secure access to the debug registers from EL1 or EL0, other than the registers trapped by the TDRA and TDOSA bits, is trapped to EL2.

If HCR_EL2.TGE == 1 or MDCR_EL2.TDE == 1, then this bit is ignored and treated as though it is 1 other than for the value read back from MDCR_EL2.

On Warm reset, the field reset value is architecturally UNKNOWN.

TDE, bit [8]

Route Software debug exceptions from Non-secure EL1 and EL0 to EL2. Also enables traps on all debug register accesses to EL2.

If HCR_EL2.TGE == 1, then this bit is ignored and treated as though it is 1 other than for the value read back from MDCR_EL2.

On Warm reset, the field reset value is architecturally UNKNOWN.

HPME, bit [7]

Hypervisor Performance Monitors Enable. The possible values of this bit are:

`0` EL2 Performance Monitors disabled.

`1` EL2 Performance Monitors enabled.

When this bit is set to 1, the Performance Monitors counters that are reserved for use from EL2 or Secure state are enabled. For more information see the description of the HPMN field.

If the Performance Monitors extension is not implemented, this field is RES0.

On Warm reset, the field reset value is architecturally UNKNOWN.

TPM, bit [6]

Trap Performance Monitors accesses. The possible values of this bit are:

`0` Has no effect on Performance Monitors accesses.

`1` Trap Non-secure EL0 and EL1 accesses to Performance Monitors registers that are not UNALLOCATED to EL2.

If the Performance Monitors extension is not implemented, this field is RES0.

On Warm reset, the field reset value is architecturally UNKNOWN.

TPMCR, bit [5]

Trap PMCR_EL0 accesses. The possible values of this bit are:

0 Has no effect on PMCR_EL0 accesses.

1 Trap Non-secure EL0 and EL1 accesses to PMCR_EL0 to EL2.

If the Performance Monitors extension is not implemented, this field is RES0.

On Warm reset, the field reset value is architecturally UNKNOWN.

HPMN, bits [4:0]

Defines the number of Performance Monitors counters that are accessible from Non-secure EL0 and EL1 modes.

If the Performance Monitors extension is not implemented, this field is RES0.

In Non-secure state, HPMN divides the Performance Monitors counters as follows. For counter n in Non-secure state:

- If n is in the range 0<=n<HPMN, the counter is accessible from EL1 and EL2, and from EL0 if permitted by PMUSERENR_EL0. PMCR_EL0.E enables the operation of counters in this range.
- If n is in the range HPMN<=n<PMCR_EL0.N, the counter is accessible only from EL2. MDCR_EL2.HPME enables the operation of counters in this range.

If this field is set to 0, or to a value larger than PMCR_EL0.N, then the behavior in Non-secure EL0 and EL1 is CONSTRAINED UNPREDICTABLE, and one of the following must happen:

- The number of counters accessible is an UNKNOWN non-zero value less than PMCR_EL0.N.
- There is no access to any counters.

For reads of MDCR_EL2.HPMN by EL2 or higher, if this field is set to 0 or to a value larger than PMCR_EL0.N, the processor must return a CONSTRAINED UNPREDICTABLE value being one of:

- PMCR_EL0.N.
- The value that was written to MDCR_EL2.HPMN.
- (The value that was written to MDCR_EL2.HPMN) modulo 2^h, where h is the smallest number of bits required for a value in the range 0 to PMCR_EL0.N.

On Warm reset, the field resets to the value of PMCR_EL0.N.

Accessing the MDCR_EL2

To access the MDCR_EL2:

```
MRS <Xt>, MDCR_EL2 ; Read MDCR_EL2 into Xt
MSR MDCR_EL2, <Xt> ; Write Xt to MDCR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0001	0001	001

D7.3.18 MDCR_EL3, Monitor Debug Configuration Register (EL3)

The MDCR_EL3 characteristics are:

Purpose

Provides configuration options for the Security extensions to self-hosted debug.

This register is part of:

- the Debug registers functional group
- the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

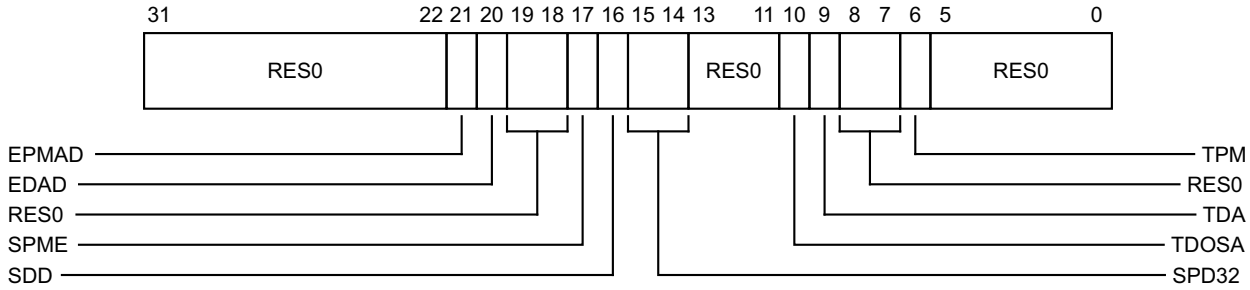
MDCR_EL3 can be mapped to AArch32 register SDCR, but this is not architecturally mandated.

Attributes

MDCR_EL3 is a 32-bit register.

Field descriptions

The MDCR_EL3 bit assignments are:



Bits [31:22]

Reserved, RES0.

EPMAD, bit [21]

External debugger access to Performance Monitors registers disabled. This disables access to these registers by an external debugger:

0 Access to Performance Monitors registers from external debugger is permitted.

1 Access to Performance Monitors registers from external debugger is disabled, unless overridden by authentication interface.

On Warm reset, the field resets to 0.

EDAD, bit [20]

External debugger access to breakpoint and watchpoint registers disabled. This disables access to these registers by an external debugger:

0 Access to breakpoint and watchpoint registers from external debugger is permitted.

1 Access to breakpoint and watchpoint registers from external debugger is disabled, unless overridden by authentication interface.

On Warm reset, the field resets to 0.

Bits [19:18]

Reserved, RES0.

SPME, bit [17]

Secure performance monitors enable. This allows event counting in Secure state:

0 Event counting prohibited in Secure state, unless overridden by the authentication interface.

1 Event counting allowed in Secure state.

On Warm reset, the field resets to 0.

SDD, bit [16]

AArch64 secure self-hosted invasive debug disable. Disables Software debug exceptions in Secure state, other than Software breakpoint instruction.

0 Taking Software debug events as debug exceptions is permitted from Secure EL0 and EL1, if enabled by the relevant MDSCR_EL1 and PSTATE.D flags.

1 Software debug events, other than software breakpoint instruction debug events, are disabled from all exception levels in Secure state.

SDD only applies when both of the following are true:

- The processor is executing in Secure state.
- Secure EL1 is using AArch64.

On Warm reset, the field reset value is architecturally UNKNOWN.

SPD32, bits [15:14]

AArch32 secure self-hosted privileged invasive debug. Enables or disables debug exceptions from Secure state if Secure EL1 is using AArch32, other than Software breakpoint instructions. Valid values for this field are:

00 Legacy mode. Debug exceptions from Secure EL1 are enabled by the authentication interface.

10 Secure privileged debug disabled. Debug exceptions from Secure EL1 are disabled.

11 Secure privileged debug enabled. Debug exceptions from Secure EL1 are enabled.

Other values are reserved.

If Secure EL1 is using AArch32 then:

- If debug exceptions from Secure EL1 are enabled, then debug exceptions from Secure EL0 are also enabled.
- Otherwise, debug exceptions from Secure EL0 are enabled only if SDER32_EL3.SUIDEN == 1.

Ignored if Secure EL1 is using AArch64, and in Non-secure state. Debug exceptions from Software breakpoint instruction debug events are always enabled.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bits [13:11]

Reserved, RES0.

TDOSA, bit [10]

Trap debug OS-related register access. The possible values of this bit are:

0 Has no effect on accesses to OS-related debug registers.

1 Trap valid accesses to OS-related debug registers to EL3.

When this bit is set to 1, any access to the following registers from EL2 or below is trapped to EL3:

AArch32: DBGOSLAR, DBGOSLSR, DBGOSDLR, DBGPRCR.

AArch64: OSLAR_EL1, OSLSR_EL1, OSDLR_EL1, DBGPRCR_EL1.

On Warm reset, the field reset value is architecturally UNKNOWN.

TDA, bit [9]

Trap debug access. The possible values of this bit are:

0 Has no effect on accesses to Debug registers.

1 Trap valid Non-secure accesses to Debug registers to EL3.

When this bit is set to 1, any valid Non-secure access to the debug registers from EL2 or below, other than the registers trapped by the TDRA and TDOSA bits, is trapped to EL3.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bits [8:7]

Reserved, RES0.

TPM, bit [6]

Trap Performance Monitors accesses. The possible values of this bit are:

0 Has no effect on Performance Monitors accesses.

1 Trap Non-secure EL0, EL1 and EL2 accesses to Performance Monitors registers that are not UNALLOCATED, or trapped to a lower exception level, to EL3.

If the Performance Monitors extension is not implemented, this field is RES0.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bits [5:0]

Reserved, RES0.

Accessing the MDCR_EL3

To access the MDCR_EL3:

```
MRS <Xt>, MDCR_EL3 ; Read MDCR_EL3 into Xt
MSR MDCR_EL3, <Xt> ; Write Xt to MDCR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0001	0011	001

D7.3.19 MDRAR_EL1, Monitor Debug ROM Address Register

The MDRAR_EL1 characteristics are:

Purpose

Defines the base physical address of a 4KB-aligned memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

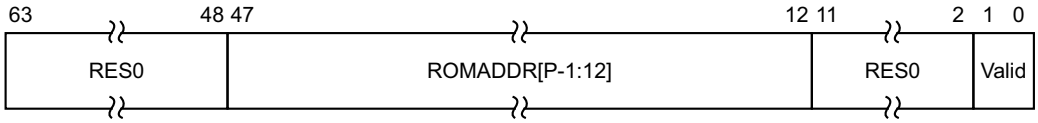
MDRAR_EL1 is architecturally mapped to AArch32 register DBGDRAR.

Attributes

MDRAR_EL1 is a 64-bit register.

Field descriptions

The MDRAR_EL1 bit assignments are:



Bits [63:48]

Reserved, RES0.

ROMADDR[P-1:12], bits [47:12]

Bits[P-1:12] of the ROM table physical address, where P is the physical address size in bits (up to 48 bits) as stored in ID_AA64MMFR0_EL1. If P is less than 48, bits[47:P] of this register are RES0.

Bits [11:0] of the ROM table physical address are zero.

If EL3 is implemented, ROMADDR is an address in Non-secure memory. Whether the ROM table is also accessible in Secure memory is IMPLEMENTATION DEFINED.

Bits [11:2]

Reserved, RES0.

Valid, bits [1:0]

This field indicates whether the ROM Table address is valid. The permitted values of this field are:

`00` ROM Table address is not valid

`11` ROM Table address is valid.

Other values are reserved.

Accessing the MDRAR_EL1

To access the MDRAR_EL1:

```
MRS <Xt>, MDRAR_EL1 ; Read MDRAR_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0001	0000	000

D7.3.20 MDSCR_EL1, Monitor Debug System Control Register

The MDSCR_EL1 characteristics are:

Purpose

Main control register for the debug implementation.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

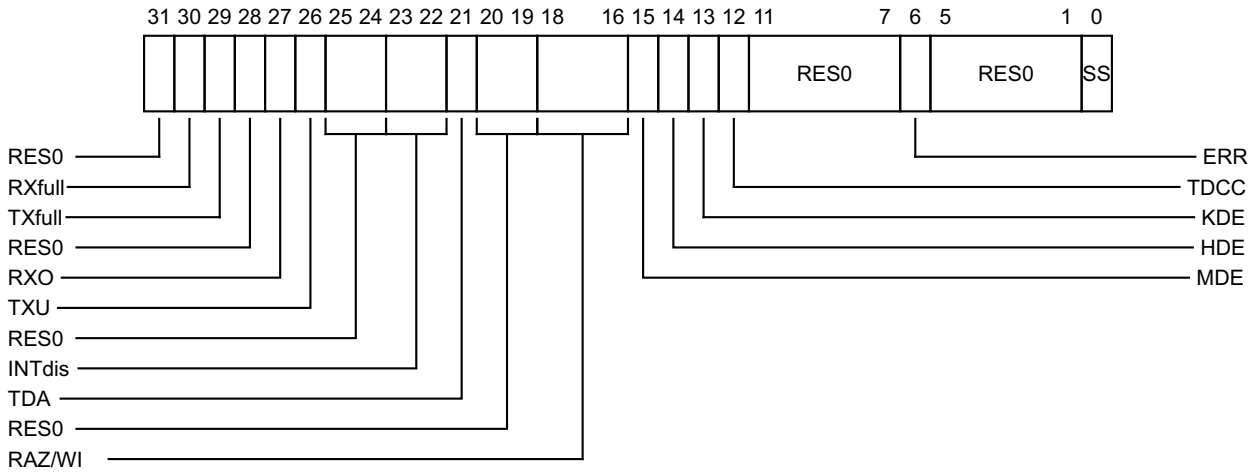
MDSCR_EL1 is architecturally mapped to AArch32 register DBGDSCRext.

Attributes

MDSCR_EL1 is a 32-bit register.

Field descriptions

The MDSCR_EL1 bit assignments are:



Bit [31]

Reserved, RES0.

RXfull, bit [30]

Used for save/restore of EDSCR.RXfull.

When OSLSR_EL1.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When OSLSR_EL1.OSLK == 1 (the OS lock is locked), this bit is RW.

TXfull, bit [29]

Used for save/restore of EDSCR.TXfull.

When OSLSR_EL1.OSLK == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When OSLSR_EL1.OSLK == 1 (the OS lock is locked), this bit is RW.

Bit [28]

Reserved, RES0.

RXO, bit [27]

Used for save/restore of EDSCR.RXO.

When OSLSR_EL1.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When OSLSR_EL1.OSLK == 1 (the OS lock is locked), this bit is RW.

TXU, bit [26]

Used for save/restore of EDSCR.TXU.

When OSLSR_EL1.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When OSLSR_EL1.OSLK == 1 (the OS lock is locked), this bit is RW.

Bits [25:24]

Reserved, RES0.

INTdis, bits [23:22]

Used for save/restore of EDSCR.INTdis.

When OSLSR_EL1.OSLK == 0 (the OS lock is unlocked), this field is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When OSLSR_EL1.OSLK == 1 (the OS lock is locked), this field is RW.

TDA, bit [21]

Used for save/restore of EDSCR.TDA.

When OSLSR_EL1.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When OSLSR_EL1.OSLK == 1 (the OS lock is locked), this bit is RW.

Bits [20:19]

Reserved, RES0.

Bits [18:16]

Reserved, RAZ/WI. Hardware must implement this as RAZ/WI. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

MDE, bit [15]

Monitor debug events. Enable Breakpoint, Watchpoint, and Vector catch debug exceptions.

`0` Breakpoint, Watchpoint, and Vector catch debug exceptions disabled.

`1` Breakpoint, Watchpoint, and Vector catch debug exceptions enabled.

On Warm reset, the field reset value is architecturally UNKNOWN.

HDE, bit [14]

Used for save/restore of EDSCR.HDE.

When OSLSR_EL1.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When OSLSR_EL1.OSLK == 1 (the OS lock is locked), this bit is RW.

KDE, bit [13]

Local (kernel) debug enable. If EL_D is using AArch64, enable Software debug events within EL_D. Permitted values are:

`0` Software debug events, other than Software breakpoint instructions, disabled within EL_D.

`1` Software debug events enabled within EL_D.

RES0 if EL_D is using AArch32.

On Warm reset, the field reset value is architecturally UNKNOWN.

TDCC, bit [12]

Trap Debug Communications Channel access. When set, any EL0 access to the following registers is trapped to EL1:

AArch32: DBGDIDR, DBGDRAR, DBGDSAR, DBGDSCRint, DBGDTRTXint, DBGDTRRXint.

AArch64: MDCCSR_EL0, DBGDTR_EL0, DBGDTRTX_EL0, DBGDTRRX_EL0.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bits [11:7]

Reserved, RES0.

ERR, bit [6]

Used for save/restore of EDSCR.ERR.

When OSLSR_EL1.OSLK == 0 (the OS lock is unlocked), this bit is RO. Software must treat it as UNKNOWN and use an SBZP policy for writes.

When OSLSR_EL1.OSLK == 1 (the OS lock is locked), this bit is RW.

Bits [5:1]

Reserved, RES0.

SS, bit [0]

Software step control bit. If EL_D is using AArch64, enable Software step. Permitted values are:

`0` Software step disabled

`1` Software step enabled.

RES0 if EL_D is using AArch32.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the MDSCR_EL1

To access the MDSCR_EL1:

```
MRS <Xt>, MDSCR_EL1 ; Read MDSCR_EL1 into Xt
MSR MDSCR_EL1, <Xt> ; Write Xt to MDSCR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0000	0010	010

D7.3.21 OSDLR_EL1, OS Double Lock Register

The OSDLR_EL1 characteristics are:

Purpose

Used to control the OS Double Lock.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

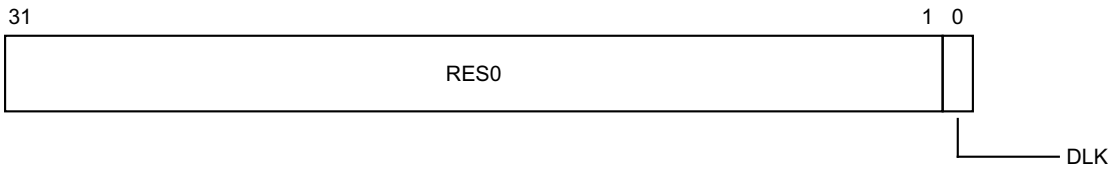
OSDLR_EL1 is architecturally mapped to AArch32 register DBGOSDLR.

Attributes

OSDLR_EL1 is a 32-bit register.

Field descriptions

The OSDLR_EL1 bit assignments are:



Bits [31:1]

Reserved, RES0.

DLK, bit [0]

OS Double Lock control bit. Possible values are:

0 OS Double Lock unlocked.

1 OS Double Lock locked, if DBGPRCR_EL1.CORENPDRQ (Core no power-down request) bit is set to 0 and the processor is in Non-debug state.

On Warm reset, the field resets to 0.

Accessing the OSDLR_EL1

To access the OSDLR_EL1:

```
MRS <Xt>, OSDLR_EL1 ; Read OSDLR_EL1 into Xt
MSR OSDLR_EL1, <Xt> ; Write Xt to OSDLR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0001	0011	100

D7.3.22 OSDTRRX_EL1, OS Lock Data Transfer Register, Receive

The OSDTRRX_EL1 characteristics are:

Purpose

Used for save/restore of DBGDTRRX_EL0. It is a component of the Debug Communications Channel.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

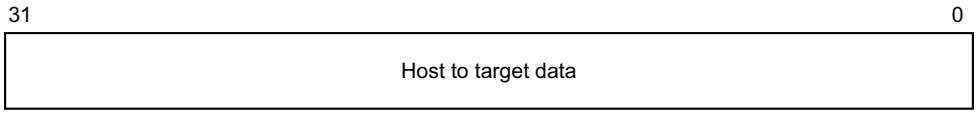
OSDTRRX_EL1 is architecturally mapped to AArch32 register DBGDTRRXext.

Attributes

OSDTRRX_EL1 is a 32-bit register.

Field descriptions

The OSDTRRX_EL1 bit assignments are:



Bits [31:0]

Host to target data. One word of data for transfer from the debug host to the debug target.

For the full behavior of the Debug Communications Channel, see The Debug Communication Channel and Instruction Transfer Register.

Accessing the OSDTRRX_EL1

To access the OSDTRRX_EL1:

```
MRS <Xt>, OSDTRRX_EL1 ; Read OSDTRRX_EL1 into Xt
MSR OSDTRRX_EL1, <Xt> ; Write Xt to OSDTRRX_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0000	0000	010

D7.3.23 OSDTRTX_EL1, OS Lock Data Transfer Register, Transmit

The OSDTRTX_EL1 characteristics are:

Purpose

Used for save/restore of DBGDTRTX_EL0. It is a component of the Debug Communications Channel.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

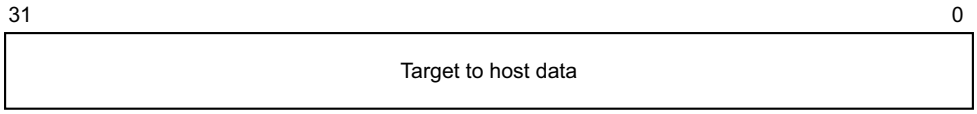
OSDTRTX_EL1 is architecturally mapped to AArch32 register DBGDTRTXext.

Attributes

OSDTRTX_EL1 is a 32-bit register.

Field descriptions

The OSDTRTX_EL1 bit assignments are:



Bits [31:0]

Target to host data. One word of data for transfer from the debug target to the debug host.

For the full behavior of the Debug Communications Channel, see The Debug Communication Channel and Instruction Transfer Register.

Accessing the OSDTRTX_EL1

To access the OSDTRTX_EL1:

```
MRS <Xt>, OSDTRTX_EL1 ; Read OSDTRTX_EL1 into Xt
MSR OSDTRTX_EL1, <Xt> ; Write Xt to OSDTRTX_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0000	0011	010

D7.3.24 OSECCR_EL1, OS Lock Exception Catch Control Register

The OSECCR_EL1 characteristics are:

Purpose

Provides a mechanism for an operating system to access the contents of EDECCR that are otherwise invisible to software, so it can save/restore the contents of EDECCR over powerdown on behalf of the external debugger.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

OSECCR_EL1 is architecturally mapped to AArch32 register DBGOSECCR.

OSECCR_EL1 is architecturally mapped to external register EDECCR.

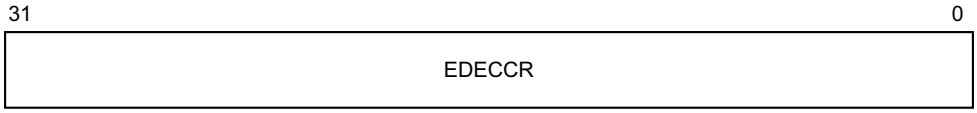
Attributes

OSECCR_EL1 is a 32-bit register.

Field descriptions

The OSECCR_EL1 bit assignments are:

When OSLSR.OSLK==1:



EDECCR, bits [31:0]

Used for save/restore to EDECCR over powerdown.

Accessing the OSECCR_EL1

To access the OSECCR_EL1:

```
MRS <Xt>, OSECCR_EL1 ; Read OSECCR_EL1 into Xt
MSR OSECCR_EL1, <Xt> ; Write Xt to OSECCR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0000	0110	010

D7.3.25 OSLAR_EL1, OS Lock Access Register

The OSLAR_EL1 characteristics are:

Purpose

Used to lock or unlock the OS lock.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

Configurations

OSLAR_EL1 is architecturally mapped to AArch32 register DBGOSLAR.

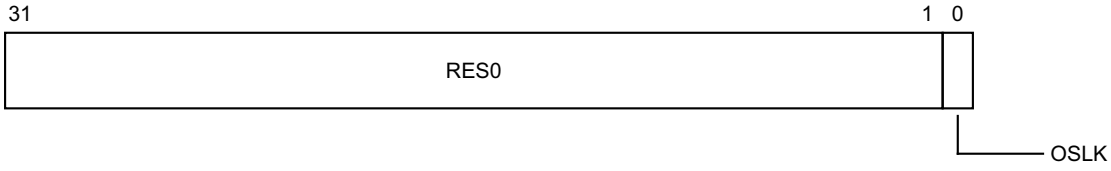
OSLAR_EL1 is architecturally mapped to external register OSLAR_EL1.

Attributes

OSLAR_EL1 is a 32-bit register.

Field descriptions

The OSLAR_EL1 bit assignments are:



Bits [31:1]

Reserved, RES0.

OSLK, bit [0]

On writes to OSLAR_EL1, bit[0] is copied to the OS lock.

Use OSLSR_EL1.OSLK to check the current status of the lock.

Accessing the OSLAR_EL1

To access the OSLAR_EL1:

```
MSR OSLAR_EL1, <Xt> ; Write Xt to OSLAR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0001	0000	100

D7.3.26 OSLSR_EL1, OS Lock Status Register

The OSLSR_EL1 characteristics are:

Purpose

Provides the status of the OS lock.

This register is part of the Debug registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

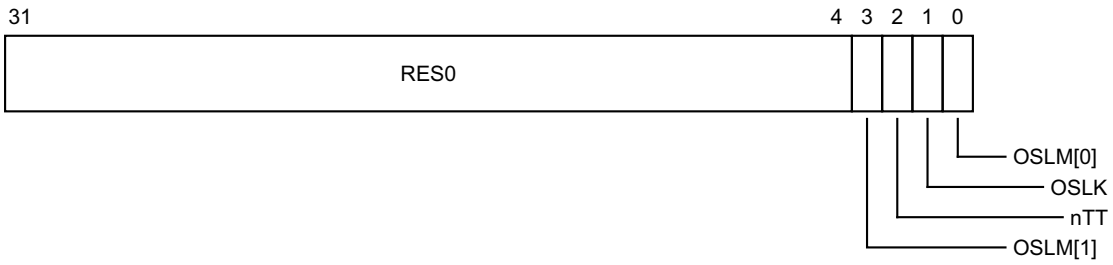
OSLSR_EL1 is architecturally mapped to AArch32 register DBGOSLSR.

Attributes

OSLSR_EL1 is a 32-bit register.

Field descriptions

The OSLSR_EL1 bit assignments are:



Bits [31:4]

Reserved, RES0.

OSLM[1], bit [3]

See below for description of the OSLM field.

nTT, bit [2]

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

OSLK, bit [1]

OS Lock Status. The possible values are:

`0` OS lock unlocked.

`1` OS lock locked.

The OS Lock is locked and unlocked by writing to the OS Lock Access Register.

On Cold reset, the field resets to 1.

OSLM[0], bit [0]

OS lock model implemented. Identifies the form of OS save and restore mechanism implemented. In v8-A these bits are as follows:

`10` OS lock implemented. DBGOSSRR not implemented.

All other values are reserved.

Accessing the OSLSR_EL1

To access the OSLSR_EL1:

```
MRS <Xt>, OSLSR_EL1 ; Read OSLSR_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
10	000	0001	0001	100

D7.3.27 SDER32_EL3, AArch32 Secure Debug Enable Register

The SDER32_EL3 characteristics are:

Purpose

Allows access to the AArch32 register SDER from AArch64 state only. Its value has no effect on execution in AArch64 state.

This register is part of:

- the Debug registers functional group
- the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

SDER32_EL3 is architecturally mapped to AArch32 register SDER.

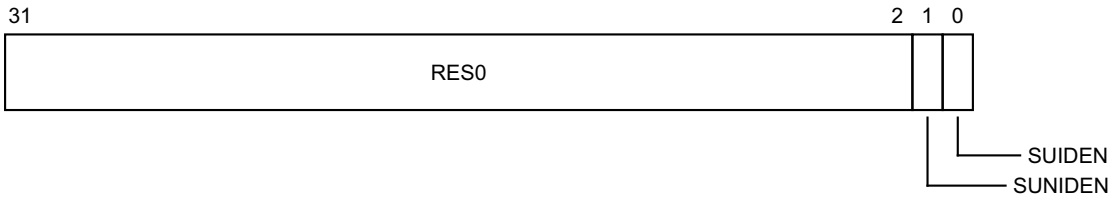
If EL1 does not support AArch32, SDER32_EL3 is not implemented.

Attributes

SDER32_EL3 is a 32-bit register.

Field descriptions

The SDER32_EL3 bit assignments are:



Bits [31:2]

Reserved, RES0.

SUNIDEN, bit [1]

Secure User Non-Invasive Debug Enable:

0 Non-invasive debug not permitted in Secure EL0 mode.

1 Non-invasive debug permitted in Secure EL0 mode.

SUIDEN, bit [0]

Secure User Invasive Debug Enable:

0 Invasive debug not permitted in Secure EL0 mode.

1 Invasive debug permitted in Secure EL0 mode.

Accessing the SDER32_EL3

To access the SDER32_EL3:

```
MRS <Xt>, SDER32_EL3 ; Read SDER32_EL3 into Xt
MSR SDER32_EL3, <Xt> ; Write Xt to SDER32_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0001	0001	001

D7.4 Performance Monitors registers

This section lists the Performance Monitoring registers in AArch64.

D7.4.1 PMCCFILTR_EL0, Performance Monitors Cycle Count Filter Register

The PMCCFILTR_EL0 characteristics are:

Purpose

Determines the modes in which the Cycle Counter, PMCCNTR_EL0, increments.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR_EL0.EN is set to 1.

PMCCFILTR_EL0 can also be accessed by using PMXEVTYPER_EL0 with PMSELR_EL0.SEL set to `0b11111`.

Configurations

PMCCFILTR_EL0 is architecturally mapped to AArch32 register PMCCFILTR.

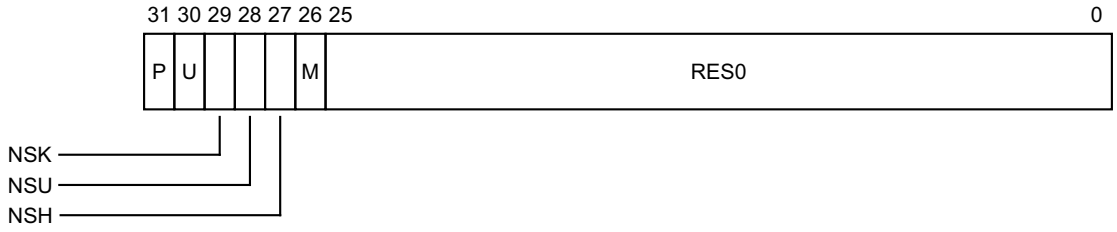
PMCCFILTR_EL0 is architecturally mapped to external register PMCCFILTR_EL0.

Attributes

PMCCFILTR_EL0 is a 32-bit register.

Field descriptions

The PMCCFILTR_EL0 bit assignments are:



P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

`0` Count cycles in EL1.

1 Do not count cycles in EL1.

On Warm reset, the field reset value is architecturally UNKNOWN.

U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

0 Count cycles in EL0.

1 Do not count cycles in EL0.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSK, bit [29]

Non-secure kernel modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSU, bit [28]

Non-secure user modes filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSH, bit [27]

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count cycles in EL2.

1 Count cycles in EL2.

On Warm reset, the field reset value is architecturally UNKNOWN.

M, bit [26]

Secure EL3 filtering bit. Most applications can ignore this bit and set the value to zero. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bits [25:0]

Reserved, RES0.

Accessing the PMCCFILTR_EL0

To access the PMCCFILTR_EL0:

```
MRS <Xt>, PMCCFILTR_EL0 ; Read PMCCFILTR_EL0 into Xt
MSR PMCCFILTR_EL0, <Xt> ; Write Xt to PMCCFILTR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1110	1111	111

D7.4.2 PMCCNTR_EL0, Performance Monitors Cycle Count Register

The PMCCNTR_EL0 characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR_EL0.EN or PMUSERENR_EL0.CR is set to 1.

Configurations

PMCCNTR_EL0 is architecturally mapped to AArch32 register PMCCNTR when accessing as a 64-bit register.

PMCCNTR_EL0 is architecturally mapped to external register PMCCNTR_EL0.

PMCCNTR_EL0[31:0] is architecturally mapped to AArch32 register PMCCNTR.

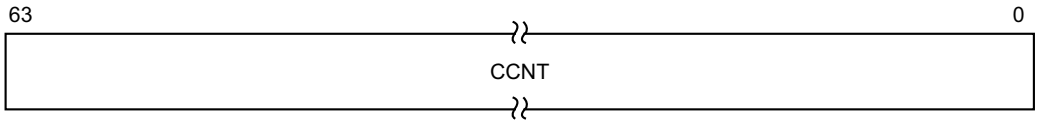
All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONSTRAINED UNPREDICTABLE whether or not PMCCNTR_EL0 continues to increment when clocks are stopped by WFI and WFE instructions.

Attributes

PMCCNTR_EL0 is a 64-bit register.

Field descriptions

The PMCCNTR_EL0 bit assignments are:



CCNT, bits [63:0]

Cycle count. Depending on the values of PMCR_EL0.{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

This field can be reset to zero by writing 1 to PMCR_EL0.C.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMCCNTR_EL0

To access the PMCCNTR_EL0:

```
MRS <Xt>, PMCCNTR_EL0 ; Read PMCCNTR_EL0 into Xt
MSR PMCCNTR_EL0, <Xt> ; Write Xt to PMCCNTR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1001	1101	000

D7.4.3 PMCEID0_EL0, Performance Monitors Common Event Identification register 0

The PMCEID0_EL0 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 when PMUSERENR_EL0.EN is set to 1.

Configurations

PMCEID0_EL0 is architecturally mapped to AArch32 register PMCEID0.

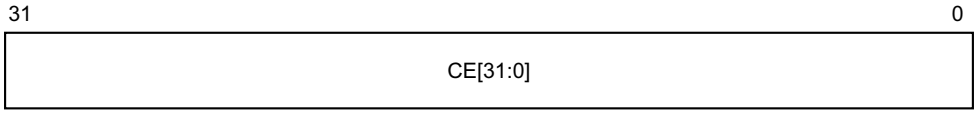
PMCEID0_EL0 is architecturally mapped to external register PMCEID0_EL0.

Attributes

PMCEID0_EL0 is a 32-bit register.

Field descriptions

The PMCEID0_EL0 bit assignments are:



CE[31:0], bits [31:0]

Common architectural and microarchitectural feature events that can be counted by the PMU event counters.

For each bit described in the following table, the event is implemented if the bit is set to 1, or not implemented if the bit is set to 0.

Bit	Event number	Event mnemonic
31	0x01F	L1D_CACHE_ALLOCATE
30	0x01E	CHAIN
29	0x01D	BUS_CYCLES
28	0x01C	TTBR_WRITE_RETIRED
27	0x01B	INST_SPEC
26	0x01A	MEMORY_ERROR
25	0x019	BUS_ACCESS

Bit	Event number	Event mnemonic
24	0x018	L2D_CACHE_WB
23	0x017	L2D_CACHE_REFILL
22	0x016	L2D_CACHE
21	0x015	L1D_CACHE_WB
20	0x014	L1I_CACHE
19	0x013	MEM_ACCESS
18	0x012	BR_PRED
17	0x011	CPU_CYCLES
16	0x010	BR_MIS_PRED
15	0x00F	UNALIGNED_LDST_RETIRED
14	0x00E	BR_RETURN_RETIRED
13	0x00D	BR_IMMED_RETIRED
12	0x00C	PC_WRITE_RETIRED
11	0x00B	CID_WRITE_RETIRED
10	0x00A	EXC_RETURN
9	0x009	EXC_TAKEN
8	0x008	INST_RETIRED
7	0x007	ST_RETIRED
6	0x006	LD_RETIRED
5	0x005	L1D_TLB_REFILL
4	0x004	L1D_CACHE
3	0x003	L1D_CACHE_REFILL
2	0x002	L1I_TLB_REFILL
1	0x001	L1I_CACHE_REFILL
0	0x000	SW_INCR

Accessing the PMCEID0_EL0

To access the PMCEID0_EL0:

```
MRS <Xt>, PMCEID0_EL0 ; Read PMCEID0_EL0 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1001	1100	110

D7.4.4 PMCEID1_EL0, Performance Monitors Common Event Identification register 1

The PMCEID1_EL0 characteristics are:

Purpose

Reserved for future indication of which common architectural and common microarchitectural feature events are implemented.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 when PMUSERENR_EL0.EN is set to 1.

Configurations

PMCEID1_EL0 is architecturally mapped to AArch32 register PMCEID1.

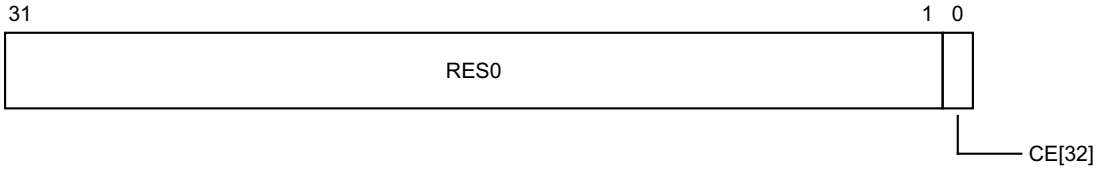
PMCEID1_EL0 is architecturally mapped to external register PMCEID1_EL0.

Attributes

PMCEID1_EL0 is a 32-bit register.

Field descriptions

The PMCEID1_EL0 bit assignments are:



Bits [31:1]

Reserved, RES0.

CE[32], bit [0]

Common architectural and microarchitectural feature events that can be counted by the PMU event counters.

For the bit described in the following table, the event is implemented if the bit is set to 1, or not implemented if the bit is set to 0.

Bit	Event number	Event mnemonic
0	0x020	L2D_CACHE_ALLOCATE

Accessing the PMCEID1_EL0

To access the PMCEID1_EL0:

```
MRS <Xt>, PMCEID1_EL0 ; Read PMCEID1_EL0 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1001	1100	111

D7.4.5 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register

The PMCNTENCLR_EL0 characteristics are:

Purpose

Disables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<x>. Reading this register shows which counters are enabled.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR_EL0.EN is set to 1.

Configurations

PMCNTENCLR_EL0 is architecturally mapped to AArch32 register PMCNTENCLR.

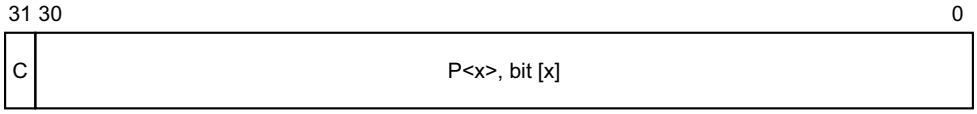
PMCNTENCLR_EL0 is architecturally mapped to external register PMCNTENCLR_EL0.

Attributes

PMCNTENCLR_EL0 is a 32-bit register.

Field descriptions

The PMCNTENCLR_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 disable bit. Disables the cycle counter register. Possible values are:

`0` When read, means the cycle counter is disabled. When written, has no effect.

`1` When read, means the cycle counter is enabled. When written, disables the cycle counter.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<x>, bit [x], for x = 0 to 30

Event counter disable bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

Possible values of each bit are:

`0` When read, means that PMEVCNTR<x> is disabled. When written, has no effect.

`1` When read, means that PMEVCNTR<x> is enabled. When written, disables PMEVCNTR<x>.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMCNTENCLR_EL0

To access the PMCNTENCLR_EL0:

```
MRS <Xt>, PMCNTENCLR_EL0 ; Read PMCNTENCLR_EL0 into Xt
MSR PMCNTENCLR_EL0, <Xt> ; Write Xt to PMCNTENCLR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1001	1100	010

D7.4.6 PMCNTENSET_EL0, Performance Monitors Count Enable Set register

The PMCNTENSET_EL0 characteristics are:

Purpose

Enables the Cycle Count Register, PMCCNTR_EL0, and any implemented event counters PMEVCNTR<x>. Reading this register shows which counters are enabled.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR_EL0.EN is set to 1.

Configurations

PMCNTENSET_EL0 is architecturally mapped to AArch32 register PMCNTENSET.

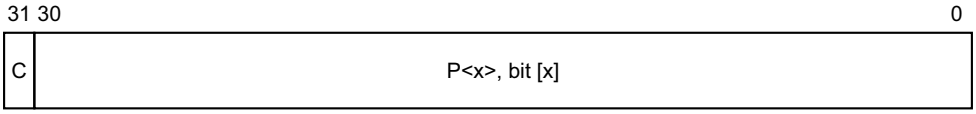
PMCNTENSET_EL0 is architecturally mapped to external register PMCNTENSET_EL0.

Attributes

PMCNTENSET_EL0 is a 32-bit register.

Field descriptions

The PMCNTENSET_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 enable bit. Enables the cycle counter register. Possible values are:

`0` When read, means the cycle counter is disabled. When written, has no effect.

`1` When read, means the cycle counter is enabled. When written, enables the cycle counter.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<x>, bit [x], for x = 0 to 30

Event counter enable bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

Possible values of each bit are:

`0` When read, means that PMEVCNTR<x> is disabled. When written, has no effect.

`1` When read, means that PMEVCNTR<x> event counter is enabled. When written, enables PMEVCNTR<x>.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMCNTENSET_EL0

To access the PMCNTENSET_EL0:

```
MRS <Xt>, PMCNTENSET_EL0 ; Read PMCNTENSET_EL0 into Xt
MSR PMCNTENSET_EL0, <Xt> ; Write Xt to PMCNTENSET_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1001	1100	001

D7.4.7 PMCR_EL0, Performance Monitors Control Register

The PMCR_EL0 characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR_EL0.EN is set to 1.

Configurations

PMCR_EL0 is architecturally mapped to AArch32 register PMCR.

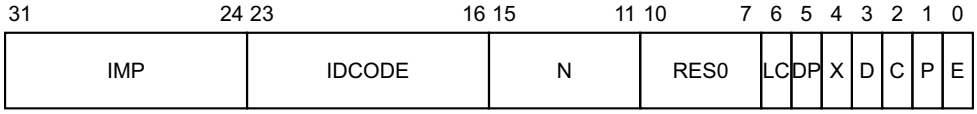
PMCR_EL0 is architecturally mapped to external register PMCR_EL0.

Attributes

PMCR_EL0 is a 32-bit register.

Field descriptions

The PMCR_EL0 bit assignments are:



IMP, bits [31:24]

Implementer code. This field is RO with an IMPLEMENTATION DEFINED value.

The implementer codes are allocated by ARM. Values have the same interpretation as bits [31:24] of the MIDR.

IDCODE, bits [23:16]

Identification code. This field is RO with an IMPLEMENTATION DEFINED value.

Each implementer must maintain a list of identification codes that is specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.

N, bits [15:11]

Number of event counters. This field is RO with an IMPLEMENTATION DEFINED value that indicates the number of counters implemented.

The value of this field is the number of counters implemented, from `0b00000` for no counters to `0b11111` for 31 counters.

An implementation can implement only the Cycle Count Register, PMCCNTR_EL0. This is indicated by a value of `0b00000` for the N field.

Bits [10:7]

Reserved, RES0.

LC, bit [6]

Long cycle counter enable. Determines which PMCCNTR_EL0 bit generates an overflow recorded by PMOVSR[31].

0 Cycle counter overflow on increment that changes PMCCNTR_EL0[31] from 1 to 0.

1 Cycle counter overflow on increment that changes PMCCNTR_EL0[63] from 1 to 0.

ARM deprecates use of PMCR_EL0.LC = 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

0 PMCCNTR_EL0, if enabled, counts when event counting is prohibited.

1 PMCCNTR_EL0 does not count when event counting is prohibited.

Event counting is prohibited when ProfilingProhibited(IsSecure(),PSTATE.EL) == TRUE.

This bit is RW.

On Warm reset, the field reset value is architecturally UNKNOWN.

X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

0 Do not export events.

1 Export events where not prohibited.

This bit is used to permit events to be exported to another debug device, such as an OPTIONAL trace extension, over an event bus. If the implementation does not include such an event bus, this bit is RAZ/WI.

This bit does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the processor.

If the implementation does not include an exported event stream, this bit is RAZ/WI. Otherwise this bit is RW.

On Warm reset, the field reset value is architecturally UNKNOWN.

D, bit [3]

Clock divider. The possible values of this bit are:

0 When enabled, PMCCNTR_EL0 counts every clock cycle.

1 When enabled, PMCCNTR_EL0 counts once every 64 clock cycles.

This bit is RW.

If PMCR_EL0.LC == 1, this bit is ignored and the cycle counter counts every clock cycle.

ARM deprecates use of PMCR.D = 1.

On Warm reset, the field reset value is architecturally UNKNOWN.

C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

0 No action.

1 Reset PMCCNTR_EL0 to zero.

This bit is always RAZ.

Resetting PMCCNTR_EL0 does not clear the PMCCNTR_EL0 overflow bit to 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

0 No action.

1 Reset all event counters accessible in the current EL, not including PMCCNTR_EL0, to zero.

This bit is always RAZ.

In Non-secure EL0 and EL1, if EL2 is implemented, a write of 1 to this bit does not reset event counters that MDCR_EL2.HPMN reserves for EL2 use.

In EL2 and EL3, a write of 1 to this bit resets all the event counters.

Resetting the event counters does not clear any overflow bits to 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

E, bit [0]

Enable. The possible values of this bit are:

0 All counters, including PMCCNTR_EL0, are disabled.

1 All counters are enabled by PMCNTENSET_EL0.

This bit is RW.

In Non-secure EL0 and EL1, if EL2 is implemented, this bit does not affect the operation of event counters that MDCR_EL2.HPMN reserves for EL2 use.

On Warm reset, the field resets to 0.

Accessing the PMCR_EL0

To access the PMCR_EL0:

```
MRS <Xt>, PMCR_EL0 ; Read PMCR_EL0 into Xt
MSR PMCR_EL0, <Xt> ; Write Xt to PMCR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1001	1100	000

D7.4.8 PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>_EL0 characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register can be read at EL0 when PMUSERENR_EL0.EN or PMUSERENR_EL0.ER is set to 1, and can be written at EL0 when PMUSERENR_EL0.ER is set to 1.

PMEVCNTR<n>_EL0 can also be accessed by using PMXEVCNTR_EL0 with PMSELR_EL0.SEL set to n.

If <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVCNTR<n>_EL0 are CONSTRAINED UNPREDICTABLE, and must behave as one of the following:

- UNALLOCATED.
- RAZ/WI.
- A `NOP`.

Configurations

PMEVCNTR<n>_EL0 is architecturally mapped to AArch32 register PMEVCNTR<n>.

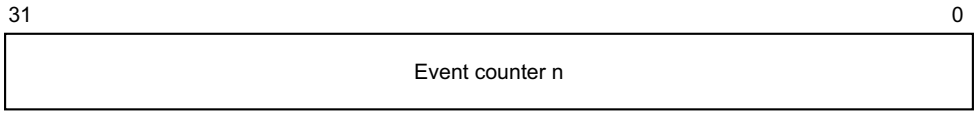
PMEVCNTR<n>_EL0 is architecturally mapped to external register PMEVCNTR<n>_EL0.

Attributes

PMEVCNTR<n>_EL0 is a 32-bit register.

Field descriptions

The PMEVCNTR<n>_EL0 bit assignments are:



Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMEVCNTR<n>_EL0

To access the PMEVCNTR<n>_EL0:

```
MRS <Xt>, PMEVCNTR<n>_EL0 ; Read PMEVCNTR<n>_EL0 into Xt, where n is in the range 0 to 30
MSR PMEVCNTR<n>_EL0, <Xt> ; Write Xt to PMEVCNTR<n>_EL0, where n is in the range 0 to 30
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1110	10:n<4:3>	n<2:0>

D7.4.9 PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n>_EL0 characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR_EL0.EN is set to 1.

PMEVTYPER<n>_EL0 can also be accessed by using PMXEVTYPER_EL0 with PMSELR_EL0.SEL set to n.

If <n> is greater than the number of counters available in the current Exception level and state, reads and writes of PMEVTYPER<n>_EL0 are CONSTRAINED UNPREDICTABLE, and must behave as one of the following:

- UNALLOCATED.
- RAZ/WI.
- A NOP.

Configurations

PMEVTYPER<n>_EL0 is architecturally mapped to AArch32 register PMEVTYPER<n>.

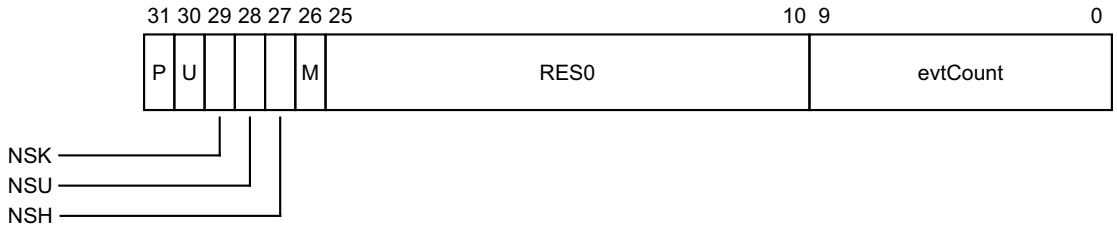
PMEVTYPER<n>_EL0 is architecturally mapped to external register PMEVTYPER<n>_EL0.

Attributes

PMEVTYPER<n>_EL0 is a 32-bit register.

Field descriptions

The PMEVTYPER<n>_EL0 bit assignments are:



P, bit [31]

EL1 modes filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

0 Count events in EL1.

1 Do not count events in EL1.

On Warm reset, the field reset value is architecturally UNKNOWN.

U, bit [30]

EL0 filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

`0` Count events in EL0.

`1` Do not count events in EL0.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSK, bit [29]

Non-secure kernel modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSU, bit [28]

Non-secure user modes filtering bit. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted.

Otherwise, events in Non-secure EL0 are not counted.

On Warm reset, the field reset value is architecturally UNKNOWN.

NSH, bit [27]

Non-secure Hyp modes filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

`0` Do not count events in EL2.

`1` Count events in EL2.

On Warm reset, the field reset value is architecturally UNKNOWN.

M, bit [26]

Secure EL3 filtering bit. Most applications can ignore this bit and set the value to zero. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Secure EL3 are counted.

Otherwise, events in Secure EL3 are not counted.

On Warm reset, the field reset value is architecturally UNKNOWN.

Bits [25:10]

Reserved, RES0.

evtCount, bits [9:0]

Event to count. The event number of the event that is counted by event counter PMEVCNTR<n>_EL0.

Software must program this field with an event defined by the processor or a common event defined by the architecture.

If evtCount is programmed to an event that is reserved or not implemented, the behavior depends on the event type.

For common architectural and microarchitectural events:

- No events are counted.
- The value read back on evtCount is the value written.

For IMPLEMENTATION DEFINED events:

- It is UNPREDICTABLE what event, if any, is counted. UNPREDICTABLE in this case means the event must not expose privileged information.
- The value read back on evtCount is an UNKNOWN value with the same effect.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMEVTYPER<n>_EL0

To access the PMEVTYPER<n>_EL0:

```
MRS <Xt>, PMEVTYPER<n>_EL0 ; Read PMEVTYPER<n>_EL0 into Xt, where n is in the range 0 to 30
MSR PMEVTYPER<n>_EL0, <Xt> ; Write Xt to PMEVTYPER<n>_EL0, where n is in the range 0 to 30
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1110	11:n<4:3>	n<2:0>

D7.4.10 PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR_EL1 characteristics are:

Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

PMINTENCLR_EL1 is architecturally mapped to AArch32 register PMINTENCLR.

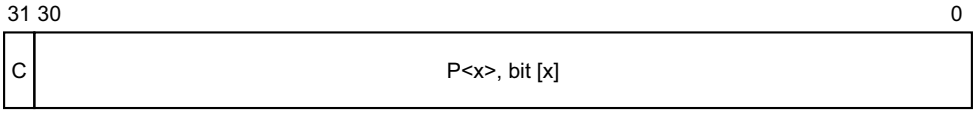
PMINTENCLR_EL1 is architecturally mapped to external register PMINTENCLR_EL1.

Attributes

PMINTENCLR_EL1 is a 32-bit register.

Field descriptions

The PMINTENCLR_EL1 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow interrupt request disable bit. Possible values are:

`0` When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

`1` When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<x>, bit [x], for x = 0 to 30

Event counter overflow interrupt request disable bit for PMEVCNTR<x>_EL0.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

Bits [30:N] are RAZ/WI.

Possible values are:

`0` When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is disabled. When written, has no effect.

`1` When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is enabled. When written, disables the PMEVCNTR<x>_EL0 interrupt request.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMINTENCLR_EL1

To access the PMINTENCLR_EL1:

```
MRS <Xt>, PMINTENCLR_EL1 ; Read PMINTENCLR_EL1 into Xt
MSR PMINTENCLR_EL1, <Xt> ; Write Xt to PMINTENCLR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1001	1110	010

D7.4.11 PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register

The PMINTENSET_EL1 characteristics are:

Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, PMCCNTR_EL0, and the event counters PMEVCNTR<n>_EL0. Reading the register shows which overflow interrupt requests are enabled.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

PMINTENSET_EL1 is architecturally mapped to AArch32 register PMINTENSET.

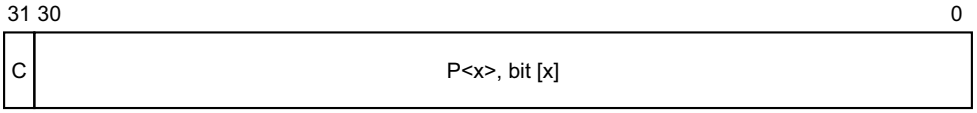
PMINTENSET_EL1 is architecturally mapped to external register PMINTENSET_EL1.

Attributes

PMINTENSET_EL1 is a 32-bit register.

Field descriptions

The PMINTENSET_EL1 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow interrupt request enable bit. Possible values are:

0 When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect.

1 When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<x>, bit [x], for x = 0 to 30

Event counter overflow interrupt request enable bit for PMEVCNTR<x>_EL0.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

Bits [30:N] are RAZ/WI.

Possible values are:

0 When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is disabled. When written, has no effect.

1 When read, means that the PMEVCNTR<x>_EL0 event counter interrupt request is enabled. When written, enables the PMEVCNTR<x>_EL0 interrupt request.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMINTENSET_EL1

To access the PMINTENSET_EL1:

```
MRS <Xt>, PMINTENSET_EL1 ; Read PMINTENSET_EL1 into Xt
MSR PMINTENSET_EL1, <Xt> ; Write Xt to PMINTENSET_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1001	1110	001

D7.4.12 PMOVSCLR_EL0, Performance Monitors Overflow Flag Status Clear Register

The PMOVSCLR_EL0 characteristics are:

Purpose

Contains the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<x>. Writing to this register clears these bits.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR_EL0.EN is set to 1.

Configurations

PMOVSCLR_EL0 is architecturally mapped to AArch32 register PMOVSR.

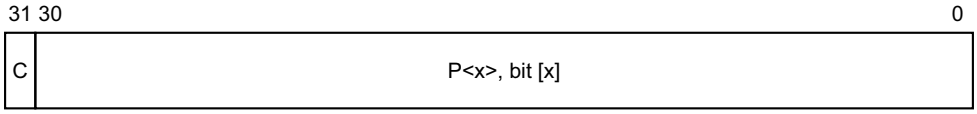
PMOVSCLR_EL0 is architecturally mapped to external register PMOVSCLR_EL0.

Attributes

PMOVSCLR_EL0 is a 32-bit register.

Field descriptions

The PMOVSCLR_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow bit. Possible values are:

`0` When read, means the cycle counter has not overflowed. When written, has no effect.

`1` When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.

PMCR_EL0.LC is used to control from which bit of PMCCNTR_EL0 (bit 31 or bit 63) an overflow is detected.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<x>, bit [x], for x = 0 to 30

Event counter overflow clear bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

Possible values of each bit are:

`0` When read, means that PMEVCNTR<x> has not overflowed. When written, has no effect.

`1` When read, means that PMEVCNTR<x> has overflowed. When written, clears the PMEVCNTR<x> overflow bit to 0.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMOVSCLR_EL0

To access the PMOVSCLR_EL0:

```
MRS <Xt>, PMOVSCLR_EL0 ; Read PMOVSCLR_EL0 into Xt
MSR PMOVSCLR_EL0, <Xt> ; Write Xt to PMOVSCLR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1001	1100	011

D7.4.13 PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register

The PMOVSSET_EL0 characteristics are:

Purpose

Sets the state of the overflow bit for the Cycle Count Register, PMCCNTR_EL0, and each of the implemented event counters PMEVCNTR<x>.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR_EL0.EN is set to 1.

Configurations

PMOVSSET_EL0 is architecturally mapped to AArch32 register PMOVSSET.

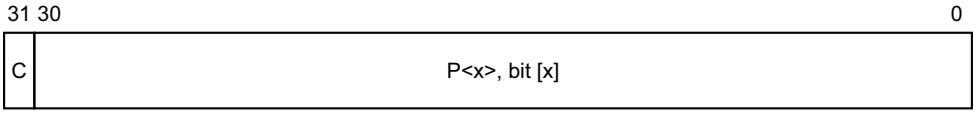
PMOVSSET_EL0 is architecturally mapped to external register PMOVSSET_EL0.

Attributes

PMOVSSET_EL0 is a 32-bit register.

Field descriptions

The PMOVSSET_EL0 bit assignments are:



C, bit [31]

PMCCNTR_EL0 overflow bit. Possible values are:

`0` When read, means the cycle counter has not overflowed. When written, has no effect.

`1` When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.

On Warm reset, the field reset value is architecturally UNKNOWN.

P<x>, bit [x], for x = 0 to 30

Event counter overflow set bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR_EL0.N.

Possible values are:

`0` When read, means that PMEVCNTR<x> has not overflowed. When written, has no effect.

`1` When read, means that PMEVCNTR<x> has overflowed. When written, sets the PMEVCNTR<x> overflow bit to 1.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMOVSSET_EL0

To access the PMOVSSET_EL0:

```
MRS <Xt>, PMOVSSET_EL0 ; Read PMOVSSET_EL0 into Xt
MSR PMOVSSET_EL0, <Xt> ; Write Xt to PMOVSSET_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1001	1110	011

D7.4.14 PMSELR_EL0, Performance Monitors Event Counter Selection Register

The PMSELR_EL0 characteristics are:

Purpose

Selects the current event counter PMEVCNTR<x> or the cycle counter, CCNT.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR_EL0.EN or PMUSERENR_EL0.ER is set to 1.

Configurations

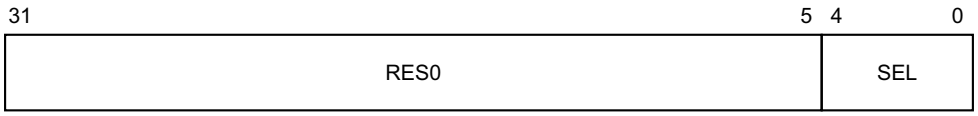
PMSELR_EL0 is architecturally mapped to AArch32 register PMSELR.

Attributes

PMSELR_EL0 is a 32-bit register.

Field descriptions

The PMSELR_EL0 bit assignments are:



Bits [31:5]

Reserved, RES0.

SEL, bits [4:0]

Selects event counter, PMEVCNTR<x>, where x is the value held in this field. This value identifies which event counter is accessed when a subsequent access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 occurs.

This field can take any value from 0 (`0b00000`) to (PMCR.N)-1, or 31 (`0b11111`).

When PMSELR_EL0.SEL is `0b11111` it selects the cycle counter and:

- A read of the PMXEVTYPER_EL0 returns the value of PMCCFILTR_EL0.
- A write of the PMXEVTYPER_EL0 writes to PMCCFILTR_EL0.
- A read or write of PMXEVCNTR_EL0 has CONSTRAINED UNPREDICTABLE effects, that can be one of the following:
  - Access to PMXEVCNTR_EL0 is UNDEFINED.
  - Access to PMXEVCNTR_EL0 behaves as a NOP.
  - Access to PMXEVCNTR_EL0 behaves as if the register is RAZ/WI.
  - Access to PMXEVCNTR_EL0 behaves as if the PMSELR_EL0.SEL field contains an UNKNOWN value.

If this field is set to a value greater than or equal to the number of implemented counters, but not equal to 31, the results of access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 is UNDEFINED.
- Access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 behaves as a NOP.
- Access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 behaves as if the register is RAZ/WI.
- Access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 behaves as if the PMSELR_EL0.SEL field contains an UNKNOWN value.
- Access to PMXEVTYPER_EL0 or PMXEVCNTR_EL0 behaves as if the PMSELR_EL0.SEL field contains 0b11111.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMSELR_EL0

To access the PMSELR_EL0:

```
MRS <Xt>, PMSELR_EL0 ; Read PMSELR_EL0 into Xt
MSR PMSELR_EL0, <Xt> ; Write Xt to PMSELR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1001	1100	101

D7.4.15 PMSWINC_EL0, Performance Monitors Software Increment register

The PMSWINC_EL0 characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event `0x00`.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-WO	WO	WO	WO	WO	WO

This register is accessible at EL0 when PMUSERENR_EL0.EN or PMUSERENR_EL0.SW is set to 1.

Configurations

PMSWINC_EL0 is architecturally mapped to AArch32 register PMSWINC.

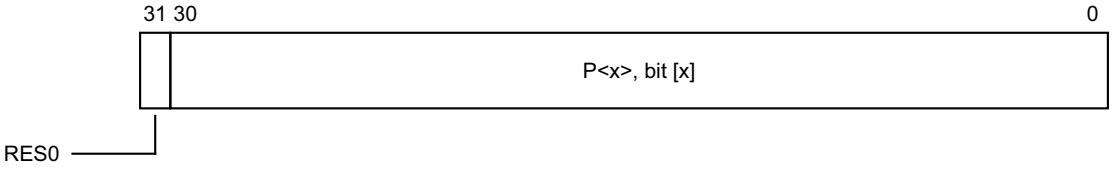
PMSWINC_EL0 is architecturally mapped to external register PMSWINC_EL0.

Attributes

PMSWINC_EL0 is a 32-bit register.

Field descriptions

The PMSWINC_EL0 bit assignments are:



Bit [31]

Reserved, RES0.

P<x>, bit [x], for x = 0 to 30

Event counter software increment bit for PMEVCNTR<x>.

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in MDCR_EL2.HPMN. Otherwise, N is the value in PMCR.N.

The effects of writing to this bit are:

`0` No action. The write to this bit is ignored.

`1` If PMEVCNTR<x> is enabled and configured to count the software increment event, increments PMEVCNTR<x> by 1. If PMEVCNTR<x> is disabled, or not configured to count the software increment event, the write to this bit is ignored.

Accessing the PMSWINC_EL0

To access the PMSWINC_EL0:

```
MSR PMSWINC_EL0, <Xt> ; Write Xt to PMSWINC_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1001	1100	100

D7.4.16 PMUSERENR_EL0, Performance Monitors User Enable Register

The PMUSERENR_EL0 characteristics are:

Purpose

Enables or disables EL0 access to the Performance Monitors.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RO	RW	RW	RW	RW	RW

Configurations

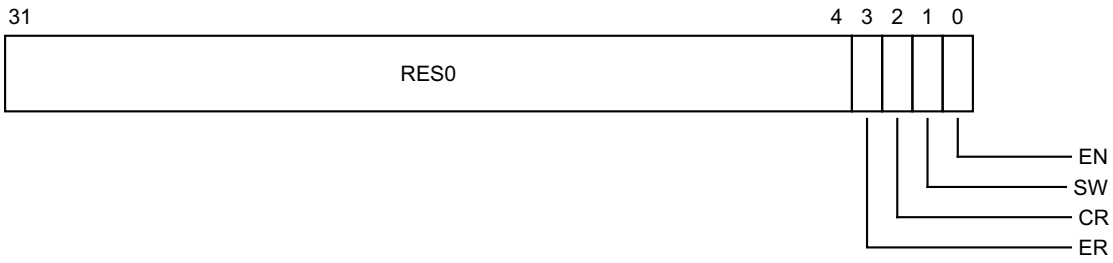
PMUSERENR_EL0 is architecturally mapped to AArch32 register PMUSERENR.

Attributes

PMUSERENR_EL0 is a 32-bit register.

Field descriptions

The PMUSERENR_EL0 bit assignments are:



Bits [31:4]

Reserved, RES0.

ER, bit [3]

Event counter read enable. The possible values of this bit are:

0 EL0 read access to PMXEVCNTR_EL0 / PMEVCNTR<n>_EL0 and read/write access to PMSELR_EL0 disabled if PMUSERENR_EL0.EN is also 0.

1 EL0 read access to PMXEVCNTR_EL0 / PMEVCNTR<n>_EL0 and read/write access to PMSELR_EL0 enabled.

On Warm reset, the field reset value is architecturally UNKNOWN.

CR, bit [2]

Cycle counter read enable. The possible values of this bit are:

0 EL0 read access to PMCCNTR_EL0 disabled if PMUSERENR_EL0.EN is also 0.

1 EL0 read access to PMCCNTR_EL0 enabled.

On Warm reset, the field reset value is architecturally UNKNOWN.

SW, bit [1]

Software Increment write enable. The possible values of this bit are:

0 EL0 write access to PMSWINC_EL0 disabled if PMUSERENR_EL0.EN is also 0.

1 EL0 write access to PMSWINC_EL0 enabled.

On Warm reset, the field reset value is architecturally UNKNOWN.

EN, bit [0]

EL0 access enable bit. The possible values of this bit are:

0 EL0 access to the Performance Monitors disabled.

1 EL0 access to the Performance Monitors enabled. Can access all PMU registers at EL0, except for writes to PMUSERENR_EL0 and reads/writes of PMINTENSET_EL1 and PMINTENCLR_EL1.

On Warm reset, the field reset value is architecturally UNKNOWN.

Accessing the PMUSERENR_EL0

To access the PMUSERENR_EL0:

```
MRS <Xt>, PMUSERENR_EL0 ; Read PMUSERENR_EL0 into Xt
MSR PMUSERENR_EL0, <Xt> ; Write Xt to PMUSERENR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1001	1110	000

D7.4.17 PMXEVCNTR_EL0, Performance Monitors Selected Event Count Register

The PMXEVCNTR_EL0 characteristics are:

Purpose

Reads or writes the value of the selected event counter, PMEVCNTR<x>_EL0. PMSELR_EL0.SEL determines which event counter is selected.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register can be read at EL0 when PMUSERENR_EL0.EN or PMUSERENR_EL0.ER is set to 1, and can be written at EL0 when PMUSERENR_EL0.ER is set to 1.

Configurations

PMXEVCNTR_EL0 is architecturally mapped to AArch32 register PMXEVCNTR.

Attributes

PMXEVCNTR_EL0 is a 32-bit register.

Field descriptions

The PMXEVCNTR_EL0 bit assignments are:

PMEVCNTR<x>, bits [31:0]

Value of the selected event counter, PMEVCNTR<x>_EL0, where x is the value stored in PMSELR_EL0.SEL.

Accessing the PMXEVCNTR_EL0

To access the PMXEVCNTR_EL0:

```
MRS <Xt>, PMXEVCNTR_EL0 ; Read PMXEVCNTR_EL0 into Xt
MSR PMXEVCNTR_EL0, <Xt> ; Write Xt to PMXEVCNTR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1001	1101	010

D7.4.18 PMXEVTYPER_EL0, Performance Monitors Selected Event Type Register

The PMXEVTYPER_EL0 characteristics are:

Purpose

When PMSELR_EL0.SEL selects an event counter, this accesses a PMEVTYPER<n>_EL0 register. When PMSELR_EL0.SEL selects the cycle counter, this accesses PMCCFILTR_EL0.

This register is part of the Performance Monitors registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when PMUSERENR_EL0.EN is set to 1.

Configurations

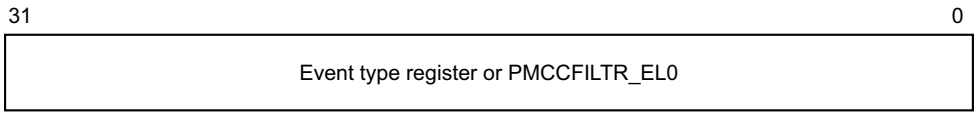
PMXEVTYPER_EL0 is architecturally mapped to AArch32 register PMXEVTYPER.

Attributes

PMXEVTYPER_EL0 is a 32-bit register.

Field descriptions

The PMXEVTYPER_EL0 bit assignments are:



Bits [31:0]

Event type register or PMCCFILTR_EL0.

When PMSELR_EL0.SEL == 31, this register accesses PMCCFILTR_EL0.

Otherwise, this register accesses PMEVTYPER<n>_EL0 where n is the value in PMSELR_EL0.SEL.

Accessing the PMXEVTYPER_EL0

To access the PMXEVTYPER_EL0:

```
MRS <Xt>, PMXEVTYPER_EL0 ; Read PMXEVTYPER_EL0 into Xt
MSR PMXEVTYPER_EL0, <Xt> ; Write Xt to PMXEVTYPER_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1001	1101	001

D7.5 Generic Timer registers

This section lists the Generic Timer registers in AArch64.

D7.5.1 CNTFRQ_EL0, Counter-timer Frequency register

The CNTFRQ_EL0 characteristics are:

Purpose

Holds the clock frequency of the system counter.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	RO	RO	RO	RW	RW

Can only be written at the highest exception level implemented. For example, if EL3 is the highest implemented exception level, CNTFRQ_EL0 can only be written at EL3.

This register is accessible and read-only at EL0 when CNTKCTL_EL1.EL0PCTEN or CNTKCTL_EL1.EL0VCTEN is set to 1.

Configurations

CNTFRQ_EL0 is architecturally mapped to AArch32 register CNTFRQ.

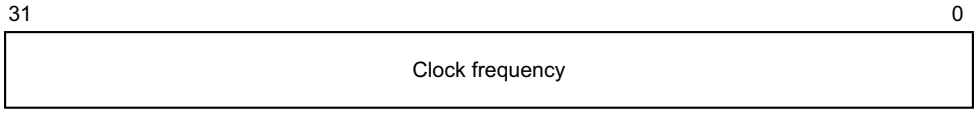
CNTFRQ_EL0 is architecturally mapped to external register CNTFRQ.

Attributes

CNTFRQ_EL0 is a 32-bit register.

Field descriptions

The CNTFRQ_EL0 bit assignments are:



Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

Accessing the CNTFRQ_EL0

To access the CNTFRQ_EL0:

```
MRS <Xt>, CNTFRQ_EL0 ; Read CNTFRQ_EL0 into Xt
MSR CNTFRQ_EL0, <Xt> ; Write Xt to CNTFRQ_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1110	0000	000

D7.5.2 CNTHCTL_EL2, Counter-timer Hypervisor Control register

The CNTHCTL_EL2 characteristics are:

Purpose

Controls the generation of an event stream from the physical counter, and access from Non-secure EL1 to the physical counter and the Non-secure EL1 physical timer.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

CNTHCTL_EL2 is architecturally mapped to AArch32 register CNTHCTL.

