<shift>	The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and any encoding is permitted. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

In T32 assembly:

- Outside an IT block, if `ADCS <Rd>, <Rn>, <Rd>` has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though `ADCS <Rd>, <Rn>` had been written.
- Inside an IT block, if `ADC<c> <Rd>, <Rn>, <Rd>` has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though `ADC<c> <Rd>, <Rn>` had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax `ADC<c>S` is equivalent to `ADCS<c>`.

Operation

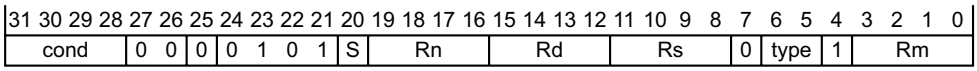
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.3 ADC (register-shifted register)

Add with Carry (register-shifted register) adds a register value, the Carry flag value, and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding A1

```
ADC{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ADC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page F2-2330.

<Rd> — The destination register.

<Rn> — The first operand register.

<Rm> — The register that is shifted and used as the second operand.

<type> — The type of shift to apply to the value read from <Rm>. It must be one of:

- ASR — Arithmetic shift right, encoded as type = 0b10.
- LSL — Logical shift left, encoded as type = 0b00.
- LSR — Logical shift right, encoded as type = 0b01.
- ROR — Rotate right, encoded as type = 0b11.

<Rs> — The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax ADC<c>S is equivalent to ADCS<c>.

Operation

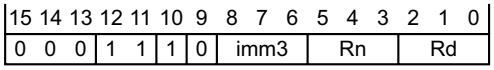
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.4 ADD (immediate), T32

This instruction adds an immediate value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

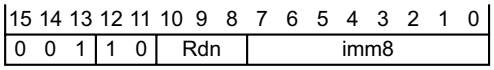
```
ADDS <Rd>, <Rn>, #<imm3>                    Outside IT block.
ADD<c> <Rd>, <Rn>, #<imm3>                  Inside IT block.
```



```
d = UInt(Rd);  n = UInt(Rn);  setflags = !InITBlock();  imm32 = ZeroExtend(imm3, 32);
```

Encoding T2

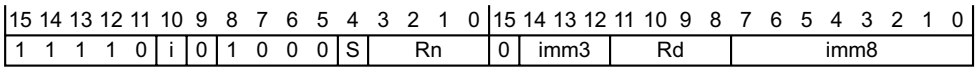
```
ADDS <Rdn>, #<imm8>                         Outside IT block.
ADD<c> <Rdn>, #<imm8>                       Inside IT block.
```



```
d = UInt(Rdn);  n = UInt(Rdn);  setflags = !InITBlock();  imm32 = ZeroExtend(imm8, 32);
```

Encoding T3

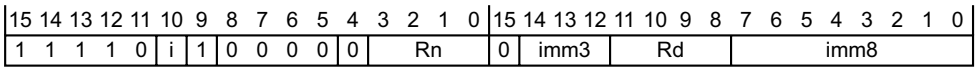
```
ADD{S}<c>.W <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE CMN (immediate);
if Rn == '1101' then SEE ADD (SP plus immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = T32ExpandImm(i:imm3:imm8);
if (d == 15 && S == '0') || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding T4

```
ADDW<c> <Rd>, <Rn>, #<imm12>
```



```
if Rn == '1111' then SEE ADR;
if Rn == '1101' then SEE ADD (SP plus immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = FALSE;  imm32 = ZeroExtend(i:imm3:imm8, 32);
if d == 15 then UNPREDICTABLE;   // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`ADD{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>`	All encodings permitted
`ADDW{<c>}{<q>}  {<Rd>,} <Rn>, #<const>`	Only encoding T4 permitted

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register. If `<Rn>` is SP, see *ADD (SP plus immediate)* on page F7-2466. If `<Rn>` is PC, see *ADR* on page F7-2472.

`<const>` The immediate value to be added to the value obtained from `<Rn>`. The range of values is 0-7 for encoding T1, 0-255 for encoding T2 and 0-4095 for encoding T4. See *Modified immediate constants in T32 instructions* on page F3-2358 for the range of values for encoding T3.

When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4 (if encoding T4 is required, use the `ADDW` syntax). Encoding T1 is preferred to encoding T2 if `<Rd>` is specified and encoding T2 is preferred to encoding T1 if `<Rd>` is omitted.

The pre-UAL syntax `ADD<c>S` is equivalent to `ADDS<c>`.

Operation

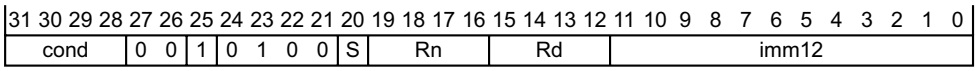
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], imm32, '0');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.5 ADD (immediate), A32

This instruction adds an immediate value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1

```
ADD{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rn == '1111' && S == '0' then SEE ADR;
if Rn == '1101' then SEE ADD (SP plus immediate);
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = A32ExpandImm(imm12);
```

Assembler syntax

```
ADD{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. If S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
<Rn>	The first operand register. If the SP is specified for <Rn>, see *ADD (SP plus immediate)* on page F7-2466. If the PC is specified for <Rn>, see *ADR* on page F7-2472.
<const>	The immediate value to be added to the value obtained from <Rn>. See *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

The pre-UAL syntax ADD<c>S is equivalent to ADDS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], imm32, '0');
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

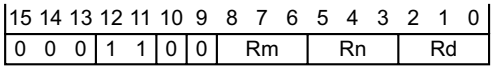
F7.1.6 ADD (register), T32

This instruction adds a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

`ADDS <Rd>, <Rn>, <Rm>` Outside IT block.

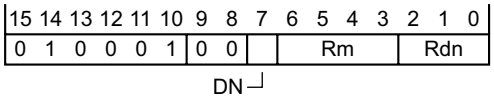
`ADD<c> <Rd>, <Rn>, <Rm>` Inside IT block.



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

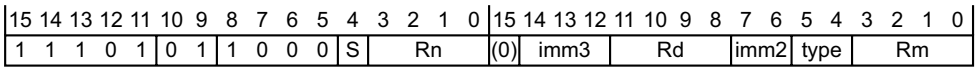
`ADD<c> <Rdn>, <Rm>` If `<Rdn>` is the PC, must be outside or last in IT block.



```
if (DN:Rdn) == '1101' || Rm == '1101' then SEE ADD (SP plus register);
d = UInt(DN:Rdn);  n = d;  m = UInt(Rm);  setflags = FALSE;  (shift_t, shift_n) = (SRType_LSL, 0);
if n == 15 && m == 15 then UNPREDICTABLE;
if d == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T3

`ADD{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}`



```
if Rd == '1111' && S == '1' then SEE CMN (register);
if Rn == '1101' then SEE ADD (SP plus register);
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if (d == 15 && S == '0') || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ADD{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register. If `S` is specified and `<Rd>` is the PC, see *CMN (register)* on page F7-2506. If omitted, `<Rd>` is the same as `<Rn>` and encoding T2 is preferred to encoding T1 inside an IT block. If `<Rd>` is present, encoding T1 is preferred to encoding T2. If `<Rd>` is the PC and `S` is not specified, encoding T2 is used and the instruction is a branch to the address calculated by the operation. This is a simple branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
`<Rn>`	The first operand register. The PC can be used in encoding T2. If `<Rn>` is SP, see *ADD (SP plus register), T32* on page F7-2468.
`<Rm>`	The register that is optionally shifted and used as the second operand. The PC can be used in encoding T2.
`<shift>`	The shift to apply to the value read from `<Rm>`. If present, only encoding T3 is permitted. If omitted, no shift is applied and any encoding is permitted. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

Inside an IT block, if `ADD<c> <Rd>, <Rn>, <Rd>` cannot be assembled using encoding T1, it is assembled using encoding T2 as though `ADD<c> <Rd>, <Rn>` had been written. To prevent this happening, use the `.W` qualifier.

The pre-UAL syntax `ADD<c>S` is equivalent to `ADDS<c>`.

Operation

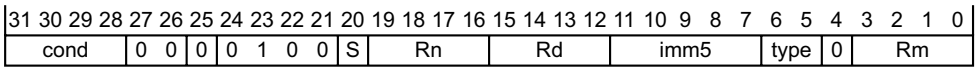
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.7 ADD (register), A32

This instruction adds a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1

```
ADD{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
if Rn == '1101' then SEE ADD (SP plus register);
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
ADD{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, A32* on page F7-3032. If omitted, `<Rd>` is the same as `<Rn>`.

If `<Rd>` is the PC and `S` is not specified, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<Rn>` The first operand register. The PC can be used. If `<Rn>` is SP, see *ADD (SP plus register), A32* on page F7-2470.

`<Rm>` The register that is optionally shifted and used as the second operand. The PC can be used.

`<shift>` The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

The pre-UAL syntax `ADD<c>S` is equivalent to `ADDS<c>`.

Operation

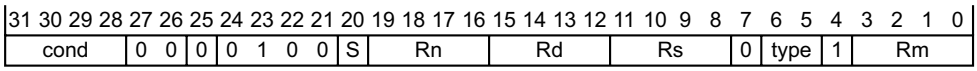
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.8 ADD (register-shifted register)

Add (register-shifted register) adds a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding A1

```
ADD{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ADD{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

S
: If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q>
: See *Standard assembler syntax fields* on page F2-2330.

<Rd>
: The destination register.

<Rn>
: The first operand register.

<Rm>
: The register that is shifted and used as the second operand.

<type>
: The type of shift to apply to the value read from <Rm>. It must be one of:

  ASR
  : Arithmetic shift right, encoded as type = 0b10.

  LSL
  : Logical shift left, encoded as type = 0b00.

  LSR
  : Logical shift right, encoded as type = 0b01.

  ROR
  : Rotate right, encoded as type = 0b11.

<Rs>
: The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax ADD<c>S is equivalent to ADDS<c>.

Operation

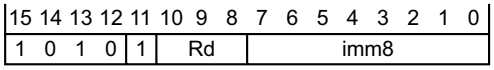
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.9 ADD (SP plus immediate)

This instruction adds an immediate value to the SP value, and writes the result to the destination register.

Encoding T1

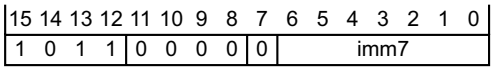
ADD<c> <Rd>, SP, #<imm>



```
d = UInt(Rd);  setflags = FALSE;  imm32 = ZeroExtend(imm8:'00', 32);
```

Encoding T2

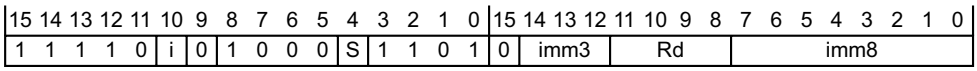
ADD<c> SP, SP, #<imm>



```
d = 13;  setflags = FALSE;  imm32 = ZeroExtend(imm7:'00', 32);
```

Encoding T3

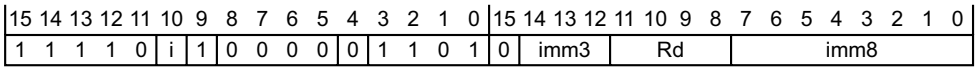
ADD{S}<c>.W <Rd>, SP, #<const>



```
if Rd == '1111' && S == '1' then SEE CMN (immediate);
d = UInt(Rd);  setflags = (S == '1');  imm32 = T32ExpandImm(i:imm3:imm8);
if d == 15 && S == '0' then UNPREDICTABLE;
```

Encoding T4

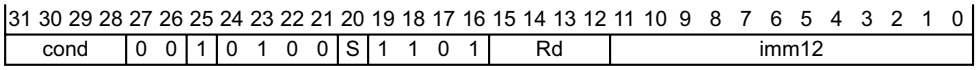
ADDW<c> <Rd>, SP, #<imm12>



```
d = UInt(Rd);  setflags = FALSE;  imm32 = ZeroExtend(i:imm3:imm8, 32);
if d == 15 then UNPREDICTABLE;
```

Encoding A1

ADD{S}<c> <Rd>, SP, #<const>



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  setflags = (S == '1');  imm32 = A32ExpandImm(imm12);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`ADD{S}{<c>}{<q>}  {<Rd>,} SP, #<const>`	All encodings permitted
`ADDW{<c>}{<q>}  {<Rd>,} SP, #<const>`	Only encoding T4 is permitted

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. If omitted, `<Rd>` is SP.

In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<const>` The immediate value to be added to the value obtained from SP. Values are multiples of 4 in the range 0-1020 for encoding T1, multiples of 4 in the range 0-508 for encoding T2 and any value in the range 0-4095 for encoding T4. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values for encodings T3 and A1.

When both 32-bit encodings are available for an instruction, encoding T3 is preferred to encoding T4.

Note

If encoding T4 is required, use the `ADDW` syntax.

The pre-UAL syntax `ADD<c>S` is equivalent to `ADDS<c>`.

Operation

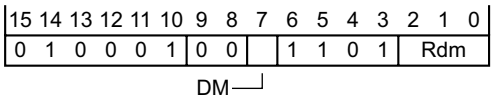
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(SP, imm32, '0');
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.10 ADD (SP plus register), T32

This instruction adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

Encoding T1

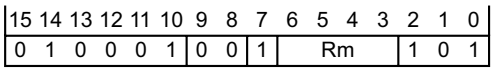
```
ADD<c> <Rdm>, SP, <Rdm>
```



```
d = UInt(DM:Rdm);  m = UInt(DM:Rdm);  setflags = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
if d == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T2

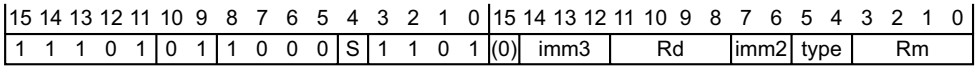
```
ADD<c> SP, <Rm>
```



```
if Rm == '1101' then SEE encoding T1;
d = 13;  m = UInt(Rm);  setflags = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T3

```
ADD{S}<c>.W <Rd>, SP, <Rm>{, <shift>}
```



```
if Rd == '1111' && S == '1' then SEE CMN (register);
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if (d == 15 && S == '0') || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ADD{S}{<c>}{<q>}  {<Rd>,} SP, <Rm>{, <shift>}
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page F2-2330.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *CMN (register)* on page F7-2506. This register can be SP. If omitted, <Rd> is SP. This register can be the PC, but if it is, encoding T3 is not permitted. ARM deprecates using the PC.

If <Rd> is the PC and S is not specified, encoding T1 is used and the instruction is a branch to the address calculated by the operation. This is a simple branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

<Rm> — The register that is optionally shifted and used as the second operand. This register can be the PC, but if it is, encoding T3 is not permitted. ARM deprecates using the PC. This register can be the SP, but:

- ARM deprecates using the SP.
- Only encoding T1 is available and so the instruction can only be ADD SP, SP, SP.

<shift> — The shift to apply to the value read from <Rm>. If omitted, no shift is applied and any encoding is permitted. If present, only encoding T3 is permitted. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

If <Rd> is SP or omitted, <shift> is only permitted to be omitted, LSL #1, LSL #2, or LSL #3.

The pre-UAL syntax ADD<c>S is equivalent to ADDS<c>.

Operation

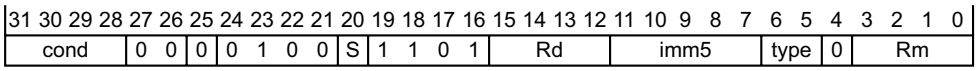
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(SP, shifted, '0');
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.11 ADD (SP plus register), A32

This instruction adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

Encoding A1

```
ADD{S}<c> <Rd>, SP, <Rm>{, <shift>}
```



31 30 29 28	27 26 25	24 23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8 7	6 5	4	3 2 1 0
cond	0 0 0	0 1 0 0	S	1 1 0 1	Rd	imm5	type	0	Rm

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
ADD{S}{<c>}{<q>}  {<Rd>,} SP, <Rm>{, <shift>}
```

where:

S
: If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q>
: See *Standard assembler syntax fields* on page F2-2330.

<Rd>
: The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions, A32* on page F7-3032. This register can be SP. If omitted, <Rd> is SP. This register can be the PC, but ARM deprecates using the PC.

  If S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

<Rm>
: The register that is optionally shifted and used as the second operand. This register can be the PC, but ARM deprecates using the PC. This register can be the SP, but ARM deprecates using the SP.

<shift>
: The shift to apply to the value read from <Rm>. If omitted, no shift is applied and any encoding is permitted. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

The pre-UAL syntax ADD<c>S is equivalent to ADDS<c>.

Operation

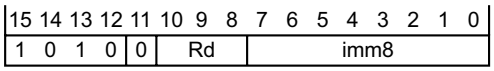
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(SP, shifted, '0');
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.12 ADR

This instruction adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

Encoding T1

```
ADR<c> <Rd>, <label>
```

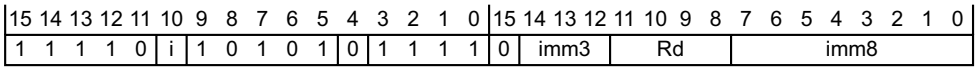


```
d = UInt(Rd);  imm32 = ZeroExtend(imm8:'00', 32);  add = TRUE;
```

Encoding T2

```
ADR<c>.W <Rd>, <label>
```
<label> before current instruction

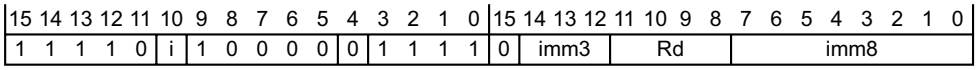
```
SUB <Rd>, PC, #0
```
Special case for subtraction of zero



```
d = UInt(Rd);  imm32 = ZeroExtend(i:imm3:imm8, 32);  add = FALSE;
if d == 15 then UNPREDICTABLE;     // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding T3

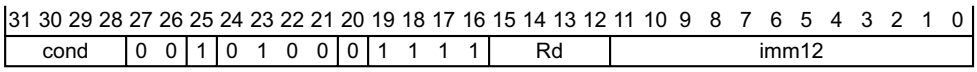
```
ADR<c>.W <Rd>, <label>
```
<label> after current instruction



```
d = UInt(Rd);  imm32 = ZeroExtend(i:imm3:imm8, 32);  add = TRUE;
if d == 15 then UNPREDICTABLE;   // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
ADR<c> <Rd>, <label>
```
<label> after current instruction

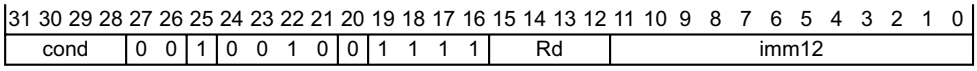


```
d = UInt(Rd);  imm32 = A32ExpandImm(imm12);  add = TRUE;
```

Encoding A2

```
ADR<c> <Rd>, <label>
```
<label> before current instruction

```
SUB <Rd>, PC, #0
```
Special case for subtraction of zero



```
d = UInt(Rd);  imm32 = A32ExpandImm(imm12);  add = FALSE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`ADR{<c>}{<q>} <Rd>, <label>`	Normal syntax
`ADD{<c>}{<q>} <Rd>, PC, #<const>`	Alternative for encodings T1, T3, A1
`SUB{<c>}{<q>} <Rd>, PC, #<const>`	Alternative for encoding T2, A2

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register. In A32 instructions, if `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<label>` The label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the `ADR` instruction to this label.

If the offset is zero or positive, encodings T1, T3, and A1 are permitted, with `imm32` equal to the offset.

If the offset is negative, encodings T2 and A2 are permitted, with `imm32` equal to the size of the offset. That is, the use of encoding T2 or A2 indicates that the required offset is minus the value of `imm32`.

Permitted values of the size of the offset are:

Encoding T1	Multiples of 4 in the range 0 to 1020.
Encodings T2, T3	Any value in the range 0 to 4095.
Encodings A1, A2	Any of the constants described in *Modified immediate constants in A32 instructions* on page F4-2387.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-2297.

Operation

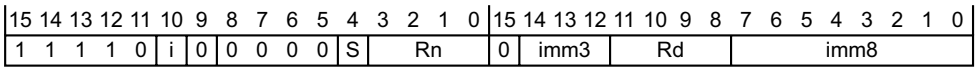
```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if d == 15 then          // Can only occur for A32 encodings
        ALUWritePC(result);
    else
        R[d] = result;
```

F7.1.13 AND (immediate)

This instruction performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

Encoding T1

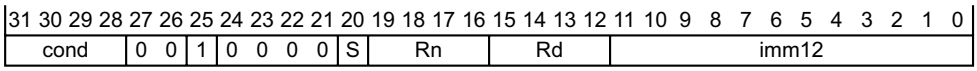
```
AND{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE TST (immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if (d == 15 && S == '0') || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
AND{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
AND{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
<Rn>	The first operand register. The PC can be used in A32 instructions.
<const>	The immediate value to be ANDed with the value obtained from <Rn>. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

The pre-UAL syntax AND<c>S is equivalent to ANDS<c>.

Operation

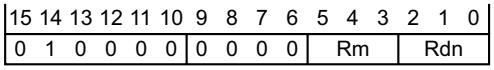
```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND imm32;
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

F7.1.14 AND (register)

This instruction performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

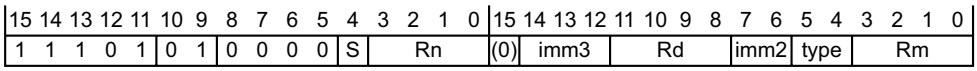
```
ANDS   <Rdn>, <Rm>          Outside IT block.
AND<c> <Rdn>, <Rm>          Inside IT block.
```



```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

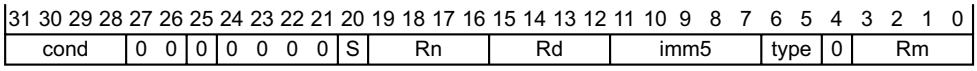
```
AND{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}
```



```
if Rd == '1111' && S == '1' then SEE TST (register);
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if (d == 15 && S == '0') || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
AND{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
AND{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page F2-2330.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032.

In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

<Rn> — The first operand register. The PC can be used in A32 instructions.

<Rm> — The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.

<shift> — The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

In T32 assembly:

- Outside an IT block, if `ANDS <Rd>, <Rn>, <Rd>` has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though `ANDS <Rd>, <Rn>` had been written.
- Inside an IT block, if `AND<c> <Rd>, <Rn>, <Rd>` has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though `AND<c> <Rd>, <Rn>` had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax `AND<c>S` is equivalent to `ANDS<c>`.

Operation

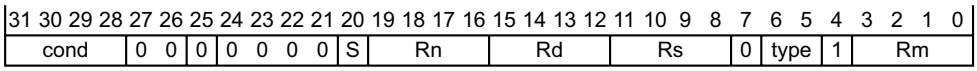
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

F7.1.15 AND (register-shifted register)

This instruction performs a bitwise AND of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding A1

```
AND{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
AND{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax `AND<c>S` is equivalent to `ANDS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

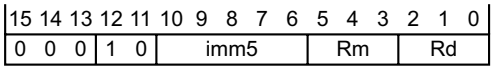
F7.1.16 ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

`ASRS <Rd>, <Rm>, #<imm>` Outside IT block.

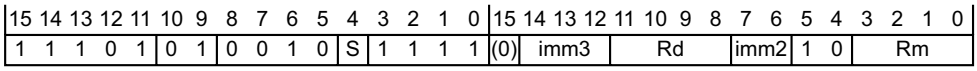
`ASR<c> <Rd>, <Rm>, #<imm>` Inside IT block.



```
d = UInt(Rd);  m = UInt(Rm);  setflags = !InITBlock();
(-, shift_n) = DecodeImmShift('10', imm5);
```

Encoding T2

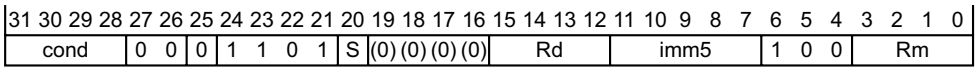
`ASR{S}<c>.W <Rd>, <Rm>, #<imm>`



```
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(-, shift_n) = DecodeImmShift('10', imm3:imm2);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`ASR{S}<c> <Rd>, <Rm>, #<imm>`



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(-, shift_n) = DecodeImmShift('10', imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ASR{S}{<c>}{<q>}  {<Rd>,} <Rm>, #<imm>
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register. In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
<Rm>	The first operand register. The PC can be used in A32 instructions.
<imm>	The shift amount, in the range 1 to 32. See *Shifts applied to a register* on page F2-2334.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry) = Shift_C(R[m], SRType_ASR, shift_n, PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

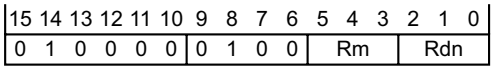
F7.1.17 ASR (register)

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register. It can optionally update the condition flags based on the result.

Encoding T1

`ASRS <Rdn>, <Rm>` Outside IT block.

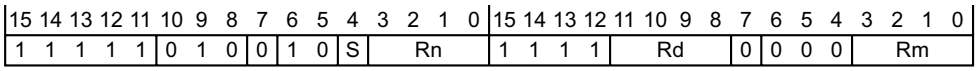
`ASR<c> <Rdn>, <Rm>` Inside IT block.



```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
```

Encoding T2

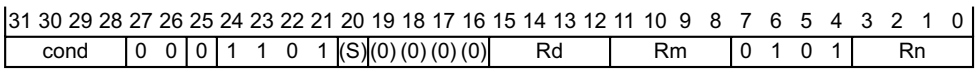
`ASR{S}<c>.W <Rd>, <Rn>, <Rm>`



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`ASR{S}<c> <Rd>, <Rn>, <Rm>`



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ASR{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The register whose bottom byte contains the amount to shift by.

Operation

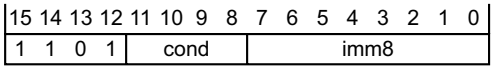
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[m]<7:0>);
    (result, carry) = Shift_C(R[n], SRType_ASR, shift_n, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

F7.1.18 B

Branch causes a branch to a target address.

Encoding T1

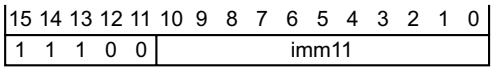
`B<c> <label>` Not permitted in IT block.



```
if cond == '1110' then SEE UDF;
if cond == '1111' then SEE SVC;
imm32 = SignExtend(imm8:'0', 32);
if InITBlock() then UNPREDICTABLE;
```

Encoding T2

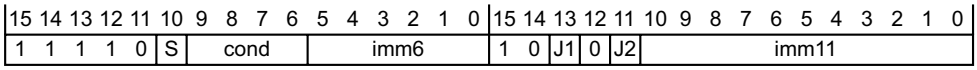
`B<c> <label>` Outside or last in IT block



```
imm32 = SignExtend(imm11:'0', 32);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T3

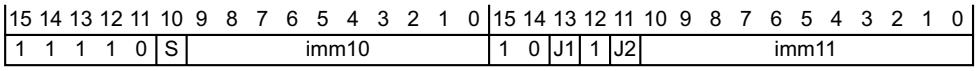
`B<c>.W <label>` Not permitted in IT block.



```
if cond<3:1> == '111' then SEE "Related encodings";
imm32 = SignExtend(S:J2:J1:imm6:imm11:'0', 32);
if InITBlock() then UNPREDICTABLE;
```

Encoding T4

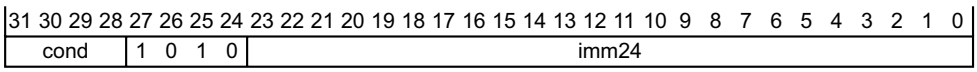
`B<c>.W <label>` Outside or last in IT block



```
I1 = NOT(J1 EOR S);  I2 = NOT(J2 EOR S);  imm32 = SignExtend(S:I1:I2:imm10:imm11:'0', 32);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1

`B<c> <label>`



```
imm32 = SignExtend(imm24:'00', 32);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings See *Branches and miscellaneous control* on page F3-2361.

Assembler syntax

```
B{<c>}{<q>}  <label>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

Note

Encodings T1 and T3 are conditional in their own right, and do not require an `IT` instruction to make them conditional.

For encodings T1 and T3, `<c>` must not be `AL` or omitted. The 4-bit encoding of the condition is placed in the instruction and not in a preceding `IT` instruction, and the instruction must not be in an IT block. As a result, encodings T1 and T2 are never both available to the assembler, nor are encodings T3 and T4.

`<label>` The label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the `B` instruction to this label, then selects an encoding that sets `imm32` to that offset.

Permitted offsets are:

Encoding T1	Even numbers in the range –256 to 254.
Encoding T2	Even numbers in the range –2048 to 2046.
Encoding T3	Even numbers in the range –1048576 to 1048574.
Encoding T4	Even numbers in the range –16777216 to 16777214.
Encoding A1	Multiples of 4 in the range –33554432 to 33554428.

Operation

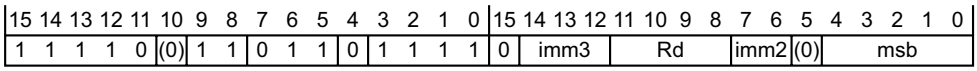
```
if ConditionPassed() then
    EncodingSpecificOperations();
    BranchWritePC(PC + imm32);
```

F7.1.19 BFC

Bit Field Clear clears any number of adjacent bits at any position in a register, without affecting the other bits in the register.

Encoding T1

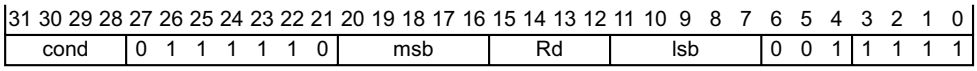
```
BFC<c> <Rd>, #<lsb>, #<width>
```



```
d = UInt(Rd);  msbit = UInt(msb);  lsbit = UInt(imm3:imm2);
if d == 15 then UNPREDICTABLE;  // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
BFC<c> <Rd>, #<lsb>, #<width>
```



```
d = UInt(Rd);  msbit = UInt(msb);  lsbit = UInt(lsb);
if d == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *BFC* on page AppxA-4793.

Assembler syntax

```
BFC{<c>}{<q>}  <Rd>, #<lsb>, #<width>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<lsb>` The least significant bit that is to be cleared, in the range 0 to 31. This determines the required value of `lsbit`.

`<width>` The number of bits to be cleared, in the range 1 to 32-`<lsb>`. The required value of `msbit` is `<lsb>+<width>-1`.

Operation

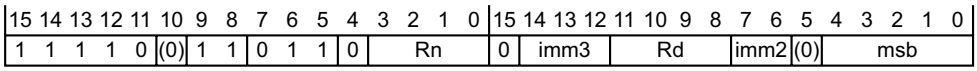
```
if ConditionPassed() then
    EncodingSpecificOperations();
    if msbit >= lsbit then
        R[d]<msbit:lsbit> = Replicate('0', msbit-lsbit+1);
        // Other bits of R[d] are unchanged
    else
        UNPREDICTABLE;
```

F7.1.20 BFI

Bit Field Insert copies any number of low order bits from a register into the same number of adjacent bits at any position in the destination register.

Encoding T1

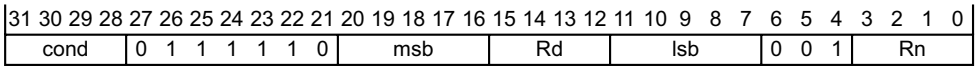
```
BFI<c> <Rd>, <Rn>, #<lsb>, #<width>
```



```
if Rn == '1111' then SEE BFC;
d = UInt(Rd);  n = UInt(Rn);  msbit = UInt(msb);  lsbit = UInt(imm3:imm2);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
BFI<c> <Rd>, <Rn>, #<lsb>, #<width>
```



```
if Rn == '1111' then SEE BFC;
d = UInt(Rd);  n = UInt(Rn);  msbit = UInt(msb);  lsbit = UInt(lsb);
if d == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *BFI* on page AppxA-4793.

Assembler syntax

```
BFI{<c>}{<q>}  <Rd>, <Rn>, #<lsb>, #<width>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The source register.

`<lsb>` The least significant destination bit, in the range 0 to 31. This determines the required value of `lsbit`.

`<width>` The number of bits to be copied, in the range 1 to 32-`<lsb>`. The required value of `msbit` is `<lsb>+<width>-1`.

Operation

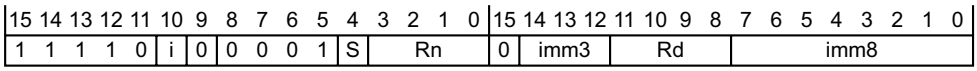
```
if ConditionPassed() then
    EncodingSpecificOperations();
    if msbit >= lsbit then
        R[d]<msbit:lsbit> = R[n]<(msbit-lsbit):0>;
        // Other bits of R[d] are unchanged
    else
        UNPREDICTABLE;
```

F7.1.21 BIC (immediate)

Bitwise Bit Clear (immediate) performs a bitwise AND of a register value and the complement of an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

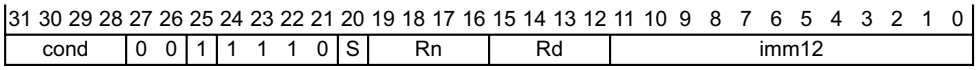
```
BIC{S}<c> <Rd>, <Rn>, #<const>
```



```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 || n == 15 then UNPREDICTABLE;  // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
BIC{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
BIC{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
<Rn>	The register that contains the operand. The PC can be used in A32 instructions.
<const>	The immediate value to be bitwise inverted and ANDed with the value obtained from <Rn>. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

The pre-UAL syntax BIC<c>S is equivalent to BICS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND NOT(imm32);
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

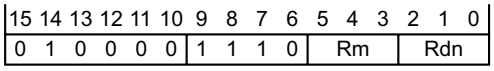
F7.1.22 BIC (register)

Bitwise Bit Clear (register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

`BICS <Rdn>, <Rm>` Outside IT block.

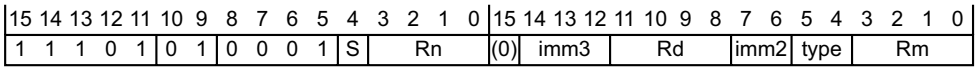
`BIC<c> <Rdn>, <Rm>` Inside IT block.



```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

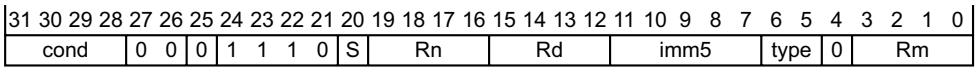
`BIC{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}`



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;  // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`BIC{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}`



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
BIC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
`<Rn>`	The first operand register. The PC can be used in A32 instructions.
`<Rm>`	The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.
`<shift>`	The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

The pre-UAL syntax `BIC<c>S` is equivalent to `BICS<c>`.

Operation

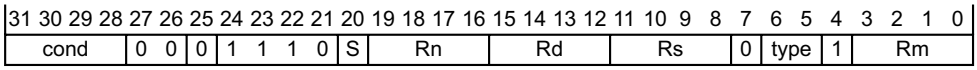
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND NOT(shifted);
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

F7.1.23 BIC (register-shifted register)

Bitwise Bit Clear (register-shifted register) performs a bitwise AND of a register value and the complement of a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding A1

```
BIC{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
BIC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax `BIC<c>S` is equivalent to `BICS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND NOT(shifted);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

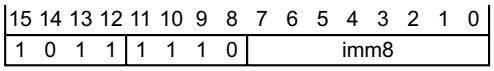
F7.1.24 BKPT

Breakpoint causes a software breakpoint to occur.

Breakpoint is always unconditional, even when inside an IT block.

Encoding T1

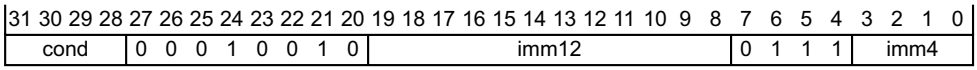
```
BKPT #<imm8>
```



```
imm16 = ZeroExtend(imm8, 16);
```

Encoding A1

```
BKPT #<imm16>
```



```
imm16 = imm12:imm4;
if cond != '1110' then UNPREDICTABLE;  // BKPT must be encoded with AL condition
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *BKPT* on page AppxA-4793.

Assembler syntax

```
BKPT{<q>}  {#}<imm>
```

where:

<q> See *Standard assembler syntax fields* on page F2-2330. A BKPT instruction must be unconditional.

<imm> Specifies a value that is stored in the instruction, in the range 0-255 for a T32 instruction or 0-65535 for an A32 instruction. This value is ignored by the PE, but can be used by a debugger to store more information about the breakpoint.

Operation

```
EncodingSpecificOperations();
AArch32.BKPTInstrDebugEvent(imm16);
```

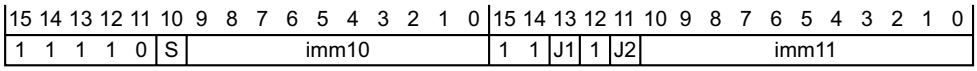
F7.1.25 BL, BLX (immediate)

Branch with Link calls a subroutine at a PC-relative address.

Branch with Link and Exchange Instruction Sets (immediate) calls a subroutine at a PC-relative address, and changes instruction set from A32 to T32, or from T32 to A32.

Encoding T1

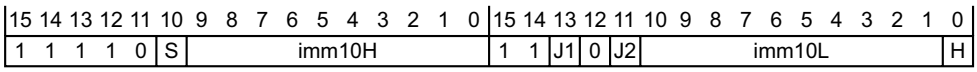
```
BL<c> <label>                                                    Outside or last in IT block
```



```
I1 = NOT(J1 EOR S);  I2 = NOT(J2 EOR S);  imm32 = SignExtend(S:I1:I2:imm10:imm11:'0', 32);
targetInstrSet = CurrentInstrSet();
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T2

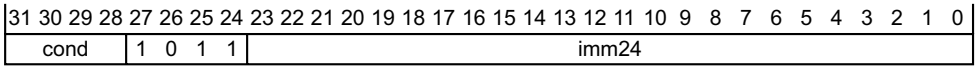
```
BLX<c> <label>                                                   Outside or last in IT block
```



```
if H == '1' then UNDEFINED;
I1 = NOT(J1 EOR S);  I2 = NOT(J2 EOR S);  imm32 = SignExtend(S:I1:I2:imm10H:imm10L:'00', 32);
targetInstrSet = InstrSet_A32;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1

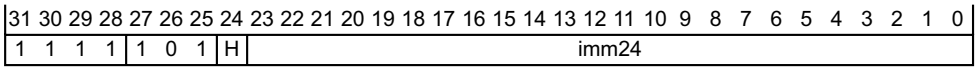
```
BL<c> <label>
```



```
imm32 = SignExtend(imm24:'00', 32);  targetInstrSet = InstrSet_A32;
```

Encoding A2

```
BLX <label>
```



```
imm32 = SignExtend(imm24:H:'0', 32);  targetInstrSet = InstrSet_T32;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
BL{X}{<c>}{<q>}  <label>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `BLX` (immediate) instruction must be unconditional.

`X` If present, specifies a change of instruction set (from A32 to T32 or from T32 to A32). If X is omitted, the PE remains in the same state.

`<label>` The label of the instruction that is to be branched to.

`BL` uses encoding T1 or A1. The assembler calculates the required value of the offset from the PC value of the `BL` instruction to this label, then selects an encoding with `imm32` set to that offset.

`BLX` uses encoding T2 or A2. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the `BLX` instruction to this label, then selects an encoding with `imm32` set to that offset.

Permitted offsets are:

Encoding T1 Even numbers in the range –16777216 to 16777214.

Encoding T2 Multiples of 4 in the range –16777216 to 16777212.

Encoding A1 Multiples of 4 in the range –33554432 to 33554428.

Encoding A2 Even numbers in the range –33554432 to 33554430.

Operation

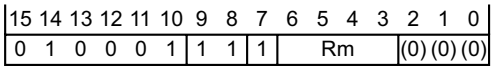
```
if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentInstrSet() == InstrSet_A32 then
        LR = PC - 4;
    else
        LR = PC<31:1> : '1';
    if targetInstrSet == InstrSet_A32 then
        targetAddress = Align(PC,4) + imm32;
    else
        targetAddress = PC + imm32;
    SelectInstrSet(targetInstrSet);
    BranchWritePC(targetAddress);
```

F7.1.26 BLX (register)

Branch with Link and Exchange (register) calls a subroutine at an address and instruction set specified by a register.

Encoding T1

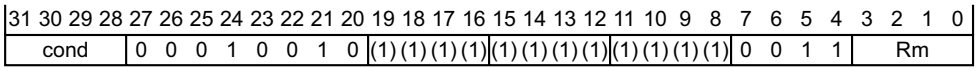
`BLX<c> <Rm>` Outside or last in IT block



```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1

`BLX<c> <Rm>`



```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`BLX{<c>}{<q>}  <Rm>`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rm>` The register that contains the branch target address and instruction set selection bit. This register can be the SP in both A32 and T32 instructions, but ARM deprecates this use of the SP.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    target = R[m];
    if CurrentInstrSet() == InstrSet_A32 then
        next_instr_addr = PC - 4;
        LR = next_instr_addr;
    else
        next_instr_addr = PC - 2;
        LR = next_instr_addr<31:1> : '1';
    BXWritePC(target);
```

F7.1.27 BX

Branch and Exchange causes a branch to an address and instruction set specified by a register.

Encoding T1

`BX<c> <Rm>` Outside or last in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	1	1	1	0	Rm				(0)	(0)	(0)

```
m = UInt(Rm);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1

`BX<c> <Rm>`

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	0	0	1	0	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	0	0	0	1	Rm			

```
m = UInt(Rm);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`BX{<c>}{<q>}  <Rm>`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rm>` The register that contains the branch target address and instruction set selection bit.This can be the PC. This register can be the SP in both A32 and T32 instructions, but ARM deprecates this use of the SP.