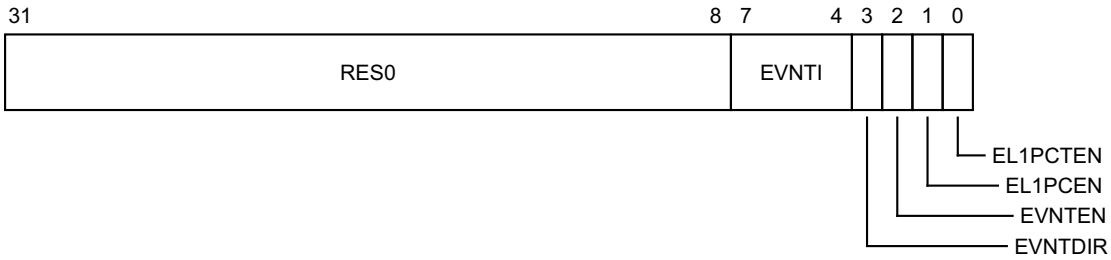
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

CNTHCTL_EL2 is a 32-bit register.

Field descriptions

The CNTHCTL_EL2 bit assignments are:



Bits [31:8]

Reserved, RES0.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the corresponding counter register (CNTPCT_EL0 or CNTVCT_EL0) is the trigger for the event stream generated from that counter, when that stream is enabled.

Reset value is architecturally UNKNOWN.

EVNTDIR, bit [3]

Controls which transition of the counter register (CNTPCT_EL0 or CNTVCT_EL0) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

`0` A 0 to 1 transition of the trigger bit triggers an event.

`1` A 1 to 0 transition of the trigger bit triggers an event.

Reset value is architecturally UNKNOWN.

EVNTEN, bit [2]

Enables the generation of an event stream from the corresponding counter:

0 Disables the event stream.

1 Enables the event stream.

Resets to 0.

EL1PCEN, bit [1]

Controls whether the physical timer registers are accessible from Non-secure EL1 and EL0 modes:

0 The CNTP_CVAL_EL0, CNTP_TVAL_EL0, and CNTP_CTL_EL0 registers are not accessible from Non-secure EL1 and EL0 modes.

1 The CNTP_CVAL_EL0, CNTP_TVAL_EL0, and CNTP_CTL_EL0 registers are accessible from Non-secure EL1 and EL0 modes.

If EL3 is implemented and EL2 is not implemented, this bit is treated as if it is 1 for all purposes other than reading the register.

Reset value is architecturally UNKNOWN.

EL1PCTEN, bit [0]

Controls whether the physical counter, CNTPCT_EL0, is accessible from Non-secure EL1 and EL0 modes:

0 The CNTPCT_EL0 register is not accessible from Non-secure EL1 and EL0 modes.

1 The CNTPCT_EL0 register is accessible from Non-secure EL1 and EL0 modes.

If EL3 is implemented and EL2 is not implemented, this bit is treated as if it is 1 for all purposes other than reading the register.

Reset value is architecturally UNKNOWN.

Accessing the CNTHCTL_EL2

To access the CNTHCTL_EL2:

```
MRS <Xt>, CNTHCTL_EL2 ; Read CNTHCTL_EL2 into Xt
MSR CNTHCTL_EL2, <Xt> ; Write Xt to CNTHCTL_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1110	0001	000

D7.5.3 CNTHP_CTL_EL2, Counter-timer Hypervisor Physical Timer Control register

The CNTHP_CTL_EL2 characteristics are:

Purpose

Control register for the EL2 physical timer.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

CNTHP_CTL_EL2 is architecturally mapped to AArch32 register CNTHP_CTL.

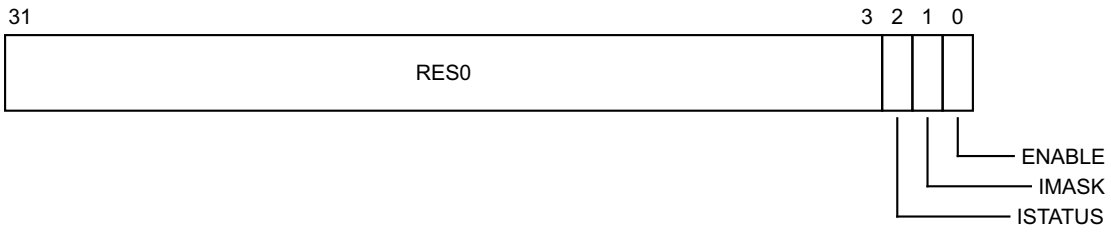
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

CNTHP_CTL_EL2 is a 32-bit register.

Field descriptions

The CNTHP_CTL_EL2 bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer interrupt. This bit is read-only. Permitted values are:

`0` Interrupt not asserted.

`1` Interrupt asserted.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

Reset value is architecturally UNKNOWN.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0` Timer interrupt is not masked.

`1` Timer interrupt is masked.

Reset value is architecturally UNKNOWN.

ENABLE, bit [0]

Enables the timer. Permitted values are:

0 Timer disabled.

1 Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

Resets to 0.

Accessing the CNTHP_CTL_EL2

To access the CNTHP_CTL_EL2:

```
MRS <Xt>, CNTHP_CTL_EL2 ; Read CNTHP_CTL_EL2 into Xt
MSR CNTHP_CTL_EL2, <Xt> ; Write Xt to CNTHP_CTL_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1110	0010	001

D7.5.4 CNTHP_CVAL_EL2, Counter-timer Hypervisor Physical Timer CompareValue register

The CNTHP_CVAL_EL2 characteristics are:

Purpose

Holds the compare value for the EL2 physical timer.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

CNTHP_CVAL_EL2 is architecturally mapped to AArch32 register CNTHP_CVAL.

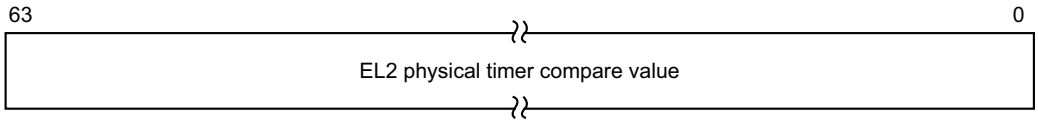
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

CNTHP_CVAL_EL2 is a 64-bit register.

Field descriptions

The CNTHP_CVAL_EL2 bit assignments are:



Bits [63:0]

EL2 physical timer compare value.

Accessing the CNTHP_CVAL_EL2

To access the CNTHP_CVAL_EL2:

```
MRS <Xt>, CNTHP_CVAL_EL2 ; Read CNTHP_CVAL_EL2 into Xt
MSR CNTHP_CVAL_EL2, <Xt> ; Write Xt to CNTHP_CVAL_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1110	0010	010

D7.5.5 CNTHP_TVAL_EL2, Counter-timer Hypervisor Physical Timer TimerValue register

The CNTHP_TVAL_EL2 characteristics are:

Purpose

Holds the timer value for the EL2 physical timer.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

CNTHP_TVAL_EL2 is architecturally mapped to AArch32 register CNTHP_TVAL.

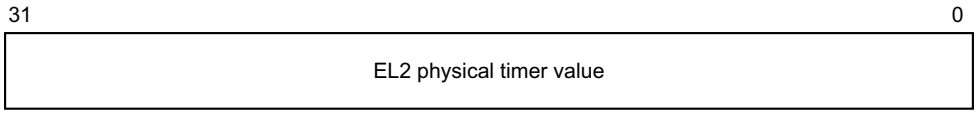
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

CNTHP_TVAL_EL2 is a 32-bit register.

Field descriptions

The CNTHP_TVAL_EL2 bit assignments are:



Bits [31:0]

EL2 physical timer value.

Accessing the CNTHP_TVAL_EL2

To access the CNTHP_TVAL_EL2:

```
MRS <Xt>, CNTHP_TVAL_EL2 ; Read CNTHP_TVAL_EL2 into Xt
MSR CNTHP_TVAL_EL2, <Xt> ; Write Xt to CNTHP_TVAL_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1110	0010	000

D7.5.6 CNTKCTL_EL1, Counter-timer Kernel Control register

The CNTKCTL_EL1 characteristics are:

Purpose

Controls the generation of an event stream from the virtual counter, and access from EL0 to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

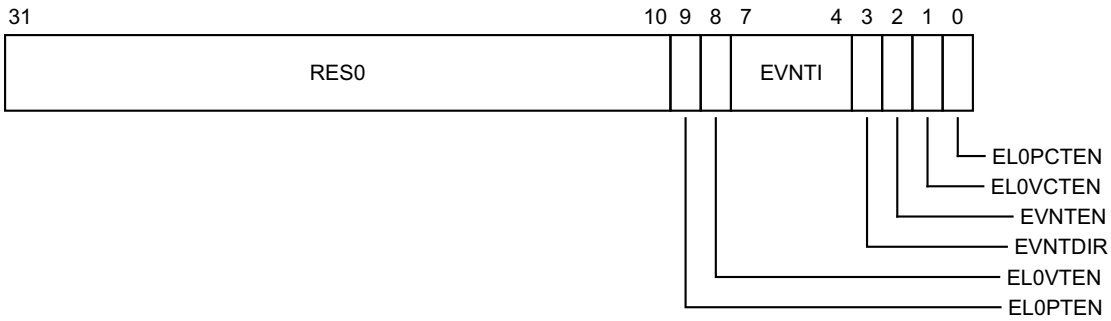
CNTKCTL_EL1 is architecturally mapped to AArch32 register CNTKCTL.

Attributes

CNTKCTL_EL1 is a 32-bit register.

Field descriptions

The CNTKCTL_EL1 bit assignments are:



Bits [31:10]

Reserved, RES0.

EL0PTEN, bit [9]

Controls whether the physical timer registers are accessible from EL0 modes:

0 The CNTP_CVAL_EL0, CNTP_CTL_EL0, and CNTP_TVAL_EL0 registers are not accessible from EL0.

1 The CNTP_CVAL_EL0, CNTP_CTL_EL0, and CNTP_TVAL_EL0 registers are accessible from EL0.

Reset value is architecturally UNKNOWN.

EL0VTEN, bit [8]

Controls whether the virtual timer registers are accessible from EL0 modes:

0 The CNTV_CVAL_EL0, CNTV_CTL_EL0, and CNTV_TVAL_EL0 registers are not accessible from EL0.

1 The CNTV_CVAL_EL0, CNTV_CTL_EL0, and CNTV_TVAL_EL0 registers are accessible from EL0.

Reset value is architecturally UNKNOWN.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the corresponding counter register (CNTPCT_EL0 or CNTVCT_EL0) is the trigger for the event stream generated from that counter, when that stream is enabled.

Reset value is architecturally UNKNOWN.

EVNTDIR, bit [3]

Controls which transition of the counter register (CNTPCT_EL0 or CNTVCT_EL0) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

0 A 0 to 1 transition of the trigger bit triggers an event.

1 A 1 to 0 transition of the trigger bit triggers an event.

Reset value is architecturally UNKNOWN.

EVNTEN, bit [2]

Enables the generation of an event stream from the corresponding counter:

0 Disables the event stream.

1 Enables the event stream.

Resets to 0.

EL0VCTEN, bit [1]

Controls whether the virtual counter, CNTVCT_EL0, and the frequency register CNTFRQ_EL0, are accessible from EL0 modes:

0 CNTVCT_EL0 is not accessible from EL0. If EL0PCTEN is set to 0, CNTFRQ_EL0 is not accessible from EL0.

1 CNTVCT_EL0 and CNTFRQ_EL0 are accessible from EL0.

Reset value is architecturally UNKNOWN.

EL0PCTEN, bit [0]

Controls whether the physical counter, CNTPCT_EL0, and the frequency register CNTFRQ_EL0, are accessible from EL0 modes:

0 CNTPCT_EL0 is not accessible from EL0 modes. If EL0VCTEN is set to 0, CNTFRQ_EL0 is not accessible from EL0.

1 CNTPCT_EL0 and CNTFRQ_EL0 are accessible from EL0.

Reset value is architecturally UNKNOWN.

Accessing the CNTKCTL_EL1

To access the CNTKCTL_EL1:

```
MRS <Xt>, CNTKCTL_EL1 ; Read CNTKCTL_EL1 into Xt
MSR CNTKCTL_EL1, <Xt> ; Write Xt to CNTKCTL_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1110	0001	000

D7.5.7 CNTP_CTL_EL0, Counter-timer Physical Timer Control register

The CNTP_CTL_EL0 characteristics are:

Purpose

Control register for the EL1 physical timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

This register is accessible at EL0 when CNTKCTL_EL1.EL0PTEN is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when CNTHCTL_EL2.EL1PCEN is set to 1.

Configurations

CNTP_CTL_EL0 is architecturally mapped to AArch32 register CNTP_CTL (NS).

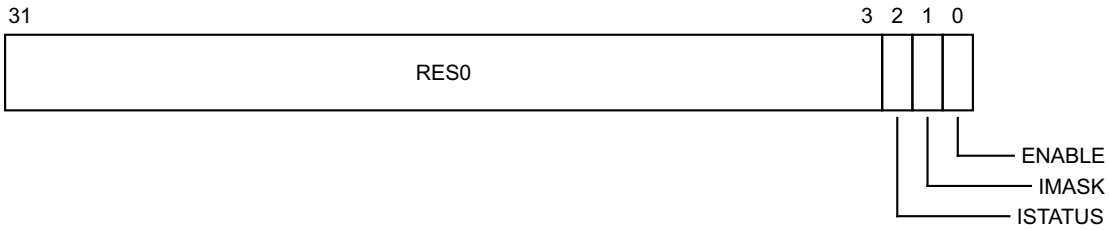
CNTP_CTL_EL0 is architecturally mapped to external register CNTP_CTL.

Attributes

CNTP_CTL_EL0 is a 32-bit register.

Field descriptions

The CNTP_CTL_EL0 bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer interrupt. This bit is read-only. Permitted values are:

`0` Interrupt not asserted.

`1` Interrupt asserted.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

Reset value is architecturally UNKNOWN.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0` Timer interrupt is not masked.

1 Timer interrupt is masked.

Reset value is architecturally UNKNOWN.

ENABLE, bit [0]

Enables the timer. Permitted values are:

0 Timer disabled.

1 Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

Resets to 0.

Accessing the CNTP_CTL_EL0

To access the CNTP_CTL_EL0:

```
MRS <Xt>, CNTP_CTL_EL0 ; Read CNTP_CTL_EL0 into Xt
MSR CNTP_CTL_EL0, <Xt> ; Write Xt to CNTP_CTL_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1110	0010	001

D7.5.8 CNTP_CVAL_EL0, Counter-timer Physical Timer CompareValue register

The CNTP_CVAL_EL0 characteristics are:

Purpose

Holds the compare value for the EL1 physical timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

This register is accessible at EL0 when CNTKCTL_EL1.EL0PTEN is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when CNTHCTL_EL2.EL1PCEN is set to 1.

Configurations

CNTP_CVAL_EL0 is architecturally mapped to AArch32 register CNTP_CVAL (NS).

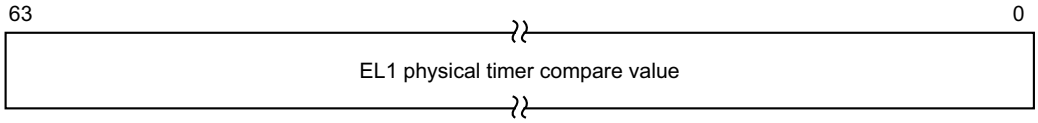
CNTP_CVAL_EL0 is architecturally mapped to external register CNTP_CVAL.

Attributes

CNTP_CVAL_EL0 is a 64-bit register.

Field descriptions

The CNTP_CVAL_EL0 bit assignments are:



Bits [63:0]

EL1 physical timer compare value.

Accessing the CNTP_CVAL_EL0

To access the CNTP_CVAL_EL0:

```
MRS <Xt>, CNTP_CVAL_EL0 ; Read CNTP_CVAL_EL0 into Xt
MSR CNTP_CVAL_EL0, <Xt> ; Write Xt to CNTP_CVAL_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1110	0010	010

D7.5.9 CNTP_TVAL_EL0, Counter-timer Physical Timer TimerValue register

The CNTP_TVAL_EL0 characteristics are:

Purpose

Holds the timer value for the EL1 physical timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	Config-RW	RW	RW	RW	RW

This register is accessible at EL0 when CNTKCTL_EL1.EL0PTEN is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when CNTHCTL_EL2.EL1PCEN is set to 1.

Configurations

CNTP_TVAL_EL0 is architecturally mapped to AArch32 register CNTP_TVAL (NS).

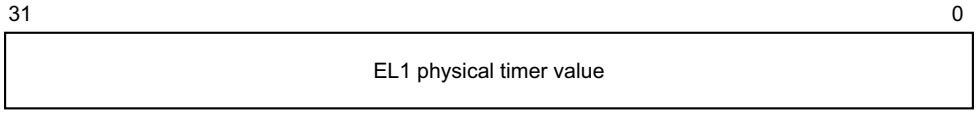
CNTP_TVAL_EL0 is architecturally mapped to external register CNTP_TVAL.

Attributes

CNTP_TVAL_EL0 is a 32-bit register.

Field descriptions

The CNTP_TVAL_EL0 bit assignments are:



Bits [31:0]

EL1 physical timer value.

Accessing the CNTP_TVAL_EL0

To access the CNTP_TVAL_EL0:

```
MRS <Xt>, CNTP_TVAL_EL0 ; Read CNTP_TVAL_EL0 into Xt
MSR CNTP_TVAL_EL0, <Xt> ; Write Xt to CNTP_TVAL_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1110	0010	000

D7.5.10 CNTPCT_EL0, Counter-timer Physical Count register

The CNTPCT_EL0 characteristics are:

Purpose

Holds the 64-bit physical count value.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	Config-RO	RO	RO	RO	RO

This register is accessible at EL0 when CNTKCTL_EL1.EL0PCTEN is set to 1.

If EL2 is implemented, this register is accessible at Non-secure EL1 and EL0 when CNTHCTL_EL2.EL1PCTEN is set to 1.

Configurations

CNTPCT_EL0 is architecturally mapped to AArch32 register CNTPCT.

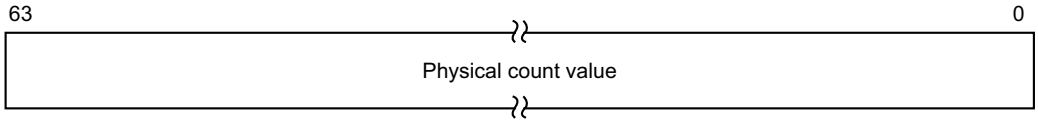
CNTPCT_EL0 is architecturally mapped to external register CNTPCT.

Attributes

CNTPCT_EL0 is a 64-bit register.

Field descriptions

The CNTPCT_EL0 bit assignments are:



Bits [63:0]

Physical count value.

Accessing the CNTPCT_EL0

To access the CNTPCT_EL0:

```
MRS <Xt>, CNTPCT_EL0 ; Read CNTPCT_EL0 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1110	0000	001

D7.5.11 CNTPS_CTL_EL1, Counter-timer Physical Secure Timer Control register

The CNTPS_CTL_EL1 characteristics are:

Purpose

Control register for the secure physical timer, usually accessible at EL3 but can be configured to be accessible at EL1 in Secure state.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	Config-RW	-	RW	RW

This register is accessible at Secure EL1 when SCR_EL3.ST is set to 1.

Configurations

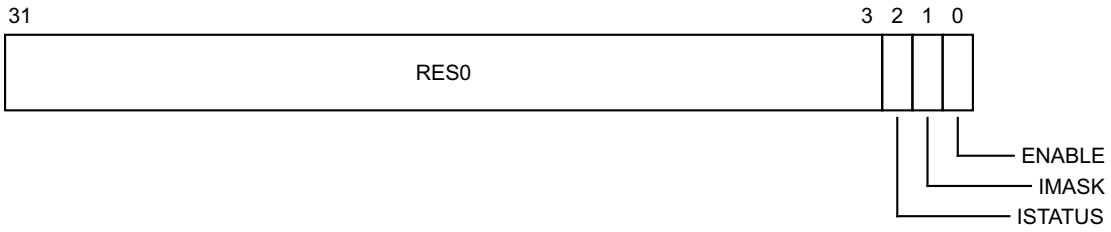
There are no configuration notes.

Attributes

CNTPS_CTL_EL1 is a 32-bit register.

Field descriptions

The CNTPS_CTL_EL1 bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer interrupt. This bit is read-only. Permitted values are:

`0` Interrupt not asserted.

`1` Interrupt asserted.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

Reset value is architecturally UNKNOWN.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0` Timer interrupt is not masked.

`1` Timer interrupt is masked.

Reset value is architecturally UNKNOWN.

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0` Timer disabled.

`1` Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

Resets to 0.

Accessing the CNTPS_CTL_EL1

To access the CNTPS_CTL_EL1:

```
MRS <Xt>, CNTPS_CTL_EL1 ; Read CNTPS_CTL_EL1 into Xt
MSR CNTPS_CTL_EL1, <Xt> ; Write Xt to CNTPS_CTL_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	111	1110	0010	001

D7.5.12 CNTPS_CVAL_EL1, Counter-timer Physical Secure Timer CompareValue register

The CNTPS_CVAL_EL1 characteristics are:

Purpose

Holds the compare value for the secure physical timer, usually accessible at EL3 but can be configured to be accessible at EL1 in Secure state.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	Config-RW	-	RW	RW

This register is accessible at Secure EL1 when SCR_EL3.ST is set to 1.

Configurations

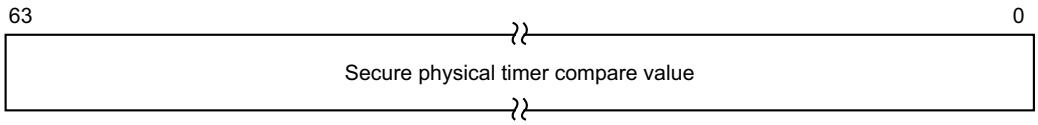
There are no configuration notes.

Attributes

CNTPS_CVAL_EL1 is a 64-bit register.

Field descriptions

The CNTPS_CVAL_EL1 bit assignments are:



Bits [63:0]

Secure physical timer compare value.

Accessing the CNTPS_CVAL_EL1

To access the CNTPS_CVAL_EL1:

```
MRS <Xt>, CNTPS_CVAL_EL1 ; Read CNTPS_CVAL_EL1 into Xt
MSR CNTPS_CVAL_EL1, <Xt> ; Write Xt to CNTPS_CVAL_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	111	1110	0010	010

D7.5.13 CNTPS_TVAL_EL1, Counter-timer Physical Secure Timer TimerValue register

The CNTPS_TVAL_EL1 characteristics are:

Purpose

Holds the timer value for the secure physical timer, usually accessible at EL3 but can be configured to be accessible at EL1 in Secure state.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	Config-RW	-	RW	RW

This register is accessible at Secure EL1 when SCR_EL3.ST is set to 1.

Configurations

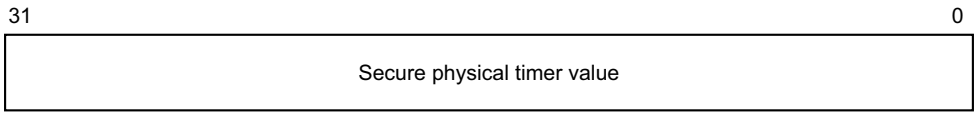
There are no configuration notes.

Attributes

CNTPS_TVAL_EL1 is a 32-bit register.

Field descriptions

The CNTPS_TVAL_EL1 bit assignments are:



Bits [31:0]

Secure physical timer value.

Accessing the CNTPS_TVAL_EL1

To access the CNTPS_TVAL_EL1:

```
MRS <Xt>, CNTPS_TVAL_EL1 ; Read CNTPS_TVAL_EL1 into Xt
MSR CNTPS_TVAL_EL1, <Xt> ; Write Xt to CNTPS_TVAL_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	111	1110	0010	000

D7.5.14 CNTV_CTL_EL0, Counter-timer Virtual Timer Control register

The CNTV_CTL_EL0 characteristics are:

Purpose

Control register for the virtual timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when CNTKCTL_EL1.EL0VTEN is set to 1.

Configurations

CNTV_CTL_EL0 is architecturally mapped to AArch32 register CNTV_CTL.

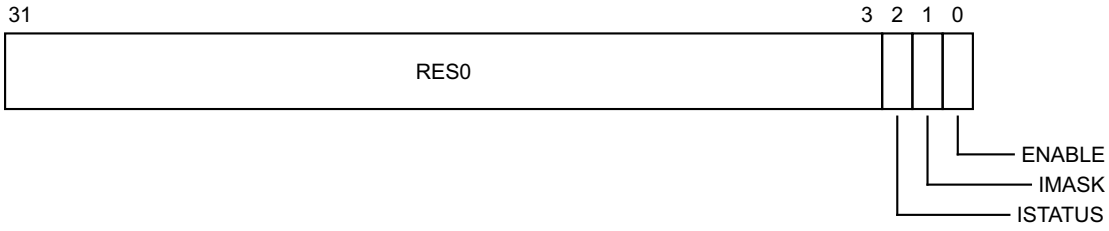
CNTV_CTL_EL0 is architecturally mapped to external register CNTV_CTL.

Attributes

CNTV_CTL_EL0 is a 32-bit register.

Field descriptions

The CNTV_CTL_EL0 bit assignments are:



Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer interrupt. This bit is read-only. Permitted values are:

`0` Interrupt not asserted.

`1` Interrupt asserted.

A register write that sets IMASK to 1 latches this bit to reflect the status of the interrupt immediately before that write.

Reset value is architecturally UNKNOWN.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

`0` Timer interrupt is not masked.

`1` Timer interrupt is masked.

Reset value is architecturally UNKNOWN.

ENABLE, bit [0]

Enables the timer. Permitted values are:

`0` Timer disabled.

`1` Timer enabled.

Disabling the timer masks the timer interrupt, but the timer value continues to count down.

Resets to 0.

Accessing the CNTV_CTL_EL0

To access the CNTV_CTL_EL0:

```
MRS <Xt>, CNTV_CTL_EL0 ; Read CNTV_CTL_EL0 into Xt
MSR CNTV_CTL_EL0, <Xt> ; Write Xt to CNTV_CTL_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1110	0011	001

D7.5.15 CNTV_CVAL_EL0, Counter-timer Virtual Timer CompareValue register

The CNTV_CVAL_EL0 characteristics are:

Purpose

Holds the compare value for the virtual timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when CNTKCTL_EL1.EL0VTEN is set to 1.

Configurations

CNTV_CVAL_EL0 is architecturally mapped to AArch32 register CNTV_CVAL.

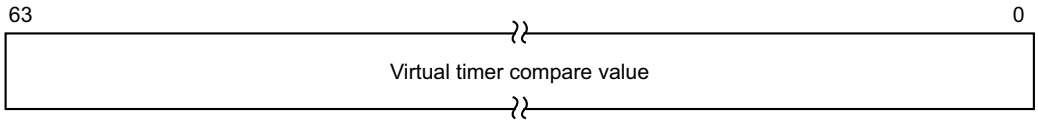
CNTV_CVAL_EL0 is architecturally mapped to external register CNTV_CVAL.

Attributes

CNTV_CVAL_EL0 is a 64-bit register.

Field descriptions

The CNTV_CVAL_EL0 bit assignments are:



Bits [63:0]

Virtual timer compare value.

Accessing the CNTV_CVAL_EL0

To access the CNTV_CVAL_EL0:

```
MRS <Xt>, CNTV_CVAL_EL0 ; Read CNTV_CVAL_EL0 into Xt
MSR CNTV_CVAL_EL0, <Xt> ; Write Xt to CNTV_CVAL_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1110	0011	010

D7.5.16 CNTV_TVAL_EL0, Counter-timer Virtual Timer TimerValue register

The CNTV_TVAL_EL0 characteristics are:

Purpose

Holds the timer value for the virtual timer.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when CNTKCTL_EL1.EL0VTEN is set to 1.

Configurations

CNTV_TVAL_EL0 is architecturally mapped to AArch32 register CNTV_TVAL.

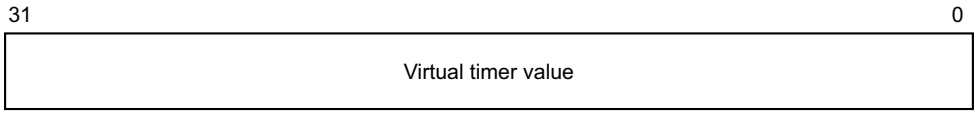
CNTV_TVAL_EL0 is architecturally mapped to external register CNTV_TVAL.

Attributes

CNTV_TVAL_EL0 is a 32-bit register.

Field descriptions

The CNTV_TVAL_EL0 bit assignments are:



Bits [31:0]

Virtual timer value.

Accessing the CNTV_TVAL_EL0

To access the CNTV_TVAL_EL0:

```
MRS <Xt>, CNTV_TVAL_EL0 ; Read CNTV_TVAL_EL0 into Xt
MSR CNTV_TVAL_EL0, <Xt> ; Write Xt to CNTV_TVAL_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1110	0011	000

D7.5.17 CNTVCT_EL0, Counter-timer Virtual Count register

The CNTVCT_EL0 characteristics are:

Purpose

Holds the 64-bit virtual count value.

This register is part of the Generic Timer registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RO	RO	RO	RO	RO	RO

This register is accessible at EL0 when CNTKCTL_EL1.EL0VCTEN is set to 1.

Configurations

CNTVCT_EL0 is architecturally mapped to AArch32 register CNTVCT.

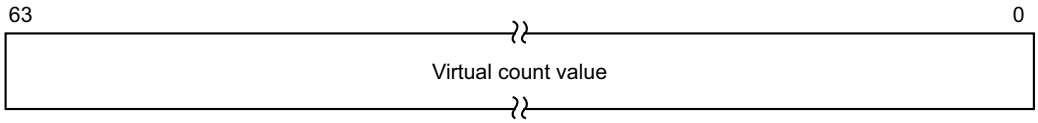
CNTVCT_EL0 is architecturally mapped to external register CNTVCT.

Attributes

CNTVCT_EL0 is a 64-bit register.

Field descriptions

The CNTVCT_EL0 bit assignments are:



Bits [63:0]

Virtual count value.

Accessing the CNTVCT_EL0

To access the CNTVCT_EL0:

```
MRS <Xt>, CNTVCT_EL0 ; Read CNTVCT_EL0 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	1110	0000	010

D7.5.18 CNTVOFF_EL2, Counter-timer Virtual Offset register

The CNTVOFF_EL2 characteristics are:

Purpose

Holds the 64-bit virtual offset.

This register is part of:

- the Generic Timer registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

CNTVOFF_EL2 is architecturally mapped to AArch32 register CNTVOFF.

CNTVOFF_EL2 is architecturally mapped to external register CNTVOFF.

CNTVOFF_EL2 is architecturally mapped to external register CNTVOFF<n>.

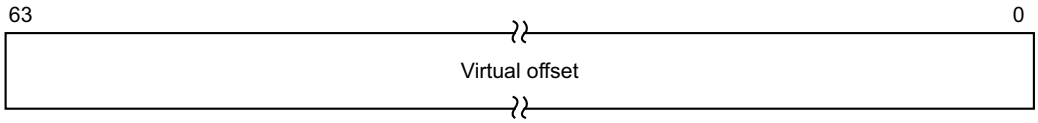
If EL2 is not implemented, this register is RES0 from EL3.

Attributes

CNTVOFF_EL2 is a 64-bit register.

Field descriptions

The CNTVOFF_EL2 bit assignments are:



Bits [63:0]

Virtual offset.

Accessing the CNTVOFF_EL2

To access the CNTVOFF_EL2:

```
MRS <Xt>, CNTVOFF_EL2 ; Read CNTVOFF_EL2 into Xt
MSR CNTVOFF_EL2, <Xt> ; Write Xt to CNTVOFF_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1110	0000	011

D7.6 Generic Interrupt Controller CPU interface registers

This section lists the GIC CPU interface registers in AArch64 state.

D7.6.1 ICC_AP0R0_EL1, Interrupt Controller Active Priorities Register (0,0)

The ICC_AP0R0_EL1 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

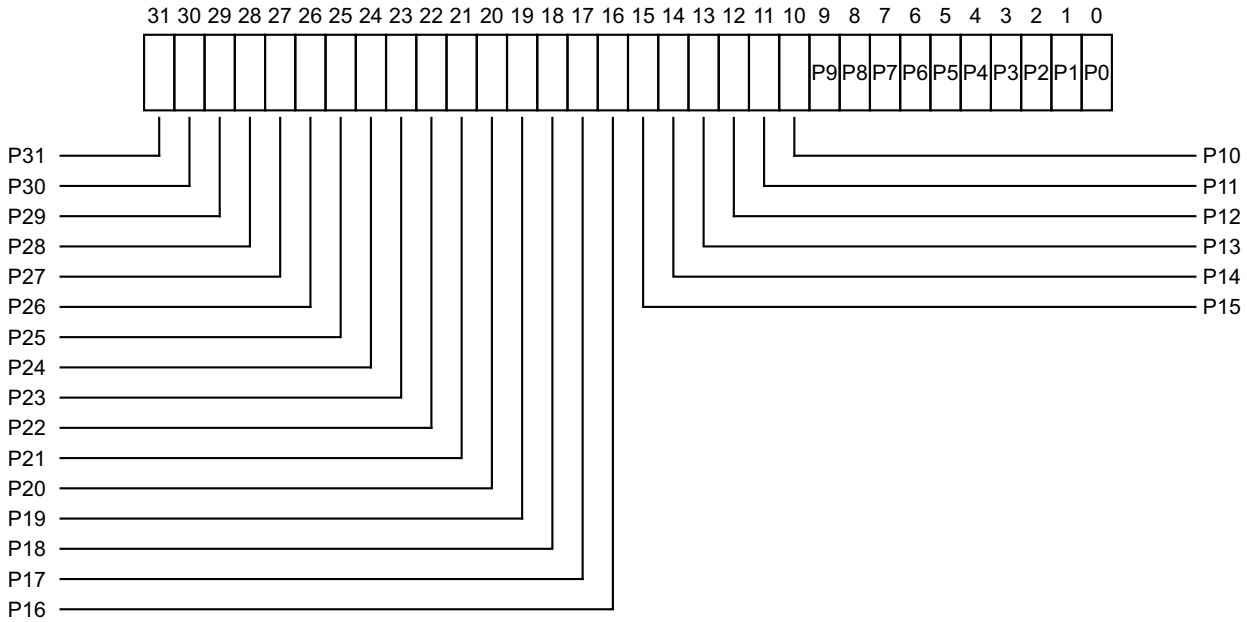
ICC_AP0R0_EL1 is architecturally mapped to AArch32 register ICC_AP0R0.

Attributes

ICC_AP0R0_EL1 is a 32-bit register.

Field descriptions

The ICC_AP0R0_EL1 bit assignments are:



P<n>, bit [n], for n = 0 to 31

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP0R0_EL1

To access the ICC_AP0R0_EL1:

```
MRS <Xt>, ICC_AP0R0_EL1 ; Read ICC_AP0R0_EL1 into Xt
MSR ICC_AP0R0_EL1, <Xt> ; Write Xt to ICC_AP0R0_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1000	100

D7.6.2 ICC_AP0R1_EL1, Interrupt Controller Active Priorities Register (0,1)

The ICC_AP0R1_EL1 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

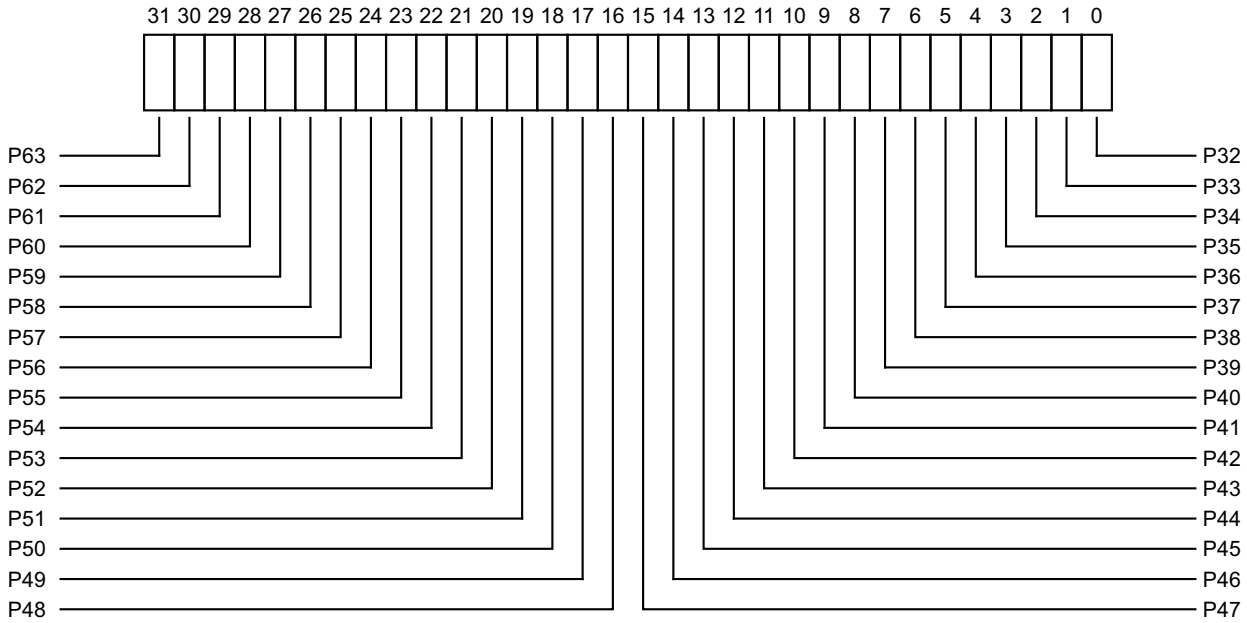
ICC_AP0R1_EL1 is architecturally mapped to AArch32 register ICC_AP0R1.

Attributes

ICC_AP0R1_EL1 is a 32-bit register.

Field descriptions

The ICC_AP0R1_EL1 bit assignments are:



P<n>, bit [(n-32)], for (n-32) = 32 to 63

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP0R1_EL1

To access the ICC_AP0R1_EL1:

```
MRS <Xt>, ICC_AP0R1_EL1 ; Read ICC_AP0R1_EL1 into Xt
MSR ICC_AP0R1_EL1, <Xt> ; Write Xt to ICC_AP0R1_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1000	101

D7.6.3 ICC_AP0R2_EL1, Interrupt Controller Active Priorities Register (0,2)

The ICC_AP0R2_EL1 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

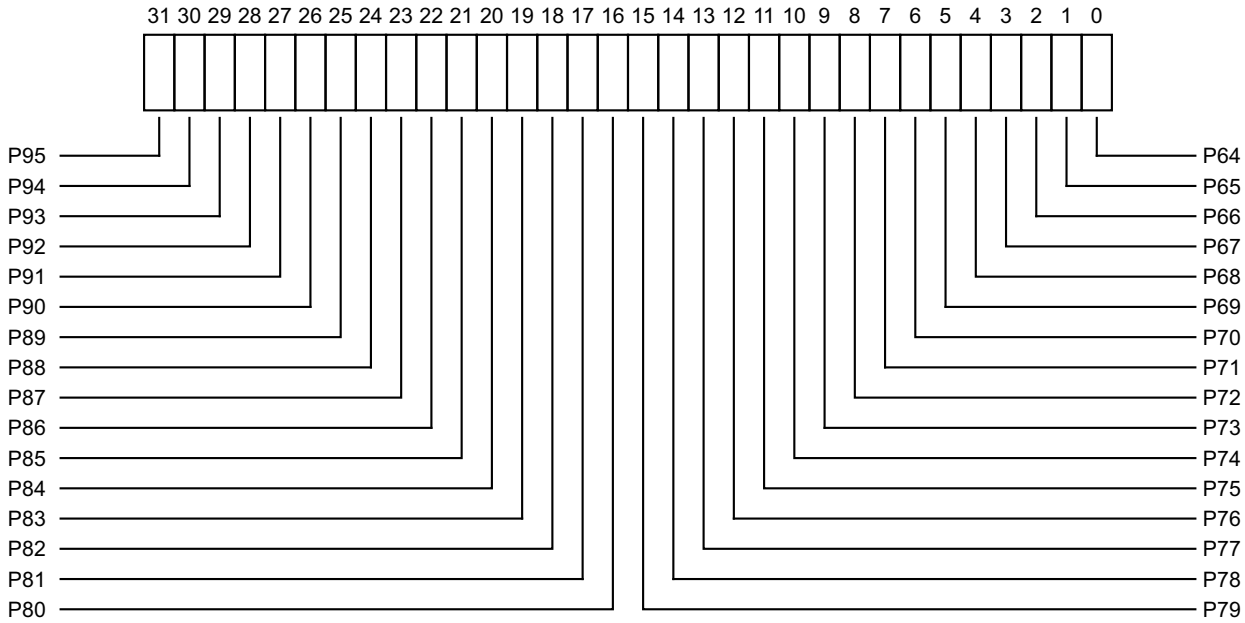
ICC_AP0R2_EL1 is architecturally mapped to AArch32 register ICC_AP0R2.

Attributes

ICC_AP0R2_EL1 is a 32-bit register.

Field descriptions

The ICC_AP0R2_EL1 bit assignments are:



P<n>, bit [(n-64)], for (n-64) = 64 to 95

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP0R2_EL1

To access the ICC_AP0R2_EL1:

```
MRS <Xt>, ICC_AP0R2_EL1 ; Read ICC_AP0R2_EL1 into Xt
MSR ICC_AP0R2_EL1, <Xt> ; Write Xt to ICC_AP0R2_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1000	110

D7.6.4 ICC_AP0R3_EL1, Interrupt Controller Active Priorities Register (0,3)

The ICC_AP0R3_EL1 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

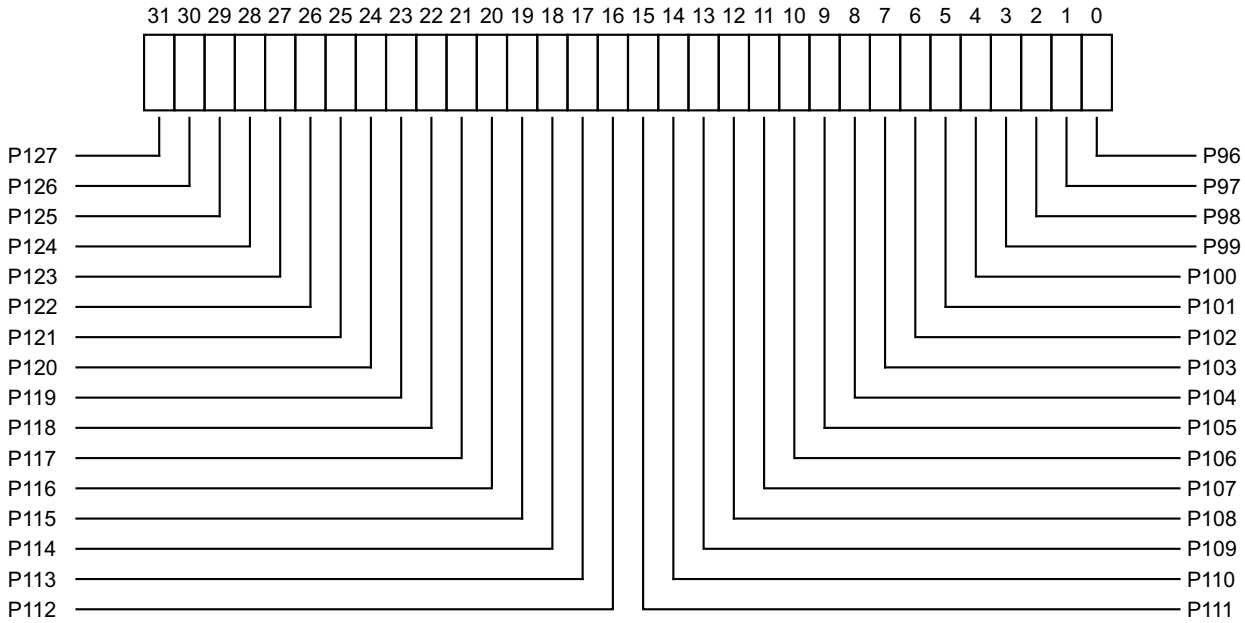
ICC_AP0R3_EL1 is architecturally mapped to AArch32 register ICC_AP0R3.

Attributes

ICC_AP0R3_EL1 is a 32-bit register.

Field descriptions

The ICC_AP0R3_EL1 bit assignments are:



P<n>, bit [(n-96)], for (n-96) = 96 to 127

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP0R3_EL1

To access the ICC_AP0R3_EL1:

```
MRS <Xt>, ICC_AP0R3_EL1 ; Read ICC_AP0R3_EL1 into Xt
MSR ICC_AP0R3_EL1, <Xt> ; Write Xt to ICC_AP0R3_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1000	111

D7.6.5 ICC_AP1R0_EL1, Interrupt Controller Active Priorities Register (1,0)

The ICC_AP1R0_EL1 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

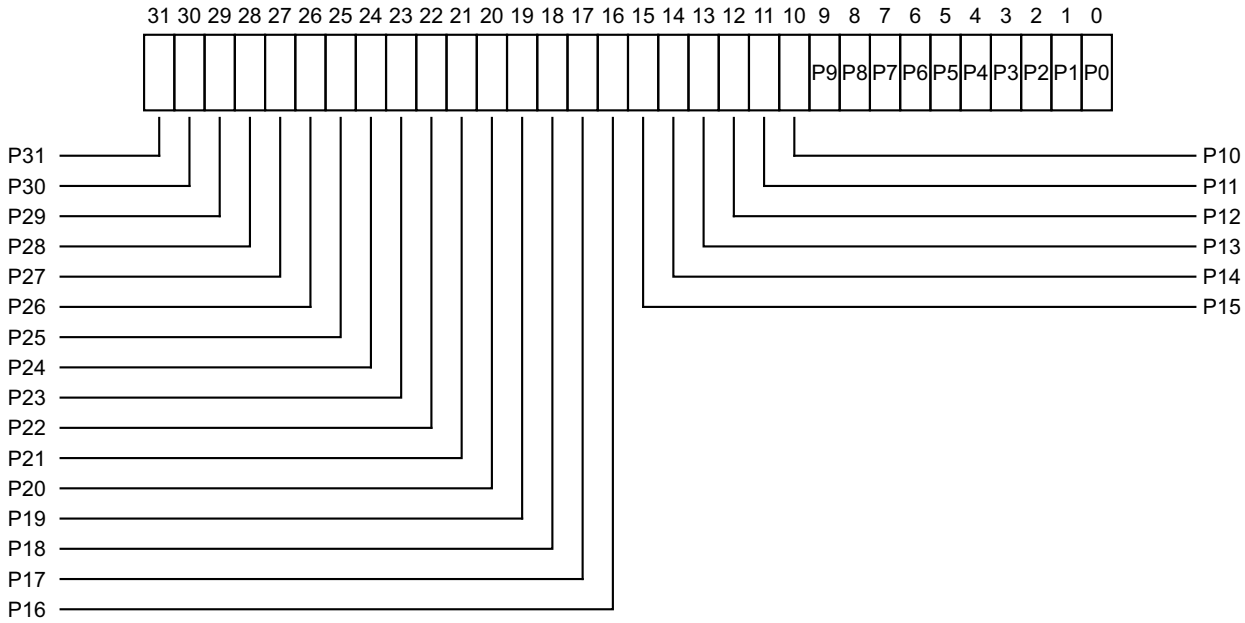
ICC_AP1R0_EL1 is architecturally mapped to AArch32 register ICC_AP1R0.

Attributes

ICC_AP1R0_EL1 is a 32-bit register.

Field descriptions

The ICC_AP1R0_EL1 bit assignments are:



P<n>, bit [n], for n = 0 to 31

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and Security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP1R0_EL1

To access the ICC_AP1R0_EL1:

```
MRS <Xt>, ICC_AP1R0_EL1 ; Read ICC_AP1R0_EL1 into Xt
MSR ICC_AP1R0_EL1, <Xt> ; Write Xt to ICC_AP1R0_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1001	000

D7.6.6 ICC_AP1R1_EL1, Interrupt Controller Active Priorities Register (1,1)

The ICC_AP1R1_EL1 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

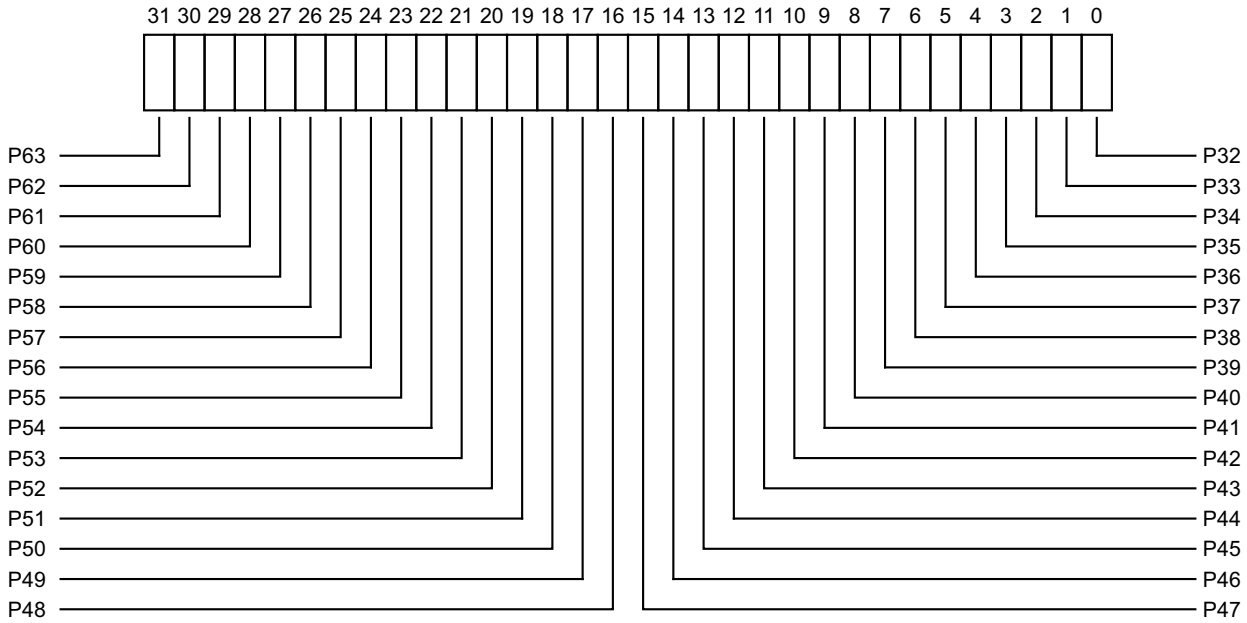
ICC_AP1R1_EL1 is architecturally mapped to AArch32 register ICC_AP1R1.

Attributes

ICC_AP1R1_EL1 is a 32-bit register.

Field descriptions

The ICC_AP1R1_EL1 bit assignments are:



P<n>, bit [(n-32)], for (n-32) = 32 to 63

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and Security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP1R1_EL1

To access the ICC_AP1R1_EL1:

```
MRS <Xt>, ICC_AP1R1_EL1 ; Read ICC_AP1R1_EL1 into Xt
MSR ICC_AP1R1_EL1, <Xt> ; Write Xt to ICC_AP1R1_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1001	001

D7.6.7 ICC_AP1R2_EL1, Interrupt Controller Active Priorities Register (1,2)

The ICC_AP1R2_EL1 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

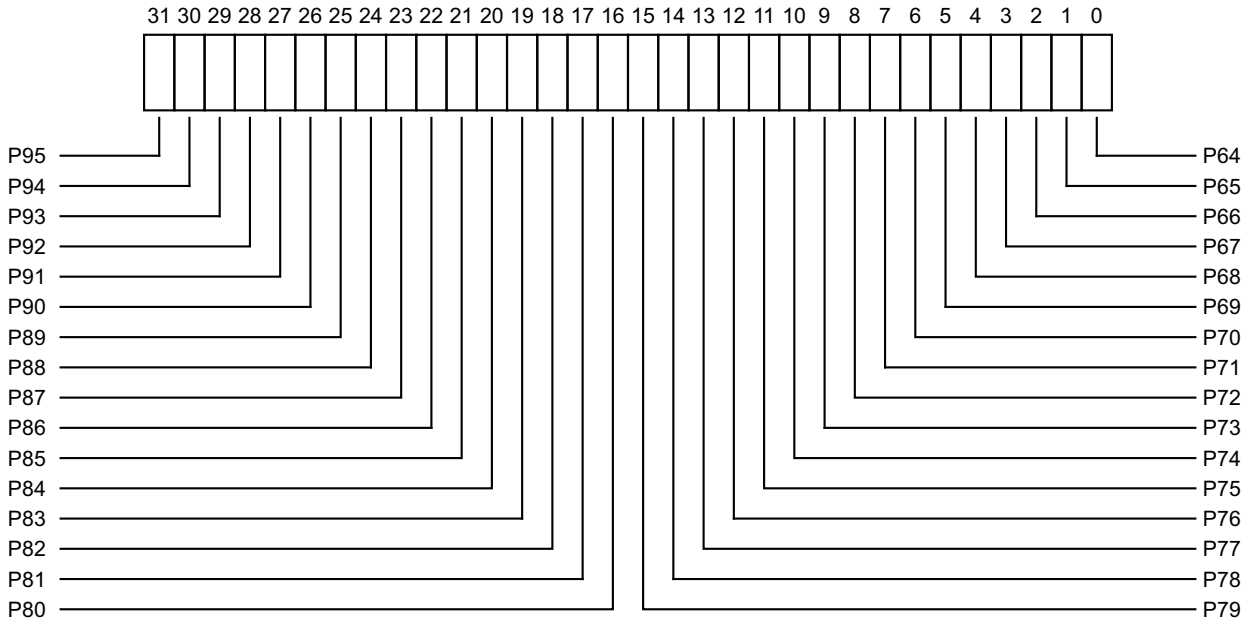
ICC_AP1R2_EL1 is architecturally mapped to AArch32 register ICC_AP1R2.

Attributes

ICC_AP1R2_EL1 is a 32-bit register.

Field descriptions

The ICC_AP1R2_EL1 bit assignments are:



P<n>, bit [(n-64)], for (n-64) = 64 to 95

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and Security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP1R2_EL1

To access the ICC_AP1R2_EL1:

```
MRS <Xt>, ICC_AP1R2_EL1 ; Read ICC_AP1R2_EL1 into Xt
MSR ICC_AP1R2_EL1, <Xt> ; Write Xt to ICC_AP1R2_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1001	010

D7.6.8 ICC_AP1R3_EL1, Interrupt Controller Active Priorities Register (1,3)

The ICC_AP1R3_EL1 characteristics are:

Purpose

Provides information about the active priorities for the current interrupt regime.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

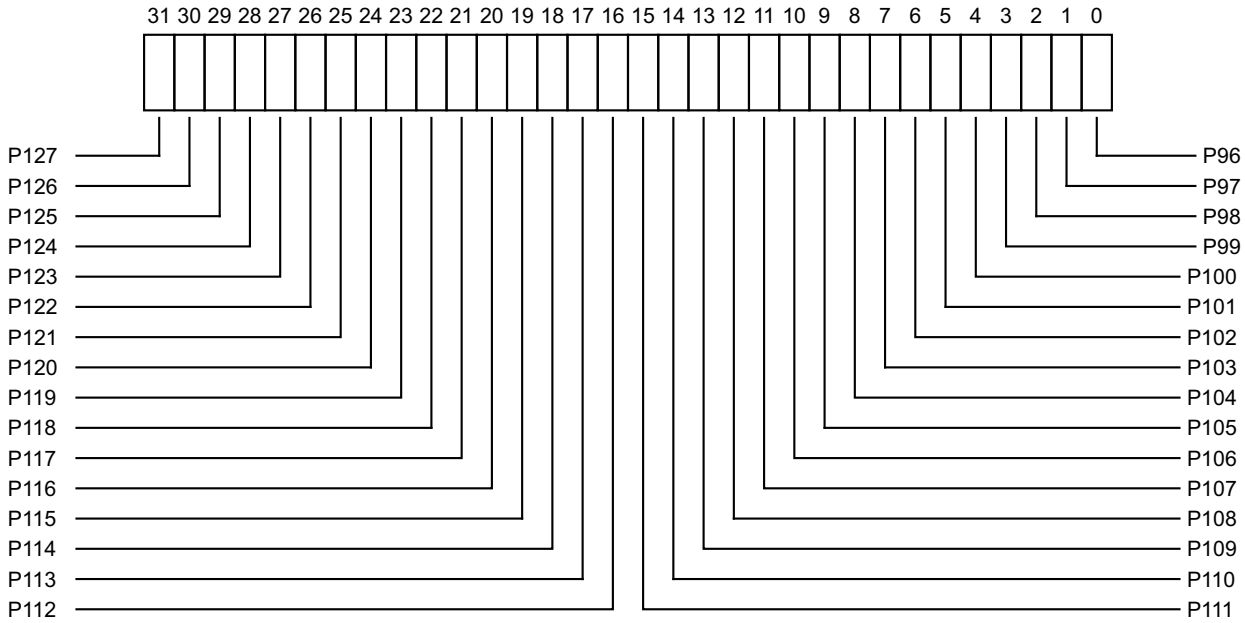
ICC_AP1R3_EL1 is architecturally mapped to AArch32 register ICC_AP1R3.

Attributes

ICC_AP1R3_EL1 is a 32-bit register.

Field descriptions

The ICC_AP1R3_EL1 bit assignments are:



P<n>, bit [(n-96)], for (n-96) = 96 to 127

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == 0b100:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and Security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICC_AP1R3_EL1

To access the ICC_AP1R3_EL1:

```
MRS <Xt>, ICC_AP1R3_EL1 ; Read ICC_AP1R3_EL1 into Xt
MSR ICC_AP1R3_EL1, <Xt> ; Write Xt to ICC_AP1R3_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1001	011

D7.6.9 ICC_ASGI1R_EL1, Interrupt Controller Alias Software Generated Interrupt group 1 Register

The ICC_ASGI1R_EL1 characteristics are:

Purpose

Provides software the ability to generate group 1 SGIs for the other Security state.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_ASGI1R_EL1(S):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	-	-	WO

When accessed as ICC_ASGI1R_EL1(NS):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
WO	-	WO	WO	-

Configurations

There are separate Secure and Non-secure instances of this register.

ICC_ASGI1R_EL1(S) is architecturally mapped to AArch32 register ICC_ASGI1R (S).

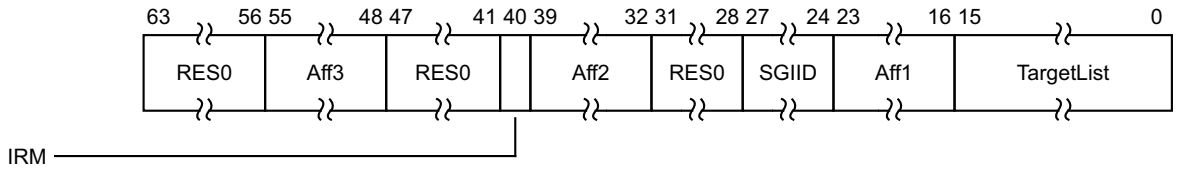
ICC_ASGI1R_EL1(NS) is architecturally mapped to AArch32 register ICC_ASGI1R (NS).

Attributes

ICC_ASGI1R_EL1 is a 64-bit register.

Field descriptions

The ICC_ASGI1R_EL1 bit assignments are:



Bits [63:56]

Reserved, RES0.

Aff3, bits [55:48]

The affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [47:41]

Reserved, RES0.

IRM, bit [40]

Interrupt Routing Mode. Determines how the generated interrupts should be distributed to processors. Possible values are:

`0` Interrupts routed to the processors specified by a.b.c.{target list}. In this routing, a, b, and c are the values of fields Aff3, Aff2, and Aff1 respectively.

`1` Interrupts routed to all processors in the system, excluding self.

Aff2, bits [39:32]

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [31:28]

Reserved, RES0.

SGIID, bits [27:24]

SGI Interrupt ID.

Aff1, bits [23:16]

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated.

TargetList, bits [15:0]

Target List. The set of processors for which SGI interrupts will be generated. Each bit corresponds to the processor within a cluster with an Affinity 0 value equal to the bit number.

If a bit is 1 and the bit does not correspond to a valid target processor, the bit must be ignored by the Distributor. In such cases, a Distributor may optionally generate an SError interrupt.

This restricts distribution of SGIs to the first 16 processors of an affinity 1 cluster.

Accessing the ICC_ASGI1R_EL1

To access the ICC_ASGI1R_EL1:

```
MSR ICC_ASGI1R_EL1, <Xt> ; Write Xt to ICC_ASGI1R_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1011	110

D7.6.10 ICC_BPR0_EL1, Interrupt Controller Binary Point Register 0

The ICC_BPR0_EL1 characteristics are:

Purpose

Defines the point at which the priority value fields split into two parts, the group priority field and the subpriority field. The group priority field is used to determine interrupt preemption.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_BPR0_EL1(S):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	-	-	RW

When accessed as ICC_BPR0_EL1(NS):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	-	RW	RW	-

In Secure state, this register is the binary point register for Group 0 interrupts. In Non-secure state, this is the BPR for Group 1 interrupts.

The minimum binary point value is IMPLEMENTATION DEFINED in the range:

- 0-3 if the implementation supports one Security state, and for the Secure copy of the register if the implementation supports two Security states.
- 1-4 for the Non-secure copy of the register.

An attempt to program the binary point field to a value less than the minimum value sets the field to the minimum value. On a reset, the binary point field is set to the minimum supported value.

Configurations

There are separate Secure and Non-secure instances of this register.

ICC_BPR0_EL1(S) is architecturally mapped to AArch32 register ICC_BPR0 (S).

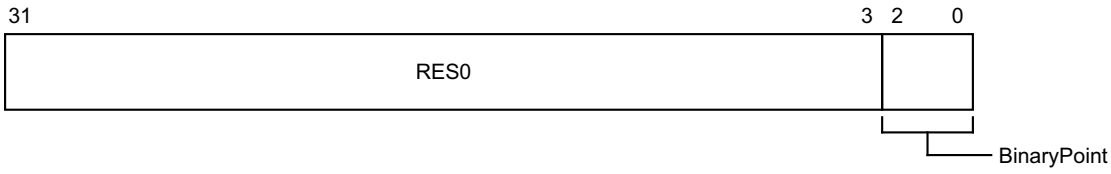
ICC_BPR0_EL1(NS) is architecturally mapped to AArch32 register ICC_BPR0 (NS).

Attributes

ICC_BPR0_EL1 is a 32-bit register.

Field descriptions

The ICC_BPR0_EL1 bit assignments are:



Bits [31:3]

Reserved, RES0.

BinaryPoint, bits [2:0]

The value of this field controls how the 8-bit interrupt priority field is split into a group priority field, used to determine interrupt preemption, and a subpriority field. This is done as follows:

Binary point value	Group priority field	Subpriority field	Field with binary point
0	[7:1]	[0]	ggggggg.s
1	[7:2]	[1:0]	gggggg.ss
2	[7:3]	[2:0]	ggggg.sss
3	[7:4]	[3:0]	gggg.ssss
4	[7:5]	[4:0]	ggg.sssss
5	[7:6]	[5:0]	gg.ssssss
6	[7]	[6:0]	g.sssssss
7	No preemption	[7:0]	.ssssssss

Accessing the ICC_BPR0_EL1

To access the ICC_BPR0_EL1:

```
MRS <Xt>, ICC_BPR0_EL1 ; Read ICC_BPR0_EL1 into Xt
MSR ICC_BPR0_EL1, <Xt> ; Write Xt to ICC_BPR0_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1000	011

D7.6.11 ICC_BPR1_EL1, Interrupt Controller Binary Point Register 1

The ICC_BPR1_EL1 characteristics are:

Purpose

Defines the point at which the priority value fields split into two parts, the group priority field and the subpriority field. The group priority field is used to determine Group 1 interrupt preemption.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

This register is an alias of the Non-secure view of ICC_BPR0_EL1, and a Secure access to this register is identical to a Non-secure access to ICC_BPR0_EL1.

The minimum binary point value is IMPLEMENTATION DEFINED in the range 1-4.

An attempt to program the binary point field to a value less than the minimum value sets the field to the minimum value. On a reset, the binary point field is set to the minimum supported value.

Configurations

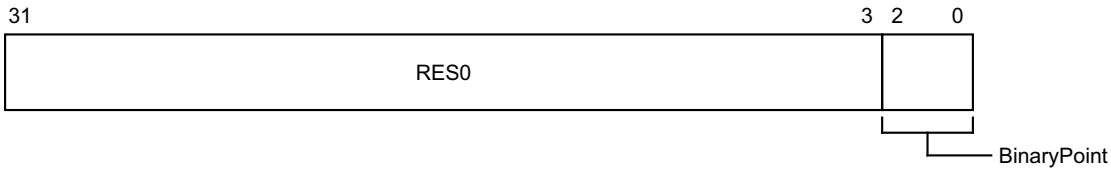
ICC_BPR1_EL1 is architecturally mapped to AArch32 register ICC_BPR1.

Attributes

ICC_BPR1_EL1 is a 32-bit register.

Field descriptions

The ICC_BPR1_EL1 bit assignments are:



Bits [31:3]

Reserved, RES0.

BinaryPoint, bits [2:0]

The value of this field controls how the 8-bit interrupt priority field is split into a group priority field, used to determine interrupt preemption, and a subpriority field. This is done as follows:

Binary point value	Group priority field	Subpriority field	Field with binary point
0	[7:1]	[0]	ggggggg.s
1	[7:2]	[1:0]	gggggg.ss
2	[7:3]	[2:0]	ggggg.sss

Binary point value	Group priority field	Subpriority field	Field with binary point
3	[7:4]	[3:0]	gggg.ssss
4	[7:5]	[4:0]	ggg.sssss
5	[7:6]	[5:0]	gg.ssssss
6	[7]	[6:0]	g.sssssss
7	No preemption	[7:0]	.ssssssss

Accessing the ICC_BPR1_EL1

To access the ICC_BPR1_EL1:

```
MRS <Xt>, ICC_BPR1_EL1 ; Read ICC_BPR1_EL1 into Xt
MSR ICC_BPR1_EL1, <Xt> ; Write Xt to ICC_BPR1_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1100	011

D7.6.12 ICC_CTLR_EL1, Interrupt Controller Control Register (EL1)

The ICC_CTLR_EL1 characteristics are:

Purpose

Controls aspects of the behavior of the GIC CPU interface and provides information about the features implemented.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_CTLR_EL1(S):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	-	-	RW

When accessed as ICC_CTLR_EL1(NS):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	-	RW	RW	-

Configurations

There are separate Secure and Non-secure instances of this register.

ICC_CTLR_EL1(S) is architecturally mapped to AArch32 register ICC_CTLR (S).

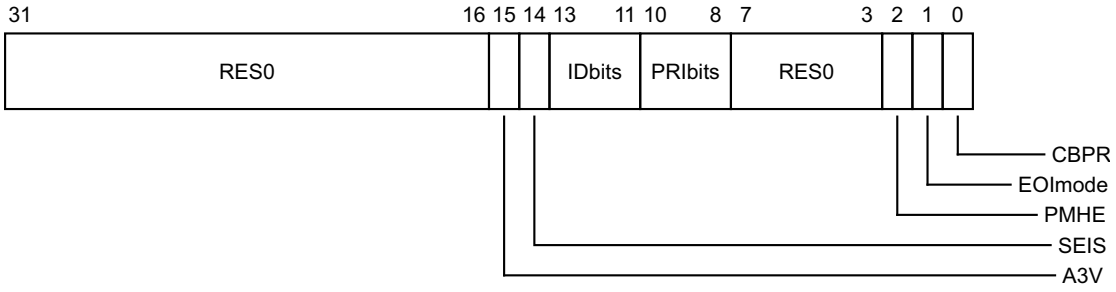
ICC_CTLR_EL1(NS) is architecturally mapped to AArch32 register ICC_CTLR (NS).

Attributes

ICC_CTLR_EL1 is a 32-bit register.

Field descriptions

The ICC_CTLR_EL1 bit assignments are:



Bits [31:16]

Reserved, RES0.