Note

If `<Rm>` is the PC in a T32 instruction at a non word-aligned address, it results in UNPREDICTABLE behavior because the address passed to the `BXWritePC()` pseudocode function has bits<1:0> = '10'.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BXWritePC(R[m]);
```

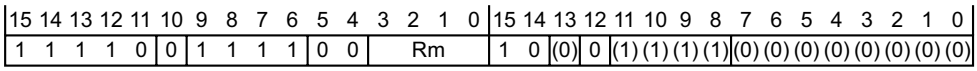
F7.1.28 BXJ

In ARMv8, BXJ behaves as a BX instruction, see *BX* on page F7-2497. This means it causes a branch to an address and instruction set specified by a register.

Encoding T1

BXJ<c> <Rm>

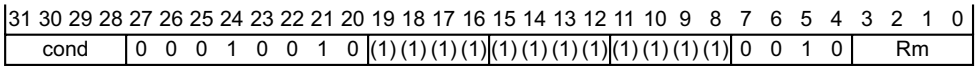
Outside or last in IT block



```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;  // ARMv8-A removes UNPREDICTABLE for R13
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1

BXJ<c> <Rm>



```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

BXJ{<c>}{<q>} <Rm>

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2330.

<Rm> The register that specifies the branch target address and instruction set selection bit.

Operation

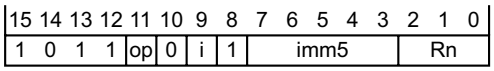
```
if ConditionPassed() then
    EncodingSpecificOperations();
    BXWritePC(R[m]);
```

F7.1.29 CBNZ, CBZ

Compare and Branch on Nonzero and Compare and Branch on Zero compare the value in a register with zero, and conditionally branch forward a constant value. They do not affect the condition flags.

Encoding T1

`CB{N}Z <Rn>, <label>` Not permitted in IT block.



```
n = UInt(Rn);  imm32 = ZeroExtend(i:imm5:'0', 32);  nonzero = (op == '1');
if InITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`CB{N}Z{<q>}  <Rn>, <label>`

where:

`N` If specified, causes the branch to occur when the contents of `<Rn>` are nonzero (encoded as op = 1). If omitted, causes the branch to occur when the contents of `<Rn>` are zero (encoded as op = 0).

`<q>` See *Standard assembler syntax fields* on page F2-2330. A `CBZ` or `CBNZ` instruction must be unconditional.

`<Rn>` The operand register.

`<label>` The label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the `CBZ` or `CBNZ` instruction to this label, then selects an encoding that sets `imm32` to that offset. Permitted offsets are even numbers in the range 0 to 126.

Operation

```
EncodingSpecificOperations();
if nonzero != IsZero(R[n]) then
    BranchWritePC(PC + imm32);
```

F7.1.30 CDP, CDP2

Coprocessor Data Processing is a generic coprocessor instruction. None of the fields have any functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1`, `opc2`, `CRd`, `CRn`, and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid `CDP` and `CDP2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page E1-2244.

Encoding T1/A1

```
CDP<c> <coproc>, <opc1>, <CRd>, <CRn>, <CRm>, <opc2>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	1	0	opc1				CRn				CRd				coproc				opc2			0	CRm			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	1	1	0	opc1				CRn				CRd				coproc				opc2			0	CRm			

```
if coproc == '101x' then SEE "Floating-point instructions";
cp = UInt(coproc);
```

Encoding T2/A2

```
CDP2<c> <coproc>, <opc1>, <CRd>, <CRn>, <CRm>, <opc2>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	0	opc1				CRn				CRd				coproc				opc2			0	CRm			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	0	opc1				CRn				CRd				coproc				opc2			0	CRm			

```
if coproc == '101x' then SEE "Floating-point instructions";
cp = UInt(coproc);
```

Floating-point instructions See *Floating-point data-processing instructions* on page F5-2427

Assembler syntax

```
CDP{2}{<c>}{<q>}  <coproc>, {#}<opc1>, <CRd>, <CRn>, <CRm> {, {#}<opc2>}
```

where:

`2`	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330. An A32 `CDP2` instruction must be unconditional.
`<coproc>`	The name of the coprocessor, and causes the corresponding coprocessor number to be placed in the cp_num field of the instruction. The generic coprocessor names are p0-p15.
`<opc1>`	Is a coprocessor-specific opcode, in the range 0 to 15.
`<CRd>`	The destination coprocessor register for the instruction.
`<CRn>`	The coprocessor register that contains the first operand.
`<CRm>`	The coprocessor register that contains the second operand.
`<opc2>`	Is a coprocessor-specific opcode in the range 0 to 7. If it is omitted, `<opc2>` is 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        Coproc_InternalOperation(cp, ThisInstr());
```

F7.1.31 CLREX

Clear-Exclusive clears the local monitor of the executing PE.

Encoding T1

CLREX<c>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	1	(1)	(1)	(1)	(1)	1	0	(0)	0	(1)	(1)	(1)	(1)	0	0	1	0	(1)	(1)	(1)	(1)

```
// No additional decoding required
```

Encoding A1

CLREX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	1	0	1	1	1	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	0	0	1	(1)	(1)	(1)	(1)

```
// No additional decoding required
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

CLREX{<c>}{<q>}

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2330. An A32 CLREX instruction must be unconditional.

Operation

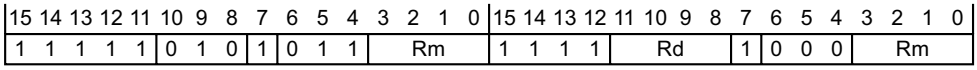
```
if ConditionPassed() then
    EncodingSpecificOperations();
    ClearExclusiveLocal(ProcessorID());
```

F7.1.32 CLZ

Count Leading Zeros returns the number of binary zero bits before the first binary one bit in a value.

Encoding T1

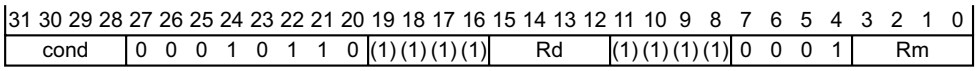
```
CLZ<c> <Rd>, <Rm>
```



```
if !Consistent(Rm) then UNPREDICTABLE;
d = UInt(Rd);  m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
CLZ<c> <Rd>, <Rm>
```



```
d = UInt(Rd);  m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *CLZ* on page AppxA-4793.

Assembler syntax

```
CLZ{<c>}{<q>}  <Rd>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rm>` The register that contains the operand. Its number must be encoded twice in encoding T1.

Operation

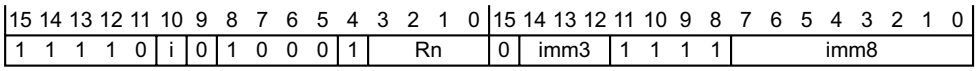
```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = CountLeadingZeroBits(R[m]);
    R[d] = result<31:0>;
```

F7.1.33 CMN (immediate)

Compare Negative (immediate) adds a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

Encoding T1

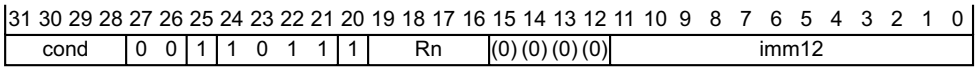
```
CMN<c> <Rn>, #<const>
```



```
n = UInt(Rn);  imm32 = T32ExpandImm(i:imm3:imm8);
if n == 15 then UNPREDICTABLE;
```

Encoding A1

```
CMN<c> <Rn>, #<const>
```



```
n = UInt(Rn);  imm32 = A32ExpandImm(imm12);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
CMN{<c>}{<q>}  <Rn>, #<const>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The register that contains the operand. SP can be used in T32 and A32 instructions. The PC can be used in A32 instructions.

`<const>` The immediate value to be added to the value obtained from `<Rn>`. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

Operation

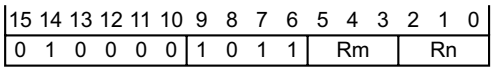
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], imm32, '0');
    PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.34 CMN (register)

Compare Negative (register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

Encoding T1

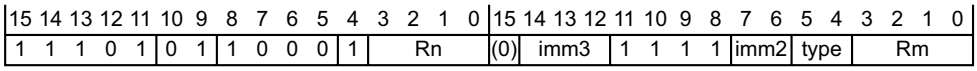
```
CMN<c> <Rn>, <Rm>
```



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

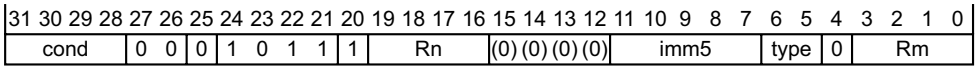
```
CMN<c>.W  <Rn>, <Rm>{, <shift>}
```



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
CMN<c> <Rn>, <Rm>{, <shift>}
```



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
CMN{<c>}{<q>}  <Rn>, <Rm> {, <shift>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The first operand register. SP can be used in T32 instructions (encoding T2) and in A32 instructions. The PC can be used in A32 instructions.

`<Rm>` The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

Operation

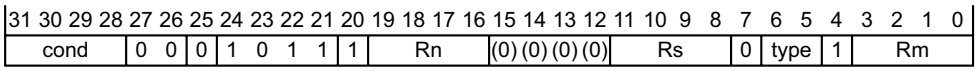
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.35 CMN (register-shifted register)

Compare Negative (register-shifted register) adds a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

Encoding A1

```
CMN<c> <Rn>, <Rm>, <type> <Rs>
```



```
n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
CMN{<c>}{<q>}  <Rn>, <Rm>, <type>  <Rs>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

Operation

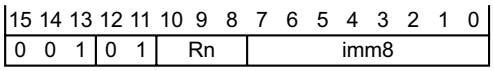
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.36 CMP (immediate)

Compare (immediate) subtracts an immediate value from a register value. It updates the condition flags based on the result, and discards the result.

Encoding T1

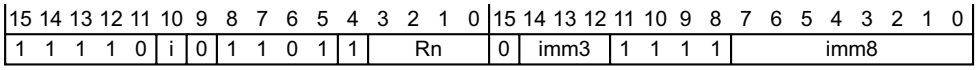
CMP<c> <Rn>, #<imm8>



```
n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
```

Encoding T2

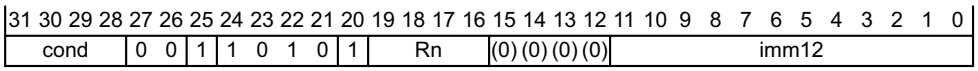
CMP<c>.W <Rn>, #<const>



```
n = UInt(Rn);  imm32 = T32ExpandImm(i:imm3:imm8);
if n == 15 then UNPREDICTABLE;
```

Encoding A1

CMP<c> <Rn>, #<const>



```
n = UInt(Rn);  imm32 = A32ExpandImm(imm12);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
CMP{<c>}{<q>}  <Rn>, #<const>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The first operand register. SP can be used in T32 instructions (encoding T2) and in A32 instructions. The PC can be used in A32 instructions.

`<const>` The immediate value to be compared with the value obtained from `<Rn>`. The range of values is 0-255 for encoding T1. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values for encoding T2 and A1.

Operation

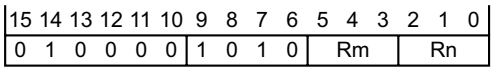
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], NOT(imm32), '1');
    PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.37 CMP (register)

Compare (register) subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

Encoding T1

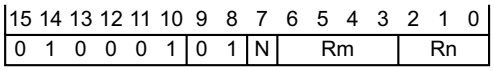
`CMP<c> <Rn>, <Rm>` — `<Rn>` and `<Rm>` both from R0-R7



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

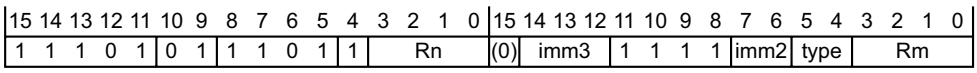
`CMP<c> <Rn>, <Rm>` — `<Rn>` and `<Rm>` not both from R0-R7



```
n = UInt(N:Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, 0);
if n < 8 && m < 8 then UNPREDICTABLE;
if n == 15 || m == 15 then UNPREDICTABLE;
```

Encoding T3

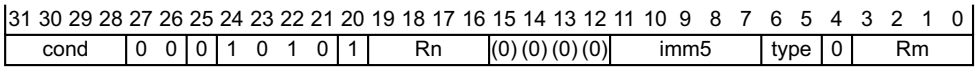
`CMP<c>.W <Rn>, <Rm> {, <shift>}`



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`CMP<c> <Rn>, <Rm>{, <shift>}`



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *CMP (register)* on page AppxA-4794.

Assembler syntax

```
CMP{<c>}{<q>}  <Rn>, <Rm> {, <shift>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The first operand register. The SP can be used. The PC can be used in A32 instructions.

`<Rm>` The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.The SP can be used in both A32 and T32 instructions, but:

- ARM deprecates the use of SP.
- When assembling for the T32 instruction set, only encoding T2 is available.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encodings T1 and T2 are not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

Operation

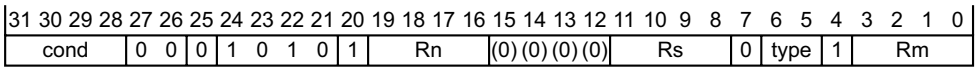
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
    PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.38 CMP (register-shifted register)

Compare (register-shifted register) subtracts a register-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

Encoding A1

```
CMP<c> <Rn>, <Rm>, <type> <Rs>
```



```
n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
CMP{<c>}{<q>}  <Rn>, <Rm>, <type>  <Rs>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
    PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.39 CPS

Change PE State is a system instruction, see *CPS, T32* on page F7-2998 and *CPS, A32* on page F7-3000.

F7.1.40 CPY

Copy is a pre-UAL synonym for `MOV` (register). See *MOV (register), T32* on page F7-2641 and *MOV (register), A32* on page F7-2643.

Assembler syntax

```
CPY  <Rd>, <Rn>
```

This is equivalent to:

```
MOV  <Rd>, <Rn>
```

F7.1.41 CRC32, CRC32C

CRC32 performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It is an OPTIONAL instruction. It performs a CRC on an input value that can be 8, 16, or 32 bits, taking an input CRC value from a second register, and returning the output CRC value to the that supplied the input CRC. To align with common usage, the bit order of the values is reversed as part of the operation, and:

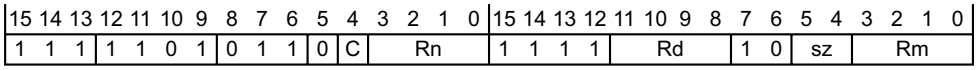
- The CRC32 form of the instruction uses the polynomial 0x04C11DB7 for the CRC calculation.
- The CRC32C form of the instruction uses the polynomial 0x1EDC6F41 for the CRC calculation.

Note

ID_ISAR5.CRC32 indicates whether this instruction is supported in the T32 and A32 instruction sets.

Encoding T1

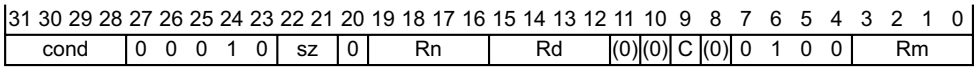
CRC32{C}<y> Rd, Rn, Rm



```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
size = 8 << UInt(sz);
crc32c = (C == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if size == 64 then UNPREDICTABLE;
if InITBlock() then UNPREDICTABLE;
```

Encoding A1

CRC32{C}<y><c> Rd, Rn, Rm



```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
size = 8 << UInt(sz);
crc32c = (C == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if size == 64 then UNPREDICTABLE;
if cond != '1110' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *CRC32, CRC32C* on page AppxA-4794.

Assembler syntax

```
CRC32{C}<y><c> Rd, Rn, Rm
```

where:

`C` Specified the polynomial to be used for the CRC calculation:
- If `C` is omitted, the calculation uses the polynomial `0x04C11DB7`.
- If `C` is included, the calculation uses the polynomial `0x1EDC6F41`.

`<y>` Is one of:

`B` Specifies that the instruction takes a byte of new data, encoded as `sz = '00'`.

`H` Specifies that the instruction takes a halfword of new data, encoded as `sz = '01'`.

`H` Specifies that the instruction takes a word of new data, encoded as `sz = '10'`.

`<c>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register for the output CRC value.

`<Rn>` The first operand register, that holds the input CRC value.

`<Rm>` The second operand register, that holds the data that the CRC is to be performed on.

Operation

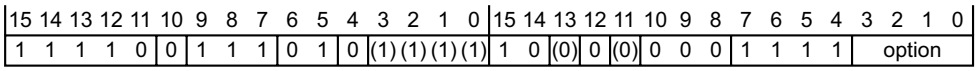
```
if ConditionPassed() then
    EncodingSpecificOperations();
    acc = R[n];             // accumulator
    val = R[m]<size-1:0>;   // input value
    poly = (if crc32c then 0x1EDC6F41 else 0x04C11DB7)<31:0>;
    tempacc = BitReverse(acc):Zeros(size);
    tempval = BitReverse(val):Zeros(32);
    // Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
    R[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

F7.1.42 DBG

Debug Hint provides a hint to debug and related systems. See the system documentation for what use (if any) is made of this instruction.

Encoding T1

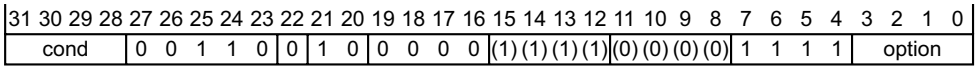
```
DBG<c> #<option>
```



```
// Any decoding of 'option' is specified by the debug system
```

Encoding A1

```
DBG<c> #<option>
```



```
// Any decoding of 'option' is specified by the debug system
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
DBG{<c>}{<q>}  #<option>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<option>` Provides extra information about the hint, and is in the range 0 to 15.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    Hint_Debug(option);
```

F7.1.43 DCPS1, DCPS2, DCPS3

DCPSx allows the debugger to move the PE into a higher Exception Level or to a specific mode at the current Exception Level.

DCPSx is always UNDEFINED in Non-debug state.

For more information on the operation of DCPSx, see *DCPS* on page H2-4422.

Encoding T1

DCPS<opt>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	1	1	1	0	0	0	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	opt	

```
if !Halted() || opt == '00' then UNDEFINED;
```

Assembler syntax

DCPS<opt>

where:

<opt> Specifies the target Exception Level and the mode the PE enters.

Is one of:

1 The target Exception Level is EL1 and:

- If EL1 is using AArch32, the PE enters SVC mode.

  Note

  If EL3 is using AArch32, Secure SVC mode is an EL3 mode. This means DCPS1 causes the PE to enter EL3.

- If EL1 is using AArch64, the PE enters EL1h, and executes future instructions as A64 instructions.

Encoded as opt = 01.

2 The target Exception Level is EL2 and:

- If EL2 is using AArch32, the PE enters Hyp mode.
- If EL2 is using AArch64, the PE enters EL2h, and executes future instructions as A64 instructions.

Encoded as opt = 10.

3 The target Exception Level is EL3 and:

- If EL3 is using AArch32, the PE enters Monitor mode.
- If EL3 is using AArch64, the PE enters EL3h, and executes future instructions as A64 instructions.

Encoded as opt = 11.

Operation

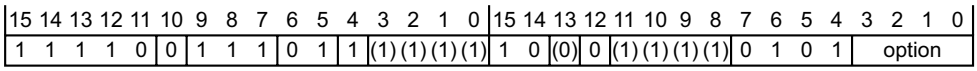
```
DCPSInstruction(opt);
```

F7.1.44 DMB

Data Memory Barrier is a memory barrier that ensures the ordering of observations of memory accesses, see *Data Memory Barrier (DMB)* on page E2-2269.

Encoding T1

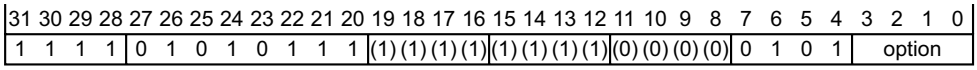
`DMB<c> <option>`



```
// No additional decoding required
```

Encoding A1

`DMB <option>`



```
// No additional decoding required
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`DMB{<c>}{<q>}  {<option>}`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `DMB` instruction must be unconditional.

`<option>` Specifies an optional limitation on the DMB operation. Values are:

- `SY` Full system is the required shareability domain, reads and writes are the required access types. Can be omitted.
  This option is referred to as the full system DMB. Encoded as option = `0b1111`.
- `ST` Full system is the required shareability domain, writes are the required access type. `SYST` is a synonym for `ST`. Encoded as option = `0b1110`.
- `LD` Full system is the required shareability domain, reads are the required access type. Encoded as option = `0b1101`.
- `ISH` Inner Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = `0b1011`.
- `ISHST` Inner Shareable is the required shareability domain, writes are the required access type. Encoded as option = `0b1010`.
- `ISHLD` Inner Shareable is the required shareability domain, reads are the required access type. Encoded as option = `0b1001`.
- `NSH` Non-shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = `0b0111`.
- `NSHST` Non-shareable is the required shareability domain, writes are the required access type. Encoded as option = `0b0110`.
- `NSHLD` Non-shareable is the required shareability domain, reads are the required access type. Encoded as option = `0b0101`.
- `OSH` Outer Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = `0b0011`.

OSHST Outer Shareable is the required shareability domain, writes are the required access type. Encoded as option = 0b0010.

OSHLD Outer Shareable is the required shareability domain, reads are the required access type. Encoded as option = 0b0001.

All other encodings of option are reserved. It is IMPLEMENTATION DEFINED whether options other than SY are implemented. All unsupported and reserved options must execute as a full system DMB operation, but software must not rely on this behavior.

Note

The instruction supports the following alternative <option> values, but ARM recommends that software does not use these alternative values:

- SH as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST is an alias for NSHST.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    case option of
        when '0001'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_Reads;
        when '0010'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_Writes;
        when '0011'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_All;
        when '0101'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_Reads;
        when '0110'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_Writes;
        when '0111'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_All;
        when '1001'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_Reads;
        when '1010'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_Writes;
        when '1011'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_All;
        when '1101'  domain = MBReqDomain_FullSystem;      types = MBReqTypes_Reads;
        when '1110'  domain = MBReqDomain_FullSystem;      types = MBReqTypes_Writes;
        otherwise    domain = MBReqDomain_FullSystem;      types = MBReqTypes_All;

    if HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} then
        if HCR.BSU == '11' then
            domain = MBReqDomain_FullSystem;
        if HCR.BSU == '10' && domain != MBReqDomain_FullSystem then
            domain = MBReqDomain_OuterShareable;
        if HCR.BSU == '01' && domain == MBReqDomain_Nonshareable then
            domain = MBReqDomain_InnerShareable;

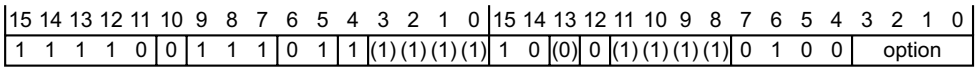
    DataMemoryBarrier(domain, types);
```

F7.1.45 DSB

Data Synchronization Barrier is a memory barrier that ensures the completion of memory accesses, see *Data Synchronization Barrier (DSB)* on page E2-2270.

Encoding T1

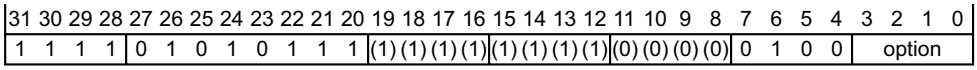
`DSB<c> <option>`



```
// No additional decoding required
```

Encoding A1

`DSB <option>`



```
// No additional decoding required
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`DSB{<c>}{<q>}  {<option>}`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `DSB` instruction must be unconditional.

`<option>` Specifies an optional limitation on the DSB operation. Values are:

- `SY` Full system is the required shareability domain, reads and writes are the required access types. Can be omitted.
  This option is referred to as the full system DSB. Encoded as option = `0b1111`.
- `ST` Full system is the required shareability domain, writes are the required access type. `SYST` is a synonym for `ST`. Encoded as option = `0b1110`.
- `LD` Full system is the required shareability domain, reads are the required access type. Encoded as option = `0b1101`.
- `ISH` Inner Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = `0b1011`.
- `ISHST` Inner Shareable is the required shareability domain, writes are the required access type. Encoded as option = `0b1010`.
- `ISHLD` Inner Shareable is the required shareability domain, reads are the required access type. Encoded as option = `0b1001`.
- `NSH` Non-shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = `0b0111`.
- `NSHST` Non-shareable is the required shareability domain, writes are the required access type. Encoded as option = `0b0110`.
- `NSHLD` Non-shareable is the required shareability domain, reads are the required access type. Encoded as option = `0b0101`.
- `OSH` Outer Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = `0b0011`.

OSHST Outer Shareable is the required shareability domain, writes are the required access type. Encoded as option = 0b0010.

OSHLD Outer Shareable is the required shareability domain, reads are the required access type. Encoded as option = 0b0001.

All other encodings of option are reserved. It is IMPLEMENTATION DEFINED whether options other than SY are implemented. All unsupported and reserved options must execute as a full system DSB operation, but software must not rely on this behavior.

Note

The instruction supports the following alternative <option> values, but ARM recommends that software does not use these alternative values:

- SH as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST is an alias for NSHST.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    case option of
        when '0001'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_Reads;
        when '0010'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_Writes;
        when '0011'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_All;
        when '0101'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_Reads;
        when '0110'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_Writes;
        when '0111'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_All;
        when '1001'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_Reads;
        when '1010'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_Writes;
        when '1011'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_All;
        when '1101'  domain = MBReqDomain_FullSystem;      types = MBReqTypes_Reads;
        when '1110'  domain = MBReqDomain_FullSystem;      types = MBReqTypes_Writes;
        otherwise    domain = MBReqDomain_FullSystem;      types = MBReqTypes_All;

    if HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1}  then
        if HCR.BSU == '11' then
            domain = MBReqDomain_FullSystem;
        if HCR.BSU == '10' && domain != MBReqDomain_FullSystem then
            domain = MBReqDomain_OuterShareable;
        if HCR.BSU == '01' && domain == MBReqDomain_Nonshareable then
            domain = MBReqDomain_InnerShareable;

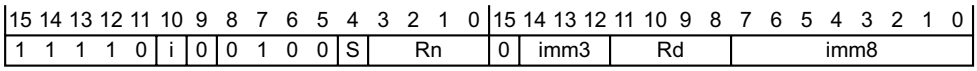
    DataSynchronizationBarrier(domain, types);
```

F7.1.46 EOR (immediate)

Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

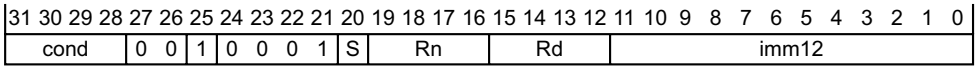
```
EOR{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE TEQ (immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if (d == 15 && S == '0') || n == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
EOR{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
EOR{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S
: If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q>
: See *Standard assembler syntax fields* on page F2-2330.

<Rd>
: The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032.

  In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

<Rn>
: The register that contains the operand. The PC can be used in A32 instructions.

<const>
: The immediate value to be exclusive ORed with the value obtained from <Rn>. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

The pre-UAL syntax EOR<c>S is equivalent to EORS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] EOR imm32;
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

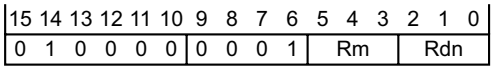
F7.1.47 EOR (register)

Bitwise Exclusive OR (register) performs a bitwise Exclusive OR of a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

`EORS <Rdn>, <Rm>` Outside IT block.

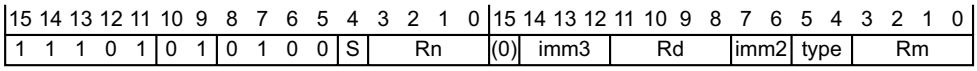
`EOR<c> <Rdn>, <Rm>` Inside IT block.



```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

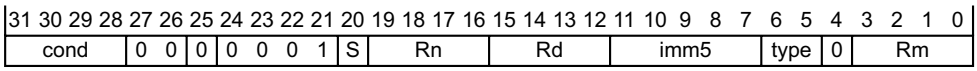
`EOR{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}`



```
if Rd == '1111' && S == '1' then SEE TEQ (register);
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if (d == 15 && S == '0') || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`EOR{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}`



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`EOR{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}`

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032.

In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<Rn>` The first operand register. The PC can be used in A32 instructions.

`<Rm>` The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted.*Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

In T32 assembly:

- Outside an IT block, if `EORS <Rd>, <Rn>, <Rd>` has `<Rd>` and `<Rn>` both in the range R0-R7, it is assembled using encoding T1 as though `EORS <Rd>, <Rn>` had been written
- Inside an IT block, if `EOR<c> <Rd>, <Rn>, <Rd>` has `<Rd>` and `<Rn>` both in the range R0-R7, it is assembled using encoding T1 as though `EOR<c> <Rd>, <Rn>` had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax `EOR<c>S` is equivalent to `EORS<c>`.

Operation

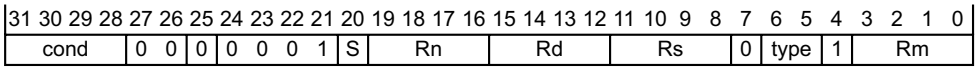
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

F7.1.48 EOR (register-shifted register)

Bitwise Exclusive OR (register-shifted register) performs a bitwise Exclusive OR of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding A1

```
EOR{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
EOR{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax `EOR<c>S` is equivalent to `EORS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

F7.1.49 ERET

Exception Return is a system instruction, see *ERET* on page F7-3002.

F7.1.50 HLT

Halting breakpoint causes a software breakpoint to occur.

Halting breakpoint is always unconditional, even inside an IT block.

Encoding T1

```
HLT #<imm6>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	0	1	0	1	0	imm6					

```
if EDSCR.HDE == '0' || !HaltingAllowed() then UNDEFINED;
// imm6 is for assembly/disassembly only and ignored by hardware
```

Encoding A1

```
HLT #<imm16>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	0	0	0	0	imm12												0	1	1	1	imm4			

```
if EDSCR.HDE == '0' || !HaltingAllowed() then UNDEFINED;
if cond != '1110' then UNPREDICTABLE; // HLT must be encoded with AL condition
// imm12:imm4 are for assembly/disassembly only and ignored by hardware
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *HLT* on page AppxA-4794.

Assembler syntax

```
HLT{<q>}  {#}<imm>
```

where:

<q> See *Standard assembler syntax fields* on page F2-2330. An HLT instruction must be unconditional.

<imm> Specifies a value that is stored in the instruction, in the range 0-63 for a T32 instruction or 0-65535 for an A32 instruction. This value is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

Operation

```
EncodingSpecificOperations();
Halt(DebugHalt_HaltInstruction);
```

F7.1.51 HVC

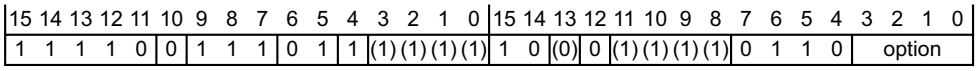
Hypervisor Call is a system instruction, see *HVC* on page F7-3004.

F7.1.52 ISB

Instruction Synchronization Barrier flushes the pipeline in the PE, so that all instructions following the `ISB` are fetched from cache or memory, after the instruction has been completed. It ensures that the effects of context changing operations executed before the `ISB` instruction are visible to the instructions fetched after the `ISB`. Context changing operations include changing the *Address Space Identifier* (ASID), TLB maintenance instructions, branch predictor maintenance operations, and all changes to the System registers. In addition, any branches that appear in program order after the `ISB` instruction are written into the branch prediction logic with the context that is visible after the `ISB` instruction. This is needed to ensure correct execution of the instruction stream.

Encoding T1

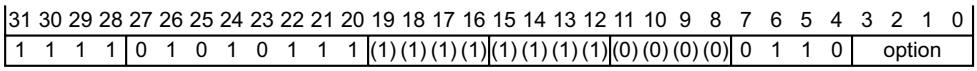
`ISB<c> <option>`



```
// No additional decoding required
```

Encoding A1

`ISB <option>`



```
// No additional decoding required
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`ISB{<c>}{<q>}  {<option>}`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `ISB` instruction must be unconditional.

`<option>` Specifies an optional limitation on the ISB operation. Values are:

`SY` Full system ISB operation, encoded as option = `0b1111`. Can be omitted.

All other encodings of option are reserved. The corresponding instructions execute as full system ISB operations, but must not be relied upon by software.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    InstructionSynchronizationBarrier();
```

F7.1.53 IT

If-Then makes up to four following instructions (the *IT block*) conditional. The conditions for the instructions in the IT block are the same as, or the inverse of, the condition the IT instruction specifies for the first instruction in the block.

The IT instruction itself does not affect the condition flags, but the execution of the instructions in the IT block can change the condition flags.

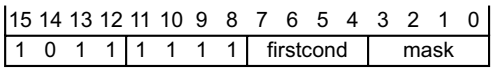
16-bit instructions in the IT block, other than CMP, CMN and TST, do not set the condition flags. An IT instruction with the AL condition can change the behavior without conditional execution.

The architecture permits exception return to an instruction in the IT block only if the restoration of the CPSR restores ITSTATE to a state consistent with the conditions specified by the IT instruction. Any other exception return to an instruction in an IT block is UNPREDICTABLE. Any branch to a target instruction in an IT block is not permitted, and if such a branch is made it is UNPREDICTABLE what condition is used when executing that target instruction and any subsequent instruction in the IT block.

See also *Conditional instructions* on page F1-2297 and *Conditional execution* on page F2-2331.

Encoding T1

`IT{<x>{<y>{<z>}}} <firstcond>` Not permitted in IT block



```
if mask == '0000' then SEE "Related encodings";
if firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1) then UNPREDICTABLE;
if InITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *IT* on page AppxA-4795.

Related encodings See *If-Then, and hints* on page F3-2355.

Assembler syntax

`IT{<x>{<y>{<z>}}}{<q>} <firstcond>`

where:

<x> The condition for the second instruction in the IT block.

<y> The condition for the third instruction in the IT block.

<z> The condition for the fourth instruction in the IT block.

<q> See *Standard assembler syntax fields* on page F2-2330. An IT instruction must be unconditional.

<firstcond> The condition for the first instruction in the IT block. See Table F2-1 on page F2-2331 for the range of conditions available, and the encodings.

Each of <x>, <y>, and <z> can be either:

T Then. The condition for the instruction is <firstcond>.

E Else. The condition for the instruction is the inverse of <firstcond>. The condition code is the same as <firstcond>, except that the least significant bit is inverted. E must not be specified if <firstcond> is AL.

Table F7-1 on page F7-2534 shows how the values of <x>, <y>, and <z> determine the value of the mask field.

Table F7-1 Determination of mask field

<x>	<y>	<z>	mask[3]	mask[2]	mask[1]	mask[0]
Omitted	Omitted	Omitted	1	0	0	0
T	Omitted	Omitted	firstcond[0]	1	0	0
E	Omitted	Omitted	NOT firstcond[0]	1	0	0
T	T	Omitted	firstcond[0]	firstcond[0]	1	0
E	T	Omitted	NOT firstcond[0]	firstcond[0]	1	0
T	E	Omitted	firstcond[0]	NOT firstcond[0]	1	0
E	E	Omitted	NOT firstcond[0]	NOT firstcond[0]	1	0
T	T	T	firstcond[0]	firstcond[0]	firstcond[0]	1
E	T	T	NOT firstcond[0]	firstcond[0]	firstcond[0]	1
T	E	T	firstcond[0]	NOT firstcond[0]	firstcond[0]	1
E	E	T	NOT firstcond[0]	NOT firstcond[0]	firstcond[0]	1
T	T	E	firstcond[0]	firstcond[0]	NOT firstcond[0]	1
E	T	E	NOT firstcond[0]	firstcond[0]	NOT firstcond[0]	1
T	E	E	firstcond[0]	NOT firstcond[0]	NOT firstcond[0]	1
E	E	E	NOT firstcond[0]	NOT firstcond[0]	NOT firstcond[0]	1

The conditions specified in an IT instruction must match those specified in the syntax of the instructions in its IT block. When assembling to A32 code, assemblers check IT instruction syntax for validity but do not generate assembled instructions for them. See *Conditional instructions* on page F1-2297.

Operation

```
EncodingSpecificOperations();
AArch32.CheckITEnabled(mask);
PSTATE.IT<7:0> = firstcond:mask;
```

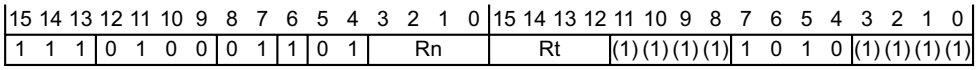
F7.1.54 LDA

Load Acquire Word loads a word from memory and writes it to a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2271

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

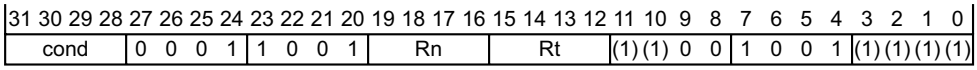
LDA<c> <Rt>, [<Rn>]



```
t = UInt(Rt); n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

Encoding A1

LDA <Rt>, [<Rn>]



```
t = UInt(Rt); n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
LDA{<c>}{<q>} <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    acctype = AccType_ORDERED;
    aligned = (address == Align(address, 4));
    R[t] = MemA_with_type[address, 4, acctype, aligned];
```

F7.1.55 LDAB

Load-Acquire Byte loads a byte from memory, zero-extends it to form a 32-bit word and writes it to a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2271.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

```
LDAB<c> <Rt>, [<Rn>]
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	0	1	1	0	1	Rn				Rt				(1)	(1)	(1)	(1)	1	0	0	0	(1)	(1)	(1)	(1)

```
t = UInt(Rt); n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

Encoding A1

```
LDAB <Rt>, [<Rn>]
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	1	1	0	1	Rn				Rt				(1)	(1)	0	0	1	0	0	1	(1)	(1)	(1)	(1)

```
t = UInt(Rt); n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
LDAB{<c>}{<q>} <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    acctype = AccType_ORDERED;
    aligned = TRUE;
    R[t] = ZeroExtend(MemA_with_type[address, 4, acctype, aligned], 32);
```

F7.1.56 LDAEX

Load-Acquire Exclusive Word loads a word from memory, writes it to a register and:

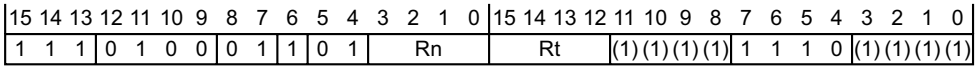
- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2271.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

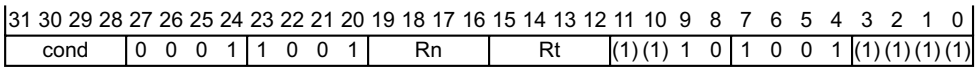
```
LDAEX<c> <Rt>, [<Rn>]
```



```
t = UInt(Rt);  n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

Encoding A1

```
LDAEX <Rt>, [<Rn>]
```



```
t = UInt(Rt);  n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDAEX* on page AppxA-4808.

Assembler syntax

```
LDAEX{<c>}{<q>} <Rt>, [<Rn>]
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rt>`	The destination register.
`<Rn>`	The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    acctype = AccType_ORDERED;
    aligned = (address == Align(address, 4));
    AArch32.SetExclusiveMonitors(address, 4);
    R[t] = MemA_with_type[address, 4, acctype, aligned];
```

F7.1.57 LDAEXB

Load-Acquire Exclusive Byte loads a byte from memory, zero-extends it to form a 32-bit word, writes it to a register and:

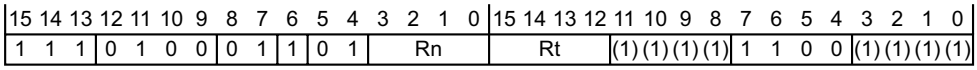
- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2271.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

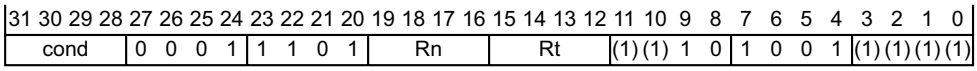
```
LDAEXB<c> <Rt>, [<Rn>]
```



```
t = UInt(Rt);  n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

Encoding A1

```
LDAEXB <Rt>, [<Rn>]
```



```
t = UInt(Rt);  n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDAEXB* on page AppxA-4809.

Assembler syntax

```
LDAEXB{<c>}{<q>} <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    acctype = AccType_ORDERED;
    aligned = TRUE;
    AArch32.SetExclusiveMonitors(address, 1);
    R[t] = ZeroExtend(MemA_with_type[address, 1, acctype, aligned], 32);
```

F7.1.58 LDAEXD

Load-Acquire Exclusive Doubleword loads a doubleword from memory, writes it to two registers and:

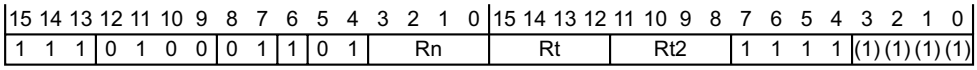
- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also acts as a barrier instruction with the ordering requirements described in *Load-Acquire, Store-Release* on page E2-2271.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

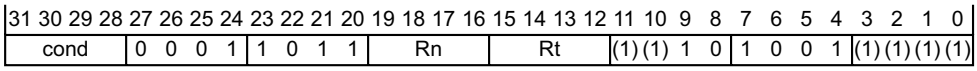
```
LDAEXD<c> <Rt>, <Rt2>, [<Rn>]
```



```
t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);
if t == 15 || t2 == 15 || t == t2 || n == 15 then UNPREDICTABLE;
```

Encoding A1

```
LDAEXD <Rt>, <Rt2>, [<Rn>]
```



```
t = UInt(Rt);  t2 = t + 1;  n = UInt(Rn);
if Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDAEXD* on page AppxA-4809.

Assembler syntax

```
LDAEXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rt>`	The first destination register. For an A32 instruction, `<Rt>` must be even-numbered and not R14.
`<Rt2>`	The second destination register. For an A32 instruction, `<Rt2>` must be `<R(t+1)>`.
`<Rn>`	The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    AArch32.SetExclusiveMonitors(address, 8);
    acctype = AccType_ORDERED;
    aligned = (address == Align(address, 8));
    value = MemA_with_type[address, 8, acctype, aligned];
    // Extract words from 64-bit loaded value such that R[t] is
    // loaded from address and R[t2] from address+4.
    R[t]  = if BigEndian() then value<63:32> else value<31:0>;
    R[t2] = if BigEndian() then value<31:0>  else value<63:32>;
```

F7.1.59 LDAEXH

Load-Acquire Exclusive Halfword loads a halfword from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2271.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

```
LDAEXH<c> <Rt>, [<Rn>]
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDAEXH* on page AppxA-4808.

Assembler syntax

```
LDAEXH{<c>}{<q>} <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    acctype = AccType_ORDERED;
    aligned = (address == Align(address, 2));
    AArch32.SetExclusiveMonitors(address, 2);
    R[t] = ZeroExtend(MemA_with_type[address, 2, acctype, aligned], 32);
```

F7.1.60 LDAH

Load-Acquire Halfword loads a halfword from memory, zero-extends it to form a 32-bit word and writes it to a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2271.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

    address = R[n];
    acctype = AccType_ORDERED;
    aligned = (address == Align(address, 2));
    R[t] = ZeroExtend(MemA_with_type[address, 2, acctype, aligned], 32);
```

F7.1.61 LDC, LDC2 (immediate)

Load Coprocessor loads memory data from a sequence of consecutive memory addresses to a conceptual coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `D` bit, the `CRd` field, and in the Unindexed addressing mode only, the `imm8` field. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid `LDC` and `LDC2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page E1-2244.

In an implementation that includes EL2, the permitted `LDC` access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an `LDC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Trapping general CP14 accesses to debug registers* on page G1-3500.

Note

For simplicity, the `LDC` pseudocode does not show this possible trap to Hyp mode.

Encoding T1/A1

```
LDC{L}<c> <coproc>, <CRd>, [<Rn>, #+/-<imm>]{!}
LDC{L}<c> <coproc>, <CRd>, [<Rn>], #+/-<imm>

```

Advanced SIMD and floating-point See *Advanced SIMD and floating-point register load/store instructions* on page F5-2430

Assembler syntax

`LDC{2}{L}{<c>}{<q>} <coproc>, <CRd>, [<Rn>{, #+/-<imm>}]`	Offset. P = 1, W = 0.
`LDC{2}{L}{<c>}{<q>} <coproc>, <CRd>, [<Rn>, #+/-<imm>]!`	Pre-indexed. P = 1, W = 1.
`LDC{2}{L}{<c>}{<q>} <coproc>, <CRd>, [<Rn>], #+/-<imm>`	Post-indexed. P = 0, W = 1.
`LDC{2}{L}{<c>}{<q>} <coproc>, <CRd>, [<Rn>], <option>`	Unindexed. P = 0, W = 0, U = 1.

where:

`2` If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.

`L` If specified, selects the D == 1 form of the encoding. If omitted, selects the D == 0 form.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `LDC2` instruction must be unconditional.

`<coproc>` The name of the coprocessor. The generic coprocessor names are p0-p15.

`<CRd>` The coprocessor destination register.

`<Rn>` The base register. The SP can be used. For PC use see *LDC, LDC2 (literal)* on page F7-2549.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`, encoded as U ==1), or – if it is to be subtracted (`add == FALSE`, encoded as U==0). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Values are multiples of 4 in the range 0-1020. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of +0.

`<option>` A coprocessor option. An integer in the range 0-255 enclosed in { }. Encoded in imm8.

The pre-UAL syntax `LDC<c>L` is equivalent to `LDCL<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        repeat
            Coproc_SendLoadedWord(MemA[address,4], cp, ThisInstr());
            address = address + 4;
        until Coproc_DoneLoading(cp, ThisInstr());
        if wback then R[n] = offset_addr;
```

F7.1.62 LDC, LDC2 (literal)

Load Coprocessor loads memory data from a sequence of consecutive memory addresses to a conceptual coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `D` bit, the `CRd` field, and in the Unindexed addressing mode only, the `imm8` field. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid `LDC` and `LDC2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page E1-2244.

In an implementation that includes EL2, the permitted `LDC` access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an `LDC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Trapping general CP14 accesses to debug registers* on page G1-3500.

Note

For simplicity, the `LDC` pseudocode does not show this possible trap to Hyp mode.

if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDC/LDC2 (literal)* on page AppxA-4795.

Advanced SIMD and floating-point See *Advanced SIMD and floating-point register load/store instructions* on page F5-2430

Assembler syntax

`LDC{2}{L}{<c>}{<q>}  <coproc>, <CRd>, <label>`	Normal form with P = 1, W = 0
`LDC{2}{L}{<c>}{<q>}  <coproc>, <CRd>, [PC, #+/-<imm>]`	Alternative form with P = 1, W = 0
`LDC{2}{L}{<c>}{<q>}  <coproc>, <CRd>, [PC], <option>`	Unindexed form with P = 0, U = 1, W = 0, encoding A1/A2 only

where:

`2` If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.

`L` If specified, selects the D == 1 form of the encoding. If omitted, selects the D == 0 form.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `LDC2` instruction must be unconditional.

`<coproc>` The name of the coprocessor. The generic coprocessor names are p0-p15.

`<CRd>` The coprocessor destination register.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE` (encoded as U == 1).

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE (encoded as U == 0)`.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-2297.

The unindexed form is permitted for the A32 instruction set only. In it, `<option>` is a coprocessor option, written as an integer 0-255 enclosed in { } and encoded in `imm8`.

The pre-UAL syntax `LDC<c>L` is equivalent to `LDCL<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        offset_addr = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
        address = if index then offset_addr else Align(PC,4);
        repeat
            Coproc_SendLoadedWord(MemA[address,4], cp, ThisInstr());
            address = address + 4;
        until Coproc_DoneLoading(cp, ThisInstr());
```

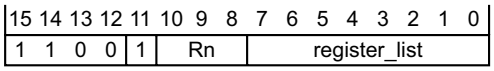
F7.1.63 LDM (LDMIA, LDMFD), T32

Load Multiple Increment After (Load Multiple Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address. Related system instructions are *LDM (User registers)* on page F7-3008 and *LDM (exception return)* on page F7-3006.

Encoding T1

`LDM<c> <Rn>!, <registers>` — `<Rn>` not included in `<registers>`

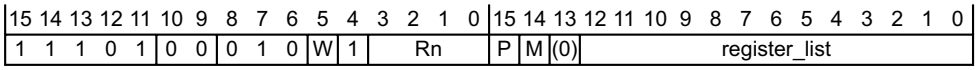
`LDM<c> <Rn>, <registers>` — `<Rn>` included in `<registers>`



```
n = UInt(Rn);  registers = '00000000':register_list;  wback = (registers<n> == '0');
if BitCount(registers) < 1 then UNPREDICTABLE;
```

Encoding T2

`LDM<c>.W <Rn>{!}, <registers>`



```
if W == '1' && Rn == '1101' then SEE POP (T32);
n = UInt(Rn);  registers = P:M:'0':register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDM/LDMIA/LDMFD (T32)* on page AppxA-4795.

Assembler syntax

```
LDM{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The base register. SP can be used. If it is the SP and ! is specified, the instruction is treated as described in *POP, T32* on page F7-2689.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1. If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

Encoding T2 does not support a list containing only one register. If an `LDMIA` instruction with just one register `<Rt>` in the list is assembled to T32 and encoding T1 is not available, it is assembled to the equivalent `LDR{<c>}{<q>} <Rt>, [<Rn>]{, #4}` instruction.

The SP cannot be in the list.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210. If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

If `!` is specified, `<registers>` cannot include the base register.

`LDMIA` and `LDMFD` are pseudo-instructions for `LDM`. `LDMFD` refers to its use for popping data from Full Descending stacks.

The pre-UAL syntaxes `LDM<c>IA` and `LDM<c>FD` are equivalent to `LDM<c>`.

Operation

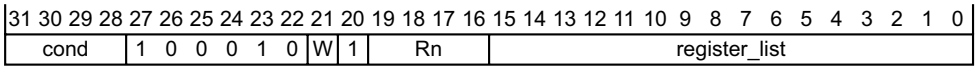
```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

F7.1.64 LDM (LDMIA, LDMFD), A32

Load Multiple Increment After (Load Multiple Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address. Related system instructions are *LDM (User registers)* on page F7-3008 and *LDM (exception return)* on page F7-3006.

Encoding A1

```
LDM<c> <Rn>{!}, <registers>
```



```
if W == '1' && Rn == '1101' && BitCount(register_list) > 1 then SEE POP (A32);
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDM/LDMIA/LDMFD (A32)* on page AppxA-4796.

Assembler syntax

```
LDM{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The base register. SP can be used. If the SP is used, ! is specified, and there is more than one register in the `<registers>` list, the instruction is treated as described in *POP, A32* on page F7-2691.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1. If ! is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

The SP can be in the list. However, ARM deprecates using these instructions with SP in the list.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

ARM deprecates using these instructions with both the LR and the PC in the list.

`LDMIA` and `LDMFD` are pseudo-instructions for `LDM`. `LDMFD` refers to its use for popping data from Full Descending stacks.

The pre-UAL syntaxes `LDM<c>IA` and `LDM<c>FD` are equivalent to `LDM<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

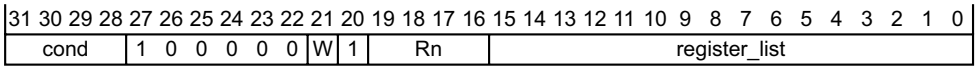
F7.1.65 LDMDA (LDMFA)

Load Multiple Decrement After (Load Multiple Full Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address.

Related system instructions are *LDM (User registers)* on page F7-3008 and *LDM (exception return)* on page F7-3006.

Encoding A1

```
LDMDA<c> <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDMDA/LDMFA* on page AppxA-4796.

Assembler syntax

```
LDMDA{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The base register. SP can be used.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be loaded, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

The SP can be in the list. However, instructions that include the SP in the list are deprecated.

The PC can be in the list. If it is, the instruction branches to the address (data) loaded to the PC. This branch is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

Instructions that include both the LR and the PC in the list are deprecated.

`LDMFA` is a pseudo-instruction for `LDMDA`, referring to its use for popping data from Full Ascending stacks.

The pre-UAL syntaxes `LDM<c>DA` and `LDM<c>FA` are equivalent to `LDMDA<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers) + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] - 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

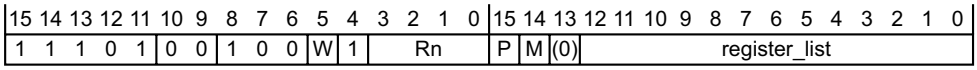
F7.1.66 LDMDB (LDMEA)

Load Multiple Decrement Before (Load Multiple Empty Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the lowest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address.

Related system instructions are *LDM (User registers)* on page F7-3008 and *LDM (exception return)* on page F7-3006.

Encoding T1

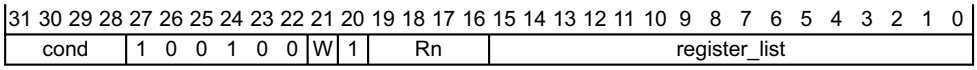
```
LDMDB<c> <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = P:M:'0':register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1

```
LDMDB<c> <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDMDB/LDMEA* on page AppxA-4797.

Assembler syntax

```
LDMDB{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The base register. The SP can be used.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be loaded, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

Encoding T1 does not support a list containing only one register. If an `LDMDB` instruction with just one register `<Rt>` in the list is assembled to T32, it is assembled to the equivalent `LDR{<c>}{<q>} <Rt>, [<Rn>, #-4]{!}` instruction.

The SP can be in the list in A32 instructions, but not in T32 instructions. However, A32 instructions that include the SP in the list are deprecated.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210. In T32 instructions, if the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

A32 instructions that include both the LR and the PC in the list are deprecated.

`LDMEA` is a pseudo-instruction for `LDMDB`, referring to its use for popping data from Empty Ascending stacks.

The pre-UAL syntaxes `LDM<c>DB` and `LDM<c>EA` are equivalent to `LDMDB<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] - 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

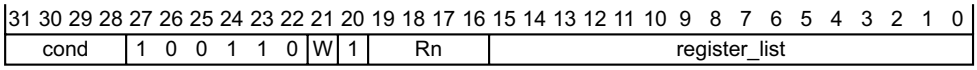
F7.1.67 LDMIB (LDMED)

Load Multiple Increment Before (Load Multiple Empty Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address.

Related system instructions are *LDM (User registers)* on page F7-3008 and *LDM (exception return)* on page F7-3006.

Encoding A1

```
LDMIB<c> <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDMIB/LDMED* on page AppxA-4797.

Assembler syntax

```
LDMIB{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The base register. The SP can be used.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be loaded, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

The SP can be in the list. However, instructions that include the SP in the list are deprecated.

The PC can be in the list. If it is, the instruction branches to the address (data) loaded to the PC. This branch is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

Instructions that include both the LR and the PC in the list are deprecated.

`LDMED` is a pseudo-instruction for `LDMIB`, referring to its use for popping data from Empty Descending stacks.

The pre-UAL syntaxes `LDM<c>IB` and `LDM<c>ED` are equivalent to `LDMIB<c>`.

Operation

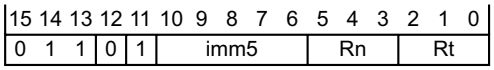
```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

F7.1.68 LDR (immediate), T32

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

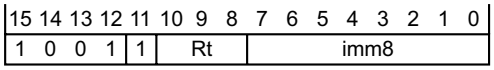
```
LDR<c> <Rt>, [<Rn>{, #<imm>}]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5:'00', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T2

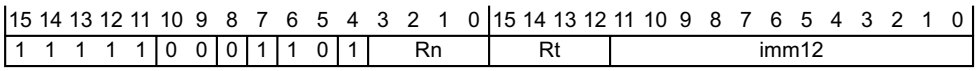
```
LDR<c> <Rt>, [SP{, #<imm>}]
```



```
t = UInt(Rt);  n = 13;  imm32 = ZeroExtend(imm8:'00', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T3

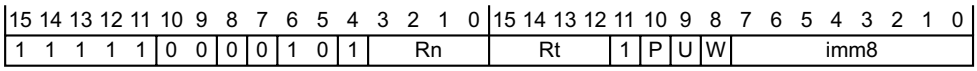
```
LDR<c>.W <Rt>, [<Rn>{, #<imm12>}]
```



```
if Rn == '1111' then SEE LDR (literal);
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32); index = TRUE;  add = TRUE;
wback = FALSE; if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T4

```
LDR<c> <Rt>, [<Rn>, #-<imm8>]
LDR<c> <Rt>, [<Rn>], #+/-<imm8>
LDR<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if Rn == '1111' then SEE LDR (literal);
if P == '1' && U == '1' && W == '0' then SEE LDRT;
if Rn == '1101' && P == '0' && U == '1' && W == '1' && imm8 == '00000100' then SEE POP;
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);
imm32 = ZeroExtend(imm8, 32); index = (P == '1');  add = (U == '1');  wback = (W == '1');
if (wback && n == t) || (t == 15 && InITBlock() && !LastInITBlock()) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDR (immediate, T32)* on page AppxA-4798.

Assembler syntax

`LDR{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`LDR{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`LDR{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<Rn>` The base register. The SP can be used. For PC use see *LDR (literal)* on page F7-2565.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`, encoded as U ==1), or – if it is to be subtracted (`add == FALSE`, encoded as U ==0). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0. Values are:

Encoding T1 Multiples of 4 in the range 0-124.

Encoding T2 Multiples of 4 in the range 0-1020.

Encoding T3 Any value in the range 0-4095.

Encoding T4 Any value in the range 0-255.

Operation

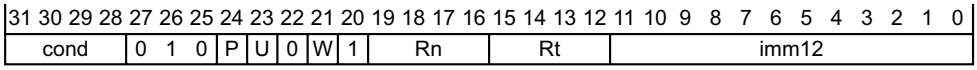
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,4];
    if wback then R[n] = offset_addr;
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    else
        R[t] = data;
```

F7.1.69 LDR (immediate), A32

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding A1

```
LDR<c> <Rt>, [<Rn>{, #+/-<imm12>}]
LDR<c> <Rt>, [<Rn>], #+/-<imm12>
LDR<c> <Rt>, [<Rn>, #+/-<imm12>]!
```



```
if Rn == '1111' then SEE LDR (literal);
if P == '0' && W == '1' then SEE LDRT;
if Rn == '1101' && P == '0' && U == '1' && W == '0' && imm12 == '000000000100' then SEE POP;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if wback && n == t then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDR (immediate, A32)* on page AppxA-4798.

Assembler syntax

`LDR{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`LDR{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`LDR{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register. The SP or the PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<Rn>` The base register. The SP can be used. For PC use see *LDR (literal)* on page F7-2565.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`, encoded as U ==1), or – if it is to be subtracted (`add == FALSE`, encoded as U ==0). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0. Any value in the range 0-4095 is permitted.

Operation

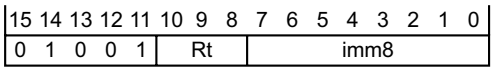
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,4];
    if wback then R[n] = offset_addr;
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    else
        R[t] = data;
```

F7.1.70 LDR (literal)

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

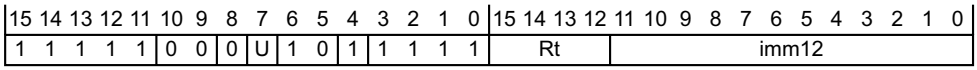
```
LDR<c> <Rt>, <label>
```



```
t = UInt(Rt);  imm32 = ZeroExtend(imm8:'00', 32);  add = TRUE;
```

Encoding T2

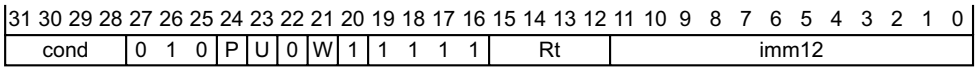
```
LDR<c>.W <Rt>, <label>
LDR<c>.W <Rt>, [PC, #-0]                                    Special case
```



```
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1

```
LDR<c> <Rt>, <label>
LDR<c> <Rt>, [PC, #-0]                                      Special case
```



```
if P == '0' && W == '1' then SEE LDRT;
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if wback then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDR (literal)* on page AppxA-4803.

Assembler syntax

`LDR{<c>}{<q>}  <Rt>, <label>`	Normal form
`LDR{<c>}{<q>}  <Rt>, [PC, #+/-<imm>]`	Alternative form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This branch is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are:

Encoding T1 Multiples of four in the range 0 to 1020.

Encoding T2 or A1 Any value in the range -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as U == 1 in encoding T2.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as U == 0. Negative offset is not available in encoding T1.

Note

In examples in this manual, the syntax `=<value>` is used for the label of a memory word whose contents is constant and equal to `<value>`. The actual syntax for such a label is assembler-dependent.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-2297.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,4];
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    else
        R[t] = data;
```

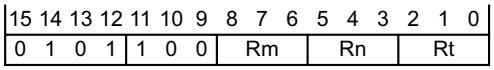
F7.1.71 LDR (register), T32

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses, see *Memory accesses* on page F2-2337.

The T32 form of LDR (register) does not support register writeback.

Encoding T1

```
LDR<c> <Rt>, [<Rn>, <Rm>]
```

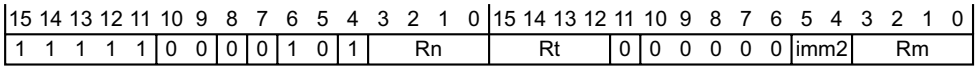


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	0	0	Rm			Rn			Rt		

```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

```
LDR<c>.W <Rt>, [<Rn>, <Rm>{, LSL #<imm2>}]
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	0	0	0	1	0	1	Rn				Rt				0	0	0	0	0	0	imm2		Rm			

```
if Rn == '1111' then SEE LDR (literal);
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`LDR{<c>}{<q>}  <Rt>, [<Rn>, {+}<Rm>{, <shift>}]` Offset addressing

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This branch is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<Rn>` The base register. The SP can be used. In the T32 instruction set, the PC cannot be used with this form of the `LDR` instruction.

`+` In T32 instructions, the optionally shifted value of `<Rm>` is added to the base register value. T32 instructions cannot subtract `<Rm>` from the base register value.

`<Rm>` The offset that is optionally shifted and applied to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. For encoding T2, `<shift>` can only be omitted, encoded as imm2 = `0b00`, or `LSL #<imm>` with `<imm>` = 1, 2, or 3, and `<imm>` encoded in imm2.

Operation

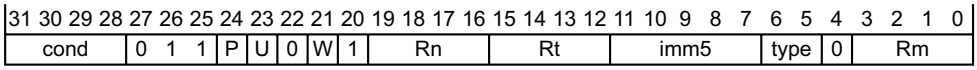
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = (R[n] + offset);
    address = offset_addr;
    data = MemU[address,4];
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    else
        R[t] = data;
```

F7.1.72 LDR (register), A32

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses, see *Memory accesses* on page F2-2337.

Encoding A1

```
LDR<c> <Rt>, [<Rn>,+/-<Rm>{, <shift>}]{!}
LDR<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```



```
if P == '0' && W == '1' then SEE LDRT;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDR (register, A32)* on page AppxA-4799.

Assembler syntax

`LDR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]`	Offset: `index==TRUE`, `wback==FALSE`
`LDR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`LDR{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register. The SP can be used. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This branch is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<Rn>` The base register. The SP can be used. The PC can be used for offset addressing only.

`+/-` If + or omitted, the optionally shifted value of `<Rm>` is added to the base register value (`add == TRUE` encoded as U == 1).

If –, the optionally shifted value of `<Rm>` is subtracted from the base register value (`add == FALSE` encoded as U == 0).

`<Rm>` The offset that is optionally shifted and applied to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If absent, no shift is applied. Otherwise, see *Shifts applied to a register* on page F2-2334.

Operation

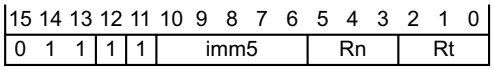
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    data = MemU[address,4];
    if wback then R[n] = offset_addr;
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    else
        R[t] = data;
```

F7.1.73 LDRB (immediate), T32

Load Register Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

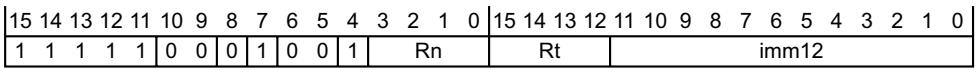
```
LDRB<c> <Rt>, [<Rn>{, #<imm5>}]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T2

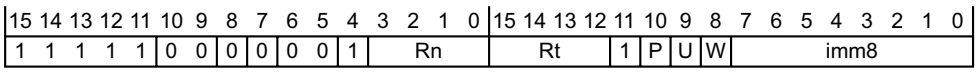
```
LDRB<c>.W <Rt>, [<Rn>{, #<imm12>}]
```



```
if Rt == '1111' then SEE PLD;
if Rn == '1111' then SEE LDRB (literal);
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding T3

```
LDRB<c> <Rt>, [<Rn>, #-<imm8>]
LDRB<c> <Rt>, [<Rn>], #+/-<imm8>
LDRB<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE PLD, PLDW (immediate);
if Rn == '1111' then SEE LDRB (literal);
if P == '1' && U == '1' && W == '0' then SEE LDRBT;
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if  (t == 15 &&  W == '1') || (wback && n == t) then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRB (immediate, T32)* on page AppxA-4799.

Assembler syntax

`LDRB{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE`, `wback==FALSE`
`LDRB{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`LDRB{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used. For PC use see *LDRB (literal)* on page F7-2575.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`, encoded as U == 1), or – if it is to be subtracted (`add == FALSE`, encoded as U == 0). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0. Values are:

Encoding T1 Any value in the range 0-31.

Encoding T2 Any value in the range 0-4095.

Encoding T3 Any value in the range 0-255.

The pre-UAL syntax `LDR<c>B` is equivalent to `LDRB<c>`.

Operation

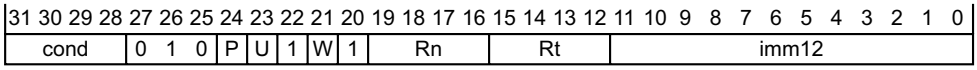
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    R[t] = ZeroExtend(MemU[address,1], 32);
    if wback then R[n] = offset_addr;
```

F7.1.74 LDRB (immediate), A32

Load Register Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding A1

```
LDRB<c> <Rt>, [<Rn>{, #+/-<imm12>}]
LDRB<c> <Rt>, [<Rn>], #+/-<imm12>
LDRB<c> <Rt>, [<Rn>, #+/-<imm12>]!
```



```
if Rn == '1111' then SEE LDRB (literal);
if P == '0' && W == '1' then SEE LDRBT;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRB (immediate, A32)* on page AppxA-4799.

Assembler syntax

`LDRB{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`LDRB{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`LDRB{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used. For PC use see *LDRB (literal)* on page F7-2575.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`, encoded as U == 1), or – if it is to be subtracted (`add == FALSE`, encoded as U == 0). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0. Any value in the range 0-4095 is permitted.

The pre-UAL syntax `LDR<c>B` is equivalent to `LDRB<c>`.

Operation

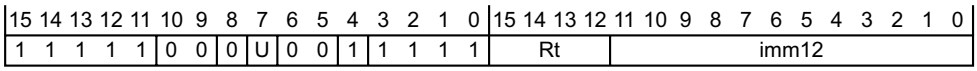
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    R[t] = ZeroExtend(MemU[address,1], 32);
    if wback then R[n] = offset_addr;
```

F7.1.75 LDRB (literal)

Load Register Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

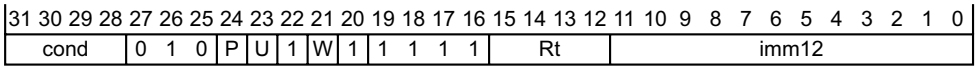
```
LDRB<c> <Rt>, <label>
LDRB<c> <Rt>, [PC, #-0]                                   Special case
```



```
if Rt == '1111' then SEE PLD;
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDRB<c> <Rt>, <label>
LDRB<c> <Rt>, [PC, #-0]                                   Special case
```



```
if P == '0' && W == '1' then SEE LDRBT;
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRB (literal)* on page AppxA-4804.

Assembler syntax

`LDRB{<c>}{<q>}  <Rt>, <label>`	Normal form
`LDRB{<c>}{<q>}  <Rt>, [PC, #+/-<imm>]`	Alternative form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as U == 1.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as U == 0.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-2297.

The pre-UAL syntax `LDR<c>B` is equivalent to `LDRB<c>`.

Operation

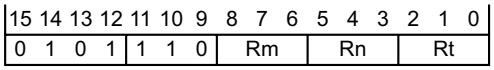
```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    R[t] = ZeroExtend(MemU[address,1], 32);
```

F7.1.76 LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

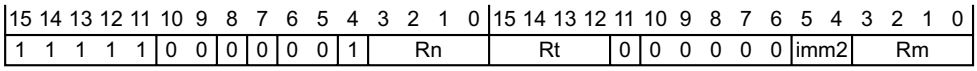
```
LDRB<c> <Rt>, [<Rn>, <Rm>]
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

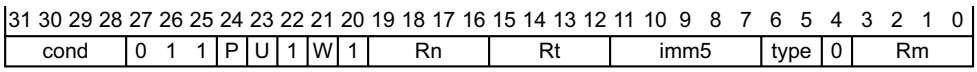
```
LDRB<c>.W <Rt>, [<Rn>, <Rm>{, LSL #<imm2>}]
```



```
if Rt == '1111' then SEE PLD;
if Rn == '1111' then SEE LDRB (literal);
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDRB<c> <Rt>, [<Rn>,+/-<Rm>{, <shift>}]{!}
LDRB<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```



```
if P == '0' && W == '1' then SEE LDRBT;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRB (register)* on page AppxA-4799.

Assembler syntax

`LDRB{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>{, <shift>}]`	Offset: `index==TRUE, wback==FALSE`
`LDRB{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>{, <shift>}]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`LDRB{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm>{, <shift>}`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used. In the A32 instruction set the PC can be used, for the offset addressing form of the instruction only. In the T32 instruction set, the PC cannot be used with any of these forms of the `LDRB` instruction.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`, encoded as U == 1 in encoding A1), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE, encoded as U == 0`).

`<Rm>` Contains the offset that is optionally shifted and applied to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. For encoding T2, `<shift>` can only be omitted, encoded as imm2 = `0b00`, or `LSL #<imm>` with `<imm>` = 1, 2, or 3, and `<imm>` encoded in imm2. For encoding A1, see *Shifts applied to a register* on page F2-2334.

The pre-UAL syntax `LDR<c>B` is equivalent to `LDRB<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    R[t] = ZeroExtend(MemU[address,1],32);
    if wback then R[n] = offset_addr;
```

F7.1.77 LDRBT

Load Register Byte Unprivileged loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-2337.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

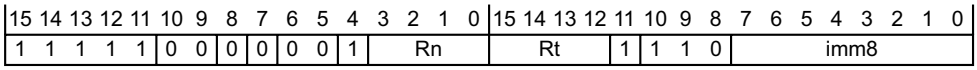
LDRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

Encoding T1

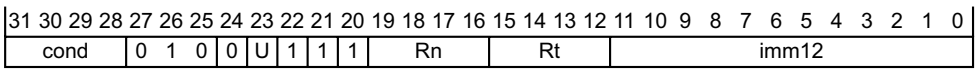
```
LDRBT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then SEE LDRB (literal);
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

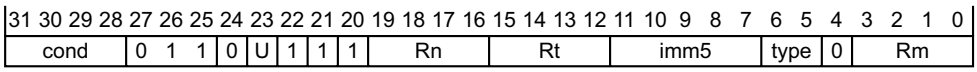
```
LDRBT<c> <Rt>, [<Rn>], #+/-<imm12>
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2

```
LDRBT<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;  (shift_t, shift_n) = DecodeImmShift(type, imm5);
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRBT* on page AppxA-4800.

Assembler syntax

`LDRBT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: T32 only
`LDRBT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: A32 only
`LDRBT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm> {, <shift>}`	Post-indexed: A32 only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`, encoded as U == 1 in encodings A1 and A2), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`, encoded as U == 0).

`<imm>` The immediate offset applied to the value of `<Rn>`. Values are 0-255 for encoding T1, and 0-4095 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is optionally shifted and applied to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

The pre-UAL syntax `LDR<c>BT` is equivalent to `LDRBT<c>`.

Operation

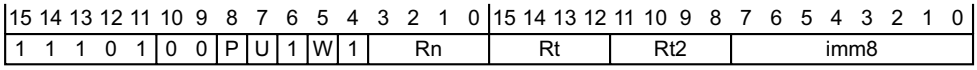
```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    R[t] = ZeroExtend(MemU_unpriv[address,1],32);
    if postindex then R[n] = offset_addr;
```

F7.1.78 LDRD (immediate)

Load Register Dual (immediate) calculates an address from a base register value and an immediate offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

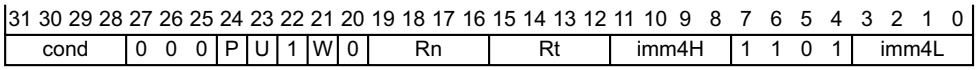
```
LDRD<c> <Rt>, <Rt2>, [<Rn>{, #+/-<imm>}]
LDRD<c> <Rt>, <Rt2>, [<Rn>], #+/-<imm>
LDRD<c> <Rt>, <Rt2>, [<Rn>, #+/-<imm>]!
```



```
if P == '0' && W == '0' then SEE "Related encodings";
if Rn == '1111' then SEE LDRD (literal);
t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if wback && (n == t || n == t2) then UNPREDICTABLE;
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDRD<c> <Rt>, <Rt2>, [<Rn>{, #+/-<imm8>}]
LDRD<c> <Rt>, <Rt2>, [<Rn>], #+/-<imm8>
LDRD<c> <Rt>, <Rt2>, [<Rn>, #+/-<imm8>]!
```



```
if Rn == '1111' then SEE LDRD (literal);
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if wback && (n == t || n == t2) then UNPREDICTABLE;
if t2 == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRD (immediate)* on page AppxA-4806.

Related encodings See *Load/Store dual, Load/Store-Exclusive, Load-Acquire/Store-Release, table branch* on page F3-2364.

Assembler syntax

`LDRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`LDRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`LDRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The first destination register. For an A32 instruction, `<Rt>` must be even-numbered and not R14.

`<Rt2>` The second destination register. For an A32 instruction, `<Rt2>` must be `<R(t+1)>`.

`<Rn>` The base register. The SP can be used. For PC use see *LDRD (literal)* on page F7-2583.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`, encoded as U == 1), or – if it is to be subtracted (`add == FALSE`, encoded as U == 0). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0. Values are:

Encoding T1 Multiples of 4 in the range 0-1020.

Encoding A1 Any value in the range 0-255.

The pre-UAL syntax `LDR<c>D` is equivalent to `LDRD<c>`.

Operation

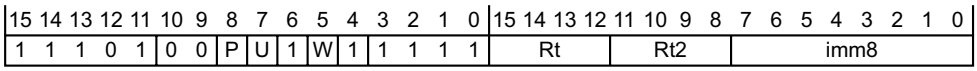
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    if address == Align(address, 8) then
        data = MemA[address,8];
        if BigEndian()  then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];
    if wback then R[n] = offset_addr;
```

F7.1.79 LDRD (literal)

Load Register Dual (literal) calculates an address from the PC value and an immediate offset, loads two words from memory, and writes them to two registers. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

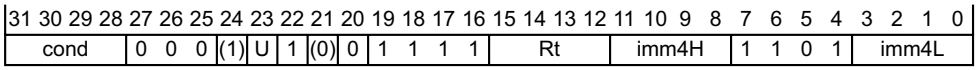
```
LDRD<c> <Rt>, <Rt2>, <label>
LDRD<c> <Rt>, <Rt2>, [PC, #-0]                                  Special case
```



```
if P == '0' && W == '0' then SEE "Related encodings";
t = UInt(Rt);  t2 = UInt(Rt2);
imm32 = ZeroExtend(imm8:'00', 32);  add = (U == '1');
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if W == '1' then UNPREDICTABLE;
```

Encoding A1

```
LDRD<c> <Rt>, <Rt2>, <label>
LDRD<c> <Rt>, <Rt2>, [PC, #-0]                                  Special case
```



```
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt);  t2 = t+1;  imm32 = ZeroExtend(imm4H:imm4L, 32);  add = (U == '1');
if t2 == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRD (literal)* on page AppxA-4807.

Related encodings See *Load/Store dual, Load/Store-Exclusive, Load-Acquire/Store-Release, table branch* on page F3-2364.

Assembler syntax

`LDRD{<c>}{<q>}  <Rt>, <Rt2>, <label>`	Normal form
`LDRD{<c>}{<q>}  <Rt>, <Rt2>, [PC, #+/-<imm>]`	Alternative form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The first destination register. For an A32 instruction, `<Rt>` must be even-numbered and not R14.

`<Rt2>` The second destination register. For an A32 instruction, `<Rt2>` must be `<R(t+1)>`.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are:

Encoding T1 Multiples of 4 in the range -1020 to 1020.

Encoding A1 Any value in the range -255 to 255.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as U == 1.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as U == 0.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-2297.

The pre-UAL syntax `LDR<c>D` is equivalent to `LDRD<c>`.

Operation

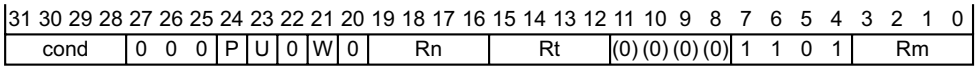
```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if address == Align(address, 8) then
        data = MemA[address,8];
        if BigEndian() then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];
```

F7.1.80 LDRD (register)

Load Register Dual (register) calculates an address from a base register value and a register offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding A1

```
LDRD<c> <Rt>, <Rt2>, [<Rn>,+/-<Rm>]{!}
LDRD<c> <Rt>, <Rt2>, [<Rn>],+/-<Rm>
```



31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
cond	0 0 0	P	U	0	W	0	Rn	Rt	(0) (0) (0) (0)	1 1 0 1	Rm

```
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if t2 == 15 || m == 15 || m == t || m == t2 then UNPREDICTABLE;
if wback && (n == 15 || n == t || n == t2) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRD (register)* on page AppxA-4806.

Assembler syntax

`LDRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>, +/-<Rm>]`	Offset: `index==TRUE, wback==FALSE`
`LDRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>, +/-<Rm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`LDRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>], +/-<Rm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The first destination register. This register must be even-numbered and not R14.

`<Rt2>` The second destination register. This register must be `<R(t+1)>`.

`<Rn>` The base register. The SP can be used. The PC can be used, for offset addressing only.

`+/-` Is + or omitted if the value of `<Rm>` is to be added to the base register value (`add == TRUE`, encoded as U == 1), or – if it is to be subtracted (`add == FALSE`, encoded as U == 0).

`<Rm>` Contains the offset that is applied to the value of `<Rn>` to form the address.

The pre-UAL syntax `LDR<c>D` is equivalent to `LDRD<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + R[m]) else (R[n] - R[m]);
    address = if index then offset_addr else R[n];
    if address == Align(address, 8) then
        data = MemA[address,8];
        if BigEndian() then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];

    if wback then R[n] = offset_addr;
```

F7.1.81 LDREX

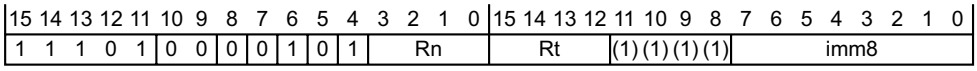
Load Register Exclusive calculates an address from a base register value and an immediate offset, loads a word from memory, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

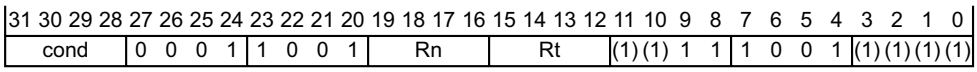
```
LDREX<c> <Rt>, [<Rn>{, #<imm>}]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
if t == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDREX <Rt>, [<Rn>]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = Zeros(32); // Zero offset
if t == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDREX* on page AppxA-4808.

Assembler syntax

```
LDREX{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

`<imm>` The immediate offset added to the value of `<Rn>` to form the address. `<imm>` can be omitted, meaning an offset of 0. Values are:

Encoding T1 Multiples of 4 in the range 0-1020.

Encoding A1 Omitted or 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + imm32;
    AArch32.SetExclusiveMonitors(address,4);
    R[t] = MemA[address,4];
```

F7.1.82 LDREXB

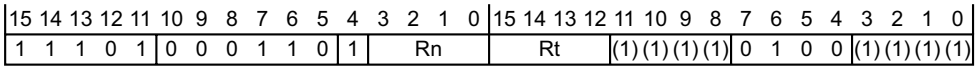
Load Register Exclusive Byte derives an address from a base register value, loads a byte from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

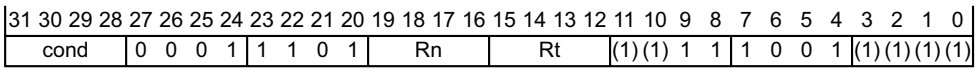
```
LDREXB<c> <Rt>, [<Rn>]
```



```
t = UInt(Rt);  n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDREXB <Rt>, [<Rn>]
```



```
t = UInt(Rt);  n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDREXB* on page AppxA-4808.

Assembler syntax

```
LDREXB{<c>}{<q>}  <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    AArch32.SetExclusiveMonitors(address,1);
    R[t] = ZeroExtend(MemA[address,1], 32);
```

F7.1.83 LDREXD

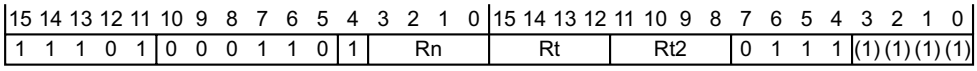
Load Register Exclusive Doubleword derives an address from a base register value, loads a 64-bit doubleword from memory, writes it to two registers and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

```
LDREXD<c> <Rt>, <Rt2>, [<Rn>]
```

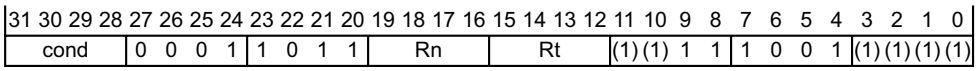


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	0	1	1	0	1	Rn				Rt				Rt2				0	1	1	1	(1)	(1)	(1)	(1)

```
t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);
if t == 15 || t2 == 15 || t == t2 || n == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDREXD <Rt>, <Rt2>, [<Rn>]
```



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	1	0	1	1	Rn				Rt				(1)	(1)	1	1	1	0	0	1	(1)	(1)	(1)	(1)

```
t = UInt(Rt);  t2 = t + 1;  n = UInt(Rn);
if Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDREXD* on page AppxA-4809.

Assembler syntax

```
LDREXD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>]
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rt>`	The first destination register. For an A32 instruction, `<Rt>` must be even-numbered and not R14.
`<Rt2>`	The second destination register. For an A32 instruction, `<Rt2>` must be `<R(t+1)>`.
`<Rn>`	The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    AArch32.SetExclusiveMonitors(address,8);
    value = MemA[address,8];
    // Extract words from 64-bit loaded value such that R[t] is
    // loaded from address and R[t2] from address+4.
    R[t]  = if BigEndian() then value<63:32> else value<31:0>;
    R[t2] = if BigEndian() then value<31:0> else value<63:32>;
```

F7.1.84 LDREXH

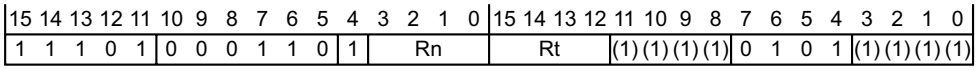
Load Register Exclusive Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

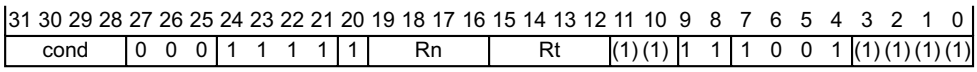
```
LDREXH<c> <Rt>, [<Rn>]
```



```
t = UInt(Rt);  n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDREXH <Rt>, [<Rn>]
```



```
t = UInt(Rt);  n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDREXH* on page AppxA-4808.