A3V, bit [15]

Affinity 3 Valid. Read-only. Possible values are:

0 The CPU interface logic only supports zero values of Affinity 3 in SGI generation system registers.

1 The CPU interface logic supports non-zero values of Affinity 3 in SGI generation system registers.

Virtual accesses return the value from ICH_VTR_EL2.A3V.

SEIS, bit [14]

SEI Support. Read-only. Indicates whether the CPU interface supports local generation of SEIs:

0 The CPU interface logic does not support local generation of SEIs by the CPU interface.

1 The CPU interface logic supports local generation of SEIs by the CPU interface.

Virtual accesses return the value from ICH_VTR_EL2.SEIS.

IDbits, bits [13:11]

The number of physical interrupt identifier bits supported:

000 16 bits.

001 24 bits.

All other values are reserved.

Virtual accesses return the value from ICH_VTR_EL2.IDbits.

Reset value is architecturally UNKNOWN.

PRIbits, bits [10:8]

The number of priority bits implemented, minus one. Read-only.

Virtual accesses return the value from ICH_VTR_EL2.PRIbits.

Bits [7:3]

Reserved, RES0.

PMHE, bit [2]

Priority Mask Hint Enable.

If EL3 is present and GICD_CTLR.DS == 0, this bit is a read-only alias of ICC_CTLR_EL3.PMHE.

If EL3 is present and GICD_CTLR.DS == 1, this bit is writable at EL1 and EL2.

Resets to 0.

EOImode, bit [1]

Alias of ICC_CTLR_EL3.EOImode_EL1{S,NS} as appropriate to the current Security state.

Virtual accesses modify ICH_VMCR_EL2.VEOIM.

Reset value is architecturally UNKNOWN.

CBPR, bit [0]

Common Binary Point Register.

If EL3 is present and GICD_CTLR.DS == 0, this bit is a read-only alias of ICC_CTLR_EL3.CBPR_EL1{S,NS} as appropriate.

If EL3 is not present, this field resets to zero.

If EL3 is present and GICD_CTLR.DS == 1, this bit is writable at EL1 and EL2.

Virtual accesses modify ICH_VMCR_EL2.VCBPR. An access is virtual when accessed at non-secure EL1 and either of FIQ or IRQ has been virtualized. That is, when (SCR_EL3.NS == '1' && (HCR_EL2.FMO == '1' || HCR_EL2.IMO == '1')).

Accessing the ICC_CTLR_EL1

To access the ICC_CTLR_EL1:

```
MRS <Xt>, ICC_CTLR_EL1 ; Read ICC_CTLR_EL1 into Xt
MSR ICC_CTLR_EL1, <Xt> ; Write Xt to ICC_CTLR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1100	100

D7.6.13 ICC_CTLR_EL3, Interrupt Controller Control Register (EL3)

The ICC_CTLR_EL3 characteristics are:

Purpose

Controls aspects of the behavior of the GIC CPU interface and provides information about the features implemented.

This register is part of:

- the GIC registers functional group
- the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

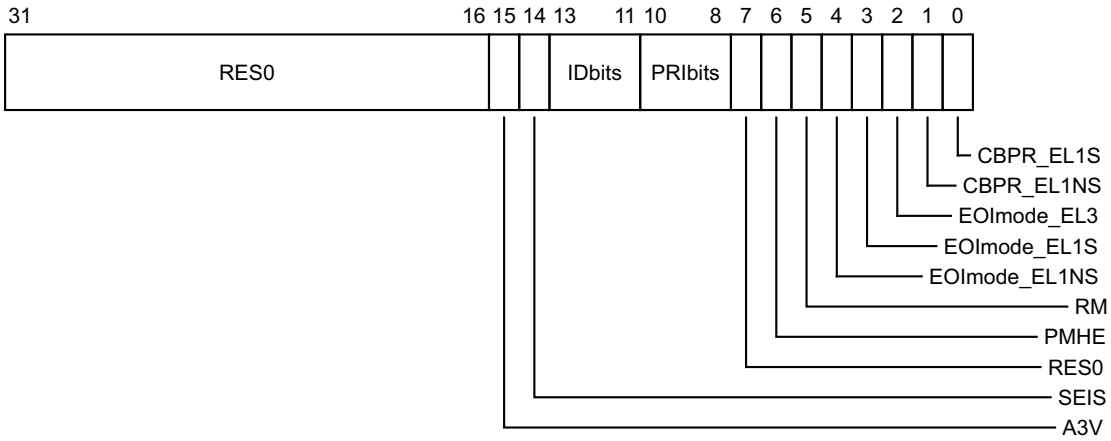
ICC_CTLR_EL3 is architecturally mapped to AArch32 register ICC_MCTLR.

Attributes

ICC_CTLR_EL3 is a 32-bit register.

Field descriptions

The ICC_CTLR_EL3 bit assignments are:



Bits [31:16]

Reserved, RES0.

A3V, bit [15]

Affinity 3 Valid. Read-only. Possible values are:

0 The CPU interface logic only supports zero values of Affinity 3 in SGI generation system registers.

1 The CPU interface logic supports non-zero values of Affinity 3 in SGI generation system registers.

Virtual accesses return the value from ICH_VTR_EL2.A3V.

SEIS, bit [14]

SEI Support. Read-only. Indicates whether the CPU interface supports generation of SEIs:

0 The CPU interface logic does not support generation of SEIs.

1 The CPU interface logic supports generation of SEIs.

Virtual accesses return the value from ICH_VTR_EL2.SEIS.

IDbits, bits [13:11]

The number of physical interrupt identifier bits supported:

000 16 bits.

001 24 bits.

All other values are reserved.

Reset value is architecturally UNKNOWN.

PRIbits, bits [10:8]

The number of priority bits implemented, minus one. Read-only.

Bit [7]

Reserved, RES0.

PMHE, bit [6]

Priority Mask Hint Enable.

When set, enables use of the PMR as a hint for interrupt distribution.

Resets to 0.

RM, bit [5]

Routing Modifier. This bit is used to modify the behavior of ICC_IAR0_EL1 and ICC_IAR1_EL1 such that systems with legacy secure software may be supported correctly.

0 Reading ICC_IAR0_EL1 and ICC_IAR1_EL1 at EL3 acknowledges interrupts normally.

1 Reading ICC_IAR0_EL1 and ICC_IAR1_EL1 at EL3 returns special values:

- Reading ICC_IAR0_EL1 at EL3 returns ID 1020, indicating the interrupt should be handled at Secure EL1.
- Reading ICC_IAR1_EL1 at EL3 returns ID 1021, indicating the interrupt should be handled at Non-secure EL1 or EL2.

Reset value is architecturally UNKNOWN.

EOImode_EL1NS, bit [4]

EOI mode for interrupts handled at non-secure EL1 and EL2.

Reset value is architecturally UNKNOWN.

EOImode_EL1S, bit [3]

EOI mode for interrupts handled at secure EL1.

Reset value is architecturally UNKNOWN.

EOImode_EL3, bit [2]

EOI mode for interrupts handled at EL3.

Reset value is architecturally UNKNOWN.

CBPR_EL1NS, bit [1]

When set, non-secure accesses to GICC_BPR and ICC_BPR1_EL1 access the state of ICC_BPR0_EL1. ICC_BPR0_EL1 is used to determine the preemption group for Non-secure Group 1 interrupts.

Reset value is architecturally UNKNOWN.

CBPR_EL1S, bit [0]

When set, secure EL1 accesses to ICC_BPR1_EL1 access the state of ICC_BPR0_EL1. ICC_BPR0_EL1 is used to determine the preemption group for Secure Group 1 interrupts.

Reset value is architecturally UNKNOWN.

Accessing the ICC_CTLR_EL3

To access the ICC_CTLR_EL3:

```
MRS <Xt>, ICC_CTLR_EL3 ; Read ICC_CTLR_EL3 into Xt
MSR ICC_CTLR_EL3, <Xt> ; Write Xt to ICC_CTLR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	1100	1100	100

D7.6.14 ICC_DIR_EL1, Interrupt Controller Deactivate Interrupt Register

The ICC_DIR_EL1 characteristics are:

Purpose

When interrupt priority drop is separated from interrupt deactivation, a write to this register deactivates the specified interrupt.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

Configurations

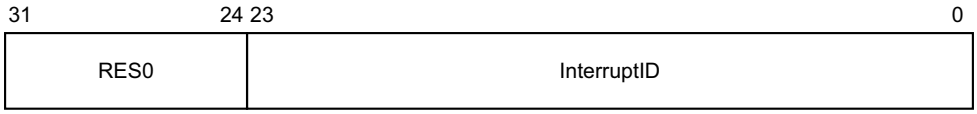
ICC_DIR_EL1 is architecturally mapped to AArch32 register ICC_DIR.

Attributes

ICC_DIR_EL1 is a 32-bit register.

Field descriptions

The ICC_DIR_EL1 bit assignments are:



Bits [31:24]

Reserved, RES0.

InterruptID, bits [23:0]

The interrupt ID.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_DIR_EL1

To access the ICC_DIR_EL1:

```
MSR ICC_DIR_EL1, <Xt> ; Write Xt to ICC_DIR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1011	001

D7.6.15 ICC_EOIR0_EL1, Interrupt Controller End Of Interrupt Register 0

The ICC_EOIR0_EL1 characteristics are:

Purpose

A processor writes to this register to inform the CPU interface that it has completed the processing of the specified interrupt.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_EOIR0_EL1(S):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	-	-	WO

When accessed as ICC_EOIR0_EL1(NS):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
WO	-	WO	WO	-

A write to this register must correspond to the most recent valid read from an Interrupt Acknowledge Register. A valid read is a read that returns a valid interrupt ID, that is not a spurious interrupt ID.

Configurations

There are separate Secure and Non-secure instances of this register.

ICC_EOIR0_EL1(S) is architecturally mapped to AArch32 register ICC_EOIR0 (S).

ICC_EOIR0_EL1(NS) is architecturally mapped to AArch32 register ICC_EOIR0 (NS).

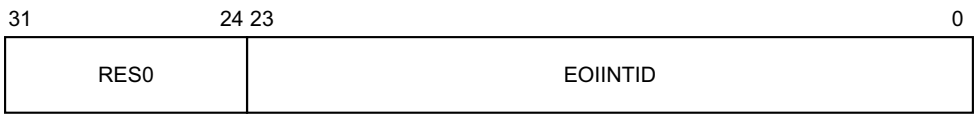
In Secure state, this register is the end of interrupt register for Group 0 interrupts. In Non-secure state, this is the EOIR for Group 1 interrupts.

Attributes

ICC_EOIR0_EL1 is a 32-bit register.

Field descriptions

The ICC_EOIR0_EL1 bit assignments are:



Bits [31:24]

Reserved, RES0.

EOIINTID, bits [23:0]

The InterruptID value from the corresponding GICC_IAR access.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_EOIR0_EL1

To access the ICC_EOIR0_EL1:

```
MSR ICC_EOIR0_EL1, <Xt> ; Write Xt to ICC_EOIR0_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1000	001

D7.6.16 ICC_EOIR1_EL1, Interrupt Controller End Of Interrupt Register 1

The ICC_EOIR1_EL1 characteristics are:

Purpose

A processor writes to this register to inform the CPU interface that it has completed the processing of the specified Group 1 interrupt.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

A write to this register must correspond to the most recent valid read from an Interrupt Acknowledge Register. A valid read is a read that returns a valid interrupt ID, that is not a spurious interrupt ID.

Configurations

ICC_EOIR1_EL1 is architecturally mapped to AArch32 register ICC_EOIR1.

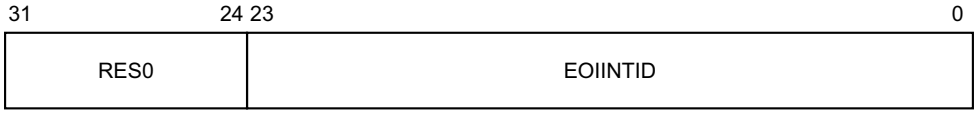
This register is an alias of the Non-secure view of ICC_EOIR0_EL1, and a Secure access to this register is identical to a Non-secure access to ICC_EOIR0_EL1.

Attributes

ICC_EOIR1_EL1 is a 32-bit register.

Field descriptions

The ICC_EOIR1_EL1 bit assignments are:



Bits [31:24]

Reserved, RES0.

EOIINTID, bits [23:0]

The InterruptID value from the corresponding GICC_IAR access.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_EOIR1_EL1

To access the ICC_EOIR1_EL1:

```
MSR ICC_EOIR1_EL1, <Xt> ; Write Xt to ICC_EOIR1_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1100	001

D7.6.17 ICC_HPPIR0_EL1, Interrupt Controller Highest Priority Pending Interrupt Register 0

The ICC_HPPIR0_EL1 characteristics are:

Purpose

Indicates the Interrupt ID, and processor ID if appropriate, of the highest priority pending interrupt on the CPU interface.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_HPPIR0_EL1(S):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	-	-	RO

When accessed as ICC_HPPIR0_EL1(NS):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RO	-	RO	RO	-

Configurations

There are separate Secure and Non-secure instances of this register.

ICC_HPPIR0_EL1(S) is architecturally mapped to AArch32 register ICC_HPPIR0 (S).

ICC_HPPIR0_EL1(NS) is architecturally mapped to AArch32 register ICC_HPPIR0 (NS).

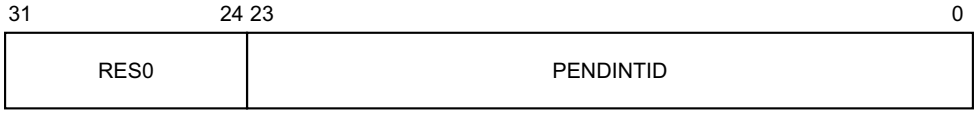
In Secure state, this register is the highest priority pending interrupt register for Group 0 interrupts. In Non-secure state, this is the HPPIR for Group 1 interrupts.

Attributes

ICC_HPPIR0_EL1 is a 32-bit register.

Field descriptions

The ICC_HPPIR0_EL1 bit assignments are:



Bits [31:24]

Reserved, RES0.

PENDINTID, bits [23:0]

The interrupt ID of the highest priority pending interrupt.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_HPPIR0_EL1

To access the ICC_HPPIR0_EL1:

```
MRS <Xt>, ICC_HPPIR0_EL1 ; Read ICC_HPPIR0_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1000	010

D7.6.18 ICC_HPPIR1_EL1, Interrupt Controller Highest Priority Pending Interrupt Register 1

The ICC_HPPIR1_EL1 characteristics are:

Purpose

If the highest priority pending interrupt on the CPU interface is a Group 1 interrupt, returns the interrupt ID of that interrupt. Otherwise, returns a spurious interrupt ID of 1023.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ICC_HPPIR1_EL1 is architecturally mapped to AArch32 register ICC_HPPIR1.

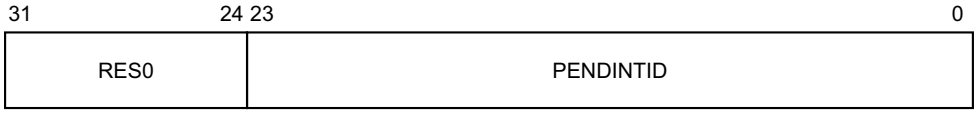
This register is an alias of the Non-secure view of ICC_HPPIR0_EL1, and a Secure access to this register is identical to a Non-secure access to ICC_HPPIR0_EL1.

Attributes

ICC_HPPIR1_EL1 is a 32-bit register.

Field descriptions

The ICC_HPPIR1_EL1 bit assignments are:



Bits [31:24]

Reserved, RES0.

PENDINTID, bits [23:0]

The interrupt ID of the highest priority pending interrupt.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_HPPIR1_EL1

To access the ICC_HPPIR1_EL1:

```
MRS <Xt>, ICC_HPPIR1_EL1 ; Read ICC_HPPIR1_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1100	010

D7.6.19 ICC_IAR0_EL1, Interrupt Controller Interrupt Acknowledge Register 0

The ICC_IAR0_EL1 characteristics are:

Purpose

The processor reads this register to obtain the interrupt ID of the signaled interrupt. This read acts as an acknowledge for the interrupt.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_IAR0_EL1(S):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	-	-	RO

When accessed as ICC_IAR0_EL1(NS):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RO	-	RO	RO	-

Configurations

There are separate Secure and Non-secure instances of this register.

ICC_IAR0_EL1(S) is architecturally mapped to AArch32 register ICC_IAR0 (S).

ICC_IAR0_EL1(NS) is architecturally mapped to AArch32 register ICC_IAR0 (NS).

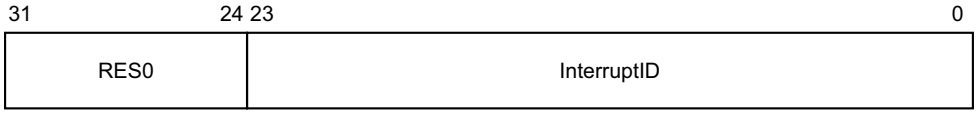
In Secure state, this register is the interrupt acknowledge register for Group 0 interrupts. In Non-secure state, this is the IAR for Group 1 interrupts.

Attributes

ICC_IAR0_EL1 is a 32-bit register.

Field descriptions

The ICC_IAR0_EL1 bit assignments are:



Bits [31:24]

Reserved, RES0.

InterruptID, bits [23:0]

The ID of the signaled interrupt. IDs 1020 to 1023 are reserved and convey additional information such as spurious interrupts.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_IAR0_EL1

To access the ICC_IAR0_EL1:

```
MRS <Xt>, ICC_IAR0_EL1 ; Read ICC_IAR0_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1000	000

D7.6.20 ICC_IAR1_EL1, Interrupt Controller Interrupt Acknowledge Register 1

The ICC_IAR1_EL1 characteristics are:

Purpose

The processor reads this register to obtain the interrupt ID of the signaled Group 1 interrupt. This read acts as an acknowledge for the interrupt.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

Configurations

ICC_IAR1_EL1 is architecturally mapped to AArch32 register ICC_IAR1.

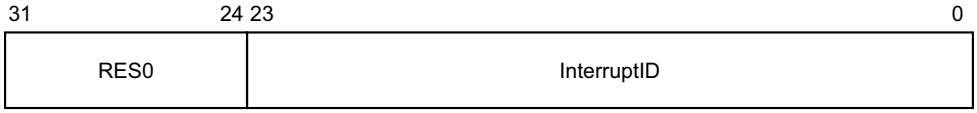
This register is an alias of the Non-secure view of ICC_IAR0_EL1, and a Secure access to this register is identical to a Non-secure access to ICC_IAR0_EL1.

Attributes

ICC_IAR1_EL1 is a 32-bit register.

Field descriptions

The ICC_IAR1_EL1 bit assignments are:



Bits [31:24]

Reserved, RES0.

InterruptID, bits [23:0]

The ID of the signaled interrupt. IDs 1020 to 1023 are reserved and convey additional information such as spurious interrupts.

This field has either 16 or 24 bits implemented. The number of implemented bits can be found in ICC_CTLR_EL1.IDbits and ICC_CTLR_EL3.IDbits. If only 16 bits are implemented, bits [23:16] of this register are RES0.

Accessing the ICC_IAR1_EL1

To access the ICC_IAR1_EL1:

```
MRS <Xt>, ICC_IAR1_EL1 ; Read ICC_IAR1_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1100	000

D7.6.21 ICC_IGRPEN0_EL1, Interrupt Controller Interrupt Group 0 Enable register

The ICC_IGRPEN0_EL1 characteristics are:

Purpose

Controls whether Group 0 interrupts are enabled or not.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_IGRPEN0_EL1(S):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	-	-	RW

When accessed as ICC_IGRPEN0_EL1(NS):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	-	RW	RW	-

The lowest exception level at which this register may be accessed is governed by the exception level to which FIQ is routed. This routing depends on SCR_EL3.FIQ, SCR_EL3.NS and HCR_EL2.FMO.

If an interrupt is pending within the CPU interface when Enable becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different processor.

Configurations

There are separate Secure and Non-secure instances of this register.

ICC_IGRPEN0_EL1(S) is architecturally mapped to AArch32 register ICC_IGRPEN0 (S).

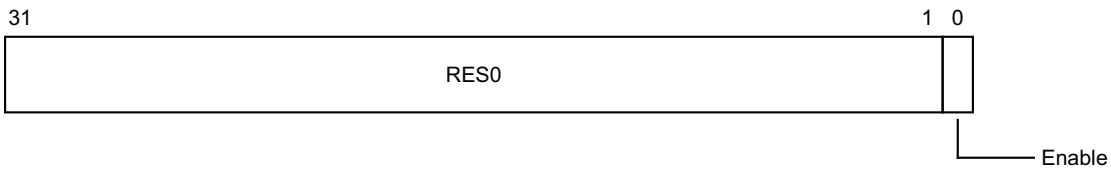
ICC_IGRPEN0_EL1(NS) is architecturally mapped to AArch32 register ICC_IGRPEN0 (NS).

Attributes

ICC_IGRPEN0_EL1 is a 32-bit register.

Field descriptions

The ICC_IGRPEN0_EL1 bit assignments are:



Bits [31:1]

Reserved, RES0.

Enable, bit [0]

Enables Group 0 interrupts.

0 Group 0 interrupts are disabled.

1 Group 0 interrupts are enabled.

Virtual accesses to this register update ICH_VMCR_EL2.VENG0.

Resets to 0.

Accessing the ICC_IGRPEN0_EL1

To access the ICC_IGRPEN0_EL1:

```
MRS <Xt>, ICC_IGRPEN0_EL1 ; Read ICC_IGRPEN0_EL1 into Xt
MSR ICC_IGRPEN0_EL1, <Xt> ; Write Xt to ICC_IGRPEN0_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1100	110

D7.6.22 ICC_IGRPEN1_EL1, Interrupt Controller Interrupt Group 1 Enable register

The ICC_IGRPEN1_EL1 characteristics are:

Purpose

Controls whether Group 1 interrupts are enabled for the current Security state.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

The lowest exception level at which this register may be accessed is governed by the exception level to which FIQ is routed. This routing depends on SCR_EL3.FIQ, SCR_EL3.NS and HCR_EL2.FMO.

If an interrupt is pending within the CPU interface when Enable becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different processor.

Configurations

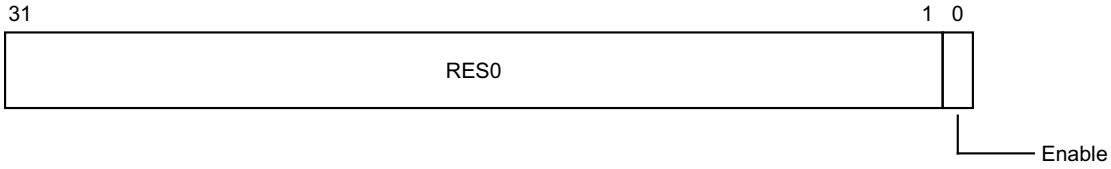
ICC_IGRPEN1_EL1 is architecturally mapped to AArch32 register ICC_IGRPEN1.

Attributes

ICC_IGRPEN1_EL1 is a 32-bit register.

Field descriptions

The ICC_IGRPEN1_EL1 bit assignments are:



Bits [31:1]

Reserved, RES0.

Enable, bit [0]

Enables Group 1 interrupts for the current Security state.

0 Group 1 interrupts are disabled for the current Security state.

1 Group 1 interrupts are enabled for the current Security state.

Virtual accesses to this register update ICH_VMCR_EL2.VENG1.

When this register is accessed at EL3, the copy of this register appropriate to the current setting of SCR_EL3.NS is accessed.

Resets to 0.

Accessing the ICC_IGRPEN1_EL1

To access the ICC_IGRPEN1_EL1:

```
MRS <Xt>, ICC_IGRPEN1_EL1 ; Read ICC_IGRPEN1_EL1 into Xt
MSR ICC_IGRPEN1_EL1, <Xt> ; Write Xt to ICC_IGRPEN1_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1100	111

D7.6.23 ICC_IGRPEN1_EL3, Interrupt Controller Interrupt Group 1 Enable register (EL3)

The ICC_IGRPEN1_EL3 characteristics are:

Purpose

Controls whether Group 1 interrupts are enabled or not.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

If an interrupt is pending within the CPU interface when an Enable bit becomes 0, the interrupt must be released to allow the Distributor to forward the interrupt to a different processor.

Configurations

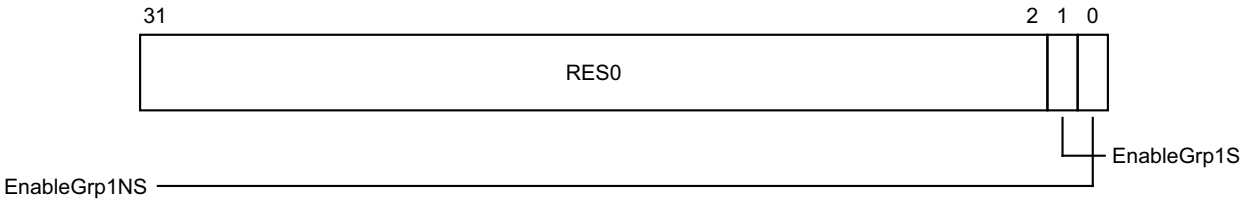
ICC_IGRPEN1_EL3 is architecturally mapped to AArch32 register ICC_MGRPEN1.

Attributes

ICC_IGRPEN1_EL3 is a 32-bit register.

Field descriptions

The ICC_IGRPEN1_EL3 bit assignments are:



Bits [31:2]

Reserved, RES0.

EnableGrp1S, bit [1]

Enables Group 1 interrupts for the Secure state.

0 Group 1 interrupts are disabled for the Secure state.

1 Group 1 interrupts are enabled for the Secure state.

Resets to 0.

EnableGrp1NS, bit [0]

Enables Group 1 interrupts for the Non-secure state.

0 Group 1 interrupts are disabled for the Non-secure state.

1 Group 1 interrupts are enabled for the Non-secure state.

Resets to 0.

Accessing the ICC_IGRPEN1_EL3

To access the ICC_IGRPEN1_EL3:

```
MRS <Xt>, ICC_IGRPEN1_EL3 ; Read ICC_IGRPEN1_EL3 into Xt
MSR ICC_IGRPEN1_EL3, <Xt> ; Write Xt to ICC_IGRPEN1_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	1100	1100	111

D7.6.24 ICC_PMR_EL1, Interrupt Controller Interrupt Priority Mask Register

The ICC_PMR_EL1 characteristics are:

Purpose

Provides an interrupt priority filter. Only interrupts with higher priority than the value in this register are signaled to the processor.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

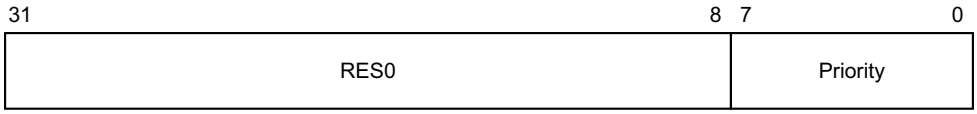
ICC_PMR_EL1 is architecturally mapped to AArch32 register ICC_PMR.

Attributes

ICC_PMR_EL1 is a 32-bit register.

Field descriptions

The ICC_PMR_EL1 bit assignments are:



Bits [31:8]

Reserved, RES0.

Priority, bits [7:0]

The priority mask level for the CPU interface. If the priority of an interrupt is higher than the value indicated by this field, the interface signals the interrupt to the processor.

If the GIC supports fewer than 256 priority levels then some bits are RAZ/WI, as follows:

`128 supported levels`Bit [0] = 0.

`64 supported levels`Bits [1:0] = `0b00`.

`32 supported levels`Bits [2:0] = `0b000`.

`16 supported levels`Bits [3:0] = `0b0000`.

The possible priority field values are as follows:

Implemented priority bits	Possible priority field values	Number of priority levels
[7:0]	`0x00-0xFF` (0-255), all values	256
[7:1]	`0x00-0xFE` (0-254), even values only	128

Implemented priority bits	Possible priority field values	Number of priority levels
[7:2]	0x00-0xFC (0-252), in steps of 4	64
[7:3]	0x00-0xF8 (0-248), in steps of 8	32
[7:4]	0x00-0xF0 (0-240), in steps of 16	16

Accessing the ICC_PMR_EL1

To access the ICC_PMR_EL1:

```
MRS <Xt>, ICC_PMR_EL1 ; Read ICC_PMR_EL1 into Xt
MSR ICC_PMR_EL1, <Xt> ; Write Xt to ICC_PMR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0100	0110	000

D7.6.25 ICC_RPR_EL1, Interrupt Controller Running Priority Register

The ICC_RPR_EL1 characteristics are:

Purpose

Indicates the Running priority of the CPU interface.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

If there is no active interrupt on the CPU interface, the value returned is the Idle priority.

Software cannot determine the number of implemented priority bits from a read of this register.

Configurations

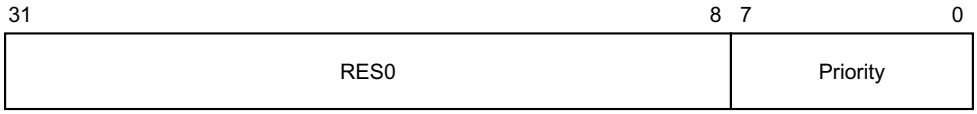
ICC_RPR_EL1 is architecturally mapped to AArch32 register ICC_RPR.

Attributes

ICC_RPR_EL1 is a 32-bit register.

Field descriptions

The ICC_RPR_EL1 bit assignments are:



Bits [31:8]

Reserved, RES0.

Priority, bits [7:0]

The current running priority on the CPU interface. This is the priority of the current active interrupt.

Accessing the ICC_RPR_EL1

To access the ICC_RPR_EL1:

```
MRS <Xt>, ICC_RPR_EL1 ; Read ICC_RPR_EL1 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1011	011

D7.6.26 ICC_SEIEN_EL1, Interrupt Controller System Error Interrupt Enable register

The ICC_SEIEN_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED controls for SError Interrupts generated by bus message.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

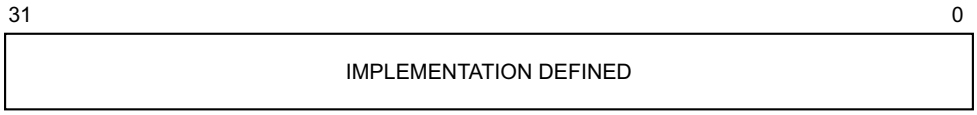
ICC_SEIEN_EL1 is architecturally mapped to AArch32 register ICC_SEIEN.

Attributes

ICC_SEIEN_EL1 is a 32-bit register.

Field descriptions

The ICC_SEIEN_EL1 bit assignments are:



Accessing the ICC_SEIEN_EL1

To access the ICC_SEIEN_EL1:

```
MRS <Xt>, ICC_SEIEN_EL1 ; Read ICC_SEIEN_EL1 into Xt
MSR ICC_SEIEN_EL1, <Xt> ; Write Xt to ICC_SEIEN_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1101	000

D7.6.27 ICC_SGI0R_EL1, Interrupt Controller Software Generated Interrupt group 0 Register

The ICC_SGI0R_EL1 characteristics are:

Purpose

Provides software the ability to generate secure group 0 SGIs, including from the Non-secure state when permitted by GICR_NSACR.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

Configurations

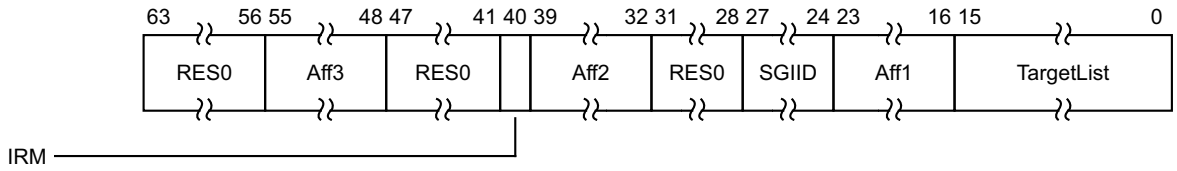
ICC_SGI0R_EL1 is architecturally mapped to AArch32 register ICC_SGI0R.

Attributes

ICC_SGI0R_EL1 is a 64-bit register.

Field descriptions

The ICC_SGI0R_EL1 bit assignments are:



Bits [63:56]

Reserved, RES0.

Aff3, bits [55:48]

The affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [47:41]

Reserved, RES0.

IRM, bit [40]

Interrupt Routing Mode. Determines how the generated interrupts should be distributed to processors. Possible values are:

`0` Interrupts routed to the processors specified by a.b.c.{target list}. In this routing, a, b, and c are the values of fields Aff3, Aff2, and Aff1 respectively.

`1` Interrupts routed to all processors in the system, excluding self.

Aff2, bits [39:32]

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [31:28]

Reserved, RES0.

SGIID, bits [27:24]

SGI Interrupt ID.

Aff1, bits [23:16]

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated.

TargetList, bits [15:0]

Target List. The set of processors for which SGI interrupts will be generated. Each bit corresponds to the processor within a cluster with an Affinity 0 value equal to the bit number.

If a bit is 1 and the bit does not correspond to a valid target processor, the bit must be ignored by the Distributor. In such cases, a Distributor may optionally generate an SError interrupt.

This restricts distribution of SGIs to the first 16 processors of an affinity 1 cluster.

Accessing the ICC_SGI0R_EL1

To access the ICC_SGI0R_EL1:

```
MSR ICC_SGI0R_EL1, <Xt> ; Write Xt to ICC_SGI0R_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1011	111

D7.6.28 ICC_SGI1R_EL1, Interrupt Controller Software Generated Interrupt group 1 Register

The ICC_SGI1R_EL1 characteristics are:

Purpose

Provides software the ability to generate group 1 SGIs for the current Security state.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_SGI1R_EL1(S):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	-	-	WO

When accessed as ICC_SGI1R_EL1(NS):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
WO	-	WO	WO	-

Configurations

There are separate Secure and Non-secure instances of this register.

ICC_SGI1R_EL1(S) is architecturally mapped to AArch32 register ICC_SGI1R (S).

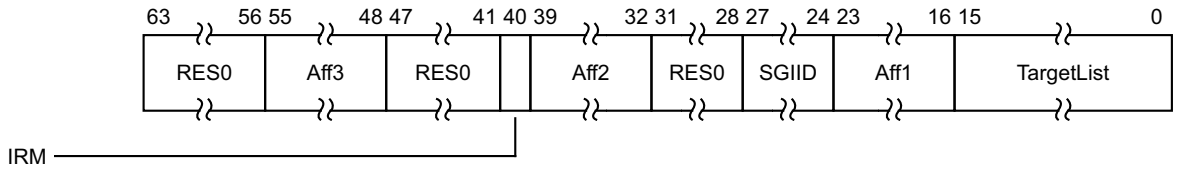
ICC_SGI1R_EL1(NS) is architecturally mapped to AArch32 register ICC_SGI1R (NS).

Attributes

ICC_SGI1R_EL1 is a 64-bit register.

Field descriptions

The ICC_SGI1R_EL1 bit assignments are:



Bits [63:56]

Reserved, RES0.

Aff3, bits [55:48]

The affinity 3 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [47:41]

Reserved, RES0.

IRM, bit [40]

Interrupt Routing Mode. Determines how the generated interrupts should be distributed to processors. Possible values are:

`0` Interrupts routed to the processors specified by a.b.c.{target list}. In this routing, a, b, and c are the values of fields Aff3, Aff2, and Aff1 respectively.

`1` Interrupts routed to all processors in the system, excluding self.

Aff2, bits [39:32]

The affinity 2 value of the affinity path of the cluster for which SGI interrupts will be generated.

Bits [31:28]

Reserved, RES0.

SGIID, bits [27:24]

SGI Interrupt ID.

Aff1, bits [23:16]

The affinity 1 value of the affinity path of the cluster for which SGI interrupts will be generated.

TargetList, bits [15:0]

Target List. The set of processors for which SGI interrupts will be generated. Each bit corresponds to the processor within a cluster with an Affinity 0 value equal to the bit number.

If a bit is 1 and the bit does not correspond to a valid target processor, the bit must be ignored by the Distributor. In such cases, a Distributor may optionally generate an SError interrupt.

This restricts distribution of SGIs to the first 16 processors of an affinity 1 cluster.

Accessing the ICC_SGI1R_EL1

To access the ICC_SGI1R_EL1:

```
MSR ICC_SGI1R_EL1, <Xt> ; Write Xt to ICC_SGI1R_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1011	101

D7.6.29 ICC_SRE_EL1, Interrupt Controller System Register Enable register (EL1)

The ICC_SRE_EL1 characteristics are:

Purpose

Controls whether the system register interface or the memory mapped interface to the GIC CPU interface is used for EL0 and EL1.

This register is part of the GIC registers functional group.

Usage constraints

This register is accessible as shown below:

When accessed as ICC_SRE_EL1(S):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	-	-	RW

When accessed as ICC_SRE_EL1(NS):

EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	-	RW	RW	-

Configurations

There are separate Secure and Non-secure instances of this register.

ICC_SRE_EL1(S) is architecturally mapped to AArch32 register ICC_SRE (S).

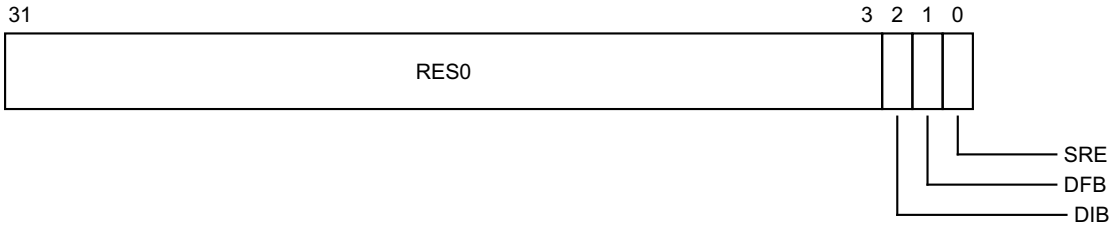
ICC_SRE_EL1(NS) is architecturally mapped to AArch32 register ICC_SRE (NS).

Attributes

ICC_SRE_EL1 is a 32-bit register.

Field descriptions

The ICC_SRE_EL1 bit assignments are:



Bits [31:3]

Reserved, RES0.

DIB, bit [2]

Disable IRQ bypass.

If EL3 is present, this field is a read-only alias of ICC_SRE_EL3.DIB.

If EL3 is not present and EL2 is present, this field is a read-only alias of ICC_SRE_EL2.DIB.

Resets to 0.

DFB, bit [1]

Disable FIQ bypass.

If EL3 is present, this field is a read-only alias of ICC_SRE_EL3.DFB.

If EL3 is not present and EL2 is present, this field is a read-only alias of ICC_SRE_EL2.DFB.

Resets to 0.

SRE, bit [0]

System Register Enable.

0 The memory mapped interface must be used. Access at EL1 to any ICC_* system register other than ICC_SRE_EL1 results in an Undefined exception.

1 The system register interface for the current Security state is enabled.

Virtual accesses modify ICH_VMCR_EL2.VSRE.

Resets to 0.

Accessing the ICC_SRE_EL1

To access the ICC_SRE_EL1:

```
MRS <Xt>, ICC_SRE_EL1 ; Read ICC_SRE_EL1 into Xt
MSR ICC_SRE_EL1, <Xt> ; Write Xt to ICC_SRE_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	1100	1100	101

D7.6.30 ICC_SRE_EL2, Interrupt Controller System Register Enable register (EL2)

The ICC_SRE_EL2 characteristics are:

Purpose

Controls whether the system register interface or the memory mapped interface to the GIC CPU interface is used for EL2.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	-

If EL3 is present and ICC_SRE_EL3.Enable is 0, EL2 accesses to this register will trap to EL3.

Configurations

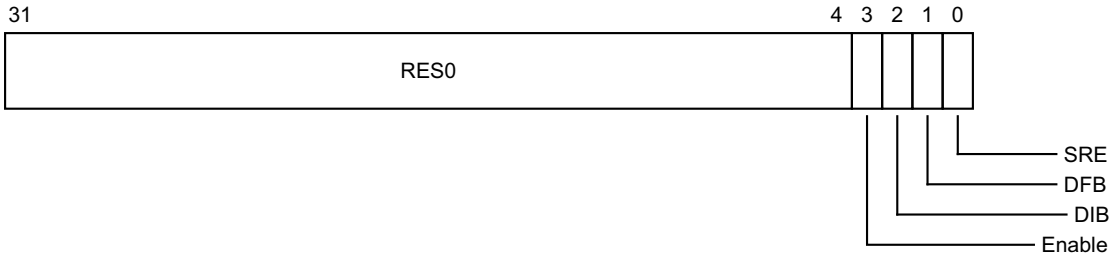
ICC_SRE_EL2 is architecturally mapped to AArch32 register ICC_HSRE.

Attributes

ICC_SRE_EL2 is a 32-bit register.

Field descriptions

The ICC_SRE_EL2 bit assignments are:



Bits [31:4]

Reserved, RES0.

Enable, bit [3]

Enable. Enables lower exception level access to ICC_SRE_EL1.

0 Non-secure EL1 accesses to ICC_SRE_EL1 trap to EL2.

1 Non-secure EL1 accesses to ICC_SRE_EL1 are permitted if EL3 is not present or ICC_SRE_EL3.Enable is 1, otherwise Non-secure EL1 accesses to ICC_SRE_EL1 trap to EL3.

Resets to 0.

DIB, bit [2]

Disable IRQ bypass.

If EL3 is present and GICD_CTLR.DS is 0, this field is a read-only alias of ICC_SRE_EL3.DIB.

Resets to 0.

DFB, bit [1]

Disable FIQ bypass.

If EL3 is present and GICD_CTLR.DS is 0, this field is a read-only alias of ICC_SRE_EL3.DFB.

Resets to 0.

Accessing the ICC_SRE_EL2

To access the ICC_SRE_EL2:

```
MRS <Xt>, ICC_SRE_EL2 ; Read ICC_SRE_EL2 into Xt
MSR ICC_SRE_EL2, <Xt> ; Write Xt to ICC_SRE_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1001	101

D7.6.31 ICC_SRE_EL3, Interrupt Controller System Register Enable register (EL3)

The ICC_SRE_EL3 characteristics are:

Purpose

Controls whether the system register interface or the memory mapped interface to the GIC CPU interface is used for EL2.

This register is part of:

- the GIC registers functional group
- the Security registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

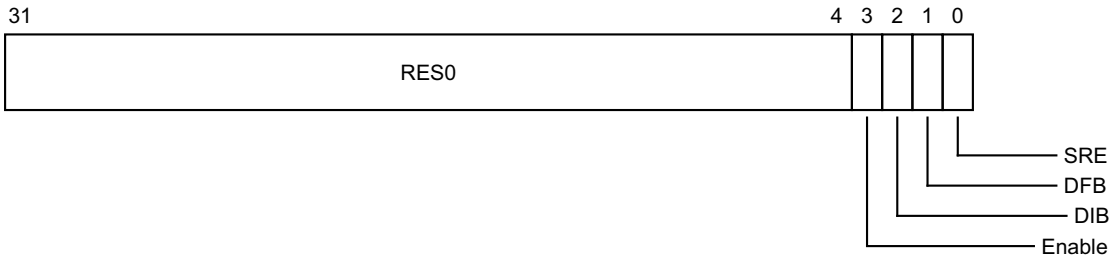
ICC_SRE_EL3 is architecturally mapped to AArch32 register ICC_MSRE.

Attributes

ICC_SRE_EL3 is a 32-bit register.

Field descriptions

The ICC_SRE_EL3 bit assignments are:



Bits [31:4]

Reserved, RES0.

Enable, bit [3]

Enable. Enables lower exception level access to ICC_SRE_EL1 and ICC_SRE_EL2.

0 EL1 and EL2 accesses to ICC_SRE_EL1 or ICC_SRE_EL2 trap to EL3.

1 EL2 accesses to ICC_SRE_EL2 are permitted. If the Enable bit of ICC_SRE_EL2 is 1, then EL1 accesses to ICC_SRE_EL1 are also permitted.

Resets to 0.

DIB, bit [2]

Disable IRQ bypass.

Resets to 0.

DFB, bit [1]

Disable FIQ bypass.

Resets to 0.

SRE, bit [0]

System Register Enable.

0 The memory mapped interface must be used. Access at EL3 to any ICH_* system register, or any EL1, EL2, or EL3 ICC_* register other than ICC_SRE_EL1, ICC_SRE_EL2, or ICC_SRE_EL3, results in an Undefined exception.

1 The system register interface to the ICH_* registers and the EL1, EL2, and EL3 ICC_* registers is enabled for EL3.

Resets to 0.

Accessing the ICC_SRE_EL3

To access the ICC_SRE_EL3:

```
MRS <Xt>, ICC_SRE_EL3 ; Read ICC_SRE_EL3 into Xt
MSR ICC_SRE_EL3, <Xt> ; Write Xt to ICC_SRE_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	1100	1100	101

D7.6.32 ICH_AP0R0_EL2, Interrupt Controller Hyp Active Priorities Register (0,0)

The ICH_AP0R0_EL2 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

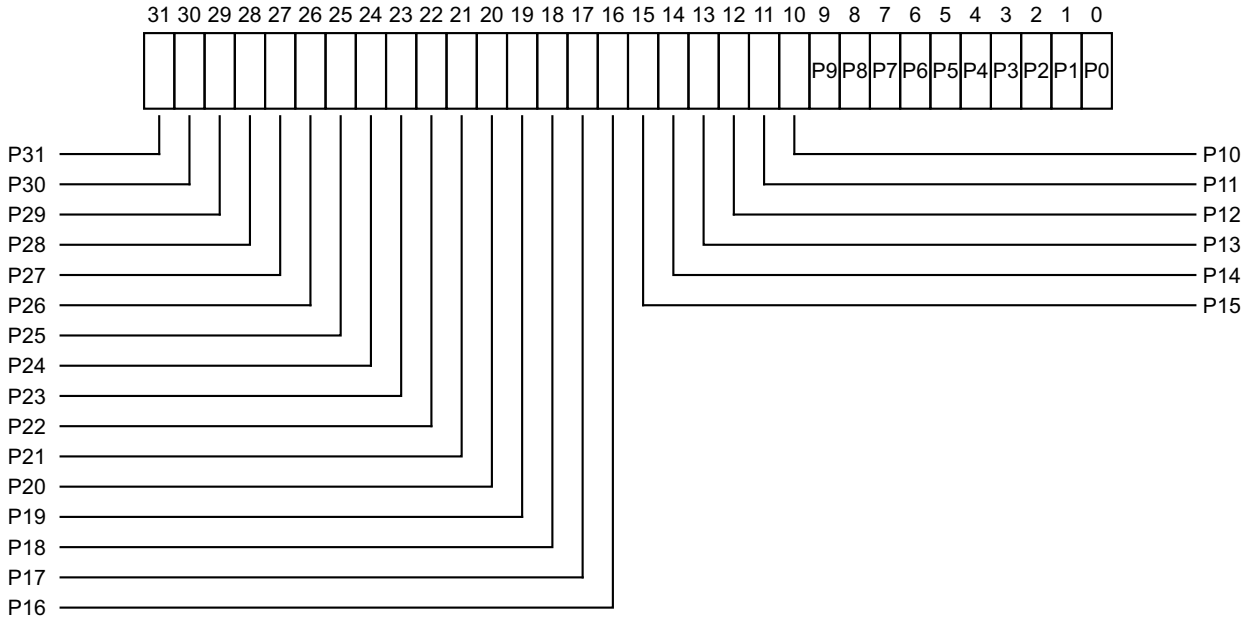
ICH_AP0R0_EL2 is architecturally mapped to AArch32 register ICH_AP0R0.

Attributes

ICH_AP0R0_EL2 is a 32-bit register.

Field descriptions

The ICH_AP0R0_EL2 bit assignments are:



P<n>, bit [n], for n = 0 to 31

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP0R0_EL2

To access the ICH_AP0R0_EL2:

```
MRS <Xt>, ICH_AP0R0_EL2 ; Read ICH_AP0R0_EL2 into Xt
MSR ICH_AP0R0_EL2, <Xt> ; Write Xt to ICH_AP0R0_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1000	000

D7.6.33 ICH_AP0R1_EL2, Interrupt Controller Hyp Active Priorities Register (0,1)

The ICH_AP0R1_EL2 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

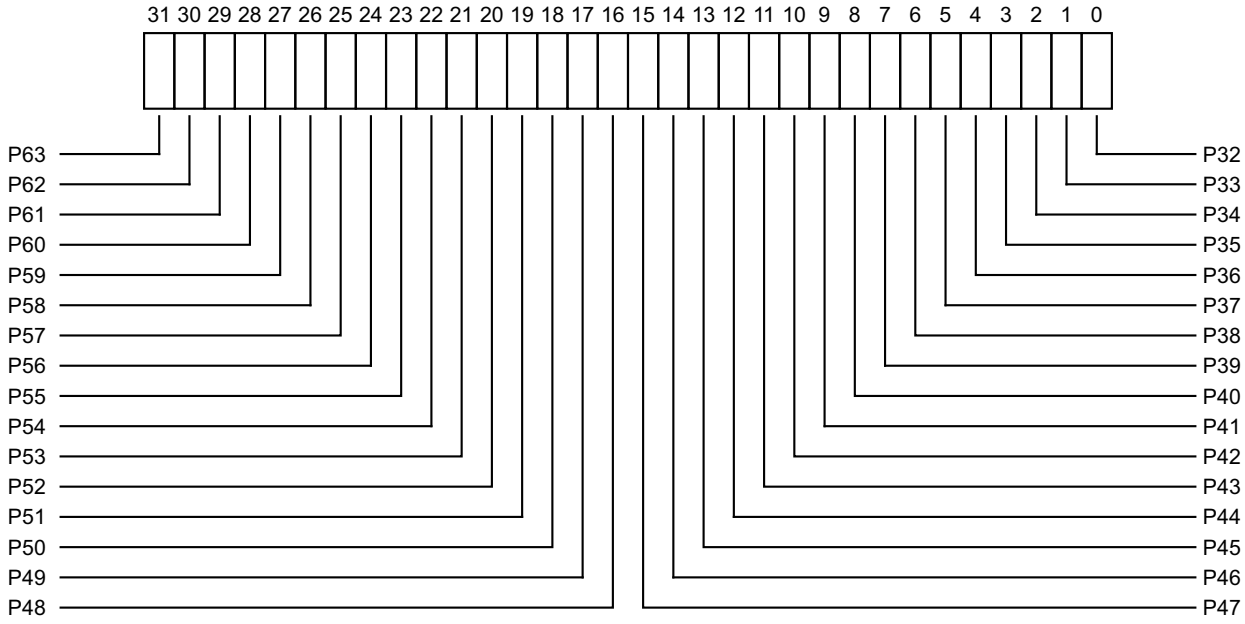
ICH_AP0R1_EL2 is architecturally mapped to AArch32 register ICH_AP0R1.

Attributes

ICH_AP0R1_EL2 is a 32-bit register.

Field descriptions

The ICH_AP0R1_EL2 bit assignments are:



P<n>, bit [(n-32)], for (n-32) = 32 to 63

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP0R1_EL2

To access the ICH_AP0R1_EL2:

```
MRS <Xt>, ICH_AP0R1_EL2 ; Read ICH_AP0R1_EL2 into Xt
MSR ICH_AP0R1_EL2, <Xt> ; Write Xt to ICH_AP0R1_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1000	001

D7.6.34 ICH_AP0R2_EL2, Interrupt Controller Hyp Active Priorities Register (0,2)

The ICH_AP0R2_EL2 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

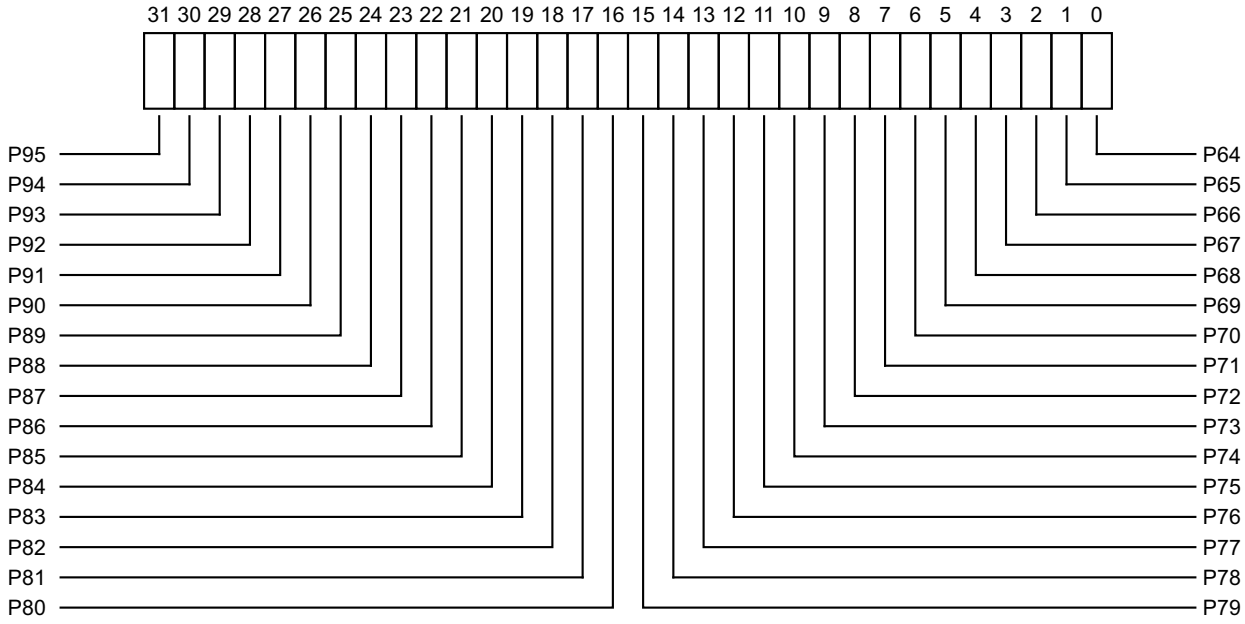
ICH_AP0R2_EL2 is architecturally mapped to AArch32 register ICH_AP0R2.

Attributes

ICH_AP0R2_EL2 is a 32-bit register.

Field descriptions

The ICH_AP0R2_EL2 bit assignments are:



P<n>, bit [(n-64)], for (n-64) = 64 to 95

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP0R2_EL2

To access the ICH_AP0R2_EL2:

```
MRS <Xt>, ICH_AP0R2_EL2 ; Read ICH_AP0R2_EL2 into Xt
MSR ICH_AP0R2_EL2, <Xt> ; Write Xt to ICH_AP0R2_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1000	010

D7.6.35 ICH_AP0R3_EL2, Interrupt Controller Hyp Active Priorities Register (0,3)

The ICH_AP0R3_EL2 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

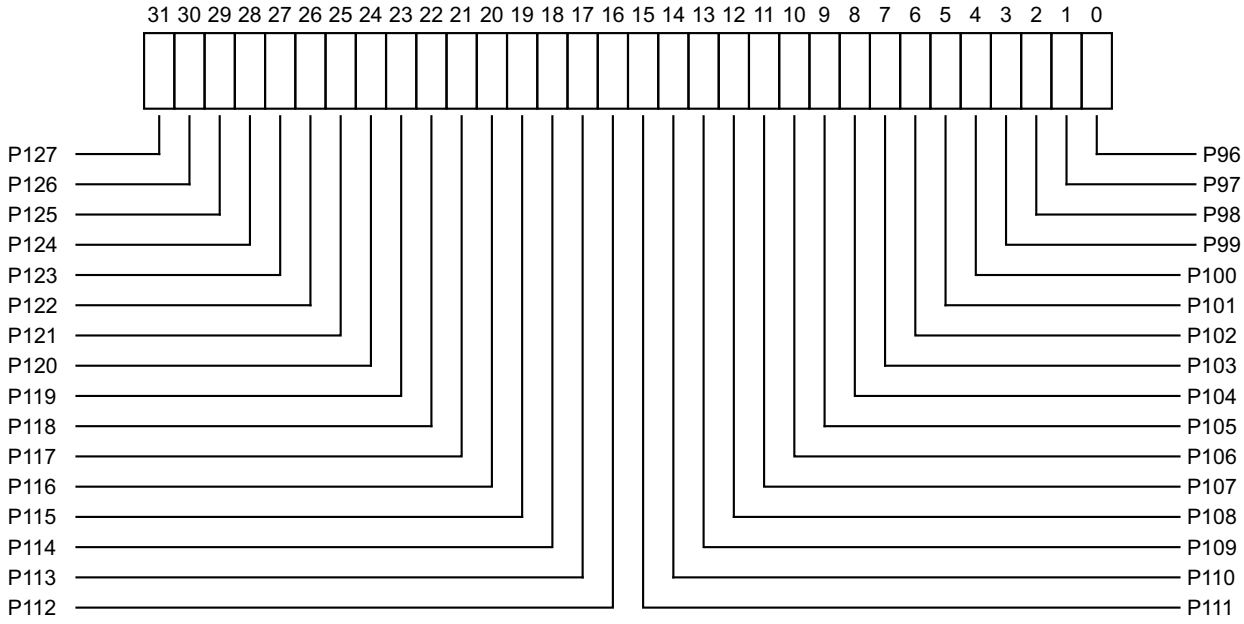
ICH_AP0R3_EL2 is architecturally mapped to AArch32 register ICH_AP0R3.

Attributes

ICH_AP0R3_EL2 is a 32-bit register.

Field descriptions

The ICH_AP0R3_EL2 bit assignments are:



P<n>, bit [(n-96)], for (n-96) = 96 to 127

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Exception level	AP0Rn access
(Secure) EL3	Permitted. Accesses Group 0 Secure active priorities.
Secure EL1	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 access for a Virtual interrupt	ICH_AP0Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 0 Secure active priorities.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 0 active priorities.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP0R3_EL2

To access the ICH_AP0R3_EL2:

```
MRS <Xt>, ICH_AP0R3_EL2 ; Read ICH_AP0R3_EL2 into Xt
MSR ICH_AP0R3_EL2, <Xt> ; Write Xt to ICH_AP0R3_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1000	011

D7.6.36 ICH_AP1R0_EL2, Interrupt Controller Hyp Active Priorities Register (1,0)

The ICH_AP1R0_EL2 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

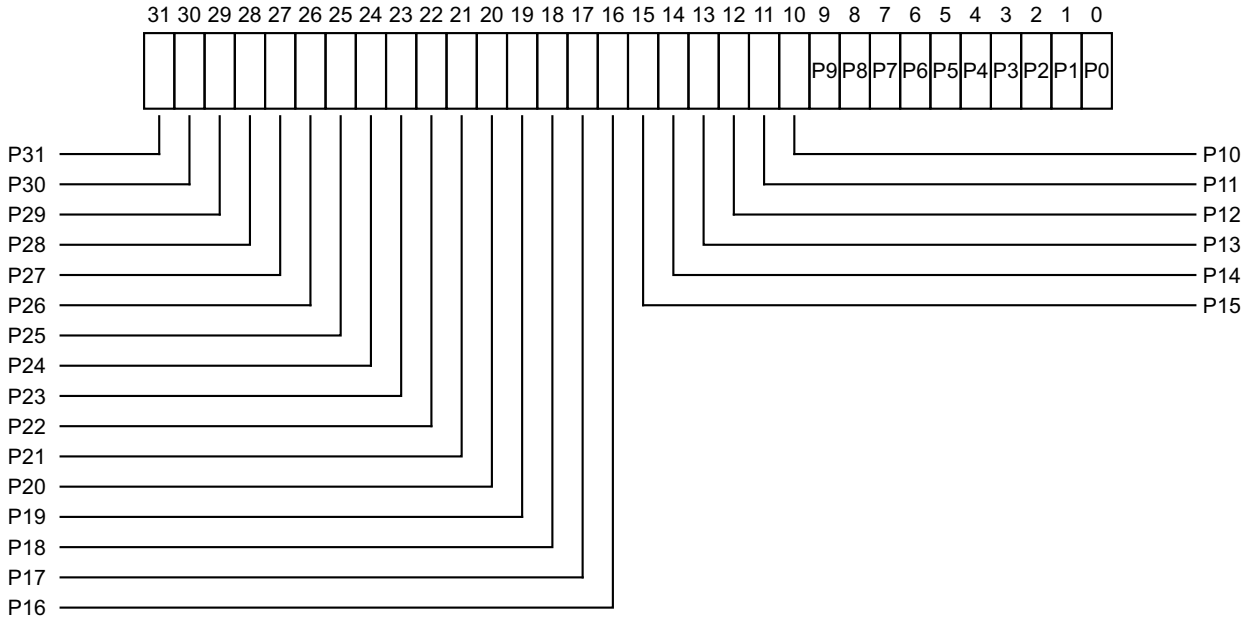
ICH_AP1R0_EL2 is architecturally mapped to AArch32 register ICH_AP1R0.

Attributes

ICH_AP1R0_EL2 is a 32-bit register.

Field descriptions

The ICH_AP1R0_EL2 bit assignments are:



P<n>, bit [n], for n = 0 to 31

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and Security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP1R0_EL2

To access the ICH_AP1R0_EL2:

```
MRS <Xt>, ICH_AP1R0_EL2 ; Read ICH_AP1R0_EL2 into Xt
MSR ICH_AP1R0_EL2, <Xt> ; Write Xt to ICH_AP1R0_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1001	000

D7.6.37 ICH_AP1R1_EL2, Interrupt Controller Hyp Active Priorities Register (1,1)

The ICH_AP1R1_EL2 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

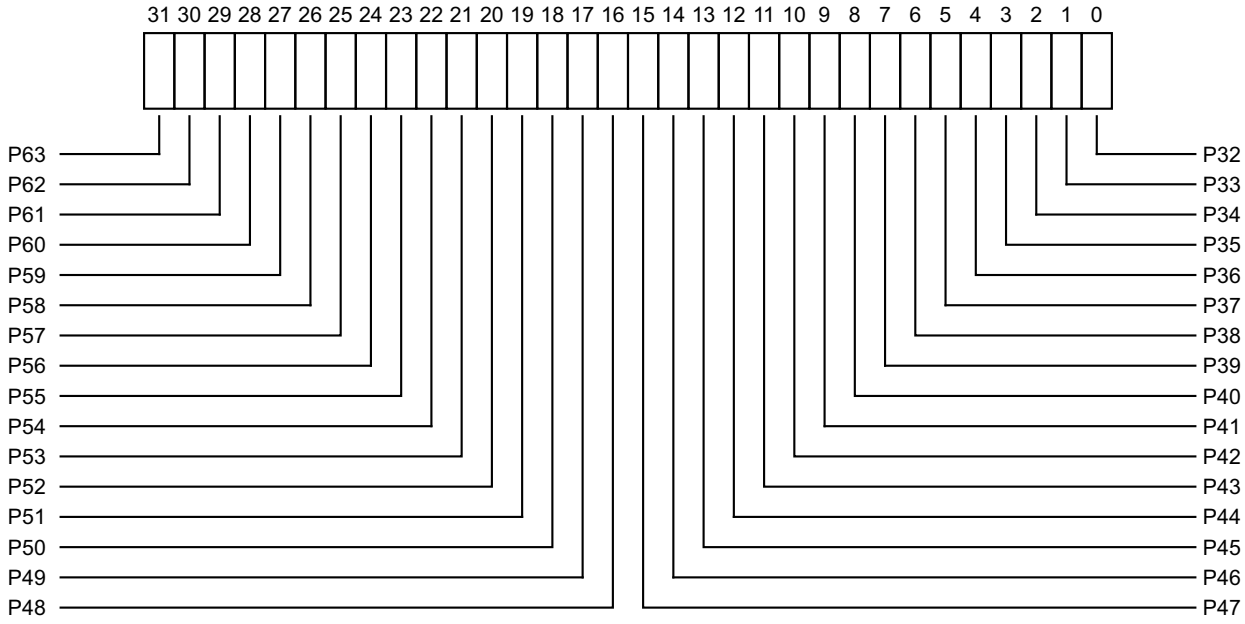
ICH_AP1R1_EL2 is architecturally mapped to AArch32 register ICH_AP1R1.

Attributes

ICH_AP1R1_EL2 is a 32-bit register.

Field descriptions

The ICH_AP1R1_EL2 bit assignments are:



P<n>, bit [(n-32)], for (n-32) = 32 to 63

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and Security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP1R1_EL2

To access the ICH_AP1R1_EL2:

```
MRS <Xt>, ICH_AP1R1_EL2 ; Read ICH_AP1R1_EL2 into Xt
MSR ICH_AP1R1_EL2, <Xt> ; Write Xt to ICH_AP1R1_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1001	001

D7.6.38 ICH_AP1R2_EL2, Interrupt Controller Hyp Active Priorities Register (1,2)

The ICH_AP1R2_EL2 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

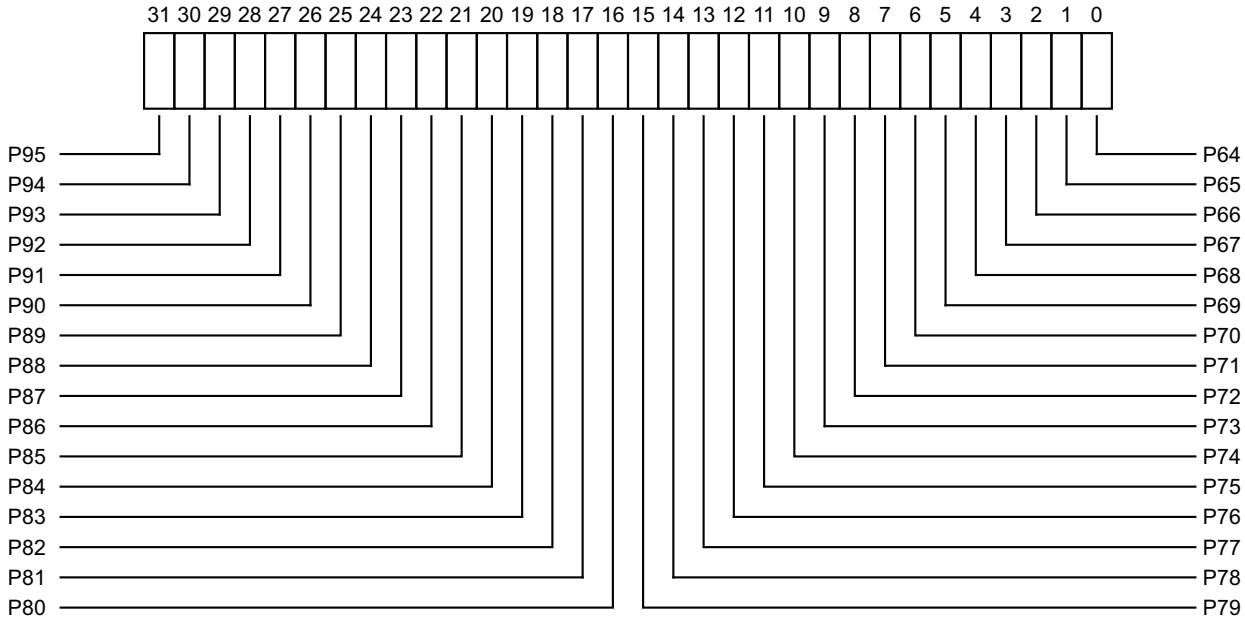
ICH_AP1R2_EL2 is architecturally mapped to AArch32 register ICH_AP1R2.

Attributes

ICH_AP1R2_EL2 is a 32-bit register.