Assembler syntax

```
LDREXH{<c>}{<q>}  <Rt>, [<Rn>]
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rt>`	The destination register.
`<Rn>`	The base register. The SP can be used.

Operation

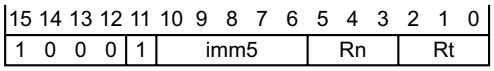
```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    AArch32.SetExclusiveMonitors(address,2);
    R[t] = ZeroExtend(MemA[address,2], 32);
```

F7.1.85 LDRH (immediate), T32

Load Register Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

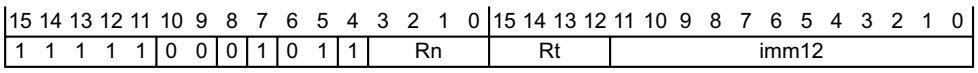
```
LDRH<c> <Rt>, [<Rn>{, #<imm>}]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5:'0', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T2

```
LDRH<c>.W <Rt>, [<Rn>{, #<imm12>}]
```



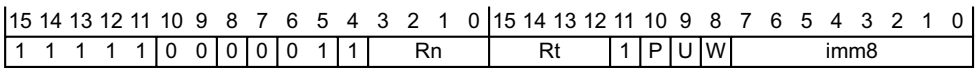
```
if Rt == '1111' then SEE PLD (immediate);
if Rn == '1111' then SEE LDRH (literal);
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding T3

```
LDRH<c> <Rt>, [<Rn>, #-<imm8>]
```

```
LDRH<c> <Rt>, [<Rn>], #+/-<imm8>
```

```
LDRH<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if Rn == '1111' then SEE LDRH (literal);
if P == '1' && U == '0' && W == '0' then SEE PLDW (immediate);
if P == '1' && U == '1' && W == '0' then SEE LDRHT;
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRH (immediate, T32)* on page AppxA-4800.

Assembler syntax

`LDRH{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`LDRH{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`LDRH{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used. For PC use see *LDRH (literal)* on page F7-2599.

`+/-` Is + or omitted to indicate that the immediate offset is added to the base register value (`add == TRUE`), or – to indicate that the offset is to be subtracted (`add == FALSE`). Different instructions are generated for `#0` and `#-0`.

`<imm>` The immediate offset used for forming the address. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0. Values are:

Encoding T1 Multiples of 2 in the range 0-62.

Encoding T2 Any value in the range 0-4095.

Encoding T3 Any value in the range 0-255.

The pre-UAL syntax `LDR<c>H` is equivalent to `LDRH<c>`.

Operation

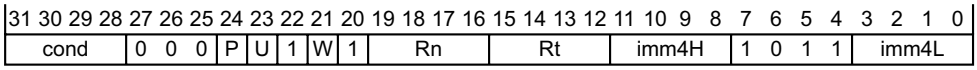
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    R[t] = ZeroExtend(data, 32);
```

F7.1.86 LDRH (immediate), A32

Load Register Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding A1

```
LDRH<c> <Rt>, [<Rn>{, #+/-<imm8>}]
LDRH<c> <Rt>, [<Rn>], #+/-<imm8>
LDRH<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if Rn == '1111' then SEE LDRH (literal);
if P == '0' && W == '1' then SEE LDRHT;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRH (immediate, A32)* on page AppxA-4800.

Assembler syntax

`LDRH{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`LDRH{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`LDRH{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used. For PC use see *LDRH (literal)* on page F7-2599.

`+/-` Is + or omitted to indicate that the immediate offset is added to the base register value (`add == TRUE`), or – to indicate that the offset is to be subtracted (`add == FALSE`). Different instructions are generated for `#0` and `#-0`.

`<imm>` The immediate offset used for forming the address. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0. Any value in the range 0-255 is permitted.

The pre-UAL syntax `LDR<c>H` is equivalent to `LDRH<c>`.

Operation

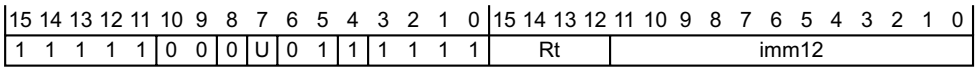
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    R[t] = ZeroExtend(data, 32);
```

F7.1.87 LDRH (literal)

Load Register Halfword (literal) calculates an address from the PC value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

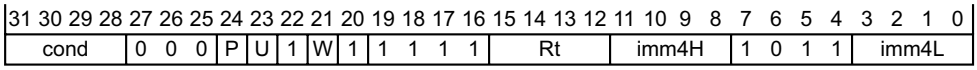
```
LDRH<c> <Rt>, <label>
LDRH<c> <Rt>, [PC, #-0]                                   Special case
```



```
if Rt == '1111' then SEE PLD (literal);
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDRH<c> <Rt>, <label>
LDRH<c> <Rt>, [PC, #-0]                                   Special case
```



```
if P == '0' && W == '1' then SEE LDRHT;
t = UInt(Rt);  imm32 = ZeroExtend(imm4H:imm4L, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRH (literal)* on page AppxA-4804.

Assembler syntax

`LDRH{<c>}{<q>}  <Rt>, <label>`	Normal form
`LDRH{<c>}{<q>}  <Rt>, [PC, #+/-<imm>]`	Alternative form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are:

Encoding T1 Any value in the range -4095 to 4095.

Encoding A1 Any value in the range -255 to 255.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-2297.

The pre-UAL syntax `LDR<c>H` is equivalent to `LDRH<c>`.

Operation

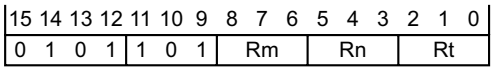
```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,2];
    R[t] = ZeroExtend(data, 32);
```

F7.1.88 LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

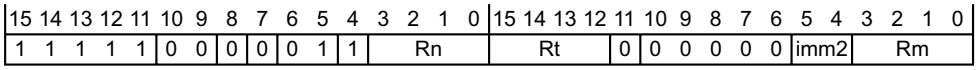
```
LDRH<c> <Rt>, [<Rn>, <Rm>]
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

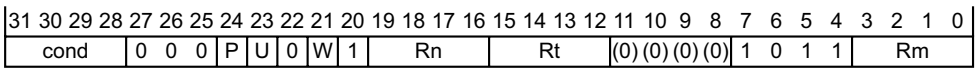
```
LDRH<c>.W <Rt>, [<Rn>, <Rm>{, LSL #<imm2>}]
```



```
if Rn == '1111' then SEE LDRH (literal);
if Rt == '1111' then SEE PLDW (register);
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDRH<c> <Rt>, [<Rn>,+/-<Rm>]{!}
LDRH<c> <Rt>, [<Rn>],+/-<Rm>
```



```
if P == '0' && W == '1' then SEE LDRHT;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRType_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRH (register)* on page AppxA-4801.

Assembler syntax

`LDRH{<c>}{<q>} <Rt>, [<Rn>, <Rm>{, LSL #<imm>}]`	Offset: `index==TRUE`, `wback==FALSE`
`LDRH{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>]`	Offset: `index==TRUE`, `wback==FALSE`
`LDRH{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`LDRH{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used. In the A32 instruction set the PC can be used, for offset addressing forms of the instruction only. In the T32 instruction set, the PC cannot be used for any of these forms of the `LDRH` instruction.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`).

`<Rm>` Contains the offset that is optionally left shifted and added to the value of `<Rn>` to form the address.

`<imm>` If present, the size of the left shift to apply to the value from `<Rm>`, in the range 1-3. Only encoding T2 is permitted, and `<imm>` is encoded in imm2.

If absent, no shift is specified and all encodings are permitted. In encoding T2, imm2 is encoded as `0b00`.

The pre-UAL syntax `LDR<c>H` is equivalent to `LDRH<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    R[t] = ZeroExtend(data, 32);
```

F7.1.89 LDRHT

Load Register Halfword Unprivileged loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-2337.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

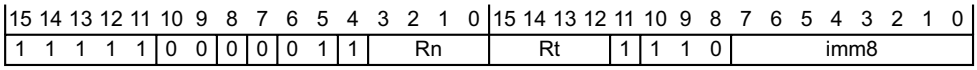
LDRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

Encoding T1

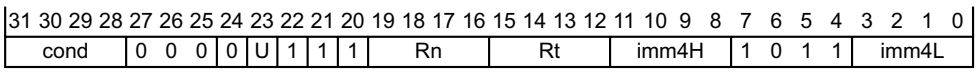
```
LDRHT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then SEE LDRH (literal);
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

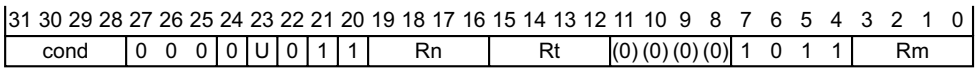
```
LDRHT<c> <Rt>, [<Rn>] {, #+/-<imm8>}
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2

```
LDRHT<c> <Rt>, [<Rn>], +/-<Rm>
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRHT* on page AppxA-4801.

Assembler syntax

`LDRHT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: T32 only
`LDRHT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: A32 only
`LDRHT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: A32 only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value.Encoded as `add = TRUE`.

Is – if `<imm>` or the optionally shifted value of `<Rm>` is to be subtracted from the base register value. This is permitted in A32 instructions only, and is encoded as `add = FALSE`.

`<imm>` The immediate offset applied to the value of `<Rn>`. Any value in the range 0-255 is permitted. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is applied to the value of `<Rn>` to form the address.

Operation

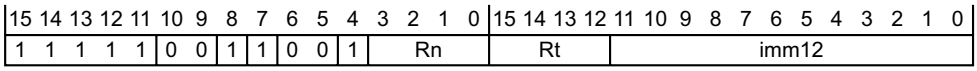
```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,2];
    if postindex then R[n] = offset_addr;
    R[t] = ZeroExtend(data, 32);
```

F7.1.90 LDRSB (immediate)

Load Register Signed Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

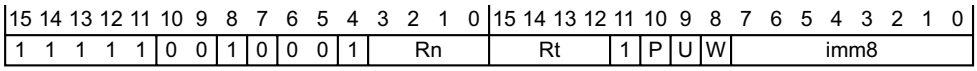
```
LDRSB<c> <Rt>, [<Rn>, #<imm12>]
```



```
if Rt == '1111' then SEE PLI;
if Rn == '1111' then SEE LDRSB (literal);
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding T2

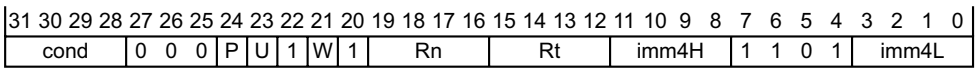
```
LDRSB<c> <Rt>, [<Rn>, #-<imm8>]
LDRSB<c> <Rt>, [<Rn>], #+/-<imm8>
LDRSB<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE PLI;
if Rn == '1111' then SEE LDRSB (literal);
if P == '1' && U == '1' && W == '0' then SEE LDRSBT;
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDRSB<c> <Rt>, [<Rn>{, #+/-<imm8>}]
LDRSB<c> <Rt>, [<Rn>], #+/-<imm8>
LDRSB<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if Rn == '1111' then SEE LDRSB (literal);
if P == '0' && W == '1' then SEE LDRSBT;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRSB (immediate)* on page AppxA-4801.

Assembler syntax

`LDRSB{<c>}{<q>}  <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE`, `wback==FALSE`
`LDRSB{<c>}{<q>}  <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`LDRSB{<c>}{<q>}  <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used. For PC use see *LDRSB (literal)* on page F7-2607.

`+/-` Is + or omitted to indicate that the immediate offset is added to the base register value (`add == TRUE`), or – to indicate that the offset is to be subtracted (`add == FALSE`). Different instructions are generated for `#0` and `#-0`.

`<imm>` The immediate offset used for forming the address. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0. Values are:

Encoding T1 Any value in the range 0-4095.

Encoding T2 or A1 Any value in the range0-255.

The pre-UAL syntax `LDR<c>SB` is equivalent to `LDRSB<c>`.

Operation

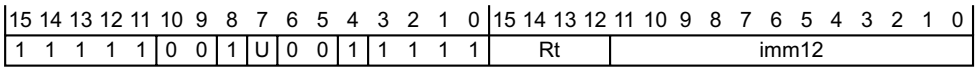
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    R[t] = SignExtend(MemU[address,1], 32);
    if wback then R[n] = offset_addr;
```

F7.1.91 LDRSB (literal)

Load Register Signed Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

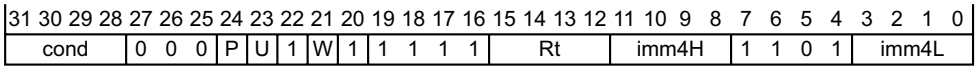
```
LDRSB<c> <Rt>, <label>
LDRSB<c> <Rt>, [PC, #-0]                                    Special case
```



```
if Rt == '1111' then SEE PLI;
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDRSB<c> <Rt>, <label>
LDRSB<c> <Rt>, [PC, #-0]                                    Special case
```



```
if P == '0' && W == '1' then SEE LDRSBT;
t = UInt(Rt);  imm32 = ZeroExtend(imm4H:imm4L, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRSB (literal)* on page AppxA-4805.

Assembler syntax

`LDRSB{<c>}{<q>}  <Rt>, <label>`	Normal form
`LDRSB{<c>}{<q>}  <Rt>, [PC, #+/-<imm>]`	Alternative form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are:

Encoding T1 Any value in the range -4095 to 4095.

Encoding A1 Any value in the range -255 to 255.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-2297.

The pre-UAL syntax `LDR<c>SB` is equivalent to `LDRSB<c>`.

Operation

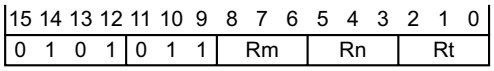
```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    R[t] = SignExtend(MemU[address,1], 32);
```

F7.1.92 LDRSB (register)

Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

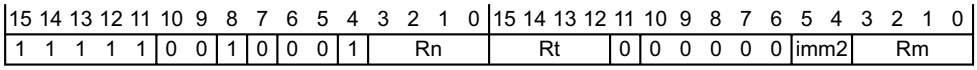
```
LDRSB<c> <Rt>, [<Rn>, <Rm>]
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

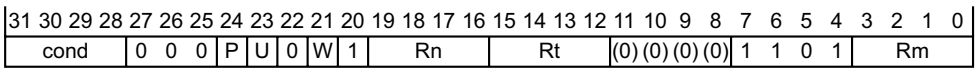
```
LDRSB<c>.W <Rt>, [<Rn>, <Rm>{, LSL #<imm2>}]
```



```
if Rt == '1111' then SEE PLI;
if Rn == '1111' then SEE LDRSB (literal);
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDRSB<c> <Rt>, [<Rn>,+/-<Rm>]{!}
LDRSB<c> <Rt>, [<Rn>],+/-<Rm>
```



```
if P == '0' && W == '1' then SEE LDRSBT;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRType_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRSB (register)* on page AppxA-4801.

Assembler syntax

`LDRSB{<c>}{<q>} <Rt>, [<Rn>, <Rm>{, LSL #<imm>}]`	Offset: `index==TRUE`, `wback==FALSE`
`LDRSB{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>]`	Offset: `index==TRUE`, `wback==FALSE`
`LDRSB{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`LDRSB{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used. In the A32 instruction set the PC can be used, for the offset addressing forms of the instruction only. In the T32 instruction set, the PC cannot be used for any of these forms of the `LDRSB` instruction.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`).

`<Rm>` Contains the offset that is optionally left shifted and added to the value of `<Rn>` to form the address.

`<imm>` If present, the size of the left shift to apply to the value from `<Rm>`, in the range 1-3. Only encoding T2 is permitted, and `<imm>` is encoded in imm2.

If absent, no shift is specified and all encodings are permitted. In encoding T2, imm2 is encoded as `0b00`.

The pre-UAL syntax `LDR<c>SB` is equivalent to `LDRSB<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    R[t] = SignExtend(MemU[address,1], 32);
    if wback then R[n] = offset_addr;
```

F7.1.93 LDRSBT

Load Register Signed Byte Unprivileged loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-2337.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

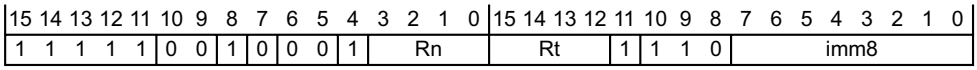
LDRSBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

Encoding T1

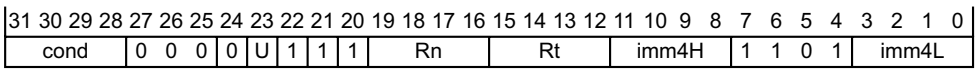
```
LDRSBT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then SEE LDRSB (literal);
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

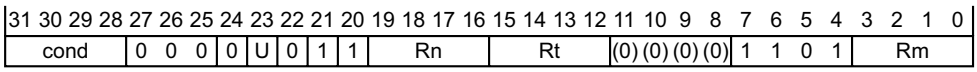
```
LDRSBT<c> <Rt>, [<Rn>] {, #+/-<imm8>}
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2

```
LDRSBT<c> <Rt>, [<Rn>], +/-<Rm>
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRSBT* on page AppxA-4802.

Assembler syntax

`LDRSBT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: T32 only
`LDRSBT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: A32 only
`LDRSBT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: A32 only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`).

`<imm>` The immediate offset applied to the value of `<Rn>`. Any value in the range 0-255 is permitted. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is applied to the value of `<Rn>` to form the address.

Operation

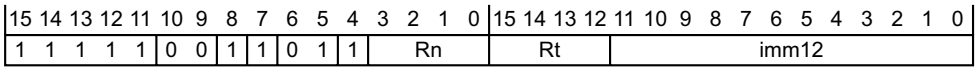
```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    R[t] = SignExtend(MemU_unpriv[address,1], 32);
    if postindex then R[n] = offset_addr;
```

F7.1.94 LDRSH (immediate)

Load Register Signed Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

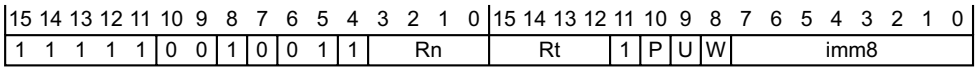
```
LDRSH<c> <Rt>, [<Rn>, #<imm12>]
```



```
if Rn == '1111' then SEE LDRSH (literal);
if Rt == '1111' then SEE "Related instructions";
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding T2

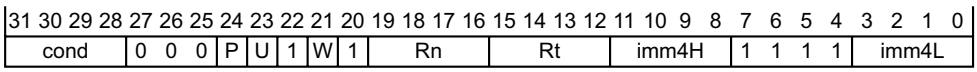
```
LDRSH<c> <Rt>, [<Rn>, #-<imm8>]
LDRSH<c> <Rt>, [<Rn>], #+/-<imm8>
LDRSH<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if Rn == '1111' then SEE LDRSH (literal);
if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE "Related instructions";
if P == '1' && U == '1' && W == '0' then SEE LDRSHT;
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDRSH<c> <Rt>, [<Rn>{, #+/-<imm8>}]
LDRSH<c> <Rt>, [<Rn>], #+/-<imm8>
LDRSH<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if Rn == '1111' then SEE LDRSH (literal);
if P == '0' && W == '1' then SEE LDRSHT;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRSH (immediate)* on page AppxA-4802.

Related instructions See *Load halfword, memory hints* on page F3-2367

Assembler syntax

`LDRSH{<c>}{<q>}  <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`LDRSH{<c>}{<q>}  <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`LDRSH{<c>}{<q>}  <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used. For PC use see *LDRSH (literal)* on page F7-2615.

`+/-` Is + or omitted to indicate that the immediate offset is added to the base register value (`add == TRUE`), or – to indicate that the offset is to be subtracted (`add == FALSE`). Different instructions are generated for `#0` and `#-0`.

`<imm>` The immediate offset used for forming the address, Values are 0-4095 for encoding T1, and 0-255 for encoding T2 or A1. For the offset syntax, `<imm>` can be omitted, meaning an offset of 0.

The pre-UAL syntax `LDR<c>SH` is equivalent to `LDRSH<c>`.

Operation

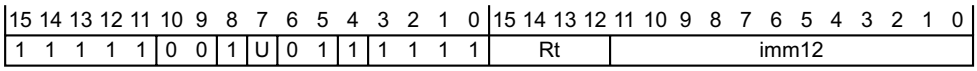
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    R[t] = SignExtend(data, 32);
```

F7.1.95 LDRSH (literal)

Load Register Signed Halfword (literal) calculates an address from the PC value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

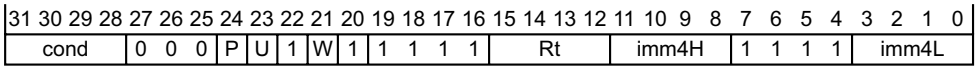
```
LDRSH<c> <Rt>, <label>
LDRSH<c> <Rt>, [PC, #-0]                                  Special case
```



```
if Rt == '1111' then SEE "Related instructions";
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDRSH<c> <Rt>, <label>
LDRSH<c> <Rt>, [PC, #-0]                                  Special case
```



```
if P == '0' && W == '1' then SEE LDRSHT;
t = UInt(Rt);  imm32 = ZeroExtend(imm4H:imm4L, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRSH (literal)* on page AppxA-4805 on page AppxA-4788.

Related instructions See *Load halfword, memory hints* on page F3-2367

Assembler syntax

`LDRSH{<c>}{<q>}  <Rt>, <label>`	Normal form
`LDRSH{<c>}{<q>}  <Rt>, [PC, #+/-<imm>]`	Alternative form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are:

Encoding T1 Any value in the range -4095 to 4095.

Encoding A1 Any value in the range -255 to 255.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-2297.

The pre-UAL syntax `LDR<c>SH` is equivalent to `LDRSH<c>`.

Operation

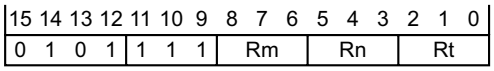
```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,2];
    R[t] = SignExtend(data, 32);
```

F7.1.96 LDRSH (register)

Load Register Signed Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

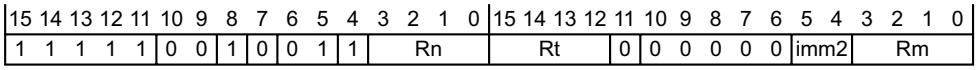
```
LDRSH<c> <Rt>, [<Rn>, <Rm>]
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

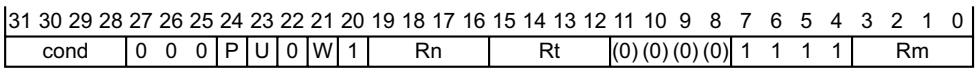
```
LDRSH<c>.W <Rt>, [<Rn>, <Rm>{, LSL #<imm2>}]
```



```
if Rn == '1111' then SEE LDRSH (literal);
if Rt == '1111' then SEE "Related instructions";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
LDRSH<c> <Rt>, [<Rn>,+/-<Rm>]{!}
LDRSH<c> <Rt>, [<Rn>],+/-<Rm>
```



```
if P == '0' && W == '1' then SEE LDRSHT;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRType_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRSH (register)* on page AppxA-4802.

Related instructions See *Load halfword, memory hints* on page F3-2367

Assembler syntax

`LDRSH{<c>}{<q>}  <Rt>, [<Rn>, <Rm>{, LSL #<imm>}]`	Offset: `index==TRUE`, `wback==FALSE`
`LDRSH{<c>}{<q>}  <Rt>, [<Rn>, +/-<Rm>]`	Offset: `index==TRUE`, `wback==FALSE`
`LDRSH{<c>}{<q>}  <Rt>, [<Rn>, +/-<Rm>]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`LDRSH{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used. In the A32 instruction set the PC can be used, for the offset addressing forms of the instruction only. In the T32 instruction set, the PC cannot be used for any of these forms of the `LDRSH` instruction.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`).

`<Rm>` Contains the offset that is optionally left shifted and added to the value of `<Rn>` to form the address.

`<imm>` If present, the size of the left shift to apply to the value from `<Rm>`, in the range 1-3. Only encoding T2 is permitted, and `<imm>` is encoded in imm2.

If absent, no shift is specified and all encodings are permitted. In encoding T2, imm2 is encoded as `0b00`.

The pre-UAL syntax `LDR<c>SH` is equivalent to `LDRSH<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    R[t] = SignExtend(data, 32);
```

F7.1.97 LDRSHT

Load Register Signed Halfword Unprivileged loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-2337.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

Encoding T1

```
LDRSHT<c> <Rt>, [<Rn>, #<imm8>]
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	0	1	0	0	1	1	Rn				Rt				1	1	1	0	imm8							

```
if Rn == '1111' then SEE LDRSH (literal);
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRSHT* on page AppxA-4803.

Assembler syntax

`LDRSHT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: T32 only
`LDRSHT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: A32 only
`LDRSHT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: A32 only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`).

`<imm>` The immediate offset applied to the value of `<Rn>`. Any value in the range 0-255 is permitted. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is applied to the value of `<Rn>` to form the address.

Operation

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,2];
    if postindex then R[n] = offset_addr;
    R[t] = SignExtend(data, 32);
```

F7.1.98 LDRT

Load Register Unprivileged loads a word from memory, and writes it to a register. For information about memory accesses see *Memory accesses* on page F2-2337.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

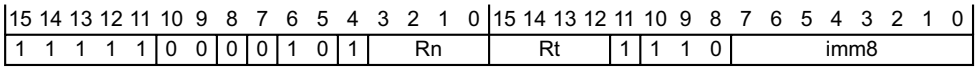
LDRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

Encoding T1

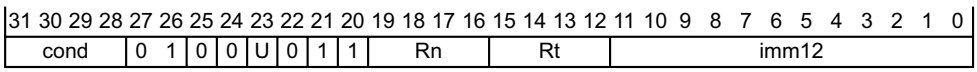
```
LDRT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then SEE LDR (literal);
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

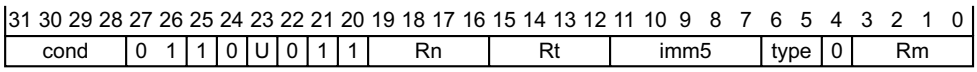
```
LDRT<c> <Rt>, [<Rn>] {, #+/-<imm12>}
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2

```
LDRT<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;  (shift_t, shift_n) = DecodeImmShift(type, imm5);
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRT* on page AppxA-4803.

Assembler syntax

`LDRT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: T32 only
`LDRT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: A32 only
`LDRT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm> {, <shift>}`	Post-indexed: A32 only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`).

`<imm>` The immediate offset applied to the value of `<Rn>`. Values are 0-255 for encoding T1, and 0-4095 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is optionally shifted and applied to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

The pre-UAL syntax `LDR<c>T` is equivalent to `LDRT<c>`.

Operation

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,4];
    if postindex then R[n] = offset_addr;
    R[t] = data;
```

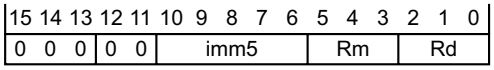
F7.1.99 LSL (immediate)

Logical Shift Left (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

`LSLS <Rd>, <Rm>, #<imm5>` Outside IT block.

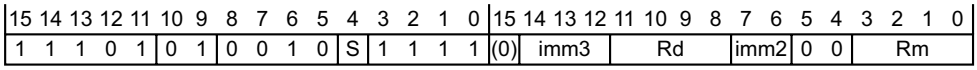
`LSL<c> <Rd>, <Rm>, #<imm5>` Inside IT block.



```
if imm5 == '00000' then SEE MOV (register);
d = UInt(Rd);  m = UInt(Rm);  setflags = !InITBlock();
(-, shift_n) = DecodeImmShift('00', imm5);
```

Encoding T2

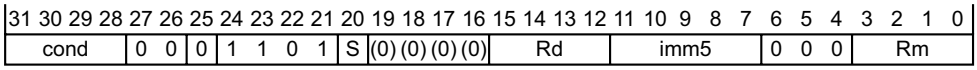
`LSL{S}<c>.W <Rd>, <Rm>, #<imm5>`



```
if (imm3:imm2) == '00000' then SEE MOV (register);
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(-, shift_n) = DecodeImmShift('00', imm3:imm2);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`LSL{S}<c> <Rd>, <Rm>, #<imm5>`



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
if imm5 == '00000' then SEE MOV (register);
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(-, shift_n) = DecodeImmShift('00', imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
LSL{S}{<c>}{<q>}  {<Rd>,} <Rm>, #<imm5>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register. In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
`<Rm>`	The first operand register. The PC can be used in A32 instructions.
`<imm5>`	The shift amount, in the range 1 to 31. See *Shifts applied to a register* on page F2-2334.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry) = Shift_C(R[m], SRType_LSL, shift_n, PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

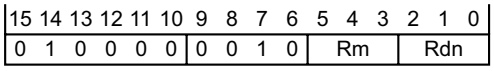
F7.1.100 LSL (register)

Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register. It can optionally update the condition flags based on the result.

Encoding T1

`LSLS <Rdn>, <Rm>` Outside IT block.

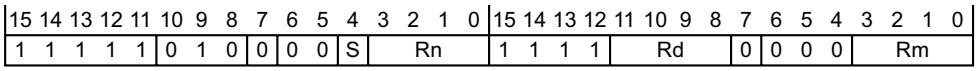
`LSL<c> <Rdn>, <Rm>` Inside IT block.



```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
```

Encoding T2

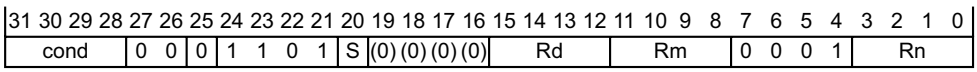
`LSL{S}<c>.W <Rd>, <Rn>, <Rm>`



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`LSL{S}<c> <Rd>, <Rn>, <Rm>`



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
LSL{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The register whose bottom byte contains the amount to shift by.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[m]<7:0>);
    (result, carry) = Shift_C(R[n], SRType_LSL, shift_n, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

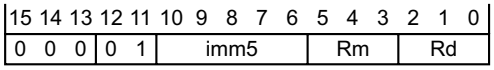
F7.1.101 LSR (immediate)

Logical Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

`LSRS <Rd>, <Rm>, #<imm>` Outside IT block.

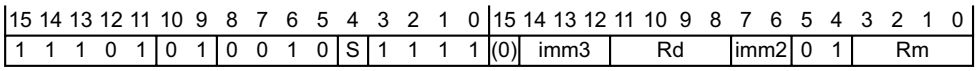
`LSR<c> <Rd>, <Rm>, #<imm>` Inside IT block.



```
d = UInt(Rd);  m = UInt(Rm);  setflags = !InITBlock();
(-, shift_n) = DecodeImmShift('01', imm5);
```

Encoding T2

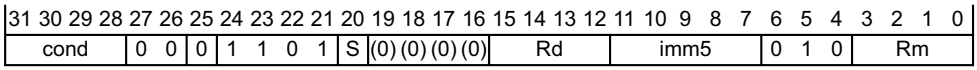
`LSR{S}<c>.W <Rd>, <Rm>, #<imm>`



```
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(-, shift_n) = DecodeImmShift('01', imm3:imm2);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`LSR{S}<c> <Rd>, <Rm>, #<imm>`



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(-, shift_n) = DecodeImmShift('01', imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
LSR{S}{<c>}{<q>}  {<Rd>,} <Rm>, #<imm>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register. In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
`<Rm>`	The first operand register. The PC can be used in A32 instructions.
`<imm>`	The shift amount, in the range 1 to 32. See *Shifts applied to a register* on page F2-2334.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry) = Shift_C(R[m], SRType_LSR, shift_n, PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

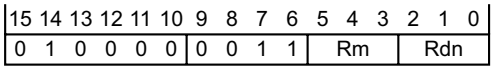
F7.1.102 LSR (register)

Logical Shift Right (register) shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register. It can optionally update the condition flags based on the result.

Encoding T1

`LSRS <Rdn>, <Rm>` Outside IT block.

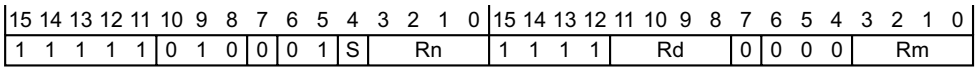
`LSR<c> <Rdn>, <Rm>` Inside IT block.



```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
```

Encoding T2

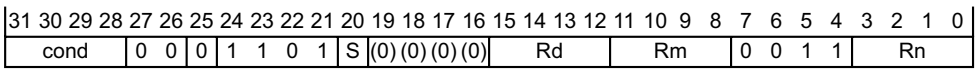
`LSR{S}<c>.W <Rd>, <Rn>, <Rm>`



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`LSR{S}<c> <Rd>, <Rn>, <Rm>`



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
LSR{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The register whose bottom byte contains the amount to shift by.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[m]<7:0>);
    (result, carry) = Shift_C(R[n], SRType_LSR, shift_n, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

F7.1.103 MCR, MCR2

Move to Coprocessor from general-purpose register passes the value of a general-purpose register to a coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1`, `opc2`, `CRn`, and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid `MCR` and `MCR2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page E1-2244.

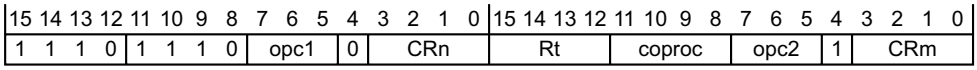
In an implementation that includes EL2, `MCR` accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an `MCR` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *EL2 configurable instruction enables, disables, and traps* on page G1-3482.

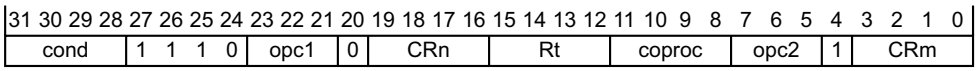
Note

Because of the range of possible traps to Hyp mode, the `MCR` pseudocode does not show these possible traps.

Encoding T1/A1

```
MCR<c> <coproc>, <opc1>, <Rt>, <CRn>, <CRm>{, <opc2>}
```

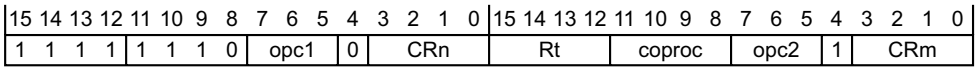


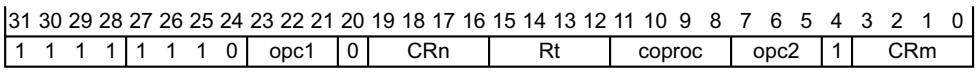


```
if coproc == '101x' then SEE "Advanced SIMD and Floating-point";
t = UInt(Rt);  cp = UInt(coproc);
if t == 15  then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding T2/A2

```
MCR2<c> <coproc>, <opc1>, <Rt>, <CRn>, <CRm>{, <opc2>}
```





```
if coproc == '101x' then UNDEFINED;
t = UInt(Rt);  cp = UInt(coproc);
if t == 15  then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Advanced SIMD and floating-point

See *8, 16, and 32-bit transfers accessing the SIMD and floating-point register file* on page F5-2434

Assembler syntax

```
MCR{2}{<c>}{<q>}  <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

where:

`2`	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330. An A32 `MCR2` instruction must be unconditional.
`<coproc>`	The name of the coprocessor. The generic coprocessor names are p0-p15.
`<opc1>`	Is a coprocessor-specific opcode in the range 0 to 7.
`<Rt>`	Is the general-purpose register whose value is transferred to the coprocessor.
`<CRn>`	Is the destination coprocessor register.
`<CRm>`	Is an additional destination coprocessor register.
`<opc2>`	Is a coprocessor-specific opcode in the range 0-7. If omitted, `<opc2>` is assumed to be 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        Coproc_SendOneWord(R[t], cp, ThisInstr());
```

F7.1.104 MCRR, MCRR2

Move to Coprocessor from two general-purpose registers passes the values of two general-purpose registers to a coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1` and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid `MCRR` and `MCRR2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page E1-2244.

In an implementation that includes EL2, `MCRR` accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an `MCRR` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *EL2 configurable instruction enables, disables, and traps* on page G1-3482.

Note

Because of the range of possible traps to Hyp mode, the `MCRR` pseudocode does not show these possible traps.

Encoding T1/A1

`MCRR<c> <coproc>, <opc1>, <Rt>, <Rt2>, <CRm>`

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

if coproc == '101x' then UNDEFINED;
t = UInt(Rt);  t2 = UInt(Rt2);  cp = UInt(coproc);
if t == 15 || t2 == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *MRRC, MRRC2* on page AppxA-4810.

Advanced SIMD and floating-point

See *64-bit transfers accessing the SIMD and floating-point register file* on page F5-2435

Assembler syntax

```
MCRR{2}{<c>}{<q>}  <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

where:

`2`	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330. An A32 `MCRR2` instruction must be unconditional.
`<coproc>`	The name of the coprocessor. The generic coprocessor names are p0-p15.
`<opc1>`	Is a coprocessor-specific opcode in the range 0 to 15.
`<Rt>`	Is the first general-purpose register whose value is transferred to the coprocessor.
`<Rt2>`	Is the second general-purpose register whose value is transferred to the coprocessor.
`<CRm>`	Is the destination coprocessor register.

Note

The relative significance of `Rt2` and `Rt` is IMPLEMENTATION DEFINED, but all uses within this manual treat `Rt2` as more significant than `Rt`

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        Coproc_SendTwoWords(R[t2], R[t], cp, ThisInstr());
```

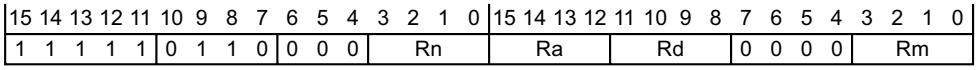
F7.1.105 MLA

Multiply Accumulate multiplies two register values, and adds a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

In an A32 instruction, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

Encoding T1

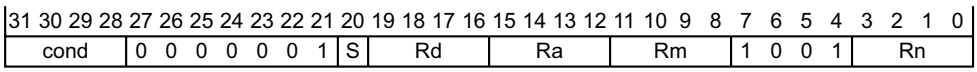
`MLA<c> <Rd>, <Rn>, <Rm>, <Ra>`



```
if Ra == '1111' then SEE MUL;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  setflags = FALSE;
if d == 15 || n == 15 || m  == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`MLA{S}<c> <Rd>, <Rn>, <Rm>, <Ra>`



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
MLA{S}{<c>}{<q>}  <Rd>, <Rn>, <Rm>, <Ra>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated. `S` can be specified only for the A32 instruction set.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.
`<Ra>`	The register containing the accumulate value.

The pre-UAL syntax `MLA<c>S` is equivalent to `MLAS<c>`.

Operation

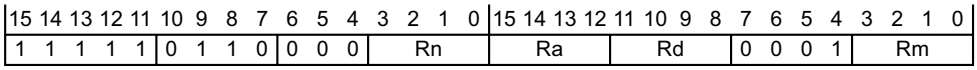
```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    addend   = SInt(R[a]);  // addend   = UInt(R[a]) produces the same final results
    result = operand1 * operand2 + addend;
    R[d] = result<31:0>;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result<31:0>);
        // PSTATE.C, PSTATE.V unchanged
```

F7.1.106 MLS

Multiply and Subtract multiplies two register values, and subtracts the product from a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

Encoding T1

```
MLS<c> <Rd>, <Rn>, <Rm>, <Ra>
```

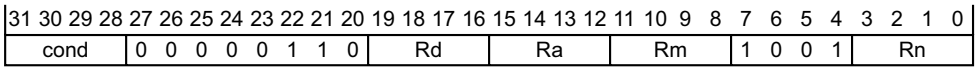


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	1	0	0	0	0	Rn				Ra				Rd				0	0	0	1	Rm			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
MLS<c> <Rd>, <Rn>, <Rm>, <Ra>
```



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	0	0	1	1	0	Rd				Ra				Rm				1	0	0	1	Rn			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
MLS{<c>}{<q>}  <Rd>, <Rn>, <Rm>, <Ra>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.
`<Ra>`	The register containing the accumulate value.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    addend   = SInt(R[a]);  // addend   = UInt(R[a]) produces the same final results
    result = addend - operand1 * operand2;
    R[d] = result<31:0>;
```

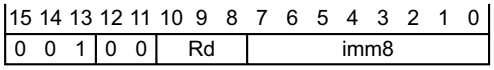
F7.1.107 MOV (immediate)

Move (immediate) writes an immediate value to the destination register. It can optionally update the condition flags based on the value.

Encoding T1

`MOVS <Rd>, #<imm8>` Outside IT block.

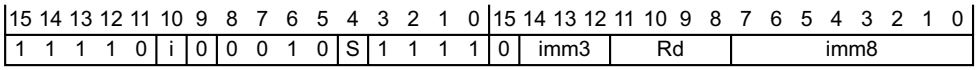
`MOV<c> <Rd>, #<imm8>` Inside IT block.



```
d = UInt(Rd);  setflags = !InITBlock();  imm32 = ZeroExtend(imm8, 32);  carry = PSTATE.C;
```

Encoding T2

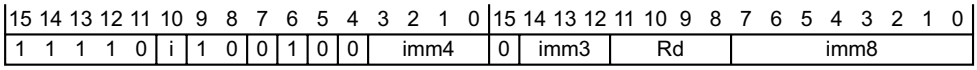
`MOV{S}<c>.W <Rd>, #<const>`



```
d = UInt(Rd);  setflags = (S == '1');  (imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding T3

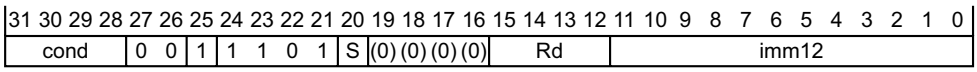
`MOVW<c> <Rd>, #<imm16>`



```
d = UInt(Rd);  setflags = FALSE;  imm32 = ZeroExtend(imm4:i:imm3:imm8, 32);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

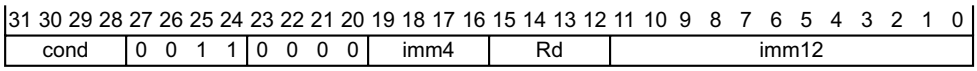
`MOV{S}<c> <Rd>, #<const>`



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  setflags = (S == '1');  (imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

Encoding A2

`MOVW<c> <Rd>, #<imm16>`



```
d = UInt(Rd);  setflags = FALSE;  imm32 = ZeroExtend(imm4:imm12, 32);
if d == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`MOV{S}{<c>}{<q>}  <Rd>, #<const>`	All encodings permitted
`MOVW{<c>}{<q>}  <Rd>, #<const>`	Only encoding T3 or A2 permitted

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032.

In A32 instructions, if `S` is not specified and `<Rd>` is the PC, encoding A2 is not permitted, and for encoding A1 the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<const>` The immediate value to be placed in `<Rd>`. The range of values is 0-255 for encoding T1 and 0-65535 for encoding T3 or A2. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values for encoding T2 or A1.

When both 32-bit encodings are available for an instruction, encoding T2 or A1 is preferred to encoding T3 or A2 (if encoding T3 or A2 is required, use the `MOVW` syntax).

The pre-UAL syntax `MOV<c>S` is equivalent to `MOVS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = imm32;
    if d == 15 then          // Can only occur for encoding A1
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

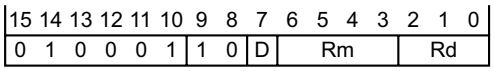
F7.1.108 MOV (register), T32

Move (register) copies a value from a register to the destination register. It can optionally update the condition flags based on the value.

Encoding T1

`MOV<c> <Rd>, <Rm>`

If `<Rd>` is the PC, must be outside or last in IT block.

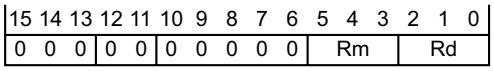


```
d = UInt(D:Rd);  m = UInt(Rm);  setflags = FALSE;
if d == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T2

`MOVS <Rd>, <Rm>`

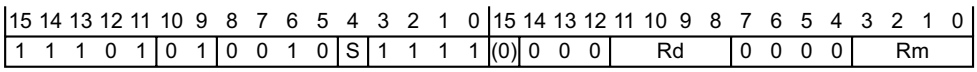
Not permitted in IT block



```
d = UInt(Rd);  m = UInt(Rm);  setflags = TRUE;
if InITBlock() then UNPREDICTABLE;
```

Encoding T3

`MOV{S}<c>.W <Rd>, <Rm>`



```
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *MOV (register, T32)* on page AppxA-4810.

Assembler syntax

```
MOV{S}{<c>}{<q>}  <Rd>, <Rm>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page F2-2330.

<Rd> — The destination register. This register can be the SP or PC. S must not be specified if <Rd> is the SP.

If <Rd> is the PC and S is not specified:

- The instruction causes a branch to the address moved to the PC. This is a simple branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
- The instruction must either be outside an IT block or the last instruction of an IT block.

<Rm> — The source register. This register can be the SP or PC. S must not be specified if <Rm> is the SP or PC.

Encoding T3 is not permitted if <Rd> or <Rm> is the PC.

Note

- ARM deprecates the use of the following MOV (register) instructions:
  - Ones in which <Rd> is the SP or PC and <Rm> is also the SP or PC.
  - Ones in which S is specified and <Rm> is the SP, or <Rm> is the PC.
- See also *Branch instructions* on page F1-2299 about the use of the MOV PC, LR instruction.

The pre-UAL syntax MOV<c>S is equivalent to MOVS<c>.

Operation

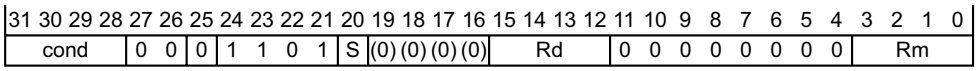
```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[m];
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            // PSTATE.C unchanged
            // PSTATE.V unchanged
```

F7.1.109 MOV (register), A32

Move (register) copies a value from a register to the destination register. It can optionally update the condition flags based on the value.

Encoding A1

```
MOV{S}<c> <Rd>, <Rm>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
MOV{S}{<c>}{<q>}  <Rd>, <Rm>
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions, A32* on page F7-3032. This register can be the SP or PC. If <Rd> is the PC and S is not specified, the instruction causes a branch to the address moved to the PC. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
<Rm>	The source register. This register can be the SP or PC.

Note

- ARM deprecates the use of the following MOV (register) instructions:
  - Ones in which <Rd> is the SP or PC and <Rm> is also the SP or PC.
  - Ones in which S is specified and <Rd> is the SP, <Rm> is the SP, or <Rm> is the PC.
- See also *Branch instructions* on page F1-2299 about the use of the MOV PC, LR instruction.

The pre-UAL syntax MOV<c>S is equivalent to MOVS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[m];
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            // PSTATE.C unchanged
            // PSTATE.V unchanged
```

F7.1.110 MOV (shifted register)

For the special case of MOVS where <Rd> is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 and *SUBS PC, LR and related instructions, A32* on page F7-3032. Otherwise, MOV (shifted register) is a pseudo-instruction for ASR, LSL, LSR, ROR, and RRX. For more information see the following sections:

- *ASR (immediate)* on page F7-2480.
- *ASR (register)* on page F7-2482.
- *LSL (immediate)* on page F7-2623.
- *LSL (register)* on page F7-2625.
- *LSR (immediate)* on page F7-2627.
- *LSR (register)* on page F7-2629.
- *ROR (immediate)* on page F7-2723.
- *ROR (register)* on page F7-2725.
- *RRX* on page F7-2727.

Assembler syntax

Table F7-2 shows the equivalences between MOV (shifted register) and other instructions.

Table F7-2 MOV (shifted register) equivalences

MOV instruction	Canonical form
MOV{S} <Rd>, <Rm>, ASR #<n>	ASR{S} <Rd>, <Rm>, #<n>
MOV{S} <Rd>, <Rm>, LSL #<n>	LSL{S} <Rd>, <Rm>, #<n>
MOV{S} <Rd>, <Rm>, LSR #<n>	LSR{S} <Rd>, <Rm>, #<n>
MOV{S} <Rd>, <Rm>, ROR #<n>	ROR{S} <Rd>, <Rm>, #<n>
MOV{S} <Rd>, <Rm>, ASR <Rs>	ASR{S} <Rd>, <Rm>, <Rs>
MOV{S} <Rd>, <Rm>, LSL <Rs>	LSL{S} <Rd>, <Rm>, <Rs>
MOV{S} <Rd>, <Rm>, LSR <Rs>	LSR{S} <Rd>, <Rm>, <Rs>
MOV{S} <Rd>, <Rm>, ROR <Rs>	ROR{S} <Rd>, <Rm>, <Rs>
MOV{S} <Rd>, <Rm>, RRX	RRX{S} <Rd>, <Rm>

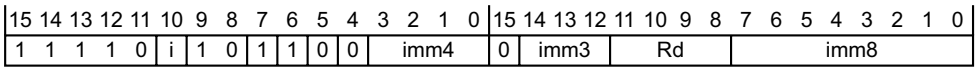
Disassembly produces the canonical form of the instruction.

F7.1.111 MOVT

Move Top writes an immediate value to the top halfword of the destination register. It does not affect the contents of the bottom halfword.

Encoding T1

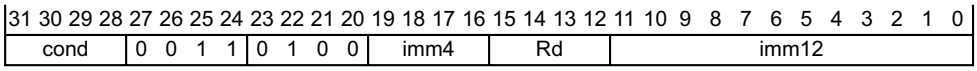
MOVT<c> <Rd>, #<imm16>



```
d = UInt(Rd);  imm16 = imm4:i:imm3:imm8;
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

MOVT<c> <Rd>, #<imm16>



```
d = UInt(Rd);  imm16 = imm4:imm12;
if d == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

MOVT{<c>}{<q>} <Rd>, #<imm16>

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2330.

<Rd> The destination register.

<imm16> The immediate value to be written to <Rd>. It must be in the range 0-65535.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R[d]<31:16> = imm16;
    // R[d]<15:0> unchanged
```

F7.1.112 MRC, MRC2

Move to general-purpose register from Coprocessor causes a coprocessor to transfer a value to a general-purpose register or to the condition flags. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1`, `opc2`, `CRn`, and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid `MRC` and `MRC2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page E1-2244.

In an implementation that includes EL2, `MRC` accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an `MRC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *EL2 configurable instruction enables, disables, and traps* on page G1-3482.

Note

Because of the range of possible traps to Hyp mode, the `MRC` pseudocode does not show these possible traps.

Encoding T1/A1

```
MRC<c> <coproc>, <opc1>, <Rt>, <CRn>, <CRm>{, <opc2>}
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	1	0	opc1			1	CRn				Rt				coproc				opc2			1	CRm			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	1	1	0	opc1			1	CRn				Rt				coproc				opc2			1	CRm			

```
if coproc == '101x' then SEE "Advanced SIMD and Floating-point";
t = UInt(Rt);  cp = UInt(coproc);
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding T2/A2

```
MRC2<c> <coproc>, <opc1>, <Rt>, <CRn>, <CRm>{, <opc2>}
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	0	opc1			1	CRn				Rt				coproc				opc2			1	CRm			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	0	opc1			1	CRn				Rt				coproc				opc2			1	CRm			

```
if coproc == '101x' then UNDEFINED;
t = UInt(Rt);  cp = UInt(coproc);
// ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Advanced SIMD and floating-point

See *8, 16, and 32-bit transfers accessing the SIMD and floating-point register file* on page F5-2434

Assembler syntax

```
MRC{2}{<c>}{<q>}  <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

where:

`2`	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330. An A32 `MRC2` instruction must be unconditional.
`<coproc>`	The name of the coprocessor. The generic coprocessor names are p0-p15.
`<opc1>`	Is a coprocessor-specific opcode in the range 0 to 7.
`<Rt>`	Is the destination general-purpose register. This register can be R0-R14 or APSR_nzcv. The last form writes bits[31:28] of the transferred value to the N, Z, C and V condition flags and is specified by setting the Rt field of the encoding to `0b1111`. In pre-UAL assembler syntax, PC was written instead of APSR_nzcv to select this form.
`<CRn>`	Is the coprocessor register that contains the first operand.
`<CRm>`	Is an additional source or destination coprocessor register.
`<opc2>`	Is a coprocessor-specific opcode in the range 0 to 7. If omitted, `<opc2>` is assumed to be 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        value = Coproc_GetOneWord(cp, ThisInstr());
        if t != 15 then
            R[t] = value;
        else
            PSTATE.<N,Z,C,V> = value<31:28>;
            // value<27:0> are not used.
```

F7.1.113 MRRC, MRRC2

Move to two general-purpose registers from Coprocessor causes a coprocessor to transfer values to two general-purpose registers. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1` and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid `MRRC` and `MRRC2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page E1-2244.

In an implementation that includes EL2, `MRRC` accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an `MRRC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *EL2 configurable instruction enables, disables, and traps* on page G1-3482.

Note

Because of the range of possible traps to Hyp mode, the `MRRC` pseudocode does not show these possible traps.

Encoding T1/A1

`MRRC<c> <coproc>, <opc>, <Rt>, <Rt2>, <CRm>`

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	1	0	0	0	1	0	1	Rt2				Rt				coproc				opc1				CRm			

```
if coproc == '101x' then SEE "Advanced SIMD and Floating-point";
t = UInt(Rt);  t2 = UInt(Rt2);  cp = UInt(coproc);
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *MRRC, MRRC2* on page AppxA-4810.

Encoding T2/A2

`MRRC2<c> <coproc>, <opc>, <Rt>, <Rt2>, <CRm>`

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	0	0	0	1	0	1	Rt2				Rt				coproc				opc1				CRm			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	0	0	0	1	0	1	Rt2				Rt				coproc				opc1				CRm			

```
if coproc == '101x' then UNDEFINED;
t = UInt(Rt);  t2 = UInt(Rt2);  cp = UInt(coproc);
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Advanced SIMD and floating-point

See *64-bit transfers accessing the SIMD and floating-point register file* on page F5-2435

Assembler syntax

```
MRRC{2}{<c>}{<q>}  <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

where:

`2`	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330. An A32 `MRRC2` instruction must be unconditional.
`<coproc>`	The name of the coprocessor. The generic coprocessor names are p0-p15.
`<opc1>`	Is a coprocessor-specific opcode in the range 0 to 15.
`<Rt>`	Is the first destination general-purpose register.
`<Rt2>`	Is the second destination general-purpose register.
`<CRm>`	Is the coprocessor register that supplies the data to be transferred.

Note

The relative significance of `Rt2` and `Rt` is IMPLEMENTATION DEFINED, but all uses within this manual treat `Rt2` as more significant than `Rt`

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        (R[t2], R[t]) = Coproc_GetTwoWords(cp, ThisInstr());
```

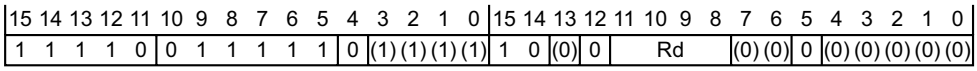
F7.1.114 MRS

Move to Register from Special register moves the value from the APSR into a general-purpose register.

For details of system level use of this instruction, see *MRS* on page F7-3010.

Encoding T1

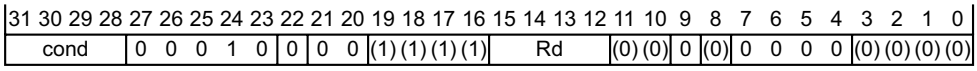
```
MRS<c> <Rd>, <spec_reg>
```



```
d = UInt(Rd);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
MRS<c> <Rd>, <spec_reg>
```



```
d = UInt(Rd);
if d == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
MRS{<c>}{<q>}  <Rd>, <spec_reg>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<spec_reg>` Is one of:

- `APSR`.
- `CPSR`.

When the `MRS` instruction is executed in User mode, `CPSR` is treated as a synonym of `APSR`.

ARM recommends that application level software uses the `APSR` form. For more information, see *The Application Program Status Register (APSR)* on page E1-2211.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R[d] = APSR;
```

F7.1.115 MRS (Banked register)

Move to Register from Banked or Special register is a system instruction, see *MRS (Banked register)* on page F7-3012.

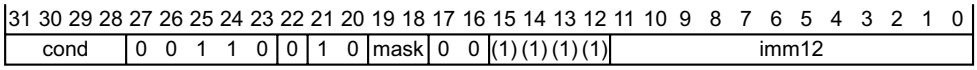
F7.1.116 MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the corresponding bits in the APSR.

For details of system level use of this instruction, see *MSR (immediate)* on page F7-3016.

Encoding A1

```
MSR<c> <spec_reg>, #<const>
```



```
if mask == '00' then SEE "Related encodings";
imm32 = A32ExpandImm(imm12);  write_nzcvq = (mask<1> == '1');  write_g = (mask<0> == '1');
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings See *MSR (immediate), and hints* on page F4-2393.

Assembler syntax

```
MSR{<c>}{<q>}  <spec_reg>, #<imm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<spec_reg>` Is one of:

- `APSR_<bits>`.
- `CPSR_<fields>`.

ARM recommends that application level software uses the `APSR` forms. For more information, see *The Application Program Status Register (APSR)* on page E1-2211.

`<imm>` Is the immediate value to be transferred to `<spec_reg>`. See *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

`<bits>` Is one of `nzcvq`, `g`, or `nzcvqg`.

In the A and R profiles:

- `APSR_nzcvq` is the same as `CPSR_f`.
- `APSR_g` is the same as `CPSR_s`.
- `APSR_nzcvqg` is the same as `CPSR_fs`.

`<fields>` Is a sequence of one or more of the following: `s`, `f`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_nzcvq then
        PSTATE.<N,Z,C,V,Q> = imm32<31:27>;
    if write_g then
        PSTATE.GE = imm32<19:16>;
```

Usage

For details of the APSR see *The Application Program Status Register (APSR)* on page E1-2211. Because of the Do-Not-Modify nature of its reserved bits, the immediate form of `MSR` is normally only useful at the Application level for writing to `APSR_nzcvq` (`CPSR_f`).

MSR (immediate) on page F7-3016 describes additional functionality that is available using the reserved bits. This includes some deprecated functionality that is also available to unprivileged software and therefore can be used at the Application level.

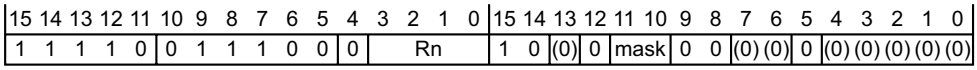
F7.1.117 MSR (register)

Move to Special register from general-purpose register moves selected bits of a general-purpose register to the APSR.

For details of system level use of this instruction, see *MSR (register)* on page F7-3018.

Encoding T1

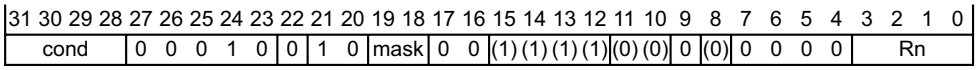
```
MSR<c> <spec_reg>, <Rn>
```



```
n = UInt(Rn);  write_nzcvq = (mask<1> == '1');  write_g = (mask<0> == '1');
if mask == '00' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
MSR<c> <spec_reg>, <Rn>
```



```
n = UInt(Rn);  write_nzcvq = (mask<1> == '1');  write_g = (mask<0> == '1');
if mask == '00' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *MSR (register)* on page AppxA-4810.

Assembler syntax

```
MSR{<c>}{<q>}  <spec_reg>, <Rn>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<spec_reg>` Is one of:

- `APSR_<bits>`.
- `CPSR_<fields>`.

ARM recommends that application level software uses the `APSR` form. For more information, see *The Application Program Status Register (APSR)* on page E1-2211.

`<Rn>` Is the general-purpose register to be transferred to `<spec_reg>`.

`<bits>` Is one of `nzcvq`, `g`, or `nzcvqg`.

In the A and R profiles:

- `APSR_nzcvq` is the same as `CPSR_f`.
- `APSR_g` is the same as `CPSR_s`.
- `APSR_nzcvqg` is the same as `CPSR_fs`.

`<fields>` Is a sequence of one or more of the following: `s`, `f`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_nzcvq then
        PSTATE.<N,Z,C,V,Q> = R[n]<31:27>;
    if write_g then
        PSTATE.GE = R[n]<19:16>;
```

Usage

For details of the APSR see *The Application Program Status Register (APSR)* on page E1-2211. Because of the Do-Not-Modify nature of its reserved bits, a read-modify-write sequence is normally needed when the `MSR` instruction is being used at Application level and its destination is not `APSR_nzcvq` (`CPSR_f`).

MSR (register) on page F7-3018 describes additional functionality that is available using the reserved bits. This includes some deprecated functionality that is also available to unprivileged software and therefore can be used at the Application level.

F7.1.118 MSR (Banked register)

Move to Banked or Special register from general-purpose register is a system instruction, see *MSR (Banked register)* on page F7-3014.

F7.1.119 MUL

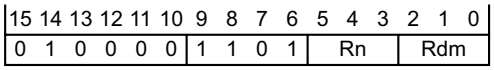
Multiply multiplies two register values. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

Optionally, it can update the condition flags based on the result. In the T32 instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many implementations.

Encoding T1

`MULS <Rdm>, <Rn>, <Rdm>` Outside IT block.

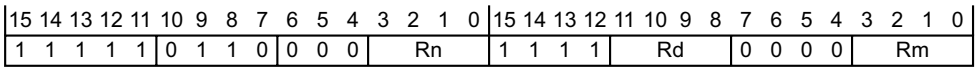
`MUL<c> <Rdm>, <Rn>, <Rdm>` Inside IT block.



```
d = UInt(Rdm);  n = UInt(Rn);  m = UInt(Rdm);  setflags = !InITBlock();
```

Encoding T2

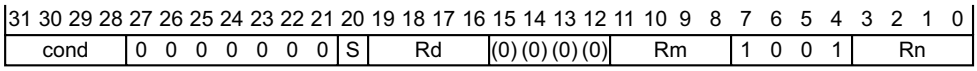
`MUL<c> <Rd>, <Rn>, <Rm>`



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = FALSE;
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`MUL{S}<c> <Rd>, <Rn>, <Rm>`



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
MUL{S}{<c>}{<q>}  <Rd>, <Rn>{, <Rm>}
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated. In the T32 instruction set, `S` can be specified only if both `<Rn>` and `<Rm>` are R0-R7 and the instruction is outside an IT block.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register. If omitted, `<Rd>` is used.

The pre-UAL syntax `MUL<c>S` is equivalent to `MULS<c>`.

Operation

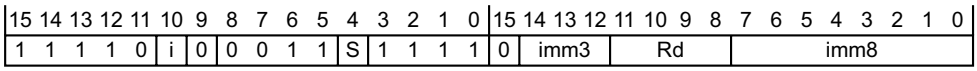
```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    result = operand1 * operand2;
    R[d] = result<31:0>;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result<31:0>);
        // PSTATE.C, PSTATE.V unchanged
```

F7.1.120 MVN (immediate)

Bitwise NOT (immediate) writes the bitwise inverse of an immediate value to the destination register. It can optionally update the condition flags based on the value.

Encoding T1

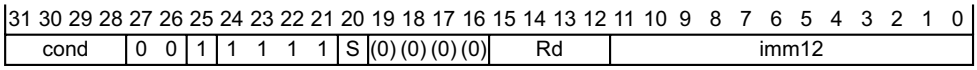
```
MVN{S}<c> <Rd>, #<const>
```



```
d = UInt(Rd);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
MVN{S}<c> <Rd>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
MVN{S}{<c>}{<q>}  <Rd>, #<const>
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032.

In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<const>` The immediate value to be bitwise inverted. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

The pre-UAL syntax `MVN<c>S` is equivalent to `MVNS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = NOT(imm32);
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

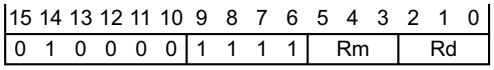
F7.1.121 MVN (register)

Bitwise NOT (register) writes the bitwise inverse of a register value to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

`MVNS <Rd>, <Rm>` Outside IT block.

`MVN<c> <Rd>, <Rm>` Inside IT block.

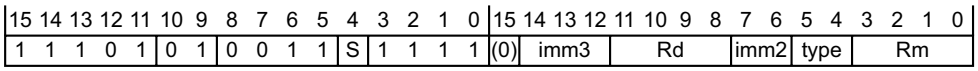


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	0	1	1	1	1	Rm			Rd		

```
d = UInt(Rd);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

`MVN{S}<c>.W <Rd>, <Rm>{, <shift>}`

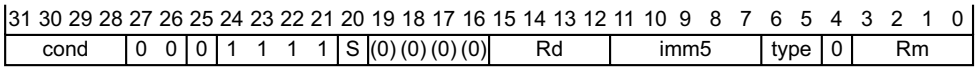


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1		0	1	0	0	1	1	S	1	1	1	1	(0)	imm3			Rd			imm2		type		Rm			

```
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`MVN{S}<c> <Rd>, <Rm>{, <shift>}`



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	1	1	1	S	(0)	(0)	(0)	(0)	Rd				imm5					type		0	Rm			

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
MVN{S}{<c>}{<q>}  <Rd>, <Rm> {, <shift>}
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
`<Rm>`	The register that is optionally shifted and used as the source register. The PC can be used in A32 instructions.
`<shift>`	The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

The pre-UAL syntax `MVN<c>S` is equivalent to `MVNS<c>`.

Operation

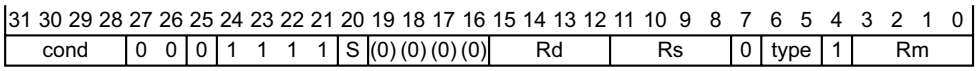
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = NOT(shifted);
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

F7.1.122 MVN (register-shifted register)

Bitwise NOT (register-shifted register) writes the bitwise inverse of a register-shifted register value to the destination register. It can optionally update the condition flags based on the result.

Encoding A1

```
MVN{S}<c> <Rd>, <Rm>, <type> <Rs>
```



31 30 29 28	27 26	25	24 23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0
cond	0 0	0	1 1 1 1	S	(0) (0) (0) (0)	Rd	Rs	0	type	1	Rm

```
d = UInt(Rd);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
MVN{S}{<c>}{<q>}  <Rd>, <Rm>, <type>  <Rs>
```

where:

S
: If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q>
: See *Standard assembler syntax fields* on page F2-2330.

<Rd>
: The destination register.

<Rm>
: The register that is shifted and used as the operand.

<type>
: The type of shift to apply to the value read from <Rm>. It must be one of:

  ASR
  : Arithmetic shift right, encoded as type = 0b10.

  LSL
  : Logical shift left, encoded as type = 0b00.

  LSR
  : Logical shift right, encoded as type = 0b01.

  ROR
  : Rotate right, encoded as type = 0b11.

<Rs>
: The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax MVN<c>S is equivalent to MVNS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = NOT(shifted);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

F7.1.123 NEG

Negate is a pre-UAL synonym for RSB (immediate) with an immediate value of 0. For details see *RSB (immediate)* on page F7-2729.

Assembler syntax

```
NEG{<c>}{<q>}  <Rd>, <Rm>
```

This is equivalent to:

```
RSBS{<c>}{<q>}  <Rd>, <Rm>, #0
```

F7.1.124 NOP

No Operation does nothing. This instruction can be used for instruction alignment purposes.

Note

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

Encoding T1

```
NOP<c>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	1	1	0	0	0	0	0	0	0	0

```
// No additional decoding required
```

Encoding T2

```
NOP<c>.W
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	0	(1)	(1)	(1)	(1)	1	0	(0)	0	(0)	0	0	0	0	0	0	0	0	0	0	0

```
// No additional decoding required
```

Encoding A1

```
NOP<c>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	1	1	0	0	1	0	0	0	0	0	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	0	0	0	0	0	0	0

```
// No additional decoding required
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
NOP{<c>}{<q>}
```

where:

`{<c>}{<q>}` See *Standard assembler syntax fields* on page F2-2330.

Operation

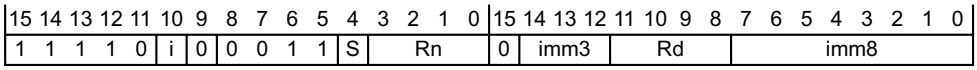
```
if ConditionPassed() then
    EncodingSpecificOperations();
    // Do nothing
```

F7.1.125 ORN (immediate)

Bitwise OR NOT (immediate) performs a bitwise (inclusive) OR of a register value and the complement of an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

```
ORN{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rn == '1111' then SEE MVN (immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ORN{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The register that contains the operand.
`<const>`	The immediate value to be bitwise inverted and ORed with the value obtained from `<Rn>`. See *Modified immediate constants in T32 instructions* on page F3-2358 for the range of values.

Operation

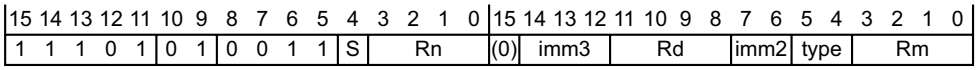
```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] OR NOT(imm32);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

F7.1.126 ORN (register)

Bitwise OR NOT (register) performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

```
ORN{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}
```



```
if Rn == '1111' then SEE MVN (register);
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ORN{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The register that is optionally shifted and used as the second operand.
`<shift>`	The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

Operation

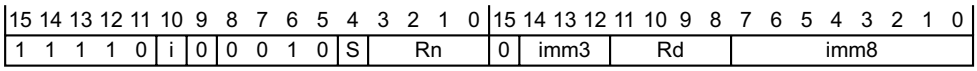
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] OR NOT(shifted);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

F7.1.127 ORR (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

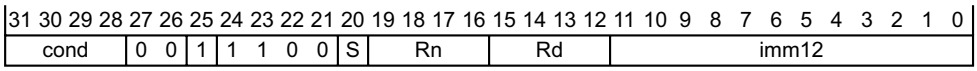
```
ORR{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rn == '1111' then SEE MOV (immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
ORR{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ORR{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
`<Rn>`	The register that contains the operand. The PC can be used in A32 instructions.
`<const>`	The immediate value to be bitwise ORed with the value obtained from `<Rn>`. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

The pre-UAL syntax `ORR<c>S` is equivalent to `ORRS<c>`.

Operation

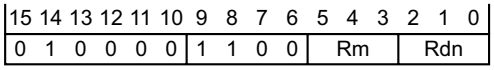
```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] OR imm32;
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

F7.1.128 ORR (register)

Bitwise OR (register) performs a bitwise (inclusive) OR of a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

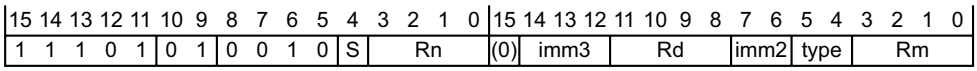
```
ORRS   <Rdn>, <Rm>                    Outside IT block.
ORR<c> <Rdn>, <Rm>                    Inside IT block.
```



```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

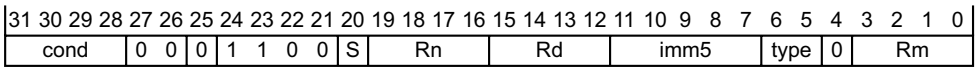
```
ORR{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}
```



```
if Rn == '1111' then SEE "Related encodings";
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
ORR{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings See *Move register and immediate shifts* on page F3-2371.

Assembler syntax

`ORR{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}`

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032.

In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<Rn>` The first operand register. The PC can be used in A32 instructions.

`<Rm>` The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

In T32 assembly:

- Outside an IT block, if `ORRS <Rd>, <Rn>, <Rd>` is written with `<Rd>` and `<Rn>` both in the range R0-R7, it is assembled using encoding T1 as though `ORRS <Rd>, <Rn>` had been written.
- Inside an IT block, if `ORR<c> <Rd>, <Rn>, <Rd>` is written with `<Rd>` and `<Rn>` both in the range R0-R7, it is assembled using encoding T1 as though `ORR<c> <Rd>, <Rn>` had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax `ORR<c>S` is equivalent to `ORRS<c>`.

Operation

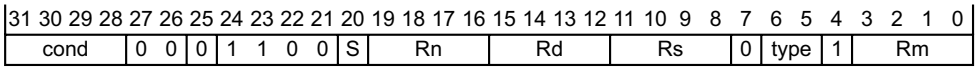
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] OR shifted;
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

F7.1.129 ORR (register-shifted register)

Bitwise OR (register-shifted register) performs a bitwise (inclusive) OR of a register value and a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1

```
ORR{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ORR{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax `ORR<c>S` is equivalent to `ORRS<c>`.

Operation

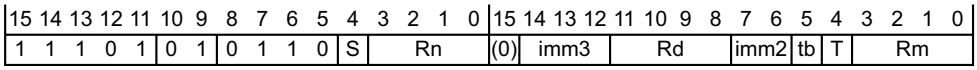
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] OR shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

F7.1.130 PKHBT, PKHTB

Pack Halfword combines one halfword of its first operand with the other halfword of its shifted second operand.

Encoding T1

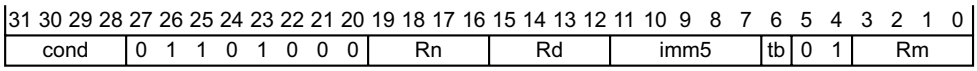
```
PKHBT<c> <Rd>, <Rn>, <Rm>{, LSL #<imm>}
PKHTB<c> <Rd>, <Rn>, <Rm>{, ASR #<imm>}
```



```
if S == '1' || T == '1' then UNDEFINED;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  tbform = (tb == '1');
(shift_t, shift_n) = DecodeImmShift(tb:'0', imm3:imm2);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
PKHBT<c> <Rd>, <Rn>, <Rm>{, LSL #<imm>}
PKHTB<c> <Rd>, <Rn>, <Rm>{, ASR #<imm>}
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  tbform = (tb == '1');
(shift_t, shift_n) = DecodeImmShift(tb:'0', imm5);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`PKHBT{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, LSL #<imm>}`	tbform == FALSE
`PKHTB{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, ASR #<imm>}`	tbform == TRUE

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The register that is optionally shifted and used as the second operand.

`<imm>` The shift to apply to the value read from `<Rm>`, encoded in imm3:imm2 for encoding T1 and imm5 for encoding A1.

For `PKHBT`, it is one of:

omitted No shift, encoded as `0b00000`.

1-31 Left shift by specified number of bits, encoded as a binary number.

For `PKHTB`, it is one of:

omitted Instruction is a pseudo-instruction and is assembled as though `PKHBT{<c>}{<q>} <Rd>, <Rm>, <Rn>` had been written.

1-32 Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as `0b00000`. Other shift amounts are encoded as binary numbers.

Note

An assembler can permit `<imm>` = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = Shift(R[m], shift_t, shift_n, PSTATE.C);  // PSTATE.C ignored
    R[d]<15:0>  = if tbform then operand2<15:0> else R[n]<15:0>;
    R[d]<31:16> = if tbform then R[n]<31:16>    else operand2<31:16>;
```

F7.1.131 PLD, PLDW (immediate)

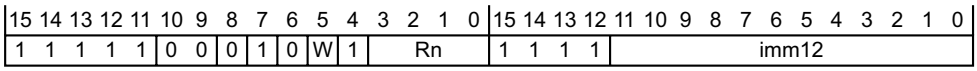
Preload Data signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the data cache.

On an architecture variant that includes both the PLD and PLDW instructions, the PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW instruction is IMPLEMENTATION DEFINED. For more information, see *Preloading caches* on page E2-2254.

Encoding T1

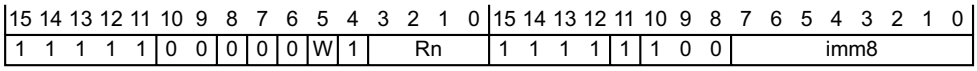
PLD{W}<c> [<Rn>, #<imm12>]



```
if Rn == '1111' then SEE PLD (literal);
n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);  add = TRUE;  is_pldw = (W == '1');
```

Encoding T2

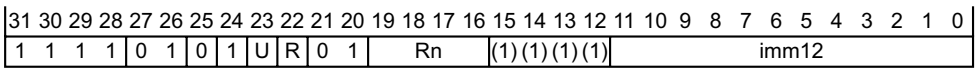
PLD{W}<c> [<Rn>, #-<imm8>]



```
if Rn == '1111' then SEE PLD (literal);
n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);  add = FALSE;  is_pldw = (W == '1');
```

Encoding A1

PLD{W} [<Rn>, #+/-<imm12>]



```
if Rn == '1111' then SEE PLD (literal);
n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');  is_pldw = (R == '0');
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
PLD{W}{<c>}{<q>}  [<Rn> {, #+/-<imm>}]
```

where:

`W` If specified, selects PLDW, encoded as W = 1 in T32 encodings and R = 0 in A32 encodings. If omitted, selects PLD, encoded as W = 0 in T32 encodings and R = 1 in A32 encodings.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `PLD` or `PLDW` instruction must be unconditional.

`<Rn>` The base register. The SP can be used. For PC use in the `PLD` instruction, see *PLD (literal)* on page F7-2681.

`+/-` Is + or omitted to indicate that the immediate offset is added to the base register value (`add == TRUE`), or – to indicate that the offset is to be subtracted (`add == FALSE`). Different instructions are generated for `#0` and `#-0`.

`<imm>` The immediate offset used for forming the address. This offset can be omitted, meaning an offset of 0. Values are:

Encoding T1, A1 Any value in the range 0-4095.

Encoding T2 Any value in the range 0-255.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (R[n] + imm32) else (R[n] - imm32);
    if is_pldw then
        Hint_PreloadDataForWrite(address);
    else
        Hint_PreloadData(address);
```

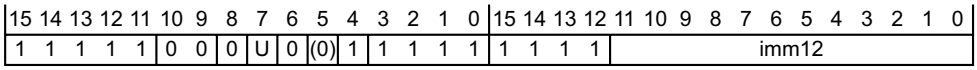
F7.1.132 PLD (literal)

Preload Data signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the data cache.

The effect of a PLD instruction is IMPLEMENTATION DEFINED. For more information, see *Preloading caches* on page E2-2254.

Encoding T1

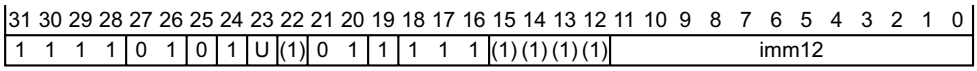
```
PLD<c> <label>
PLD<c> [PC, #-0]                                        Special case
```



```
imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
```

Encoding A1

```
PLD <label>
PLD [PC, #-0]                                           Special case
```



```
imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`PLD{<c>}{<q>}  <label>`	Normal form
`PLD{<c>}{<q>}  [PC, #+/-<imm>]`	Alternative form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `PLD` instruction must be unconditional.

`<label>` The label of the literal data item that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. The offset must be in the range –4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

`+/-` Is + or omitted to indicate that the immediate offset is added to the `Align(PC, 4)` value (`add == TRUE`), or – to indicate that the offset is to be subtracted (`add == FALSE`). Different instructions are generated for `#0` and `#-0`.

`<imm>` The immediate offset used for forming the address. Values are in the range 0-4095.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-2297.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    Hint_PreloadData(address);
```

F7.1.133 PLD, PLDW (register)

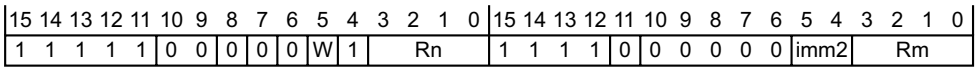
Preload Data signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the data cache.

On an architecture variant that includes both the PLD and PLDW instructions, the PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW instruction is IMPLEMENTATION DEFINED. For more information, see *Preloading caches* on page E2-2254.

Encoding T1

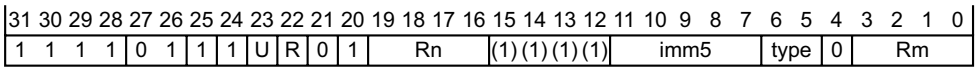
PLD{W}<c> [<Rn>, <Rm>{, LSL #<imm2>}]



```
if Rn == '1111' then SEE PLD (literal);
n = UInt(Rn);  m = UInt(Rm);  add = TRUE;  is_pldw = (W == '1');
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

PLD{W} [<Rn>,+/-<Rm>{, <shift>}]



```
n = UInt(Rn);  m = UInt(Rm);  add = (U == '1');  is_pldw = (R == '0');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if m == 15 || (n == 15 && is_pldw) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
PLD[W]{<c>}{<q>}  [<Rn>, +/-<Rm> {, <shift>}]
```

where:

W	If specified, selects PLDW, encoded as W = 1 in T32 encodings and R = 0 in A32 encodings. If omitted, selects PLD, encoded as W = 0 in T32 encodings and R = 1 in A32 encodings.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330. An A32 PLD or PLDW instruction must be unconditional.
<Rn>	Is the base register. The SP can be used. The PC can be used in A32 PLD instructions, but not in T32 PLD instructions or in any PLDW instructions.
+/-	Is + or omitted if the optionally shifted value of <Rm> is to be added to the base register value (add == TRUE), or – if it is to be subtracted (permitted in A32 instructions only, add == FALSE).
<Rm>	Contains the offset that is optionally shifted and applied to the value of <Rn> to form the address.
<shift>	The shift to apply to the value read from <Rm>. If absent, no shift is applied. For encoding T1, <shift> can only be omitted, encoded as imm2 = 0b00, or LSL #<imm> with <imm> = 1, 2, or 3, with <imm> encoded in imm2. For encoding A1, see *Shifts applied to a register* on page F2-2334.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    address = if add then (R[n] + offset) else (R[n] - offset);
    if is_pldw then
        Hint_PreloadDataForWrite(address);
    else
        Hint_PreloadData(address);
```

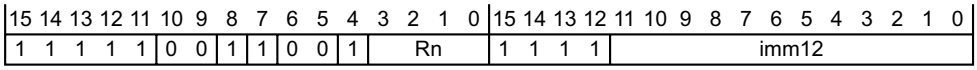
F7.1.134 PLI (immediate, literal)

Preload Instruction signals the memory system that instruction memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the instruction cache.

The effect of a PLI instruction is IMPLEMENTATION DEFINED. For more information, see *Preloading caches* on page E2-2254.

Encoding T1

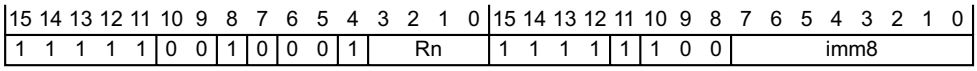
```
PLI<c> [<Rn>, #<imm12>]
```



```
if Rn == '1111' then SEE encoding T3;
n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);  add = TRUE;
```

Encoding T2

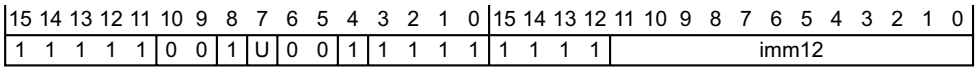
```
PLI<c> [<Rn>, #-<imm8>]
```



```
if Rn == '1111' then SEE encoding T3;
n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);  add = FALSE;
```

Encoding T3

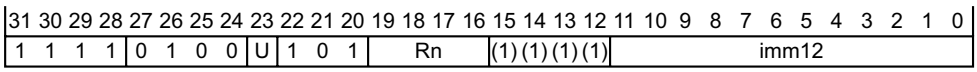
```
PLI<c> <label>
PLI<c> [PC, #-0]                                    Special case
```



```
n = 15;  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
```

Encoding A1

```
PLI [<Rn>, #+/-<imm12>]
PLI <label>
PLI [PC, #-0]                                       Special case
```



```
n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`PLI{<c>}{<q>} [<Rn> {, #+/-<imm>}]`	Immediate form
`PLI{<c>}{<q>} <label>`	Normal literal form
`PLI{<c>}{<q>} [PC, #+/-<imm>]`	Alternative literal form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `PLI` instruction must be unconditional.

`<Rn>` Is the base register. The SP can be used.

`+/-` Is + or omitted to indicate that the immediate offset is added to the base register value (`add == TRUE`), or – to indicate that the offset is to be subtracted (`add == FALSE`). Different instructions are generated for `#0` and `#-0`.

`<imm>` The immediate offset used for forming the address. For the immediate form of the syntax, `<imm>` can be omitted, in which case the `#0` form of the instruction is assembled. Values are:

Encoding T1, T3, A1 Any value in the range 0 to 4095.

Encoding T2 Any value in the range 0 to 255.

`<label>` The label of the instruction that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. The offset must be in the range –4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

For the literal forms of the instruction, encoding T3 is used, or Rn is encoded as `0b1111` in encoding A1, to indicate that the PC is the base register.

The alternative literal syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-2297.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    Hint_PreloadInstr(address);
```

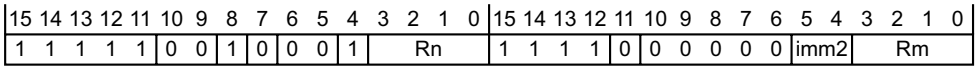
F7.1.135 PLI (register)

Preload Instruction signals the memory system that instruction memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the instruction cache.

The effect of a PLI instruction is IMPLEMENTATION DEFINED. For more information, see *Preloading caches* on page E2-2254.

Encoding T1

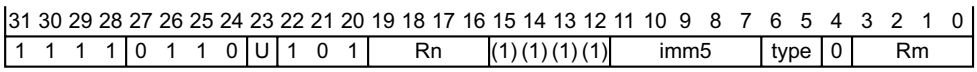
```
PLI<c> [<Rn>, <Rm>{, LSL #<imm2>}]
```



```
if Rn == '1111' then SEE PLI (immediate, literal);
n = UInt(Rn);  m = UInt(Rm);  add = TRUE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
PLI [<Rn>,+/-<Rm>{, <shift>}]
```



```
n = UInt(Rn);  m = UInt(Rm);  add = (U == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
PLI{<c>}{<q>}  [<Rn>, +/-<Rm> {, <shift>}]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `PLI` instruction must be unconditional.