Field descriptions

The ICH_AP1R2_EL2 bit assignments are:



P<n>, bit [(n-64)], for (n-64) = 64 to 95

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and Security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP1R2_EL2

To access the ICH_AP1R2_EL2:

```
MRS <Xt>, ICH_AP1R2_EL2 ; Read ICH_AP1R2_EL2 into Xt
MSR ICH_AP1R2_EL2, <Xt> ; Write Xt to ICH_AP1R2_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1001	010

D7.6.39 ICH_AP1R3_EL2, Interrupt Controller Hyp Active Priorities Register (1,3)

The ICH_AP1R3_EL2 characteristics are:

Purpose

Provides information about the active priorities for the current EL2 interrupt regime.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

In implementations supporting fewer than 8 bits of priority, some of these registers correspond to unimplemented priority levels. Access to such registers will generate an Undefined exception.

Configurations

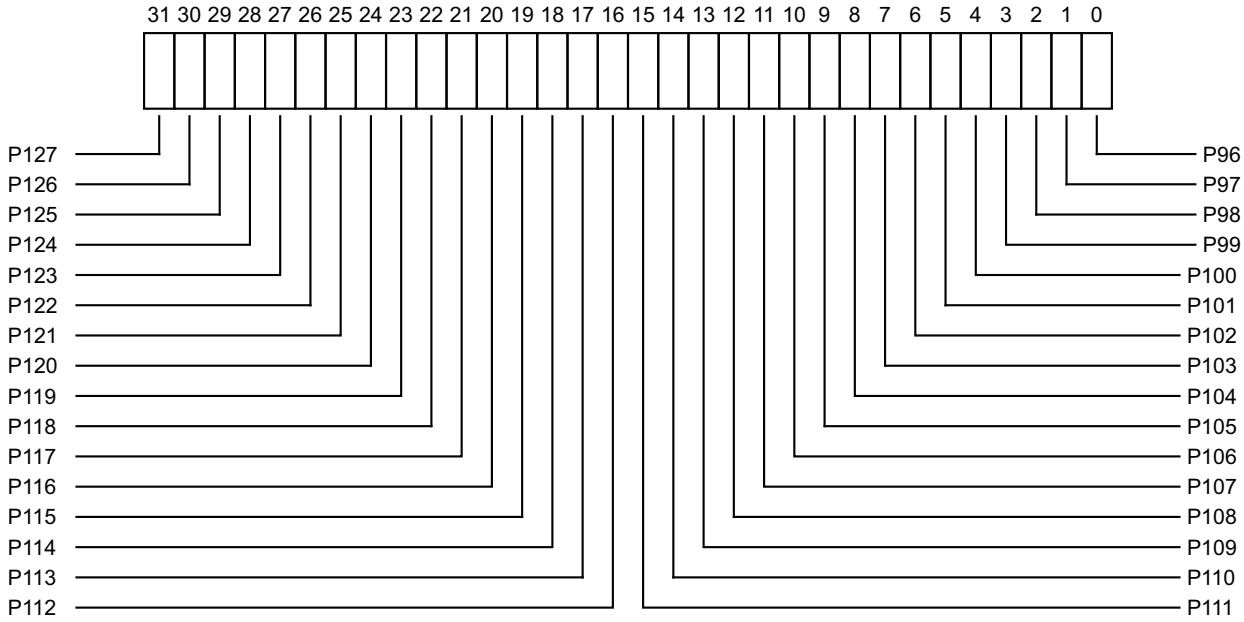
ICH_AP1R3_EL2 is architecturally mapped to AArch32 register ICH_AP1R3.

Attributes

ICH_AP1R3_EL2 is a 32-bit register.

Field descriptions

The ICH_AP1R3_EL2 bit assignments are:



P<n>, bit [(n-96)], for (n-96) = 96 to 127

Provides information about priority M, according to the following relationship:

Bit P<n> corresponds to priority (M divided by 2^U) minus 1, where U is the number of unimplemented bits of priority and is equal to (7 - ICC_CTLR_EL1.PRIbits).

For example, in a system with ICC_CTLR_EL1.PRIbits == `0b100`:

- There are 5 bits of implemented priority.
- This means there are 3 bits of unimplemented priority, which are always at the least significant end (bits [2:0] are RES0).
- Valid priorities are 8, 16, 24, 32, and so on. Dividing these by 2^3 gives 1, 2, 3, 4, and so on.
- Subtracting 1 from each gives bits 0, 1, 2, 3, and so on that provide information about those priorities.

Accesses to these registers from an interrupt regime give a view of the active priorities that is appropriate for that interrupt regime, to allow save and restore of the appropriate state.

Interrupt regime and the number of Security states supported by the Distributor affect the view as follows. Unless otherwise stated, when a bit is successfully set to one, this clears any other active priorities corresponding to that bit.

Current exception level and Security state	AP1Rn access
(Secure) EL3	Permitted. When SCR_EL3.NS is 0, accesses Group 1 Secure active priorities. When SCR_EL3.NS is 1, accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Secure EL1	Permitted. Accesses Group 1 Secure active priorities (unshifted). When a bit is written, the bit is only updated if the corresponding Group 0 Secure active priority is zero.
Non-secure EL1 access for a Virtual interrupt	ICH_AP1Rn_EL2
Non-secure EL1 or EL2 when GIC Distributor supports two Security states	Permitted. Accesses Group 1 Non-secure active priorities (shifted). When a bit is written, the bit is only updated if the corresponding Group 0 and Group 1 Secure active priority is zero.
Non-secure EL1 or EL2 when GIC Distributor supports one Security state	Permitted. Accesses Group 1 Non-secure active priorities (unshifted). When a bit is written, the bit is only updated if the Group 0 active priority is zero.

A Virtual interrupt in this case means that the interrupt group associated with the register has been virtualized.

Accessing the ICH_AP1R3_EL2

To access the ICH_AP1R3_EL2:

```
MRS <Xt>, ICH_AP1R3_EL2 ; Read ICH_AP1R3_EL2 into Xt
MSR ICH_AP1R3_EL2, <Xt> ; Write Xt to ICH_AP1R3_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1001	011

D7.6.40 ICH_EISR_EL2, Interrupt Controller End of Interrupt Status Register

The ICH_EISR_EL2 characteristics are:

Purpose

When a maintenance interrupt is received, this register helps determine which List registers have outstanding EOI interrupts that require servicing.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RO	RO	RO

Configurations

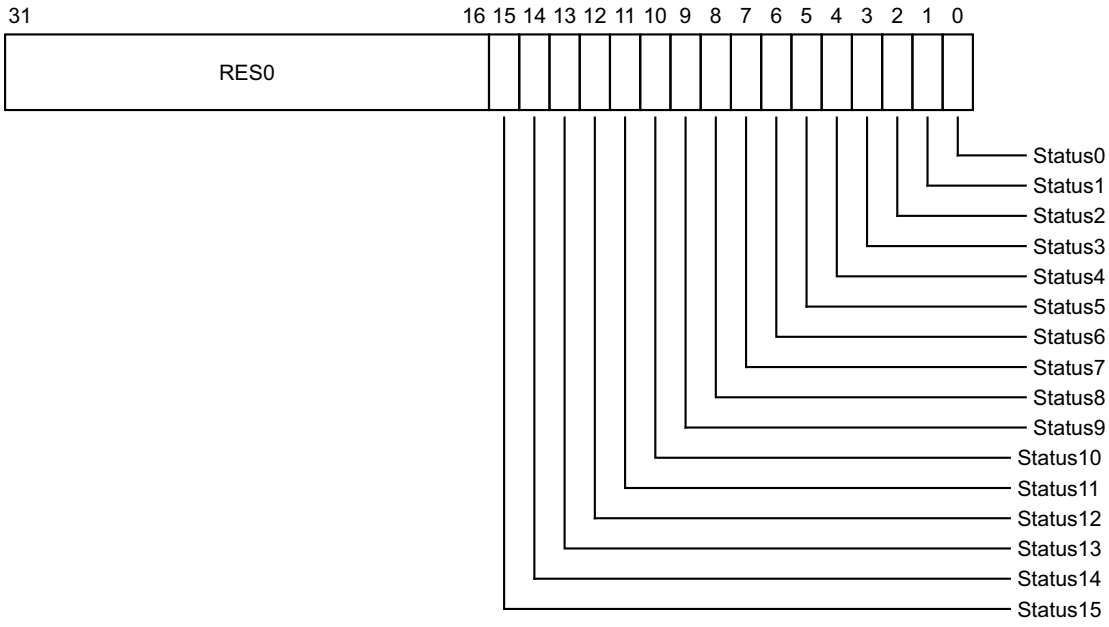
ICH_EISR_EL2 is architecturally mapped to AArch32 register ICH_EISR.

Attributes

ICH_EISR_EL2 is a 32-bit register.

Field descriptions

The ICH_EISR_EL2 bit assignments are:



Bits [31:16]

Reserved, RES0.

Status<n>, bit [n], for n = 0 to 15

EOI status bit for List register <n>:

`0` List register <n>, ICH_LR<n>_EL2, does not have an EOI.

`1` List register <n>, ICH_LR<n>_EL2, has an EOI.

For any ICH_LR<n>_EL2, the corresponding status bit is set to 1 if ICH_LR<n>_EL2.State is `0b00` and ICH_LR<n>_EL2.HW is 0 and ICH_LR<n>_EL2.EOI is 1.

Accessing the ICH_EISR_EL2

To access the ICH_EISR_EL2:

```
MRS <Xt>, ICH_EISR_EL2 ; Read ICH_EISR_EL2 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1011	011

D7.6.41 ICH_ELSR_EL2, Interrupt Controller Empty List Register Status Register

The ICH_ELSR_EL2 characteristics are:

Purpose

This register can be used to locate a usable List register when the hypervisor is delivering an interrupt to a Guest OS.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RO	RO	RO

Configurations

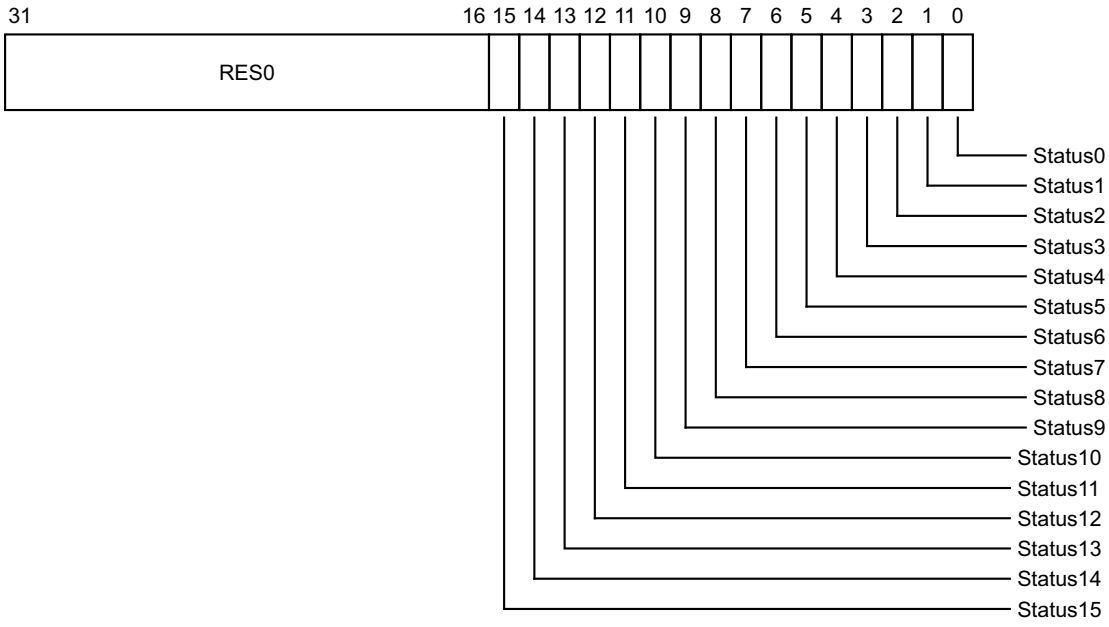
ICH_ELSR_EL2 is architecturally mapped to AArch32 register ICH_ELSR.

Attributes

ICH_ELSR_EL2 is a 32-bit register.

Field descriptions

The ICH_ELSR_EL2 bit assignments are:



Bits [31:16]

Reserved, RES0.

Status<n>, bit [n], for n = 0 to 15

Status bit for List register <n>, ICH_LR<n>_EL2:

`0` List register ICH_LR<n>_EL2, if implemented, contains a valid interrupt. Using this List register can result in overwriting a valid interrupt.

`1` List register ICH_LR<n>_EL2 does not contain a valid interrupt. The List register is empty and can be used without overwriting a valid interrupt or losing an EOI maintenance interrupt.

For any ICH_LR<n>_EL2, the corresponding status bit is set to 1 if ICH_LR<n>_EL2.State is `0b00` and either ICH_LR<n>_EL2.HW is 1 or ICH_LR<n>_EL2.EOI is 0.

Accessing the ICH_ELSR_EL2

To access the ICH_ELSR_EL2:

```
MRS <Xt>, ICH_ELSR_EL2 ; Read ICH_ELSR_EL2 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1011	101

D7.6.42 ICH_HCR_EL2, Interrupt Controller Hyp Control Register

The ICH_HCR_EL2 characteristics are:

Purpose

Controls the environment for guest operating systems.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

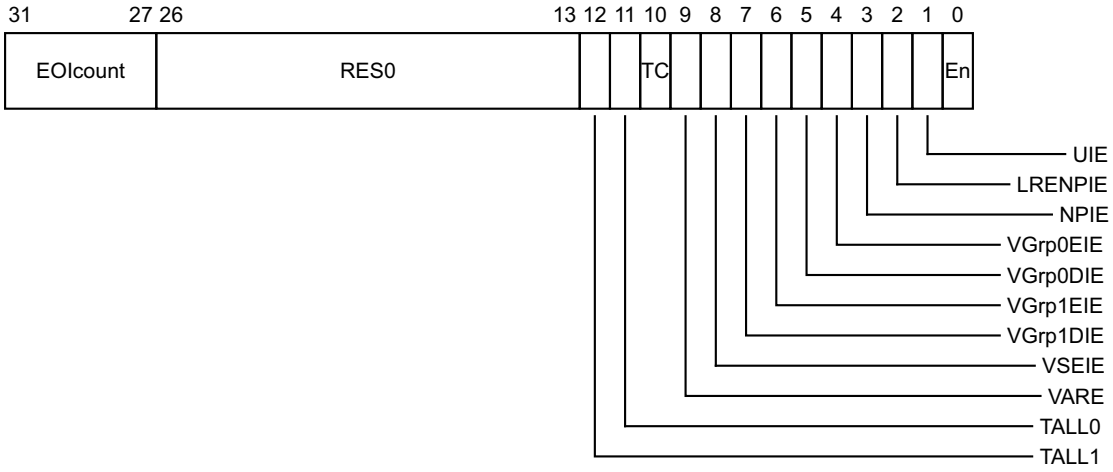
ICH_HCR_EL2 is architecturally mapped to AArch32 register ICH_HCR.

Attributes

ICH_HCR_EL2 is a 32-bit register.

Field descriptions

The ICH_HCR_EL2 bit assignments are:



EOIcount, bits [31:27]

Counts the number of EOIs received that do not have a corresponding entry in the List registers. The virtual CPU interface increments this field automatically when a matching EOI is received.

EOIs that do not clear a bit in one of the Active Priorities registers ICH_APmRn_EL2 do not cause an increment.

Although not possible under correct operation, if an EOI occurs when the value of this field is 31, this field wraps to 0.

The maintenance interrupt is asserted whenever this field is non-zero and the LRENPIE bit is set to 1.

Bits [26:13]

Reserved, RES0.

TALL1, bit [12]

Trap all Non-secure EL1 accesses to ICC_* system registers for group 1 interrupts to EL2.

0 Non-Secure EL1 accesses to ICC_* registers for group 1 interrupts proceed as normal.

1 Any Non-secure EL1 accesses to ICC_* registers for group 1 interrupts trap to EL2.

TALL0, bit [11]

Trap all Non-secure EL1 accesses to ICC_* system registers for group 0 interrupts to EL2.

0 Non-Secure EL1 accesses to ICC_* registers for group 0 interrupts proceed as normal.

1 Any Non-secure EL1 accesses to ICC_* registers for group 0 interrupts trap to EL2.

TC, bit [10]

Trap all Non-secure El1 accesses to system registers that are common to group 0 and group 1 to EL2.

0 Non-secure EL1 accesses to common registers proceed as normal.

1 Any Non-secure EL1 accesses to common registers trap to EL2.

This affects ICC_DIR_EL1, ICC_PMR_EL1, and ICC_RPR_EL1.

VARE, bit [9]

Virtual ARE.

0 The guest operating system does not use affinity routing and expects a Source CPU ID for SGIs.

1 The guest operating system uses affinity routing.

When VARE is 0, the guest operating system does not support LPIs and software must ensure that no LPIs are presented to the guest either using the List registers or from the Distributor.

VSEIE, bit [8]

Virtual SEI Enable. Enables the signaling of a maintenance interrupt when performing a virtual access to a system register and a condition that would result in an (optional) SEI for a physical access is detected.

0 VSEIE maintenance interrupt is disabled.

1 VSEIE maintenance interrupt is enabled.

VGrp1DIE, bit [7]

VM Disable Group 1 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 1 interrupts from the virtual CPU interface to the connected virtual machine is disabled:

0 Maintenance interrupt disabled.

1 Maintenance interrupt signaled while GICV_CTLR.EnableGrp1 is set to 0.

VGrp1EIE, bit [6]

VM Enable Group 1 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 1 interrupts from the virtual CPU interface to the connected virtual machine is enabled:

0 Maintenance interrupt disabled.

1 Maintenance interrupt signaled while GICV_CTLR.EnableGrp1 is set to 1.

VGrp0DIE, bit [5]

VM Disable Group 0 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 0 interrupts from the virtual CPU interface to the connected virtual machine is disabled:

0 Maintenance interrupt disabled.

1 Maintenance interrupt signaled while GICV_CTLR.EnableGrp0 is set to 0.

VGrp0EIE, bit [4]

VM Enable Group 0 Interrupt Enable. Enables the signaling of a maintenance interrupt while signaling of Group 0 interrupts from the virtual CPU interface to the connected virtual machine is enabled:

0 Maintenance interrupt disabled.

1 Maintenance interrupt signaled while GICV_CTLR.EnableGrp0 is set to 1.

NPIE, bit [3]

No Pending Interrupt Enable. Enables the signaling of a maintenance interrupt while no pending interrupts are present in the List registers:

0 Maintenance interrupt disabled.

1 Maintenance interrupt signaled while the List registers contain no interrupts in the pending state.

LRENPIE, bit [2]

List Register Entry Not Present Interrupt Enable. Enables the signaling of a maintenance interrupt while the virtual CPU interface does not have a corresponding valid List register entry for an EOI request:

0 Maintenance interrupt disabled.

1 A maintenance interrupt is asserted while the EOIcount field is not 0.

UIE, bit [1]

Underflow Interrupt Enable. Enables the signaling of a maintenance interrupt when the List registers are empty, or hold only one valid entry:

0 Maintenance interrupt disabled.

1 A maintenance interrupt is asserted if none, or only one, of the List register entries is marked as a valid interrupt.

En, bit [0]

Enable. Global enable bit for the virtual CPU interface:

0 Virtual CPU interface operation disabled.

1 Virtual CPU interface operation enabled.

When this field is set to 0:

- The virtual CPU interface does not signal any maintenance interrupts.
- The virtual CPU interface does not signal any virtual interrupts.
- A read of GICV_IAR or GICV_AIAR returns a spurious interrupt ID.

Accessing the ICH_HCR_EL2

To access the ICH_HCR_EL2:

```
MRS <Xt>, ICH_HCR_EL2 ; Read ICH_HCR_EL2 into Xt
MSR ICH_HCR_EL2, <Xt> ; Write Xt to ICH_HCR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1011	000

D7.6.43 ICH_LR<n>_EL2, Interrupt Controller List Registers, n = 0 - 15

The ICH_LR<n>_EL2 characteristics are:

Purpose

Provides interrupt context information for the virtual CPU interface.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

ICH_LR<n>_EL2[31:0] is architecturally mapped to AArch32 register ICH_LR<n>.

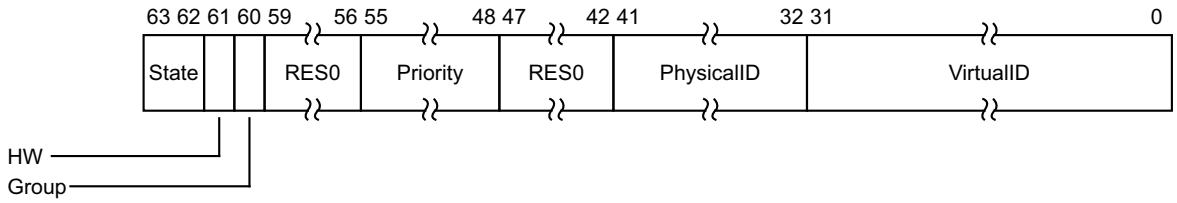
ICH_LR<n>_EL2[63:32] is architecturally mapped to AArch32 register ICH_LRC<n>.

Attributes

ICH_LR<n>_EL2 is a 64-bit register.

Field descriptions

The ICH_LR<n>_EL2 bit assignments are:



State, bits [63:62]

The state of the interrupt:

`00` Invalid

`01` Pending

`10` Active

`11` Pending and active.

The GIC updates these state bits as virtual interrupts proceed through the interrupt life cycle. Entries in the invalid state are ignored, except for the purpose of generating virtual maintenance interrupts.

For hardware interrupts, the pending and active state is held in the physical Distributor rather than the virtual CPU interface. A hypervisor must only use the pending and active state for software originated interrupts, which are typically associated with virtual devices, or SGIs.

HW, bit [61]

Indicates whether this virtual interrupt is a hardware interrupt, meaning that it corresponds to a physical interrupt. Deactivation of the virtual interrupt also causes the deactivation of the physical interrupt with the ID that the PhysicalID field indicates.

`0` The interrupt is triggered entirely in software. No notification is sent to the Distributor when the virtual interrupt is deactivated.

`1` The interrupt is a hardware interrupt. A deactivate interrupt request is sent to the Distributor when the virtual interrupt is deactivated, using the PhysicalID field from this register to indicate the physical interrupt ID.

If GICV_CTLR.EOImode is 0, this request corresponds to a write to the GICV_EOIR or GICV_AEOIR, otherwise it corresponds to a write to the GICV_DIR.

Bits [59:56]

Reserved, RES0.

Priority, bits [55:48]

The priority of this interrupt.

It is IMPLEMENTATION DEFINED how many bits of priority are implemented, though at least five bits must be implemented. Unimplemented bits are RES0 and start from bit [48] up to bit [50]. The number of implemented bits can be discovered from ICH_VTR_EL2.PRIbits, and determines how many GICH_APR<n> registers exist.

Bits [47:42]

Reserved, RES0.

PhysicalID, bits [41:32]

Physical ID, for hardware interrupts.

When HW is 0 (i.e. there is no corresponding physical interrupt), some of these bits have a special meaning:

`Bit [39]` EOI. When this bit is 1, a maintenance interrupt is asserted to signal EOI when the interrupt state is invalid, which typically occurs when the interrupt is deactivated.

`Bits [38:32]`Reserved, RES0.

A hardware physical identifier is only required in List Registers for interrupts that require an EOI or Deactivate. This means only 10 bits of Physical ID are required, regardless of the number specified by ICC_CTLR_EL1.IDbits.

VirtualID, bits [31:0]

Virtual ID of the interrupt.

When VARE is zero, software must ensure the correct Source CPU ID is provided in bits [12:10].

Software must ensure there is only a single valid entry for a given VirtualID.

It is IMPLEMENTATION DEFINED how many bits are implemented, though at least 16 bits must be implemented. Unimplemented bits are RES0. The number of implemented bits can be discovered from ICH_VTR_EL2.IDbits.

Accessing the ICH_LR<n>_EL2

To access the ICH_LR<n>_EL2:

```
MRS <Xt>, ICH_LR<n>_EL2 ; Read ICH_LR<n>_EL2 into Xt, where n is in the range 0 to 15
MSR ICH_LR<n>_EL2, <Xt> ; Write Xt to ICH_LR<n>_EL2, where n is in the range 0 to 15
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	110:n<3>	n<2:0>

D7.6.44 ICH_MISR_EL2, Interrupt Controller Maintenance Interrupt State Register

The ICH_MISR_EL2 characteristics are:

Purpose

Indicates which maintenance interrupts are asserted.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RO	RO	RO

Configurations

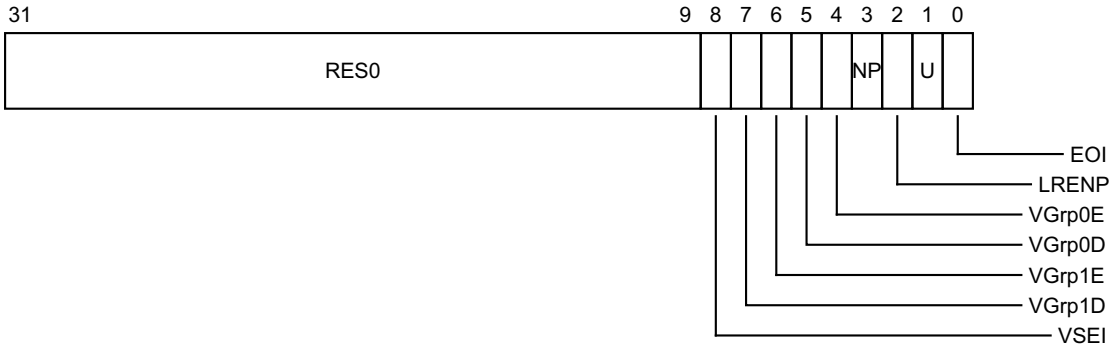
ICH_MISR_EL2 is architecturally mapped to AArch32 register ICH_MISR.

Attributes

ICH_MISR_EL2 is a 32-bit register.

Field descriptions

The ICH_MISR_EL2 bit assignments are:



Bits [31:9]

Reserved, RES0.

VSEI, bit [8]

Virtual SEI. Set to 1 when a condition that would result in generation of an SEI is detected during a virtual access to an ICC_* system register.

VGrp1D, bit [7]

Disabled Group 1 maintenance interrupt.

Asserted whenever ICH_HCR_EL2.VGrp1DIE is 1 and ICH_VMCR_EL2.VMGrp1En is 0.

VGrp1E, bit [6]

Enabled Group 1 maintenance interrupt.

Asserted whenever ICH_HCR_EL2.VGrp1EIE is 1 and ICH_VMCR_EL2.VMGrp1En is 1.

VGrp0D, bit [5]

Disabled Group 0 maintenance interrupt.

Asserted whenever ICH_HCR_EL2.VGrp0DIE is 1 and ICH_VMCR_EL2.VMGrp0En is 0.

VGrp0E, bit [4]

Enabled Group 0 maintenance interrupt.

Asserted whenever ICH_HCR_EL2.VGrp0EIE is 1 and ICH_VMCR_EL2.VMGrp0En is 1.

NP, bit [3]

No Pending maintenance interrupt.

Asserted whenever ICH_HCR_EL2.NPIE is 1 and no List register is in pending state.

LRENP, bit [2]

List Register Entry Not Present maintenance interrupt.

Asserted whenever ICH_HCR_EL2.LRENPIE is 1 and ICH_HCR_EL2.EOIcount is non-zero.

U, bit [1]

Underflow maintenance interrupt.

Asserted whenever ICH_HCR_EL2.UIE is 1 and if none, or only one, of the List register entries are marked as a valid interrupt, that is, if the corresponding ICH_LR<n>_EL2.State bits do not equal `0x0`.

EOI, bit [0]

EOI maintenance interrupt.

Asserted whenever at least one List register is asserting an EOI interrupt. That is, when at least one bit in ICH_EISR0_EL1 or ICH_EISR1_EL1 is 1.

Accessing the ICH_MISR_EL2

To access the ICH_MISR_EL2:

```
MRS <Xt>, ICH_MISR_EL2 ; Read ICH_MISR_EL2 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1011	010

D7.6.45 ICH_VMCR_EL2, Interrupt Controller Virtual Machine Control Register

The ICH_VMCR_EL2 characteristics are:

Purpose

Enables the hypervisor to save and restore the virtual machine view of the GIC state.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

When EL2 is using system register access, EL1 using either system register or memory-mapped access must be supported.

Configurations

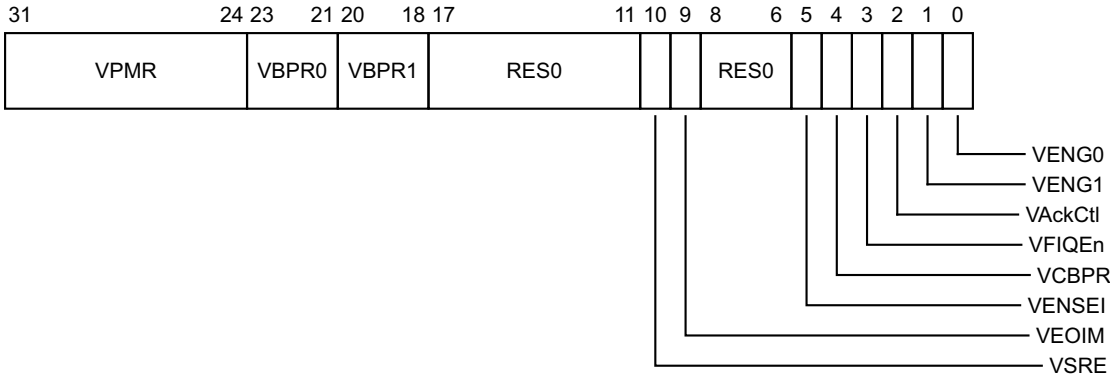
ICH_VMCR_EL2 is architecturally mapped to AArch32 register ICH_VMCR.

Attributes

ICH_VMCR_EL2 is a 32-bit register.

Field descriptions

The ICH_VMCR_EL2 bit assignments are:



VPMR, bits [31:24]

Virtual Priority Mask.

Visible to the guest OS as ICC_PMR_EL1 / GICV_PMR.

VBPR0, bits [23:21]

Virtual BPR0.

Visible to the guest OS as ICC_BPR0_EL1 / GICV_BPR.

VBPR1, bits [20:18]

Virtual BPR1.

Visible to the guest OS as ICC_BPR1_EL1 / GICV_ABPR.

Bits [17:11]

Reserved, RES0.

VSRE, bit [10]

Virtual SRE.

Visible to the guest OS as ICC_SRE_EL1.SRE.

If EL2 is not configured to use system registers, this bit is treated as if it is 0.

VEOIM, bit [9]

Virtual EOImode.

Visible to the guest OS as ICC_CTLR_EL1.EOImode / GICV_CTLR.EOImode.

Bits [8:6]

Reserved, RES0.

VENSEI, bit [5]

IMPLEMENTATION DEFINED control of Virtual SEIs.

If an implementation does not have functionality associated with this bit, ARM recommends that the bit is RES0.

VCBPR, bit [4]

Virtual CBPR.

Visible to the guest OS as ICC_CTLR_EL1.CBPR / GICV_CTLR.CBPR.

VFIQEn, bit [3]

Virtual FIQ enable.

Visible to the guest OS as GICV_CTLR.FIQEn.

VAckCtl, bit [2]

Virtual AckCtl.

Visible to the guest OS as GICV_CTLR.AckCtl.

VENG1, bit [1]

Virtual group 1 interrupt enable.

Visible to the guest OS as ICC_IGRPEN1_EL1.Enable / GICV_CTLR.EnableGrp1.

VENG0, bit [0]

Virtual group 0 interrupt enable.

Visible to the guest OS as ICC_IGRPEN0_EL1.Enable / GICV_CTLR.EnableGrp0.

Accessing the ICH_VMCR_EL2

To access the ICH_VMCR_EL2:

```
MRS <Xt>, ICH_VMCR_EL2 ; Read ICH_VMCR_EL2 into Xt
MSR ICH_VMCR_EL2, <Xt> ; Write Xt to ICH_VMCR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1011	111

D7.6.46 ICH_VSEIR_EL2, Interrupt Controller Virtual System Error Interrupt Register

The ICH_VSEIR_EL2 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED generation of virtual SError interrupts.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

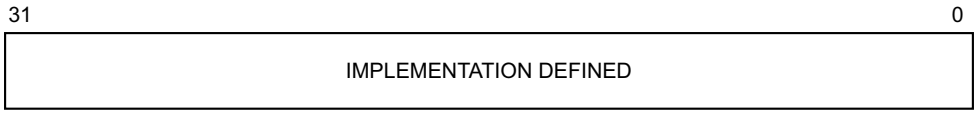
ICH_VSEIR_EL2 is architecturally mapped to AArch32 register ICH_VSEIR.

Attributes

ICH_VSEIR_EL2 is a 32-bit register.

Field descriptions

The ICH_VSEIR_EL2 bit assignments are:



Accessing the ICH_VSEIR_EL2

To access the ICH_VSEIR_EL2:

```
MRS <Xt>, ICH_VSEIR_EL2 ; Read ICH_VSEIR_EL2 into Xt
MSR ICH_VSEIR_EL2, <Xt> ; Write Xt to ICH_VSEIR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1001	100

D7.6.47 ICH_VTR_EL2, Interrupt Controller VGIC Type Register

The ICH_VTR_EL2 characteristics are:

Purpose

Describes the number of implemented virtual priority bits and List registers.

This register is part of:

- the GIC registers functional group
- the Virtualization registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RO	RO	RO

Configurations

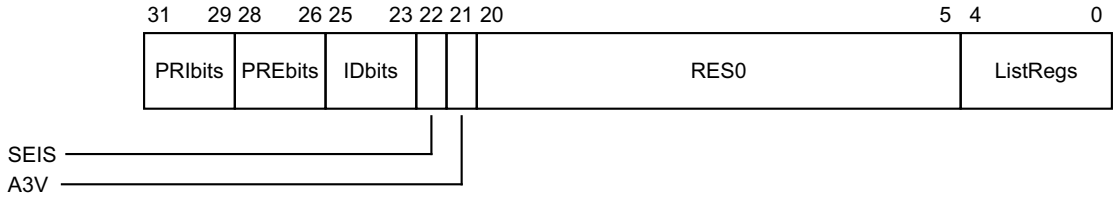
ICH_VTR_EL2 is architecturally mapped to AArch32 register ICH_VTR.

Attributes

ICH_VTR_EL2 is a 32-bit register.

Field descriptions

The ICH_VTR_EL2 bit assignments are:



PRIbits, bits [31:29]

The number of virtual priority bits implemented, minus one.

PREbits, bits [28:26]

The number of virtual preemption bits implemented, minus one.

IDbits, bits [25:23]

The number of virtual interrupt identifier bits supported:

`000` 16 bits.

`001` 24 bits.

All other values are reserved.

SEIS, bit [22]

SEI Support. Indicates whether the virtual CPU interface supports generation of SEIs:

`0` The virtual CPU interface logic does not support generation of SEIs.

`1` The virtual CPU interface logic supports generation of SEIs.

Virtual system errors may still be generated by writing to ICH_VSEIR_EL2 regardless of the value of this field.

A3V, bit [21]

Affinity 3 Valid. Possible values are:

`0` The virtual CPU interface logic only supports zero values of Affinity 3 in SGI generation system registers.

`1` The virtual CPU interface logic supports non-zero values of Affinity 3 in SGI generation system registers.

Bits [20:5]

Reserved, RES0.

ListRegs, bits [4:0]

The number of implemented List registers, minus one. For example, a value of `0b01111` indicates that the maximum of 16 List registers are implemented.

Accessing the ICH_VTR_EL2

To access the ICH_VTR_EL2:

```
MRS <Xt>, ICH_VTR_EL2 ; Read ICH_VTR_EL2 into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	1100	1011	001

Part E
The AArch32 Application Level Architecture

Chapter E1
The AArch32 Application Level Programmers' Model

This chapter gives an Application level description of the programmers' model for software executing in AArch32 state. This means it describes execution in EL0 when EL0 is using AArch32. It contains the following sections:

E1.1 About the Application level programmers' model

This chapter contains the programmers' model information required for the development of applications that will execute in AArch32 state.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of that system information is needed to put the Application level programmers' model into context.

Depending on the implementation, the architecture supports multiple levels of execution privilege. These privilege levels are indicated by different *Exception levels* that number upwards from EL0, where EL0 corresponds to the lowest privilege level and is often described as *unprivileged*. The Application level programmers' model is the programmers' model for software executing at EL0. For more information see *ARMv8 architectural concepts* on page A1-33.

System software determines the Exception level, and therefore the level of privilege, at which application software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged. This:

- Means the operating system can allocate system resources to an application in a unique or shared manner.
- Provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some System level understanding is helpful, and if appropriate it gives a reference to the System level description.

When included in an implementation:

- EL3 provides two Security states, Secure and Non-secure. Secure state provides additional hardware features that support the development of secure applications.
- EL2 provides virtualization of operation in Non-secure state.

However, application level software is generally unaware of its Security state, and of any virtualization. For more information, see *The ARMv8-A security model* on page G1-3373 and *The effect of implementing EL2 on the Exception model* on page G1-3376.

Note

- When an implementation includes EL3, application and operating system software normally executes in Non-secure state.
- EL2, that provides the virtualization features, is implemented only in Non-secure state.
- Older documentation, describing implementations or architecture versions that support only two privilege levels, often refers to execution at EL1 as *privileged* execution.
- In this manual, the terms *CONSTRAINED UNPREDICTABLE*, *IMPLEMENTATION DEFINED*. *OPTIONAL*, RES0, RES1, *SUBARCHITECTURE DEFINED*, *UNDEFINED*, *UNKNOWN*, and *UNPREDICTABLE* have special meanings, as defined in the *Glossary*. In body text, these terms are shown in small caps, for example IMPLEMENTATION DEFINED.

E1.2 Additional information about the programmers' model in AArch32 state

The following sections give more information about the Application level programmer's model in AArch32 state:

- *Instruction sets, arithmetic operations, and register files*.
- *Core data types and arithmetic in AArch32 state*.
- *The general-purpose registers, and the PC, in AArch32 state* on page E1-2208.
- *The Application Program Status Register (APSR)* on page E1-2211.
- *Execution State registers* on page E1-2212.

E1.2.1 Instruction sets, arithmetic operations, and register files

The A32 and T32 instruction sets both provide a wide range of integer arithmetic and logical operations, that operate on a register file of sixteen 32-bit registers, that comprise the AArch32 general-purpose registers and the PC. As described in *The general-purpose registers, and the PC, in AArch32 state* on page E1-2208, these registers include the special registers SP and LR. *Core data types and arithmetic in AArch32 state* gives more information about these operations.

In addition, an implementation that implements the T32 and A32 instruction sets includes both:

- Scalar floating-point instructions.
- The Advanced SIMD vector instructions.

Floating-point and vector instructions operate on a separate common register file, described in *The SIMD and floating-point register file* on page E1-2216. *Advanced SIMD and floating-point instructions* on page E1-2216 gives more information about these instructions.

E1.2.2 Core data types and arithmetic in AArch32 state

When executing in AArch32 state, a PE supports the following data types in memory:

Byte 8 bits
Halfword 16 bits
Word 32 bits
Doubleword 64 bits.

PE registers are 32 bits in size. The instruction sets provide instructions that use the following data types for data held in registers:

- 32-bit pointers.
- Unsigned or signed 32-bit integers.
- Unsigned 16-bit or 8-bit integers, held in zero-extended form.
- Signed 16-bit or 8-bit integers, held in sign-extended form.
- Two 16-bit integers packed into a register.
- Four 8-bit integers packed into a register.
- Unsigned or signed 64-bit integers held in two registers.

Load and store operations can transfer bytes, halfwords, or words to and from memory. Loads of bytes or halfwords zero-extend or sign-extend the data as it is loaded, as specified in the appropriate load instruction.

The instruction sets include load and store operations that transfer two or more words to and from memory. Software can load and store doublewords using these instructions.

Note

For information about the atomicity of memory accesses see *Atomicity in the ARM architecture* on page E2-2261.

When any of the data types is described as *unsigned*, the N-bit data value represents a non-negative integer in the range 0 to 2^N-1, using normal binary format.

When any of these types is described as *signed*, the N-bit data value represents an integer in the range $-2^{(N-1)}$ to $+2^{(N-1)}$-1, using two's complement format.

The instructions that operate on packed halfwords or bytes include some multiply instructions that use only one of two halfwords, and SIMD instructions that perform parallel addition or subtraction on all of the halfwords or bytes.

Note

These SIMD instructions operate on values held in the general-purpose registers. Do not confuse them with the Advanced SIMD instructions that operate on a separate register file that provides registers of up to 128 bits.

Direct instruction support for 64-bit integers is limited, and most 64-bit operations require sequences of two or more instructions to synthesize them.

Integer arithmetic

The instruction set provides a wide range of operations on the values in registers, including bitwise logical operations, shifts, additions, subtractions, multiplications, and divisions. The pseudocode described in Appendix H *ARM Pseudocode Definition* defines these operations, usually in one of three ways:

- By direct use of the pseudocode operators and built-in functions defined in *Operators and built-in functions* on page AppxH-5147.
- By use of pseudocode helper functions defined in the main text. See Appendix I *Pseudocode Index*.
- By a sequence of the form:
  1. Use of the `SInt()`, `UInt()`, and `Int()` built-in functions defined in *Converting bitstrings to integers* on page AppxH-5149 to convert the bitstring contents of the instruction operands to the unbounded integers that they represent as two's complement or unsigned integers.
  2. Use of mathematical operators, built-in functions and helper functions on those unbounded integers to calculate other such integers.
  3. Use of either the bitstring extraction operator defined in *Bitstring extraction* on page AppxH-5148 or of the saturation helper functions described in *Pseudocode details of saturation* on page E1-2207 to convert an unbounded integer result into a bitstring result that can be written to a register.

Shift and rotate operations

The following types of shift and rotate operations are used in instructions:

Logical Shift Left

(`LSL`) moves each bit of a bitstring left by a specified number of bits. Zeros are shifted in at the right end of the bitstring. Bits that are shifted off the left end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Logical Shift Right

(`LSR`) moves each bit of a bitstring right by a specified number of bits. Zeros are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Arithmetic Shift Right

(`ASR`) moves each bit of a bitstring right by a specified number of bits. Copies of the leftmost bit are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Rotate Right (`ROR`) moves each bit of a bitstring right by a specified number of bits. Each bit that is shifted off the right end of the bitstring is re-introduced at the left end. The last bit shifted off the right end of the bitstring can be produced as a carry output.

Rotate Right with Extend

(`RRX`) moves each bit of a bitstring right by one bit. A carry input is shifted in at the left end of the bitstring. The bit shifted off the right end of the bitstring can be produced as a carry output.

Pseudocode details of shift and rotate operations

These shift and rotate operations are supported in pseudocode by the following functions:

```
// LSL_C()
// =======

(bits(N), bit) LSL_C(bits(N) x, integer shift)
    assert shift > 0;
    extended_x = x : Zeros(shift);
    result = extended_x<N-1:0>;
    carry_out = extended_x<N>;
    return (result, carry_out);

// LSL()
// =====

bits(N) LSL(bits(N) x, integer shift)
    assert shift >= 0;
    if shift == 0 then
        result = x;
    else
        (result, -) = LSL_C(x, shift);
    return result;

// LSR_C()
// =======

(bits(N), bit) LSR_C(bits(N) x, integer shift)
    assert shift > 0;
    extended_x = ZeroExtend(x, shift+N);
    result = extended_x<shift+N-1:shift>;
    carry_out = extended_x<shift-1>;
    return (result, carry_out);

// LSR()
// =====

bits(N) LSR(bits(N) x, integer shift)
    assert shift >= 0;
    if shift == 0 then
        result = x;
    else
        (result, -) = LSR_C(x, shift);
    return result;

// ASR_C()
// =======

(bits(N), bit) ASR_C(bits(N) x, integer shift)
    assert shift > 0;
    extended_x = SignExtend(x, shift+N);
    result = extended_x<shift+N-1:shift>;
    carry_out = extended_x<shift-1>;
    return (result, carry_out);

// ASR()
// =====

bits(N) ASR(bits(N) x, integer shift)
    assert shift >= 0;
    if shift == 0 then
        result = x;
    else
        (result, -) = ASR_C(x, shift);
    return result;

// ROR_C()
```

```
// =======

(bits(N), bit) ROR_C(bits(N) x, integer shift)
    assert shift != 0;
    m = shift MOD N;
    result = LSR(x,m) OR LSL(x,N-m);
    carry_out = result<N-1>;
    return (result, carry_out);

// ROR()
// =====

bits(N) ROR(bits(N) x, integer shift)
    assert shift >= 0;
    if shift == 0 then
        result = x;
    else
        (result, -) = ROR_C(x, shift);
    return result;

// RRX_C()
// =======

(bits(N), bit) RRX_C(bits(N) x, bit carry_in)
    result = carry_in : x<N-1:1>;
    carry_out = x<0>;
    return (result, carry_out);

// RRX()
// =====

bits(N) RRX(bits(N) x, bit carry_in)
    (result, -) = RRX_C(x, carry_in);
    return result;
```

Pseudocode details of addition and subtraction

In pseudocode, addition and subtraction can be performed on any combination of unbounded integers and bitstrings, provided that if they are performed on two bitstrings, the bitstrings must be identical in length. The result is another unbounded integer if both operands are unbounded integers, and a bitstring of the same length as the bitstring operand or operands otherwise. For the definition of these operations, see *Addition and subtraction* on page AppxH-5150.

The main addition and subtraction instructions can produce status information about both unsigned carry and signed overflow conditions. When necessary, multi-word additions and subtractions can be synthesized from this status information. In pseudocode the `AddWithCarry()` function provides an addition with a carry input and a set of output condition flags including carry output and overflow:

```
// AddWithCarry()
// ==============
// Integer addition with carry input, returning result and NZCV flags

(bits(N), bits(4)) AddWithCarry(bits(N) x, bits(N) y, bit carry_in)
    integer unsigned_sum = UInt(x) + UInt(y) + UInt(carry_in);
    integer signed_sum = SInt(x) + SInt(y) + UInt(carry_in);
    bits(N) result = unsigned_sum<N-1:0>; // same value as signed_sum<N-1:0>
    bit n = result<N-1>;
    bit z = if IsZero(result) then '1' else '0';
    bit c = if UInt(result) == unsigned_sum then '0' else '1';
    bit v = if SInt(result) == signed_sum then '0' else '1';
    return (result, n:z:c:v);
```

An important property of the `AddWithCarry()` function is that if:

```
(result, nzcv) = AddWithCarry(x, NOT(y), carry_in)
```

Then:

- If `carry_in == '1'`, then `result == x-y` with:
  - `nzcv<0> == '1'` if signed overflow occurred during the subtraction.
  - `nzcv<1> == '1'` if unsigned borrow did not occur during the subtraction, that is, if x≥y.
- If `carry_in == '0'`, then `result == x-y-1` with:
  - `nzcv<0> == '1'` if signed overflow occurred during the subtraction.
  - `nzcv<1> == '1'` if unsigned borrow did not occur during the subtraction, that is, if x≥y.

Taken together, this means that the `carry_in` and `nzcv<1>` output in `AddWithCarry()` calls can act as NOT borrow flags for subtractions as well as carry flags for additions.

Pseudocode details of saturation

Some instructions perform *saturating arithmetic*, that is, if the result of the arithmetic overflows the destination signed or unsigned N-bit integer range, the result produced is the largest or smallest value in that range, rather than wrapping around modulo 2^N. This is supported in pseudocode by:

- The `SignedSatQ()` and `UnsignedSatQ()` functions when an operation requires, in addition to the saturated result, a Boolean argument that indicates whether saturation occurred.
- The `SignedSat()` and `UnsignedSat()` functions when only the saturated result is required.

```
// SignedSatQ()
// ============

(bits(N), boolean) SignedSatQ(integer i, integer N)
    if i > 2^(N-1) - 1 then
        result = 2^(N-1) - 1;  saturated = TRUE;
    elsif i < -(2^(N-1)) then
        result = -(2^(N-1));  saturated = TRUE;
    else
        result = i;  saturated = FALSE;
    return (result<N-1:0>, saturated);

// UnsignedSatQ()
// ==============

(bits(N), boolean) UnsignedSatQ(integer i, integer N)
    if i > 2^N - 1 then
        result = 2^N - 1;  saturated = TRUE;
    elsif i < 0 then
        result = 0;  saturated = TRUE;
    else
        result = i;  saturated = FALSE;
    return (result<N-1:0>, saturated);

// SignedSat()
// ===========

bits(N) SignedSat(integer i, integer N)
    (result, -) = SignedSatQ(i, N);
    return result;

// UnsignedSat()
// =============

bits(N) UnsignedSat(integer i, integer N)
    (result, -) = UnsignedSatQ(i, N);
    return result;
```

`SatQ(i, N, unsigned)` returns either `UnsignedSatQ(i, N)` or `SignedSatQ(i, N)` depending on the value of its third argument, and `Sat(i, N, unsigned)` returns either `UnsignedSat(i, N)` or `SignedSat(i, N)` depending on the value of its third argument:

```
// SatQ()
// ======

(bits(N), boolean) SatQ(integer i, integer N, boolean unsigned)
    (result, sat) = if unsigned then UnsignedSatQ(i, N) else SignedSatQ(i, N);
    return (result, sat);

// Sat()
// =====

bits(N) Sat(integer i, integer N, boolean unsigned)
    result = if unsigned then UnsignedSat(i, N) else SignedSat(i, N);
    return result;
```

E1.2.3 The general-purpose registers, and the PC, in AArch32 state

In the AArch32 Application level view, a PE has:

- Fifteen general-purpose 32-bit registers, R0 to R14, of which R13 and R14 have alternative names reflecting how they are, or can be, used:
  - R13 is usually identified as SP.
  - R14 is usually identified as LR.
- The PC (*program counter*), that can be described as R15.

The specialized uses of the SP (R13), LR (R14), and PC (R15) are:

SP, the stack pointer

The PE uses SP as a pointer to the active stack.

In the T32 instruction set, some instructions cannot access SP, and for most T32 instructions ARM deprecates using SP as a general-purpose register. The only T32 instructions for which the use of SP is not deprecated are those designed to use SP as a stack pointer.

The A32 instruction set provides more general access to the SP, and it can be used as a general-purpose register. However, ARM deprecates the use of SP for any purpose other than as a stack pointer.

Note

- Using SP for any purpose other than as a stack pointer is likely to break the requirements of operating systems, debuggers, and other software systems, causing them to malfunction.
- Before ARMv8, for most T32 instructions, using SP as a general-purpose register was UNPREDICTABLE. In ARMv8, most of these uses of SP behave predictably, but are deprecated by ARM. The instruction descriptions give more information.

Software can refer to SP as R13.

LR, the link register

The link register is a special register that can hold return link information. Some cases described in this manual require this use of the LR. When software does not require the LR for linking, it can use it for other purposes. Software can refer to LR as R14.

PC, the program counter

- When executing an A32 instruction, PC reads as the address of the current instruction plus 8.
- When executing a T32 instruction, PC reads as the address of the current instruction plus 4.
- Writing an address to PC causes a branch to that address.

Most T32 instructions cannot access PC.

The A32 instruction set provides more general access to the PC, and many A32 instructions can use the PC as a general-purpose register. However, ARM deprecates the use of PC for any purpose other than as the program counter. See *Writing to the PC* on page E1-2209 for more information.

Software can refer to PC as R15.

See *AArch32 general-purpose registers, and the PC* on page G1-3383 for the system level view of these registers.

Note

In general, ARM strongly recommends using the names SP, LR and PC instead of R13, R14 and R15. However, sometimes it is simpler to use the R13-R15 names when referring to a group of registers. For example, it is simpler to refer to *registers R8 to R15*, rather than to *registers R8 to R12, the SP, LR and PC*. These two descriptions of the group of registers have exactly the same meaning.

Writing to the PC

In the A32 and T32 instruction sets, many data-processing instructions can write to the PC. Writes to the PC are handled as follows:

- In T32 state, the following 16-bit T32 instruction encodings branch to the value written to the PC:
  - Encoding T2 of *ADD (register), T32* on page F7-2460.
  - Encoding T1 of *MOV (register), T32* on page F7-2641.

  The value written to the PC is forced to be halfword-aligned by ignoring its least significant bit, treating that bit as being 0.
- The `B`, `BL`, `CBNZ`, `CBZ`, `CHKA`, `HB`, `HBL`, `HBLP`, `HBP`, `TBB`, and `TBH` instructions remain in the same instruction set state and branch to the value written to the PC.

  The definition of each of these instructions ensures that the value written to the PC is correctly aligned for the current instruction set state.
- The `BLX` (immediate) instruction switches between A32 and T32 states and branches to the value written to the PC. Its definition ensures that the value written to the PC is correctly aligned for the new instruction set state.
- The following instructions write a value to the PC, treating that value as an interworking address to branch to, with low-order bits that determine the new instruction set state:
  - `BLX` (register), `BX`, and `BXJ`.
  - `LDR` instructions with `<Rt>` equal to the PC.
  - `POP` and all forms of `LDM` except `LDM` (exception return), when the register list includes the PC.
  - In A32 state only, `ADC`, `ADD`, `ADR`, `AND`, `ASR` (immediate), `BIC`, `EOR`, `LSL` (immediate), `LSR` (immediate), `MOV`, `MVN`, `ORR`, `ROR` (immediate), `RRX`, `RSB`, `RSC`, `SBC`, and `SUB` instructions with `<Rd>` equal to the PC and without flag-setting specified.

  For details of how an interworking address specifies the new instruction set state and instruction address, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

  Note

  The register-shifted register instructions, that are available only in the A32 instruction set and are summarized in *Data-processing (register-shifted register)* on page F4-2385, are UNPREDICTABLE if they attempt to write to the PC.
- Some instructions are treated as exception return instructions, and write both the PC and the CPSR. For more information, including which instructions are exception return instructions, see *Exception return to an Exception level using AArch32* on page G1-3412.
- Some instructions cause an exception, and the exception handler address is written to the PC as part of the exception entry.

Pseudocode details of operations on the AArch32 general-purpose registers and the PC

In pseudocode, the uses of the R[] function are:

- Reading or writing R0-R12, SP, and LR, using n = 0-12, 13, and 14 respectively.
- Reading the PC, using n = 15.

This function has prototypes:

```
array bits(64) _R[0..30];
```

Pseudocode details of general-purpose register and PC operations on page G1-3384 explains the full operation of this function.

Descriptions of A32 store instructions that store the PC value use the PCStoreValue() pseudocode function to specify the PC value stored by the instruction:

```
// PCStoreValue()
// ==============

bits(32) PCStoreValue()
    // This function returns the PC value. On architecture versions before ARMv7, it
    // is permitted to instead return PC+4, provided it does so consistently. It is
    // used only to describe A32 instructions, so it returns the address of the current
    // instruction plus 8 (normally) or 12 (when the alternative is permitted).
    return PC;
```

Writing an address to the PC causes either a simple branch to that address or an *interworking* branch that also selects the instruction set to execute after the branch. A simple branch is performed by the BranchWritePC() function:

```
// BranchWritePC()
// ===============

BranchWritePC(bits(32) address)
    if CurrentInstrSet() == InstrSet_A32 then
        address<1:0> = '00';
    else
        address<0> = '0';
    BranchTo(address, BranchType_UNKNOWN);
```

An interworking branch is performed by the BXWritePC() function:

```
// BXWritePC()
// ===========

BXWritePC(bits(32) address)
    if address<0> == '1' then
        SelectInstrSet(InstrSet_T32);
        address<0> = '0';
    else
        SelectInstrSet(InstrSet_A32);
        // For branches to an unaligned PC counter in A32 state, the processor takes the branch
        // and does one of:
        // * Forces the address to be aligned
        // * Leaves the PC unaligned, meaning the target generates a PC Alignment fault.
        if address<1> == '1' && ConstrainUnpredictableBool() then
            address<1> = '0';
    BranchTo(address, BranchType_UNKNOWN);
```

The LoadWritePC() and ALUWritePC() functions are used for two cases where the behavior was systematically modified between architecture versions:

```
// LoadWritePC()
// =============

LoadWritePC(bits(32) address)
    BXWritePC(address);

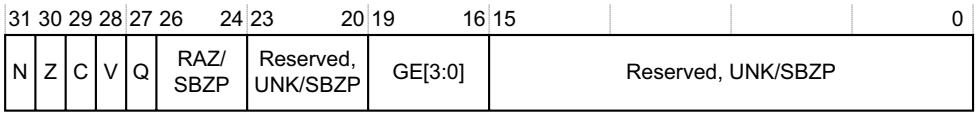
// ALUWritePC()
```

```
// ============

ALUWritePC(bits(32) address)
    if CurrentInstrSet() == InstrSet_A32 then
        BXWritePC(address);
    else
        BranchWritePC(address);
```

E1.2.4 The Application Program Status Register (APSR)

Program status is reported in the 32-bit *Application Program Status Register* (APSR). The APSR bit assignments are:



The APSR bit categories are:

- Reserved bits, that are allocated to system features, or are available for future expansion. Unprivileged execution ignores writes to fields that are accessible only at EL1 or higher. However, application level software that writes to the APSR must treat reserved bits as *Do-Not-Modify* (DNM) bits. For more information about the reserved bits, see *Format of the CPSR and SPSRs* on page G1-3388.
- Bits that can be set by many instructions:
  - The Condition flags:

    N, bit[31] Negative condition flag. Set to bit[31] of the result of the instruction. If the result is regarded as a two's complement signed integer, then the PE sets N to 1 if the result is negative, and sets N to 0 if it is positive or zero.

    Z, bit[30] Zero condition flag. Set to 1 if the result of the instruction is zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

    C, bit[29] Carry condition flag. Set to 1 if the instruction results in a carry condition, for example an unsigned overflow on an addition.

    V, bit[28] Overflow condition flag. Set to 1 if the instruction results in an overflow condition, for example a signed overflow on an addition.
  - The Overflow or saturation flag:

    Q, bit[27] Set to 1 to indicate overflow or saturation occurred in some instructions, normally related to *digital signal processing* (DSP). For more information, see *Pseudocode details of saturation* on page E1-2207.
  - The Greater than or Equal flags:

    GE[3:0], bits[19:16]

    The instructions described in *Parallel addition and subtraction instructions* on page F1-2306 update these flags to indicate the results from individual bytes or halfwords of the operation. These flags can control a later `SEL` instruction. For more information, see *SEL* on page F7-2757.
- Bits[26:24] are RAZ/SBZP. Therefore, software can use `MSR` instructions that write the top byte of the APSR without using a read, modify, write sequence. If it does this, it must write zeros to bits[26:24].

Instructions can test the N, Z, C, and V condition flags, combining these with the *condition code* for the instruction to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution see *Conditional execution* on page F2-2331.

In AArch32 state, the APSR is the same register as the CPSR, but the APSR must be used only to access the N, Z, C, V, Q, and GE[3:0] bits. For more information, see *Program Status Registers (PSRs)* on page G1-3387.

E1.2.5 Execution State registers

The Execution State registers modify the execution of instructions. They control:

- Whether instructions are interpreted as T32 instructions or A32 instructions. For more information, see *Instruction set state register, ISETSTATE*.
- In T32 state, the condition codes that apply to the next one to four instructions. For more information, see *IT block state register, ITSTATE* on page E1-2213.
- Whether data is interpreted as big-endian or little-endian. For more information, see *Endianness mapping register, ENDIANSTATE* on page E1-2215.

In AArch32 state, the Execution State registers are part of the Current Program Status Register. For more information, see *Program Status Registers (PSRs)* on page G1-3387.

There is no direct access to the Execution State registers from application level instructions, but they can be changed by side-effects of application level instructions.

Instruction set state register, ISETSTATE

The instruction set state register, ISETSTATE, format is:

The J bit and the T bit determine the current *instruction set state* for the PE, as Table E1-1 shows.

Table E1-1 J and T bit encoding in ISETSTATE

J	T	Instruction set state
0	0	A32
0	1	T32
1	0	Reserved
1	1	Reserved

A32 state The PE executes the A32 instruction set summarized in Chapter F4 *A32 Base Instruction Set Encoding* and Chapter F5 *T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings*.

T32 state The PE executes the T32 instruction set summarized in Chapter F3 *T32 Base Instruction Set Encoding* and Chapter F5 *T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings*.

Reserved, T32EE state and Jazelle state before ARMv8

Before ARMv8. the {J, T} encoding {1,0} selected Jazelle state, and the encoding {1, 1} selected T32EE state. ARMv8 does not support either of these states and these encodings select unimplemented instruction set states, see *Unimplemented instruction sets* on page G1-3394.

Note

In AArch32 state, ARMv8 requires a Trivial Jazelle implementation, see *Trivial implementation of the Jazelle extension* on page G1-3394.

Pseudocode details of ISETSTATE operations

The following pseudocode functions return the current instruction set and select a new instruction set:

```
enumeration InstrSet {InstrSet_A64, InstrSet_A32, InstrSet_T32};

// CurrentInstrSet()
// =================

InstrSet CurrentInstrSet()

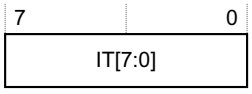
    if UsingAArch32() then
        case PSTATE.<J,T> of
            when '00'  result = InstrSet_A32;
            when '01'  result = InstrSet_T32;
            // Implementation of T32EE or non-trivial implementation of Jazelle not permitted
            when '1x'  Unreachable();
    else
        return InstrSet_A64;
    return result;

// SelectInstrSet()
// ================

SelectInstrSet(InstrSet iset)
    assert CurrentInstrSet() != InstrSet_A64;
    case iset of
        when InstrSet_A32  PSTATE.<J,T> = '00';
        when InstrSet_T32  PSTATE.<J,T> = '01';
        otherwise          Unreachable();
    return;
```

IT block state register, ITSTATE

The IT block state register, ITSTATE, format is:



This field holds the If-Then Execution State bits for the T32 `IT` instruction, that applies to the *IT block* of one to four instructions that immediately follow the `IT` instruction. See *IT* on page F7-2533 for a description of the `IT` instruction and the associated IT block.

ITSTATE divides into two subfields:

IT[7:5] Holds the *base condition* for the current IT block. The base condition is the top 3 bits of the condition code specified by the `<firstcond>` field of the `IT` instruction.

This subfield is `0b000` when no IT block is active.

IT[4:0] Encodes:

- The size of the IT block. This is the number of instructions that are to be conditionally executed. The size of the block is implied by the position of the least significant 1 in this field, as shown in Table E1-2 on page E1-2214.
- The value of the least significant bit of the condition code for each instruction in the block.

  Note

  Changing the value of the least significant bit of a condition code from 0 to 1 has the effect of inverting the condition code.

This subfield is `0b00000` when no IT block is active.

When an IT instruction is executed, these bits are set according to the `<firstcond>` condition code in the instruction, and the *Then* and *Else* (T and E) parameters in the instruction. For more information, see *IT* on page F7-2533.

When permitted, an instruction in an IT block is conditional, see *Conditional instructions* on page F1-2297 and *Conditional execution* on page F2-2331. The condition code used is the current value of IT[7:4]. When an instruction in an IT block completes its execution normally, ITSTATE advances to the next line of Table E1-2. A few instructions, for example BKPT, cannot be conditional and therefore are always executed, ignoring the current ITSTATE.

For details of what happens if an instruction in an IT block takes an exception, see *Overview of exception entry* on page G1-3401.

An instruction that might complete its normal execution by branching is only permitted in an IT block as the last instruction in the block. This means that normal execution of the instruction always results in ITSTATE advancing to normal execution.

Table E1-2 Effect of IT Execution State bits

IT bits [a]						Note
[7:5]	[4]	[3]	[2]	[1]	[0]	
cond_base	P1	P2	P3	P4	1	Entry point for 4-instruction IT block
cond_base	P1	P2	P3	1	0	Entry point for 3-instruction IT block
cond_base	P1	P2	1	0	0	Entry point for 2-instruction IT block
cond_base	P1	1	0	0	0	Entry point for 1-instruction IT block
000	0	0	0	0	0	Normal execution, not in an IT block

a. Combinations of the IT bits not shown in this table are reserved.

On a branch or an exception return, if ITSTATE is set to a value that is not consistent with the instruction stream being branched to or returned to, then instruction execution is UNPREDICTABLE.

ITSTATE affects instruction execution only in T32 state. In A32 state, ITSTATE must be '00000000', otherwise the behavior is UNPREDICTABLE.

Pseudocode details of ITSTATE operations

ITSTATE advances after normal execution of an IT block instruction. This is described by the ITAdvance() pseudocode function:

```
// AArch32.ITAdvance()
// ===================

AArch32.ITAdvance()
    if PSTATE.IT<2:0> == '000' then
        PSTATE.IT = '00000000';
    else
        PSTATE.IT<4:0> = LSL(PSTATE.IT<4:0>, 1);
    return;
```

The following functions test whether the current instruction is in an IT block, and whether it is the last instruction of an IT block:

```
// InITBlock()
// ===========

boolean InITBlock()
    if CurrentInstrSet() == InstrSet_T32 then
        return PSTATE.IT<3:0> != '0000';
    else
        return FALSE;

// LastInITBlock()
```

```
// ===============

boolean LastInITBlock()
    return (PSTATE.IT<3:0> == '1000');
```

Endianness mapping register, ENDIANSTATE

ARMv8 supports configuration between little-endian and big-endian interpretations of data memory, as Table E1-3 shows. The endianness is controlled by ENDIANSTATE.

Table E1-3 ENDIANSTATE encoding of endianness

ENDIANSTATE	Endian mapping
0	Little-endian
1	Big-endian

The A32 and T32 instruction sets both include an instruction to manipulate ENDIANSTATE:

`SETEND BE` Sets ENDIANSTATE to 1, for big-endian operation.

`SETEND LE` Sets ENDIANSTATE to 0, for little-endian operation.

The `SETEND` instruction is unconditional. For more information, see *SETEND* on page F7-2759.

Pseudocode details of ENDIANSTATE operations

The `BigEndian()` pseudocode function tests whether big-endian memory accesses are currently selected.

```
// BigEndian()
// ===========

boolean BigEndian()
    boolean bigend;
    if UsingAArch32() then
        bigend = (PSTATE.E != '0');
    elsif PSTATE.EL == EL0 then
        bigend = (SCTLR_EL1.E0E != '0');
    else
        bigend = (SCTLR[].EE != '0');
    return bigend;
```

E1.2.6 Jazelle support

ARMv8 requires AArch32 state to include a trivial implementation of the Jazelle extension, as described in *Trivial implementation of the Jazelle extension* on page G1-3394. For execution at EL0, this means:

- The JIDR is RO and RAZ.
- A `BXJ` instruction behaves as a `BX` instruction, see *BXJ* on page F7-2498.

E1.3 Advanced SIMD and floating-point instructions

In general, ARMv8 requires implementation of Advanced SIMD and floating-point instructions in the T32 and A32 instruction sets, but see *Implications of not including Advanced SIMD and floating-point support* on page E1-2223.

The Advanced SIMD instructions perform packed *Single Instruction Multiple Data* (SIMD) operations, either integer or single-precision floating-point. The floating-point instructions perform single-precision or double-precision scalar floating-point operations.

These instructions permit *floating-point exceptions*, such as overflow or division by zero, to be handled without trapping. When handled in this way, a floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation.

ARMv8 also optionally supports the trapping of floating-point exceptions, see *Trapping of floating-point exception* on page E1-2220.

For more information about floating-point exceptions see *Floating-point exceptions* on page E1-2220.

The floating-point and Advanced SIMD instructions also provide conversion functions in both directions between half-precision floating-point and single-precision floating-point.

For system level information about the Advanced SIMD and Floating-point implementation see *Advanced SIMD and floating-point support* on page G1-3466.

Some Advanced SIMD instructions support polynomial arithmetic over {0, 1}, as described in *Polynomial arithmetic over {0, 1}* on page A1-45.

E1.3.1 Floating-point standards, and terminology

Floating-point standards, and terminology on page A1-48 describes the ARMv8 alignment with the IEEE 754 standard, and the floating-point terminology used throughout this manual.

E1.3.2 The SIMD and floating-point register file

The Advanced SIMD and floating-point instructions use the same register file, that comprises 32 registers. This is distinct from the register file that holds the general-purpose registers and the PC.

The Advanced SIMD and floating-point views of the register file are different. The following sections describe these different views. Figure E1-1 on page E1-2217 shows the views of the register file, and the way the word, doubleword, and quadword registers overlap.

Advanced SIMD views of the register file

Advanced SIMD can view this register file as:

- Sixteen 128-bit quadword registers, Q0-Q15.
- Thirty-two 64-bit doubleword registers, D0-D31.

These views can be used simultaneously. For example, a program might hold 64-bit vectors in `D0` and `D1` and a 128-bit vector in `Q1`.

Floating-point views of the register file

The Advanced SIMD and floating-point register file consists of thirty-two doubleword registers, that can be viewed as:

- Thirty-two 64-bit doubleword registers, D0-D31. This view is also available to Advanced SIMD instructions.
- Thirty-two 32-bit single word registers, S0-S31. Only half of the set is accessible in this view.

The two views can be used simultaneously.

SIMD and Floating-point register file mapping onto registers

Figure E1-1 shows the different views of the SIMD and floating-point register file, and the relationship between them.

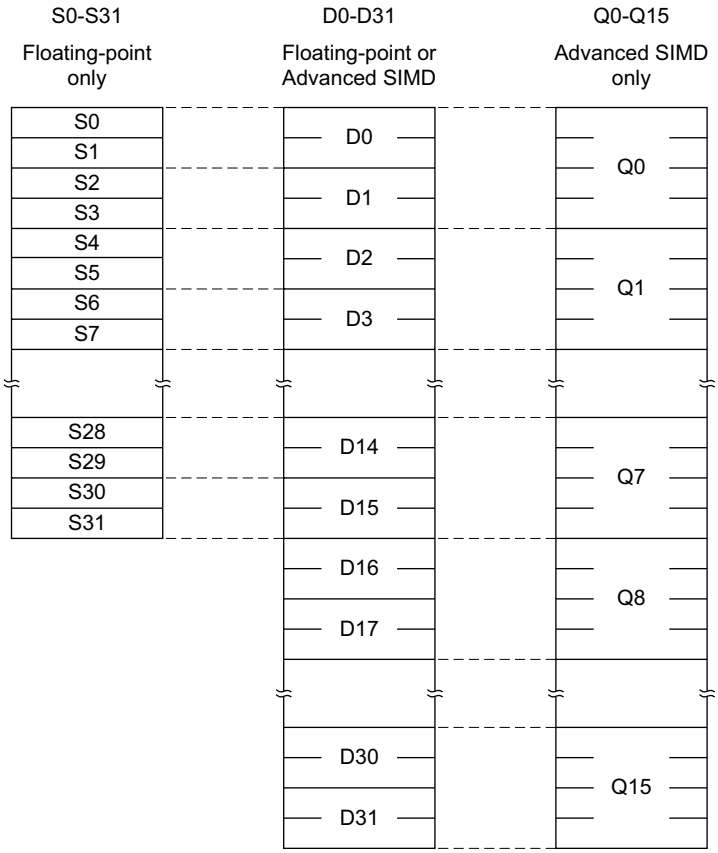


Figure E1-1 SIMD and floating-point register file, AArch32 operation

The mapping between the registers is as follows:

- S<2n> maps to the least significant half of D<n>.
- S<2n+1> maps to the most significant half of D<n>.
- D<2n> maps to the least significant half of Q<n>.
- D<2n+1> maps to the most significant half of Q<n>.