`<Rn>` Is the base register. The SP can be used.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`).

`<Rm>` Contains the offset that is optionally shifted and applied to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If absent, no shift is applied. For encoding T1, `<shift>` can only be omitted, encoded as imm2 = `0b00`, or `LSL #<imm>` with `<imm>` = 1, 2, or 3, with `<imm>` encoded in imm2. For encoding A1, see *Shifts applied to a register* on page F2-2334.

Operation

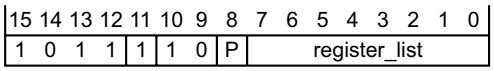
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    address = if add then (R[n] + offset) else (R[n] - offset);
    Hint_PreloadInstr(address);
```

F7.1.136 POP, T32

Pop Multiple Registers loads multiple registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data.

Encoding T1

```
POP<c> <registers>
```

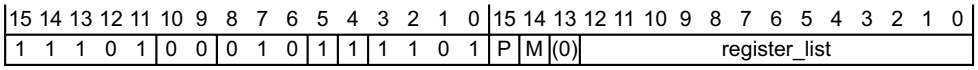


```
registers = P:'0000000':register_list;   UnalignedAllowed = FALSE;
if BitCount(registers) < 1 then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T2

```
POP<c>.W <registers>
```

<registers> contains more than one register

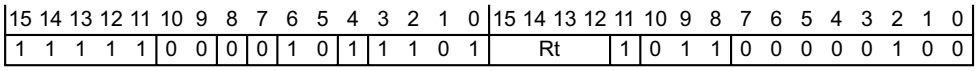


```
registers = P:M:'0':register_list;  UnalignedAllowed = FALSE;
if BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T3

```
POP<c>.W <registers>
```

<registers> contains one register, <Rt>



```
t = UInt(Rt);  registers = Zeros(16);  registers<t> = '1';  UnalignedAllowed = TRUE;
if t == 13 || (t == 15 && InITBlock() && !LastInITBlock()) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *POP (T32)* on page AppxA-4811.

Assembler syntax

`POP{<c>}{<q>}  <registers>`	Standard syntax
`LDM{<c>}{<q>}  SP!, <registers>`	Equivalent `LDM` syntax

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<registers>` Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

If the list contains more than one register, the instruction is assembled to encoding T1 or T2. If the list contains exactly one register, the instruction is assembled to encoding T1 or T3.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210. If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation

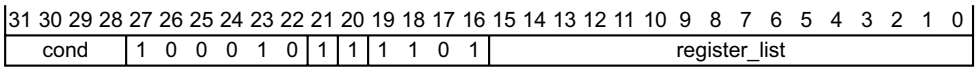
```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = SP;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = if UnalignedAllowed then MemU[address,4] else MemA[address,4];
            address = address + 4;
    if registers<15> == '1' then
        if UnalignedAllowed then
            if address<1:0> == '00' then
                LoadWritePC(MemU[address,4]);
            else
                UNPREDICTABLE;
        else
            LoadWritePC(MemA[address,4]);
    if registers<13> == '0' then SP = SP + 4*BitCount(registers);
    if registers<13> == '1' then SP = bits(32) UNKNOWN;
```

F7.1.137 POP, A32

Pop Multiple Registers loads multiple registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data.

Encoding A1

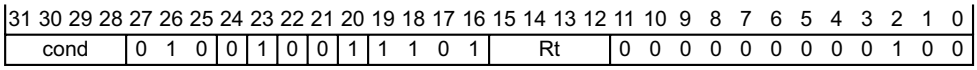
`POP<c> <registers>` — `<registers>` contains more than one register



```
if BitCount(register_list) < 2 then SEE LDM / LDMIA / LDMFD;
registers = register_list;  UnalignedAllowed = FALSE;
if registers<13> == '1' then UNPREDICTABLE;
```

Encoding A2

`POP<c> <registers>` — `<registers>` contains one register, `<Rt>`



```
t = UInt(Rt);  registers = Zeros(16);  registers<t> = '1';  UnalignedAllowed = TRUE;
// ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *POP (A32)* on page AppxA-4812.

Assembler syntax

`POP{<c>}{<q>}  <registers>`	Standard syntax
`LDM{<c>}{<q>}  SP!, <registers>`	Equivalent `LDM` syntax

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<registers>` Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

If the list contains more than one register, the instruction is assembled to encoding A1. If the list contains exactly one register, the instruction is assembled to encoding A2.

ARM deprecates any use of A32 instructions that include the SP, and the value of the SP after such an instruction is UNKNOWN.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

ARM deprecates the use of this instruction with both the LR and the PC in the list.

Operation

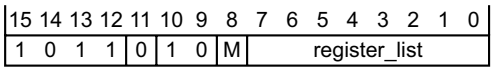
```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = SP;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = if UnalignedAllowed then MemU[address,4] else MemA[address,4];
            address = address + 4;
    if registers<15> == '1' then
        if UnalignedAllowed then
            if address<1:0> == '00' then
                LoadWritePC(MemU[address,4]);
            else
                UNPREDICTABLE;
        else
            LoadWritePC(MemA[address,4]);
    if registers<13> == '0' then SP = SP + 4*BitCount(registers);
    if registers<13> == '1' then SP = bits(32) UNKNOWN;
```

F7.1.138 PUSH

Push Multiple Registers stores multiple registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data.

Encoding T1

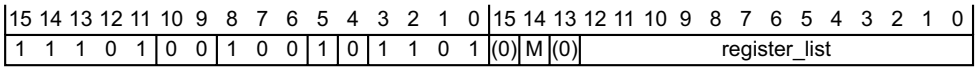
PUSH<c> <registers>



```
registers = '0':M:'000000':register_list;  UnalignedAllowed = FALSE;
if BitCount(registers) < 1 then UNPREDICTABLE;
```

Encoding T2

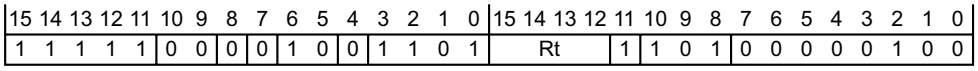
PUSH<c>.W <registers> <registers> contains more than one register



```
registers = '0':M:'0':register_list;  UnalignedAllowed = FALSE;
if BitCount(registers) < 2 then UNPREDICTABLE;
```

Encoding T3

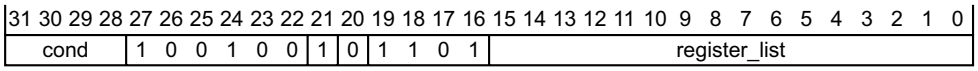
PUSH<c>.W <registers> <registers> contains one register, <Rt>



```
t = UInt(Rt);  registers = Zeros(16);  registers<t> = '1';  UnalignedAllowed = TRUE;
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

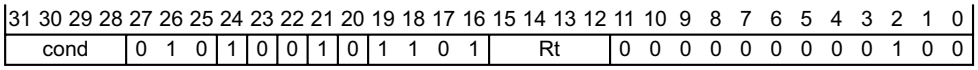
PUSH<c> <registers> <registers> contains more than one register



```
if BitCount(register_list) < 2 then SEE STMDB / STMFD;
registers = register_list;  UnalignedAllowed = FALSE;
```

Encoding A2

PUSH<c> <registers> <registers> contains one register, <Rt>



```
t = UInt(Rt);  registers = Zeros(16);  registers<t> = '1';  UnalignedAllowed = TRUE;
// ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *PUSH* on page AppxA-4812.

Assembler syntax

```
PUSH{<c>}{<q>}  <registers>                    Standard syntax
STMDB{<c>}{<q>}  SP!, <registers>              Equivalent STM syntax
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<registers>` Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

If the list contains more than one register, the instruction is assembled to encoding T1, T2, or A1. If the list contains exactly one register, the instruction is assembled to encoding T1, T3, or A2.

The SP and PC can be in the list in A32 instructions, but not in T32 instructions. However:

- ARM deprecates the use of A32 instructions that include the PC in the list.
- If the SP is in the list, and it is not the lowest-numbered register in the list, the instruction stores an UNKNOWN value for the SP.

Operation

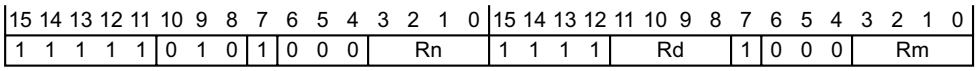
```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = SP - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == 13 && i != LowestSetBit(registers) then  // Only possible for encoding A1
                MemA[address,4] = bits(32) UNKNOWN;
            else
                if UnalignedAllowed then
                    MemU[address,4] = R[i];
                else
                    MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then  // Only possible for encoding A1 or A2
        if UnalignedAllowed then
            MemU[address,4] = PCStoreValue();
        else
            MemA[address,4] = PCStoreValue();
    SP = SP - 4*BitCount(registers);
```

F7.1.139 QADD

Saturating Add adds two register values, saturates the result to the 32-bit signed integer range -2^{31} to $(2^{31} - 1)$, and writes the result to the destination register. If saturation occurs, it sets the Q flag in the APSR.

Encoding T1

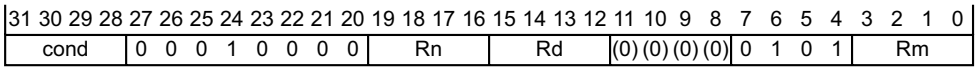
```
QADD<c> <Rd>, <Rm>, <Rn>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
QADD<c> <Rd>, <Rm>, <Rn>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
QADD{<c>}{<q>}  {<Rd>,} <Rm>, <Rn>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rm>`	The first operand register.
`<Rn>`	The second operand register.

Operation

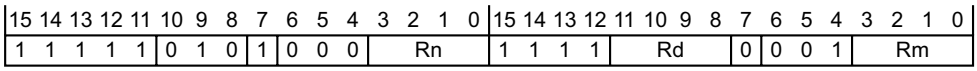
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (R[d], sat) = SignedSatQ(SInt(R[m]) + SInt(R[n]), 32);
    if sat then
        PSTATE.Q = '1';
```

F7.1.140 QADD8

Saturating Add 8 performs four 8-bit integer additions, saturates the results to the 8-bit signed integer range $-2^7 \le x \le 2^7 - 1$, and writes the results to the destination register.

Encoding T1

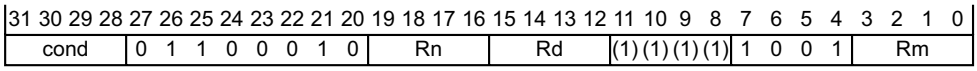
```
QADD8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
QADD8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
QADD8{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

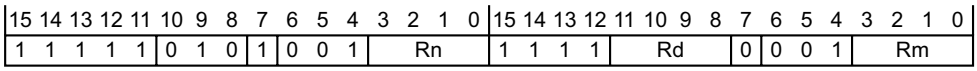
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = SInt(R[n]<7:0>) + SInt(R[m]<7:0>);
    sum2 = SInt(R[n]<15:8>) + SInt(R[m]<15:8>);
    sum3 = SInt(R[n]<23:16>) + SInt(R[m]<23:16>);
    sum4 = SInt(R[n]<31:24>) + SInt(R[m]<31:24>);
    R[d]<7:0>   = SignedSat(sum1, 8);
    R[d]<15:8>  = SignedSat(sum2, 8);
    R[d]<23:16> = SignedSat(sum3, 8);
    R[d]<31:24> = SignedSat(sum4, 8);
```

F7.1.141 QADD16

Saturating Add 16 performs two 16-bit integer additions, saturates the results to the 16-bit signed integer range $-2^{15} \le x \le 2^{15} - 1$, and writes the results to the destination register.

Encoding T1

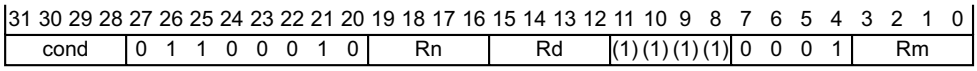
```
QADD16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
QADD16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
QADD16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

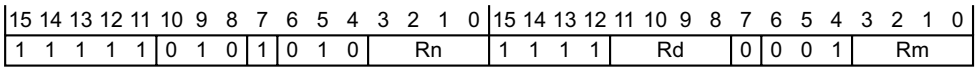
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = SInt(R[n]<15:0>) + SInt(R[m]<15:0>);
    sum2 = SInt(R[n]<31:16>) + SInt(R[m]<31:16>);
    R[d]<15:0>  = SignedSat(sum1, 16);
    R[d]<31:16> = SignedSat(sum2, 16);
```

F7.1.142 QASX

Saturating Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one 16-bit integer addition and one 16-bit subtraction, saturates the results to the 16-bit signed integer range $-2^{15} \le x \le 2^{15} - 1$, and writes the results to the destination register.

Encoding T1

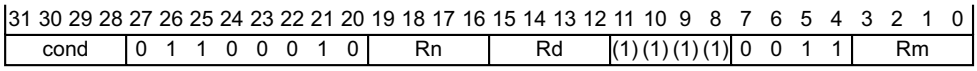
```
QASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
QASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
QASX{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

The pre-UAL syntax `QADDSUBX<c>` is equivalent to `QASX<c>`.

Operation

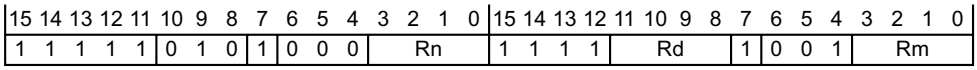
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff = SInt(R[n]<15:0>) - SInt(R[m]<31:16>);
    sum  = SInt(R[n]<31:16>) + SInt(R[m]<15:0>);
    R[d]<15:0>  = SignedSat(diff, 16);
    R[d]<31:16> = SignedSat(sum, 16);
```

F7.1.143 QDADD

Saturating Double and Add adds a doubled register value to another register value, and writes the result to the destination register. Both the doubling and the addition have their results saturated to the 32-bit signed integer range $-2^{31} \le x \le 2^{31} - 1$. If saturation occurs in either operation, it sets the Q flag in the APSR.

Encoding T1

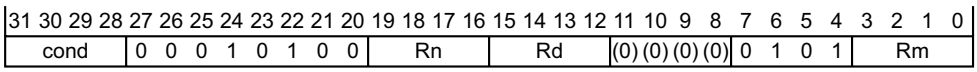
```
QDADD<c> <Rd>, <Rm>, <Rn>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
QDADD<c> <Rd>, <Rm>, <Rn>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
QDADD{<c>}{<q>}  {<Rd>,} <Rm>, <Rn>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rm>`	The first operand register.
`<Rn>`	The second operand register.

Operation

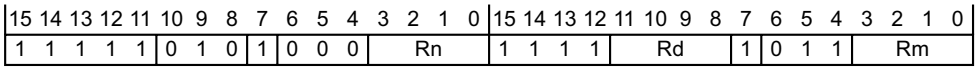
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (doubled, sat1) = SignedSatQ(2 * SInt(R[n]), 32);
    (R[d], sat2)  = SignedSatQ(SInt(R[m]) + SInt(doubled), 32);
    if sat1 || sat2 then
        PSTATE.Q = '1';
```

F7.1.144 QDSUB

Saturating Double and Subtract subtracts a doubled register value from another register value, and writes the result to the destination register. Both the doubling and the subtraction have their results saturated to the 32-bit signed integer range $-2^{31} \leq x \leq 2^{31} - 1$. If saturation occurs in either operation, it sets the Q flag in the APSR.

Encoding T1

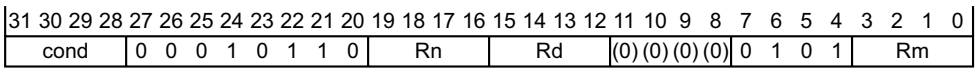
```
QDSUB<c> <Rd>, <Rm>, <Rn>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
QDSUB<c> <Rd>, <Rm>, <Rn>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
QDSUB{<c>}{<q>}  {<Rd>,} <Rm>, <Rn>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rm>`	The first operand register.
`<Rn>`	The second operand register.

Operation

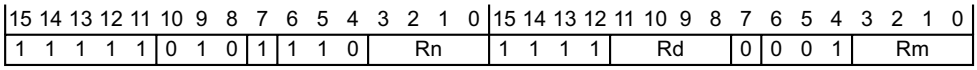
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (doubled, sat1) = SignedSatQ(2 * SInt(R[n]), 32);
    (R[d], sat2)  = SignedSatQ(SInt(R[m]) - SInt(doubled), 32);
    if sat1 || sat2 then
        PSTATE.Q = '1';
```

F7.1.145 QSAX

Saturating Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one 16-bit integer subtraction and one 16-bit addition, saturates the results to the 16-bit signed integer range $-2^{15} \le x \le 2^{15} - 1$, and writes the results to the destination register.

Encoding T1

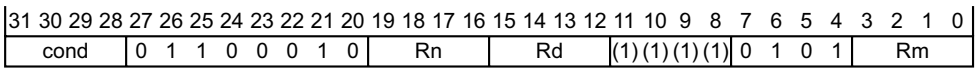
```
QSAX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
QSAX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
QSAX{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

The pre-UAL syntax `QSUBADDX<c>` is equivalent to `QSAX<c>`.

Operation

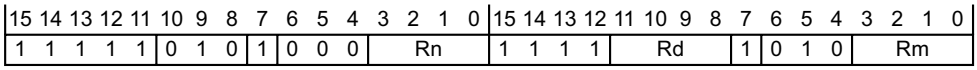
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum  = SInt(R[n]<15:0>) + SInt(R[m]<31:16>);
    diff = SInt(R[n]<31:16>) - SInt(R[m]<15:0>);
    R[d]<15:0>  = SignedSat(sum, 16);
    R[d]<31:16> = SignedSat(diff, 16);
```

F7.1.146 QSUB

Saturating Subtract subtracts one register value from another register value, saturates the result to the 32-bit signed integer range $-2^{31} \le x \le 2^{31} - 1$, and writes the result to the destination register. If saturation occurs, it sets the Q flag in the APSR.

Encoding T1

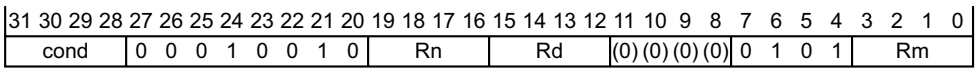
```
QSUB<c> <Rd>, <Rm>, <Rn>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
QSUB<c> <Rd>, <Rm>, <Rn>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
QSUB{<c>}{<q>}  {<Rd>,} <Rm>, <Rn>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rm>`	The first operand register.
`<Rn>`	The second operand register.

Operation

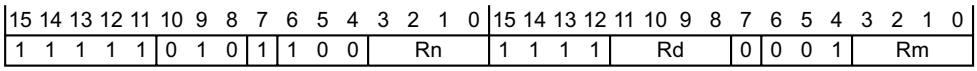
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (R[d], sat) = SignedSatQ(SInt(R[m]) - SInt(R[n]), 32);
    if sat then
        PSTATE.Q = '1';
```

F7.1.147 QSUB8

Saturating Subtract 8 performs four 8-bit integer subtractions, saturates the results to the 8-bit signed integer range $-2^7 \le x \le 2^7 - 1$, and writes the results to the destination register.

Encoding T1

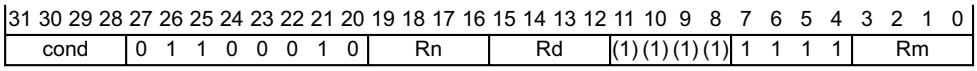
```
QSUB8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
QSUB8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
QSUB8{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

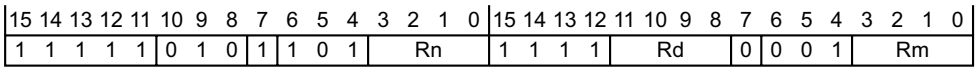
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = SInt(R[n]<7:0>) - SInt(R[m]<7:0>);
    diff2 = SInt(R[n]<15:8>) - SInt(R[m]<15:8>);
    diff3 = SInt(R[n]<23:16>) - SInt(R[m]<23:16>);
    diff4 = SInt(R[n]<31:24>) - SInt(R[m]<31:24>);
    R[d]<7:0>   = SignedSat(diff1, 8);
    R[d]<15:8>  = SignedSat(diff2, 8);
    R[d]<23:16> = SignedSat(diff3, 8);
    R[d]<31:24> = SignedSat(diff4, 8);
```

F7.1.148 QSUB16

Saturating Subtract 16 performs two 16-bit integer subtractions, saturates the results to the 16-bit signed integer range $-2^{15} \le x \le 2^{15} - 1$, and writes the results to the destination register.

Encoding T1

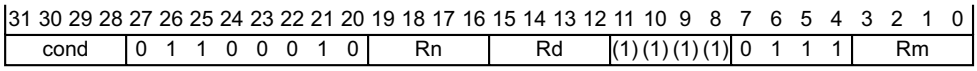
```
QSUB16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
QSUB16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
QSUB16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

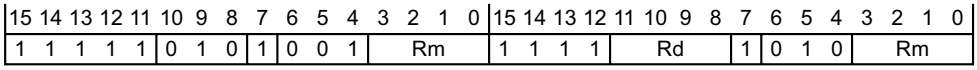
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = SInt(R[n]<15:0>) - SInt(R[m]<15:0>);
    diff2 = SInt(R[n]<31:16>) - SInt(R[m]<31:16>);
    R[d]<15:0>  = SignedSat(diff1, 16);
    R[d]<31:16> = SignedSat(diff2, 16);
```

F7.1.149 RBIT

Reverse Bits reverses the bit order in a 32-bit register.

Encoding T1

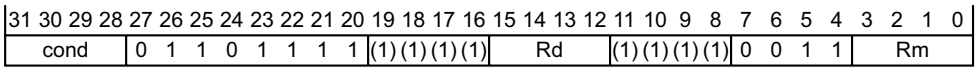
```
RBIT<c> <Rd>, <Rm>
```



```
if !Consistent(Rm) then UNPREDICTABLE;
d = UInt(Rd);  m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
RBIT<c> <Rd>, <Rm>
```



```
d = UInt(Rd);  m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *RBIT* on page AppxA-4813.

Assembler syntax

```
RBIT{<c>}{<q>}  <Rd>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rm>` The register that contains the operand. In encoding T1, its number must be encoded twice.

Operation

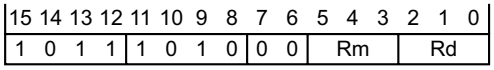
```
if ConditionPassed() then
    EncodingSpecificOperations();
    bits(32) result;
    for i = 0 to 31
        result<31-i> = R[m]<i>;
    R[d] = result;
```

F7.1.150 REV

Byte-Reverse Word reverses the byte order in a 32-bit register.

Encoding T1

```
REV<c> <Rd>, <Rm>
```

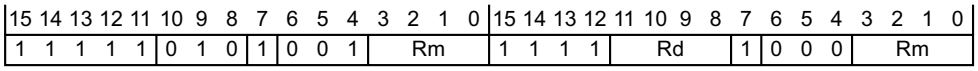


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	0	1	0	0	0	Rm			Rd		

```
d = UInt(Rd);  m = UInt(Rm);
```

Encoding T2

```
REV<c>.W <Rd>, <Rm>
```

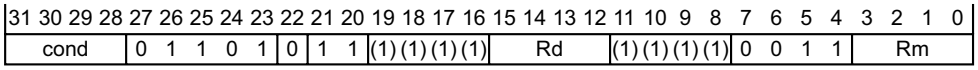


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	1	0	0	1	Rm				1	1	1	1	Rd				1	0	0	0	Rm			

```
if !Consistent(Rm) then UNPREDICTABLE;
d = UInt(Rd);  m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
REV<c> <Rd>, <Rm>
```



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	1	1	0	1	0	1	1	(1)	(1)	(1)	(1)	Rd				(1)	(1)	(1)	(1)	0	0	1	1	Rm			

```
d = UInt(Rd);  m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *REV* on page AppxA-4813.

Assembler syntax

```
REV{<c>}{<q>}  <Rd>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rm>` The register that contains the operand. Its number must be encoded twice in encoding T2.

Operation

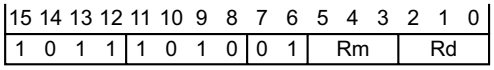
```
if ConditionPassed() then
    EncodingSpecificOperations();
    bits(32) result;
    result<31:24> = R[m]<7:0>;
    result<23:16> = R[m]<15:8>;
    result<15:8>  = R[m]<23:16>;
    result<7:0>   = R[m]<31:24>;
    R[d] = result;
```

F7.1.151 REV16

Byte-Reverse Packed Halfword reverses the byte order in each16-bit halfword of a 32-bit register.

Encoding T1

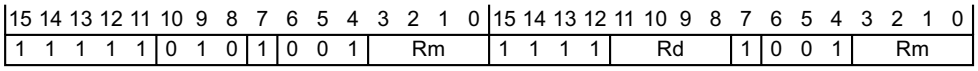
```
REV16<c> <Rd>, <Rm>
```



```
d = UInt(Rd);  m = UInt(Rm);
```

Encoding T2

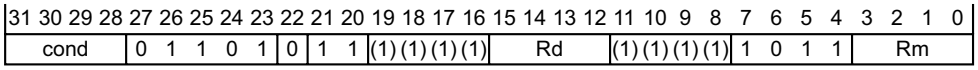
```
REV16<c>.W <Rd>, <Rm>
```



```
if !Consistent(Rm) then UNPREDICTABLE;
d = UInt(Rd);  m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
REV16<c> <Rd>, <Rm>
```



```
d = UInt(Rd);  m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *REV16* on page AppxA-4813.

Assembler syntax

```
REV16{<c>}{<q>}  <Rd>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rm>` The register that contains the operand. Its number must be encoded twice in encoding T2.

Operation

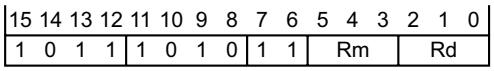
```
if ConditionPassed() then
    EncodingSpecificOperations();
    bits(32) result;
    result<31:24> = R[m]<23:16>;
    result<23:16> = R[m]<31:24>;
    result<15:8>  = R[m]<7:0>;
    result<7:0>   = R[m]<15:8>;
    R[d] = result;
```

F7.1.152 REVSH

Byte-Reverse Signed Halfword reverses the byte order in the lower 16-bit halfword of a 32-bit register, and sign-extends the result to 32 bits.

Encoding T1

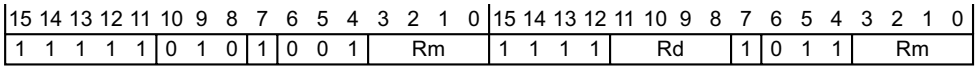
```
REVSH<c> <Rd>, <Rm>
```



```
d = UInt(Rd);  m = UInt(Rm);
```

Encoding T2

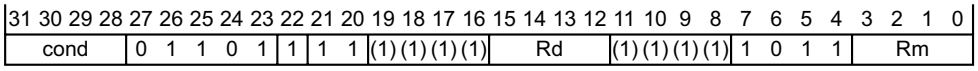
```
REVSH<c>.W <Rd>, <Rm>
```



```
if !Consistent(Rm) then UNPREDICTABLE;
d = UInt(Rd);  m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
REVSH<c> <Rd>, <Rm>
```



```
d = UInt(Rd);  m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *REVSH* on page AppxA-4814.

Assembler syntax

```
REVSH{<c>}{<q>}  <Rd>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rm>` The register that contains the operand. Its number must be encoded twice in encoding T2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    bits(32) result;
    result<31:8>  = SignExtend(R[m]<7:0>, 24);
    result<7:0>   = R[m]<15:8>;
    R[d] = result;
```

F7.1.153 RFE

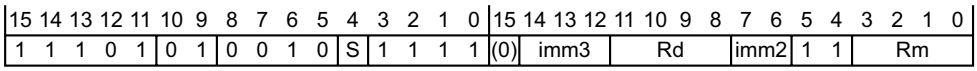
Return From Exception is a system instruction. For details see *RFE* on page F7-3020.

F7.1.154 ROR (immediate)

Rotate Right (immediate) provides the value of the contents of a register rotated by a constant value. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. It can optionally update the condition flags based on the result.

Encoding T1

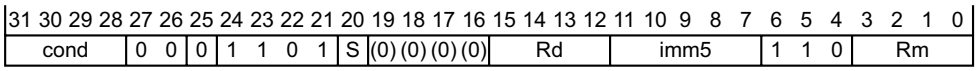
```
ROR{S}<c> <Rd>, <Rm>, #<imm>
```



```
if (imm3:imm2) == '00000' then SEE RRX;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(-, shift_n) = DecodeImmShift('11', imm3:imm2);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
ROR{S}<c> <Rd>, <Rm>, #<imm>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
if imm5 == '00000' then SEE RRX;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(-, shift_n) = DecodeImmShift('11', imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ROR{S}{<c>}{<q>}  {<Rd>,} <Rm>, #<imm>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register. In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
`<Rm>`	The first operand register. The PC can be used in A32 instructions.
`<imm>`	The shift amount, in the range 1 to 31. See *Shifts applied to a register* on page F2-2334.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry) = Shift_C(R[m], SRType_ROR, shift_n, PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

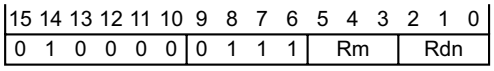
F7.1.155 ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The variable number of bits is read from the bottom byte of a register. It can optionally update the condition flags based on the result.

Encoding T1

`RORS <Rdn>, <Rm>` Outside IT block.

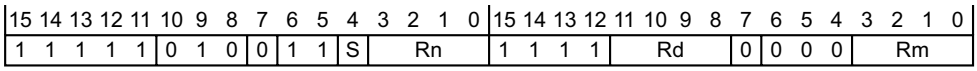
`ROR<c> <Rdn>, <Rm>` Inside IT block.



```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
```

Encoding T2

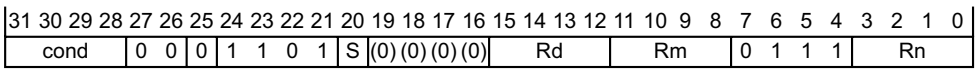
`ROR{S}<c>.W <Rd>, <Rn>, <Rm>`



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`ROR{S}<c> <Rd>, <Rn>, <Rm>`



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ROR{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The register whose bottom byte contains the amount to rotate by.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[m]<7:0>);
    (result, carry) = Shift_C(R[n], SRType_ROR, shift_n, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

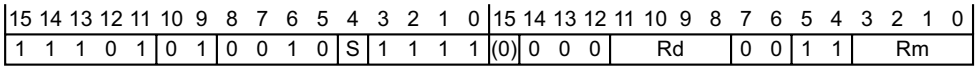
F7.1.156 RRX

Rotate Right with Extend provides the value of the contents of a register shifted right by one place, with the Carry flag shifted into bit[31].

RRX can optionally update the condition flags based on the result. In that case, bit[0] is shifted into the Carry flag.

Encoding T1

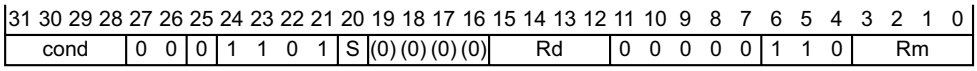
```
RRX{S}<c> <Rd>, <Rm>
```



```
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
RRX{S}<c> <Rd>, <Rm>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
RRX{S}{<c>}{<q>}  {<Rd>,} <Rm>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register. In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
`<Rm>`	The register that contains the operand. The PC can be used in A32 instructions.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry) = Shift_C(R[m], SRType_RRX, 1, PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

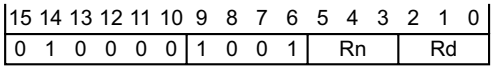
F7.1.157 RSB (immediate)

Reverse Subtract (immediate) subtracts a register value from an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

`RSBS <Rd>, <Rn>, #0` Outside IT block.

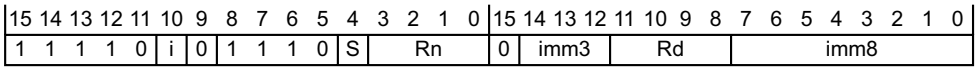
`RSB<c> <Rd>, <Rn>, #0` Inside IT block.



```
d = UInt(Rd);  n = UInt(Rn);  setflags = !InITBlock();  imm32 = Zeros(32); // immediate = #0
```

Encoding T2

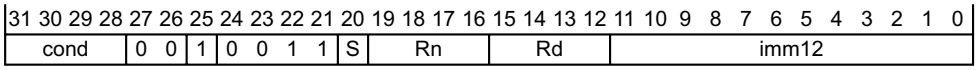
`RSB{S}<c>.W <Rd>, <Rn>, #<const>`



```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = T32ExpandImm(i:imm3:imm8);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`RSB{S}<c> <Rd>, <Rn>, #<const>`



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = A32ExpandImm(imm12);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
RSB{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032.

In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<Rn>` The first operand register. The PC can be used in A32 instructions.

`<const>` The immediate value to be added to the value obtained from `<Rn>`. The only permitted value for encoding T1 is 0. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values for encoding T2 or A1.

The pre-UAL syntax `RSB<c>S` is equivalent to `RSBS<c>`.

Operation

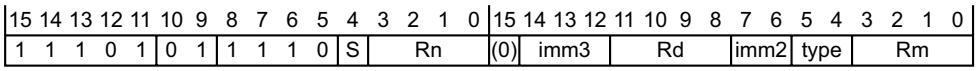
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(NOT(R[n]), imm32, '1');
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.158 RSB (register)

Reverse Subtract (register) subtracts a register value from an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

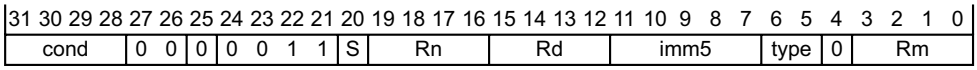
```
RSB{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
RSB{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
RSB{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
`<Rn>`	The first operand register. The PC can be used in A32 instructions.
`<Rm>`	The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.
`<shift>`	The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

The pre-UAL syntax `RSB<c>S` is equivalent to `RSBS<c>`.

Operation

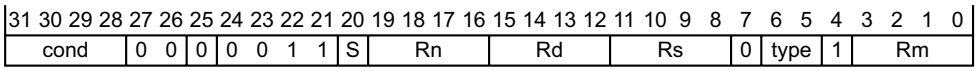
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(NOT(R[n]), shifted, '1');
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.159 RSB (register-shifted register)

Reverse Subtract (register-shifted register) subtracts a register value from a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1

```
RSB{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
RSB{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax `RSB<c>S` is equivalent to `RSBS<c>`.

Operation

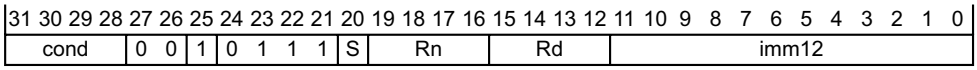
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(NOT(R[n]), shifted, '1');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.160 RSC (immediate)

Reverse Subtract with Carry (immediate) subtracts a register value and the value of NOT (Carry flag) from an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1

```
RSC{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = A32ExpandImm(imm12);
```

Assembler syntax

```
RSC{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032.
`<Rn>`	The first operand register. The PC can be used.
`<const>`	The immediate value that the value obtained from `<Rn>` is to be subtracted from. See *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

The pre-UAL syntax `RSC<c>S` is equivalent to `RSCS<c>`.

Operation

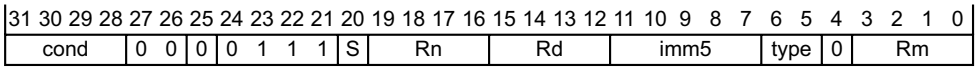
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(NOT(R[n]), imm32, PSTATE.C);
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.161 RSC (register)

Reverse Subtract with Carry (register) subtracts a register value and the value of NOT (Carry flag) from an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1

```
RSC{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
RSC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
<Rn>	The first operand register. The PC can be used.
<Rm>	The register that is optionally shifted and used as the second operand. The PC can be used.
<shift>	The shift to apply to the value read from <Rm>. If omitted, no shift is applied. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

The pre-UAL syntax RSC<c>S is equivalent to RSCS<c>.

Operation

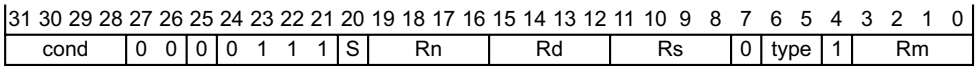
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(NOT(R[n]), shifted, PSTATE.C);
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.162 RSC (register-shifted register)

Reverse Subtract (register-shifted register) subtracts a register value and the value of NOT (Carry flag) from a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1

```
RSC{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



31 30 29 28	27 26	25	24 23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0
cond	0 0	0	0 1 1 1	S	Rn	Rd	Rs	0	type	1	Rm

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
RSC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax `RSC<c>S` is equivalent to `RSCS<c>`.

Operation

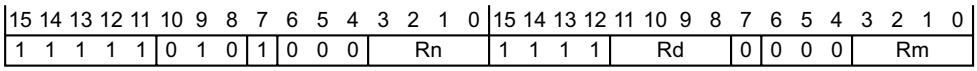
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(NOT(R[n]), shifted, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.163 SADD8

Signed Add 8 performs four 8-bit signed integer additions, and writes the results to the destination register. It sets the APSR.GE bits according to the results of the additions.

Encoding T1

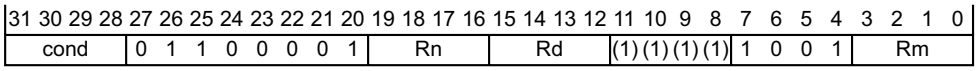
SADD8<c> <Rd>, <Rn>, <Rm>



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

SADD8<c> <Rd>, <Rn>, <Rm>



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SADD8{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

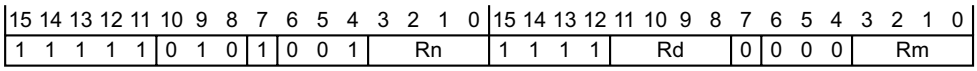
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = SInt(R[n]<7:0>) + SInt(R[m]<7:0>);
    sum2 = SInt(R[n]<15:8>) + SInt(R[m]<15:8>);
    sum3 = SInt(R[n]<23:16>) + SInt(R[m]<23:16>);
    sum4 = SInt(R[n]<31:24>) + SInt(R[m]<31:24>);
    R[d]<7:0>   = sum1<7:0>;
    R[d]<15:8>  = sum2<7:0>;
    R[d]<23:16> = sum3<7:0>;
    R[d]<31:24> = sum4<7:0>;
    PSTATE.GE<0>  = if sum1 >= 0 then '1' else '0';
    PSTATE.GE<1>  = if sum2 >= 0 then '1' else '0';
    PSTATE.GE<2>  = if sum3 >= 0 then '1' else '0';
    PSTATE.GE<3>  = if sum4 >= 0 then '1' else '0';
```

F7.1.164 SADD16

Signed Add 16 performs two 16-bit signed integer additions, and writes the results to the destination register. It sets the APSR.GE bits according to the results of the additions.

Encoding T1

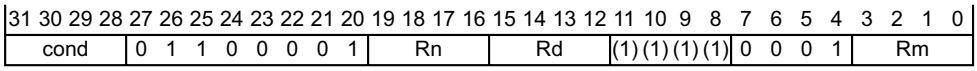
SADD16<c> <Rd>, <Rn>, <Rm>



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

SADD16<c> <Rd>, <Rn>, <Rm>



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SADD16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

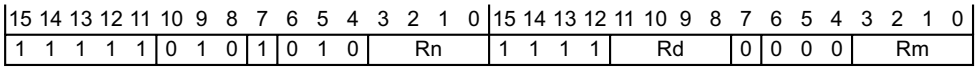
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = SInt(R[n]<15:0>) + SInt(R[m]<15:0>);
    sum2 = SInt(R[n]<31:16>) + SInt(R[m]<31:16>);
    R[d]<15:0>  = sum1<15:0>;
    R[d]<31:16> = sum2<15:0>;
    PSTATE.GE<1:0> = if sum1 >= 0 then '11' else '00';
    PSTATE.GE<3:2> = if sum2 >= 0 then '11' else '00';
```

F7.1.165 SASX

Signed Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one 16-bit integer addition and one 16-bit subtraction, and writes the results to the destination register. It sets the APSR.GE bits according to the results.

Encoding T1

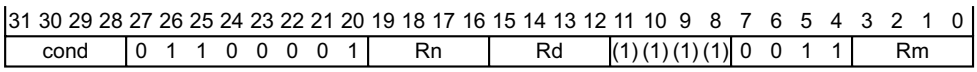
```
SASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SASX{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

The pre-UAL syntax `SADDSUBX<c>` is equivalent to `SASX<c>`.

Operation

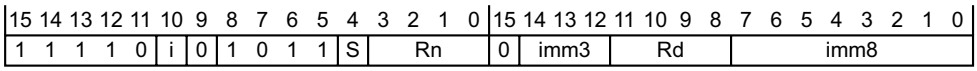
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff = SInt(R[n]<15:0>) - SInt(R[m]<31:16>);
    sum  = SInt(R[n]<31:16>) + SInt(R[m]<15:0>);
    R[d]<15:0>  = diff<15:0>;
    R[d]<31:16> = sum<15:0>;
    PSTATE.GE<1:0> = if diff >= 0 then '11' else '00';
    PSTATE.GE<3:2> = if sum  >= 0 then '11' else '00';
```

F7.1.166 SBC (immediate)

Subtract with Carry (immediate) subtracts an immediate value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

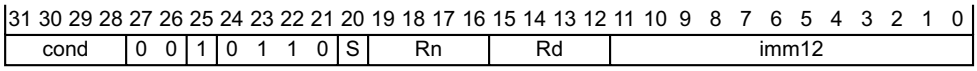
```
SBC{S}<c> <Rd>, <Rn>, #<const>
```



```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = T32ExpandImm(i:imm3:imm8);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SBC{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = A32ExpandImm(imm12);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SBC{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
<Rn>	The first operand register. The PC can be used in A32 instructions.
<const>	The immediate value to be subtracted from the value obtained from <Rn>. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

The pre-UAL syntax SBC<c>S is equivalent to SBCS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], NOT(imm32), PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

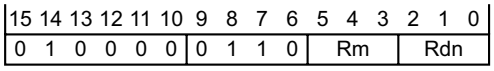
F7.1.167 SBC (register)

Subtract with Carry (register) subtracts an optionally-shifted register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

`SBCS <Rdn>, <Rm>` Outside IT block.

`SBC<c> <Rdn>, <Rm>` Inside IT block.

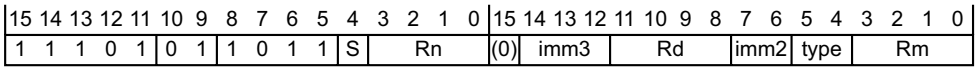


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	0	0	1	1	0	Rm			Rdn		

```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

`SBC{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}`



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

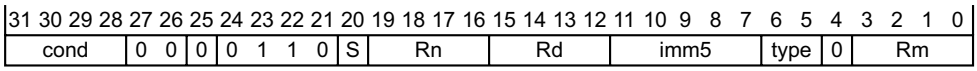
```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

`SBC{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}`



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	0	1	1	0	S	Rn				Rd				imm5					type		0	Rm			

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SBC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032.

In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<Rn>` The first operand register. The PC can be used in A32 instructions.

`<Rm>` The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

The pre-UAL syntax `SBC<c>S` is equivalent to `SBCS<c>`.

Operation

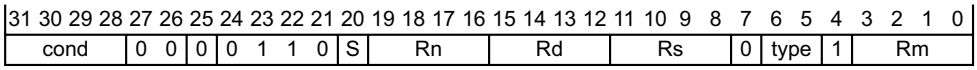
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.168 SBC (register-shifted register)

Subtract with Carry (register-shifted register) subtracts a register-shifted register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1

```
SBC{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SBC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax `SBC<c>S` is equivalent to `SBCS<c>`.

Operation

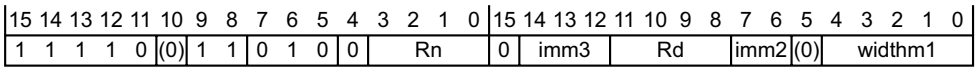
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.169 SBFX

Signed Bit Field Extract extracts any number of adjacent bits at any position from a register, sign-extends them to 32 bits, and writes the result to the destination register.

Encoding T1

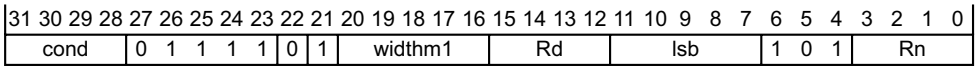
```
SBFX<c> <Rd>, <Rn>, #<lsb>, #<width>
```



```
d = UInt(Rd);  n = UInt(Rn);
lsbit = UInt(imm3:imm2);  widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SBFX<c> <Rd>, <Rn>, #<lsb>, #<width>
```



```
d = UInt(Rd);  n = UInt(Rn);
lsbit = UInt(lsb);  widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *SBFX* on page AppxA-4814.

Assembler syntax

```
SBFX{<c>}{<q>}  <Rd>, <Rn>, #<lsb>, #<width>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<lsb>`	Is the bit number of the least significant bit in the field, in the range 0-31. This determines the required value of `lsbit`.
`<width>`	Is the width of the field, in the range 1 to 32-`<lsb>`. The required value of `widthminus1` is `<width>`-1.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsbit + widthminus1;
    if msbit <= 31 then
        R[d] = SignExtend(R[n]<msbit:lsbit>, 32);
    else
        UNPREDICTABLE;
```

F7.1.170 SDIV

Signed Divide divides a 32-bit signed integer register value by a 32-bit signed integer register value, and writes the result to the destination register. The condition flags are not affected.

Encoding T1

```
SDIV<c> <Rd>, <Rn>, <Rm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	1	1	0	0	1	Rn				(1)	(1)	(1)	(1)	Rd				1	1	1	1	Rm			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SDIV<c> <Rd>, <Rn>, <Rm>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	1	1	1	0	0	0	1	Rd				(1)	(1)	(1)	(1)	Rm				0	0	0	1	Rn			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *SDIV* on page AppxA-4814.

Assembler syntax

```
SDIV{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The register that contains the dividend.

`<Rm>` The register that contains the divisor.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if SInt(R[m]) == 0 then
        if IntegerZeroDivideTrappingEnabled() then
            GenerateIntegerZeroDivide();
        else
            result = 0;
    else
        result = RoundTowardsZero(SInt(R[n]) / SInt(R[m]));
    R[d] = result<31:0>;
```

Overflow

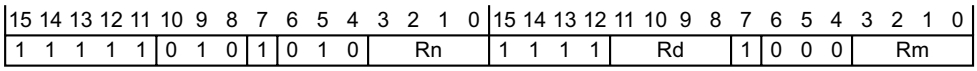
If the signed integer division `0x80000000 / 0xFFFFFFFF` is performed, the pseudocode produces the intermediate integer result $+2^{31}$, that overflows the 32-bit signed integer range. No indication of this overflow case is produced, and the 32-bit result written to `R[d]` must be the bottom 32 bits of the binary representation of $+2^{31}$. So the result of the division is `0x80000000`.

F7.1.171 SEL

Select Bytes selects each byte of its result from either its first operand or its second operand, according to the values of the GE flags.

Encoding T1

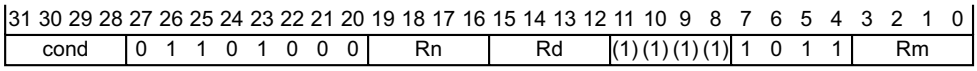
SEL<c> <Rd>, <Rn>, <Rm>



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

SEL<c> <Rd>, <Rn>, <Rm>



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SEL{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R[d]<7:0>   = if PSTATE.GE<0> == '1' then R[n]<7:0>   else R[m]<7:0>;
    R[d]<15:8>  = if PSTATE.GE<1> == '1' then R[n]<15:8>  else R[m]<15:8>;
    R[d]<23:16> = if PSTATE.GE<2> == '1' then R[n]<23:16> else R[m]<23:16>;
    R[d]<31:24> = if PSTATE.GE<3> == '1' then R[n]<31:24> else R[m]<31:24>;
```

F7.1.172 SETEND

Set Endianness writes a new value to ENDIANSTATE.

Encoding T1

```
SETEND <endian_specifier>
```

Not permitted in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	0	1	1	0	0	1	0	(1)	E	(0)	(0)	(0)

```
set_bigend = (E == '1');
if InITBlock() then UNPREDICTABLE;
```

Encoding A1

```
SETEND <endian_specifier>
```

Cannot be conditional

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	0	1	0	0	0	0	(0)	(0)	(0)	1	(0)	(0)	(0)	(0)	(0)	(0)	E	(0)	0	0	0	0	(0)	(0)	(0)	(0)

```
set_bigend = (E == '1');
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SETEND{<q>}  <endian_specifier>
```

where:

`<q>` See *Standard assembler syntax fields* on page F2-2330. A `SETEND` instruction must be unconditional.

`<endian_specifier>`

Is one of:

`BE` Sets the E bit in the instruction. This sets ENDIANSTATE.

`LE` Clears the E bit in the instruction. This clears ENDIANSTATE.

Operation

```
EncodingSpecificOperations();
AArch32.CheckSETENDEnabled();
PSTATE.E = if set_bigend then '1' else '0';
```

F7.1.173 SEV

Send Event is a hint instruction. It causes an event to be signaled to all PEs in the multiprocessor system. For more information, see *Wait For Event and Send Event* on page G1-3457.

Encoding T1

SEV<c>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	1	1	0	1	0	0	0	0	0	0

```
// No additional decoding required
```

Encoding T2

SEV<c>.W

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	0	(1)	(1)	(1)	(1)	1	0	(0)	0	(0)	0	0	0	0	0	0	0	0	1	0	0

```
// No additional decoding required
```

Encoding A1

SEV<c>

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	1	1	0	0	1	0	0	0	0	0	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	0	0	0	0	1	0	0

```
// No additional decoding required
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SEV{<c>}{<q>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    SendEvent();
```

F7.1.174 SEVL

Send Event Local is a hint instruction. It causes an event to be signaled locally without the requirement to affect other PEs in the multiprocessor system. It can prime a wait-loop which starts with a `WFE` instruction.

Encoding T1

`SEVL<c>`

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	1	1	0	1	0	1	0	0	0	0

```
// No additional decoding required
```

Encoding T2

`SEVL<c>.W`

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
// No additional decoding required
```

Encoding A1

`SEVL<c>`

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	1	1	0	0	1	0	0	0	0	0	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	0	0	0	0	1	0	1

```
// No additional decoding required
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SEVL{<c>}{<q>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

Operation

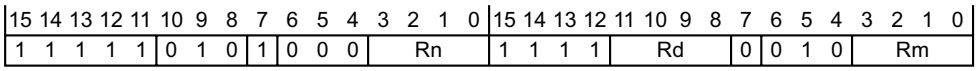
```
if ConditionPassed() then
    EncodingSpecificOperations();
    EventRegisterSet();
```

F7.1.175 SHADD8

Signed Halving Add 8 performs four signed 8-bit integer additions, halves the results, and writes the results to the destination register.

Encoding T1

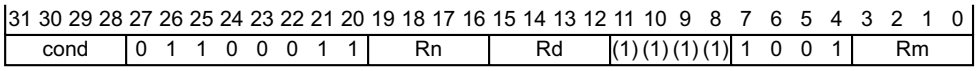
```
SHADD8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SHADD8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SHADD8{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

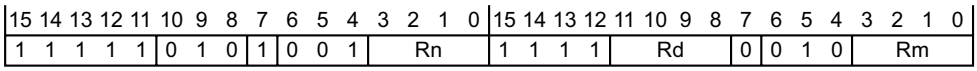
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = SInt(R[n]<7:0>) + SInt(R[m]<7:0>);
    sum2 = SInt(R[n]<15:8>) + SInt(R[m]<15:8>);
    sum3 = SInt(R[n]<23:16>) + SInt(R[m]<23:16>);
    sum4 = SInt(R[n]<31:24>) + SInt(R[m]<31:24>);
    R[d]<7:0>   = sum1<8:1>;
    R[d]<15:8>  = sum2<8:1>;
    R[d]<23:16> = sum3<8:1>;
    R[d]<31:24> = sum4<8:1>;
```

F7.1.176 SHADD16

Signed Halving Add 16 performs two signed 16-bit integer additions, halves the results, and writes the results to the destination register.

Encoding T1

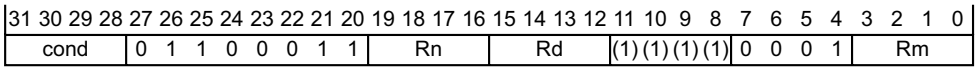
```
SHADD16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SHADD16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SHADD16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

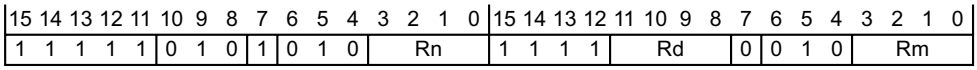
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = SInt(R[n]<15:0>) + SInt(R[m]<15:0>);
    sum2 = SInt(R[n]<31:16>) + SInt(R[m]<31:16>);
    R[d]<15:0>  = sum1<16:1>;
    R[d]<31:16> = sum2<16:1>;
```

F7.1.177 SHASX

Signed Halving Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one signed 16-bit integer addition and one signed 16-bit subtraction, halves the results, and writes the results to the destination register.

Encoding T1

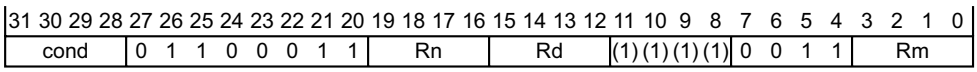
```
SHASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SHASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SHASX{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

The pre-UAL syntax `SHADDSUBX<c>` is equivalent to `SHASX<c>`.

Operation

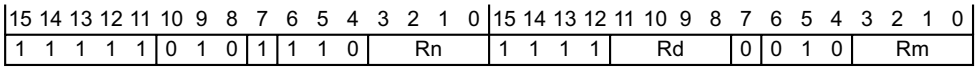
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff = SInt(R[n]<15:0>) - SInt(R[m]<31:16>);
    sum  = SInt(R[n]<31:16>) + SInt(R[m]<15:0>);
    R[d]<15:0>  = diff<16:1>;
    R[d]<31:16> = sum<16:1>;
```

F7.1.178 SHSAX

Signed Halving Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one signed 16-bit integer subtraction and one signed 16-bit addition, halves the results, and writes the results to the destination register.

Encoding T1

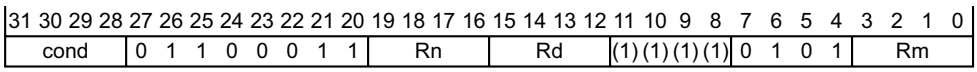
SHSAX<c> <Rd>, <Rn>, <Rm>



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

SHSAX<c> <Rd>, <Rn>, <Rm>



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SHSAX{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

The pre-UAL syntax `SHSUBADDX<c>` is equivalent to `SHSAX<c>`.

Operation

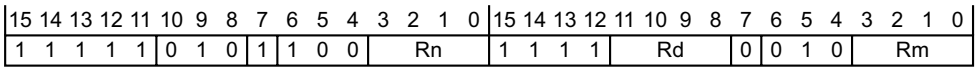
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum  = SInt(R[n]<15:0>) + SInt(R[m]<31:16>);
    diff = SInt(R[n]<31:16>) - SInt(R[m]<15:0>);
    R[d]<15:0>  = sum<16:1>;
    R[d]<31:16> = diff<16:1>;
```

F7.1.179 SHSUB8

Signed Halving Subtract 8 performs four signed 8-bit integer subtractions, halves the results, and writes the results to the destination register.

Encoding T1

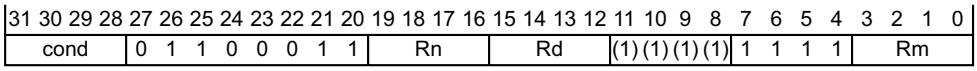
```
SHSUB8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SHSUB8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SHSUB8{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

Operation

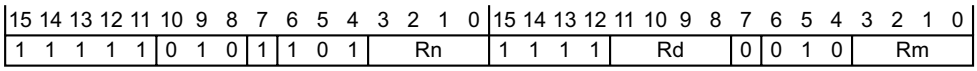
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = SInt(R[n]<7:0>) - SInt(R[m]<7:0>);
    diff2 = SInt(R[n]<15:8>) - SInt(R[m]<15:8>);
    diff3 = SInt(R[n]<23:16>) - SInt(R[m]<23:16>);
    diff4 = SInt(R[n]<31:24>) - SInt(R[m]<31:24>);
    R[d]<7:0>   = diff1<8:1>;
    R[d]<15:8>  = diff2<8:1>;
    R[d]<23:16> = diff3<8:1>;
    R[d]<31:24> = diff4<8:1>;
```

F7.1.180 SHSUB16

Signed Halving Subtract 16 performs two signed 16-bit integer subtractions, halves the results, and writes the results to the destination register.

Encoding T1

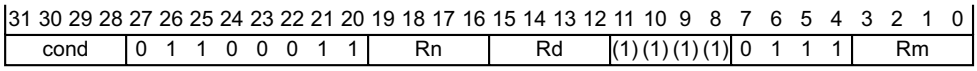
```
SHSUB16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SHSUB16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SHSUB16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = SInt(R[n]<15:0>) - SInt(R[m]<15:0>);
    diff2 = SInt(R[n]<31:16>) - SInt(R[m]<31:16>);
    R[d]<15:0>  = diff1<16:1>;
    R[d]<31:16> = diff2<16:1>;
```

F7.1.181 SMC

Secure Monitor Call is a system instruction. For details see *SMC* on page F7-3022.

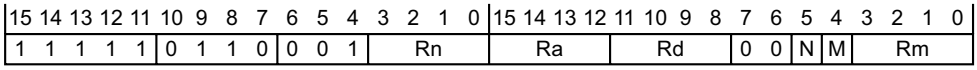
F7.1.182 SMLABB, SMLABT, SMLATB, SMLATT

Signed Multiply Accumulate (halfwords) performs a signed multiply accumulate operation. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is added to a 32-bit accumulate value and the result is written to the destination register.

If overflow occurs during the addition of the accumulate value, the instruction sets the Q flag in the APSR. It is not possible for overflow to occur during the multiplication.

Encoding T1

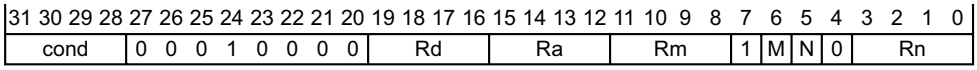
```
SMLA<x><y><c> <Rd>, <Rn>, <Rm>, <Ra>
```



```
if Ra == '1111' then SEE SMULBB, SMULBT, SMULTB, SMULTT;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
n_high = (N == '1');  m_high = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SMLA<x><y><c> <Rd>, <Rn>, <Rm>, <Ra>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
n_high = (N == '1');  m_high = (M == '1');
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SMLA<x><y>{<c>}{<q>}  <Rd>, <Rn>, <Rm>, <Ra>
```

where:

`<x>` Specifies which half of the source register `<Rn>` is used as the first multiply operand. If `<x>` is `B`, then the bottom half (bits[15:0]) of `<Rn>` is used. If `<x>` is `T`, then the top half (bits[31:16]) of `<Rn>` is used.

`<y>` Specifies which half of the source register `<Rm>` is used as the second multiply operand. If `<y>` is `B`, then the bottom half (bits[15:0]) of `<Rm>` is used. If `<y>` is `T`, then the top half (bits[31:16]) of `<Rm>` is used.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The source register whose bottom or top half (selected by `<x>`) is the first multiply operand.

`<Rm>` The source register whose bottom or top half (selected by `<y>`) is the second multiply operand.

`<Ra>` The register that contains the accumulate value.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = if n_high then R[n]<31:16> else R[n]<15:0>;
    operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
    result = SInt(operand1) * SInt(operand2) + SInt(R[a]);
    R[d] = result<31:0>;
    if result != SInt(result<31:0>) then  // Signed overflow
        PSTATE.Q = '1';
```

F7.1.183 SMLAD

Signed Multiply Accumulate Dual performs two signed 16 × 16-bit multiplications. It adds the products to a 32-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top × bottom and bottom × top multiplication.

This instruction sets the Q flag if the accumulate operation overflows. Overflow cannot occur during the multiplications.

Encoding T1

```
SMLAD{X}<c> <Rd>, <Rn>, <Rm>, <Ra>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	1	0	0	1	0	Rn				Ra				Rd				0	0	0	M	Rm			

```
if Ra == '1111' then SEE SMUAD;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
m_swap = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SMLAD{X}<c> <Rd>, <Rn>, <Rm>, <Ra>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	1	1	1	0	0	0	0	Rd				Ra				Rm				0	0	M	1	Rn			

```
if Ra == '1111' then SEE SMUAD;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
m_swap = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SMLAD{X}{<c>}{<q>}  <Rd>, <Rn>, <Rm>, <Ra>
```

where:

X	If X is present (encoded as M = 1), the multiplications are bottom × top and top × bottom. If the X is omitted (encoded as M = 0), the multiplications are bottom × bottom and top × top.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register.
<Rn>	The first operand register.
<Rm>	The second operand register.
<Ra>	The register that contains the accumulate value.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = if m_swap then ROR(R[m],16) else R[m];
    product1 = SInt(R[n]<15:0>) * SInt(operand2<15:0>);
    product2 = SInt(R[n]<31:16>) * SInt(operand2<31:16>);
    result = product1 + product2 + SInt(R[a]);
    R[d] = result<31:0>;
    if result != SInt(result<31:0>) then  // Signed overflow
        PSTATE.Q = '1';
```

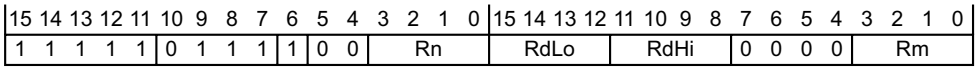
F7.1.184 SMLAL

Signed Multiply Accumulate Long multiplies two signed 32-bit values to produce a 64-bit value, and accumulates this with a 64-bit value.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

Encoding T1

```
SMLAL<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```

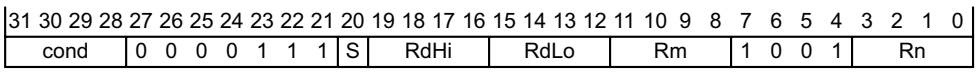


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	1	1	1	0	0	Rn				RdLo				RdHi				0	0	0	0	Rm			

```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

Encoding A1

```
SMLAL{S}<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	0	1	1	1	S	RdHi				RdLo				Rm				1	0	0	1	Rn			

```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *SMLAL* on page AppxA-4816.

Assembler syntax

```
SMLAL{S}{<c>}{<q>}  <RdLo>, <RdHi>, <Rn>, <Rm>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated. `S` can be specified only for the A32 instruction set.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<RdLo>`	Supplies the lower 32 bits of the accumulate value, and is the destination register for the lower 32 bits of the result.
`<RdHi>`	Supplies the upper 32 bits of the accumulate value, and is the destination register for the upper 32 bits of the result.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

The pre-UAL syntax `SMLAL<c>S` is equivalent to `SMLALS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = SInt(R[n]) * SInt(R[m]) + SInt(R[dHi]:R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
    if setflags then
        PSTATE.N = result<63>;
        PSTATE.Z = IsZeroBit(result<63:0>);
        // PSTATE.C, PSTATE.V unchanged
```

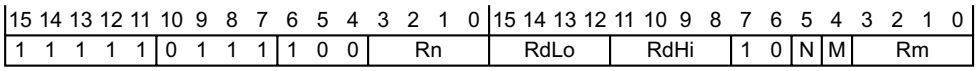
F7.1.185 SMLALBB, SMLALBT, SMLALTB, SMLALTT

Signed Multiply Accumulate Long (halfwords) multiplies two signed 16-bit values to produce a 32-bit value, and accumulates this with a 64-bit value. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is sign-extended and accumulated with a 64-bit accumulate value.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo 2^{64}.

Encoding T1

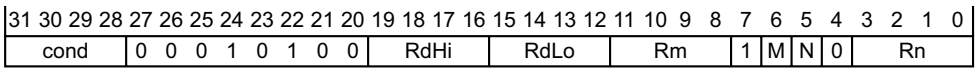
```
SMLAL<x><y><c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);
n_high = (N == '1');  m_high = (M == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

Encoding A1

```
SMLAL<x><y><c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);
n_high = (N == '1');  m_high = (M == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *SMLALBB, SMLALBT, SMLALTB, SMLALTT* on page AppxA-4816.

Assembler syntax

```
SMLAL<x><y>{<c>}{<q>}  <RdLo>, <RdHi>, <Rn>, <Rm>
```

where:

`<x>` Specifies which half of the source register `<Rn>` is used as the first multiply operand. If `<x>` is `B`, then the bottom half (bits[15:0]) of `<Rn>` is used. If `<x>` is `T`, then the top half (bits[31:16]) of `<Rn>` is used.

`<y>` Specifies which half of the source register `<Rm>` is used as the second multiply operand. If `<y>` is `B`, then the bottom half (bits[15:0]) of `<Rm>` is used. If `<y>` is `T`, then the top half (bits[31:16]) of `<Rm>` is used.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<RdLo>` Supplies the lower 32 bits of the accumulate value, and is the destination register for the lower 32 bits of the result.

`<RdHi>` Supplies the upper 32 bits of the accumulate value, and is the destination register for the upper 32 bits of the result.

`<Rn>` The source register whose bottom or top half (selected by `<x>`) is the first multiply operand.

`<Rm>` The source register whose bottom or top half (selected by `<y>`) is the second multiply operand.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = if n_high then R[n]<31:16> else R[n]<15:0>;
    operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
    result = SInt(operand1) * SInt(operand2) + SInt(R[dHi]:R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
```

F7.1.186 SMLALD

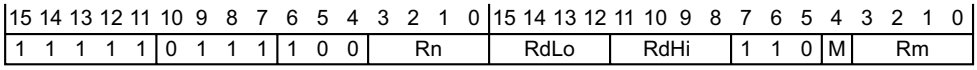
Signed Multiply Accumulate Long Dual performs two signed 16 × 16-bit multiplications. It adds the products to a 64-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top × bottom and bottom × top multiplication.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo 2^{64}.

Encoding T1

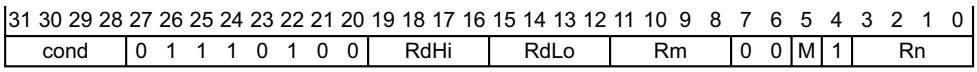
```
SMLALD{X}<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  m_swap = (M == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

Encoding A1

```
SMLALD{X}<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  m_swap = (M == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *SMLALD* on page AppxA-4816.

Assembler syntax

```
SMLALD{X}{<c>}{<q>}  <RdLo>, <RdHi>, <Rn>, <Rm>
```

where:

X	If X is present, the multiplications are bottom × top and top × bottom. If the X is omitted, the multiplications are bottom × bottom and top × top.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<RdLo>	Supplies the lower 32 bits of the accumulate value, and is the destination register for the lower 32 bits of the result.
<RdHi>	Supplies the upper 32 bits of the accumulate value, and is the destination register for the upper 32 bits of the result.
<Rn>	The first operand register.
<Rm>	The second operand register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = if m_swap then ROR(R[m],16) else R[m];
    product1 = SInt(R[n]<15:0>) * SInt(operand2<15:0>);
    product2 = SInt(R[n]<31:16>) * SInt(operand2<31:16>);
    result = product1 + product2 + SInt(R[dHi]:R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
```

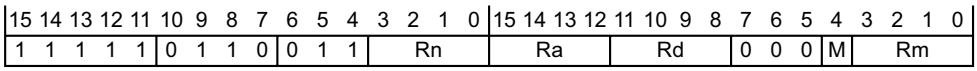
F7.1.187 SMLAWB, SMLAWT

Signed Multiply Accumulate (word by halfword) performs a signed multiply accumulate operation. The multiply acts on a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are added to a 32-bit accumulate value and the result is written to the destination register. The bottom 16 bits of the 48-bit product are ignored.

If overflow occurs during the addition of the accumulate value, the instruction sets the Q flag in the APSR. No overflow can occur during the multiplication.

Encoding T1

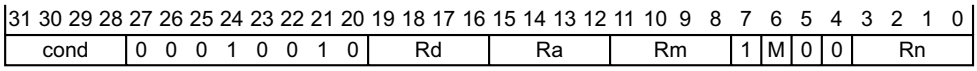
SMLAW<y><c> <Rd>, <Rn>, <Rm>, <Ra>



```
if Ra == '1111' then SEE SMULWB, SMULWT;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  m_high = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

SMLAW<y><c> <Rd>, <Rn>, <Rm>, <Ra>



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  m_high = (M == '1');
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SMLAW<y>{<c>}{<q>}  <Rd>, <Rn>, <Rm>, <Ra>
```

where:

`<y>`	Specifies which half of the source register `<Rm>` is used as the second multiply operand. If `<y>` is `B`, then the bottom half (bits[15:0]) of `<Rm>` is used. If `<y>` is `T`, then the top half (bits[31:16]) of `<Rm>` is used.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The source register whose bottom or top half (selected by `<y>`) is the second multiply operand.
`<Ra>`	The register that contains the accumulate value.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
    result = SInt(R[n]) * SInt(operand2) + (SInt(R[a]) << 16);
    R[d] = result<47:16>;
    if (result >> 16) != SInt(R[d]) then  // Signed overflow
        PSTATE.Q = '1';
```

F7.1.188 SMLSD

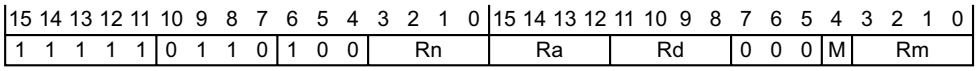
Signed Multiply Subtract Dual performs two signed 16 × 16-bit multiplications. It adds the difference of the products to a 32-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top × bottom and bottom × top multiplication.

This instruction sets the Q flag if the accumulate operation overflows. Overflow cannot occur during the multiplications or subtraction.

Encoding T1

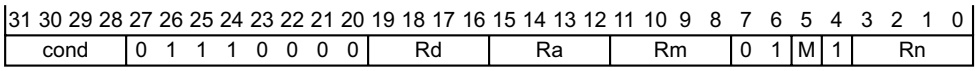
```
SMLSD{X}<c> <Rd>, <Rn>, <Rm>, <Ra>
```



```
if Ra == '1111' then SEE SMUSD;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  m_swap = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SMLSD{X}<c> <Rd>, <Rn>, <Rm>, <Ra>
```



```
if Ra == '1111' then SEE SMUSD;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  m_swap = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SMLSD{X}{<c>}{<q>}  <Rd>, <Rn>, <Rm>, <Ra>
```

where:

X	If X is present, the multiplications are bottom × top and top × bottom. If the X is omitted, the multiplications are bottom × bottom and top × top.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register.
<Rn>	The first operand register.
<Rm>	The second operand register.
<Ra>	The register that contains the accumulate value.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = if m_swap then ROR(R[m],16) else R[m];
    product1 = SInt(R[n]<15:0>) * SInt(operand2<15:0>);
    product2 = SInt(R[n]<31:16>) * SInt(operand2<31:16>);
    result = product1 - product2 + SInt(R[a]);
    R[d] = result<31:0>;
    if result != SInt(result<31:0>) then  // Signed overflow
        PSTATE.Q = '1';
```

F7.1.189 SMLSLD

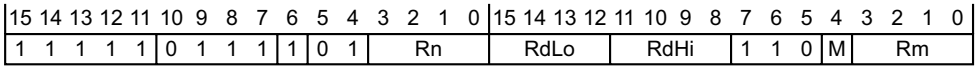
Signed Multiply Subtract Long Dual performs two signed 16 × 16-bit multiplications. It adds the difference of the products to a 64-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top × bottom and bottom × top multiplication.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo 2^{64}.

Encoding T1

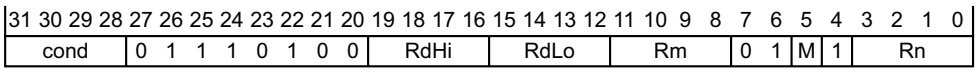
```
SMLSLD{X}<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  m_swap = (M == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

Encoding A1

```
SMLSLD{X}<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  m_swap = (M == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *SMLSLD* on page AppxA-4816.

Assembler syntax

```
SMLSLD{X}{<c>}{<q>}  <RdLo>, <RdHi>, <Rn>, <Rm>
```

where:

X	If X is present, the multiplications are bottom × top and top × bottom. If the X is omitted, the multiplications are bottom × bottom and top × top.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<RdLo>	Supplies the lower 32 bits of the accumulate value, and is the destination register for the lower 32 bits of the result.
<RdHi>	Supplies the upper 32 bits of the accumulate value, and is the destination register for the upper 32 bits of the result.
<Rn>	The first operand register.
<Rm>	The second operand register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = if m_swap then ROR(R[m],16) else R[m];
    product1 = SInt(R[n]<15:0>) * SInt(operand2<15:0>);
    product2 = SInt(R[n]<31:16>) * SInt(operand2<31:16>);
    result = product1 - product2 + SInt(R[dHi]:R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
```

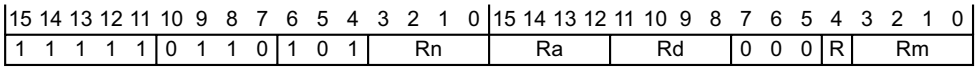
F7.1.190 SMMLA

Signed Most Significant Word Multiply Accumulate multiplies two signed 32-bit values, extracts the most significant 32 bits of the result, and adds an accumulate value.

Optionally, the instruction can specify that the result is rounded instead of being truncated. In this case, the constant `0x80000000` is added to the product before the high word is extracted.

Encoding T1

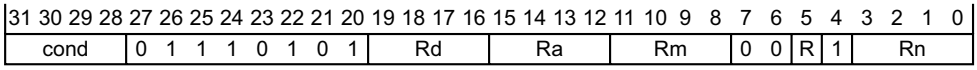
```
SMMLA{R}<c> <Rd>, <Rn>, <Rm>, <Ra>
```



```
if Ra == '1111' then SEE SMMUL;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  round = (R == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SMMLA{R}<c> <Rd>, <Rn>, <Rm>, <Ra>
```



```
if Ra == '1111' then SEE SMMUL;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  round = (R == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SMMLA{R}{<c>}{<q>}  <Rd>, <Rn>, <Rm>, <Ra>
```

where:

R	If R is present, the multiplication is rounded. If the R is omitted, the multiplication is truncated.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register.
<Rn>	The register that contains the first multiply operand.
<Rm>	The register that contains the second multiply operand.
<Ra>	The register that contains the accumulate value.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = (SInt(R[a]) << 32) + SInt(R[n]) * SInt(R[m]);
    if round then result = result + 0x80000000;
    R[d] = result<63:32>;
```

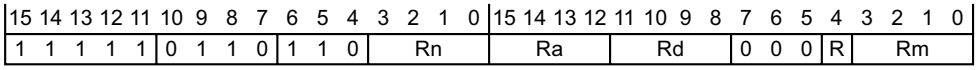
F7.1.191 SMMLS

Signed Most Significant Word Multiply Subtract multiplies two signed 32-bit values, subtracts the result from a 32-bit accumulate value that is shifted left by 32 bits, and extracts the most significant 32 bits of the result of that subtraction.

Optionally, the instruction can specify that the result of the instruction is rounded instead of being truncated. In this case, the constant `0x80000000` is added to the result of the subtraction before the high word is extracted.

Encoding T1

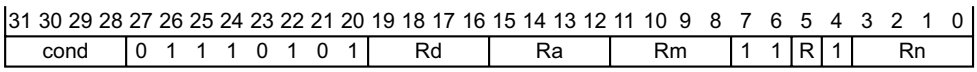
```
SMMLS{R}<c> <Rd>, <Rn>, <Rm>, <Ra>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  round = (R == '1');
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SMMLS{R}<c> <Rd>, <Rn>, <Rm>, <Ra>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  round = (R == '1');
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SMMLS{R}{<c>}{<q>}  <Rd>, <Rn>, <Rm>, <Ra>
```

where:

R	If R is present, the multiplication is rounded. If the R is omitted, the multiplication is truncated.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register.
<Rn>	The register that contains the first multiply operand.
<Rm>	The register that contains the second multiply operand.
<Ra>	The register that contains the accumulate value.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = (SInt(R[a]) << 32) - SInt(R[n]) * SInt(R[m]);
    if round then result = result + 0x80000000;
    R[d] = result<63:32>;
```

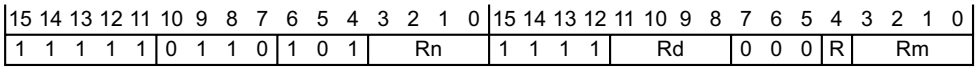
F7.1.192 SMMUL

Signed Most Significant Word Multiply multiplies two signed 32-bit values, extracts the most significant 32 bits of the result, and writes those bits to the destination register.

Optionally, the instruction can specify that the result is rounded instead of being truncated. In this case, the constant `0x80000000` is added to the product before the high word is extracted.

Encoding T1

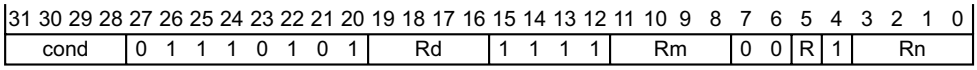
```
SMMUL{R}<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  round = (R == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SMMUL{R}<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  round = (R == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SMMUL{R}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`R`	If R is present, the multiplication is rounded. If the R is omitted, the multiplication is truncated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = SInt(R[n]) * SInt(R[m]);
    if round then result = result + 0x80000000;
    R[d] = result<63:32>;
```

F7.1.193 SMUAD

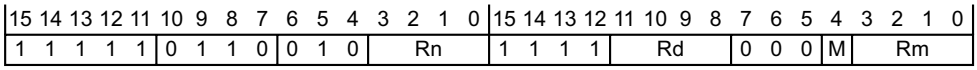
Signed Dual Multiply Add performs two signed 16 × 16-bit multiplications. It adds the products together, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top × bottom and bottom × top multiplication.

This instruction sets the Q flag if the addition overflows. The multiplications cannot overflow.

Encoding T1

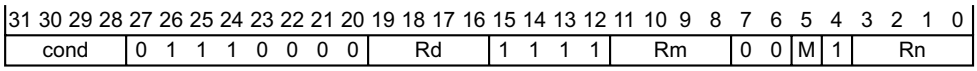
```
SMUAD{X}<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  m_swap = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SMUAD{X}<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  m_swap = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SMUAD{X}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

X	If X is present, the multiplications are bottom × top and top × bottom. If the X is omitted, the multiplications are bottom × bottom and top × top.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register.
<Rn>	The first operand register.
<Rm>	The second operand register.

Operation

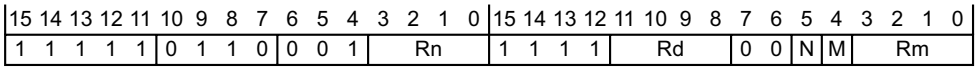
```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = if m_swap then ROR(R[m],16) else R[m];
    product1 = SInt(R[n]<15:0>) * SInt(operand2<15:0>);
    product2 = SInt(R[n]<31:16>) * SInt(operand2<31:16>);
    result = product1 + product2;
    R[d] = result<31:0>;
    if result != SInt(result<31:0>) then  // Signed overflow
        PSTATE.Q = '1';
```

F7.1.194 SMULBB, SMULBT, SMULTB, SMULTT

Signed Multiply (halfwords) multiplies two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is written to the destination register. No overflow is possible during this instruction.

Encoding T1

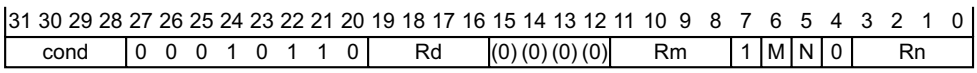
```
SMUL<x><y><c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
n_high = (N == '1');  m_high = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SMUL<x><y><c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
n_high = (N == '1');  m_high = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SMUL<x><y>{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<x>` Specifies which half of the source register `<Rn>` is used as the first multiply operand. If `<x>` is `B`, then the bottom half (bits[15:0]) of `<Rn>` is used. If `<x>` is `T`, then the top half (bits[31:16]) of `<Rn>` is used.

`<y>` Specifies which half of the source register `<Rm>` is used as the second multiply operand. If `<y>` is `B`, then the bottom half (bits[15:0]) of `<Rm>` is used. If `<y>` is `T`, then the top half (bits[31:16]) of `<Rm>` is used.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The source register whose bottom or top half (selected by `<x>`) is the first multiply operand.

`<Rm>` The source register whose bottom or top half (selected by `<y>`) is the second multiply operand.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = if n_high then R[n]<31:16> else R[n]<15:0>;
    operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
    result = SInt(operand1) * SInt(operand2);
    R[d] = result<31:0>;
    // Signed overflow cannot occur
```

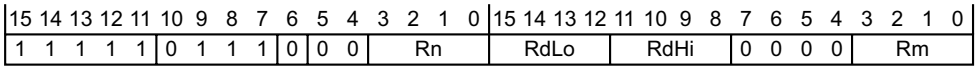
F7.1.195 SMULL

Signed Multiply Long multiplies two 32-bit signed values to produce a 64-bit result.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

Encoding T1

```
SMULL<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```

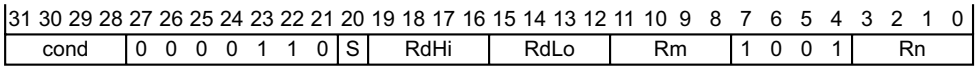


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	1	1	0	0	0	Rn				RdLo				RdHi				0	0	0	0	Rm			

```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

Encoding A1

```
SMULL{S}<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	0	1	1	0	S	RdHi				RdLo				Rm				1	0	0	1	Rn			

```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *SMULL* on page AppxA-4815.

Assembler syntax

```
SMULL{S}{<c>}{<q>}  <RdLo>, <RdHi>, <Rn>, <Rm>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated. `S` can be specified only for the A32 instruction set.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<RdLo>`	Stores the lower 32 bits of the result.
`<RdHi>`	Stores the upper 32 bits of the result.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

The pre-UAL syntax `SMULL<c>S` is equivalent to `SMULLS<c>`.

Operation

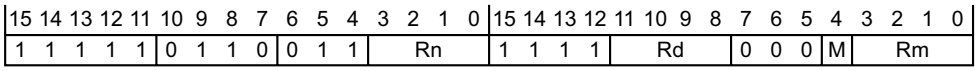
```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = SInt(R[n]) * SInt(R[m]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
    if setflags then
        PSTATE.N = result<63>;
        PSTATE.Z = IsZeroBit(result<63:0>);
        // PSTATE.C, PSTATE.V unchanged
```

F7.1.196 SMULWB, SMULWT

Signed Multiply (word by halfword) multiplies a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are written to the destination register. The bottom 16 bits of the 48-bit product are ignored. No overflow is possible during this instruction.

Encoding T1

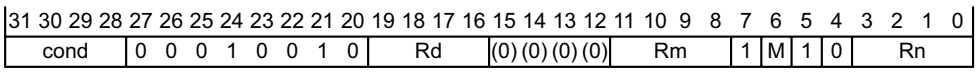
```
SMULW<y><c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  m_high = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SMULW<y><c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  m_high = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SMULW<y>{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

<y>	Specifies which half of the source register <Rm> is used as the second multiply operand. If <y> is B, then the bottom half (bits[15:0]) of <Rm> is used. If <y> is T, then the top half (bits[31:16]) of <Rm> is used.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register.
<Rn>	The first operand register.
<Rm>	The source register whose bottom or top half (selected by <y>) is the second multiply operand.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
    product = SInt(R[n]) * SInt(operand2);
    R[d] = product<47:16>;
    // Signed overflow cannot occur
```

F7.1.197 SMUSD

Signed Multiply Subtract Dual performs two signed 16 × 16-bit multiplications. It subtracts one of the products from the other, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top × bottom and bottom × top multiplication.

Overflow cannot occur.