For example, software can access the least significant half of the elements of a vector in Q6 by referring to D12, and the most significant half of the elements by referring to D13.

Pseudocode details of the SIMD and Floating-point register file

The array `_V` defines the SIMD and floating-point register file:

```
array bits(128) _V[0..31];
```

Note

AArch32 only uses the first 16 of the registers, V0 - V15.

The following functions provide the `S0-S31`, `D0-D31`, and `Q0-Q15` views of the registers:

```
array bits(64) _Dclone[0..31];

// S[] - non-assignment form
```

```
// ========================

bits(32) S[integer n]
    assert n >= 0 && n <= 31;
    base = (n MOD 4) * 32;
    return _V[n DIV 4]<base+31:base>;

// S[] - assignment form
// =====================

S[integer n] = bits(32) value
    assert n >= 0 && n <= 31;
    base = (n MOD 4) * 32;
    _V[n DIV 4]<base+31:base> = value;
    return;

// D[] - non-assignment form
// =========================

bits(64) D[integer n]
    assert n >= 0 && n <= 31;
    base = (n MOD 2) * 64;
    return _V[n DIV 2]<base+63:base>;

// D[] - assignment form
// =====================

D[integer n] = bits(64) value
    assert n >= 0 && n <= 31;
    base = (n MOD 2) * 64;
    _V[n DIV 2]<base+63:base> = value;
    return;
```

The `Din[]` function returns a Doubleword register from the `_Dclone[]` copy of the SIMD and Floating-point register file, and the `Qin[]` function returns a Quadword register from that register file.

Note

The `CheckAdvancedSIMDEnabled()` function copies the `D[]` register file to `_Dclone[]`, see *Pseudocode details of enabling Advanced SIMD and floating-point functionality* on page G1-3471.

```
// Din[] - non-assignment form
// ===========================

bits(64) Din[integer n]
    assert n >= 0 && n <= 31;
    return _Dclone[n];

// Qin[] - non-assignment form
// ===========================

bits(128) Qin[integer n]
    assert n >= 0 && n <= 15;
    return Din[2*n+1]:Din[2*n];
```

E1.3.3 Data types supported by the Advanced SIMD implementation

Advanced SIMD instructions can operate on integer and floating-point data, and the implementation defines a set of data types that support the required data formats. *Vector formats in AArch32 state* on page A1-38 describes these formats.

Advanced SIMD vectors

In an implementation that includes support for Advanced SIMD operation, a register can hold one or more packed elements, all of the same size and type. The combination of a register and a data type describes a vector of elements. The vector is considered to be an array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the size of the register.

Vector indices are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant end of the vector. In *Vector formats in AArch32 state* on page A1-38, Figure A1-3 on page A1-40 shows the Advanced SIMD vector formats.

Pseudocode details of Advanced SIMD vectors

The pseudocode function `Elem[]` accesses the element of a specified index and size in a vector:

```
// Elem[] - non-assignment form
// ============================

bits(size) Elem[bits(N) vector, integer e, integer size]
    assert e >= 0 && (e+1)*size <= N;
    return vector<e*size+size-1 : e*size>;

// Elem[] - non-assignment form
// ============================

bits(size) Elem[bits(N) vector, integer e]
    return Elem[vector, e, size];

// Elem[] - assignment form
// ========================

Elem[bits(N) &vector, integer e, integer size] = bits(size) value
    assert e >= 0 && (e+1)*size <= N;
    vector<(e+1)*size-1:e*size> = value;
    return;

// Elem[] - assignment form
// ========================

Elem[bits(N) &vector, integer e] = bits(size) value
    Elem[vector, e, size] = value;
    return;
```

E1.3.4 Advanced SIMD and floating-point system registers

The Advanced SIMD and floating-point instructions have a shared register space for system registers. Only one register in this space is accessible at the Application level, see *FPSCR, Floating-Point Status and Control Register* on page G5-3898.

Writes to the FPSCR can have side-effects on various aspects of PE operation. All of these side-effects are synchronous to the FPSCR write. This means they are guaranteed not to be visible to earlier instructions in the execution stream, and they are guaranteed to be visible to later instructions in the execution stream.

See *Advanced SIMD and floating-point system registers* on page G1-3472 for the system level view of the registers.

These registers can be described as the *SIMD and floating-point system registers*.

E1.3.5 Trapping of floating-point exception

It is IMPLEMENTATION DEFINED whether the floating-point implementation supports the trapping of floating-point exceptions:

- If it does, the FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable the exception traps.
- Otherwise, the FPSCR trap bits are RES0.

Trapped exception handling never causes the corresponding cumulative exception bit of the FPSCR to be set to 1. If this behavior is desired, the trap handler routine must use a read, modify, write sequence on the FPSCR to set the cumulative exception bit.

E1.3.6 Floating-point data types and arithmetic

The T32 and A32 floating-point instructions support single-precision (32-bit) and double-precision (64-bit) data types and arithmetic as defined by the IEEE 754 floating-point standard. They also support the half-precision (16-bit) floating-point data type for data storage only, by supporting conversions between single-precision and half-precision data types.

ARM standard floating-point arithmetic means IEEE 754 floating-point arithmetic with the restrictions described in *Floating-point and Advanced SIMD support* on page A1-46, including supporting only the input and output values described in *ARM standard floating-point input and output values* on page A1-48.

The AArch32 Advanced SIMD instructions support only single-precision ARM standard floating-point arithmetic.

Note

The floating-point instructions require *support code* to be installed in the system if trapped floating-point exception handling is required. See *Floating-point exception traps, serialization, and floating-point exception barriers* on page G1-3473.

The following sections describe the Advanced SIMD and floating-point formats:

- *Half-precision floating-point formats* on page A1-40.
- *Single-precision floating-point format* on page A1-42.
- *Double-precision floating-point format* on page A1-43.

The following sections describe features of Advanced SIMD and floating-point processing:

- *Flush-to-zero* on page A1-49.
- *NaN handling and the Default NaN* on page A1-50.

E1.3.7 Floating-point exceptions

ARM Advanced SIMD and floating-point instructions record the following floating-point exceptions in the FPSCR cumulative bits:

FPSCR.IOC Invalid Operation. The bit is set to 1 if the result of an operation has no mathematical value or cannot be represented. Cases include, for example:

- (infinity) × 0.
- (+infinity) + (–infinity).

These tests are made after flush-to-zero processing. For example, if flush-to-zero mode is selected, multiplying a denormalized number and an infinity is treated as (0 × infinity), and causes an Invalid Operation floating-point exception.

IOC is also set on any floating-point operation with one or more signaling NaNs as operands, except for negation and absolute value, as described in *Floating-point negation and absolute value* on page E1-2225.

FPSCR.DZC Division by Zero. The bit is set to 1 if a divide operation has a zero divisor and a dividend that is not zero, an infinity or a NaN. These tests are made after flush-to-zero processing, so if flush-to-zero processing is selected, a denormalized dividend is treated as zero and prevents Division by Zero from occurring, and a denormalized divisor is treated as zero and causes Division by Zero to occur if the dividend is a normalized number.

For the reciprocal and reciprocal square root estimate functions the dividend is assumed to be +1.0. This means that a zero or denormalized operand to these functions sets the DZC bit.

FPSCR.OFC Overflow. The bit is set to 1 if the absolute value of the result of an operation, produced after rounding, is greater than the maximum positive normalized number for the destination precision.

FPSCR.UFC Underflow. The bit is set to 1 if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, and the rounded result is inexact.

The criteria for the Underflow exception to occur are different in Flush-to-zero mode. For details, see *Flush-to-zero* on page A1-49.

FPSCR.IXC Inexact. The bit is set to 1 if the result of an operation is not equivalent to the value that would be produced if the operation were performed with unbounded precision and exponent range.

The criteria for the Inexact exception to occur are different in Flush-to-zero mode. For details, see *Flush-to-zero* on page A1-49.

FPSCR.IDC Input Denormal. The bit is set to 1 if a denormalized input operand is replaced in the computation by a zero, as described in *Flush-to-zero* on page A1-49.

For Advanced SIMD instructions, and for floating-point instructions when floating-point exception trapping is not supported, these are non-trapping exceptions and the data-processing instructions do not generate any trapped exceptions.

For floating-point instructions when floating-point exception trapping is supported:

- These exceptions can be trapped, by setting trap enable bits in the FPSCR, see *Trapping of floating-point exception* on page E1-2220. The way in which trapped floating-point exceptions are delivered to user software is IMPLEMENTATION DEFINED.
- The definition of the Underflow exception is different in the trapped and cumulative exception cases. In the trapped case the definition is:
  - The trapped Underflow exception occurs if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, regardless of whether the rounded result is inexact.
- As with cumulative exceptions, higher priority trapped exceptions can prevent lower priority exceptions from occurring, as described in *Combinations of exceptions* on page E1-2222.
- For Invalid Operation exceptions, for details of which quiet NaN is produced as the default result see *NaN handling and the Default NaN* on page A1-50.
- For Overflow exceptions, the sign bit of the default result is determined normally for the overflowing operation.
- For Division by Zero exceptions, the sign bit of the default result is determined normally for a division. This means it is the exclusive OR of the sign bits of the two operands.

Table E1-4 on page E1-2222 shows the results of untrapped floating-point exceptions:

In Table E1-4 on page E1-2222:

MaxNorm The maximum normalized number of the destination precision.

RM Round towards Minus Infinity mode, as defined in the IEEE 754 standard.

RN Round to Nearest mode, as defined in the IEEE 754 standard.

RP Round towards Plus Infinity mode, as defined in the IEEE 754 standard.

RZ Round towards Zero mode, as defined in the IEEE 754 standard.

Table E1-4 Results of untrapped floating-point exceptions

Exception type	Default result for positive sign	Default result for negative sign
IOC, Invalid Operation	Quiet NaN	Quiet NaN
DZC, Division by Zero	+infinity	-infinity
OFC, Overflow	RN, RP: +infinity RM, RZ: +MaxNorm	RN, RM: -infinity RP, RZ: -MaxNorm
UFC, Underflow	Normal rounded result	Normal rounded result
IXC, Inexact	Normal rounded result	Normal rounded result
IDC, Input Denormal	Normal rounded result	Normal rounded result

Combinations of exceptions

The following pseudocode functions perform *floating-point operations*:

```
FixedToFP()
FPAdd()
FPCompare()
FPCompareEQ()
FPCompareGE()
FPCompareGT()
FPDiv()
FPDoubleToSingle()
FPHalfToSingle()
FPMax()
FPMin()
FPMul()
FPMulAdd()
FPRecipEstimate()
FPRecipStep()
FPRSqrtEstimate()
FPRSqrtStep()
FPSingleToDouble()
FPSingleToHalf()
FPSqrt()
FPSub()
FPToFixed()
```

All of these operations can generate floating-point exceptions.

Note

`FPAbs()` and `FPNeg()` are not classified as *floating-point operations* because:

- They cannot generate floating-point exceptions.
- The floating-point operation behavior described in the following sections does not apply to them:
  - — *Flush-to-zero* on page A1-49.
  - — *NaN handling and the Default NaN* on page A1-50.

More than one exception can occur on the same operation. The only combinations of exceptions that can occur are:

- Overflow with Inexact.
- Underflow with Inexact.
- Input Denormal with other exceptions.

When none of the exceptions caused by an operation are trapped, any exception that occurs causes the associated cumulative bit in the FPSCR to be set.

When one or more exceptions caused by an operation are trapped, the behavior of the instruction depends on the priority of the exceptions. The Inexact exception is treated as lowest priority, and Input Denormal as highest priority:

- If the higher priority exception is trapped, its trap handler is called. It is IMPLEMENTATION DEFINED whether the parameters to the trap handler include information about the lower priority exception. Apart from this, the lower priority exception is ignored in this case.
- If the higher priority exception is untrapped, its cumulative bit is set to 1 and its default result is evaluated. Then the lower priority exception is handled normally, using this default result.

Some floating-point instructions specify more than one floating-point operation, as indicated by the pseudocode descriptions of the instruction. In such cases, an exception on one operation is treated as higher priority than an exception on another operation if the occurrence of the second exception depends on the result of the first operation. Otherwise, it is UNPREDICTABLE which exception is treated as higher priority.

For example, a `VMLA.F32` instruction specifies a floating-point multiplication followed by a floating-point addition. The addition can generate Overflow, Underflow and Inexact exceptions, all of which depend on both operands to the addition and so are treated as lower priority than any exception on the multiplication. The same applies to Invalid Operation exceptions on the addition caused by adding opposite-signed infinities. The addition can also generate an Input Denormal exception, caused by the addend being a denormalized number while in Flush-to-zero mode. It is UNPREDICTABLE which of an Input Denormal exception on the addition and an exception on the multiplication is treated as higher priority, because the occurrence of the Input Denormal exception does not depend on the result of the multiplication. The same applies to an Invalid Operation exception on the addition caused by the addend being a signaling NaN.

Note

- The `VFMA` instruction performs a vector addition and a vector multiplication as a single operation. The `VFMS` instruction performs a vector subtraction and a vector multiplication as a single operation.
- Like other details of Floating-point instruction execution, these rules about exception handling apply to the overall results produced by an instruction when the system uses a combination of hardware and support code to implement it. See *Floating-point exception traps, serialization, and floating-point exception barriers* on page G1-3473 for more information.

E1.3.8 Implications of not including Advanced SIMD and floating-point support

In general, ARMv8 requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. Exceptionally, for implementation targeting specialized markets, ARM might produce or license an ARMv8-A implementation that does not provide any support for Advanced SIMD and floating-point instructions. In such an implementation, in AArch32 state:

- Each of the CPACR.{cp10, cp11} fields is RES0.
- The CPACR.ASEDIS bit is RES1.
- Each of the HCPTR.{TASE, TCP10, TCP11} fields is RES1.
- Each of the NSACR.{NSASEDIS, cp10, cp11} fields is RES0.
- The FPEXC register is UNDEFINED.

E1.3.9 Pseudocode details of floating-point operations

The following subsections contain pseudocode definitions of the floating-point functionality supported by the ARMv8 architecture:

- *Floating-point maximum and minimum* on page E1-2231.
- *Floating-point addition and subtraction* on page E1-2232.
- *Floating-point multiplication and division* on page E1-2233.
- *Floating-point fused multiply-add* on page E1-2234.
- *Floating-point reciprocal estimate and step* on page E1-2235.
- *Floating-point square root* on page E1-2237.
- *Floating-point reciprocal square root estimate and step* on page E1-2238.
- *Floating-point conversions* on page E1-2241.

Generation of specific floating-point values

The following pseudocode functions generate specific floating-point values. The `sign` argument is `'0'` for the positive version and `'1'` for the negative version.

```
// FPInfinity()
// ============

bits(N) FPInfinity(bit sign)
    assert N IN {16,32,64};
    constant integer E = (if N == 16 then 5 elsif N == 32 then 8 else 11);
    constant integer F = N - E - 1;
    exp  = Ones(E);
    frac = Zeros(F);
    return sign : exp : frac;

// FPMaxNormal()
// =============

bits(N) FPMaxNormal(bit sign)
    assert N IN {16,32,64};
    constant integer E = (if N == 16 then 5 elsif N == 32 then 8 else 11);
    constant integer F = N - E - 1;
    exp  = Ones(E-1):'0';
    frac = Ones(F);
    return sign : exp : frac;

// FPZero()
// ========

bits(N) FPZero(bit sign)
    assert N IN {16,32,64};
    constant integer E = (if N == 16 then 5 elsif N == 32 then 8 else 11);
    constant integer F = N - E - 1;
    exp  = Zeros(E);
    frac = Zeros(F);
    return sign : exp : frac;

// FPTwo()
// =======

bits(N) FPTwo(bit sign)
    assert N IN {32,64};
    constant integer E = (if N == 32 then 8 else 11);
    constant integer F = N - E - 1;
    exp  = '1':Zeros(E-1);
    frac = Zeros(F);
    return sign : exp : frac;

// FPThree()
// =========

bits(N) FPThree(bit sign)
    assert N IN {32,64};
    constant integer E = (if N == 32 then 8 else 11);
    constant integer F = N - E - 1;
```

```
    exp  = '1':Zeros(E-1);
    frac = '1':Zeros(F-1);
    return sign : exp : frac;

// FPDefaultNaN()
// ==============

bits(N) FPDefaultNaN()
    assert N IN {16,32,64};
    constant integer E = (if N == 16 then 5 elsif N == 32 then 8 else 11);
    constant integer F = N - E - 1;
    sign = '0';
    exp  = Ones(E);
    frac = '1':Zeros(F-1);
    return sign : exp : frac;
```

Floating-point negation and absolute value

The floating-point negation and absolute value operations only affect the sign bit. They do not treat NaN operands specially, nor denormalized number operands when flush-to-zero is selected.

```
// FPNeg()
// =======

bits(N) FPNeg(bits(N) op)
    assert N IN {32,64};
    return NOT(op<N-1>) : op<N-2:0>;

// FPAbs()
// =======

bits(N) FPAbs(bits(N) op)
    assert N IN {32,64};
    return '0' : op<N-2:0>;
```

Floating-point value unpacking

The `FPUnpack()` function determines the type and numerical value of a floating-point number. It also does flush-to-zero processing on input operands.

```
enumeration FPType      {FPType_Nonzero, FPType_Zero, FPType_Infinity,
                         FPType_QNaN, FPType_SNaN};

// FPUnpack()
// ==========
//
// Unpack a floating-point number into its type, sign bit and the real number
// that it represents. The real number result has the correct sign for numbers
// and infinities, is very large in magnitude for infinities, and is 0.0 for
// NaNs. (These values are chosen to simplify the description of comparisons
// and conversions.)
//
// The 'fpcr' argument supplies FPCR control bits. Status information is
// updated directly in the FPSR where appropriate.

(FPType, bit, real) FPUnpack(bits(N) fpval, FPCRType fpcr)
    assert N IN {16,32,64};

    if N == 16 then
        sign   = fpval<15>;
        exp16  = fpval<14:10>;
        frac16 = fpval<9:0>;
        if IsZero(exp16) then
            // Produce zero if value is zero
            if IsZero(frac16) then
                type = FPType_Zero;  value = 0.0;
```

```
            else
                type = FPType_Nonzero;  value = 2.0^-14 * (UInt(frac16) * 2.0^-10);
        elsif IsOnes(exp16) && fpcr.AHP == '0' then  // Infinity or NaN in IEEE format
            if IsZero(frac16) then
                type = FPType_Infinity;  value = 2.0^1000000;
            else
                type = if frac16<9> == '1' then FPType_QNaN else FPType_SNaN;
                value = 0.0;
        else
            type = FPType_Nonzero;  value = 2.0^(UInt(exp16)-15) * (1.0 + UInt(frac16) * 2.0^-10);

    elsif N == 32 then

        sign   = fpval<31>;
        exp32  = fpval<30:23>;
        frac32 = fpval<22:0>;
        if IsZero(exp32) then
            // Produce zero if value is zero or flush-to-zero is selected.
            if IsZero(frac32) || fpcr.FZ == '1' then
                type = FPType_Zero;  value = 0.0;
                if !IsZero(frac32) then  // Denormalized input flushed to zero
                    FPProcessException(FPExc_InputDenorm, fpcr);
            else
                type = FPType_Nonzero;  value = 2.0^-126 * (UInt(frac32) * 2.0^-23);
        elsif IsOnes(exp32) then
            if IsZero(frac32) then
                type = FPType_Infinity;  value = 2.0^1000000;
            else
                type = if frac32<22> == '1' then FPType_QNaN else FPType_SNaN;
                value = 0.0;
        else
            type = FPType_Nonzero;  value = 2.0^(UInt(exp32)-127) * (1.0 + UInt(frac32) * 2.0^-23);

    else // N == 64

        sign   = fpval<63>;
        exp64  = fpval<62:52>;
        frac64 = fpval<51:0>;
        if IsZero(exp64) then
            // Produce zero if value is zero or flush-to-zero is selected.
            if IsZero(frac64) || fpcr.FZ == '1' then
                type = FPType_Zero;  value = 0.0;
                if !IsZero(frac64) then  // Denormalized input flushed to zero
                    FPProcessException(FPExc_InputDenorm, fpcr);
            else
                type = FPType_Nonzero;  value = 2.0^-1022 * (UInt(frac64) * 2.0^-52);
        elsif IsOnes(exp64) then
            if IsZero(frac64) then
                type = FPType_Infinity;  value = 2.0^1000000;
            else
                type = if frac64<51> == '1' then FPType_QNaN else FPType_SNaN;
                value = 0.0;
        else
            type = FPType_Nonzero;  value = 2.0^(UInt(exp64)-1023) * (1.0 + UInt(frac64) * 2.0^-52);

    if sign == '1' then value = -value;
    return (type, sign, value);
```

Floating-point exception and NaN handling

The `FPProcessException()` procedure checks whether a floating-point exception is trapped, and handles it accordingly:

```
enumeration FPExc       {FPExc_InvalidOp, FPExc_DivideByZero, FPExc_Overflow,
                         FPExc_Underflow, FPExc_Inexact, FPExc_InputDenorm};

// FPProcessException()
```

```
// ====================
//
// The 'fpcr' argument supplies FPCR control bits. Status information is
// updated directly in the FPSR where appropriate.

FPProcessException(FPExc exception, FPCRType fpcr)
    // Determine the cumulative exception bit number
    case exception of
        when FPExc_InvalidOp     cumul = 0;
        when FPExc_DivideByZero  cumul = 1;
        when FPExc_Overflow      cumul = 2;
        when FPExc_Underflow     cumul = 3;
        when FPExc_Inexact       cumul = 4;
        when FPExc_InputDenorm   cumul = 7;
    enable = cumul + 8;
    if fpcr<enable> == '1' then
        // Trapping of the exception enabled.
        // It is IMPLEMENTATION DEFINED whether the enable bit may be set at all, and
        // if so then how exceptions may be accumulated before calling FPTrapException()
        IMPLEMENTATION_DEFINED "floating-point trap handling";
    else if UsingAArch32() then
        // Set the cumulative exception bit
        FPSCR<cumul> = '1';
    else
        // Set the cumulative exception bit
        FPSR<cumul> = '1';
    return;
```

The FPProcessNaN() function processes a NaN operand, producing the correct result value and generating an Invalid Operation exception if necessary:

```
// FPProcessNaN()
// ==============

bits(N) FPProcessNaN(FPType type, bits(N) op, FPCRType fpcr)
    assert N IN {32,64};
    assert type IN {FPType_QNaN, FPType_SNaN};

    topfrac = if N == 32 then 22 else 51;
    result = op;
    if type == FPType_SNaN then
        result<topfrac> = '1';
        FPProcessException(FPExc_InvalidOp, fpcr);
    if fpcr.DN == '1' then  // DefaultNaN requested
        result = FPDefaultNaN();
    return result;
```

The FPProcessNaNs() function performs the standard NaN processing for a two-operand operation:

```
// FPProcessNaNs()
// ===============
//
// The boolean part of the return value says whether a NaN has been found and
// processed. The bits(N) part is only relevant if it has and supplies the
// result of the operation.
//
// The 'fpcr' argument supplies FPCR control bits. Status information is
// updated directly in the FPSR where appropriate.

(boolean, bits(N)) FPProcessNaNs(FPType type1, FPType type2,
                                 bits(N) op1, bits(N) op2,
                                 FPCRType fpcr)
    assert N IN {32,64};
    if type1 == FPType_SNaN then
        done = TRUE;  result = FPProcessNaN(type1, op1, fpcr);
    elsif type2 == FPType_SNaN then
        done = TRUE;  result = FPProcessNaN(type2, op2, fpcr);
    elsif type1 == FPType_QNaN then
```

```
        done = TRUE;  result = FPProcessNaN(type1, op1, fpcr);
    elsif type2 == FPType_QNaN then
        done = TRUE;  result = FPProcessNaN(type2, op2, fpcr);
    else
        done = FALSE;  result = Zeros();  // 'Don't care' result
    return (done, result);
```

The FPProcessNaNs3() function performs the standard NaN processing for a three-operand operation:

```
// FPProcessNaNs3()
// ================
//
// The boolean part of the return value says whether a NaN has been found and
// processed. The bits(N) part is only relevant if it has and supplies the
// result of the operation.
//
// The 'fpcr' argument supplies FPCR control bits. Status information is
// updated directly in the FPSR where appropriate.

(boolean, bits(N)) FPProcessNaNs3(FPType type1, FPType type2, FPType type3,

Floating-point rounding

The FPRound() function rounds and encodes a floating-point result value to a specified destination format. This includes processing Overflow, Underflow and Inexact floating-point exceptions and performing flush-to-zero processing on result values.

```
// FPRound()
// =========

// Convert a real number OP into an N-bit floating-point value using the
// supplied rounding mode RMODE.

bits(N) FPRound(real op, FPCRType fpcr, FPRounding rounding)
    assert N IN {16,32,64};
    assert op != 0.0;
    assert rounding != FPRounding_TIEAWAY;
    bits(N) result;

    // Obtain format parameters - minimum exponent, numbers of exponent and fraction bits.
    if N == 16 then
        minimum_exp = -14;  E = 5;  F = 10;
    elsif N == 32 then
        minimum_exp = -126;  E = 8;  F = 23;
    else  // N == 64
        minimum_exp = -1022;  E = 11;  F = 52;

    // Split value into sign, unrounded mantissa and exponent.
    if op < 0.0 then
```

```
    sign = '1';  mantissa = -op;
else
    sign = '0';  mantissa = op;
exponent = 0;
while mantissa < 1.0 do
    mantissa = mantissa * 2.0;  exponent = exponent - 1;
while mantissa >= 2.0 do
    mantissa = mantissa / 2.0;  exponent = exponent + 1;

// Deal with flush-to-zero.
if fpcr.FZ == '1' && N != 16 && exponent < minimum_exp then
    // Flush-to-zero never generates a trapped exception
    if UsingAArch32() then
        FPSCR.UFC = '1';
    else
        FPSR.UFC = '1';
    return FPZero(sign);

// Start creating the exponent value for the result. Start by biasing the actual exponent
// so that the minimum exponent becomes 1, lower values 0 (indicating possible underflow).
biased_exp = Max(exponent - minimum_exp + 1, 0);
if biased_exp == 0 then mantissa = mantissa / 2^(minimum_exp - exponent);

// Get the unrounded mantissa as an integer, and the "units in last place" rounding error.

    return result;

// FPRound()
// =========

bits(N) FPRound(real op, FPCRType fpcr)
    return FPRound(op, fpcr, FPRoundingMode(fpcr));
```

Selection of ARM standard floating-point arithmetic

The `StandardFPSCRValue()` function returns the FPSCR value that selects ARM standard floating-point arithmetic. Most of the arithmetic functions have a Boolean `fpscr_controlled` argument that is `TRUE` for Floating-point operations and `FALSE` for Advanced SIMD operations, and that selects between using the real FPSCR value and this value.

```
// StandardFPSCRValue()
// ====================

FPCRType StandardFPSCRValue()
    return '00000' : FPSCR.AHP : '1100000000000000000000000';
```

Floating-point comparisons

The `FPCompare()` function compares two floating-point numbers, producing a {N, Z, C, V} condition flags result as shown in Table E1-5:

Table E1-5 Effect of a Floating-point comparison on the condition flags

Comparison result	N	Z	C	V
Equal	0	1	1	0
Less than	1	0	0	0
Greater than	0	0	1	0
Unordered	0	0	1	1

This result defines the operation of the `VCMP` floating-point instruction. The `VCMP` instruction writes these flag values in the FPSCR. After using a `VMRS` instruction to transfer them to the APSR, they can control conditional execution as shown in Table F2-1 on page F2-2331.

```
// FPCompare()
// ===========

bits(4) FPCompare(bits(N) op1, bits(N) op2, boolean signal_nans, FPCRType fpcr)
    assert N IN {32,64};
    (type1,sign1,value1) = FPUnpack(op1, fpcr);
    (type2,sign2,value2) = FPUnpack(op2, fpcr);
    if type1==FPType_SNaN || type1==FPType_QNaN || type2==FPType_SNaN || type2==FPType_QNaN then
        result = '0011';
        if type1==FPType_SNaN || type2==FPType_SNaN || signal_nans then
            FPProcessException(FPExc_InvalidOp, fpcr);
    else
```

```
        // All non-NaN cases can be evaluated on the values produced by FPUnpack()
        if value1 == value2 then
            result = '0110';
        elsif value1 < value2 then
            result = '1000';
        else  // value1 > value2
            result = '0010';
    return result;
```

The FPCompareEQ(), FPCompareGE() and FPCompareGT() functions describe the operation of Advanced SIMD instructions that perform floating-point comparisons.

```
// FPCompareEQ()

```

Floating-point reciprocal square root estimate and step

The Advanced SIMD implementation includes instructions that support Newton-Raphson calculation of the reciprocal of the square root of a number.

The VRSQRTE instruction produces the initial estimate of the reciprocal of the square root. It uses the following pseudocode functions:

```
// FPRSqrtEstimate()
// =================

bits(N) FPRSqrtEstimate(bits(N) operand, FPCRType fpcr)
    assert N IN {32, 64};
    (type,sign,value) = FPUnpack(operand, fpcr);
    if type == FPType_SNaN || type == FPType_QNaN then
        result = FPProcessNaN(type, operand, fpcr);
    elsif type == FPType_Zero then
        result = FPInfinity(sign);
        FPProcessException(FPExc_DivideByZero, fpcr);
    elsif sign == '1' then
        result = FPDefaultNaN();
        FPProcessException(FPExc_InvalidOp, fpcr);
    elsif type == FPType_Infinity then
        result = FPZero('0');
    else
        // Scale to a double-precision value in the range 0.25 <= x < 1.0, with the
        // evenness or oddness of the exponent unchanged, and calculate result exponent.
        // Scaled value has copied sign bit, exponent = 1022 or 1021 = double-precision
        // biased version of -1 or -2, fraction = original fraction extended with zeros.

        if N == 32 then
            fraction = operand<22:0> : Zeros(29);
            exp = UInt(operand<30:23>);
        else // N == 64
            fraction = operand<51:0>;
            exp = UInt(operand<62:52>);

        if exp == 0 then
            while fraction<51> == 0 do
                fraction = fraction<50:0> : '0';
                exp = exp - 1;
            fraction = fraction<50:0> : '0';

        if exp<0> == '0' then
            scaled = '0' : '01111111110' : fraction<51:44> : Zeros(44);
        else
            scaled = '0' : '01111111101' : fraction<51:44> : Zeros(44);

        if N == 32 then
            result_exp = (380 - exp) DIV 2;
        else // N == 64
```

```
            result_exp = (3068 - exp) DIV 2;

        // Call C function to get reciprocal estimate of scaled value.
        estimate = recip_sqrt_estimate(scaled);

        // Result is double-precision and a multiple of 1/256 in the range 1 to 511/256.
        // Convert to scaled single-precision result with copied sign bit and high-order
        // fraction bits, and exponent calculated above.

        if N == 32 then
            result = '0' : result_exp<N-25:0> : estimate<51:29>;
        else // N == 64
            result = '0' : result_exp<N-54:0> : estimate<51:0>;
    return result;

// UnsignedRSqrtEstimate()
// =======================

bits(32) UnsignedRSqrtEstimate(bits(32) operand)

    if operand<31:30> == '00' then  // Operands <= 0x3FFFFFFF produce 0xFFFFFFFF
        result = Ones(32);
    else
        // Generate double-precision value = operand * 2^(-32). This has zero sign bit, with:
        //     exponent = 1022 or 1021 = double-precision representation of 2^(-1) or 2^(-2)
        //     fraction taken from operand, excluding its most significant one or two bits.
        if operand<31> == '1' then
            dp_operand = '0 01111111110' : operand<30:0> : Zeros(21);
        else  // operand<31:30> == '01'
            dp_operand = '0 01111111101' : operand<29:0> : Zeros(22);

        // Call C function to get reciprocal estimate of scaled value.
        estimate = recip_sqrt_estimate(dp_operand);

        // Result is double-precision and a multiple of 1/256 in the range 1 to 511/256.
        // Multiply by 2^31 and convert to an unsigned integer - this just involves
        // concatenating the implicit units bit with the top 31 fraction bits.
        result = '1' : estimate<51:21>;

    return result;
```

`recip_sqrt_estimate()` is defined by the following C function:

```
double recip_sqrt_estimate(double a)
{
  int q0, q1, s;
  double r;
  if (a < 0.5)  /* range 0.25 <= a < 0.5 */
  {
    q0 = (int)(a * 512.0);       /* a in units of 1/512 rounded down */
    r = 1.0 / sqrt(((double)q0 + 0.5) / 512.0); /* reciprocal root r */
  }
  else          /* range 0.5  <= a < 1.0 */
  {
    q1 = (int)(a * 256.0);       /* a in units of 1/256 rounded down */
    r = 1.0 / sqrt(((double)q1 + 0.5) / 256.0); /* reciprocal root r */
  }
  s = (int)(256.0 * r + 0.5);  /* r in units of 1/256 rounded to nearest */
  return (double)s / 256.0;
}
```

Table E1-8 shows the results where input values are out of range.

Table E1-8 VRSQRTE results for out of range inputs

Number type	Input Vm[i]	Result Vd[i]
Integer	<= 0x3FFFFFFF	0xFFFFFFFF
Floating-point	NaN, –(normalized number), –infinity	Default NaN
Floating-point	–0 or –(denormalized number)	– infinity [a]
Floating-point	+0 or +(denormalized number)	+infinity [a]
Floating-point	+infinity	+0

a. FPSCR.DZC is set to 1.

The Newton-Raphson iteration:

$x_{n+1} = x_n(3-dx_n^2)/2$

converges to $(1/\sqrt{d})$ if x_0 is the result of VRSQRTE applied to d.

The VRSQRTS instruction performs a (3 – op1×op2)/2 calculation and can be used with two multiplications to perform a step of this iteration. The FPRSqrtStep() pseudocode function defines the functionality of this instruction:

```
// FPRSqrtStep()
// =============

bits(32) FPRSqrtStep(bits(32) op1, bits(32) op2)
    FPCRType fpcr = StandardFPSCRValue();
    (type1,sign1,value1) = FPUnpack(op1, fpcr);
    (type2,sign2,value2) = FPUnpack(op2, fpcr);
    (done,result) = FPProcessNaNs(type1, type2, op1, op2, fpcr);
    if !done then
        inf1 = (type1 == FPType_Infinity);  inf2 = (type2 == FPType_Infinity);
        zero1 = (type1 == FPType_Zero);     zero2 = (type2 == FPType_Zero);
        bits(32) product;
        if (inf1 && zero2) || (zero1 && inf2) then
            product = FPZero('0');
        else
            product = FPMul(op1, op2, fpcr);
        result = FPHalvedSub(FPThree('0'), product, fpcr);
    return result;
```

Table E1-9 shows the results where input values are out of range.

Table E1-9 VRSQRTS results for out of range inputs

Any NaN	-	Default NaN
-	Any NaN	Default NaN
±0.0 or denormalized number	±infinity	1.5
±infinity	±0.0 or denormalized number	1.5

FPRSqrtStep() calls the FPHalvedSub() pseudocode function:

```
// FPHalvedSub()
// =============
```

```
bits(N) FPHalvedSub(bits(N) op1, bits(N) op2, FPCRType fpcr)
    assert N IN {32,64};
    rounding = FPRoundingMode(fpcr);
    (type1,sign1,value1) = FPUnpack(op1, fpcr);
    (type2,sign2,value2) = FPUnpack(op2, fpcr);
    (done,result) = FPProcessNaNs(type1, type2, op1, op2, fpcr);
    if !done then
        inf1 = (type1 == FPType_Infinity);  inf2 = (type2 == FPType_Infinity);
        zero1 = (type1 == FPType_Zero);     zero2 = (type2 == FPType_Zero);
        if inf1 && inf2 && sign1 == sign2 then
            result = FPDefaultNaN();
            FPProcessException(FPExc_InvalidOp, fpcr);
        elsif (inf1 && sign1 == '0') || (inf2 && sign2 == '1') then
            result = FPInfinity('0');
        elsif (inf1 && sign1 == '1') || (inf2 && sign2 == '0') then
            result = FPInfinity('1');
        elsif zero1 && zero2 && sign1 != sign2 then
            result = FPZero(sign1);
        else
            result_value = (value1 - value2) / 2.0;
            if result_value == 0.0 then  // Sign of exact zero result depends on rounding mode
                result_sign = if rounding == FPRounding_NEGINF then '1' else '0';
                result = FPZero(result_sign);
            else
                result = FPRound(result_value, fpcr);
    return result;
```

Floating-point conversions

The following function performs conversions between half-precision, single-precision and double-precision floating-point numbers.

```
// FPConvert()
// ===========

// Convert floating point OP with N-bit precision to M-bit precision,
// with rounding controlled by ROUNDING.

bits(M) FPConvert(bits(N) op, FPCRType fpcr, FPRounding rounding)
    assert M IN {16,32,64};
    assert N IN {16,32,64};
    bits(M) result;

    // Unpack floating-point operand optionally with flush-to-zero.
    (type,sign,value) = FPUnpack(op, fpcr);

    alt_hp = (M == 16) && (fpcr.AHP == '1');

    if type == FPType_SNaN || type == FPType_QNaN then
        if alt_hp then
            result = FPZero(sign);
        elsif fpcr.DN == '1' then
            result = FPDefaultNaN();
        else
            result = FPConvertNaN(op);
        if type == FPType_SNaN || alt_hp then
            FPProcessException(FPExc_InvalidOp,fpcr);
    elsif type == FPType_Infinity then
        if alt_hp then
            result = sign:Ones(M-1);
            FPProcessException(FPExc_InvalidOp, fpcr);
        else
            result = FPInfinity(sign);
    elsif type == FPType_Zero then
        result = FPZero(sign);
    else
        result = FPRound(value, fpcr, rounding);
```

```
    return result;

// FPConvert()
// ===========

bits(M) FPConvert(bits(N) op, FPCRType fpcr)
    return FPConvert(op, fpcr, FPRoundingMode(fpcr));
```

The following functions perform conversions between floating-point numbers and integers or fixed-point numbers:

```
// FPToFixed()
// ===========

// Convert N-bit precision floating point OP to M-bit fixed point with
// FBITS fractional bits, controlled by UNSIGNED and ROUNDING.

bits(M) FPToFixed(bits(N) op, integer fbits, boolean unsigned, FPCRType fpcr, FPRounding rounding)
    assert N IN {32,64};
    assert M IN {32,64};
    assert fbits >= 0;
    assert rounding != FPRounding_ODD;

    // Unpack using fpcr to determine if subnormals are flushed-to-zero
    (type,sign,value) = FPUnpack(op, fpcr);

    // If NaN, set cumulative flag or take exception
    if type == FPType_SNaN || type == FPType_QNaN then
        FPProcessException(FPExc_InvalidOp, fpcr);

    // Scale by fractional bits and produce integer rounded towards minus-infinity
    value = value * 2^fbits;
    int_result = RoundDown(value);
    error = value - int_result;

    // Determine whether supplied rounding mode requires an increment
    case rounding of
        when FPRounding_TIEEVEN
            round_up = (error > 0.5 || (error == 0.5 && int_result<0> == '1'));
        when FPRounding_POSINF
            round_up = (error != 0.0);
        when FPRounding_NEGINF
            round_up = FALSE;
        when FPRounding_ZERO
            round_up = (error != 0.0 && int_result < 0);
        when FPRounding_TIEAWAY
            round_up = (error > 0.5 || (error == 0.5 && int_result >= 0));

    if round_up then int_result = int_result + 1;

    // Generate saturated result and exceptions
    (result, overflow) = SatQ(int_result, M, unsigned);
    if overflow then
        FPProcessException(FPExc_InvalidOp, fpcr);
    elsif error != 0.0 then
        FPProcessException(FPExc_Inexact, fpcr);

    return result;

// FixedToFP()
// ===========

// Convert M-bit fixed point OP with FBITS fractional bits to
// N-bit precision floating point, controlled by UNSIGNED and ROUNDING.

bits(N) FixedToFP(bits(M) op, integer fbits, boolean unsigned, FPCRType fpcr, FPRounding rounding)
    assert N IN {32,64};
    assert M IN {32,64};
```

```
bits(N) result;
assert fbits >= 0;
assert rounding != FPRounding_ODD;

// Correct signed-ness
int_operand = Int(op, unsigned);

// Scale by fractional bits and generate a real value
real_operand = int_operand / 2^fbits;

if real_operand == 0.0 then
    result = FPZero('0');
else
    result = FPRound(real_operand, fpcr, rounding);

return result;
```

E1.4 Coprocessor support

AArch32 state provides a coprocessor interface, that comprises the coprocessor instructions summarized in *Coprocessor instructions* on page F1-2314. These can provide access to sixteen coprocessors, described as CP0 to CP15. The following conceptual coprocessors are reserved by ARM for specific purposes, and from ARMv8 are the only supported coprocessors:

- Coprocessor 15 (CP15) provides system control functionality, by providing access to System registers. This includes architecture and feature identification, as well as control, status information and configuration support.

  The following sections give a general description of CP15:
  - *About the System registers for VMSAv8-32* on page G4-3743.
  - *Organization of the CP15 registers in VMSAv8-32* on page G4-3767.
  - *Functional grouping of VMSAv8-32 System registers* on page G4-3786.

  CP15 also provides performance monitor registers, see Chapter D5 *The Performance Monitors Extension*.

- Coprocessor 14 (CP14) provides access to additional registers, that support:
  - Debug, see Chapter G2 *AArch32 Self-hosted Debug*.
  - The Jazelle identification registers, see *Jazelle support* on page E1-2215.

- Coprocessors 10 and 11 (CP10 and CP11) together support floating-point and Advanced SIMD vector operations, and the control and configuration of Advanced SIMD and floating-point operation.

Note

To enable use of the Advanced SIMD and floating-point instructions, software must enable access to both CP10 and CP11, see *Enabling Advanced SIMD and floating-point support* on page G1-3466.

UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses on page G4-3745 gives information more information about permitted accesses to coprocessors CP14 and CP15.

Most CP14 and CP15 functions cannot be accessed by software executing at EL0. This manual clearly identifies those functions that can be accessed at EL0. However, software executing at EL1 can enable the unprivileged execution of all load, store, branch and data operation instructions associated with floating-point, Advanced SIMD and execution environment support.

E1.5 Exceptions

The ARM architecture uses the following terms to describe various types of exceptional condition:

Exceptions In the ARM architecture, an *exception* causes entry to EL1, EL2, or EL3. If the Exception level that is entered is using AArch32, it also cases entry to the PE mode in which the exception must be taken. A software handler for the exception is then executed.

Note

The term *floating-point exception* does not use this meaning of *exception*. This term is described later in this list.

Exceptions include:

- Reset.
- Interrupts.
- Memory system aborts.
- Undefined instructions.
- Supervisor calls (SVCs), Secure Monitor calls (SMCs), and hypervisor calls (HVCs).
- Debug exceptions.

Most details of exception handling are not visible to application level software, and are described in *Handling exceptions that are taken to an Exception level using AArch32* on page G1-3396. In an ARMv8 implementation that includes all the Exception levels, aspects that are visible to application level software are:

- The `SVC` instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a call to the operating system, or other system component that is accessible only at EL1.
- The `SMC` instruction causes a Secure Monitor Call exception, but only if software execution is at EL1 or higher. Unprivileged software can only cause a Secure Monitor Call exception by methods defined by the operating system, or by another component of the software system that executes at EL1 or higher.
- The `HVC` instruction causes a Hypervisor Call exception, but only if software execution is at EL1 or higher. Unprivileged software can only cause a Hypervisor Call exception by methods defined by the hypervisor, or by another component of the software system that executes at EL1 or higher.
- The `BKPT` instruction causes a Software Breakpoint Instruction exception, that is taken as a Prefetch Abort exception. This provides a mechanism for a debugger to insert breakpoints into unprivileged software, or for unprivileged software to make a call into a debugger that is accessible at EL1.
- The `WFI` (Wait for Interrupt) instruction provides a hint that nothing needs to be done until an interrupt or another WFI wake-up event occurs, see *Wait For Interrupt* on page G1-3460. This means the hardware might enter a low-power state until the wake-up event occurs.
- The `WFE` (Wait for Event) instruction provides a hint that nothing needs to be done until either an `SEV` instruction generates an event, or another WFE wake-up event occurs, see *Wait For Event and Send Event* on page G1-3457. This means the hardware might enter a low-power state until the wake-up event occurs.

Floating-point exceptions

These relate to exceptional conditions encountered during floating-point arithmetic, such as division by zero or overflow. For more information see:

- *Floating-point exceptions* on page E1-2220.
- *FPSCR, Floating-Point Status and Control Register* on page G5-3898.
- ANSI/IEEE Std. 754, *IEEE Standard for Binary Floating-Point Arithmetic*.

Chapter E2
The AArch32 Application Level Memory Model

This chapter gives an application level description of the memory model for software executing in AArch32 state. This means it describes the memory model for execution in EL0 when EL0 is using AArch32 in the following sections:

- *Address space* on page E2-2248.
- *Memory type overview* on page E2-2250.
- *Caches and memory hierarchy* on page E2-2251.
- *Alignment support* on page E2-2256.
- *Endian support* on page E2-2258.
- *Atomicity in the ARM architecture* on page E2-2261.
- *Memory ordering* on page E2-2266.
- *Memory types and attributes* on page E2-2273.
- *Mismatched memory attributes* on page E2-2281.
- *Synchronization and semaphores* on page E2-2284

Note

In this chapter, system register names usually link to the description of the register in Chapter G5 *AArch32 System Register Descriptions*, for example SCTLR.

E2.1 Address space

Address calculations are performed using 32-bit registers. Supervisory software determines the valid address range.

Attempting to access an address that is not valid generates an MMU fault.

Address calculations are performed modulo 2^{32}.

The result of an address calculation is UNKNOWN if it overflows or underflows the 32-bit address range A[31:0].

Memory accesses use the `MemA[]`, `MemU[]`, and `MemU_unpriv[]` functions:

- The `MemA[]` function makes an aligned access of the required type.
- The `MemU[]` function makes an unaligned access of the required type
- The `MemU_unpriv[]` function makes an unaligned, unprivileged access of the required type.

```
// MemA[] - non-assignment form
// ============================

bits(8*size) MemA[bits(32) address, integer size]
    acctype = AccType_ATOMIC;
    return MemU_with_type[address, size, acctype];

// MemA[] - assignment form
// ========================

MemA[bits(32) address, integer size] = bits(8*size) value
    acctype = AccType_ATOMIC;
    MemU_with_type[address, size, acctype] = value;
    return;

// MemU[] - non-assignment form
// ============================

bits(8*size) MemU[bits(32) address, integer size]
    acctype = AccType_NORMAL;
    return MemU_with_type[address, size, acctype];

// MemU[] - assignment form
// ========================

MemU[bits(32) address, integer size] = bits(8*size) value
    acctype = AccType_NORMAL;
    MemU_with_type[address, size, acctype] = value;
    return;

// MemU_unpriv[] - non-assignment form
// ===================================

bits(8*size) MemU_unpriv[bits(32) address, integer size]
    acctype = AccType_UNPRIV;
    return MemU_with_type[address, size, acctype];

// MemU_unpriv[] - assignment form
// ===============================

MemU_unpriv[bits(32) address, integer size] = bits(8*size) value
    acctype = AccType_UNPRIV;
    MemU_with_type[address, size, acctype] = value;
    return;
```

The `AccType` enumeration defines the different access types:

```
enumeration AccType {AccType_NORMAL, AccType_VEC,       // Normal loads and stores
                     AccType_STREAM, AccType_VECSTREAM, // Streaming loads and stores
                     AccType_ATOMIC,                    // Atomic loads and stores
                     AccType_ORDERED,                   // Load-Acquire and Store-Release
```

```
    AccType_UNPRIV,                 // Load and store unprivileged
    AccType_IFETCH,                 // Instruction fetch
    AccType_PTW,                    // Page table walk
    // Other operations
    AccType_DC,                     // Data cache maintenance
    AccType_IC,                     // Instruction cache maintenance
    AccType_AT};                    // Address translation
```

Note

- Chapter G3 *The AArch32 System Level Memory Model* and Chapter G4 *The AArch32 Virtual Memory System Architecture* include descriptions of memory system features that are transparent to the application, including memory access, address translation, memory maintenance instructions, and alignment checking and the associated fault handling. These chapters also include pseudocode descriptions of these operations.
- For information on the pseudocode that relates to memory accesses, see *Basic memory access* on page G3-3606, *Unaligned memory access* on page G3-3607, and *Aligned memory access* on page G3-3606.

E2.2 Memory type overview

ARMv8 provides the following mutually-exclusive memory types:

Normal This is generally used for bulk memory operations, both read-write and read-only operations.

Device The ARM architecture forbids speculative reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive locations.

Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.

Device memory has additional attributes that have the following effects:

- They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See *Gathering* on page E2-2277.
- They preserve the access order and synchronization requirements, both for accesses to a single peripheral and where there is a synchronization requirement on the observability of one or more memory write and read accesses. See *Reordering* on page E2-2278
- They indicate whether a write can be acknowledged other than at the end point. See *Early Write Acknowledgement* on page E2-2279.

- For more information on Normal memory and Device memory, see *Memory types and attributes* on page E2-2273.

Note

Earlier versions of the ARM architecture defined a single Device memory type and a Strongly-Ordered memory type. A Note in *Device memory* on page E2-2275 describes how these memory types map onto the ARMv8 memory types.

E2.3 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. ARMv8 defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- *Introduction to caches*.
- *Memory hierarchy*.
- *Implication of caches for the application programmer* on page E2-2253.
- *Preloading caches* on page E2-2254.

E2.3.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a *tag*.
- The associated data.

Caches increase the average speed of a memory access and take account of two principles of locality:

Spatial locality

An access to one location is likely to be followed by accesses to adjacent locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

Temporal locality

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a *cache line*. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a *cache hit*, and other accesses are called *cache misses*.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access is made to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. ARMv8 permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

E2.3.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, an ARMv8 memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. Figure E2-1 on page E2-2252 shows an example of such a system in an ARMv8-A system that supports virtual addressing.

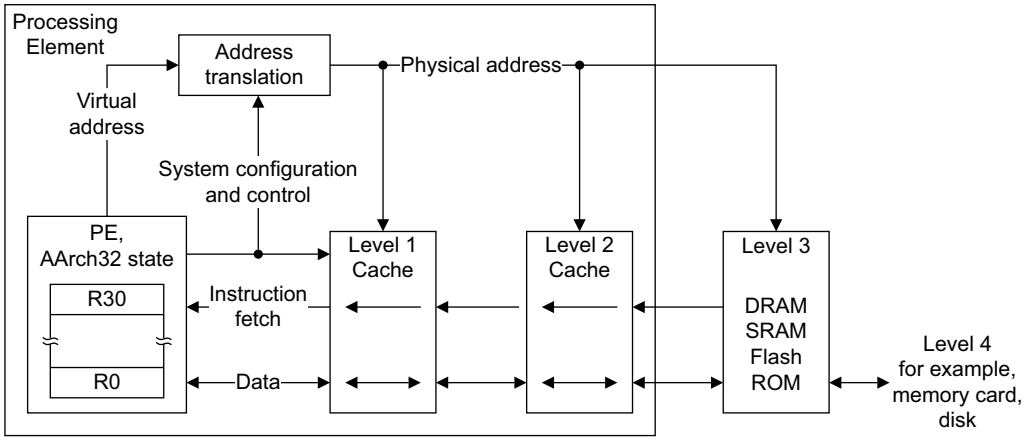

Figure E2-1 Multiple levels of cache in a memory hierarchy

Note

In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the PE, as shown in Figure E2-1.

Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches located at the levels closest to the main memory. Memory coherency for cache topologies can be defined by two conceptual points:

Point of Unification (PoU)

The point at which the instruction cache, data cache, and translation table walks of a particular PE are guaranteed to see the same copy of a memory location. In many cases, the point of unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged. The point of unification might coincide with the point of coherency.

Point of Coherency (PoC)

The point at which all agents that can access memory are guaranteed to see the same copy of a memory location. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

See also *The ARMv8 cache maintenance functionality* on page G3-3585.

The cacheability and shareability memory attributes

Cacheability and shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

Cacheability This term defines whether memory locations are allowed to be allocated into a cache or not. Cacheability can be defined independently for Inner and Outer cacheability locations.

Shareability This term defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability can be defined independently for Inner and Outer shareability domains.

For more information about cacheability and shareability see *Memory types and attributes* on page E2-2273.

E2.3.3 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.

For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.
- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

Data coherency issues

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
  - Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
  - Not enabling caches in the system.
- By using system calls to functions using cache maintenance instructions that execute at a higher Exception level.
- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see *Non-shareable Normal memory* on page E2-2275 and *Shareable, Inner Shareable, and Outer Shareable Normal memory* on page E2-2274.

  Note

  The performance of these hardware coherency mechanisms is highly implementation-specific. In some implementations the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last *Context synchronization operation* on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being re-fetched from memory.

The ARM architecture does not require the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory.

If software requires coherency between instruction execution and memory, it must manage this coherency using the `ISB` and `DSB` memory barriers and cache maintenance instructions. These can only be accessed from an Exception level that is higher than EL0, and therefore require a system call, see *Exception-generating and exception-handling instructions* on page F1-2313. The following code sequence can be used for this purpose:

```
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
```

```
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line
; instead of STR for a 16-bit instruction.
       STR Rt, [Rn]
       DCCMVAU Rn           ; Clean data cache by MVA to point of unification (PoU)
       DSB                  ; Ensure visibility of the data cleaned from cache
       ICIMVAU Rn           ; Invalidate instruction cache by MVA to PoU
       BPIMVA  Rn           ; Invalidate branch predictor by MVA to PoU
       DSB                  ; Ensure completion of the invalidations
       ISB                  ; Synchronize the fetched instruction stream
```

Note

- For accesses that are Non-cacheable or Write-Through, the clean data cache instruction is not required. For accesses that are Non-cacheable, the invalidate instruction cache is not required, because in AArch32 state these accesses are not permitted to be held in an instruction cache.
- This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The ARMv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See *Concurrent modification and execution of instructions* on page E2-2263.

E2.3.4 Preloading caches

The ARM architecture provides the memory system hints PLD (Preload Data), PLDW (Preload Data With Intent To Write) and PLI (Preload Instruction) that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring data or instruction locations into caches.

The Preload instructions are hints, and so implementations can treat them as NOPs without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous external abort, which is taken using an asynchronous Data Abort exception. For more information, see *Data Abort exception* on page G1-3439.

A PLD or PLDW instruction is guaranteed not to cause any effects to the caches, or TLB, or memory, other than the effects that, for permission or other reasons, can be caused by the equivalent load from the same location with same context and at the same Exception level.

A PLD or PLDW instruction is guaranteed not to access Device memory.

A PLI instruction is guaranteed not to cause any effect to the caches, or TLB, or memory, other than the effect that, for permission or other reasons, can be caused by the fetch resulting from changing the PC to the location specified by the PLI instruction with the same context and at the same Exception level.

A PLI instruction must not perform any access that might be performed by a speculative instruction fetch by the PE. Therefore:

- A PLI instruction cannot access memory that has a Device attribute.
- If all associated MMUs are disabled, a PLI instruction cannot access any memory location that cannot be accessed by the instruction fetches.

PrefetchHint{} defines the prefetch hint types:

```
enumeration PrefetchHint {Prefetch_READ, Prefetch_WRITE, Prefetch_EXEC};
```

The Hint_Prefetch() function signals to the memory system that memory accesses of the type hint to or from the specified address are likely to occur in the near future. The memory system might take some action to speed-up the memory accesses when they do occur, such as preloading the specified address into one or more caches as indicated by the innermost cache level target and non-temporal hint stream.

```
Hint_Prefetch(bits(64) address, PrefetchHint hint, integer target, boolean stream);
```

For more information on PLD, PLI, and PLDW, see:

- *PLD, PLDW (immediate)* on page F7-2679.
- *PLD (literal)* on page F7-2681.
- *PLD, PLDW (register)* on page F7-2683.
- *PLI (immediate, literal)* on page F7-2685.
- *PLI (register)* on page F7-2687.

E2.4 Alignment support

This section describes alignment support. It contains the following subsections:

- *Instruction alignment*.
- *Unaligned data access*.
- *Cases where unaligned accesses are UNPREDICTABLE*.
- *Unaligned data access restrictions* on page E2-2257.

E2.4.1 Instruction alignment

A32 instructions are word-aligned.

T32 instruction are halfword-aligned.

E2.4.2 Unaligned data access

An ARMv8 implementation must support unaligned data accesses by some load and store instructions, as Table E2-1 shows. Software can set SCTLR.A or HSCTLR.A to control whether a misaligned access by one of these instructions causes an Alignment fault Data Abort exception.

Table E2-1 Alignment requirements of load/store instructions

Instructions	Alignment check	Result if check fails when: SCTLR.A/ HSCTLR.A is 0	Result if check fails when: SCTLR.A/ HSCTLR.A is 1
LDRB, LDREXB, LDRBT, LDRSB, LDRSBT, STRB, STREXB, STRBT, TBB	None	-	-
LDRH, LDRHT, LDRSH, LDRSHT, STRH, STRHT, TBH	Halfword	Unaligned access	Alignment fault
LDREXH, STREXH	Halfword	Alignment fault	Alignment fault
LDR, LDRT, STR, STRT PUSH, encodings T3 and A2 only POP, encodings T3 and A2 only	Word	Unaligned access	Alignment fault
LDREX, STREX	Word	Alignment fault	Alignment fault
LDREXD, STREXD	Doubleword	Alignment fault	Alignment fault
All forms of LDM and STM, LDRD, RFE, SRS, STRD	Word	Alignment fault	Alignment fault
LDC, LDC2, STC, STC2	Word	Alignment fault	Alignment fault
VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR	Word	Alignment fault	Alignment fault
VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4, all with standard alignment	Element size	Unaligned access	Alignment fault
VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4, all with :<align> specified[a]	As specified by :<align>	Alignment fault	Alignment fault

a. Previous versions of this manual used @<align> to specify alignment. Both forms are supported, see Chapter F8 *T32 and A32 Advanced SIMD and floating-point Instruction Descriptions* for more information.

E2.4.3 Cases where unaligned accesses are UNPREDICTABLE

Any load instruction that is not faulted by the alignment restrictions shown in Table E2-1 and that loads the PC has UNPREDICTABLE behavior if the address it loads from is not word-aligned. This overrules any permitted Load/Store behavior shown in Table E2-1.

Note

- An unaligned access to Device memory generates an Alignment fault, see *Alignment faults* on page G4-3710.
- *Device memory* on page E2-2275 describes the Device memory attributes.

E2.4.4 Unaligned data access restrictions

The following points apply to unaligned data accesses in ARMv8:

- Accesses are not guaranteed to be single-copy atomic except at the byte access level, see *Atomicity in the ARM architecture* on page E2-2261.
- Unaligned accesses typically takes a number of additional cycles to complete compared to a naturally-aligned access.
- An operation that performs an unaligned access can abort on any memory access that it makes, and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the boundary.

E2.5 Endian support

General description of endianness in the ARM architecture describes the relationship between endianness and memory addressing in the ARM architecture.

The following subsections then describe the endianness schemes supported by the architecture:

- *Instruction endianness*.
- *Data endianness* on page E2-2259.

E2.5.1 General description of endianness in the ARM architecture

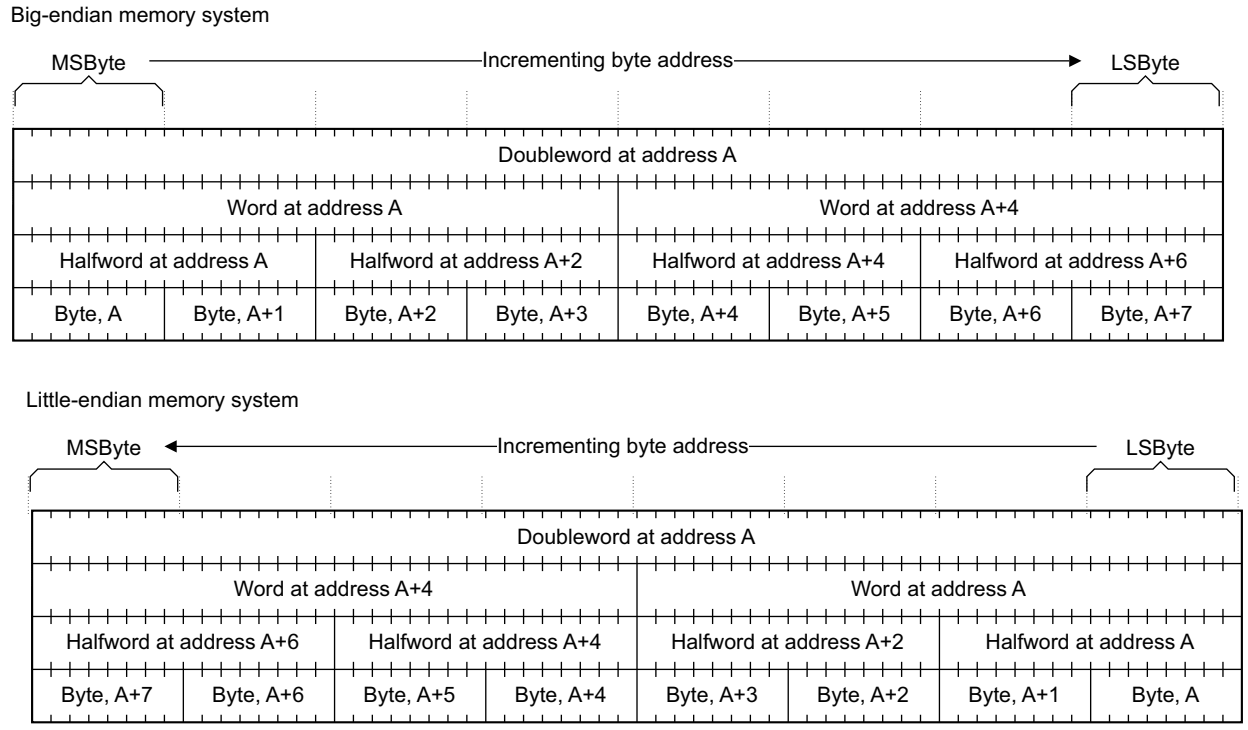
This section only describes memory addressing and the effects of endianness for data elements up to doubleword of 64 bits. However, this description can be extended to apply to larger data elements.

For an address A, Figure E2-2 shows, for big-endian and little-endian memory systems, the relationship between:

- The doubleword at address A.
- The words at addresses A and A+4.
- The halfwords at addresses A, A+2, A+4, and A+6.
- The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, and A+7.

The terms in Figure E2-2 have the following definitions:

MSByte Most-significant byte.
LSByte Least-significant byte.



In this figure, *Byte, A+1* is an abbreviation for *Byte at address A+1*

Figure E2-2 Endianness relationships in AArch32

E2.5.2 Instruction endianness

In ARMv8-A, the mapping of instruction memory is always little-endian.

E2.5.3 Data endianness

The size of the data value that is loaded or stored is the size that is used for the purpose of endian conversion for floating-point, Advanced SIMD, and general-purpose register loads and stores.

Table E2-2 shows the element sizes of all the load/store instructions, for all instruction sets.

Table E2-2 Element size of load/store instructions

Instructions	Element size
LDRB, LDREXB, LDRBT, LDRSB, LDRSBT, STRB, STREXB, STRBT, TBB	Byte
LDRH, LDREXH, LDRHT, LDRSH, LDRSHT, STRH, STREXH, STRHT, TBH	Halfword
LDR, LDRT, LDREX, STR, STRT, STREX	Word
LDRD, LDREXD, STRD, STREXD	Word
All forms of LDM, PUSH, POP, RFE, SRS, all forms of STM,	Word
LDC, LDC2, STC, STC2	Word
Forms of VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR that transfer 32-bit Si registers	Word
Forms of VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR that transfer 64-bit Di registers	Doubleword
VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4	Element size of the Advanced SIMD access

CPSR.E determines the data endianness.

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for Advanced SIMD and floating-point register and general-purpose register loads and stores.
- Is the size of the data element that is loaded or stored for Advanced SIMD element and data structure loads and stores. For more information see *Endianness in Advanced SIMD* on page E2-2260.

Instructions to reverse bytes in registers

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

Table E2-3 shows the instructions that provide this functionality in the A32 and T32 instruction sets:

Table E2-3 Byte reversal instructions

Function	T32 / A32 Instruction	Notes
Reverse bytes in whole register	REV	For use with general purpose registers.
Reverse bytes in 16-bit halfwords	REV16	For use with general purpose registers.
Reverse bytes in halfword and sign-extend	REVSH	For use with general purpose registers.
Reverse elements in doublewords, vector	VREV64	For use with registers in the SIMD and floating-point register file
Reverse elements in words, vector	VREV32	For use with registers in the SIMD and floating-point register file
Reverse elements in halfwords, vector	VREV16	For use with registers in the SIMD and floating-point register file

Endianness in Advanced SIMD

Advanced SIMD element Load/Store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used by the PE to load and store data correctly in both big-endian and little-endian systems.

Consider, for example, the A32 or T32 instruction:

```
VLD1.16 {D0}, [R1]
```

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure E2-3. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

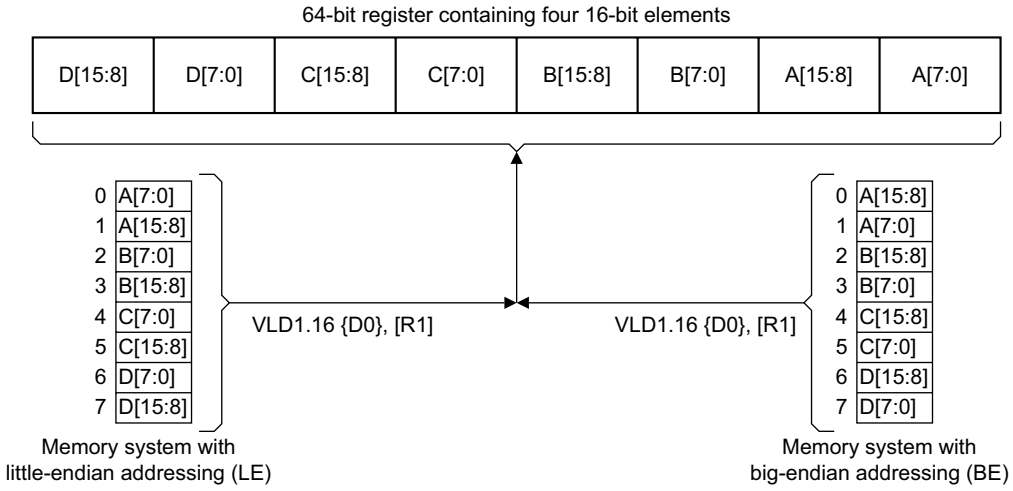


Figure E2-3 Advanced SIMD byte order example for AArch32

For information about the alignment of Advanced SIMD instructions see *Alignment support* on page E2-2256.

The `BigEndian()` function determines the current endianness of the data:

```
boolean BigEndian();
```

The pseudocode function for `BigEndianReverse()` is as follows:

```
// BigEndianReverse()
// ==================

bits(width) BigEndianReverse (bits(width) value)
    assert width IN {8, 16, 32, 64, 128};
    integer half = width DIV 2;
    if width == 8 then return value;
    return BigEndianReverse(value<half-1:0>) : BigEndianReverse(value<width-1:half>);
```

E2.6 Atomicity in the ARM architecture

Atomicity is a feature of memory accesses, described as *atomic* accesses. The ARM architecture description refers to two types of atomicity, defined in:

- *Single-copy atomicity*.
- *Multi-copy atomicity* on page E2-2263.

In the ARMv8 architecture, the atomicity requirements for memory accesses depends on the memory type, and whether the access is explicit or implicit. For more information, see:

- *Memory type overview* on page E2-2250.
- *Requirements for single-copy atomicity*.
- *Requirements for multi-copy atomicity* on page E2-2263.

E2.6.1 Single-copy atomicity

A read or write operation is *single-copy atomic* only if it meets the following conditions:

1. For a single-copy atomic store, if the store overlaps another single-copy atomic store, then all of the writes from one of the stores are inserted into the Coherence order of each overlapping byte before any of the writes of the other store are inserted into the Coherence orders of the overlapping bytes.

2. If a single-copy atomic load overlaps a single-copy atomic store and for any of the overlapping bytes the load returns the data written by the write inserted into the Coherence order of that byte by the single-copy atomic store then the load must return data from a point in the Coherence order no earlier than the writes inserted into the Coherence order by the single-copy atomic store of all of the overlapping bytes.

E2.6.2 Requirements for single-copy atomicity

In AArch32 state, the single-copy atomic PE accesses are:

- All byte accesses.
- All halfword accesses to halfword-aligned locations.
- All word accesses to word-aligned locations.
- Memory accesses caused by `LDREXD` and `STREXD` instructions to doubleword-aligned locations.

`LDM`, `LDC`, `LDC2`, `LDRD`, `STM`, `STC`, `STC2`, `STRD`, `PUSH`, `POP`, `RFE`, `SRS`, `VLDM`, `VLDR`, `VSTM`, and `VSTR` instructions are executed as a sequence of word-aligned word accesses. Each 32-bit word access is guaranteed to be single-copy atomic. The architecture does not require subsequences of two or more word accesses from the sequence to be single-copy atomic.

`LDRD` and `STRD` accesses to 64-bit aligned locations are 64-bit single-copy atomic as seen by translation table walks and accesses to translation tables.

Note

This requirement has been added to avoid the need for complex measures to avoid atomicity issues when changing translation table entries, without creating a requirement that all locations in the memory system are 64-bit single-copy atomic. This addition means:

- The system designer must ensure that all writable memory locations that might be used to hold translations, such as bulk SDRAM, can be accessed with 64-bit single-copy atomicity.

- Software must ensure that translation tables are not held in memory locations that cannot meet this atomicity requirement, such as peripherals that are typically accessed using a narrow bus.

This requirement places no burden on read-only memory locations for which reads have no side effects, since it is impossible to detect the size of memory accesses to such locations.

Advanced SIMD element and structure loads and stores are executed as a sequence of accesses of the element or structure size. The architecture requires the element accesses to be single-copy atomic if and only if both:

- The element size is 32 bits, or smaller.
- The elements are naturally aligned.

Accesses to 64-bit elements or structures that are at least word-aligned are executed as a sequence of 32-bit accesses, each of which is single-copy atomic.The architecture does not require subsequences of two or more 32-bit accesses from the sequence to be single-copy atomic.

When an access is not single-copy atomic, it is executed as a sequence of smaller accesses, each of which is single-copy atomic, at least at the byte level.

Note

In this section, the terms *before the write operation* and *after the write operation* mean before or after the write operation has had its effect on the coherence order of the bytes of the memory location accessed by the write operation.

If, according to these rules, an instruction is executed as a sequence of accesses, an exception can be taken during that sequence. This causes execution of the instruction to be abandoned. The exceptions are:

- Synchronous Data Abort exceptions.
- The following, if low interrupt latency configuration is selected and the accesses are to Normal memory:
  - IRQ interrupts.
  - FIQ interrupts.
  - Asynchronous aborts.

  For more information about this configuration, see HSCTLR.

If such an instruction is abandoned as a result of an asynchronous exception, then:

- For a load, any register being loaded other than one that is used in the address generation can contain an UNKNOWN value. Registers that are used in the generation of the address are restored to their initial value.
- For a store, any data location being stored can contain an UNKNOWN value.

If such an instruction is abandoned as a result of a Synchronous Data Abort exception, see *Data Abort exception* on page G1-3439.

If the synchronous Data Abort exception is returned from using the preferred return address, the instruction that generated the sequence of accesses is re-executed and so any access that was performed before the exception was taken is repeated.

Note

The exception behavior for these multiple access instructions means they are not suitable for use for writes to memory for the purpose of software synchronization.

For implicit accesses:

- Cache linefills and evictions have no effect on the single-copy atomicity of explicit transactions or instruction fetches.
- Instruction fetches are single-copy atomic:
  - At 32-bit granularity in A32 state.
  - At 16-bit granularity in T32 state.
- *Concurrent modification and execution of instructions* on page E2-2263 describes additional constraints on the behavior of instruction fetches.

- Translation table walks are performed using accesses that are single-copy atomic:
  - At 32-bit granularity when using Short-descriptor format translation tables.
  - At 64-bit granularity when using Long-descriptor format translation tables.

E2.6.3 Multi-copy atomicity

In a multiprocessing system, writes to a memory location are *multi-copy atomic* if the following conditions are both true:

- All writes to the same location are *serialized*, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a location does not return the value of a write until all observers observe that write.

Note

Writes that are not coherent are not multi-copy atomic.

E2.6.4 Requirements for multi-copy atomicity

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory with the non-Gathering attribute, writes that are single-copy atomic are also multi-copy atomic.

For Device memory with the Gathering attribute, writes are not required to be multi-copy atomic.

E2.6.5 Concurrent modification and execution of instructions

The ARMv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction performing any behavior that can be achieved by executing any sequence of instructions that can be executed from the same Exception level, except where the instruction before modification or the instruction after modification is a:

- `B`, `BL`, `NOP`, `BKPT`, `SVC`, `HVC`, or `SMC` A32 instruction
- `B`,`BL`, `BLX`, `NOP`, `BKPT`, or `SVC` 16-bit T32 instruction.

In addition, for the T32 instructions:

- The most-significant halfword of a32-bit `BL` immediate instruction can be concurrently modified to the most significant halfword of another `BL` immediate instruction:
  - This means that the most significant bits of the immediate value can be modified.
- The most-significant halfword of a 32-bit `BLX` immediate instruction can be concurrently modified to the most significant halfword of another `BLX` immediate instruction:
  - This means that the most significant bits of the immediate value can be modified.
- The most-significant halfword of a 32-bit `BL` immediate or `BLX` immediate instruction can be concurrently modified to a T32 16-bit `B`, `BL`, `BLX`, `BKPT`, or `SVC` instruction. This modification also works in reverse.
- The least-significant halfword of a 32-bit `BL` immediate instruction can be concurrently modified to the least significant halfword of another `BL` instruction with a different immediate:
  - This means that the least significant bits of the immediate value can be modified.
- The least-significant halfword of a 32-bit `BLX` immediate instruction can be concurrently modified to the least significant halfword of another `BLX` immediate instruction with a different immediate:
  - This means that the least significant bits of the immediate value can be modified.

- The least-significant halfword of a 32-bit B immediate instruction with a condition field can be concurrently modified to the least significant halfword of another 32-bit B immediate instruction with a condition field with a different immediate:
  - This means that the least significant bits of the immediate value can be modified.
- The least-significant halfword of a 32-bit B immediate instruction without a condition field can be concurrently modified to the least significant halfword of another 32-bit B immediate instruction without a condition field:
  - This means that the least significant bits of the immediate value can be modified.

Note

In the T32 instruction set:

- The only encodings of BKPT and SVC are 16-bit.
- The only encoding of BL is 32-bit.

For the instructions explicitly identified in this section, the architecture guarantees that, after modification of the instruction, behavior is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the modified instruction.

The instructions to which this applies are the B, BL, NOP, BKPT, SVC, HVC, and SMC instructions.

For both instruction sets, if one thread of execution changes a conditional branch instruction to another conditional branch instruction, and the change affects both the condition field and the branch target, execution of the changed instruction by another thread of execution before the change is synchronized can lead to either:

- The old condition being associated with the new target address.
- The new condition being associated with the old target address.

These possibilities apply regardless of whether the condition, either before or after the change to the branch instruction, is the always condition.

For all other instructions, to avoid UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. No PE must be executing an instruction when another PE is modifying that instruction.
2. To ensure that the modified instructions are observable, the PE that modified the instructions must issue the following sequence of instructions and operations:

```
; Coherency example for self-modifying code
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first
; line instead of STR for a 16-bit instruction.
STR <Rt>, [Rn]
DCCMVAU Rn                ; Clean data cache by MVA to point of unification (PoU)
DSB                       ; Ensure visibility of the data stored
ICIMVAU Rn                ; Invalidate instruction cache by VA to PoU
BPIMVA  Rn                ; Invalidate branch predictor by MVA to PoU
DSB                       ; Ensure completion of the invalidations
```

   Note

   The DCCMVAU operation is not required if the area of memory is either Non-cacheable or Write-through Cacheable.

3. In a multiprocessor system, the ICIMVAU and BPIMVA are broadcast to all PEs within the Inner shareable domain of the PE running this sequence. However, once the modified instructions are observable, each PE that is executing the modified instructions must issue the following instruction to ensure execution of the modified instructions:

```
ISB                           ; Synchronize fetched instruction stream
```

For more information about the required synchronization operation, see *Synchronization and coherency issues between data and instruction accesses* on page E2-2253.

Note

For information about memory accesses caused by instruction fetches, see *Ordering requirements* on page E2-2267.

E2.7 Memory ordering

This section describes observation ordering. It contains the following subsections:

- *Observability and completion*.
- *Ordering requirements* on page E2-2267.
- *Memory barriers* on page E2-2268.

For information on endpoint ordering of memory accesses, see *Reordering* on page E2-2278.

In the ARMv8 memory model, the shareability memory attribute indicates whether hardware must ensure memory coherency.

The ARMv8 memory system architecture defines additional attributes and associated behaviors, defined in the system level section of this manual. See:

- Chapter G3 *The AArch32 System Level Memory Model*.
- Chapter G4 *The AArch32 Virtual Memory System Architecture*.

See also *Mismatched memory attributes* on page E2-2281.

E2.7.1 Observability and completion

An *observer* is a master in the system that is capable of observing memory accesses. For a PE, the following mechanisms must be treated as independent observers:

- The mechanism that performs reads or writes to memory.
- A mechanism that causes an instruction cache to be filled from memory or that fetches instructions to be executed directly from memory. These are treated as reads.
- A mechanism that performs translation table walks. These are treated as reads.

The set of observers that can observe a memory access is defined by the system.

In the definitions in this subsection, *subsequent* means whichever of the following is appropriate to the context:

- After the point in time where the location is observed by that observer.
- After the point in time where the location is globally observed.

For all memory:

- A write to a location in memory is said to be *observed* by an observer when:
  - A subsequent read of the location by the same observer returns the value written by the observed write, or written by a write to that location by any observer that is sequenced in the *Coherence order* of the location after the observed write.
  - A subsequent write of the location by the same observer is sequenced in the *Coherence order* of the location after the observed write.
- A write to a location in memory is said to be *globally observed* for a shareability domain or set of observers when:
  - A subsequent read of the location by any observer in that shareability domain returns the value written by the globally observed write, or written by a write to that location by any observer that is sequenced in the *Coherence order* of the location after the globally observed write.
  - A subsequent write of the location by any observer in that shareability domain is sequenced in the *Coherence order* of the location after the globally observed write.
- A read of a location in memory is said to be observed by an observer when a subsequent write to the location by the same observer has no effect on the value returned by the read.
- A read of a location in memory is said to be globally observed for a shareability domain when a subsequent write to the location by any observer in that shareability domain has no effect on the value returned by the read.

Additionally, for Device-nGnRnE memory:

- A read or write of a memory-mapped location in a peripheral that exhibits side-effects is said to be observed, and globally observed, only when the read or write:
  - Meets the general conditions listed.
  - Can begin to affect the state of the memory-mapped peripheral.
  - Can trigger all associated side-effects, whether they affect other peripheral devices, processors, or memory.

  Note

  This definition is consistent with the memory access having reached the peripheral.

For all memory, the completion rules are defined as:

- A read or write is complete for a shareability domain when all of the following are true:
  - The read or write is globally observed for that shareability domain.
  - Any translation table walks associated with the read or write are complete for that shareability domain.
- A translation table walk is complete for a shareability domain when the memory accesses associated with the translation table walk are globally observed for that shareability domain, and the TLB is updated.
- A cache or TLB maintenance instruction is complete for a shareability domain when the effects of the instruction are globally observed for that shareability domain, and any translation table walks that arise from the instruction are complete for that shareability domain.

  The completion of any cache or TLB maintenance instruction includes its completion on all processors that are affected by both the instruction and the `DSB` operation that is required to guarantee visibility of the maintenance instruction.

Completion of side-effects of accesses to Device memory

The completion of a memory access to Device memory other than Device-nGnRnE is not guaranteed to be sufficient to determine that the side-effects of the memory access are visible to all observers. The mechanism that ensures the visibility of side-effects of a memory access is IMPLEMENTATION DEFINED.

E2.7.2 Ordering requirements

- ARMv8 defines restrictions for the permitted ordering of memory accesses. These restrictions depend on the memory locations that are being accessed. See *Memory types and attributes* on page E2-2273.

The following additional restrictions apply to the order in which accesses to Normal memory are observed:

- Reads and writes can be observed in any order provided the following constraints are met:
  - If an address dependency exists between two reads or between a read and a write, then those memory accesses are observed in program order by all observers within the shareability domain of the memory address being accessed.
  - Writes that would not occur in a simple sequential execution of the program cannot be observed by other observers. This implies that where a control, address or data dependency exists between a read and a write, those memory accesses are observed in program order by all observers within the shareability domain of the memory addresses being accessed.
  - Ordering can be achieved by using a `DMB` or `DSB` barrier. For more information on `DMB` and `DSB` instructions, see *Memory barriers* on page E2-2268.
- Reads and writes to the same location are coherent within the shareability domain of the memory address being accessed.
- Two reads of the same location by the same observer are observed in program order by all observers within the shareability domain of the memory address being accessed.

- Writes are not required to be multi-copy atomic. This means that in the absence of barriers, the observation of a store by one observer does not imply the observation of the store by another observer.
- Instructions that access multiple elements have no defined ordering requirements for the memory accesses relative to each other.

Memory accesses caused by instruction fetches are not required to be observed in program order, unless they are separated by an `ISB` or other context synchronization event.

Address dependencies and order

In the ARMv8 architecture, a register data dependency creates order between a load instruction and a subsequent memory transaction, that is between the data value returned from the load and the address used by the subsequent memory transaction.

A register data dependency exists between a first data value and a second data value exists when either:

- The register used to hold the first data value is used in the calculation of the second data value, and the calculation between the first data value and the second data value does not consist of either:
  - A conditional branch whose condition is determined by the first data value.
  - A conditional selection, move, or computation whose condition is determined by the first data value, where the input data values for the selection, move, or computation do not have a data dependency on the first data value.
- There is a register data dependency between the first data value and a third data value, and between the third data value and the second data value.

Note

A register data dependency can exist even if the value of the first data value is discarded as part of the calculation, as might be the case if it is ANDed with `0x0` or if arithmetic using the first data value cancels out its contribution.

For example, each of the following code sequences creates order between the memory transactions:

Sequence 1
```
LDR R1,[R2]
AND R1, R1, #0
LDR R4,[R3, R1]
```

Sequence 2
```
LDR R1, [R2]
ADD R3, R3, R1
SUB R3, R3, R1
STR R4, [R3]
```

E2.7.3 Memory barriers

The ARM architecture is a weakly ordered memory architecture that supports out of order completion. *Memory barrier* is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring Load/Store instructions. The memory barriers defined by the ARMv8 architecture provide a range of functionality, including:

- Ordering of Load/Store instructions.
- Completion of Load/Store instructions.
- Context synchronization.

The following subsections describe the ARMv8 memory barrier instructions:

- *Instruction Synchronization Barrier (ISB)* on page E2-2269.
- *Data Memory Barrier (DMB)* on page E2-2269.
- *Data Synchronization Barrier (DSB)* on page E2-2270.
- *Shareability and access limitations on the data barrier operations* on page E2-2271.
- *Load-Acquire, Store-Release* on page E2-2271.

Note

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are only available when software execution is at EL1 or higher.

The DMB and DSB memory barriers affect reads and writes to the memory system generated by Load/Store instructions and data or unified cache maintenance instructions being executed by the PE. Instruction fetches or accesses caused by a hardware translation table access are not explicit accesses.

AArch32 state also supports the legacy CP15 barrier operations CP15DMB, CP15DSB, and CP15ISB. These operations are accessible from EL0. However, ARM deprecates any use of these operations, and strongly recommends that software uses the DMB, DSB, and ISB instructions described in this section instead. Supervisory software can disable use of the CP15 barrier operations, meaning the encodings for these operations are unallocated:

- If EL1 is using AArch32, by setting SCTLR.CP15BEN to 0.
- If EL1 is using AArch64, by setting SCTLR_EL1.CP15BEN to 0.

Instruction Synchronization Barrier (ISB)

An ISB instruction flushes the pipeline in the PE, so that all instructions that come after the ISB instruction in program order are fetched from the cache or memory only after the ISB instruction has completed. Using an ISB ensures that the effects of context-changing operations executed before the ISB are visible to the instructions fetched after the ISB instruction. Examples of context-changing operations that require the insertion of an ISB instruction to ensure the effects of the operation are visible to instructions fetched after the ISB instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to system control registers.

Any context-changing operations appearing in program order after the ISB instruction only take effect after the ISB has been executed.

```
InstructionSynchronizationBarrier();
```

See also *Memory barriers* on page G3-3613.

Data Memory Barrier (DMB)

The DMB instruction is a data memory barrier. The PE that executes the DMB instruction is referred to as the executing PE, PEe. The DMB instruction takes the *required shareability domain* and *required access types* as arguments:

```
DataMemoryBarrier(MBReqDomain domain, MBReqTypes types);
```

See *Shareability and access limitations on the data barrier operations* on page E2-2271.

If the required shareability is *Full system* then the operation applies to all observers within the system.

A DMB creates two groups of memory accesses, Group A and Group B:

Group A Contains:

- All explicit memory accesses of the required access types from observers in the same required shareability domain as PEe that are observed by PEe before the DMB instruction. These accesses include any accesses of the required access types performed by PEe.
- All loads of required access types from an observer PEx in the same required shareability domain as PEe that have been observed by any given different observer, PEy, in the same required shareability domain as PEe before PEy has performed a memory access that is a member of Group A.

Group B Contains:

- All explicit memory accesses of the required access types by PEe that occur in program order after the DMB instruction.

- All explicit memory accesses of the required access types by any given observer PEx in the same required shareability domain as PEe that can only occur after a load by PEx has returned the result of a store that is a member of Group B.

Any observer with the same required shareability domain as PEe observes all members of Group A before it observes any member of Group B to the extent that those group members are required to be observed, as determined by the shareability and cacheability of the memory locations accessed by the group members.

If members of Group A and members of Group B access the same memory-mapped peripheral of arbitrary system-defined size, then members of Group A that are accessing Device or Normal Non-cacheable memory arrive at that peripheral before members of Group B that are accessing Device or Normal Non-cacheable memory. Where the members of Group A and Group B that must be ordered are from the same PE, a `DMB NSH` is sufficient for this guarantee.

Note

- A memory access might be in neither Group A nor Group B. The `DMB` does not affect the order of observation of such a memory access.
- The second part of the definition of Group A is recursive. Ultimately, membership of Group A derives from the observation by PEy of a load before PEy performs an access that is a member of Group A as a result of the first part of the definition of Group A.
- The second part of the definition of Group B is recursive. Ultimately, membership of Group B derives from the observation by any observer of an access by PEe that is a member of Group B as a result of the first part of the definition of Group B.

`DMB` only affects memory accesses and the operation of data cache and unified cache maintenance instructions, see *Cache maintenance instructions* on page D3-1608. It has no effect on the ordering of any other instructions executing on the PE.

See also *Memory barriers* on page D3-1630.

Data Synchronization Barrier (DSB)

The `DSB` instruction is a special memory barrier, that synchronizes the execution stream with memory accesses.

The `DSB` instruction takes the *required shareability domain* and *required access types* as arguments:

```
DataSynchronizationBarrier(MBReqDomain domain, MBReqTypes types);
```

See *Shareability and access limitations on the data barrier operations* on page E2-2271.

If the required shareability is *Full system* then the operation applies to all observers within the system.

A `DSB` behaves as a `DMB` with the same arguments, and also has the additional properties defined in this section. The PE that executes the `DSB` instruction is referred to as the executing PE, PEe.

A `DSB` completes when all of the following apply:

- All explicit memory accesses that are observed by PEe before the `DSB` is executed and are of the required access types, and are from observers in the same required shareability domain as PEe, are complete for the set of observers in the required shareability domain.
- All cache maintenance instructions issued by PEe before the `DSB` are complete for the required shareability domain.
- If the required access types of the `DSB` is *reads and writes*, all TLB maintenance instructions issued by PEe before the `DSB` are complete for the required shareability domain.

In addition, no instruction that appears in program order after the `DSB` instruction can execute until the `DSB` completes.

See also *Memory barriers* on page G3-3613.

Shareability and access limitations on the data barrier operations

The DMB and DSB instructions can each take an optional limitation argument that specifies:

- The shareability domain over which the instruction must operate. This is one of:
  - Full system.
  - Outer Shareable.
  - Inner Shareable.
  - Non-shareable.
- The accesses for which the instruction operates. This is one of:
  - Read and write accesses in Group A and Group B.
  - Write accesses only in Group A and Group B.
  - Read access only in Group A and read and write accesses in Group B.

Note

This is occasionally referred to as a Load-Load/Store barrier.

If no specifiers are used then each instruction operates for read and write accesses, over the full system. See the instruction descriptions for more information about these arguments.

Note

ISB also supports an optional limitation argument that can only contain one value that corresponds to full system operation.

Load-Acquire, Store-Release

ARMv8 provides a set of instructions with Acquire semantics for loads, and Release semantics for stores.

For all memory types, these instructions have the following ordering requirements:

- A Store-Release followed by a Load-Acquire is observed in program order by each observer within the shareability domain of the memory address being accessed by the Store-Release and the memory address being accessed by the Load-Acquire.
- A Load-Acquire is a read that must be observed by all observers in the shareability domain of the accessed memory location before any other read or write that both:
  - Is caused by an instruction that appears in program order after the Load-Acquire.
  - Accesses memory in the shareability domain accessed by the Load-Acquire.
- A Load-Acquire places no additional ordering constraints on any loads or stores appearing before the Load-Acquire.
- Store-Release is a write:
  - Where the reads and writes generated by loads and stores appearing in program order before the Store-Release are observed as required by the shareability domains of the memory addresses being accessed by those loads and stores by each observer within the shareability domain of the memory address being accessed by the Store-Release, before that observer observes the write generated by the Store-Release.
  - Where any writes that have been observed before the Store-Release by the processing element executing the Store-Release are observed as required by the shareability domains of the memory addresses being accessed by those loads and store by each observer within the shareability domain of the memory address being accessed by the Store-Release, before that observer observes the write generated by the Store-Release.
- The Store-Release places no additional ordering constraints on any loads or stores appearing after the Store-Release instruction.

- All Store-Release instructions must be multi-copy atomic when they are observed with Load-Acquire instructions.

In addition, for Device memory, these instructions have the following requirements:

- A Load-Acquire to an address in a memory-mapped peripheral of arbitrary system defined size using Device memory types will ensure that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed after the Load-Acquire will arrive at the memory-mapped peripheral after the memory access of the Load-Acquire.
- A Store-Release to an address in a memory-mapped peripheral of arbitrary system defined size using Device memory types will ensure that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed before the Store-Release will arrive at the memory-mapped peripheral before the memory access of the Store-Release.
- A memory access to a memory-mapped peripheral of arbitrary system defined size, using Device memory types that are architecturally required to be ordered before the memory access of the Store-Release ,will arrive at the memory-mapped peripheral before any memory access to the same memory-mapped peripheral using Device memory types that are architecturally required to be ordered after the memory access of a Load-Acquire to the same memory location as the Store-Release, where the Load-Acquire has observed the value stored by the Store-Release.

Load-Acquire and Store-Release, other than `LDAEXD` and `STLEXD`, access only a single data element. This access is single-copy atomic. The address of the data object must be aligned to the size of the data element being accessed, otherwise the access generates an Alignment fault.

`LDAEXD` and `STLEXD` access two data elements. The address supplied to the instructions must be doubleword aligned, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction only has the release semantics if the store is successful.

Note

- Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties that apply to the Load-Exclusive or Store-Exclusive instructions also apply to the Load-Acquire Exclusive or Store-Release Exclusive instructions.
- The Load-Acquire/Store-Release instructions can remove the requirement to use the explicit `DMB` memory barrier instruction.

E2.8 Memory types and attributes

In ARMv8 the ordering of accesses for locations of memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- *Normal memory*.
- *Device memory* on page E2-2275.
- *Memory access restrictions* on page E2-2280.

E2.8.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware might perform speculative data read accesses to these locations.

The Normal memory type has the following properties:

- A write to a memory location with the Normal attribute completes in finite time. This means that it is globally observed for the shareability domain of the memory location in finite time. For a Non-cacheable location, the location is observed by all observers in finite time.
- A completed write to a memory location with the Normal attribute is globally observed for the shareability domain of the memory location in finite time without the need for explicit cache maintenance instructions or barriers. For a Non-cacheable location, the completed write is globally observed for all observers in finite time without the need for explicit cache maintenance instructions or barriers.
- Writes to a memory location with the Normal memory attribute that are Non-cacheable must reach the endpoint for that location in the memory system in finite time.
- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.
- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See *Multi-register loads and stores that access Normal memory* on page E2-2275.

Note

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
  - Read accesses can be repeated with no side-effects.
  - Repeated read accesses return the last value written to the resource being read.
  - Read accesses can fetch additional memory locations with no side-effects.
  - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
  - Unaligned accesses can be supported.
  - Accesses can be merged before accessing the target memory system.
- An instruction that generates a sequence of accesses as described in *Atomicity in the ARM architecture* on page E2-2261 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

The following sections describe the other attributes for Normal memory:

- *Shareable Normal memory* on page E2-2274.
- *Non-shareable Normal memory* on page E2-2275.

See also:

- *Atomicity in the ARM architecture* on page E2-2261.
- *Memory barriers* on page E2-2268. For accesses to Normal memory, a `DMB` instruction is required to ensure the required ordering.
- *Concurrent modification and execution of instructions* on page E2-2263.

Shareable Normal memory

A Normal memory location has a Shareability attribute that is:

- Defined independently for the Inner Shareable and Outer Shareable shareability domains.
- Defined, for each shareability domain, as being either Shareable or Non-shareable.

The shareability attributes define the data coherency requirements of the location, that hardware must enforce. They do not affect the coherency requirements of instruction fetches, see *Synchronization and coherency issues between data and instruction accesses* on page E2-2253.

Note

- System designers can use the shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different processing elements.
- This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

Shareable, Inner Shareable, and Outer Shareable Normal memory

The ARM architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

- Each observer is only a member of a single Inner Shareability domain.
- Each observer is only a member of a single Outer Shareability domain.
- All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

Note

- Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.
- The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.

The details of the use of the shareability attributes are system-specific. Example E2-1 shows how they might be used.

Example E2-1 Use of shareability attributes

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.
- However, between the two clusters, the caches:
  - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
  - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable shareability domain.

For Shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

Non-shareable Normal memory

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more registers from the SIMD and floating-point register file from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.

E2.8.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for ARMv8 Device memory are:

Gathering Identified as G or nG, see *Gathering* on page E2-2277.

Reordering Identified as R or nR, see *Reordering* on page E2-2278.

Early Write Acknowledgement hint

Identified as E or nE, see *Early Write Acknowledgement* on page E2-2279.

The ARMv8 Device memory types are:

Device-nGnRnE Device non-Gathering, non-Reordering, No Early write acknowledgement.

Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.

Device-nGnRE Device non-Gathering, non-Reordering, Early Write Acknowledgement.

Equivalent to the Device memory type in earlier versions of the architecture.

Device-nGRE Device non-Gathering, Reordering, Early Write Acknowledgement.

ARMv8 adds this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory.

The Device-nGRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format.

Device-GRE Device Gathering, Reordering, Early Write Acknowledgement.

ARMv8 adds this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that speculative accesses to Device-GRE memory is forbidden.

The Device-GRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format.

Collectively these are referred to as *any Device memory type*. Going down the list, the memory types are described as getting *weaker*; conversely the going up the list the memory types are described as getting *stronger*.

Note

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.
- The architecture does not require an implementation to distinguish between each of these memory types and ARM recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.
- Earlier versions of the ARM architecture defined the following memory types:
  - Strongly-ordered memory. This is the equivalent of the Device-nGnRnE memory type.
  - Device memory. This is the equivalent of the Device-nGnRE memory type.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.

  An exception to this applies:

  - Reads generated by the Advanced SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.

Note

- An instruction that generates a sequence of accesses as described in *Atomicity in the ARM architecture* on page E2-2261 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program only defines a single access. For this reason, ARM strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.

  — Write speculation that is visible to other observers is prohibited for all memory types.

- A write to a memory location with any Device memory attribute completes in finite time. This means that it is globally observed for all observers in the system in finite time.
- If a location with any Device memory attribute changes without an explicit write by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.
- A completed write to a memory location with any Device memory attribute is globally observed for all observers in finite time without the need for explicit maintenance.
- Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.
- A memory location with any Device memory attribute cannot be allocated into a cache.
- Writes to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Typically, the endpoint is a peripheral or some physical memory.
- All accesses to memory with any Device memory attribute must be aligned. Any unaligned access generates an Alignment fault at the first stage of translation that defined the location as being Device.

  Note

  In the Non-secure EL1 translation regime in systems where HCR.TGE == 1 and HCR.DC == 0, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes the value of HSR.ISS.[24] to be 0.

- Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as Execute-never for all Exception levels.

  Note

  This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as Execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as Execute-never for all Exception levels is a programming error.

For instruction fetches, if branches cause the program counter to point to an area of memory with the Device attribute which is not marked as Execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
- Take a Permission fault.

Gathering

In the Device memory attribute:

G Indicates that the location has the Gathering attribute.

nG Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

- Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
- Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

- The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.
- All access occur at their programmed size, except that there is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See *Multi-register loads and stores that access Device memory* on page E2-2280.

Gathering between memory accesses separated by a memory barrier that affects those memory accesses is not permitted. This applies if one memory access is in Group A and one memory access is in Group B. That is, gathering is not permitted between a memory access in Group A and a memory access in Group B if the two accesses are separated by a barrier that affects at least one of the accesses.

Gathering between two memory accesses generated by a Load-Acquire/Store-Release is not permitted.

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

Note

- A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
  - The accesses are not separated by a `DMB` or `DSB` barrier that affects both of the accesses, for example if one access is in Group A and the other is in Group B.
  - The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
  - The accesses are not generated by a Store-Release instruction.
- The ARM architecture only defines programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the Non-gathering attribute.

An implementation is not permitted to perform an access with the Non-gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.

Reordering

In the Device memory attribute:

R Indicates that the location has the Reordering attribute.

nR Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program.That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

Note

- The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the DMB instruction.
- The ARM architecture only defines programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.

An implementation is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.

A additional relaxation is that an implementation is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses with the non-Reordering attribute and accesses with the Reordering attribute.
- Accesses with the non-Reordering attribute and accesses to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

Early Write Acknowledgement

In the Device memory attribute:

E Indicates that the location has the Early Write Acknowledgement attribute.

nE Indicates that the location has the No Early Write Acknowledgement attribute.

Early Write Acknowledgement is a hint to the platform memory system. Assigning the No Early Write Acknowledgement attribute to a Device memory location recommends that only the endpoint of the write access returns a write acknowledgement of the access, and that no earlier point in the memory system returns a write acknowledge. This means that a DSB barrier, executed by the PE that performed the write to the No Early Write Acknowledgement location, completes only after the write has reached its endpoint in the memory system. Typically, this endpoint is a peripheral or physical memory.

When the Early Write Acknowledgement attribute is assigned to a Device memory location, there is no such recommendation for the handling of accesses to that location.

Note

- The Early Write Acknowledgement hint has no effect on the ordering rules. The purpose of signalling no Early Write Acknowledgement is to signal to the interconnect that the peripheral requires the ability to signal the acknowledgement. The No Write Acknowledgement signal also provides an additional semantic that can be interpreted by the driver that is accessing the peripheral.
- This attribute is treated as a hint, as the exact nature of the interconnects attached to a PE is outside the scope of the ARM architecture definition, and not all interconnects provide a mechanism to ensure that a write has reached the physical endpoint of the memory system.
- ARM recommends that writes with the No Early Write Acknowledgement hint are used for PCIe configuration writes. However, the mechanisms by which PCIe configuration writes are identified are IMPLEMENTATION DEFINED.
- ARM strongly recommends that the Early Write Acknowledgement hint is not ignored by a PE, but is made available for use by the system.

Because the No Early Write Acknowledgement attribute is a hint:

- An implementation is permitted to perform an access with the Early Write Acknowledgement attribute in a manner consistent with the requirements specified by the No Early Write Acknowledgement attribute.

- An implementation is permitted to perform an access with the No Early Write Acknowledgement attribute in a manner consistent with the relaxations allowed by the Early Write Acknowledgement attribute.

Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load and store instructions.

For all instructions that load or store one or more registers from the SIMD and floating-point register file there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load and store instructions.

For an `LDRD`, `STRD`, or `LDM` instruction with a register list that includes the PC, or an `STM` instruction with a register list that includes the PC, the order in which the registers are accessed is not defined by the architecture.

For a load or store of an Advanced SIMD element or structure, the order in which the registers are accessed is not defined by the architecture.

For a `VLDM`, `VSTM`, `LDM` and `STM` instruction with a register list that does not include the PC, all registers are accessed in ascending address order for Device accesses with the non-Reordering attribute.

E2.8.3 Memory access restrictions

The following restrictions apply to memory accesses:

- For accesses to any two bytes, *p* and *q*, that are generated by the same instruction:
  - The bytes *p* and *q* must have the same memory type and shareability attributes. otherwise the results are CONSTRAINED UNPREDICTABLE. For example, an `LDC`, `LDM`, `LDRD` `STC`, `STM` or `STRD` instruction, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRAINED UNPREDICTABLE.
  - Except for possible differences in the cache allocation hints, ARM deprecates having different cacheability attributes for bytes *p* and *q*.

  See *Crossing a page boundary with different memory types or shareability attributes* on page AppxA-4792.
- An instruction that causes multiple accesses to Device memory must not cross a 4KB address boundary, otherwise the effect is constrained unpredictable. For this reason, it is important than an access to a volatile memory device is not made using a single instruction that crosses a 4KB address boundary.

  ARM expects this restriction to impose constraints on the placing of volatile memory devices in the memory map of a system, rather than expecting a compiler to be aware of the alignment of memory accesses.

  See *Crossing a 4KB boundary with a Device access* on page AppxA-4792.

E2.9 Mismatched memory attributes

In the ARMv8 architecture mismatched memory attributes are controlled by privileged software. For more information, see Chapter G4 *The AArch32 Virtual Memory System Architecture*.

Physical memory locations are accessed with *mismatched attributes* if all accesses to the location do not use a common definition of all of the following attributes of that location:

- Memory type, Device or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.

Collectively these are referred to as memory attributes.

Note

The terms *location* and *memory location* refer to any byte within the current coherency granule and are used interchangeably.

The following rules apply when a physical memory location is accessed with mismatched attributes:

1. When a memory location is accessed with mismatched attributes the only software visible effects are one or more of the following:
   - Uniprocessor semantics for reads and writes to that memory location might be lost. This means:
     - A read of the memory location by one agent might not return the value most recently written to that memory location by the same agent.
     - Multiple writes to the memory location by one agent with different memory attributes might not be ordered in program order.
   - There might be a loss of coherency when multiple agents attempt to access a memory location.
   - There might be a loss of properties derived from the memory type, as described in later bullets in this section.
   - If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory location do not use consistent memory attributes, the exclusive monitor state becomes UNKNOWN.
   - Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.
2. The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:
   - Prohibition of speculative read accesses.
   - Prohibition on Gathering.
   - Prohibition on Re-ordering.
   - The Write Acknowledgement guarantee with respect to the endpoint of the access.

   If the only memory type mismatch associated with a memory location across all users of the memory location is between different types of Device memory, then all accesses might take the properties of the weakest Device memory type.
3. If all aliases of a memory location that permit write access to the location assign the same shareability and cacheability attributes to that location, and all these aliases use a definition of the shareability attribute that includes all the threads of execution that can access the location, then any agent that reads the memory location using these shareability and cacheability attributes accesses it coherently, to the extent required by that common definition of the memory attributes.
4. The possible loss of software-visible effects caused by mismatched attributes for a memory location are defined more precisely if all of the mismatched attributes define the memory location as one of:
   - Any Device memory type.
   - Normal Inner Non-cacheable, Outer Non-cacheable memory.

In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:

- Possible loss of properties described in point 2 on page E2-2281, derived from the memory type when multiple agents attempt to access the memory location.
- Possible reordering of memory transactions to the memory location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting `DMB` barrier instructions between accesses to the same memory location that might use different attributes.

5. If the mismatched attributes for a memory location all assign the same shareability attribute to the location, any loss of uniprocessor semantics or coherency within a shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the coherency of cacheable locations between agents a in different shareability domains. This means:
   - Before writing to a location not using the Write-Back attribute, software must invalidate, or clean, a location from the caches if any agent might have written to the location with the Write-Back attribute. This avoids the possibility of overwriting the location with stale data.
   - After writing to a location with the Write-Back attribute, software must clean the location from the caches, to make the write visible to external memory.
   - Before reading the location with a cacheable attribute, software must invalidate the location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.

   Note

   Cache maintenance instructions can only be accessed from an Exception level that is higher than EL0, and therefore require a system call. For information on system calls, see *Exception-generating and exception-handling instructions* on page F1-2313. For information on cache maintenance instructions, see *Cache support* on page G3-3580.

   In all cases:
   - Location refers to any byte within the current coherency granule.
   - A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
   - In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see *Ordering of cache and branch predictor maintenance instructions* on page G3-3595.

   Note

   With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.

6. If the mismatched attributes for a location mean that multiple cacheable accesses to the location might be made with different shareability attributes, then coherency is guaranteed only if processing elements that accesses the location with a cacheable attribute performs a clean and invalidate of the location before and after accessing that location.

   Note

   The Note in rule 5 on page E2-2282 about possible race conditions also applies to this rule.

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a location, and the accesses from the different agents have different memory attributes associated with the location, the exclusive monitor state becomes UNKNOWN.

ARM strongly recommends that software does not use mismatched attributes for aliases of the same location. An implementation might not optimize the performance of a system that uses mismatched aliases.

E2.10 Synchronization and semaphores

ARMv8 provides non-blocking synchronization of shared memory, using *synchronization primitives*. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal and Device memory.

Note

Use of the ARMv8 synchronization primitives scales for multiprocessing system designs.

Table E2-4 shows the synchronization primitives and the associated CLREX instruction.

Table E2-4 Synchronization primitives and associated instruction

Function	A32/T32 Instruction
Load-Exclusive	
Byte	LDREXB, LDAEXB
Halfword	LDREXH, LDAEXH
Word	LDREX, LDAEX
Doubleword	LDREXD. LDAEXD
Store-Exclusive	
Byte	STREXB, STLEXB
Halfword	STREXH, STLEXH
Word	STREX,STLEX
Doubleword	STREXD, STLEXD
Clear-Exclusive	CLREX

The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address *x* is:

- The Load-Exclusive instruction reads a value from memory address *x*.
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address *x* only if no other observer, process, or thread has performed a more recent store to address *x*. The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see *Marking and the size of the marked memory block* on page E2-2289. A Store-Exclusive instruction to any address in the marked block clears the marking.

Note

In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

E2.10.1 Exclusive access instructions and Non-shareable memory locations

For memory locations that do not have the *Shareable* attribute, the exclusive access instructions rely on a *local monitor* that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

A Load-Exclusive instruction performs a load from memory, and:

- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state

- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
  - If the store took place the status value is 0.
  - Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

If the local monitor is in the Open Access state

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

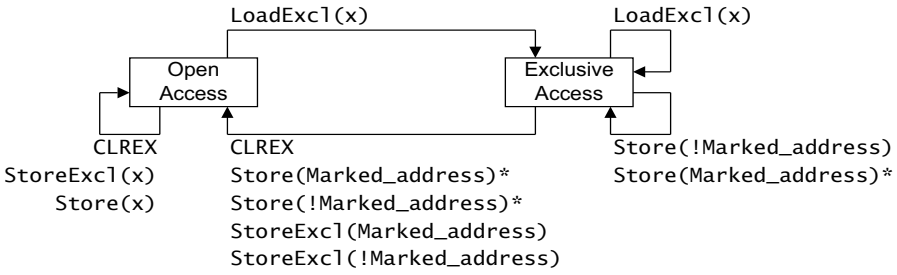
The Store-Exclusive instruction defines the register to which the status value is returned.

When a PE writes using any instruction other than a Store-Exclusive instruction:

- If the write is to a physical address that is not tagged by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a physical address that is tagged by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked physical address causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the physical address to be marked.

Figure E2-4 shows the state machine for the local monitor and the effect of each of the operations shown in the figure.



Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: `LoadExcl` represents any Load-Exclusive instruction
`StoreExcl` represents any Store-Exclusive instruction
`Store` represents any other store instruction.

Any `LoadExcl` operation updates the marked address to the most significant bits of the address `x` used for the operation.

Figure E2-4 Local monitor state machine diagram

For more information about marking see *Marking and the size of the marked memory block* on page E2-2289.

Note

For the local monitor state machine, as shown in Figure E2-4 on page E2-2285:

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any physical address, but instead treats any access as matching the address of the previous Load-Exclusive instruction.
- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.
- The architecture does not require a load instruction, by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.
- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the `Store` or `StoreExcl` is from another observer.

Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Figure E2-4 on page E2-2285.

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Figure E2-4 on page E2-2285.
- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Figure E2-4 on page E2-2285 must not indefinitely delay forward progress of execution.

E2.10.2 Exclusive access instructions and Shareable memory locations

For memory locations that have the *Shareable* attribute, exclusive access instructions rely on:

- A *local monitor* for each PE in the system, that marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in *Exclusive access instructions and Non-shareable memory locations* on page E2-2285, except that for Shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:
  - Updating memory.
  - Returning a status value of 0.

  The local monitor can ignore accesses from other PEs in the system.
- A *global monitor* that marks a physical address as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
  - Can hold one marked block.
  - Maintains a state machine for each marked block it can hold.

  Note

  For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is UNPREDICTABLE, see *Load-Exclusive and Store-Exclusive instruction usage restrictions* on page E2-2290.

Note

The global monitor can either reside in a block that is part of the hardware on which the PE executes or exist as a secondary monitor at the memory interfaces.The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For Shareable locations of memory, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

Note

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport's Bakery algorithm to achieve mutual exclusion.

Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global exclusive monitor is implemented are:

- Inner shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hint and not transient.
- Outer shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hints and not transient.

The set of memory types that support atomic instructions must include all of the memory types for which a global monitor is implemented.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive/Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an external abort.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Fault Status code of:
  - DFSR.STATUS = `0b110101` when using the Long-descriptor translation table format. The fault can also be reported in the HSR.ISS[5:0] field for exceptions to Hyp mode.
  - DFSR.FS = `0b10101` when using the Short-descriptor translation table format.
- The instruction is treated as a `NOP`.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by an ARM PE is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

Operation of the global monitor

A Load-Exclusive instruction from Shareable memory performs a load from memory, and causes the physical address of the access to be marked as exclusive access for the requesting PE. This access also causes the exclusive access mark to be removed from any other physical address that has been marked by the requesting PE.

Note

The global monitor only supports a single outstanding exclusive access to Shareable memory for each PE.

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the physical address accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
  - A status value of 0 is returned to a register to acknowledge the successful store.
  - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
  - If the address accessed is marked for exclusive access in the global monitor state machine for any other PE then that state machine transitions to Open Access state.
- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  - A status value of 1 is returned to a register to indicate that the store failed.
  - The global monitor is not affected and remains in Open Access state for the requesting PE.
- If a different physical address is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  - If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
  - If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to Shareable memory by PE(n) can respond to all the Shareable memory accesses visible to it. This means it responds to:

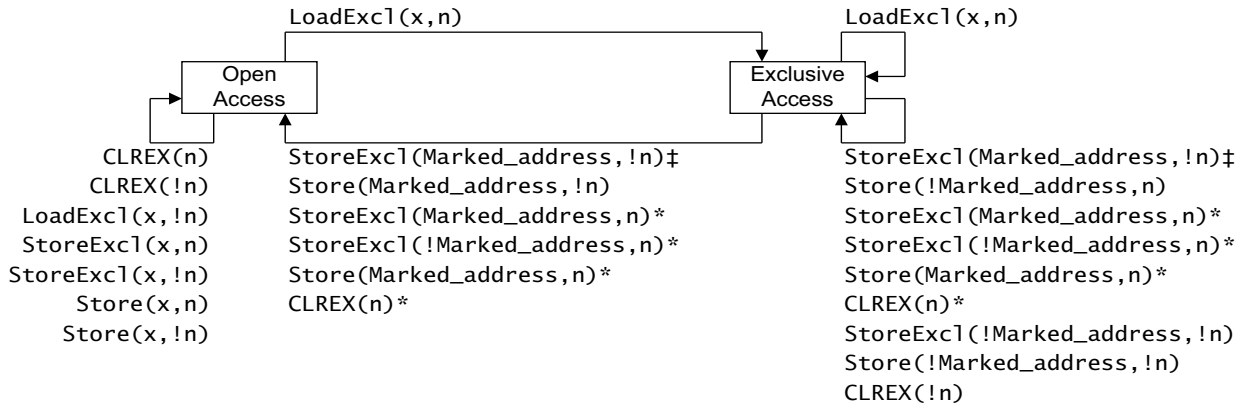
- Accesses generated by PE(n).
- Accesses generated by the other observers in the shareability domain of the memory location. These accesses are identified as (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

Clear global monitor event

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see *Wait For Event and Send Event* on page G1-3457.

Figure E2-5 on page E2-2289 shows the state machine for PE(n) in a global monitor.



‡StoreExcl(Marked_address,!n) clears the monitor only if the StoreExcl updates memory
Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: LoadExcl represents any Load-Exclusive instruction
StoreExcl represents any Store-Exclusive instruction
Store represents any other store instruction.

Any LoadExcl operation updates the marked address to the most significant bits of the address x used for the operation.

Figure E2-5 Global monitor state machine diagram for PE(n) in a multiprocessor system

For more information about marking see *Marking and the size of the marked memory block*.

Note

For the global monitor state machine, as shown in Figure E2-5:

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.
- Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked Shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, Figure E2-5 only shows how the operations by (!n) cause state transitions of the state machine for PE(n).
- A Load-Exclusive instruction can only update the marked Shareable memory address for the PE issuing the Load-Exclusive instruction.
- When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.
- It is IMPLEMENTATION DEFINED:
  - Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
  - Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

E2.10.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a Load-Exclusive instruction is executed, a marked block of size 2^a is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. For example, in an implementation where a is 4, a successful LDREXB of address 0x341B4 gives defines a marked block using bits[47:4] of the address. This means that the four words of memory from 0x341B0 to 0x341BF are marked for exclusive access.

The size of the marked memory block is called the *Exclusives Reservation Granule*. The Exclusives Reservation Granule is IMPLEMENTATION DEFINED in the range 2 - 512 words:

- 3 words in an implementation where a is 4.
- 512 words in an implementation where a is 11.

In some implementations the CTR identifies the Exclusives Reservation Granule, see CTR. Otherwise, software must assume that the maximum Exclusives Reservation Granule, 512 words, is implemented.

E2.10.4 Context switch support

An exception return clears the local monitor. As a result, performing a `CLREX` instruction as part of a context switch is not required in most situations.

Note

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

E2.10.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a `LDREX`/`STREX` pair or a `LDREXB`/`STREXB` pair. To support different implementations of these functions, software must follow the notes and restrictions given in this subsection.

The following notes describe use of a Load-Exclusive/ Store-Exclusive pair, `LoadExcl`/`StoreExcl`, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in Table E2-4 on page E2-2284:

- The exclusives support a single outstanding exclusive access for each software thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the `IsExclusiveLocal()` function. If the target virtual address of a `StoreExcl` is different from the virtual address of the preceding `LoadExcl` instruction in the same thread of execution, behavior can be UNPREDICTABLE. As a result, a `LoadExcl`/`StoreExcl` pair can only be relied upon to eventually succeed if the `LoadExcl` and the `StoreExcl` are executed with the same virtual address.

- If two `StoreExcl` instructions are executed without an intervening `LoadExcl` instruction the second `StoreExcl` instruction returns a status value of 1. This means that:
  — ARM recommends that, in a given thread of execution, every `StoreExcl` instruction has a preceding `LoadExcl` instruction associated with it.

  It is not necessary for every `LoadExcl` instruction to have a subsequent `StoreExcl` instruction.

- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a Store-Exclusive instruction is the same as the transaction size of the preceding Load-Exclusive instruction executed in that thread. If the transaction size of a Store-Exclusive instruction is different from the preceding Load-Exclusive instruction in the same thread of execution, behavior can be UNPREDICTABLE. As a result, software can rely on an `LoadExcl`/`StoreExcl` pair to eventually succeed only if they have the same size.

- An implementation might clear an exclusive monitor between the `LoadExcl` instruction and the `StoreExcl`, instruction without any application-related cause. For example, this might happen because of cache evictions. Software must, in any single thread of execution, avoid having any explicit memory accesses or cache maintenance instructions between the `LoadExcl` instruction and the associated `StoreExcl` instruction.

- Implementations can benefit from keeping the `LoadExcl` and `StoreExcl` operations close together in a single thread of execution. This minimizes the likelihood of the exclusive monitor state being cleared between the `LoadExcl` instruction and the `StoreExcl` instruction. Therefore, for best performance, ARM strongly recommends a limit of 128 bytes between `LoadExcl` and `StoreExcl` instructions in a single thread of execution.

- The architecture sets an upper limit of 2048 bytes on the exclusive reservation granule that can be marked as exclusive. For performance reasons, ARM recommends that objects that are accessed by exclusive accesses are separated by the size of the exclusive reservations granule. This is a performance guideline rather than a functional requirement.
- After taking a Data Abort exception, the state of the exclusive monitors is UNKNOWN.
- If the memory attributes for the memory being accessed by a `LoadExcl`/`StoreExcl` pair differ between the `LoadExcl` instruction and the `StoreExcl` instruction, behavior is UNPREDICTABLE. This can occur either:
  - Because the translation has changed between the `LoadExcl` and the `StoreExcl`.
  - As a result of using different virtual addresses, with different attributes, that point to the same physical address. This case is covered by another bullet point in this list.
- The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global exclusive monitor that is in the Exclusive Access state is UNPREDICTABLE. The instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same shareability domain as the PE executing the cache maintenance instruction, as determined by the shareability domain of the address being maintained.

  Note

  ARM strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

Note

In the event of repeatedly-contending Load-Exclusive/Store-Exclusive instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

E2.10.6 Use of WFE and SEV instructions by spin-locks

ARMv8 provides Wait For Event, Send Event, and Send Event Local instructions, `WFE`, `SEV`, `SEVL`, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in *Wait For Event and Send Event* on page G1-3457. However, in ARMv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

Note

This is equivalent to issuing an `SEV` instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an `SEV` instruction after clearing a spinlock.

Part F
The AArch32 Instruction Sets

Chapter F1
The AArch32 Instruction Sets Overview

This chapter describes the T32 and A32 instruction sets. It contains the following sections:

F1.1 Support for instructions in different versions of the ARM architecture

This manual describes the ARM AArch32 instruction sets, T32 and A32, for the ARMv8 architecture. Therefore, it indicates how any options or extensions in the ARMv8 architecture affect the available instructions. Also, Chapter F6 *ARMv8 Changes to the T32 and A32 Instruction Sets* provides information for those migrating from earlier versions of the architecture.

This manual does not provide any information about which T32 and A32 instructions were supported in specific earlier versions of the architecture. For this information, see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

F1.2 Unified Assembler Language

This manual uses the ARM *Unified Assembler Language* (UAL). This assembly language syntax provides a canonical form for all T32 and A32 instructions.

UAL describes the syntax for the mnemonic and the operands of each instruction. In addition, it assumes that instructions and data items can be given labels. It does not specify the syntax to be used for labels, nor what assembler directives and options are available. See your assembler documentation for these details.

Most earlier ARM assembly language mnemonics are still supported as synonyms, as described in the instruction details.

Note

Most earlier T32 assembly language mnemonics are *not* supported.

UAL includes *instruction selection* rules that specify which instruction encoding is selected when more than one can provide the required functionality. For example, both 16-bit and 32-bit encodings exist for an `ADD R0, R1, R2` instruction. The most common instruction selection rule is that when both a 16-bit encoding and a 32-bit encoding are available, the 16-bit encoding is selected, to optimize code density.

Syntax options exist to override the normal instruction selection rules and ensure that a particular encoding is selected. These are useful when disassembling code, to ensure that subsequent assembly produces the original code, and in some other situations.

F1.2.1 Conditional instructions

For maximum portability of UAL assembly language between the T32 and A32 instruction sets, ARM recommends that:

- `IT` instructions are written before conditional instructions in the correct way for the T32 instruction set.
- When assembling to the A32 instruction set, assemblers check that any `IT` instructions are correct, but do not generate any code for them.

Although other T32 instructions are unconditional, all instructions that are made conditional by an `IT` instruction must be written with a condition. These conditions must match the conditions imposed by the `IT` instruction. For example, an `ITTEE EQ` instruction imposes the `EQ` condition on the first two following instructions, and the `NE` condition on the next two. Those four instructions must be written with `EQ`, `EQ`, `NE` and `NE` conditions respectively.

Some instructions cannot be made conditional by an `IT` instruction. Some instructions can be conditional if they are the last instruction in the IT block, but not otherwise.

The branch instruction encodings that include a condition code field cannot be made conditional by an `IT` instruction. If the assembler syntax indicates a conditional branch that correctly matches a preceding `IT` instruction, it is assembled using a branch instruction encoding that does not include a condition code field.

F1.2.2 Use of labels in UAL instruction syntax

The UAL syntax for some instructions includes the label of an instruction or a literal data item that is at a fixed offset from the instruction being specified. The assembler must:

1. Calculate the `PC` or `Align(PC, 4)` value of the instruction. The `PC` value of an instruction is its address plus 4 for a T32 instruction, or plus 8 for an A32 instruction. The `Align(PC, 4)` value of an instruction is its `PC` value ANDed with `0xFFFFFFFC` to force it to be word-aligned. There is no difference between the `PC` and `Align(PC, 4)` values for an A32 instruction, but there can be for a T32 instruction.
2. Calculate the offset from the `PC` or `Align(PC, 4)` value of the instruction to the address of the labelled instruction or literal data item.
3. Assemble a *PC-relative* encoding of the instruction, that is, one that reads its `PC` or `Align(PC, 4)` value and adds the calculated offset to form the required address.

Note

For instructions that can encode a subtraction operation, if the instruction cannot encode the calculated offset but can encode minus the calculated offset, the instruction encoding specifies a subtraction of minus the calculated offset.

The syntax of the following instructions includes a label:

- `B`, `BL`, and `BLX` (immediate). The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a sign-extended immediate offset that is added to the `PC` value of the instruction to form the target address of the branch.
- `CBNZ` and `CBZ`. The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a zero-extended immediate offset that is added to the `PC` value of the instruction to form the target address of the branch. They do not support backward branches.
- `LDC`, `LDC2`, `LDR`, `LDRB`, `LDRD`, `LDRH`, `LDRSB`, `LDRSH`, `PLD`, `PLDW`, `PLI`, and `VLDR`. The normal assembler syntax of these load instructions can specify the label of a literal data item that is to be loaded. The encodings of these instructions specify a zero-extended immediate offset that is either added to or subtracted from the `Align(PC, 4)` value of the instruction to form the address of the data item. A few such encodings perform a fixed addition or a fixed subtraction and must only be used when that operation is required, but most contain a bit that specifies whether the offset is to be added or subtracted.

  When the assembler calculates an offset of 0 for the normal syntax of these instructions, it must assemble an encoding that adds 0 to the `Align(PC, 4)` value of the instruction. Encodings that subtract 0 from the `Align(PC, 4)` value cannot be specified by the normal syntax.

  There is an alternative syntax for these instructions that specifies the addition or subtraction and the immediate offset explicitly. In this syntax, the label is replaced by `[PC, #+/-<imm>]`, where:

  `+/-` Is `+` or omitted to specify that the immediate offset is to be added to the `Align(PC, 4)` value, or `-` if it is to be subtracted.

  `<imm>` Is the immediate offset.

  This alternative syntax makes it possible to assemble the encodings that subtract 0 from the `Align(PC, 4)` value, and to disassemble them to a syntax that can be re-assembled correctly.
- `ADR`. The normal assembler syntax for this instruction can specify the label of an instruction or literal data item whose address is to be calculated. Its encoding specifies a zero-extended immediate offset that is either added to or subtracted from the `Align(PC, 4)` value of the instruction to form the address of the data item, and some opcode bits that determine whether it is an addition or subtraction.

  When the assembler calculates an offset of 0 for the normal syntax of this instruction, it must assemble the encoding that adds 0 to the `Align(PC, 4)` value of the instruction. The encoding that subtracts 0 from the `Align(PC, 4)` value cannot be specified by the normal syntax.

  There is an alternative syntax for this instruction that specifies the addition or subtraction and the immediate value explicitly, by writing them as additions `ADD <Rd>, PC, #<imm>` or subtractions `SUB <Rd>, PC, #<imm>`. This alternative syntax makes it possible to assemble the encoding that subtracts 0 from the `Align(PC, 4)` value, and to disassemble it to a syntax that can be re-assembled correctly.

Note

ARM recommends that where possible, software avoids using:

- The alternative syntax for the `ADR`, `LDC`, `LDC2`, `LDR`, `LDRB`, `LDRD`, `LDRH`, `LDRSB`, `LDRSH`, `PLD`, `PLI`, `PLDW`, and `VLDR` instructions.
- The encodings of these instructions that subtract 0 from the `Align(PC, 4)` value.

F1.3 Branch instructions

Table F1-1 summarizes the branch instructions in the T32 and A32 instruction sets. In addition to providing for changes in the flow of execution, some branch instructions can change instruction set.

Table F1-1 Branch instructions

Instruction	See	Range, T32	Range, A32
Branch to target address	*B* on page F7-2484	±16MB	±32MB
Compare and Branch on Nonzero, Compare and Branch on Zero	*CBNZ, CBZ* on page F7-2499	0-126 bytes	[a]
Call a subroutine Call a subroutine, change instruction set[b]	*BL, BLX (immediate)* on page F7-2494	±16MB ±16MB	±32MB ±32MB
Call a subroutine, optionally change instruction set	*BLX (register)* on page F7-2496	Any	Any
Branch to target address, change instruction set	*BX* on page F7-2497	Any	Any
Change to Jazelle state	*BXJ* on page F7-2498	-	-
Table Branch (byte offsets) Table Branch (halfword offsets)	*TBB, TBH* on page F7-2905	0-510 bytes 0-131070 bytes	[a]

a. These instructions do not exist in the A32 instruction set.

b. The range is determined by the instruction set of the `BLX` instruction, not of the instruction it branches to.

Branches to loaded and calculated addresses can be performed by `LDR`, `LDM` and data-processing instructions. For details see *Load/store instructions* on page F1-2309, *Load/store multiple instructions* on page F1-2311, *Standard data-processing instructions* on page F1-2300, and *Shift instructions* on page F1-2302.

In addition to the branch instructions shown in Table F1-1:

- In the A32 instruction set, a data-processing instruction that targets the PC behaves as a branch instruction. For more information, see *Data-processing instructions* on page F1-2300.
- In the T32 and A32 instruction sets, a load instruction that targets the PC behaves as a branch instruction. For more information, see *Load/store instructions* on page F1-2309.

F1.4 Data-processing instructions

Core data-processing instructions belong to one of the following groups:

- *Standard data-processing instructions*.

  These instructions perform basic data-processing operations, and share a common format with some variations.
- *Shift instructions* on page F1-2302.
- *Multiply instructions* on page F1-2302.
- *Saturating instructions* on page F1-2304.
- *Saturating addition and subtraction instructions* on page F1-2304.
- *Packing and unpacking instructions* on page F1-2305.
- *Parallel addition and subtraction instructions* on page F1-2306.
- *Divide instructions* on page F1-2307.
- *Miscellaneous data-processing instructions* on page F1-2307.

For related Advanced SIMD and floating-point instructions see *Advanced SIMD data-processing instructions* on page F1-2318 and *Floating-point data-processing instructions* on page F1-2324.

F1.4.1 Standard data-processing instructions

These instructions generally have a destination register Rd, a first operand register Rn, and a second operand. The second operand can be another register Rm, or an immediate constant.

If the second operand is an immediate constant, it can be:

- Encoded directly in the instruction.
- A *modified immediate constant* that uses 12 bits of the instruction to encode a range of constants. T32 and A32 instructions have slightly different ranges of modified immediate constants. For more information, see *Modified immediate constants in T32 instructions* on page F3-2358 and *Modified immediate constants in A32 instructions* on page F4-2387.

If the second operand is another register, it can optionally be shifted in any of the following ways:

`LSL` Logical Shift Left by 1-31 bits.

`LSR` Logical Shift Right by 1-32 bits.

`ASR` Arithmetic Shift Right by 1-32 bits.

`ROR` Rotate Right by 1-31 bits.

`RRX` Rotate Right with Extend. For details see *Shift and rotate operations* on page E1-2204.

In T32 code, the amount to shift by is always a constant encoded in the instruction. In A32 code, the amount to shift by is either a constant encoded in the instruction, or the value of a register, Rs.

For instructions other than `CMN`, `CMP`, `TEQ`, and `TST`, the result of the data-processing operation is placed in the destination register. In the A32 instruction set, the destination register can be the PC, causing the result to be treated as a branch address. In the T32 instruction set, this is only permitted for some 16-bit forms of the `ADD` and `MOV` instructions.

These instructions can optionally set the condition flags, according to the result of the operation. If they do not set the flags, existing flag settings from a previous instruction are preserved.

Table F1-2 on page F1-2301 summarizes the main data-processing instructions in the T32 and A32 instruction sets. Generally, each of these instructions is described in three sections in Chapter F2 *About the T32 and A32 Instruction Descriptions*, one section for each of the following:

- `INSTRUCTION` (immediate) where the second operand is a modified immediate constant.
- `INSTRUCTION` (register) where the second operand is a register, or a register shifted by a constant.
- `INSTRUCTION` (register-shifted register) where the second operand is a register shifted by a value obtained from another register. These are only available in the A32 instruction set.

Table F1-2 Standard data-processing instructions

Instruction	Mnemonic	Notes
Add with Carry	ADC	-
Add	ADD	T32 instruction set permits use of a modified immediate constant or a zero-extended 12-bit immediate constant.
Form PC-relative Address	ADR	First operand is the PC. Second operand is an immediate constant. T32 instruction set uses a zero-extended 12-bit immediate constant. Operation is an addition or a subtraction.
Bitwise AND	AND	-
Bitwise Bit Clear	BIC	-
Compare Negative	CMN	Sets flags. Like ADD but with no destination register.
Compare	CMP	Sets flags. Like SUB but with no destination register.
Bitwise Exclusive OR	EOR	-
Copy operand to destination	MOV	Has only one operand, with the same options as the second operand in most of these instructions. If the operand is a shifted register, the instruction is an LSL, LSR, ASR, or ROR instruction instead. For details see *Shift instructions* on page F1-2302. The T32 and A32 instruction sets permit use of a modified immediate constant or a zero-extended 16-bit immediate constant.
Bitwise NOT	MVN	Has only one operand, with the same options as the second operand in most of these instructions.
Bitwise OR NOT	ORN	Not available in the A32 instruction set.
Bitwise OR	ORR	-
Reverse Subtract	RSB	Subtracts first operand from second operand. This permits subtraction from constants and shifted registers.
Reverse Subtract with Carry	RSC	Not available in the T32 instruction set.
Subtract with Carry	SBC	-
Subtract	SUB	T32 instruction set permits use of a modified immediate constant or a zero-extended 12-bit immediate constant.
Test Equivalence	TEQ	Sets flags. Like EOR but with no destination register.
Test	TST	Sets flags. Like AND but with no destination register.

F1.4.2 Shift instructions

Table F1-3 lists the shift instructions in the T32 and A32 instruction sets.

Table F1-3 Shift instructions

Instruction	See
Arithmetic Shift Right	*ASR (immediate)* on page F7-2480
Arithmetic Shift Right	*ASR (register)* on page F7-2482
Logical Shift Left	*LSL (immediate)* on page F7-2623
Logical Shift Left	*LSL (register)* on page F7-2625
Logical Shift Right	*LSR (immediate)* on page F7-2627
Logical Shift Right	*LSR (register)* on page F7-2629
Rotate Right	*ROR (immediate)* on page F7-2723
Rotate Right	*ROR (register)* on page F7-2725
Rotate Right with Extend	*RRX* on page F7-2727

In the A32 instruction set only, the destination register of these instructions can be the PC, causing the result to be treated as an address to branch to.

F1.4.3 Multiply instructions

These instructions can operate on signed or unsigned quantities. In some types of operation, the results are the same whether the operands are signed or unsigned.

- Table F1-4 summarizes the multiply instructions where there is no distinction between signed and unsigned quantities.

  The least significant 32 bits of the result are used. More significant bits are discarded.

- Table F1-5 on page F1-2303 summarizes the signed multiply instructions.

- Table F1-6 on page F1-2303 summarizes the unsigned multiply instructions.

Table F1-4 General multiply instructions

Instruction	See	Operation (number of bits)
Multiply Accumulate	*MLA* on page F7-2635	32 = 32 + 32 × 32
Multiply and Subtract	*MLS* on page F7-2637	32 = 32 – 32 × 32
Multiply	*MUL* on page F7-2657	32 = 32 × 32

Table F1-5 Signed multiply instructions

Instruction	See	Operation (number of bits)
Signed Multiply Accumulate (halfwords)	*SMLABB, SMLABT, SMLATB, SMLATT* on page F7-2777	32 = 32 + 16 × 16
Signed Multiply Accumulate Dual	*SMLAD* on page F7-2779	32 = 32 + 16 × 16 + 16 × 16
Signed Multiply Accumulate Long	*SMLAL* on page F7-2781	64 = 64 + 32 × 32
Signed Multiply Accumulate Long (halfwords)	*SMLALBB, SMLALBT, SMLALTB, SMLALTT* on page F7-2783	64 = 64 + 16 × 16
Signed Multiply Accumulate Long Dual	*SMLALD* on page F7-2785	64 = 64 + 16 × 16 + 16 × 16
Signed Multiply Accumulate (word by halfword)	*SMLAWB, SMLAWT* on page F7-2787	32 = 32 + 32 × 16 [a]
Signed Multiply Subtract Dual	*SMLSD* on page F7-2789	32 = 32 + 16 × 16 – 16 × 16
Signed Multiply Subtract Long Dual	*SMLSLD* on page F7-2791	64 = 64 + 16 × 16 – 16 × 16
Signed Most Significant Word Multiply Accumulate	*SMMLA* on page F7-2793	32 = 32 + 32 × 32 [b]
Signed Most Significant Word Multiply Subtract	*SMMLS* on page F7-2795	32 = 32 – 32 × 32 [b]
Signed Most Significant Word Multiply	*SMMUL* on page F7-2797	32 = 32 × 32 [b]
Signed Dual Multiply Add	*SMUAD* on page F7-2799	32 = 16 × 16 + 16 × 16
Signed Multiply (halfwords)	*SMULBB, SMULBT, SMULTB, SMULTT* on page F7-2801	32 = 16 × 16
Signed Multiply Long	*SMULL* on page F7-2803	64 = 32 × 32
Signed Multiply (word by halfword)	*SMULWB, SMULWT* on page F7-2805	32 = 32 × 16 [a]
Signed Dual Multiply Subtract	*SMUSD* on page F7-2807	32 = 16 × 16 – 16 × 16

a. The most significant 32 bits of the 48-bit product are used. Less significant bits are discarded.
b. The most significant 32 bits of the 64-bit product are used. Less significant bits are discarded.

Table F1-6 Unsigned multiply instructions

Instruction	See	Operation (number of bits)
Unsigned Multiply Accumulate Accumulate Long	*UMAAL* on page F7-2943	64 = 32 + 32 + 32 × 32
Unsigned Multiply Accumulate Long	*UMLAL* on page F7-2945	64 = 64 + 32 × 32
Unsigned Multiply Long	*UMULL* on page F7-2947	64 = 32 × 32

F1.4.4 Saturating instructions

Table F1-7 lists the saturating instructions in the T32 and A32 instruction sets. For more information, see *Pseudocode details of saturation* on page E1-2207.

Table F1-7 Saturating instructions

Instruction	See	Operation
Signed Saturate	*SSAT* on page F7-2809	Saturates optionally shifted 32-bit value to selected range
Signed Saturate 16	*SSAT16* on page F7-2811	Saturates two 16-bit values to selected range
Unsigned Saturate	*USAT* on page F7-2965	Saturates optionally shifted 32-bit value to selected range
Unsigned Saturate 16	*USAT16* on page F7-2967	Saturates two 16-bit values to selected range

F1.4.5 Saturating addition and subtraction instructions

Table F1-8 lists the saturating addition and subtraction instructions in the T32 and A32 instruction sets. For more information, see *Pseudocode details of saturation* on page E1-2207.

Table F1-8 Saturating addition and subtraction instructions

Instruction	See	Operation
Saturating Add	*QADD* on page F7-2695	Add, saturating result to the 32-bit signed integer range
Saturating Subtract	*QSUB* on page F7-2709	Subtract, saturating result to the 32-bit signed integer range
Saturating Double and Add	*QDADD* on page F7-2703	Doubles one value and adds a second value, saturating the doubling and the addition to the 32-bit signed integer range
Saturating Double and Subtract	*QDSUB* on page F7-2705	Doubles one value and subtracts the result from a second value, saturating the doubling and the subtraction to the 32-bit signed integer range

F1.4.6 Packing and unpacking instructions

Table F1-9 lists the packing and unpacking instructions in the T32 and A32 instruction sets.

Table F1-9 Packing and unpacking instructions

Instruction	See	Operation
Pack Halfword	*PKHBT, PKHTB* on page F7-2677	Combine halfwords
Signed Extend and Add Byte	*SXTAB* on page F7-2893	Extend 8 bits to 32 and add
Signed Extend and Add Byte 16	*SXTAB16* on page F7-2895	Dual extend 8 bits to 16 and add
Signed Extend and Add Halfword	*SXTAH* on page F7-2897	Extend 16 bits to 32 and add
Signed Extend Byte	*SXTB* on page F7-2899	Extend 8 bits to 32
Signed Extend Byte 16	*SXTB16* on page F7-2901	Dual extend 8 bits to 16
Signed Extend Halfword	*SXTH* on page F7-2903	Extend 16 bits to 32
Unsigned Extend and Add Byte	*UXTAB* on page F7-2975	Extend 8 bits to 32 and add
Unsigned Extend and Add Byte 16	*UXTAB16* on page F7-2977	Dual extend 8 bits to 16 and add
Unsigned Extend and Add Halfword	*UXTAH* on page F7-2979	Extend 16 bits to 32 and add
Unsigned Extend Byte	*UXTB* on page F7-2981	Extend 8 bits to 32
Unsigned Extend Byte 16	*UXTB16* on page F7-2983	Dual extend 8 bits to 16
Unsigned Extend Halfword	*UXTH* on page F7-2985	Extend 16 bits to 32

F1.4.7 Parallel addition and subtraction instructions

These instructions perform additions and subtractions on the values of two registers and write the result to a destination register, treating the register values as sets of two halfwords or four bytes. That is, they perform SIMD additions or subtractions on the general-purpose registers.

These instructions consist of a prefix followed by a main instruction mnemonic. The prefixes are as follows:

`S` Signed arithmetic modulo 2^8 or 2^{16}.

`Q` Signed saturating arithmetic.

`SH` Signed arithmetic, halving the results.

`U` Unsigned arithmetic modulo 2^8 or 2^{16}.

`UQ` Unsigned saturating arithmetic.

`UH` Unsigned arithmetic, halving the results.

The main instruction mnemonics are as follows:

`ADD16` Adds the top halfwords of two operands to form the top halfword of the result, and the bottom halfwords of the same two operands to form the bottom halfword of the result.

`ASX` Exchanges halfwords of the second operand, and then adds top halfwords and subtracts bottom halfwords.

`SAX` Exchanges halfwords of the second operand, and then subtracts top halfwords and adds bottom halfwords.

`SUB16` Subtracts each halfword of the second operand from the corresponding halfword of the first operand to form the corresponding halfword of the result.

`ADD8` Adds each byte of the second operand to the corresponding byte of the first operand to form the corresponding byte of the result.

`SUB8` Subtracts each byte of the second operand from the corresponding byte of the first operand to form the corresponding byte of the result.

The instruction set permits all 36 combinations of prefix and main instruction operand, as Table F1-10 shows.

See also *Advanced SIMD parallel addition and subtraction* on page F1-2319.

Table F1-10 Parallel addition and subtraction instructions

Main instruction	Signed	Saturating	Signed halving	Unsigned	Unsigned saturating	Unsigned halving
`ADD16`, add, two halfwords	`SADD16`	`QADD16`	`SHADD16`	`UADD16`	`UQADD16`	`UHADD16`
`ASX`, add and subtract with exchange	`SASX`	`QASX`	`SHASX`	`UASX`	`UQASX`	`UHASX`
`SAX`, subtract and add with exchange	`SSAX`	`QSAX`	`SHSAX`	`USAX`	`UQSAX`	`UHSAX`
`SUB16`, subtract, two halfwords	`SSUB16`	`QSUB16`	`SHSUB16`	`USUB16`	`UQSUB16`	`UHSUB16`
`ADD8`, add, four bytes	`SADD8`	`QADD8`	`SHADD8`	`UADD8`	`UQADD8`	`UHADD8`
`SUB8`, subtract, four C.bbytes	`SSUB8`	`QSUB8`	`SHSUB8`	`USUB8`	`UQSUB8`	`UHSUB8`

F1.4.8 Divide instructions

In ARMv8, signed and unsigned integer divide instructions are included in both the T32 instruction set and the A32 instruction set. For more information about their implementation in previous versions of the ARM architecture see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

For descriptions of the instructions see:

- *SDIV* on page F7-2755.
- *UDIV* on page F7-2929.

For the `SDIV` and `UDIV` instructions, divide-by-zero always returns a zero result.

The ID_ISAR0.Divide_instrs field indicates the level of support for these instructions. The field value of `0b0010` indicates they are implemented in both the T32 and A32 instruction sets.

F1.4.9 Miscellaneous data-processing instructions

Table F1-11 lists the miscellaneous data-processing instructions in the T32 and A32 instruction sets. Immediate values in these instructions are simple binary numbers.

Table F1-11 Miscellaneous data-processing instructions

Instruction	See	Notes
Bit Field Clear	*BFC* on page F7-2486	-
Bit Field Insert	*BFI* on page F7-2487	-
Count Leading Zeros	*CLZ* on page F7-2503	-
Move Top	*MOVT* on page F7-2646	Moves 16-bit immediate value to top halfword. Bottom halfword unchanged.
Reverse Bits	*RBIT* on page F7-2715	-
Byte-Reverse Word	*REV* on page F7-2717	-
Byte-Reverse Packed Halfword	*REV16* on page F7-2719	-
Byte-Reverse Signed Halfword	*REVSH* on page F7-2721	-
Signed Bit Field Extract	*SBFX* on page F7-2753	-
Select Bytes using GE flags	*SEL* on page F7-2757	-

Unsigned Sum of Absolute Differences and Accumulate	*USADA8* on page F7-2963	-

F1.5 Status register access instructions

The MRS and MSR instructions move the contents of the *Application Program Status Register* (APSR) to or from a general-purpose register, see:

- *MRS* on page F7-2651.
- *MSR (immediate)* on page F7-2653.
- *MSR (register)* on page F7-2655.

The Application Program Status Register (APSR) on page E1-2211 describes the APSR.

The condition flags in the APSR are normally set by executing data-processing instructions, and normally control the execution of conditional instructions. However, software can set the condition flags explicitly using the MSR instruction, and can read the current state of the condition flags explicitly using the MRS instruction.

At system level, software can also:

- Use these instructions to access the SPSR of the current mode.
- Use the CPS instruction to change the CPSR.M field and the CPSR.{A, I, F} interrupt mask bits.

For details of the system level use of status register access instructions CPS, MRS, and MSR, see:

- *CPS, T32* on page F7-2998.
- *CPS, A32* on page F7-3000.
- *MRS* on page F7-3010.
- *MSR (immediate)* on page F7-3016.
- *MSR (register)* on page F7-3018.

F1.5.1 Banked register access instructions

In all privileged modes, the MRS (Banked register) and MSR (Banked register) instructions move the contents of a Banked general-purpose register, the SPSR, or the ELR_hyp, to or from a general-purpose register. For instruction descriptions see:

- *MRS (Banked register)* on page F7-3012.
- *MSR (Banked register)* on page F7-3014.

Note

These are system level instructions.

F1.6 Load/store instructions

Table F1-12 summarizes the general-purpose register load/store instructions in the T32 and A32 instruction sets. Some of these instructions can also operate on the PC. See also:

- *Load/store multiple instructions* on page F1-2311.
- *Advanced SIMD and floating-point load/store instructions* on page F1-2315.

Load/store instructions have several options for addressing memory. For more information, see *Addressing modes* on page F1-2310.

Table F1-12 Load/store instructions

Data type	Load	Store	Load unprivileged	Store unprivileged	Load-Exclusive	Store-Exclusive
32-bit word	LDR	STR	LDRT	STRT	LDREX	STREX
16-bit halfword	-	STRH	-	STRHT	-	STREXH
16-bit unsigned halfword	LDRH	-	LDRHT	-	LDREXH	-
16-bit signed halfword	LDRSH	-	LDRSHT	-	-	-
8-bit byte	-	STRB	-	STRBT	-	STREXB
8-bit unsigned byte	LDRB	-	LDRBT	-	LDREXB	-
8-bit signed byte	LDRSB	-	LDRSBT	-	-	-
Two 32-bit words	LDRD	STRD	-	-	-	-
64-bit doubleword	-	-	-	-	LDREXD	STREXD

F1.6.1 Loads to the PC

The LDR instruction can load a value into the PC. The value loaded is treated as an interworking address, as described by the LoadWritePC() pseudocode function in *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

F1.6.2 Halfword and byte loads and stores

Halfword and byte stores store the least significant halfword or byte from the register, to 16 or 8 bits of memory respectively. There is no distinction between signed and unsigned stores.

Halfword and byte loads load 16 or 8 bits from memory into the least significant halfword or byte of a register. Unsigned loads zero-extend the loaded value to 32 bits, and signed loads sign-extend the value to 32 bits.

F1.6.3 Load unprivileged and Store unprivileged

When executing at EL0, a Load unprivileged or Store unprivileged instruction operates in exactly the same way as the corresponding ordinary load or store instruction. For example, an LDRT instruction executes in exactly the same way as the equivalent LDR instruction. When executed at EL1, Load unprivileged and Store unprivileged instructions behave as they would if they were executed at EL0. For example, an LDRT instruction executes in exactly the way that the equivalent LDR instruction would execute at EL0. In particular, the instructions make unprivileged memory accesses.

The Load unprivileged and Store unprivileged instructions are UNPREDICTABLE if executed at EL2.

For more information, see *Access permissions* on page G4-3665.

F1.6.4 Load-Exclusives and Store-Exclusives

Load-Exclusive and Store-Exclusives provide shared memory synchronization. For more information, see *Synchronization and semaphores* on page E2-2284.

F1.6.5 Addressing modes

The address for a load or store is formed from two parts: a value from a base register, and an offset.

The base register can be any one of the general-purpose registers R0-R12, SP, or LR.

For loads, the base register can be the PC. This provides PC-relative addressing for position-independent code. Instructions marked (literal) in their title in Chapter F2 *About the T32 and A32 Instruction Descriptions* are PC-relative loads.

The offset takes one of three formats:

Immediate The offset is an unsigned number that can be added to or subtracted from the base register value. Immediate offset addressing is useful for accessing data elements that are a fixed distance from the start of the data object, such as structure fields, stack offsets and input/output registers.

Register The offset is a value from a general-purpose register. The value can be added to, or subtracted from, the base register value. Register offsets are useful for accessing arrays or blocks of data.

Scaled register The offset is a general-purpose register, shifted by an immediate value, then added to or subtracted from the base register. This means an array index can be scaled by the size of each array element.

The offset and base register can be used in three different ways to form the memory address. The addressing modes are described as follows:

Offset The offset is added to or subtracted from the base register to form the memory address.

Pre-indexed The offset is added to or subtracted from the base register to form the memory address. The base register is then updated with this new address, to permit automatic indexing through an array or memory block.

Post-indexed The value of the base register alone is used as the memory address. The offset is then added to or subtracted from the base register. The result is stored back in the base register, to permit automatic indexing through an array or memory block.

Note

Not every variant is available for every instruction, and the range of permitted immediate values and the options for scaled registers vary from instruction to instruction. See Chapter F2 *About the T32 and A32 Instruction Descriptions* for full details for each instruction.

F1.7 Load/store multiple instructions

Load Multiple instructions load from memory a subset, or possibly all, of the general-purpose registers and the PC.

Store Multiple instructions store to memory a subset, or possibly all, of the general-purpose registers.

The memory locations are consecutive word-aligned words. The addresses used are obtained from a base register, and can be either above or below the value in the base register. The base register can optionally be updated by the total size of the data transferred.

Table F1-13 summarizes the load/store multiple instructions in the T32 and A32 instruction sets.

Table F1-13 Load/store multiple instructions

Instruction	See
Load Multiple, Increment After or Full Descending	*LDM (LDMIA, LDMFD), T32* on page F7-2551 *LDM (LDMIA, LDMFD), A32* on page F7-2553
Load Multiple, Decrement After or Full Ascending [a]	*LDMDA (LDMFA)* on page F7-2555
Load Multiple, Decrement Before or Empty Ascending	*LDMDB (LDMEA)* on page F7-2557
Load Multiple, Increment Before or Empty Descending [a]	*LDMIB (LDMED)* on page F7-2559
Pop multiple registers off the stack [b]	*POP, T32* on page F7-2689 *POP, A32* on page F7-2691
Push multiple registers onto the stack [c]	*PUSH* on page F7-2693
Store Multiple, Increment After or Empty Ascending	*STM (STMIA, STMEA)* on page F7-2835
Store Multiple, Decrement After or Empty Descending [a]	*STMDA (STMED)* on page F7-2837
Store Multiple, Decrement Before or Full Descending	*STMDB (STMFD)* on page F7-2839
Store Multiple, Increment Before or Full Ascending [a]	*STMIB (STMFA)* on page F7-2841

a. Not available in the T32 instruction set.
b. This instruction is equivalent to an `LDM` instruction with the SP as base register, and base register updating.
c. This instruction is equivalent to an `STMDB` instruction with the SP as base register, and base register updating.

When executing at EL1, variants of the `LDM` and `STM` instructions load and store User mode registers. Another system level variant of the `LDM` instruction performs an exception return.

F1.7.1 Loads to the PC

The `LDM`, `LDMDA`, `LDMDB`, `LDMIB`, and `POP` instructions can load a value into the PC. The value loaded is treated as an interworking address, as described by the `LoadWritePC()` pseudocode function in *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

F1.8 Miscellaneous instructions

Table F1-14 summarizes the miscellaneous instructions in the T32 and A32 instruction sets.

Table F1-14 Miscellaneous instructions

Instruction	See
Clear-Exclusive	*CLREX* on page F7-2502
Debug Hint	*DBG* on page F7-2518
Data Memory Barrier	*DMB* on page F7-2520
Data Synchronization Barrier	*DSB* on page F7-2522
Instruction Synchronization Barrier	*ISB* on page F7-2532

No Operation	*NOP* on page F7-2665
Preload Data	*PLD, PLDW (immediate)* on page F7-2679 *PLD (literal)* on page F7-2681 *PLD, PLDW (register)* on page F7-2683
Preload Instruction	*PLI (immediate, literal)* on page F7-2685 *PLI (register)* on page F7-2687
Set Endianness	*SETEND* on page F7-2759
Send Event, Send Event Local	*SEV* on page F7-2761 *SEVL* on page F7-2763
Wait For Event	*WFE* on page F7-2987
Wait For Interrupt	*WFI* on page F7-2989
Yield	*YIELD* on page F7-2991

F1.8.1 The Yield instruction

In a *Symmetric Multi-Threading* (SMT) design, a thread can use the `YIELD` instruction to give a hint to the PE that it is running on. The `YIELD` hint indicates that whatever the thread is currently doing is of low importance, and so could yield. For example, the thread might be sitting in a spin-lock. A similar use might be in modifying the arbitration priority of the snoop bus in a multiprocessor (MP) system. Defining such an instruction permits binary compatibility between SMT and SMP systems.

AArch32 state defines a `YIELD` instruction as a specific NOP (No Operation) hint instruction.

The `YIELD` instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use on migration to a multiprocessor or multithreading system. Operating systems can use `YIELD` in places where a yield hint is wanted, knowing that it will be treated as a `NOP` if there is no implementation benefit.

F1.9 Exception-generating and exception-handling instructions

The following instructions are intended specifically to cause a synchronous exception to occur:

- The SVC instruction generates a Supervisor Call exception. For more information, see *Supervisor Call (SVC) exception* on page G1-3433.
- The Breakpoint instruction BKPT provides software breakpoints. For more information, see *Software Breakpoint Instruction exceptions* on page G2-3523.
- In an implementation that includes EL3, when executing at EL1 or higher, the SMC instruction generates a Secure Monitor Call exception. For more information, see *Secure Monitor Call (SMC) exception* on page G1-3435.
- In an implementation that includes EL2, in software executing in a Non-secure EL1 mode, the HVC instruction generates a Hypervisor Call exception. For more information, see *Hypervisor Call (HVC) exception* on page G1-3436.

For an exception taken to a EL1 mode:

- The system level variants of the SUBS and LDM instructions perform a return from an exception.

  Note

  The variants of SUBS include MOVS. See the references to SUBS PC, LR in Table F1-15 for more information.

- The SRS instruction can be used near the start of the handler, to store return information. The RFE instruction can then perform a return from the exception using the stored return information.

In an implementation that includes EL2, the ERET instruction performs a return from an exception taken to Hyp mode.

For more information, see *Exception return to an Exception level using AArch32* on page G1-3412.

Table F1-15 summarizes the instructions, in the T32 and A32 instruction sets, for generating or handling an exception. Except for BKPT and SVC, these are system level instructions.

Table F1-15 Exception-generating and exception-handling instructions

Instruction	See
Supervisor Call	*SVC* on page F7-2891
Breakpoint	*BKPT* on page F7-2493
Secure Monitor Call	*SMC* on page F7-3022
Return From Exception	*RFE* on page F7-3020
Subtract (exception return)	*SUBS PC, LR and related instructions, T32* on page F7-3030 *SUBS PC, LR and related instructions, A32* on page F7-3032
Hypervisor Call	*HVC* on page F7-3004
Exception Return	*ERET* on page F7-3002
Load Multiple (exception return)	*LDM (exception return)* on page F7-3006
Store Return State	*SRS, T32* on page F7-3024 *SRS, A32* on page F7-3026

F1.10 Coprocessor instructions

There are three types of instruction for communicating with conceptual coprocessors. These permit the PE to:

- Initiate a coprocessor data-processing operation. For details see *CDP, CDP2* on page F7-2500.
- Transfer general-purpose registers to and from coprocessor registers. For details, see:
  - *MCR, MCR2* on page F7-2631.
  - *MCRR, MCRR2* on page F7-2633.
  - *MRC, MRC2* on page F7-2647.
  - *MRRC, MRRC2* on page F7-2649.
- Load or store the values of coprocessor registers. For details, see:
  - *LDC, LDC2 (immediate)* on page F7-2547.
  - *LDC, LDC2 (literal)* on page F7-2549.
  - *STC, STC2* on page F7-2819.

The instruction set encodings provide supports up to 16 coprocessors, CP0 to CP15,with a 4-bit field in each coprocessor instruction to identify the coprocessor number. In ARMv8 the only supported coprocessors are CP10, CP11, CP14, and CP15, and these are supported only in AArch32 state.

Note

Multiple coprocessors can be used together to proved a larger block of coprocessor instructions. CP10 and CP11 are used in this way.

CP10 and CP11 are used, together, for floating-point and some Advanced SIMD functionality. There are different instructions for accessing these coprocessors, of similar types to the instructions for CP14 and CP15, that is, to:

- Initiate a coprocessor data-processing operation, see *Floating-point data-processing instructions* on page F1-2324.
- Transfer general-purpose registers to and from coprocessor registers, see *Advanced SIMD and floating-point register transfer instructions* on page F1-2317.
- Load or store the values of coprocessor registers, see *Advanced SIMD and floating-point load/store instructions* on page F1-2315.

Coprocessor instructions are part of the instruction stream executed by the PE. Any coprocessor instruction that cannot be executed by the implemented conceptual coprocessors causes an Undefined Instruction exception.This means that, in ARMv8 AArch32 state, all coprocessor access instruction encodings for coprocessors other than CP10, CP11, CP14, and CP15 are unallocated.

F1.11 Advanced SIMD and floating-point load/store instructions

Table F1-16 summarizes the SIMD and floating-point register file load/store instructions in the Advanced SIMD and floating-point instruction sets.

Advanced SIMD also provides instructions for loading and storing multiple elements, or structures of elements, see *Element and structure load/store instructions*.

Table F1-16 SIMD and floating-point register file load/store instructions

Instruction	See	Operation
Vector Load Multiple	*VLDM* on page F8-3160	Load 1-16 consecutive 64-bit registers, Advanced SIMD and floating-point. Load 1-16 consecutive 32-bit registers, floating-point only.
Vector Load Register	*VLDR* on page F8-3162	Load one 64-bit register, Advanced SIMD and floating-point. Load one 32-bit register, floating-point only.
Vector Store Multiple	*VSTM* on page F8-3334	Store 1-16 consecutive 64-bit registers, Advanced SIMD and floating-point. Store 1-16 consecutive 32-bit registers, floating-point only.
Vector Store Register	*VSTR* on page F8-3336	Store one 64-bit register, Advanced SIMD and floating-point. Store one 32-bit register, floating-point only.

F1.11.1 Element and structure load/store instructions

Table F1-17 shows the element and structure load/store instructions available in the Advanced SIMD instruction set. Loading and storing structures of more than one element automatically de-interleaves or interleaves the elements, see Figure F1-1 on page F1-2316 for an example of de-interleaving. Interleaving is the inverse process.

Table F1-17 Element and structure load/store instructions

Instruction	See
Load single element	
Multiple elements	*VLD1 (multiple single elements)* on page F8-3136
To one lane	*VLD1 (single element to one lane)* on page F8-3138
To all lanes	*VLD1 (single element to all lanes)* on page F8-3140
Load 2-element structure	
Multiple structures	*VLD2 (multiple 2-element structures)* on page F8-3142
To one lane	*VLD2 (single 2-element structure to one lane)* on page F8-3144
To all lanes	*VLD2 (single 2-element structure to all lanes)* on page F8-3146
Load 3-element structure	
Multiple structures	*VLD3 (multiple 3-element structures)* on page F8-3148
To one lane	*VLD3 (single 3-element structure to one lane)* on page F8-3150
To all lanes	*VLD3 (single 3-element structure to all lanes)* on page F8-3152

Table F1-17 Element and structure load/store instructions (continued)

Instruction	See
Load 4-element structure	
Multiple structures	*VLD4 (multiple 4-element structures)* on page F8-3154
To one lane	*VLD4 (single 4-element structure to one lane)* on page F8-3156
To all lanes	*VLD4 (single 4-element structure to all lanes)* on page F8-3158
Store single element

From one lane	*VST1 (single element from one lane)* on page F8-3320
Store 2-element structure	
Multiple structures	*VST2 (multiple 2-element structures)* on page F8-3322
From one lane	*VST2 (single 2-element structure from one lane)* on page F8-3324
Store 3-element structure	
Multiple structures	*VST3 (multiple 3-element structures)* on page F8-3326
From one lane	*VST3 (single 3-element structure from one lane)* on page F8-3328
Store 4-element structure	
Multiple structures	*VST4 (multiple 4-element structures)* on page F8-3330
From one lane	*VST4 (single 4-element structure from one lane)* on page F8-3332

Figure F1-1 shows the de-interleaving of a `VLD3.16` (multiple 3-element structures) instruction:

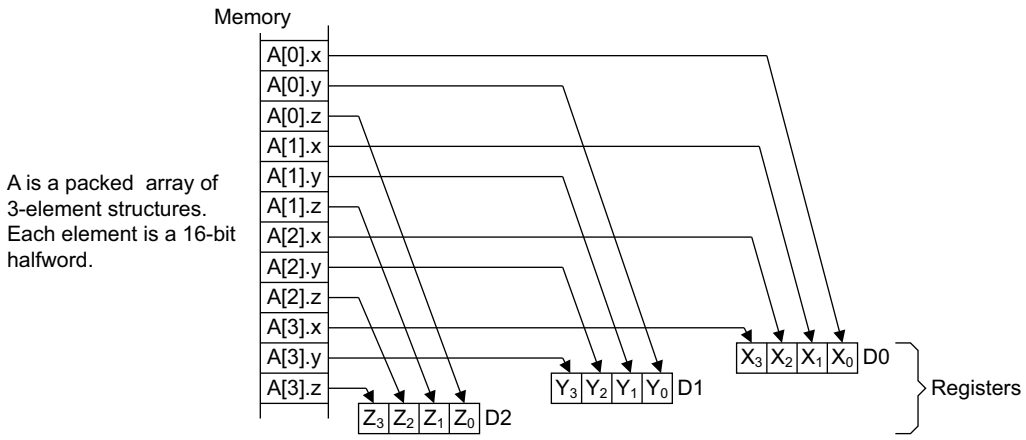

Figure F1-1 De-interleaving an array of 3-element structures

Figure F1-1 shows the `VLD3.16` instruction operating to three 64-bit registers that comprise four 16-bit elements:

- Different instructions in this group would produce similar figures, but operate on different numbers of registers. For example, `VLD4` and `VST4` instructions operate on four registers.
- Different element sizes would produce similar figures but with 8-bit or 32-bit elements.
- These instructions operate only on doubleword (64-bit) registers.

F1.12 Advanced SIMD and floating-point register transfer instructions

Table F1-18 summarizes the SIMD and floating-point register file transfer instructions in the Advanced SIMD and floating-point instruction sets. These instructions transfer data between the general-purpose registers and the registers in the SIMD and floating-point register file.

Advanced SIMD vectors, and single-precision and double-precision floating-point registers, are all views of the same register file. For details see *The SIMD and floating-point register file* on page E1-2216.

Table F1-18 SIMD and floating-point register file transfer instructions

Instruction	See
Copy element from general-purpose register to every element of an Advanced SIMD vector	*VDUP (general-purpose register)* on page F8-3124
Copy byte, halfword, or word from general-purpose register to a register in the SIMD and floating-point register file	*VMOV (general-purpose register to scalar)* on page F8-3180
Copy byte, halfword, or word from a register in the SIMD and floating-point register file to a general-purpose register	*VMOV (scalar to general-purpose register)* on page F8-3182
Copy from single-precision floating-point register to general-purpose register, or from general-purpose register to single-precision floating-point register	*VMOV (between general-purpose register and single-precision register)* on page F8-3184
Copy two words from general-purpose registers to consecutive single-precision floating-point registers, or from consecutive single-precision floating-point registers to general-purpose registers	*VMOV (between two general-purpose registers and two single-precision registers)* on page F8-3186
Copy two words from general-purpose registers to a doubleword register in the SIMD and floating-point register file, or from a doubleword register in the SIMD and floating-point register file to general-purpose registers	*VMOV (between two general-purpose registers and a doubleword floating-point register)* on page F8-3188
Copy from an Advanced SIMD and floating-point System Register to a general-purpose register	*VMRS* on page F8-3194 *VMRS* on page F8-3358 (system level view)
Copy from a general-purpose register to an Advanced SIMD and floating-point System Register	*VMSR* on page F8-3196 *VMSR* on page F8-3360 (system level view)

F1.13 Advanced SIMD data-processing instructions

Advanced SIMD data-processing instructions process registers containing vectors of elements of the same type packed together, enabling the same operation to be performed on multiple items in parallel.

Instructions operate on vectors held in 64-bit or 128-bit registers. Figure F1-2 shows an operation on two 64-bit operand vectors, generating a 64-bit vector result.

Note

Figure F1-2 and other similar figures show 64-bit vectors that consist of four 16-bit elements, and 128-bit vectors that consist of four 32-bit elements. Other element sizes produce similar figures, but with one, two, eight, or sixteen operations performed in parallel instead of four.

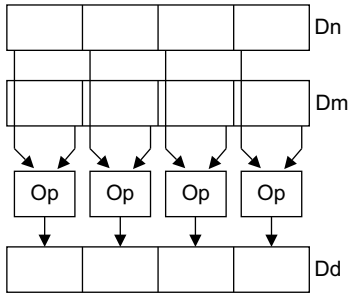

Figure F1-2 Advanced SIMD instruction operating on 64-bit registers

Many Advanced SIMD instructions have variants that produce vectors of elements double the size of the inputs. In this case, the number of elements in the result vector is the same as the number of elements in the operand vectors, but each element, and the whole vector, is double the size.

Figure F1-3 shows an example of an Advanced SIMD instruction operating on 64-bit registers, and generating a 128-bit result.

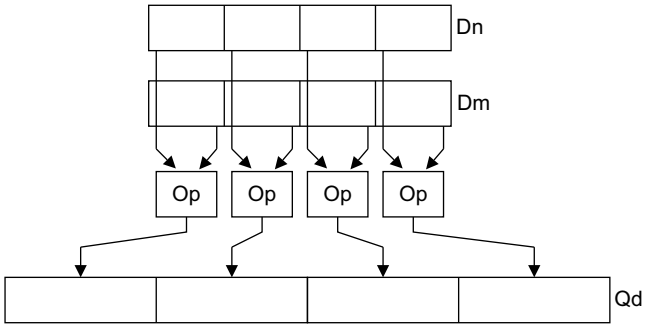

Figure F1-3 Advanced SIMD instruction producing wider result

There are also Advanced SIMD instructions that have variants that produce vectors containing elements half the size of the inputs. Figure F1-4 on page F1-2319 shows an example of an Advanced SIMD instruction operating on one 128-bit register, and generating a 64-bit result.

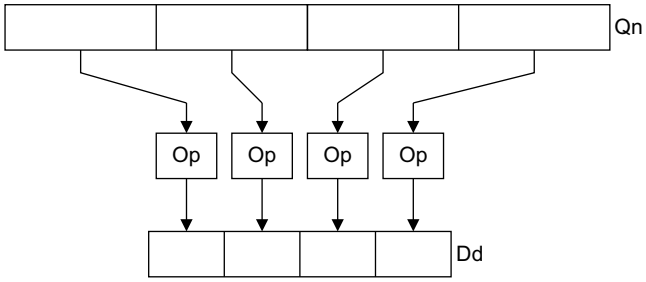

Figure F1-4 Advanced SIMD instruction producing narrower result

Some Advanced SIMD instructions do not conform to these standard patterns. Their operation patterns are described in the individual instruction descriptions.

Advanced SIMD instructions that perform floating-point arithmetic use the ARM standard floating-point arithmetic defined in *Floating-point and Advanced SIMD support* on page A1-46.

F1.13.1 Advanced SIMD parallel addition and subtraction

Table F1-19 shows the Advanced SIMD parallel add and subtract instructions.

Vector Saturating Rounding Doubling Multiply Returning High Half	*VQRDMULH* on page F8-3248
Vector Saturating Doubling Multiply Long	*VQDMULL* on page F8-3242

Advanced SIMD multiply instructions can operate on vectors of:

- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit polynomials over {0, 1}. `VMUL` and `VMULL` are the only instructions that operate on polynomials. `VMULL` produces a 16-bit polynomial over {0, 1}.
- Single-precision (32-bit) floating-point numbers.

They can also act on one vector and one scalar.

Long instructions have doubleword (64-bit) operands, and produce quadword (128-bit) results. Other Advanced SIMD multiply instructions can have either doubleword or quadword operands, and produce results of the same size.

Floating-point multiply instructions can operate on:

- Single-precision (32-bit) floating-point numbers.
- Double-precision (64-bit) floating-point numbers.

F1.13.6 Miscellaneous Advanced SIMD data-processing instructions

Table F1-24 on page F1-2323 shows miscellaneous Advanced SIMD data-processing instructions.

Chapter F2
About the T32 and A32 Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

F2.1 Format of instruction descriptions

The instruction descriptions in Chapter F7 *T32 and A32 Base Instruction Set Instruction Descriptions* and Chapter F8 *T32 and A32 Advanced SIMD and floating-point Instruction Descriptions* normally use the following format:

- Instruction section title.
- Introduction to the instruction.
- A description of each encoding of the instruction.
- Assembler syntax.
- Pseudocode describing how the instruction operates.
- Notes, if applicable.

Each of these items is described in more detail in the following subsections.

A few instruction descriptions describe an alternative mnemonics for another instruction and use an abbreviated and modified version of this format.

F2.1.1 Instruction section title

The instruction section title gives the base mnemonic for the instruction or instructions described in the section. When one mnemonic has multiple forms described in separate instruction sections, this is followed by a short description of the form in parentheses. The most common use of this is to distinguish between forms of an instruction in which one of the operands is an immediate value and forms in which it is a register.

F2.1.2 Introduction to the instruction

The introduction to the instruction briefly describes the main features of the instruction. This description is not necessarily complete and is not definitive. If there is any conflict between it and the more detailed information that follows, the latter takes priority.

F2.1.3 Instruction encodings

This is a list of one or more instruction encodings. Each instruction encoding is labelled as:

- T1, T2, T3 … for the first, second, third and any additional T32 encodings.
- A1, A2, A3 … for the first, second, third and any additional A32 encodings.

Where T32 and A32 encodings are very closely related, the two encodings are described together, for example as encoding T1/A1.

Each instruction encoding description consists of:

- An assembly syntax that ensures that the assembler selects the encoding in preference to any other encoding. In some cases, multiple syntaxes are given. The correct one to use is sometimes indicated by annotations to the syntax, such as *Inside IT block* and *Outside IT block*. In other cases, the correct one to use can be determined by looking at the assembler syntax description and using it to determine which syntax corresponds to the instruction being disassembled.

  There is usually more than one syntax that ensures re-assembly to any particular encoding, and the exact set of syntaxes that do so usually depends on the register numbers, immediate constants and other operands to the instruction. For example, when assembling to the T32 instruction set, the syntax `AND R0, R0, R8` ensures selection of a 32-bit encoding but `AND R0, R0, R1` selects a 16-bit encoding.

  The assembly syntax documented for the encoding is chosen to be the simplest one that ensures selection of that encoding for all operand combinations supported by that encoding. This often means that it includes elements that are only necessary for a small subset of operand combinations. For example, the assembler syntax documented for the 32-bit T32 `AND` (register) encoding includes the `.W` qualifier to ensure that the 32-bit encoding is selected even for the small proportion of operand combinations for which the 16-bit encoding is also available.

The assembly syntax given for an encoding is therefore a suitable one for a disassembler to disassemble that encoding to. However, disassemblers might wish to use simpler syntaxes when they are suitable for the operand combination, in order to produce more readable disassembled code.

- An encoding diagram, or a T32 encoding diagram followed by an A32 encoding diagram when they are being described together. This is half-width for 16-bit T32 encodings and full-width for 32-bit T32 and A32 encodings. The 32-bit A32 encoding diagrams number the bits from 31 to 0, while the 32-bit T32 encoding diagrams number the bits from 15 to 0 for each halfword, to distinguish them from A32 encodings and to act as a reminder that a 32-bit T32 instruction consists of two consecutive halfwords rather than a word.

  In particular, if instructions are stored using the standard little-endian instruction endianness, the encoding diagram for an A32 instruction at address A shows the bytes at addresses A+3, A+2, A+1, A from left to right, but the encoding diagram for a 32-bit T32 instruction shows them in the order A+1, A for the first halfword, followed by A+3, A+2 for the second halfword.

- Encoding-specific pseudocode. This is pseudocode that translates the encoding-specific instruction fields into inputs to the encoding-independent pseudocode in the *Operation* subsection, and that picks out any special cases in the encoding. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see Appendix H *ARM Pseudocode Definition*.

F2.1.4 Assembler syntax

The *Assembly syntax* subsection describes the standard UAL syntax for the instruction.

Each syntax description consists of the following elements:

- One or more syntax prototype lines written in a `typewriter` font, using the conventions described in *Assembler syntax prototype line conventions* on page F2-2328. Each prototype line documents the mnemonic and all appropriate operand parts of a full line of assembler code. When there is more than one such line, each prototype line is annotated to indicate required results of the encoding-specific pseudocode.

  For each instruction encoding belonging to a target instruction set, an assembler can use this information to determine whether it can use that encoding to encode the instruction requested by the UAL source. If multiple encodings can encode the instruction then:

  — If both a 16-bit encoding and a 32-bit encoding can encode the instruction, the architecture *prefers* the 16-bit encoding. This means the assembler must use the 16-bit encoding rather than the 32-bit encoding.

    Software can use the `.W` and `.N` qualifiers to specify the required encoding width, see *Standard assembler syntax fields* on page F2-2330.

  — If multiple encodings of the same length can encode the instruction, the *Assembler syntax* subsection says which encoding is preferred, and how software can, instead, select the other encodings.

    Each encoding also documents UAL syntax that selects it in preference to any other encoding.

  If no encodings of the target instruction set can encode the instruction requested by the UAL source, normally the assembler generates an error saying that the instruction is not available in that instruction set.

  Note

  In some cases, an instruction is available in one instruction set but not in another. The *Assembler syntax* subsection identifies many of these cases. For example, the A32 instructions with bits<31:28> == `0b1111` described in *Unconditional instructions* on page F4-2403 cannot have a condition code, but the equivalent T32 instructions often can, and this usually appears in the *Assembler syntax* subsection as a statement that the A32 instruction cannot be conditional.

  However, some such cases are too complex to describe in the available space, so the definitive test of whether an instruction is available in a given instruction set is whether there is an available encoding for it in that instruction set.

- The line *where:* followed by descriptions of all of the variable or optional fields of the prototype syntax line.

  Some syntax fields are standardized across all or most instructions. *Standard assembler syntax fields* on page F2-2330 describes these fields.

By default, syntax fields that specify registers, such as <Rd>, <Rn>, or <Rt>, can be any of R0-R12 or LR in T32 instructions, and any of R0-R12, SP or LR in A32 instructions. These require that the encoding-specific pseudocode set the corresponding integer variable (such as d, n, or t) to the corresponding register number, using 0-12 for R0-R12, 13 for SP, or 14 for LR:

— Normally, software can do this by setting the corresponding field in the instruction, typically named Rd, Rn, Rt, to the binary encoding of that number.

— In the case of 16-bit T32 encodings, the field is normally of length 3, and so the encoding is only available when the assembler syntax specifies one of R0-R7. Such encodings often use a register field name like Rdn. This indicates that the encoding is only available if <Rd> and <Rn> specify the same register, and that the register number of that register is encoded in the field if they do.

The description of a syntax field that specifies a register sometimes extends or restricts the permitted range of registers or documents other differences from the default rules for such fields. Examples of extensions are permitting the use of the SP in a T32 instruction, or permitting the use of the PC, identified using register number 15.

- Where appropriate, text that briefly describes changes from the pre-UAL assembler syntax. Where present, this usually consists of an alternative pre-UAL form of the assembler mnemonic. The pre-UAL assembler syntax does not conflict with UAL. ARM recommends that it is supported, as an optional extension to UAL, so that pre-UAL assembler source files can be assembled.

Assembler syntax prototype line conventions

The following conventions are used in assembler syntax prototype lines and their subfields:

< > Any item bracketed by < and > is a short description of a type of value to be supplied by the user in that position. A longer description of the item is normally supplied by subsequent text. Such items often correspond to a similarly named field in an encoding diagram for an instruction. When the correspondence only requires the binary encoding of an integer value or register number to be substituted into the instruction encoding, it is not described explicitly. For example, if the assembler syntax for an instruction contains an item <Rn> and the instruction encoding diagram contains a 4-bit field named Rn, the number of the register specified in the assembler syntax is encoded in binary in the instruction field.

If the correspondence between the assembler syntax item and the instruction encoding is more complex than simple binary encoding of an integer or register number, the item description indicates how it is encoded. This is often done by specifying a required output from the encoding-specific pseudocode, such as `add = TRUE`. The assembler must only use encodings that produce that output.

{ } Any item bracketed by { and } is optional. A description of the item and of how its presence or absence is encoded in the instruction is normally supplied by subsequent text.

Many instructions have an optional destination register. Unless otherwise stated, if such a destination register is omitted, it is the same as the immediately following source register in the instruction syntax.

In the assembler syntax, numeric constants are normally preceded by a #. Some UAL instruction syntax descriptions explicitly show this # as optional. Any UAL assembler:

- Must treat the # as optional where an instruction syntax description shows it as optional.
- Can treat the # either as mandatory or as optional where an instruction syntax description does not show it as optional.

Note

ARM recommends that UAL assemblers treat all uses of # shown in this manual as optional.

spaces Single spaces are used for clarity, to separate items. When a space is obligatory in the assembler syntax, two or more consecutive spaces are used.

+/- This indicates an optional + or - sign. If neither is coded, + is assumed.

All other characters must be encoded precisely as they appear in the assembler syntax. Apart from { and }, the special characters described above do not appear in the basic forms of assembler instructions documented in this manual. In a few places, the { and } characters must be encoded as part of a variable item. When this happens, the long description of the variable item indicates how they must be used.

F2.1.5 Pseudocode describing how the instruction operates

The *Operation* subsection contains encoding-independent pseudocode that describes the main operation of the instruction. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see Appendix H *ARM Pseudocode Definition*.

F2.1.6 Notes

Where appropriate, other notes about the instruction appear under additional subheadings.

Note

Information that was documented in notes in previous versions of the ARM Architecture Reference Manual and its supplements has often been moved elsewhere. For example, operand restrictions on the values of fields in an instruction encoding are now normally documented in the encoding-specific pseudocode for that encoding.

F2.2 Standard assembler syntax fields

The following assembler syntax fields are standard across all or most instructions:

<c> Is an optional field. It specifies the condition under which the instruction is executed. See *Conditional execution* on page F2-2331 for the range of available conditions and their encoding. If <c> is omitted, it defaults to *always* (AL).

<q> Specifies optional assembler qualifiers on the instruction. The following qualifiers are defined:

.N Meaning narrow, specifies that the assembler must select a 16-bit encoding for the instruction. If this is not possible, an assembler error is produced.

.W Meaning wide, specifies that the assembler must select a 32-bit encoding for the instruction. If this is not possible, an assembler error is produced.

If neither .W nor .N is specified, the assembler can select either 16-bit or 32-bit encodings. If both are available, it must select a 16-bit encoding. In a few cases, more than one encoding of the same length can be available for an instruction. The rules for selecting between such encodings are instruction-specific and are part of the instruction description.

Note

When assembling to the A32 instruction set, the .N qualifier produces an assembler error and the .W qualifier has no effect.

F2.3 Conditional execution

Most T32 and A32 instructions can be executed conditionally, based on the values of the APSR condition flags. Table F2-1 lists the available conditions.

Table F2-1 Condition codes

cond	Mnemonic extension	Meaning (integer)	Meaning (floating-point) [a]	Condition flags
0000	EQ	Equal	Equal	Z == 1
0001	NE	Not equal	Not equal, or unordered	Z == 0
0010	CS [b]	Carry set	Greater than, equal, or unordered	C == 1
0011	CC [c]	Carry clear	Less than	C == 0
0100	MI	Minus, negative	Less than	N == 1
0101	PL	Plus, positive or zero	Greater than, equal, or unordered	N == 0
0110	VS	Overflow	Unordered	V == 1
0111	VC	No overflow	Not unordered	V == 0
1000	HI	Unsigned higher	Greater than, or unordered	C == 1 and Z == 0
1001	LS	Unsigned lower or same	Less than or equal	C == 0 or Z == 1
1010	GE	Signed greater than or equal	Greater than or equal	N == V
1011	LT	Signed less than	Less than, or unordered	N != V
1100	GT	Signed greater than	Greater than	Z == 0 and N == V
1101	LE	Signed less than or equal	Less than, equal, or unordered	Z == 1 or N != V
1110	None (AL) [d]	Always (unconditional)	Always (unconditional)	Any

a. Unordered means at least one NaN operand.
b. HS (unsigned higher or same) is a synonym for CS.
c. LO (unsigned lower) is a synonym for CC.
d. AL is an optional mnemonic extension for always, except in IT instructions. For details see *IT* on page F7-2533.

In T32 instructions, the condition, if it is not AL, is normally encoded in a preceding IT instruction. For more information see *Conditional instructions* on page F1-2297 and *IT* on page F7-2533. Some conditional branch instructions do not require a preceding IT instruction, because they include a condition code in their encoding.

In A32 instructions, bits[31:28] of the instruction contain the condition code, or contain 0b1111 for some A32 instructions that can only be executed unconditionally.

ARM deprecates the conditional execution of any instruction encoding provided by Advanced SIMD that is not also provided by floating-point, and strongly recommends that:

- For A32 instructions, any such Advanced SIMD instruction that can be conditionally executed is executed with the <c> field omitted or set to AL.

  Note

  This applies only to VDUP, see *VDUP (general-purpose register)* on page F8-3124. The other A32 instructions do not permit conditional execution.

- For T32 instructions, such Advanced SIMD instructions are never included in an IT block. This means they must be specified with the <c> field omitted or set to AL.

This deprecation does not apply to Advanced SIMD instruction encodings that are also available as floating-point instruction encodings. That is, it does not apply to the Advanced SIMD encodings of the instructions described in the following sections:

- *VLDM* on page F8-3160.
- *VLDR* on page F8-3162.
- *VMOV (general-purpose register to scalar)* on page F8-3180.
- *VMOV (between two general-purpose registers and a doubleword floating-point register)* on page F8-3188.
- *VMRS* on page F8-3194.
- *VMSR* on page F8-3196.
- *VPOP* on page F8-3230.
- *VPUSH* on page F8-3232.
- *VSTM* on page F8-3334.
- *VSTR* on page F8-3336.

See also *Conditional execution of undefined instructions* on page G1-3430.

F2.3.1 Pseudocode details of conditional execution

The CurrentCond() pseudocode function has prototype:

```
bits(4) AArch32.CurrentCond();
```

This function returns a 4-bit condition specifier as follows:

- For A32 instructions, it returns bits[31:28] of the instruction.
- For the T1 and T3 encodings of the Branch instruction (see *B* on page F7-2484), it returns the 4-bit cond field of the encoding.
- For all other T32 instructions:
  - If ITSTATE.IT<3:0> != '0000' it returns ITSTATE.IT<7:4>.
  - If ITSTATE.IT<7:0> == '00000000' it returns '1110'.
  - Otherwise, execution of the instruction is UNPREDICTABLE.

  For more information, see *IT block state register, ITSTATE* on page E1-2213.

The ConditionPassed() function uses this condition specifier and the condition flags to determine whether the instruction must be executed:

```
// ConditionPassed()
// =================

boolean ConditionPassed()
    return ConditionHolds(AArch32.CurrentCond());

// ConditionHolds()
// ================

// Return TRUE iff COND currently holds

boolean ConditionHolds(bits(4) cond)
    // Evaluate base condition.
    case cond<3:1> of
        when ‘000’ result = (PSTATE.Z == ‘1’);                      // EQ or NE
        when ‘001’ result = (PSTATE.C == ‘1’);                      // CS or CC
        when ‘010’ result = (PSTATE.N == ‘1’);                      // MI or PL
        when ‘011’ result = (PSTATE.V == ‘1’);                      // VS or VC
        when ‘100’ result = (PSTATE.C == ‘1’ && PSTATE.Z == ‘0’);   // HI or LS
        when ‘101’ result = (PSTATE.N == PSTATE.V);                 // GE or LT
```

```
        when '110' result = (PSTATE.N == PSTATE.V && PSTATE.Z == '0');  // GT or LE
        when '111' result = TRUE;                                      // AL

    // Condition flag values in the set '111x' indicate always true
    // Otherwise, invert condition if necessary.
    if cond<0> == '1' && cond != '1111' then
        result = !result;

    return result;
```

Undefined Instruction exception on page G1-3428 describes the handling of conditional instructions that are UNDEFINED or UNPREDICTABLE. The pseudocode in the manual, as a sequential description of the instructions, has limitations in this respect. For more information, see *Limitations of the instruction pseudocode* on page AppxH-5140.

F2.4 Shifts applied to a register

A32 register offset load/store word and unsigned byte instructions can apply a wide range of different constant shifts to the offset register. Both T32 and A32 data-processing instructions can apply the same range of different constant shifts to the second operand register. For details see *Constant shifts*.

A32 data-processing instructions can apply a register-controlled shift to the second operand register.

F2.4.1 Constant shifts

These are the same in T32 and A32 instructions, except that the input bits come from different positions.

`<shift>` is an optional shift to be applied to `<Rm>`. It can be any one of:

(omitted) No shift.

`LSL #<n>` Logical shift left `<n>` bits. 1 <= `<n>` <= 31.

`LSR #<n>` Logical shift right `<n>` bits. 1 <= `<n>` <= 32.

`ASR #<n>` Arithmetic shift right `<n>` bits. 1 <= `<n>` <= 32.

`ROR #<n>` Rotate right `<n>` bits. 1 <= `<n>` <= 31.

`RRX` Rotate right one bit, with extend. Bit[0] is written to `shifter_carry_out`, bits[31:1] are shifted right one bit, and the Carry flag is shifted into bit[31].

Note

Assemblers can permit the use of some or all of `ASR #0`, `LSL #0`, `LSR #0`, and `ROR #0` to specify that no shift is to be performed. This is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must omit the shift specifier when the instruction specifies no shift.

Similarly, assemblers can permit the use of `#0` in the immediate forms of `ASR`, `LSL`, `LSR`, and `ROR` instructions to specify that no shift is to be performed, that is, that a `MOV` (register) instruction is wanted. Again, this is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must use the `MOV` (register) syntax when the instruction specifies no shift.

Encoding

The assembler encodes `<shift>` into two type bits and five immediate bits, as follows:

(omitted) type = `0b00`, immediate = 0.

`LSL #<n>` type = `0b00`, immediate = `<n>`.

`LSR #<n>` type = `0b01`.
If `<n>` < 32, immediate = `<n>`.
If `<n>` == 32, immediate = 0.

`ASR #<n>` type = `0b10`.
If `<n>` < 32, immediate = `<n>`.
If `<n>` == 32, immediate = 0.

`ROR #<n>` type = `0b11`, immediate = `<n>`.

`RRX` type = `0b11`, immediate = 0.

F2.4.2 Register controlled shifts

These are only available in A32 instructions.

<type> is the type of shift to apply to the value read from <Rm>. It must be one of:

ASR	Arithmetic shift right, encoded as type = 0b10.
LSL	Logical shift left, encoded as type = 0b00.
LSR	Logical shift right, encoded as type = 0b01.
ROR	Rotate right, encoded as type = 0b11.

The bottom byte of <Rs> contains the shift amount.

F2.4.3 Pseudocode details of instruction-specified shifts and rotates

```
enumeration SRType {SRType_LSL, SRType_LSR, SRType_ASR, SRType_ROR, SRType_RRX};

// DecodeImmShift()
// ================

(SRType, integer) DecodeImmShift(bits(2) type, bits(5) imm5)

    case type of
        when ‘00’
            shift_t = SRType_LSL;  shift_n = UInt(imm5);
        when ‘01’
            shift_t = SRType_LSR;  shift_n = if imm5 == ‘00000’ then 32 else UInt(imm5);
        when ‘10’
            shift_t = SRType_ASR;  shift_n = if imm5 == ‘00000’ then 32 else UInt(imm5);
        when ‘11’
            if imm5 == ‘00000’ then
                shift_t = SRType_RRX;  shift_n = 1;
            else
                shift_t = SRType_ROR;  shift_n = UInt(imm5);

    return (shift_t, shift_n);

// DecodeRegShift()
// ================

SRType DecodeRegShift(bits(2) type)
    case type of
        when ‘00’  shift_t = SRType_LSL;
        when ‘01’  shift_t = SRType_LSR;
        when ‘10’  shift_t = SRType_ASR;
        when ‘11’  shift_t = SRType_ROR;
    return shift_t;

// Shift()
// =======

bits(N) Shift(bits(N) value, SRType type, integer amount, bit carry_in)
    (result, -) = Shift_C(value, type, amount, carry_in);
    return result;

// Shift_C()
// =========

(bits(N), bit) Shift_C(bits(N) value, SRType type, integer amount, bit carry_in)
    assert !(type == SRType_RRX && amount != 1);

    if amount == 0 then
        (result, carry_out) = (value, carry_in);
    else
        case type of
            when SRType_LSL
                (result, carry_out) = LSL_C(value, amount);
```

```
            when SRType_LSR
                (result, carry_out) = LSR_C(value, amount);
            when SRType_ASR
                (result, carry_out) = ASR_C(value, amount);
            when SRType_ROR
                (result, carry_out) = ROR_C(value, amount);
            when SRType_RRX
                (result, carry_out) = RRX_C(value, carry_in);

    return (result, carry_out);
```

F2.5 Memory accesses

Commonly, the following addressing modes are permitted for memory access instructions:

Offset addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access. The value of the base register is unchanged.

The assembly language syntax for this mode is:

`[<Rn>, <offset>]`

Pre-indexed addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access, and written back into the base register.

The assembly language syntax for this mode is:

`[<Rn>, <offset>]!`

Post-indexed addressing

The address obtained from the base register is used, unchanged, as the address for the memory access. The offset value is applied to the address, and written back into the base register

The assembly language syntax for this mode is:

`[<Rn>], <offset>`

In each case, `<Rn>` is the base register. `<offset>` can be:

- An immediate constant, such as `<imm8>` or `<imm12>`.
- An index register, `<Rm>`.
- A shifted index register, such as `<Rm>, LSL #<shift>`.

For information about unaligned access, endianness, and exclusive access, see:

- *Alignment support* on page E2-2256.
- *Endian support* on page E2-2258.
- *Synchronization and semaphores* on page E2-2284.

F2.6 Integer arithmetic in the T32 and A32 instruction sets

The instruction set provides a wide variety of operations on the values in registers, including bitwise logical operations, shifts, additions, subtractions, multiplications and divisions.

F2.6.1 Shift and rotate operations

The following types of shift and rotate operations are used in instructions:

Logical Shift Left

`LSL` moves each bit of a bitstring left by a specified number of bits. Zeros are shifted in at the right end of the bitstring. Bits that are shifted off the left end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Logical Shift Right

`LSR` moves each bit of a bitstring right by a specified number of bits. Zeros are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Arithmetic Shift Right

`ASR` moves each bit of a bitstring right by a specified number of bits. Copies of the leftmost bit are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Rotate Right `ROR` moves each bit of a bitstring right by a specified number of bits. Each bit that is shifted off the right end of the bitstring is re-introduced at the left end. The last bit shifted off the right end of the bitstring can be produced as a carry output.

Rotate Right with Extend

`RRX` moves each bit of a bitstring right by one bit. A carry input is shifted in at the left end of the bitstring. The bit shifted off the right end of the bitstring can be produced as a carry output. This type applies to AArch32 state only.

F2.6.2 Pseudocode details of addition and subtraction

Addition and subtraction can be performed on any combination of unbounded integers and bitstrings, provided that if they are performed on two bitstrings, the two bitstrings are of identical length. The result is another unbounded integer if both operands are unbounded integers. Otherwise it is a bitstring of the same length as the bitstring operand or operands.

The addition and subtraction instructions can produce status information. If required, software can synthesize multi-word additions and subtractions from this status information. The `AddWithCarry()` function provides an addition with a carry input and carry and overflow outputs:

```
// AddWithCarry()
// ==============
// Integer addition with carry input, returning result and NZCV flags

(bits(N), bits(4)) AddWithCarry(bits(N) x, bits(N) y, bit carry_in)
    integer unsigned_sum = UInt(x) + UInt(y) + UInt(carry_in);
    integer signed_sum = SInt(x) + SInt(y) + UInt(carry_in);
    bits(N) result = unsigned_sum<N-1:0>; // same value as signed_sum<N-1:0>
    bit n = result<N-1>;
    bit z = if IsZero(result) then '1' else '0';
    bit c = if UInt(result) == unsigned_sum then '0' else '1';
    bit v = if SInt(result) == signed_sum then '0' else '1';
    return (result, n:z:c:v);
```

An important property of the `AddWithCarry()` function can be illustrated by the following line:

```
(result, carry_out, overflow) = AddWithCarry(x, NOT(y), carry_in)
```

In this case:

- If `carry_in == '1'`, then `result == x-y` with:
  - `overflow == '1'` if signed overflow occurred during the subtraction.
  - `carry_out == '1'` if unsigned borrow did not occur during the subtraction, that is, if `x >= y`
- If `carry_in == '0'`, then `result == x-y-1` with:
  - `overflow == '1'` if signed overflow occurred during the subtraction.
  - `carry_out == '1'` if unsigned borrow did not occur during the subtraction, that is, if `x > y`.

Together, these mean that the `carry_in` and `carry_out` bits in `AddWithCarry()` calls can act as *NOT borrow* flags for subtractions as well as *carry* flags for additions.

F2.6.3 Pseudocode details of saturation

Some instructions perform *saturating arithmetic*, that is, if the result of the arithmetic overflows the destination signed or unsigned N-bit integer range, the result produced is the largest or smallest value in that range, rather than wrapping around modulo 2^N. This is supported in pseudocode by:

- The `SignedSatQ()` and `UnsignedSatQ()` functions when an operation requires, in addition to the saturated result, a Boolean argument that indicates whether saturation occurred.
- The `SignedSat()` and `UnsignedSat()` functions when only the saturated result is required.

```
// SignedSatQ()
// ============

(bits(N), boolean) SignedSatQ(integer i, integer N)
    if i > 2^(N-1) - 1 then
        result = 2^(N-1) - 1;  saturated = TRUE;
    elsif i < -(2^(N-1)) then
        result = -(2^(N-1));  saturated = TRUE;
    else
        result = i;  saturated = FALSE;
    return (result<N-1:0>, saturated);

// UnsignedSatQ()
// ==============

(bits(N), boolean) UnsignedSatQ(integer i, integer N)
    if i > 2^N - 1 then
        result = 2^N - 1;  saturated = TRUE;
    elsif i < 0 then
        result = 0;  saturated = TRUE;
    else
        result = i;  saturated = FALSE;
    return (result<N-1:0>, saturated);

// SignedSat()
// ===========

bits(N) SignedSat(integer i, integer N)
    (result, -) = SignedSatQ(i, N);
    return result;

// UnsignedSat()
// =============

bits(N) UnsignedSat(integer i, integer N)
    (result, -) = UnsignedSatQ(i, N);
    return result;
```

`SatQ(i, N, unsigned)` returns either `UnsignedSatQ(i, N)` or `SignedSatQ(i, N)` depending on the value of its third argument, and `Sat(i, N, unsigned)` returns either `UnsignedSat(i, N)` or `SignedSat(i, N)` depending on the value of its third argument:

```
// SatQ()
// ======

(bits(N), boolean) SatQ(integer i, integer N, boolean unsigned)
    (result, sat) = if unsigned then UnsignedSatQ(i, N) else SignedSatQ(i, N);
    return (result, sat);

// Sat()
// =====

bits(N) Sat(integer i, integer N, boolean unsigned)
    result = if unsigned then UnsignedSat(i, N) else SignedSat(i, N);
    return result;
```

F2.7 Encoding of lists of general-purpose registers and the PC

A number of instructions operate on lists of general-purpose registers. For some load instructions, the list of registers to be loaded can include the PC. For these instructions, the assembler syntax includes a `<registers>` field, that provides a list of the registers to be operated on, with list entries separated by commas.

The registers list is encoded in the instruction encoding. Most often, this is done using an 8-bit, 13-bit, or 16-bit `register_list` field. This section gives more information about these and other possible register list encodings.

In a `register_list` field, each bit corresponds to a single register, and if the `<registers>` field of the assembler instruction includes Rt then `register_list<t>` is set to 1, otherwise it is set to 0.

The full rules for the encoding of lists of general-purpose registers, and possibly the PC, are:

- Except for the cases listed here, 16-bit T32 encodings use an 8-bit register list, and can access only registers R0-R7.

  The exceptions to this rule are:

  — The T1 encoding of `POP` uses an 8-bit register list, and an additional bit, `P`, that corresponds to the PC. This means it can access any of R0-R7 and the PC.

  — The T1 encoding of `PUSH` uses an 8-bit register list, and an additional bit, `M`, that corresponds to the LR. This means it can access any of R0-R7 and the LR.

- 32-bit T32 encodings of load operations use a 13-bit register list, and two additional bits, `M`, corresponding to the LR, and `P`, corresponding to the PC. This means these instructions can access any of R0-R12 and the LR and PC.

- 32-bit T32 encodings of store operations use a 13-bit register list, and one additional bit, `M`, corresponding to the LR. This means these instructions can access any of R0-R12 and the LR.

- Except for the case listed here, A32 encodings use a 16-bit register list. This means these instructions can access any of R0-R12 and the SP, LR, and PC.

  The exception to this rule is:

  — The system instructions `LDM` (exception return) and `LDM` (User registers) use a 15-bit register list. This means these instructions can access any of R0-R12 and the SP and LR.

- The T3 and A2 encodings of `POP`, and the T3 and A2 encodings of `PUSH`, access a single register from the set of registers {R0-R12, LR, PC} and encode the register number in the `Rt` field.

Note

`POP` is a load operation, and `PUSH` is a store operation.

In every case, the encoding-specific pseudocode converts the register list into a 32-bit variable, `registers`, with a bit corresponding to each of the registers R0-R12, SP, LR, and PC.

Note

Some floating-point and Advanced SIMD instructions operate on lists of SIMD and floating-point registers. The assembler syntax of these instructions includes a `<list>` field that specifies the registers to be operated on, and the description of the instruction in *Alphabetical list of T32 and A32 base instruction set instructions* on page F7-2450 defines the use and encoding of this field.

F2.8 Additional pseudocode support for instruction descriptions

Earlier sections of this chapter include pseudocode that describes features of the execution of A32 and T32 instructions, see:

- *Pseudocode details of conditional execution* on page F2-2332.
- *Pseudocode details of instruction-specified shifts and rotates* on page F2-2335

The following subsection gives additional pseudocode support functions for some of the instructions described in *Alphabetical list of T32 and A32 base instruction set instructions* on page F7-2450. See also *Pseudocode support for the Banked register transfer instructions* on page F7-2996.

F2.8.1 Pseudocode details of coprocessor operations

The `Coproc_Accepted()` pseudocode function determines whether a coprocessor instruction is accepted for execution.

```
boolean Coproc_Accepted(integer cp_num, bits(32) instr)
    assert UsingAArch32();
    assert !(cp_num IN {10,11});
    assert cp_num == UInt(instr<11:8>);
```

The `Coproc_DoneLoading()` pseudocode function determines, for an `LDC` instruction, whether enough words have been loaded:

```
boolean Coproc_DoneLoading(integer cp_num, bits(32) instr);
```

The `Coproc_DoneStoring()` function determines for an `STC` instruction whether enough words have been stored:

```
boolean Coproc_DoneStoring(integer cp_num, bits(32) instr);
```

The `Coproc_GetOneWord()` function obtains the word for an `MRC` instruction from the coprocessor:

```
bits(32) Coproc_GetOneWord(integer cp_num, bits(32) instr);
```

The `Coproc_GetTwoWords()` function obtains the two words for an `MRRC` instruction from the coprocessor:

```
(bits(32), bits(32)) Coproc_GetTwoWords(integer cp_num, bits(32) instr);
```

Note

The relative significance of the two words returned is IMPLEMENTATION DEFINED, but all uses within this manual present the two words in the order (most significant, least significant).

The `Coproc_GetWordToStore()` function obtains the next word to store for an `STC` instruction from the coprocessor:

```
bits(32) Coproc_GetWordToStore(integer cp_num, bits(32) instr);
```

The `Coproc_InternalOperation()` procedure instructs a coprocessor to perform the internal operation requested by a `CDP` instruction:

```
Coproc_InternalOperation(integer cp_num, bits(32) instr);
```

The `Coproc_SendLoadedWord()` procedure sends a loaded word for an `LDC` instruction to the coprocessor:

```
Coproc_SendLoadedWord(bits(32) word, integer cp_num, bits(32) instr);
```

The `Coproc_SendOneWord()` procedure sends the word for an `MCR` instruction to the coprocessor:

```
Coproc_SendOneWord(bits(32) word, integer cp_num, bits(32) instr);
```

The `Coproc_SendTwoWords()` procedure sends the two words for an `MCRR` instruction to the coprocessor:

```
Coproc_SendTwoWords(bits(32) word2, bits(32) word1, integer cp_num, bits(32) instr);
```

Note

The relative significance of word2 and word1 is IMPLEMENTATION DEFINED, but all uses within this manual treat word2 as more significant than word1.

The CP14DebugInstrDecode() pseudocode function decodes an accepted access to a CP14 debug register:

```
boolean CP15InstrDecode(bits(32) instr);
```

The CP14JazelleInstrDecode() pseudocode function decodes an accepted access to a CP14 Jazelle register:

```
boolean CP14JazelleInstrDecode(bits(32) instr);
```

The CP14TraceInstrDecode() pseudocode function decodes an accepted access to a CP14 Trace register:

```
boolean CP14TraceInstrDecode(bits(32) instr);
```

The CP15InstrDecode() pseudocode function decodes an accepted access to a CP15 register:

```
boolean CP15InstrDecode(bits(32) instr);
```

F2.8.2 Calling the supervisor

The CallSupervisor() pseudocode function generates a Supervisor Call exception, after setting up the *Use of the HSR* on page G4-3728 if the exception must be taken to Hyp mode. Valid execution of the SVC instruction calls this function.

```
// AArch32.CallSupervisor()
// ========================
// Calls the Supervisor

AArch32.CallSupervisor(bits(16) immediate)

    if AArch32.CurrentCond() != '1110' then
        immediate = bits(16) UNKNOWN;

    if AArch32.GeneralExceptionsToAArch64() then
        AArch64.CallSupervisor(immediate);
    else
        AArch32.TakeSVCException(immediate);
```

Chapter F3
T32 Base Instruction Set Encoding

This chapter introduces the T32 instruction set and describes how it uses the ARM programmers' model. It contains the following sections:

Note

In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.

F3.1 T32 instruction set encoding

The T32 instruction stream is a sequence of halfword-aligned halfwords. Each T32 instruction is either a single 16-bit halfword in that stream, or a 32-bit instruction consisting of two consecutive halfwords in that stream.

If the value of bits[15:11] of the halfword being decoded is one of the following, the halfword is the first halfword of a 32-bit instruction:

- `0b11101`.
- `0b11110`.
- `0b11111`.

Otherwise, the halfword is a 16-bit instruction.

For details of the encoding of 16-bit T32 instructions see *16-bit T32 instruction encoding* on page F3-2349.

For details of the encoding of 32-bit T32 instructions see *32-bit T32 instruction encoding* on page F3-2356.

F3.1.1 UNDEFINED and UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE.

  ARMv8-A greatly reduces the architecturally UNPREDICTABLE behavior in AArch32 state. Many cases that earlier versions of the architecture describe as unpredictable become either:

  — CONSTRAINED UNPREDICTABLE, meaning the architecture defines a limited range of permitted behaviors.

  — Fully predictable.

  For more information see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

  The AArch32 parts of this manual might sometimes describe as UNPREDICTABLE behavior that ARMv8-A makes CONSTRAINED UNPREDICTABLE.

- An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in this chapter.

An instruction is UNPREDICTABLE if:

- A bit marked (0) in the encoding diagram of an instruction is not 0, and the pseudocode for that encoding does not indicate that a different special case applies when that bit is not 0.
- A bit marked (1) in the encoding diagram of an instruction is not 1, and the pseudocode for that encoding does not indicate that a different special case applies when that bit is not 1.
- It is declared as UNPREDICTABLE in an instruction description or in this chapter.

Unless otherwise specified, T32 instructions provided as part of an architectural extension, or by an optional feature of the architecture, are UNDEFINED in an implementation that does not include that extension or feature.

Note

Examples of where this rule applies are:

- The instructions provided by the Cryptographic Extension.
- The system instructions that provide access to the System registers of the OPTIONAL Performance Monitors Extension.
- The Advanced SIMD and floating-point instructions.

For more information about UNDEFINED and UNPREDICTABLE instruction behavior, see *Undefined Instruction exception* on page G1-3428.

For more information about the behavior of T32 instructions in earlier versions of the architecture see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

F3.1.2 Use of the PC, and use of `0b1111` as a register specifier

The use of `0b1111` as a register specifier is not normally permitted in T32 instructions. When a value of `0b1111` is permitted, a variety of meanings is possible. For register reads, these meanings include:

- Read the PC value, that is, the address of the current instruction + 4. The base register of the table branch instructions `TBB` and `TBH` can be the PC. This means branch tables can be placed in memory immediately after the instruction.

  Note

  ARM deprecates use of the PC as the base register in the `STC` instruction.

- Read the word-aligned PC value, that is, the address of the current instruction + 4, with bits[1:0] forced to zero. The base register of `LDC`, `LDR`, `LDRB`, `LDRD` (pre-indexed, no writeback), `LDRH`, `LDRSB`, and `LDRSH` instructions can be the word-aligned PC. This provides PC-relative data addressing. In addition, some encodings of the `ADD` and `SUB` instructions permit their source registers to be `0b1111` for the same purpose.
- Read zero. This is done in some cases when one instruction is a special case of another, more general instruction, but with one operand zero. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.

For register writes, these meanings include:

- The PC can be specified as the destination register of an `LDR` instruction. This is done by encoding Rt as `0b1111`. The loaded value is treated as an address, and the effect of execution is a branch to that address. Bit[0] of the loaded value selects whether to execute A32 or T32 instructions after the branch.
- Some other instructions write the PC in similar ways. An instruction can specify that the PC is written:
  - Implicitly, for example, branch instructions.
  - Explicitly by a register specifier of `0b1111`, for example 16-bit `MOV` (register) instructions.
  - Explicitly by using a register mask, for example `LDM` instructions.

  The address to branch to can be:
  - A loaded value, for example, `RFE`.
  - A register value, for example, `BX`.
  - The result of a calculation, for example, `TBB` or `TBH`.

  The method of choosing the instruction set used after the branch can be:
  - Similar to the `LDR` case, for example, `LDM` or `BX`.
  - A fixed instruction set other than the one currently being used, for example, the immediate form of `BLX`.
  - Unchanged, for example, branch instructions or 16-bit `MOV` (register) instructions.
  - Set from the {J, T} bits of the SPSR, for `RFE` and `SUBS PC, LR, #imm8`.
- Discard the result of a calculation. This is done in some cases when one instruction is a special case of another, more general instruction, but with the result discarded. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.
- If the destination register specifier of an `LDRB`, `LDRH`, `LDRSB`, or `LDRSH` instruction is `0b1111`, the instruction is a memory hint instead of a load operation.
- If the destination register specifier of an `MRC` instruction is 0b1111, bits[31:28] of the value transferred from the coprocessor are written to the N, Z, C, and V condition flags in the APSR, and bits[27:0] are discarded.

F3.1.3 Use of the SP, and use of `0b1101` as a register specifier

In T32 instructions, ARM recommends that the use of `0b1101` as a register specifier specifies the SP.

Note

- The recommendation that register specifier `0b1101` is used only to specify the SP applies to both the T32 and the A32 instruction sets.
- Despite this recommendation, in ARMv8, most T32uses of R13 as a general-purpose register behave predictably. This differs from ARMv7, where many uses of R13 are UNPREDICTABLE. For more information, see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

F3.2 16-bit T32 instruction encoding

The encoding of a 16-bit T32 instruction is:

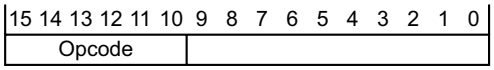

Table F3-1 shows the allocation of 16-bit instruction encodings.

Table F3-1 16-bit T32 instruction encoding

Opcode	Instruction or instruction class
00xxxx	*Shift (immediate), add, subtract, move, and compare* on page F3-2350
010000	*Data-processing* on page F3-2351
010001	*Special data instructions and branch and exchange* on page F3-2352
01001x	Load from Literal Pool, see *LDR (literal)* on page F7-2565
0101xx 011xxx 100xxx	*Load/store single data item* on page F3-2353
10100x	Generate PC-relative address, see *ADR* on page F7-2472
10101x	Generate SP-relative address, see *ADD (SP plus immediate)* on page F7-2466
1011xx	*Miscellaneous 16-bit instructions* on page F3-2354
11000x	Store multiple registers, see *STM (STMIA, STMEA)* on page F7-2835
11001x	Load multiple registers, see *LDM (LDMIA, LDMFD), T32* on page F7-2551
1101xx	*Conditional branch, and Supervisor Call* on page F3-2355
11100x	Unconditional Branch, see *B* on page F7-2484

F3.2.1 Shift (immediate), add, subtract, move, and compare

The encoding of 16-bit T32 shift (immediate), add, subtract, move, and compare instructions is:

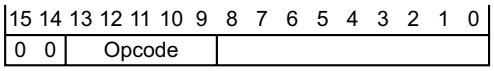

Table F3-2 shows the allocation of encodings in this space.

Table F3-2 16-bit T32 shift (immediate), add, subtract, move, and compare instructions

Opcode	Instruction	See
000xx	Logical Shift Left[a]	*LSL (immediate)* on page F7-2623
001xx	Logical Shift Right	*LSR (immediate)* on page F7-2627
010xx	Arithmetic Shift Right	*ASR (immediate)* on page F7-2480
01100	Add register	*ADD (register), T32* on page F7-2460
01101	Subtract register	*SUB (register)* on page F7-2883
01110	Add 3-bit immediate	*ADD (immediate), T32* on page F7-2456
01111	Subtract 3-bit immediate	*SUB (immediate), T32* on page F7-2879
100xx	Move	*MOV (immediate)* on page F7-2639
101xx	Compare	*CMP (immediate)* on page F7-2510
110xx	Add 8-bit immediate	*ADD (immediate), T32* on page F7-2456
111xx	Subtract 8-bit immediate	*SUB (immediate), T32* on page F7-2879

a. When `Opcode` is `0b00000`, and bits[8:6] are `0b000`, this is an encoding for `MOV`, see *MOV (register), T32* on page F7-2641.

F3.2.2 Data-processing

The encoding of 16-bit T32 data-processing instructions is:

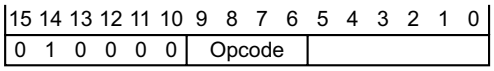

Table F3-3 shows the allocation of encodings in this space.

Table F3-3 16-bit T32 data-processing instructions

Opcode	Instruction	See
0000	Bitwise AND	*AND (register)* on page F7-2476
0001	Bitwise Exclusive OR	*EOR (register)* on page F7-2526
0010	Logical Shift Left	*LSL (register)* on page F7-2625
0011	Logical Shift Right	*LSR (register)* on page F7-2629
0100	Arithmetic Shift Right	*ASR (register)* on page F7-2482
0101	Add with Carry	*ADC (register)* on page F7-2452
0110	Subtract with Carry	*SBC (register)* on page F7-2749

1101	Multiply	*MUL* on page F7-2657
1110	Bitwise Bit Clear	*BIC (register)* on page F7-2490
1111	Bitwise NOT	*MVN (register)* on page F7-2661

F3.2.3 Special data instructions and branch and exchange

The encoding of 16-bit T32 special data instructions and branch and exchange instructions is:

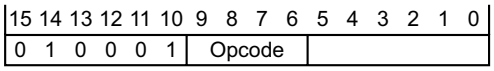

Table F3-4 shows the allocation of encodings in this space.

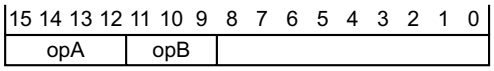
Table F3-4 16-bit T32 special data instructions and branch and exchange

Opcode	Instruction	See
0000	Add Low Registers	*ADD (register), T32* on page F7-2460
0001 001x	Add High Registers	*ADD (register), T32* on page F7-2460
01xx	Compare High Registers	*CMP (register)* on page F7-2512
1000	Move Low Registers	*MOV (register), T32* on page F7-2641
1001 101x	Move High Registers	*MOV (register), T32* on page F7-2641
110x	Branch and Exchange	*BX* on page F7-2497
111x	Branch with Link and Exchange	*BLX (register)* on page F7-2496

F3.2.4 Load/store single data item

The encoding of 16-bit T32 instructions that load or store a single data item is:



These instructions have one of the following values of `opA`:

- `0b0101`
- `0b011x`
- `0b100x`

Table F3-5 shows the allocation of encodings in this space.

Table F3-5 16-bit T32 Load/store single data item instructions

F3.3.1 Data-processing (modified immediate)

The encoding of the 32-bit T32 data-processing (modified immediate) instructions is:

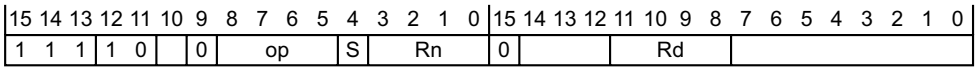

Table F3-10 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

Table F3-10 32-bit modified immediate data-processing instructions

op	Rn	Rd:S	Instruction	See
0000	-	not 11111	Bitwise AND	*AND (immediate)* on page F7-2474
		11111	Test	*TST (immediate)* on page F7-2913
0001	-	-	Bitwise Bit Clear	*BIC (immediate)* on page F7-2488
0010	not 1111	-	Bitwise OR	*ORR (immediate)* on page F7-2671
	1111	-	Move	*MOV (immediate)* on page F7-2639
0011	not 1111	-	Bitwise OR NOT	*ORN (immediate)* on page F7-2667
	1111	-	Bitwise NOT	*MVN (immediate)* on page F7-2659
0100	-	not 11111	Bitwise Exclusive OR	*EOR (immediate)* on page F7-2524
		11111	Test Equivalence	*TEQ (immediate)* on page F7-2907
1000	-	not 11111	Add	*ADD (immediate), T32* on page F7-2456
		11111	Compare Negative	*CMN (immediate)* on page F7-2504
1010	-	-	Add with Carry	*ADC (immediate)* on page F7-2450
1011	-	-	Subtract with Carry	*SBC (immediate)* on page F7-2747
1101	-	not 11111	Subtract	*SUB (immediate), T32* on page F7-2879
		11111	Compare	*CMP (immediate)* on page F7-2510
1110	-	-	Reverse Subtract	*RSB (immediate)* on page F7-2729

These instructions all have modified immediate constants, rather than a simple 12-bit binary number. This provides a more useful range of values. For details see *Modified immediate constants in T32 instructions* on page F3-2358.

F3.3.2 Modified immediate constants in T32 instructions

The encoding of a modified immediate constant in a 32-bit T32 instruction is:

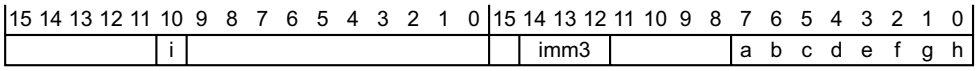

Table F3-11 shows the range of modified immediate constants available in T32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, h, and i bits, and the imm3 field, in the instruction.

Table F3-11 Encoding of modified immediates in T32 data-processing instructions

i:imm3:a	<const> [a]
0000x	`00000000 00000000 00000000 abcdefgh`
0001x	`00000000 abcdefgh 00000000 abcdefgh` [b]
0010x	`abcdefgh 00000000 abcdefgh 00000000` [b]

01000	`1bcdefgh 00000000 00000000 00000000`
01001	`01bcdefg h0000000 00000000 00000000` [c]
01010	`001bcdef gh000000 00000000 00000000`
01011	`0001bcde fgh00000 00000000 00000000` [c]
.	.
.	. 8-bit values shifted to other positions
.	.
11101	`00000000 00000000 000001bc defgh000` [c]
11110	`00000000 00000000 0000001b cdefgh00`
11111	`00000000 00000000 00000001 bcdefgh0` [c]

a. This table shows the immediate constant value in binary form, to relate `abcdefgh` to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).

b. ARM deprecates using a modified immediate with abcdefgh == 00000000.

c. Not available in A32 instructions if `h` == 1.

Note

As the footnotes to Table F3-11 show, the range of values available in T32 modified immediate constants is slightly different from the range of values available in A32 instructions. See *Modified immediate constants in A32 instructions* on page F4-2387 for the A32 values.

Carry out

A logical instruction with i:imm3:a == '00xxx' does not affect the Carry flag. Otherwise, a logical flag-setting instruction sets the Carry flag to the value of bit[31] of the modified immediate constant.

Operation of modified immediate constants, T32 instructions

```
// T32ExpandImm()
// ==============

bits(32) T32ExpandImm(bits(12) imm12)

    // PSTATE.C argument to following function call does not affect the imm32 result.
    (imm32, -) = T32ExpandImm_C(imm12, PSTATE.C);

    return imm32;

// T32ExpandImm_C()
// ================

(bits(32), bit) T32ExpandImm_C(bits(12) imm12, bit carry_in)

    if imm12<11:10> == '00' then
        case imm12<9:8> of
            when '00'
                imm32 = ZeroExtend(imm12<7:0>, 32);
            when '01'
                imm32 = '00000000' : imm12<7:0> : '00000000' : imm12<7:0>;
            when '10'
                imm32 = imm12<7:0> : '00000000' : imm12<7:0> : '00000000';
            when '11'
                imm32 = imm12<7:0> : imm12<7:0> : imm12<7:0> : imm12<7:0>;
        carry_out = carry_in;
    else
        unrotated_value = ZeroExtend('1':imm12<6:0>, 32);
        (imm32, carry_out) = ROR_C(unrotated_value, UInt(imm12<11:7>));

    return (imm32, carry_out);
```

F3.3.3 Data-processing (plain binary immediate)

The encoding of the 32-bit T32 data-processing (plain binary immediate) instructions is:

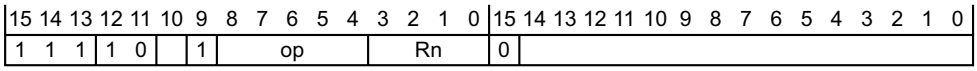

Table F3-12 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

Table F3-12 32-bit unmodified immediate data-processing instructions

For more information about specific coprocessors see *Coprocessor support* on page E1-2244.

Chapter F4
A32 Base Instruction Set Encoding

This chapter describes the encoding of the A32 instruction set. It contains the following sections:

Note

In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.

F4.1 A32 instruction set encoding

The A32 instruction stream is a sequence of word-aligned words. Each A32 instruction is a single 32-bit word in that stream. The encoding of an A32 instruction is:

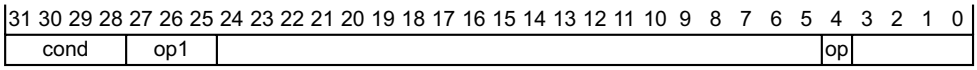

Table F4-1 shows the major subdivisions of the A32 instruction set, determined by bits[31:25, 4].

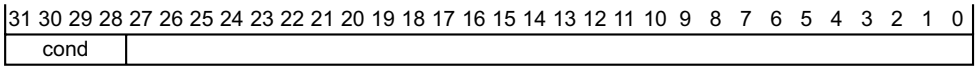
Most A32 instructions can be conditional, with a condition determined by bits[31:28] of the instruction, the `cond` field. For more information see *The condition code field*. This applies to all instructions except those with the cond field equal to `0b1111`.

Table F4-1 A32 instruction encoding

cond	op1	op	Instruction classes
not 1111	00x	-	*Data-processing and miscellaneous instructions* on page F4-2383.
	010	-	*Load/store word and unsigned byte* on page F4-2395.
	011	0	*Load/store word and unsigned byte* on page F4-2395.
		1	*Media instructions* on page F4-2396.
	10x	-	*Branch, branch with link, and block data transfer* on page F4-2401.
	11x	-	*Coprocessor instructions, and Supervisor Call* on page F4-2402. Includes floating-point instructions and Advanced SIMD data transfers, see Chapter F5 *T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings*.
1111	-	-	If the cond field is `0b1111`, the instruction can only be executed unconditionally, see *Unconditional instructions* on page F4-2403. Includes Advanced SIMD instructions, see Chapter F5 *T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings*.

F4.1.1 The condition code field

Every conditional instruction contains a 4-bit condition code field, the `cond` field, in bits 31 to 28:



This field contains one of the values `0b0000`-`0b1110`, as shown in Table F2-1 on page F2-2331. Most instruction mnemonics can be extended with the letters defined in the *mnemonic extension* column of this table.

If the *always* (`AL`) condition is specified, the instruction is executed irrespective of the value of the condition flags. The absence of a condition code on an instruction mnemonic implies the `AL` condition code.

F4.1.2 UNDEFINED and UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE.

  ARMv8-A greatly reduces the architecturally UNPREDICTABLE behavior in AArch32 state. Many cases that earlier versions of the architecture describe as unpredictable become either:

  — CONSTRAINED UNPREDICTABLE, meaning the architecture defines a limited range of permitted behaviors.

  — Fully predictable.

  For more information see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

  The AArch32 parts of this manual might sometimes describe as UNPREDICTABLE behavior that ARMv8-A makes CONSTRAINED UNPREDICTABLE.

- An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in this chapter.

An instruction is UNPREDICTABLE if:

- It is declared as UNPREDICTABLE in an instruction description or in this chapter.
- The pseudocode for that encoding does not indicate that a different special case applies, and a bit marked (0) or (1) in the encoding diagram of an instruction is not 0 or 1 respectively.

Unless otherwise specified, A32 instructions provided as part of an architectural extension, or by an optional feature of the architecture, are UNDEFINED in an implementation that does not include that extension or feature.

Note

Examples of where this rule applies are:

- The instructions provided by the Cryptographic Extension.
- The system instructions that provide access to the System registers of the OPTIONAL Performance Monitors Extension.
- The Advanced SIMD and floating-point instructions.

For more information about UNDEFINED and UNPREDICTABLE instruction behavior, see *Undefined Instruction exception* on page G1-3428.

For more information about the behavior of A32 instructions in earlier versions of the architecture see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

F4.1.3 The PC and the use of `0b1111` as a register specifier

In A32 instructions, the use of `0b1111` as a register specifier specifies the PC.

Many instructions are UNPREDICTABLE if they use `0b1111` as a register specifier. This is specified by pseudocode in the instruction description. ARMv8-A constrains the resulting UNPREDICTABLE behavior, see *Using R15* on page AppxA-4785.

Note

ARM deprecates use of the PC as the base register in any store instruction.

F4.1.4 The SP and the use of `0b1101` as a register specifier

In A32 instructions, the use of `0b1101` as a register specifier specifies the SP.

This applies to both A32 and T32 in AArch32 state. ARM deprecates using SP for any purpose other than as a stack pointer.

F4.2 Data-processing and miscellaneous instructions

The encoding of A32 data-processing instructions, and some miscellaneous, instructions is:

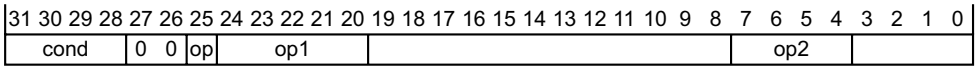


Table F4-2 shows the allocation of encodings in this space.

Table F4-2 Data-processing and miscellaneous instructions

op	op1	op2	Instruction or instruction class

1111x	-	Bitwise NOT	*MVN (register-shifted register)* on page F7-2663

F4.2.3 Data-processing (immediate)

The encoding of A32 data-processing (immediate) instructions is:

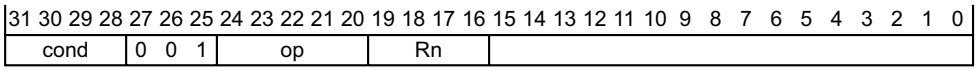

Table F4-5 shows the allocation of encodings in this space.

Table F4-5 Data-processing (immediate) instructions

op	Rn	Instruction	See
0000x	-	Bitwise AND	*AND (immediate)* on page F7-2474
0001x	-	Bitwise Exclusive OR	*EOR (immediate)* on page F7-2524
0010x	not 1111	Subtract	*SUB (immediate), A32* on page F7-2881
	1111	Form PC-relative address	*ADR* on page F7-2472
0011x	-	Reverse Subtract	*RSB (immediate)* on page F7-2729
0100x	not 1111	Add	*ADD (immediate), A32* on page F7-2458
	1111	Form PC-relative address	*ADR* on page F7-2472
0101x	-	Add with Carry	*ADC (immediate)* on page F7-2450
0110x	-	Subtract with Carry	*SBC (immediate)* on page F7-2747
0111x	-	Reverse Subtract with Carry	*RSC (immediate)* on page F7-2735
10xx0	-	See *Data-processing and miscellaneous instructions* on page F4-2383	
10001	-	Test	*TST (immediate)* on page F7-2913
10011	-	Test Equivalence	*TEQ (immediate)* on page F7-2907
10101	-	Compare	*CMP (immediate)* on page F7-2510
10111	-	Compare Negative	*CMN (immediate)* on page F7-2504
1100x	-	Bitwise OR	*ORR (immediate)* on page F7-2671
1101x	-	Move	*MOV (immediate)* on page F7-2639
1110x	-	Bitwise Bit Clear	*BIC (immediate)* on page F7-2488
1111x	-	Bitwise NOT	*MVN (immediate)* on page F7-2659

These instructions all have modified immediate constants, rather than a simple 12-bit binary number. This provides a more useful range of values. For details see *Modified immediate constants in A32 instructions* on page F4-2387.

F4.2.4 Modified immediate constants in A32 instructions

The encoding of a modified immediate constant in an A32 instruction is:

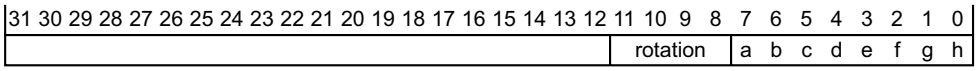

Table F4-6 shows the range of modified immediate constants available in A32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, and h bits and the rotation field in the instruction.

Table F4-6 Encoding of modified immediates in A32 processing instructions

rotation	<const> [a]
0000	`00000000 00000000 00000000 abcdefgh`
0001	`gh000000 00000000 00000000 00abcdef`
0010	`efgh0000 00000000 00000000 0000abcd`
0011	`cdefgh00 00000000 00000000 000000ab`
0100	`abcdefgh 00000000 00000000 00000000`
. . .	. . 8-bit values shifted to other even-numbered positions . .
1001	`00000000 00abcdef gh000000 00000000`
. . .	. . 8-bit values shifted to other even-numbered positions . .
1110	`00000000 00000000 0000abcd efgh0000`
1111	`00000000 00000000 000000ab cdefgh00`

a. This table shows the immediate constant value in binary form, to relate `abcdefgh` to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).

Note

The range of values available in A32 modified immediate constants is slightly different from the range of values available in 32-bit T32 instructions. See *Modified immediate constants in T32 instructions* on page F3-2358.

Carry out

A logical instruction with the rotation field set to `0b0000` does not affect APSR.C. Otherwise, a logical flag-setting instruction sets APSR.C to the value of bit[31] of the modified immediate constant.

Constants with multiple encodings

Some constant values have multiple possible encodings. In this case, a UAL assembler must select the encoding with the lowest unsigned value of the rotation field. This is the encoding that appears first in Table F4-6. For example, the constant `#3` must be encoded with (rotation, abcdefgh) == (`0b0000`, `0b00000011`), not (`0b0001`, `0b00001100`), (`0b0010`, `0b00110000`), or (`0b0011`, `0b11000000`).

In particular, this means that all constants in the range 0-255 are encoded with rotation == `0b0000`, and permitted constants outside that range are encoded with rotation != `0b0000`. A flag-setting logical instruction with a modified immediate constant therefore leaves APSR.C unchanged if the constant is in the range 0-255 and sets it to the most significant bit of the constant otherwise. This matches the behavior of T32 modified immediate constants for all constants that are permitted in both the A32 and T32 instruction sets.

An alternative syntax is available for a modified immediate constant that permits the programmer to specify the encoding directly. In this syntax, `#<const>` is instead written as `#<byte>, #<rot>`, where:

`<byte>` Is the numeric value of abcdefgh, in the range 0-255.

`<rot>` Is twice the numeric value of rotation, an even number in the range 0-30.

This syntax permits all A32 data-processing instructions with modified immediate constants to be disassembled to assembler syntax that assembles to the original instruction.

This syntax also makes it possible to write variants of some flag-setting logical instructions that have different effects on APSR.C to those obtained with the normal `#<const>` syntax. For example, `ANDS R1, R2, #12, #2` has the same behavior as `ANDS R1, R2, #3` except that it sets APSR.C to 0 instead of leaving it unchanged. Such variants of flag-setting logical instructions do not have equivalents in the T32 instruction set, and ARM deprecates their use.

Operation of modified immediate constants, A32 instructions

```
// A32ExpandImm()
// ==============

bits(32) A32ExpandImm(bits(12) imm12)

    // PSTATE.C argument to following function call does not affect the imm32 result.
    (imm32, -) = A32ExpandImm_C(imm12, PSTATE.C);

    return imm32;

// A32ExpandImm_C()
// ================

(bits(32), bit) A32ExpandImm_C(bits(12) imm12, bit carry_in)

    unrotated_value = ZeroExtend(imm12<7:0>, 32);
    (imm32, carry_out) = Shift_C(unrotated_value, SRType_ROR, 2*UInt(imm12<11:8>), carry_in);

    return (imm32, carry_out);
```

F4.2.5 Multiply and multiply accumulate

The encoding of A32 multiply and multiply accumulate instructions is:

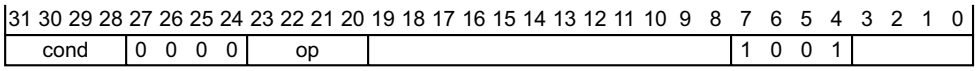

Table F4-7 shows the allocation of encodings in this space.

Table F4-7 Multiply and multiply accumulate instructions

op	Instruction	See
000x	Multiply	*MUL* on page F7-2657
001x	Multiply Accumulate	*MLA* on page F7-2635

11	Saturating Double and Subtract	*QDSUB* on page F7-2705

F4.2.7 Halfword multiply and multiply accumulate

The encoding of A32 halfword multiply and multiply accumulate instructions is:

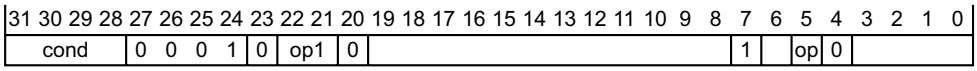

Table F4-9 shows the allocation of encodings in this space.

These encodings are signed multiply (SMUL) and signed multiply accumulate (SMLA) instructions, operating on 16-bit values, or mixed 16-bit and 32-bit values. The results and accumulators are 32-bit or 64-bit.

Table F4-9 Halfword multiply and multiply accumulate instructions

op1	op	Instruction	See

Chapter F5
T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings

This chapter gives an overview of the Advanced SIMD and floating-point instruction sets. It contains the following sections:

Note

- The Advanced SIMD architecture, its associated implementations, and supporting software, are commonly referred to as NEON™ technology.
- In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.

F5.1 Overview

All Advanced SIMD and floating-point instructions are available in both A32 and T32 instruction sets.

F5.1.1 Advanced SIMD

The following sections describe the classes of Advanced SIMD instructions:

- *Advanced SIMD data-processing instructions* on page F5-2415.
- *Advanced SIMD element or structure load/store instructions* on page F5-2431.
- *Advanced SIMD and floating-point register load/store instructions* on page F5-2430.
- *8, 16, and 32-bit transfers accessing the SIMD and floating-point register file* on page F5-2434.
- *64-bit transfers accessing the SIMD and floating-point register file* on page F5-2435.

F5.1.2 Floating-point

The following sections describe the classes of floating-point instructions:

- *Advanced SIMD and floating-point register load/store instructions* on page F5-2430.
- *8, 16, and 32-bit transfers accessing the SIMD and floating-point register file* on page F5-2434.
- *64-bit transfers accessing the SIMD and floating-point register file* on page F5-2435.
- *Floating-point data-processing instructions* on page F5-2427.

F5.2 Advanced SIMD and floating-point instruction syntax

Advanced SIMD and floating-point instructions use the general conventions of the T32 and A32 instruction sets.

Advanced SIMD and floating-point data-processing instructions use the following general format:

```
V{<modifier>}<operation>{<shape>}{<c>}{<q>}{.<dt>}  {<dest>,} <src1>, <src2>
```

All Advanced SIMD and floating-point instructions begin with a `V`. This distinguishes Advanced SIMD vector and floating-point instructions from scalar instructions.

The main operation is specified in the `<operation>` field. It is usually a three letter mnemonic the same as or similar to the corresponding scalar integer instruction.

The `<c>` and `<q>` fields are standard assembler syntax fields. For details see *Standard assembler syntax fields* on page F2-2330.

F5.2.1 Advanced SIMD instruction modifiers

The `<modifier>` field provides additional variants of some instructions. Table F5-1 provides definitions of the modifiers. Modifiers are not available for every instruction.

Table F5-1 Advanced SIMD instruction modifiers

<modifier>	Meaning
Q	The operation uses saturating arithmetic.
R	The operation performs rounding.
D	The operation doubles the result (before accumulation, if any).
H	The operation halves the result.

F5.2.2 Advanced SIMD operand shapes

The `<shape>` field provides additional variants of some instructions. Table F5-2 provides definitions of the shapes. Operand shapes are not available for every instruction.

Table F5-2 Advanced SIMD operand shapes

<shape>	Meaning	Typical register shape	
(none)	The operands and result are all the same width.	Dd, Dn, Dm	Qd, Qn, Qm
L	Long operation - result is twice the width of both operands	Qd, Dn, Dm	
N	Narrow operation - result is half the width of both operands	Dd, Qn, Qm	
W	Wide operation - result and first operand are twice the width of the second operand	Qd, Qn, Dm	

Note

- Some assemblers support a Q shape specifier, that requires all operands to be Q registers. An example of using this specifier is `VADDQ.S32  q0, q1, q2`. This is not standard UAL, and ARM recommends that programmers do not use a Q shape specifier.
- A disassembler must not generate any shape specifier not shown in Table F5-2.

F5.2.3 Data type specifiers

The <dt> field normally contains one data type specifier. Unless the assembler syntax description for the instruction indicates otherwise, this indicates the data type contained in:

- The second operand, if any.
- The operand, if there is no second operand.
- The result, if there are no operand registers.

The data types of the other operand and result are implied by the <dt> field combined with the instruction shape. For information about data type formats see *Data types supported by the Advanced SIMD implementation* on page E1-2219.

In the instruction syntax descriptions in Chapter F2 *About the T32 and A32 Instruction Descriptions*, the <dt> field is usually specified as a single field. However, where more convenient, it is sometimes specified as a concatenation of two fields, <type><size>.

Syntax flexibility

There is some flexibility in the data type specifier syntax:

- Software can specify three data types, specifying the result and both operand data types. For example:

  `VSUBW.I16.I16.S8 Q3, Q5, D0` instead of `VSUBW.S8 Q3, Q5, D0`

- Software can specify two data types, specifying the data types of the two operands. The data type of the result is implied by the instruction shape. For example:

  `VSUBW.I16.S8 Q3, Q5, D0` instead of `VSUBW.S8 Q3, Q5, D0`

- Software can specify two data types, specifying the data types of the single operand and the result. For example:

  `VMOVN.I16.I32 D0, Q1` instead of `VMOVN.I32 D0, Q1`

- Where an instruction requires a less specific data type, software can instead specify a more specific type, as shown in Table F5-3.

- Where an instruction does not require a data type, software can provide one.

- The `F32` data type can be abbreviated to `F`.

- The `F64` data type can be abbreviated to `D`.

In all cases, if software provides additional information, the additional information must match the instruction shape. Disassembly does not regenerate this additional information.

Table F5-3 Data type specification flexibility

Specified data type	Permitted more specific data types				
None	Any				
.I<size>	-	.S<size>	.U<size>	-	-
.8	.I8	.S8	.U8	.P8	-
.16	.I16	.S16	.U16	.P16	.F16
.32	.I32	.S32	.U32	-	.F32 or .F
.64	.I64	.S64	.U64	-	.F64 or .D

F5.2.4 Register specifiers

The <dest>, <src1>, and <src2> fields contain register specifiers, or in some cases scalar specifiers or register lists. Table F5-4 shows the register and scalar specifier formats that appear in the instruction descriptions.

If <dest> is omitted, it is the same as <src1>.

Table F5-4 Advanced SIMD and floating-point register specifier formats

<specifier>	Usual meaning [a]	Used in
<Qd>	A quadword destination register for the result vector.	Advanced SIMD
<Qn>	A quadword source register for the first operand vector.	Advanced SIMD
<Qm>	A quadword source register for the second operand vector.	Advanced SIMD
<Dd>	A doubleword destination register for the result vector.	Both
<Dn>	A doubleword source register for the first operand vector.	Both
<Dm>	A doubleword source register for the second operand vector.	Both
<Sd>	A singleword destination register for the result vector.	Floating-point
<Sn>	A singleword source register for the first operand vector.	Floating-point
<Sm>	A singleword source register for the second operand vector.	Floating-point
<Dd[x]>	A destination scalar for the result. Element x of vector <Dd>.	Advanced SIMD
<Dn[x]>	A source scalar for the first operand. Element x of vector <Dn>.	Both [b]
<Dm[x]>	A source scalar for the second operand. Element x of vector <Dm>.	Advanced SIMD
<Rt>	A general-purpose register, used for a source or destination address.	Both
<Rt2>	A general-purpose register, used for a source or destination address.	Both
<Rn>	A general-purpose register, used as a load or store base address.	Both
<Rm>	A general-purpose register, used as a post-indexed address source.	Both

a. In some instructions the roles of registers are different.

b. In the floating-point instructions, <Dn[x]> is used only in VMOV (scalar to general-purpose register), see *VMOV (scalar to general-purpose register)* on page F8-3182.

F5.2.5 Register lists

A register list is a list of register specifiers separated by commas and enclosed in brackets { and }. There are restrictions on what registers can appear in a register list. These restrictions are described in the individual instruction descriptions. Table F5-5 shows some register list formats, with examples of actual register lists corresponding to those formats.

Note

Register lists must not wrap around the end of the register bank.

Syntax flexibility

There is some flexibility in the register list syntax:

- Where a register list contains consecutive registers, they can be specified as a range, instead of listing every register, for example `{D0-D3}` instead of `{D0, D1, D2, D3}`.
- Where a register list contains an even number of consecutive doubleword registers starting with an even numbered register, it can be written as a list of quadword registers instead, for example `{Q1, Q2}` instead of `{D2-D5}`.
- Where a register list contains only one register, the enclosing braces can be omitted, for example `VLD1.8 D0, [R0]` instead of `VLD1.8 {D0}, [R0]`.

Table F5-5 Example register lists

Format	Example	Alternative
`{<Dd>}`	`{D3}`	`D3`
`{<Dd>, <Dd+1>, <Dd+2>}`	`{D3, D4, D5}`	`{D3-D5}`
`{<Dd[x]>, <Dd+2[x]}`	`{D0[3], D2[3]}`	-
`{<Dd[]>}`	`{D7[]}`	`D7[]`

F5.3 Register encoding

An Advanced SIMD register is either:

- *Quadword*, meaning it is 128 bits wide.
- *Doubleword*, meaning it is 64 bits wide.

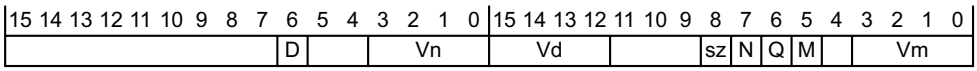
Some instructions have options for either doubleword or quadword registers. This is normally encoded in Q, bit[6], as Q = 0 for doubleword operations, or Q = 1 for quadword operations.

A floating-point register is either:

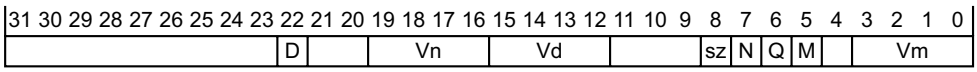
- Double-precision, meaning it is 64 bits wide.
- Single-precision, meaning it is 32 bits wide.

This is encoded in the sz field, bit[8], as sz = 1 for double-precision operations, or sz = 0 for single-precision operations.

The T32 instruction encoding of Advanced SIMD or floating-point registers is:



The A32 instruction encoding of Advanced SIMD or floating-point registers is:



Some instructions use only one or two registers, and use the unused register fields as additional opcode bits.

Table F5-6 shows the encodings for the registers.

Table F5-6 Encoding of register numbers

Register mnemonic	Usual usage	Register number encoded in[a]	Notes[a]	Used in
<Qd>	Destination (quadword)	D, Vd (bits[22, 15:13])	bit[12] == 0[b]	Advanced SIMD
<Qn>	First operand (quadword)	N, Vn (bits[7, 19:17])	bit[16] == 0[b]	Advanced SIMD
<Qm>	Second operand (quadword)	M, Vm (bits[5, 3:1])	bit[0] == 0[b]	Advanced SIMD
<Dd>	Destination (doubleword)	D, Vd (bits[22, 15:12])	-	Both
<Dn>	First operand (doubleword)	N, Vn (bits[7, 19:16])	-	Both
<Dm>	Second operand (doubleword)	M, Vm (bits[5, 3:0])	-	Both
<Sd>	Destination (single-precision)	Vd, D (bits[15:12, 22])	-	Floating-point
<Sn>	First operand (single-precision)	Vn, N (bits[19:16, 7])	-	Floating-point
<Sm>	Second operand (single-precision)	Vm, M (bits[3:0, 5])	-	Floating-point

a. Bit numbers given for the A32 instruction encoding. See the figures in this section for the equivalent bits in the T32 encoding.

b. If this bit is 1, the instruction is UNDEFINED.

F5.3.1 Advanced SIMD scalars

Advanced SIMD scalars can be 8-bit, 16-bit, 32-bit, or 64-bit. Instructions other than multiply instructions can access any element in the register set. The instruction syntax refers to the scalars using an index into a doubleword vector. The descriptions of the individual instructions contain details of the encodings.

Table F5-7 shows the form of encoding for scalars used in multiply instructions. These instructions cannot access scalars in some registers. The descriptions of the individual instructions contain cross references to this section where appropriate.

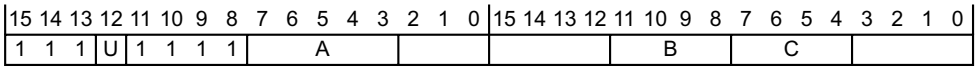
32-bit Advanced SIMD scalars, when used as single-precision floating-point numbers, are equivalent to Floating-point single-precision registers. That is, `Dm[x]` in a 32-bit context (0 <= `m` <= 15, 0 <= `x` <=1) is equivalent to `S[2m + x]`.

Table F5-7 Encoding of scalars in multiply instructions

Scalar mnemonic	Usual usage	Scalar size	Register specifier	Index specifier	Accessible registers
`<Dm[x]>`	Second operand	16-bit	Vm[2:0]	M, Vm[3]	D0-D7
		32-bit	Vm[3:0]	M	D0-D15

F5.4 Advanced SIMD data-processing instructions

The T32 encoding of Advanced SIMD data processing instructions is:



The A32 encoding of Advanced SIMD data processing instructions is:

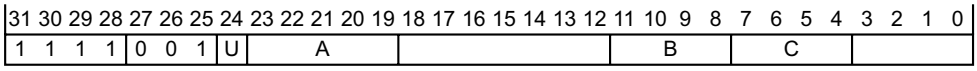


Table F5-8 shows the encoding for Advanced SIMD data-processing instructions. Other encodings in this space are UNDEFINED.

In these instructions, the U bit is in a different location in A32 and T32 instructions. This is bit[12] of the first halfword in the T32 encoding, and bit[24] in the A32 encoding. Other variable bits are in identical locations in the two encodings, after adjusting for the fact that the A32 encoding is held in memory as a single word and the T32 encoding is held as two consecutive halfwords.

The A32 instructions can only be executed unconditionally. The T32 instructions can be executed conditionally by using the `IT` instruction. For details see *IT* on page F7-2533.

	1111	UNDEFINED	-

Table F5-15 shows the modified immediate constants available with these instructions, and how they are encoded.

Table F5-15 Modified immediate values for Advanced SIMD instructions

op	cmode	Constant[a]	<dt>[b]	Notes
-	000x	`00000000 00000000 00000000 abcdefgh 00000000 00000000 00000000 abcdefgh`	I32	c
	001x	`00000000 00000000 abcdefgh 00000000 00000000 00000000 abcdefgh 00000000`	I32	c, d
	010x	`00000000 abcdefgh 00000000 00000000 00000000 abcdefgh 00000000 00000000`	I32	c, d
	011x	`abcdefgh 00000000 00000000 00000000 abcdefgh 00000000 00000000 00000000`	I32	c, d
	100x	`00000000 abcdefgh 00000000 abcdefgh 00000000 abcdefgh 00000000 abcdefgh`	I16	c
	101x	`abcdefgh 00000000 abcdefgh 00000000 abcdefgh 00000000 abcdefgh 00000000`	I16	c, d
	1100	`00000000 00000000 abcdefgh 11111111 00000000 00000000 abcdefgh 11111111`	I32	d, e
	1101	`00000000 abcdefgh 11111111 11111111 00000000 abcdefgh 11111111 11111111`	I32	d, e

Table F5-15 Modified immediate values for Advanced SIMD instructions (continued)

op	cmode	Constant[a]	<dt>[b]	Notes
0	1110	abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh	I8	f
	1111	aBbbbbbc defgh000 00000000 00000000 aBbbbbbc defgh000 00000000 00000000	F32	f, g
1	1110	aaaaaaaa bbbbbbbb cccccccc dddddddd eeeeeeee ffffffff gggggggg hhhhhhhh	I64	f
	1111	UNDEFINED	-	-

a. In this table, the immediate value is shown in binary form, to relate abcdefgh to the encoding diagram. In assembler syntax, the constant is specified by a data type and a value of that type. That value is specified in the normal way (a decimal number by default) and is replicated enough times to fill the 64-bit immediate. For example, a data type of `I32` and a value of 10 specify the 64-bit constant `0x0000000A0000000A`.

b. This specifies the data type used when the instruction is disassembled. On assembly, the data type must be matched in the table if possible. Other data types are permitted as pseudo-instructions when a program is assembled, provided the 64-bit constant specified by the data type and value is available for the instruction. If a constant is available in more than one way, the first entry in this table that can produce it is used. For example, `VMOV.I64 D0, #0x8000000080000000` does not specify a 64-bit constant that is available from the I64 line of the table, but does specify one that is available from the fourth I32 line or the F32 line. It is assembled to the first of these, and therefore is disassembled as `VMOV.I32 D0, #0x80000000`.

c. This constant is available for the `VBIC`, `VMOV`, `VMVN`, and `VORR` instructions.

d. UNPREDICTABLE if `abcdefgh` == 00000000.

e. This constant is available for the `VMOV` and `VMVN` instructions only.

f. This constant is available for the `VMOV` instruction only.

g. In this entry, `B` = NOT(`b`). The bit pattern represents the floating-point number $(-1)^S \times 2^{exp} \times$ mantissa, where S = `UInt(a)`, exp = `UInt(NOT(b):c:d)-3` and mantissa = `(16+UInt(e:f:g:h))/16`.

Advanced SIMD expand immediate pseudocode

```
// AdvSIMDExpandImm()
// ==================

bits(64) AdvSIMDExpandImm(bit op, bits(4) cmode, bits(8) imm8)

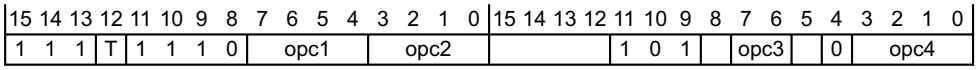
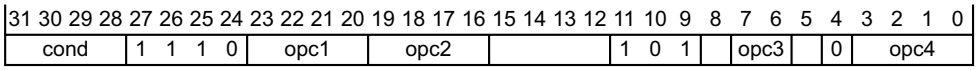
        return imm64;
```

F5.5 Floating-point data-processing instructions

The T32 encoding of floating-point data processing instructions is:



The A32 encoding of floating-point data processing instructions is:



- Table F5-16 shows the encodings for three-register floating-point data-processing instructions. Other encodings in this space are UNDEFINED.
- Table F5-17 on page F5-2428 applies only if Table F5-16 indicates that it does. It shows the encodings for floating-point data-processing instructions with two registers or a register and an immediate. Other encodings in this space are UNDEFINED.
- Table F5-18 on page F5-2428 shows the immediate constants available in the `VMOV` (immediate) instruction.

These instructions are `CDP` instructions for coprocessors 10 and 11.

Note

For some of the A32 encodings of the instructions listed in Table F5-16 and Table F5-17 on page F5-2428, `cond` must be `0b1111`. See the individual instruction descriptions for details.

Table F5-18 Floating-point modified immediate constants

Data type	opc2	opc4	Constant [a]
F32	abcd	efgh	aBbbbbbc defgh000 00000000 00000000
F64	abcd	efgh	aBbbbbbb bbcdefgh 00000000 00000000 00000000 00000000 00000000 00000000

a. In this column, B = NOT(b). The bit pattern represents the floating-point number $(-1)^S \times 2^{exp} \times$ mantissa, where S = UInt(a), exp = UInt(NOT(b):c:d)-3 and mantissa = (16+UInt(e:f:g:h))/16.

F5.5.1 Operation of modified immediate constants, floating-point

The VFPExpandImm() pseudocode function describes the operation of an immediate constant in a floating-point instruction.

```
// VFPExpandImm()
// ==============

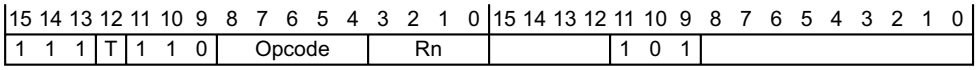
bits(N) VFPExpandImm(bits(8) imm8)
    assert N IN {32,64};
    constant integer E = (if N == 32 then 8 else 11);
    constant integer F = N - E - 1;
    sign = imm8<7>;
    exp  = NOT(imm8<6>):Replicate(imm8<6>,E-3):imm8<5:4>;
    frac = imm8<3:0>:Zeros(F-4);
```

```
return sign : exp : frac;
```

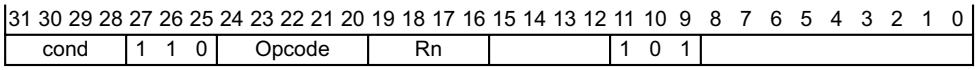
F5.6 Advanced SIMD and floating-point register load/store instructions

These are instructions that transfer data to or from the registers in the SIMD and floating-point register file.

The T32 encoding of Advanced SIMD and floating-point register load or store instructions is:



The A32 encoding of Advanced SIMD and floating-point register load or store instructions is:



If `T` == 1 in the T32 encoding or `cond` == `0b1111` in the A32 encoding, the instruction is UNDEFINED.

Otherwise, the allocation of encodings in this space is shown in Table F5-19. Other encodings in this space are UNDEFINED.

These instructions are `LDC` and `STC` instructions for coprocessors 10 and 11.

Table F5-19 Advanced SIMD and floating-point register load/store instructions

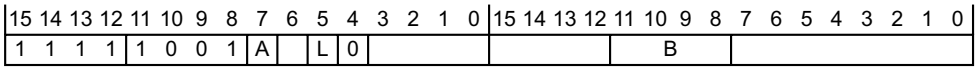
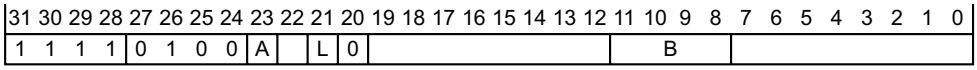
F5.7 Advanced SIMD element or structure load/store instructions

These are instructions that transfer data to or from Advanced SIMD elements or structures in the SIMD and floating-point register file.

The T32 encoding of Advanced SIMD element load or store instructions is:



The A32 encoding of Advanced SIMD element load or store instructions is:



The allocation of encodings in this space is shown in:

- Table F5-20 if L == 0. These are the encodings for store instructions.
- Table F5-21 on page F5-2432 if L == 1. These are the encodings for load instructions.

Other encodings in this space are UNDEFINED.

The variable bits are in identical locations in the two encodings, after adjusting for the fact that the A32 encoding is held in memory as a single word and the T32 encoding is held as two consecutive halfwords.

The A32 instructions can only be executed unconditionally. The T32 instructions can be executed conditionally by using the `IT` instruction. For details see *IT* on page F7-2533.

	1110	Vector Load	*VLD3 (single 3-element structure to all lanes)* on page F8-3152
	0x11 1011	Vector Load	*VLD4 (single 4-element structure to one lane)* on page F8-3156
	1111	Vector Load	*VLD4 (single 4-element structure to all lanes)* on page F8-3158

F5.7.1 Advanced SIMD addressing mode

All the element and structure load/store instructions use this addressing mode. There is a choice of three formats:

`[<Rn>{:<align>}]`
: The address is contained in general-purpose register Rn.

  Rn is not updated by this instruction.

  Encoded as Rm = `0b1111`.

  If Rn is encoded as `0b1111`, the instruction is UNPREDICTABLE.

`[<Rn>{:<align>}]!`
: The address is contained in general-purpose register Rn.

  Rn is updated by this instruction: `Rn = Rn + transfer_size`

  Encoded as Rm = `0b1101`.

  `transfer_size` is the number of bytes transferred by the instruction. This means that, after the instruction is executed, Rn points to the address in memory immediately following the last address loaded from or stored to.

  If Rn is encoded as `0b1111`, the instruction is UNPREDICTABLE.

  This addressing mode can also be written as:

  `[<Rn>{:align}], #<transfer_size>`

  However, disassembly produces the `[<Rn>{:align}]!` form.

`[<Rn>{:<align>}], <Rm>`
: The address is contained in general-purpose register `<Rn>`.

  Rn is updated by this instruction: `Rn = Rn + Rm`

  Encoded as Rm = Rm. Rm must not be encoded as `0b1111` or `0b1101`, the PC or the SP.

  If Rn is encoded as `0b1111`, the instruction is UNPREDICTABLE.

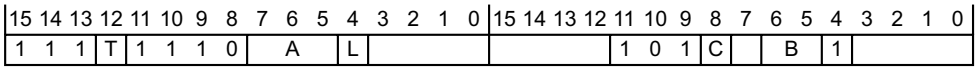
In all cases, `<align>` specifies an alignment. Details are given in the individual instruction descriptions.

Previous versions of the manual used the `@` character for alignment. So, for example, the first format in this section was shown as `[<Rn>{@<align>}]`. Both `@` and `:` are supported. However, to ensure portability of code to assemblers that treat `@` as a comment character, `:` is preferred.

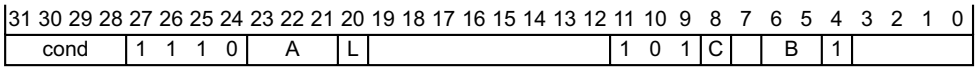
F5.8 8, 16, and 32-bit transfers accessing the SIMD and floating-point register file

These are instructions that transfer data to or from registers in the SIMD and floating-point register file.

The T32 encoding of an Advanced SIMD and floating-point 8-bit, 16-bit, or 32-bit register data transfer instructions is:



The A32 encoding of an Advanced SIMD and floating-point 8-bit, 16-bit, or 32-bit register data transfer instructions is:



If `T` == 1 in the T32 encoding or `cond` == `0b1111` in the A32 encoding, the instruction is UNDEFINED.

Otherwise, the allocation of encodings in this space is shown in Table F5-22. Other encodings in this space are UNDEFINED.

These instructions are `MRC` and `MCR` instructions for coprocessors 10 and 11.

Table F5-22 8-bit, 16-bit and 32-bit Advanced SIMD and floating-point data transfer instructions

L	C	A	B	Instruction	See

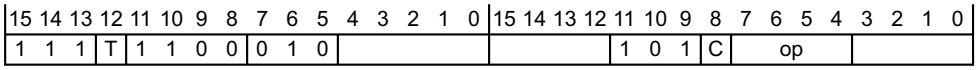
	1	xxx	-	Vector Move	*VMOV (scalar to general-purpose register)* on page F8-3182

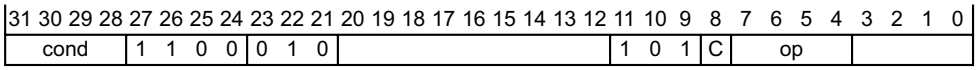
F5.9 64-bit transfers accessing the SIMD and floating-point register file

These are instructions that transfer data to or from the registers in the SIMD and floating-point register file.

The T32 encoding of Advanced SIMD and floating-point 64-bit register data transfer instructions is:



The A32 encoding of Advanced SIMD and floating-point 64-bit register data transfer instructions is:



If `T` == 1 in the T32 encoding or `cond` == `0b1111` in the A32 encoding, the instruction is UNDEFINED.

Otherwise, the allocation of encodings in this space is shown in Table F5-23. Other encodings in this space are UNDEFINED.

These instructions are `MRRC` and `MCRR` instructions for coprocessors 10 and 11.

Table F5-23 Advanced SIMD and floating-point 64-bit data transfer instructions

C	op	Instruction
0	00x1	*VMOV (between two general-purpose registers and two single-precision registers)* on page F8-3186
1	00x1	*VMOV (between two general-purpose registers and a doubleword floating-point register)* on page F8-3188

Chapter F6
ARMv8 Changes to the T32 and A32 Instruction Sets

This chapter summarizes the changes that ARMv8 makes to the T32 and A32 instruction sets. It contains the following section:

F6.1 The A32 and T32 instruction sets

This chapter describes the changes that ARMv8-A makes to the T32 and A32 instruction sets, compared to an ARMv7-A implementation that includes all of the following extensions:

- Multiprocessing Extensions.
- Large Physical Address Extension.
- Virtualization Extensions.
- Security Extensions.
- VFPv4.
- Advanced SIMDv2.

The implemented instructions are not affected by whether the ARMv8-A implementation includes either or both of EL2 and EL3.

ARMv8-A obsoletes the A32 `SWP` and `SWPB` instructions.

ARM deprecates any use of the following instructions. In ARMv8-A, privileged software can disable these instructions:

- A32 and T32 CP15 barriers CP15DSB, CP15ISB, and CP15DMB.
- A32 and T32 `SETEND` instruction.
- A subset of T32 IT instruction functionality, as described in *Partial deprecation of IT* on page F6-2439.

ARMv8-A adds new A32 and T32 instructions to align with some of the features introduced in the A64 instruction set. These are described in:

- *Partial deprecation of IT* on page F6-2439.
- *New A32 and T32 Load-Acquire/Store-Release instructions* on page F6-2440.
- *New A32 and T32 scalar floating-point instructions* on page F6-2441.
- *New A32 and T32 Advanced SIMD floating-point instructions* on page F6-2444.
- *New A32 and T32 instructions provided by the Cryptographic Extension* on page F6-2446.
- *New A32 and T32 System instructions* on page F6-2447.

Note

The existing A32 and T32 assembler syntax is unchanged from ARMv7 UAL. Where the syntax term <c> is used in this chapter, it represents a standard ARM condition code. Mnemonics that do not include <c> can not be conditionally executed.

F6.2 Partial deprecation of IT

ARMv8-A deprecates some uses of the T32 IT instruction. All uses of IT that apply to instructions other than a single subsequent 16-bit instruction from a restricted set are deprecated, as are explicit references to the PC within that single 16-bit instruction. This permits the non-deprecated forms of IT and subsequent instructions to be treated as a single 32-bit conditional instruction. Table F6-1 shows the restricted set of 16-bit instructions that are not deprecated when used in conjunction with IT.

Table F6-1 Non-deprecated IT 16-bit conditional instructions

Permitted 16-bit instructions	Class	Notes
MOV, MVN	Move	Deprecated when Rm or Rd is the PC.
LDR, LDRB, LDRH, LDRSB, LDRSH	Load	Deprecated for PC-relative load literal forms
STR, STRB, STRH	Store	-
ADD, ADC, RSB, SBC, SUB	Add/Subtract	Deprecated for ADD SP, SP, #imm, SUB SP, SP, #imm, and when Rm, Rdn, or Rdm is the PC
CMP, CMN	Compare	Deprecated when Rm or Rn is the PC
MUL	Multiply	-
ASR, LSL, LSR, ROR	Shift	-
AND, BIC, EOR, ORR, TST	Logical	-
BX, BLX	Branch to register	Deprecated when Rm is the PC

Note

The ARMv7 IT instruction functionality remains available in order to execute ARMv7 T32 code. However, to verify conformance with the deprecation, a new control bit permits privileged software to disable the deprecated forms of the IT instruction, so that their use generates an Undefined Instruction exception. See HSCTLR.ITD.

F6.3 New A32 and T32 Load-Acquire/Store-Release instructions

The new Load-Acquire/Store-Release instructions must be naturally aligned. LDAEXD and STLEXD must be aligned to 8 bytes. An unaligned address causes an alignment fault. For more information about the ordering of Load-Acquire/Store-Release, see *Load-Acquire, Store-Release* on page E2-2271.

F6.3.1 A32 and T32 Load-Acquire/Store-Release (non-exclusive) instructions

Table F6-2 shows the new A32 and T32 Load-Acquire/Store-Release (non-exclusive) instructions.

Table F6-2 A32 and T32 Load-Acquire/Store-Release (non-exclusive) instructions

Mnemonic	Instruction	See
LDA	Load-Acquire Word	*LDA* on page F7-2535

STLEXD	Store-Release Exclusive Double	*STLEXD* on page F7-2829
STLEXH	Store-Release Exclusive Halfword	*STLEXH* on page F7-2831

F6.4 New A32 and T32 scalar floating-point instructions

This section describes the new A32 and T32 scalar floating-point instructions. It contains the following subsections:

- *A32 and T32 floating-point conditional select*.
- *A32 and T32 floating-point minimum and maximum numeric*.
- *A32 and T32 floating-point to integer conversion* on page F6-2442.
- *A32 and T32 floating-point conversion between half-precision and double-precision* on page F6-2442.
- *A32 and T32 floating-point round to integral* on page F6-2442.

F6.4.1 A32 and T32 floating-point conditional select

The new `VSEL` instruction conditionally copies one of its two source registers to the destination register. For A32 it provides an alternative to a pair of conditional `VMOV` instructions, while for T32 it compensates for the partial deprecation of `IT` instruction described in *Partial deprecation of IT* on page F6-2439, since it does not require an `IT` prefix.

Table F6-4 shows the A32 and T32 floating-point conditional select instructions

Table F6-4 A32 and T32 Conditional select

Mnemonic	Instruction	See
`VSEL`	Conditional select	*VSEL* on page F8-3298

F6.4.2 A32 and T32 floating-point minimum and maximum numeric

The new `VMAXNM` and `VMINNM` instructions implement the `minNum(x,y)` and `maxNum(x,y)` operations defined by the IEEE754-2008 standard. They return the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to `VFP VMAX` and `VMIN`. These instructions cannot be conditionally executed.

Table F6-5 shows the A32 and T32 floating-point minNum and maxNum instructions.

Table F6-5 A32 and T32 floating-point minNum and maxNum instructions

Mnemonic	Instruction	See
`VMAXNM`	Single-precision maxNum (scalar)	*VMAXNM, VMINNM* on page F8-3168
`VMINNM`	Double-precision minNum (scalar)	

F6.4.3 A32 and T32 floating-point to integer conversion

These new instructions extend the ARMv7 VFP VCVT instructions by providing four additional explicit rounding modes. The syntax term <r> selects the rounding direction as follows:

N . Round to nearest, with ties to even.

A . Round to nearest, with ties to away.

P . Round towards positive infinity.

M . Round towards minus infinity.

These instructions cannot be conditionally executed.

Table F6-6 shows the A32 and T32 FP to integer conversion instructions.

Table F6-6 A32 and T32 floating-point to integer conversion instructions

Mnemonic	Instruction	See
VCVT	Floating-point convert to integer	*VCVTA, VCVTN, VCVTP, VCVTM (between floating-point and integer, floating-point)* on page F8-3116

F6.4.4 A32 and T32 floating-point conversion between half-precision and double-precision

The VFP VCVTT and VCVTB instructions are extended to permit direct conversion between half-precision and double-precision floating-point as a single operation, preventing double rounding errors. The syntax term <y> in Table F6-7 is either T, top half, and B, bottom half.

Table F6-7 shows the A32 and T32 instructions to convert between half-precision and double-precision floating-point values.

Table F6-7 A32 and T32 floating-point precision conversion

Mnemonic	Instruction	See
VCVTB	Floating-point convert single-precision to double-precision	*VCVTB, VCVTT* on page F8-3118
VCVTT	Floating-point convert double-precision to single-precision	

F6.4.5 A32 and T32 floating-point round to integral

The new round to integral instructions round a floating-point value to the nearest integral floating-point value of the same size. The floating-point exceptions that can be raised by these instructions are the Invalid operation, for a signaling NaN input, or Input Denormal, for a denormal input when flush-to-zero mode is enabled. For VRINTX only an Inexact exception can be raised if the result is numeric and does not have the same numerical value as the source. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal floating-point arithmetic.

A subset of the rounding instructions can be conditionally executed when the syntax term <x> selects the rounding direction as follows:

Z Round towards zero.

R FPSCR rounding mode.

X FPSCR rounding mode and signaling inexactness.

Table F6-8 shows the A32 and T32 round to integral instructions that can be conditionally executed.

Table F6-8 A32 and T32 floating-point round to integral instruction, conditional

Mnemonic	Instruction	See
VRINT	Floating-point round to integral	*VRINTX (floating-point)* on page F8-3278 *VRINTZ, VRINTR (floating-point)* on page F8-3282

The remaining rounding instructions cannot be conditionally executed when the syntax term <r> selects the rounding directions as follows:

N Round to nearest, with ties to even.

A Round to nearest, with ties to away.

P Round towards positive infinity.

M Round towards minus infinity.

Table F6-9 shows the A32 and T32 round to integral instructions that cannot be conditionally executed.

Table F6-9 A32 and T32 floating-point round to integral instruction, unconditional

Mnemonic	Instruction	See
VRINT	Floating-point round to integral	*VRINTA, VRINTN, VRINTP, VRINTM (floating-point)* on page F8-3274

F6.5 New A32 and T32 Advanced SIMD floating-point instructions

The AArch32 Advanced SIMD instructions support only single-precision, 32-bit, floating-point data types, with fixed operating modes of Round to Nearest, Default NaN, and Flush-to-Zero. However, they are extended by the addition of the instructions described in the following subsections:

- *A32 and T32 floating-point minimum and maximum numeric*.
- *A32 and T32 floating-point conversion*.
- *A32 and T32 floating-point round to integral*.

F6.5.1 A32 and T32 floating-point minimum and maximum numeric

Vector forms of the new `VMAXNM` and `VMINNM` instructions are described in *A32 and T32 floating-point minimum and maximum numeric* on page F6-2441.

Table F6-10 shows the A32 and T32 floating-point minNum/maxNum instructions.

Table F6-10 A32 and T32 floating-point minNum/maxNum instructions

Mnemonic	Instruction	See
`VMAXNM`	Single-precision maxNum (vector)	*VMAXNM, VMINNM* on page F8-3168
`VMINNM`	Double-precision minNum (vector)	

F6.5.2 A32 and T32 floating-point conversion

Vector forms of the floating-point to integer conversion instructions are described in *A32 and T32 floating-point to integer conversion* on page F6-2442. The syntax term <r> selects the rounding direction as follows:

N Round to nearest, with ties to even.
A Round to nearest, with ties to away.
P Round towards positive infinity.
M Round towards minus infinity.

Table F6-11 shows the A32 and T32 floating-point conversion instructions.

Table F6-11 A32 and T32 floating-point conversion instructions

Mnemonic	Instruction	See
`VCVT`	Floating-point convert to integer	*VCVTA, VCVTN, VCVTP, VCVTM (between floating-point and integer, Advanced SIMD)* on page F8-3114

F6.5.3 A32 and T32 floating-point round to integral

Vector forms of the floating-point rounding instructions are described in *A32 and T32 floating-point round to integral* on page F6-2442. The syntax term <rx> selects the rounding direction as follows:

N Round to the nearest, with ties to even.
A Round to the nearest, with ties to away.
P Round towards positive infinity.
M Round towards minus infinity.
Z Round towards zero.
X Round to the nearest, with ties to even, signaling inexactness.

Table F6-12 on page F6-2445 shows the A32 and T32 floating-point round to integral instructions.

Table F6-12 A32 and T32 SIMD floating-point round to integral instructions

Mnemonic	Instruction	See
VRINT	Floating-point round to integral	*VRINTX (Advanced SIMD)* on page F8-3276 *VRINTZ (Advanced SIMD)* on page F8-3280 *VRINTA, VRINTN, VRINTP, VRINTM (Advanced SIMD)* on page F8-3272

F6.6 New A32 and T32 instructions provided by the Cryptographic Extension

The optional Cryptographic Extension instructions use the SIMD and floating-point register file. For more information see:

- *Announcing the Advanced Encryption Standard.*
- *The Galois/Counter Mode of Operation.*
- *Announcing the Secure Hash Standard*.

Table F6-13 shows the A32 and T32 Cryptographic Extension instructions.

Table F6-13 A32 and T32 Cryptographic Extension instructions

Mnemonic	Instruction	See
AESD	AES single round decryption	*AESD* on page F8-3036
AESE	AED single round encryption	*AESE* on page F8-3037
AESIMC	AES inverse mix columns	*AESIMC* on page F8-3038
AESMC	AES mix columns	*AESMC* on page F8-3039
SHA1C	SHA1 hash update accelerator, choose	*SHA1C* on page F8-3041
SHA1M	SHA1 hash update accelerator, majority	*SHA1M* on page F8-3043
SHA1P	SHA1 hash update accelerator, parity	*SHA1P* on page F8-3044
SHA1H	SHA1 hash update accelerator, rotate left by 30	*SHA1H* on page F8-3042
SHA1SU0	SHA1 schedule update accelerator, first part	*SHA1SU0* on page F8-3045
SHA1SU1	SHA1 schedule update accelerator, second part	*SHA1SU1* on page F8-3046
SHA256H	SHA256 hash update accelerator	*SHA256H* on page F8-3047
SHA256H2	SHA256 hash update accelerator upper part	*SHA256H2* on page F8-3048
SHA256SU0	SHA256 schedule update accelerator, first part	*SHA256SU0* on page F8-3049
SHA256SU1	SHA256 schedule update accelerator, second part	*SHA256SU1* on page F8-3050
VMULL	Polynomial multiply long, 64×64 to 128-bit	*VMUL, VMULL (integer and polynomial)* on page F8-3198

F6.7 New A32 and T32 System instructions

The section describes the system instructions. It contains the following subsections:

- *External Debug*.
- *Barriers and hints*.
- *TLB Maintenance*.

F6.7.1 External Debug

Table F6-14 shows the new External Debug support instructions.

Table F6-14 External Debug support instructions

Mnemonic	Instructions	Note
`DCPS1`	Debug switch to EL1, valid in Debug state only	-
`DCPS2`	Debug switch to EL2, valid in Debug state only	-
`DCPS3`	Debug switch to EL3, valid in Debug state only	-
`HLT #uimm6`	Halting mode software breakpoint	Enters Debug state if allowed, with a 6-bit payload in `uimm6`, otherwise treated as unallocated

F6.7.2 Barriers and hints

There are new A32 and T32 barrier options and hint instructions.

Table F6-15 shows the new A32 and T32 barrier instructions.

Table F6-15 Additional barrier instructions

Mnemonic	Notes
`DMB {ISHLD, OSHLD, NSHLD, LD}`	Data Memory Barrier is extended to support the new Load-Load/Store options
`DSB {ISHLD, OSHLD, NSHLD, LD}`	Data Synchronization Barrier is extended to support the new Load-Load/Store options
`SEVL`	Send Event Locally without the requirement to affect other processors, for example to prime a wait-loop that starts with a `WFE` instructions

F6.7.3 TLB Maintenance

TLB maintenance instructions that are only required to apply to the last level translation table walk of the first stage of translation are added to A32 and T32 as shown in Table F6-16. For more information see *Translation Lookaside Buffers (TLBs)* on page G4-3686 and *TLB maintenance requirements* on page G4-3689.

Table F6-16 Additional A32 and T32 TLB maintenance instructions

Mnemonic	Relation to existing A32/T32 operation
`TLBIMVALIS`	Related to the `TLBIMVAIS` operation
`TLBIMVAALIS`	Related to the `TLBIMVAAIS` operation
`TLBIMVALHIS`	Related to the `TLBIMVAHIS` operation
`TLBIMVAL`	Related to the `TLBIMVA` operation

Table F6-16 Additional A32 and T32 TLB maintenance instructions (continued)

Mnemonic	Relation to existing A32/T32 operation
TLBIMVAAL	Related to the TLBIMVAA operation
TLBIMVALH	Related to the TLBIMVAH operation

A32 and T32 include TLB maintenance instructions that must apply to individual entries from stage 2 TLB structures, that hold IPA to PA translations. These are consistent with the A64 TLBI system instructions described in *New A32 and T32 System instructions* on page F6-2447. The relation between the A32 and T32 instructions and the A64 instructions is shown in Table F6-17.

Table F6-17 Relation of A32 TLB maintenance instructions to A64 instructions

Instruction	Relation to A64 operation
TLBIIPAS2IS	Equivalent to IPAS2E1IS
TLBIIPAS2LIS	Equivalent to IPAS2LE1IS Related to existing A32/T32 TLBIIPAS2IS operation
TLBIIPAS2	Equivalent to the A64 IPAS2E1 operation
TLBIIPAS2L	Equivalent to IPAS2LE1 operation Related to existing A32/T32 TLBIIPAS2 operation

Note

These new system operations are accessed using the MCR instruction or, if implemented, by an assembler using the SYS mnemonic followed by the TLBI operation name.

Chapter F7
T32 and A32 Base Instruction Set Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

F7.1 Alphabetical list of T32 and A32 base instruction set instructions

This section lists every instruction in the T32 and A32 base instruction sets. For details of the format used see *Format of instruction descriptions* on page F2-2326.

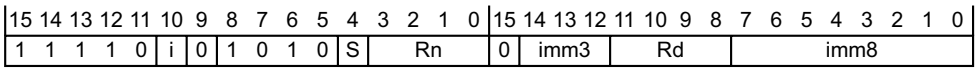
This section is formatted so that a full description of an instruction uses a double page.

F7.1.1 ADC (immediate)

Add with Carry (immediate) adds an immediate value and the Carry flag value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

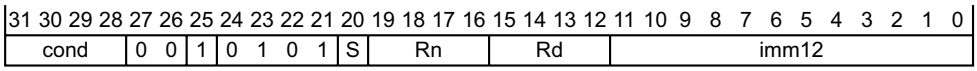
```
ADC{S}<c> <Rd>, <Rn>, #<const>
```



```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = T32ExpandImm(i:imm3:imm8);
if d == 15 || n == 15 then UNPREDICTABLE;  // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
ADC{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = A32ExpandImm(imm12);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ADC{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
<Rn>	The first operand register. The PC can be used in A32 instructions.
<const>	The immediate value to be added to the value obtained from <Rn>. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

The pre-UAL syntax ADC<c>S is equivalent to ADCS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], imm32, PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

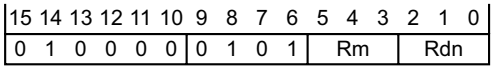
F7.1.2 ADC (register)

Add with Carry (register) adds a register value, the Carry flag value, and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

`ADCS <Rdn>, <Rm>` Outside IT block.

`ADC<c> <Rdn>, <Rm>` Inside IT block.

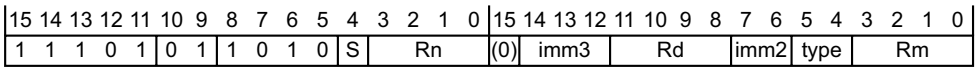


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	0	0	1	0	1	Rm			Rdn		

```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

`ADC{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}`

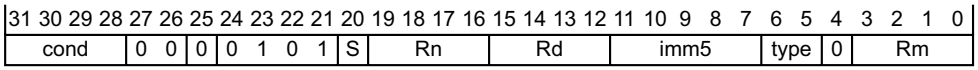


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	1	1	0	1	0	S	Rn				(0)	imm3			Rd				imm2		type		Rm			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`ADC{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}`



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	0	1	0	1	S	Rn				Rd				imm5					type		0	Rm			

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ADC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
<Rn>	The first operand register. The PC can be used in A32 instructions.
<Rm>	The optionally shifted second operand register. The PC can be used in A32 instructions.