Encoding T1

```
SMUSD{X}<c> <Rd>, <Rn>, <Rm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	1	0	1	0	0	Rn				1	1	1	1	Rd				0	0	0	M	Rm			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  m_swap = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SMUSD{X}<c> <Rd>, <Rn>, <Rm>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	1	1	1	0	0	0	0	Rd				1	1	1	1	Rm				0	1	M	1	Rn			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  m_swap = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SMUSD{X}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

X	If X is present, the multiplications are bottom × top and top × bottom. If the X is omitted, the multiplications are bottom × bottom and top × top.
<c>, <q>	See *Standard assembler syntax fields* on page F2-2330.
<Rd>	The destination register.
<Rn>	The first operand register.
<Rm>	The second operand register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = if m_swap then ROR(R[m],16) else R[m];
    product1 = SInt(R[n]<15:0>) * SInt(operand2<15:0>);
    product2 = SInt(R[n]<31:16>) * SInt(operand2<31:16>);
    result = product1 - product2;
    R[d] = result<31:0>;
    // Signed overflow cannot occur
```

F7.1.198 SRS

Store Return State is a system instruction. For details see *SRS, T32* on page F7-3024 and *SRS, A32* on page F7-3026.

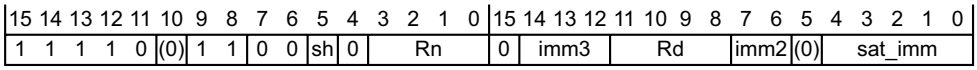
F7.1.199 SSAT

Signed Saturate saturates an optionally-shifted signed value to a selectable signed range.

The Q flag is set if the operation saturates.

Encoding T1

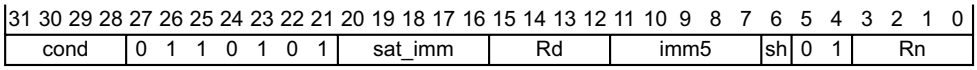
```
SSAT<c> <Rd>, #<imm>, <Rn>{, <shift>}
```



```
if sh == '1' && (imm3:imm2) == '00000' then SEE SSAT16;
d = UInt(Rd);  n = UInt(Rn);  saturate_to = UInt(sat_imm)+1;
(shift_t, shift_n) = DecodeImmShift(sh:'0', imm3:imm2);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SSAT<c> <Rd>, #<imm>, <Rn>{, <shift>}
```



```
d = UInt(Rd);  n = UInt(Rn);  saturate_to = UInt(sat_imm)+1;
(shift_t, shift_n) = DecodeImmShift(sh:'0', imm5);
if d == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SSAT{<c>}{<q>}  <Rd>, #<imm>, <Rn> {, <shift>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<imm>` The bit position for saturation, in the range 1 to 32. The `sat_imm` field of the instruction encodes this bit position, by taking the value (`<imm>`-1).

`<Rn>` The register that contains the value to be saturated.

`<shift>` The optional shift, encoded in the `sh` bit and the `immsh` field, where `immsh` is:

- `imm3:imm2` for encoding T1.
- `imm5` for encoding A1.

`<shift>` must be one of:

omitted No shift. Encoded as `sh` = 0, `immsh` = `0b00000`.

`LSL #<n>` Left shift by `<n>` bits, with `<n>` in the range 1-31.
Encoded as `sh` = 0, `immsh` = `<n>`.

`ASR #<n>` Arithmetic right shift by `<n>` bits, with `<n>` in the range 1-31.
Encoded as `sh` = 1, `immsh` = `<n>`.

`ASR #32` Arithmetic right shift by 32 bits, permitted only for encoding A1.
Encoded as `sh` = 1, `immsh` = `0b00000`.

Note

An assembler can permit `ASR #0` or `LSL #0` to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand = Shift(R[n], shift_t, shift_n, PSTATE.C);  // PSTATE.C ignored
    (result, sat) = SignedSatQ(SInt(operand), saturate_to);
    R[d] = SignExtend(result, 32);
    if sat then
        PSTATE.Q = '1';
```

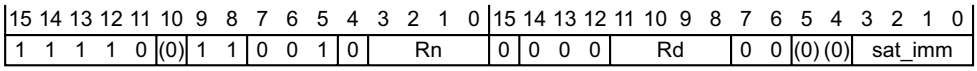
F7.1.200 SSAT16

Signed Saturate 16 saturates two signed 16-bit values to a selected signed range.

The Q flag is set if the operation saturates.

Encoding T1

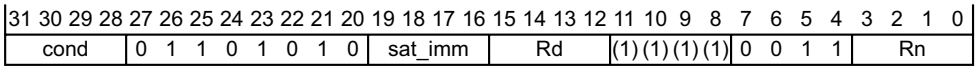
```
SSAT16<c> <Rd>, #<imm>, <Rn>
```



```
d = UInt(Rd);  n = UInt(Rn);  saturate_to = UInt(sat_imm)+1;
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SSAT16<c> <Rd>, #<imm>, <Rn>
```



```
d = UInt(Rd);  n = UInt(Rn);  saturate_to = UInt(sat_imm)+1;
if d == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SSAT16{<c>}{<q>}  <Rd>, #<imm>, <Rn>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<imm>` The bit position for saturation, in the range 1 to 16. The `sat_imm` field of the instruction encodes this bit position, by taking the value (`<imm>`-1).

`<Rn>` The register that contains the values to be saturated.

Operation

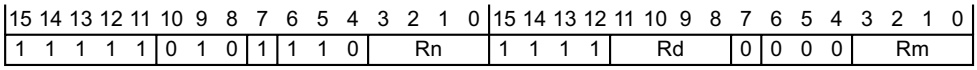
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result1, sat1) = SignedSatQ(SInt(R[n]<15:0>), saturate_to);
    (result2, sat2) = SignedSatQ(SInt(R[n]<31:16>), saturate_to);
    R[d]<15:0> = SignExtend(result1, 16);
    R[d]<31:16> = SignExtend(result2, 16);
    if sat1 || sat2 then
        PSTATE.Q = '1';
```

F7.1.201 SSAX

Signed Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one 16-bit integer subtraction and one 16-bit addition, and writes the results to the destination register. It sets the APSR.GE bits according to the results.

Encoding T1

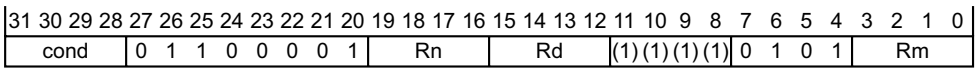
SSAX<c> <Rd>, <Rn>, <Rm>



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

SSAX<c> <Rd>, <Rn>, <Rm>



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SSAX{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

The pre-UAL syntax `SSUBADDX<c>` is equivalent to `SSAX<c>`.

Operation

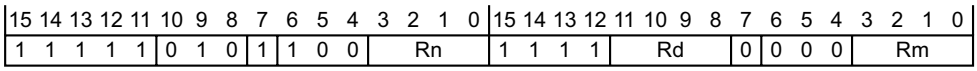
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum  = SInt(R[n]<15:0>) + SInt(R[m]<31:16>);
    diff = SInt(R[n]<31:16>) - SInt(R[m]<15:0>);
    R[d]<15:0>  = sum<15:0>;
    R[d]<31:16> = diff<15:0>;
    PSTATE.GE<1:0> = if sum  >= 0 then '11' else '00';
    PSTATE.GE<3:2> = if diff >= 0 then '11' else '00';
```

F7.1.202 SSUB8

Signed Subtract 8 performs four 8-bit signed integer subtractions, and writes the results to the destination register. It sets the APSR.GE bits according to the results of the subtractions.

Encoding T1

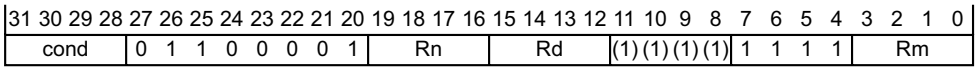
```
SSUB8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SSUB8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SSUB8{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

Operation

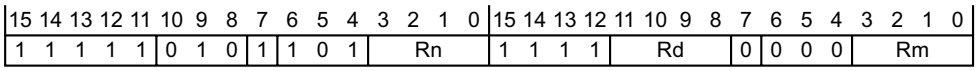
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = SInt(R[n]<7:0>) - SInt(R[m]<7:0>);
    diff2 = SInt(R[n]<15:8>) - SInt(R[m]<15:8>);
    diff3 = SInt(R[n]<23:16>) - SInt(R[m]<23:16>);
    diff4 = SInt(R[n]<31:24>) - SInt(R[m]<31:24>);
    R[d]<7:0>   = diff1<7:0>;
    R[d]<15:8>  = diff2<7:0>;
    R[d]<23:16> = diff3<7:0>;
    R[d]<31:24> = diff4<7:0>;
    PSTATE.GE<0>  = if diff1 >= 0 then '1' else '0';
    PSTATE.GE<1>  = if diff2 >= 0 then '1' else '0';
    PSTATE.GE<2>  = if diff3 >= 0 then '1' else '0';
    PSTATE.GE<3>  = if diff4 >= 0 then '1' else '0';
```

F7.1.203 SSUB16

Signed Subtract 16 performs two 16-bit signed integer subtractions, and writes the results to the destination register. It sets the APSR.GE bits according to the results of the subtractions.

Encoding T1

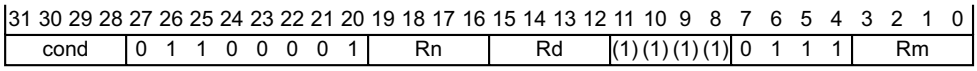
```
SSUB16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SSUB16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SSUB16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = SInt(R[n]<15:0>) - SInt(R[m]<15:0>);
    diff2 = SInt(R[n]<31:16>) - SInt(R[m]<31:16>);
    R[d]<15:0>  = diff1<15:0>;
    R[d]<31:16> = diff2<15:0>;
    PSTATE.GE<1:0> = if diff1 >= 0 then '11' else '00';
    PSTATE.GE<3:2> = if diff2 >= 0 then '11' else '00';
```

F7.1.204 STC, STC2

Store Coprocessor stores data from a coprocessor to a sequence of consecutive memory addresses. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `D` bit, the `CRd` field, and in the Unindexed addressing mode only, the `imm8` field. However, coprocessors CP8-CP15 are reserved for use by A32, and this manual defines the valid `STC` and `STC2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page E1-2244.

In an implementation that includes EL2, the permitted `STC` access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an `STC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Trapping general CP14 accesses to debug registers* on page G1-3500.

Note

For simplicity, the `STC` pseudocode does not show this possible trap to Hyp mode.

Encoding T1/A1

```
STC{L}<c> <coproc>, <CRd>, [<Rn>, #+/-<imm>]{!}
STC{L}<c> <coproc>, <CRd>, [<Rn>], #+/-<imm>
STC{L}<c> <coproc>, <CRd>, [<Rn>], <option>
```

if coproc == '101x' then UNDEFINED;
n = UInt(Rn);  cp = UInt(coproc);
imm32 = ZeroExtend(imm8:'00', 32);  index = (P == '1');  add = (U == '1');  wback = (W == '1');
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STC, STC2* on page AppxA-4817.

Advanced SIMD and floating-point See *Advanced SIMD and floating-point register load/store instructions* on page F5-2430

Assembler syntax

`STC{2}{L}{<c>}{<q>}`	`<coproc>, <CRd>, [<Rn>{, #+/-<imm>}]`	Offset. P = 1, W = 0.
`STC{2}{L}{<c>}{<q>}`	`<coproc>, <CRd>, [<Rn>, #+/-<imm>]!`	Pre-indexed. P = 1, W = 1.
`STC{2}{L}{<c>}{<q>}`	`<coproc>, <CRd>, [<Rn>], #+/-<imm>`	Post-indexed. P = 0, W = 1.
`STC{2}{L}{<c>}{<q>}`	`<coproc>, <CRd>, [<Rn>], <option>`	Unindexed. P = 0, W = 0, U = 1.

where:

`2`	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
`L`	If specified, selects the D == 1 form of the encoding. If omitted, selects the D == 0 form.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330. An A32 `STC2` instruction must be unconditional.
`<coproc>`	The name of the coprocessor. The generic coprocessor names are p0-p15.
`<CRd>`	The coprocessor source register.
`<Rn>`	The base register. The SP can be used. In the A32 instruction set, for offset and unindexed addressing only, the PC can be used. However, ARM deprecates use of the PC.
`+/-`	Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.
`<imm>`	The immediate offset used for forming the address. Values are multiples of 4 in the range 0-1020. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of +0.
`<option>`	A coprocessor option. An integer in the range 0-255 enclosed in { }. Encoded in imm8.

The pre-UAL syntax `STC<c>L` is equivalent to `STCL<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        repeat
            MemA[address,4] = Coproc_GetWordToStore(cp, ThisInstr());
            address = address + 4;
        until Coproc_DoneStoring(cp, ThisInstr());
        if wback then R[n] = offset_addr;
```

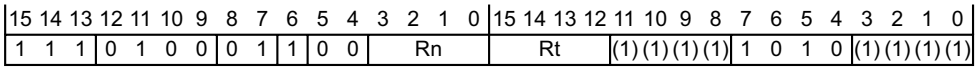
F7.1.205 STL

Store Release Word stores a word from a register to memory. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2271.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

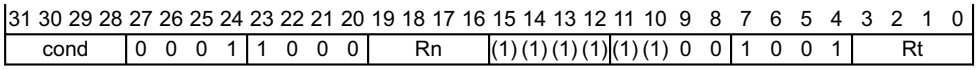
```
STL<c> <Rt>, [<Rn>]
```



```
t = UInt(Rt); n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

Encoding A1

```
STL <Rt>, [<Rn>]
```



```
t = UInt(Rt); n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
STL{<c>}{<q>} <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    acctype = AccType_ORDERED;
    aligned = (address == Align(address, 4));
    MemA_with_type[address, 4, acctype, aligned] = R[t];
```

F7.1.206 STLB

Store Release Byte stores a byte from a register to memory. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2271.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

```
STLB<c> <Rt>, [<Rn>]
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
t = UInt(Rt); n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

Encoding A1

```
STLB <Rt>, [<Rn>]
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	1	1	0	0	Rn				(1)	(1)	(1)	(1)	(1)	(1)	0	0	1	0	0	1	Rt			

```
t = UInt(Rt); n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
STLB{<c>}{<q>} <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    acctype = AccType_ORDERED;
    aligned = TRUE;
    MemA_with_type[address, 1, acctype, aligned] = R[t]<7:0>;
```

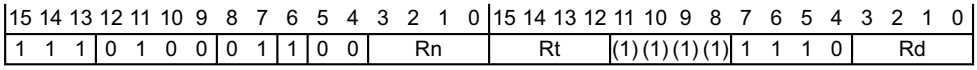
F7.1.207 STLEX

Store Release Exclusive Word stores a word from a register to memory if the executing PE has exclusive access to the memory addressed. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2271.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

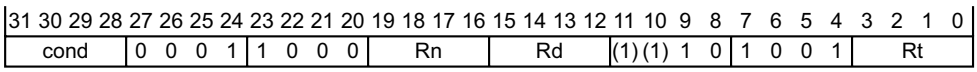
```
STLEX<c> <Rd>, <Rt>, [<Rn>]
```



```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

Encoding A1

```
STLEX <Rd>, <Rt>, [<Rn>]
```



```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
STLEX{<c>}{<q>}  <Rd>, <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register for the returned status value. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,4) then
        acctype = AccType_ORDERED;
        aligned = (address == Align(address, 4));
        MemA_with_type[address, 4, acctype, aligned] = R[t];
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Rd>` is not updated.

If SCTLR.A and SCTLR.U are both 0, a non word-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

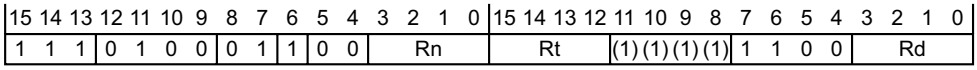
F7.1.208 STLEXB

Store Release Exclusive Byte stores a byte from a register to memory if the executing PE has exclusive access to the memory addressed. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2271.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

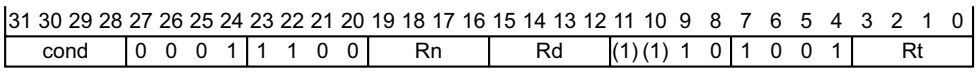
```
STLEXB<c> <Rd>, <Rt>, [<Rn>]
```



```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

Encoding A1

```
STLEXB <Rd>, <Rt>, [<Rn>]
```



```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
STLEXB{<c>}{<q>}  <Rd>, <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register for the returned status value. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,1) then
        acctype = AccType_ORDERED;
        aligned = TRUE;
        MemA_with_type[address, 1, acctype, aligned] = R[t]<7:0>;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Rd>` is not updated.

If `ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

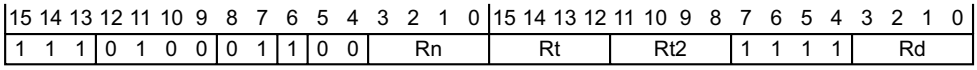
F7.1.209 STLEXD

Store Release Exclusive Doubleword stores a doubleword from two registers to memory if the executing PE has exclusive access to the memory addressed. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2271.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

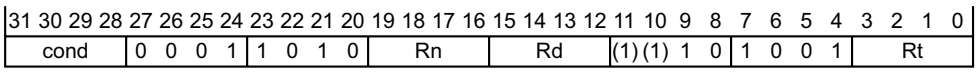
```
STLEXD<c> <Rd>, <Rt>, <Rt2>, [<Rn>]
```



```
d = UInt(Rd);  t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);
if d == 15 || t == 15 || t2 == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t || d == t2 then UNPREDICTABLE;
```

Encoding A1

```
STLEXD <Rd>, <Rt>, <Rt2>, [<Rn>]
```



```
d = UInt(Rd);  t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);
if d == 15 || Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t || d == t2 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STLEXD* on page AppxA-4834.

Assembler syntax

```
STLEXD{<c>}{<q>}  <Rd>, <Rt>, <Rt2>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register for the returned status value. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Rt>` The first source register. For an A32 instruction, `<Rt>` must be even-numbered and not R14.

`<Rt2>` The second source register. For an A32 instruction, `<Rt2>` must be `<R(t+1)>`.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    value = if BigEndian() then R[t]:R[t2] else R[t2]:R[t];
    if AArch32.ExclusiveMonitorsPass(address, 8) then
        acctype = AccType_ORDERED;
        aligned = (address == Align(address, 8));
        MemA_with_type[address, 8, acctype, aligned] = value;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Rd>` is not updated.

If SCTLR.A and SCTLR.U are both 0, a non word-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

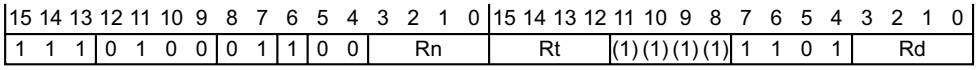
F7.1.210 STLEXH

Store Release Exclusive Halfword stores a halfword from a register to memory if the executing PE has exclusive access to the memory addressed. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2271.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

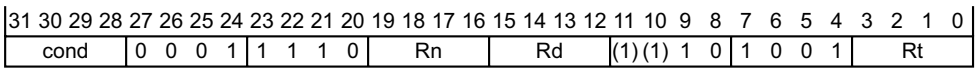
```
STLEXH<c> <Rd>, <Rt>, [<Rn>]
```



```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

Encoding A1

```
STLEXH <Rd>, <Rt>, [<Rn>]
```



```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
STLEXH{<c>}{<q>}  <Rd>, <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register for the returned status value. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,2) then
        acctype = AccType_ORDERED;
        aligned = (address == Align(address, 2));
        MemA_with_type[address, 2, acctype, aligned] = R[t]<15:0>;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- memory is not updated
- `<Rd>` is not updated.

If SCTLR.A and SCTLR.U are both 0, a non word-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

F7.1.211 STLH

Store Release Halfword stores a halfword from a register to memory. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release* on page E2-2271.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

```
STLH<c> <Rt>, [<Rn>]
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	0	1	1	0	0	Rn				Rt				(1)	(1)	(1)	(1)	1	0	0	1	(1)	(1)	(1)	(1)

```
t = UInt(Rt); n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

Encoding A1

```
STLH <Rt>, [<Rn>]
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	1	1	1	0	Rn				(1)	(1)	(1)	(1)	(1)	(1)	0	0	1	0	0	1	Rt			

```
t = UInt(Rt); n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
STLH{<c>}{<q>} <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    acctype = AccType_ORDERED;
    aligned = (address == Align(address, 2));
    MemA_with_type[address, 2, acctype, aligned] = R[t]<15:0>;
```

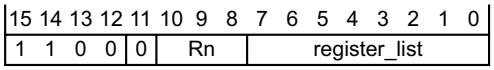
F7.1.212 STM (STMIA, STMEA)

Store Multiple Increment After (Store Multiple Empty Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the last of those locations can optionally be written back to the base register.

For details of related system instructions see *STM (User registers)* on page F7-3028.

Encoding T1

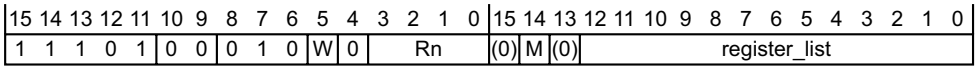
```
STM<c> <Rn>!, <registers>
```



```
n = UInt(Rn);  registers = '00000000':register_list;  wback = TRUE;
if BitCount(registers) < 1 then UNPREDICTABLE;
```

Encoding T2

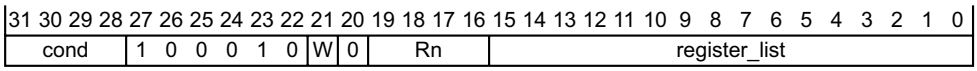
```
STM<c>.W <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = '0':M:'0':register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

Encoding A1

```
STM<c> <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STM (STMIA, STMEA)* on page AppxA-4818.

Assembler syntax

```
STM{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The base register. The SP can be used.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be stored, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

Encoding T2 does not support a list containing only one register. If an `STM` instruction with just one register `<Rt>` in the list is assembled to T32 and encoding T1 is not available, it is assembled to the equivalent `STR{<c>}{<q>} <Rt>, [<Rn>]{, #4}` instruction.

The SP and PC can be in the list in A32 instructions, but not in T32 instructions. However, ARM deprecates the use of A32 instructions that include the SP or the PC in the list.

ARM deprecates the use of instructions with the base register in the list and ! specified. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

An instruction with the base register in the list and ! specified cannot use encoding T2.

`STMEA` and `STMIA` are pseudo-instructions for `STM`. `STMEA` refers to its use for pushing data onto Empty Ascending stacks.

The pre-UAL syntaxes `STM<c>IA` and `STM<c>EA` are equivalent to `STM<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;  // Only possible for encodings T1 and A1
            else
                MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then  // Only possible for encoding A1
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] + 4*BitCount(registers);
```

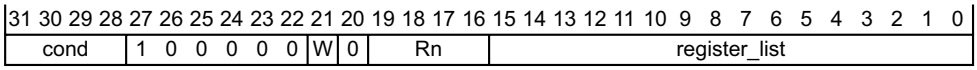
F7.1.213 STMDA (STMED)

Store Multiple Decrement After (Store Multiple Empty Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

For details of related system instructions see *STM (User registers)* on page F7-3028.

Encoding A1

```
STMDA<c> <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STMDA (STMED)* on page AppxA-4819.

Assembler syntax

```
STMDA{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The base register. The SP can be used.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be stored, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

The SP and PC can be in the list. However, instructions that include the SP or the PC in the list are deprecated.

ARM deprecates the use of instructions with the base register in the list and ! specified. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

`STMED` is s pseudo-instruction for `STMDA`, referring to its use for pushing data onto Empty Descending stacks.

The pre-UAL syntaxes `STM<c>DA` and `STM<c>ED` are equivalent to `STMDA<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers) + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;
            else
                MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] - 4*BitCount(registers);
```

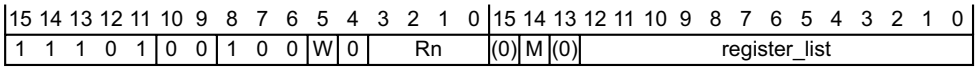
F7.1.214 STMDB (STMFD)

Store Multiple Decrement Before (Store Multiple Full Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the first of those locations can optionally be written back to the base register.

For details of related system instructions see *STM (User registers)* on page F7-3028.

Encoding T1

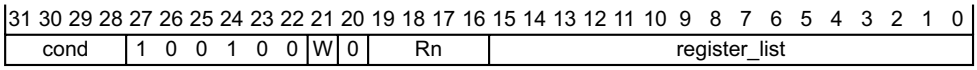
```
STMDB<c> <Rn>{!}, <registers>
```



```
if W == '1' && Rn == '1101' then SEE PUSH;
n = UInt(Rn);  registers = '0':M:'0':register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

Encoding A1

```
STMDB<c> <Rn>{!}, <registers>
```



```
if W == '1' && Rn == '1101' && BitCount(register_list) >= 2 then SEE PUSH;
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STMDB (STMFD)* on page AppxA-4820.

Assembler syntax

```
STMDB{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The base register. The SP can be used. If the SP is used, and ! is specified:

- For encoding T1, it is treated as described in *PUSH* on page F7-2693.
- For encoding A1, if there is more than one register in the `<registers>` list, it is treated as described in *PUSH* on page F7-2693.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be stored, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

Encoding T1 does not support a list containing only one register. If an `STMDB` instruction with just one register `<Rt>` in the list is assembled to T32, it is assembled to the equivalent `STR{<c>}{<q>} <Rt>, [<Rn>, #-4]{!}` instruction.

The SP and PC can be in the list in A32 instructions, but not in T32 instructions. However, ARM deprecates the use of A32 instructions that include the SP or the PC in the list.

Instructions with the base register in the list and ! specified are only available in the A32 instruction set, and ARM deprecates the use of such instructions. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

`STMFD` is a pseudo-instruction for `STMDB`, referring to its use for pushing data onto Full Descending stacks.

The pre-UAL syntaxes `STM<c>DB` and `STM<c>FD` are equivalent to `STMDB<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;  // Only possible for encoding A1
            else
                MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then  // Only possible for encoding A1
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] - 4*BitCount(registers);
```

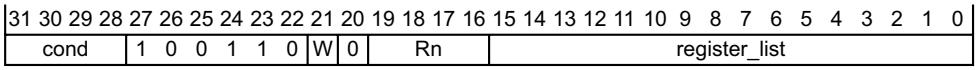
F7.1.215 STMIB (STMFA)

Store Multiple Increment Before (Store Multiple Full Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register.

For details of related system instructions see *STM (User registers)* on page F7-3028.

Encoding A1

```
STMIB<c> <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STMIB (STMFA)* on page AppxA-4819.

Assembler syntax

```
STMIB{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The base register. The SP can be used.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be stored, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

The SP and PC can be in the list. However, instructions that include the SP or the PC in the list are deprecated.

ARM deprecates the use of instructions with the base register in the list and ! specified. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

`STMFA` is a pseudo-instruction for `STMIB`, referring to its use for pushing data onto Full Ascending stacks.

The pre-UAL syntax `STM<c>IB` and `STM<c>FA` are equivalent to `STMIB<c>`.

Operation

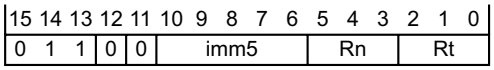
```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;
            else
                MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] + 4*BitCount(registers);
```

F7.1.216 STR (immediate), T32

Store Register (immediate) calculates an address from a base register value and an immediate offset, and stores a word from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

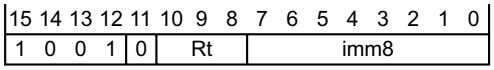
```
STR<c> <Rt>, [<Rn>{, #<imm>}]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5:'00', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T2

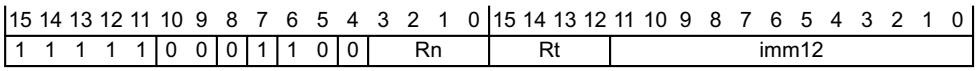
```
STR<c> <Rt>, [SP, #<imm>]
```



```
t = UInt(Rt);  n = 13;  imm32 = ZeroExtend(imm8:'00', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T3

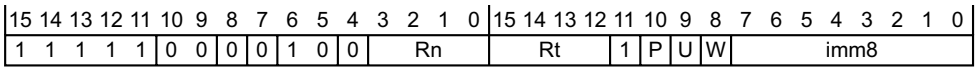
```
STR<c>.W <Rt>, [<Rn>, #<imm12>]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
if t == 15 then UNPREDICTABLE;
```

Encoding T4

```
STR<c> <Rt>, [<Rn>, #-<imm8>]
STR<c> <Rt>, [<Rn>], #+/-<imm8>
STR<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if P == '1' && U == '1' && W == '0' then SEE STRT;
if Rn == '1101' && P == '1' && U == '0' && W == '1' && imm8 == '00000100' then SEE PUSH;
if Rn == '1111' || (P == '0' && W == '0') then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STR (immediate, T32)* on page AppxA-4821.

Assembler syntax

`STR{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`STR{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`STR{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register. The SP can be used.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Values are:

Encoding T1 Multiples of 4 in the range 0-124.

Encoding T2 Multiples of 4 in the range 0-1020.

Encoding T3 Any value in the range 0-4095.

Encoding T4 Any value in the range 0-255.

For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0.

Operation

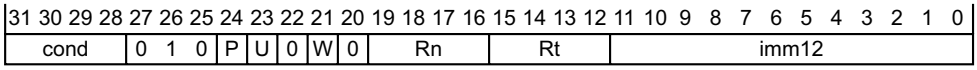
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,4] = R[t];
    if wback then R[n] = offset_addr;
```

F7.1.217 STR (immediate), A32

Store Register (immediate) calculates an address from a base register value and an immediate offset, and stores a word from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding A1

```
STR<c> <Rt>, [<Rn>{, #+/-<imm12>}]
STR<c> <Rt>, [<Rn>], #+/-<imm12>
STR<c> <Rt>, [<Rn>, #+/-<imm12>]!
```



```
if P == '0' && W == '1' then SEE STRT;
if Rn == '1101' && P == '1' && U == '0' && W == '1' && imm12 == '000000000100' then SEE PUSH;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STR (immediate, A32)* on page AppxA-4822.

Assembler syntax

`STR{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`STR{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`STR{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register. The SP or the PC can be used. However, ARM deprecates use of the PC.

`<Rn>` The base register. The SP can be used. For offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Any value in the range 0-4095 is permitted. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0.

Operation

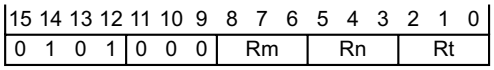
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,4] = if t == 15 then PCStoreValue() else R[t];
    if wback then R[n] = offset_addr;
```

F7.1.218 STR (register)

Store Register (register) calculates an address from a base register value and an offset register value, stores a word from a register to memory. The offset register value can optionally be shifted. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

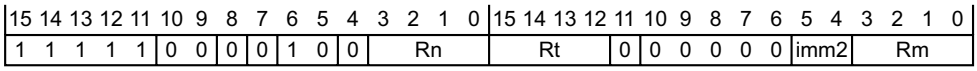
```
STR<c> <Rt>, [<Rn>, <Rm>]
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

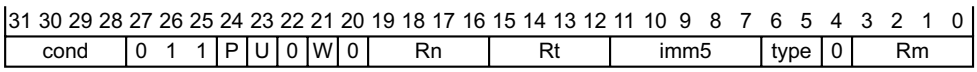
```
STR<c>.W <Rt>, [<Rn>, <Rm>{, LSL #<imm2>}]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if t == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
STR<c> <Rt>, [<Rn>,+/-<Rm>{, <shift>}]{!}
STR<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```



```
if P == '0' && W == '1' then SEE STRT;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STR (register)* on page AppxA-4822.

Assembler syntax

`STR{<c>}{<q>} <Rt>, [<Rn>, <Rm>{, <shift>}]`	Offset: `index==TRUE, wback==FALSE`
`STR{<c>}{<q>} <Rt>, [<Rn>, <Rm>{, <shift>}]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`STR{<c>}{<q>} <Rt>, [<Rn>], <Rm>{, <shift>}`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register. The SP can be used. In the A32 instruction set, the PC can be used. However, ARM deprecates use of the PC.

`<Rn>` The base register. The SP can be used. In the A32 instruction set, for offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`).

`<Rm>` Contains the offset that is optionally shifted and added to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. For encoding T2, `<shift>` can only be omitted, encoded as imm2 = `0b00`, or `LSL #<imm>` with `<imm>` = 1, 2, or 3, and `<imm>` encoded in imm2. For encoding A1, see *Shifts applied to a register* on page F2-2334.

Operation

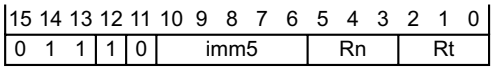
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    if t == 15 then  // Only possible for encoding A1
        data = PCStoreValue();
    else
        data = R[t];
    MemU[address,4] = data;
    if wback then R[n] = offset_addr;
```

F7.1.219 STRB (immediate), T32

Store Register Byte (immediate) calculates an address from a base register value and an immediate offset, and stores a byte from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

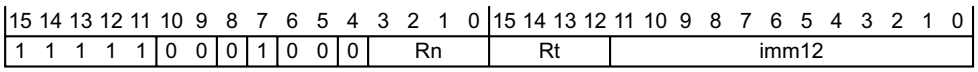
```
STRB<c> <Rt>, [<Rn>, #<imm5>]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T2

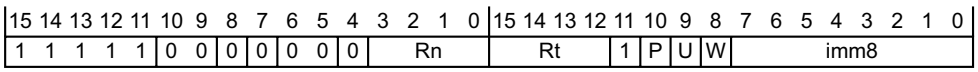
```
STRB<c>.W <Rt>, [<Rn>, #<imm12>]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding T3

```
STRB<c> <Rt>, [<Rn>, #-<imm8>]
STRB<c> <Rt>, [<Rn>], #+/-<imm8>
STRB<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if P == '1' && U == '1' && W == '0' then SEE STRBT;
if Rn == '1111' || (P == '0' && W == '0') then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRB (immediate), T32* on page AppxA-4823.

Assembler syntax

`STRB{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE`, `wback==FALSE`
`STRB{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`STRB{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Values are:

Encoding T1 Any value in the range 0-31.

Encoding T2 Any value in the range 0-4095.

Encoding T3 Any value in the range 0-255.

For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0.

The pre-UAL syntax `STR<c>B` is equivalent to `STRB<c>`.

Operation

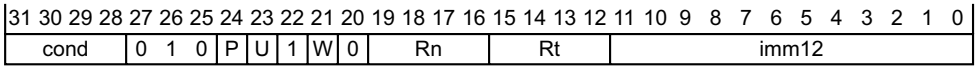
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,1] = R[t]<7:0>;
    if wback then R[n] = offset_addr;
```

F7.1.220 STRB (immediate), A32

Store Register Byte (immediate) calculates an address from a base register value and an immediate offset, and stores a byte from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding A1

```
STRB<c> <Rt>, [<Rn>{, #+/-<imm12>}]
STRB<c> <Rt>, [<Rn>], #+/-<imm12>
STRB<c> <Rt>, [<Rn>, #+/-<imm12>]!
```



```
if P == '0' && W == '1' then SEE STRBT;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRB (immediate, A32)* on page AppxA-4824.

Assembler syntax

`STRB{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`STRB{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`STRB{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used. For offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Values are 0-4095. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0.

The pre-UAL syntax `STR<c>B` is equivalent to `STRB<c>`.

Operation

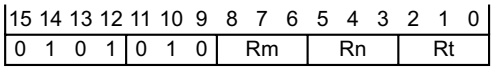
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,1] = R[t]<7:0>;
    if wback then R[n] = offset_addr;
```

F7.1.221 STRB (register)

Store Register Byte (register) calculates an address from a base register value and an offset register value, and stores a byte from a register to memory. The offset register value can optionally be shifted. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

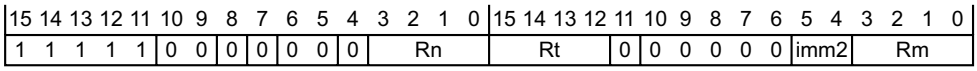
```
STRB<c> <Rt>, [<Rn>, <Rm>]
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

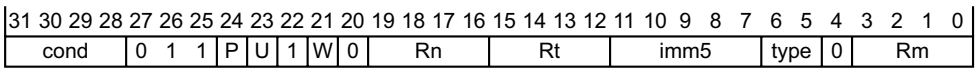
```
STRB<c>.W <Rt>, [<Rn>, <Rm>{, LSL #<imm2>}]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if t == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
STRB<c> <Rt>, [<Rn>,+/-<Rm>{, <shift>}]{!}
STRB<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```



```
if P == '0' && W == '1' then SEE STRBT;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRB (register)* on page AppxA-4824.

Assembler syntax

`STRB{<c>}{<q>} <Rt>, [<Rn>, <Rm>{, <shift>}]`	Offset: `index==TRUE`, `wback==FALSE`
`STRB{<c>}{<q>} <Rt>, [<Rn>, <Rm>{, <shift>}]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`STRB{<c>}{<q>} <Rt>, [<Rn>], <Rm>{, <shift>}`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used. In the A32 instruction set, for offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`).

`<Rm>` Contains the offset that is optionally shifted and added to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. For encoding T2, `<shift>` can only be omitted, encoded as imm2 = `0b00`, or `LSL #<imm>` with `<imm>` = 1, 2, or 3, and `<imm>` encoded in imm2. For encoding A1, see *Shifts applied to a register* on page F2-2334.

The pre-UAL syntax `STR<c>B` is equivalent to `STRB<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    MemU[address,1] = R[t]<7:0>;
    if wback then R[n] = offset_addr;
```

F7.1.222 STRBT

Store Register Byte Unprivileged stores a byte from a register to memory. For information about memory accesses see *Memory accesses* on page F2-2337.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

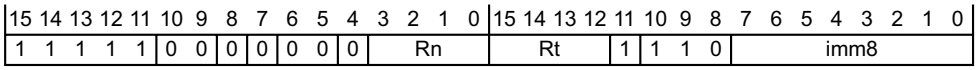
STRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

Encoding T1

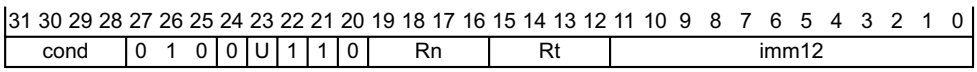
```
STRBT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

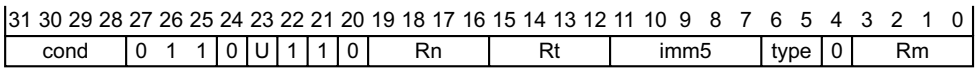
```
STRBT<c> <Rt>, [<Rn>], #+/-<imm12>
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2

```
STRBT<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;  (shift_t, shift_n) = DecodeImmShift(type, imm5);
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRBT* on page AppxA-4825.

Assembler syntax

`STRBT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: T32 only
`STRBT{<c>}{<q>}  <Rt>, [<Rn>] {, #<imm>}`	Post-indexed: A32 only
`STRBT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm> {, <shift>}`	Post-indexed: A32 only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`).

`<imm>` The immediate offset applied to the value of `<Rn>`. Values are 0-255 for encoding T1, and 0-4095 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is optionally shifted and added to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

The pre-UAL syntax `STR<c>BT` is equivalent to `STRBT<c>`.

Operation

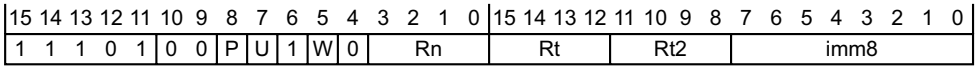
```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    MemU_unpriv[address,1] = R[t]<7:0>;
    if postindex then R[n] = offset_addr;
```

F7.1.223 STRD (immediate)

Store Register Dual (immediate) calculates an address from a base register value and an immediate offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

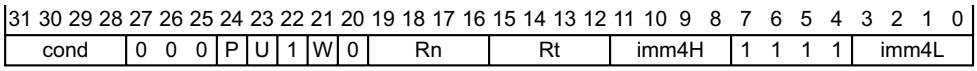
```
STRD<c> <Rt>, <Rt2>, [<Rn>{, #+/-<imm>}]
STRD<c> <Rt>, <Rt2>, [<Rn>], #+/-<imm>
STRD<c> <Rt>, <Rt2>, [<Rn>, #+/-<imm>]!
```



```
if P == '0' && W == '0' then SEE "Related encodings";
t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if wback && (n == t || n == t2) then UNPREDICTABLE;
if n == 15 || t == 15 || t2 == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
STRD<c> <Rt>, <Rt2>, [<Rn>{, #+/-<imm8>}]
STRD<c> <Rt>, <Rt2>, [<Rn>], #+/-<imm8>
STRD<c> <Rt>, <Rt2>, [<Rn>, #+/-<imm8>]!
```



```
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if wback && (n == 15 || n == t || n == t2) then UNPREDICTABLE;
if t2 == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRD (immediate)* on page AppxA-4829.

Related encodings See *Load/Store dual, Load/Store-Exclusive, Load-Acquire/Store-Release, table branch* on page F3-2364.

Assembler syntax

`STRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`STRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`STRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The first source register. For an A32 instruction, `<Rt>` must be even-numbered and not R14.

`<Rt2>` The second source register. For an A32 instruction, `<Rt2>` must be `<R(t+1)>`.

`<Rn>` The base register. The SP can be used. In the A32 instruction set, for offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Values are multiples of 4 in the range 0-1020 for encoding T1, and any value in the range 0-255 for encoding A1. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0.

The pre-UAL syntax `STR<c>D` is equivalent to `STRD<c>`.

Operation

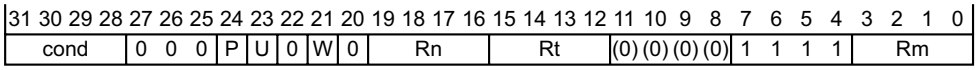
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    if address == Align(address, 8) then
        bits(64) data;
        if BigEndian() then
            data<63:32> = R[t];
            data<31:0> = R[t2];
        else
            data<31:0> = R[t];
            data<63:32> = R[t2];
        MemA[address,8] = data;
    else
        MemA[address,4] = R[t];
        MemA[address+4,4] = R[t2];
    if wback then R[n] = offset_addr;
```

F7.1.224 STRD (register)

Store Register Dual (register) calculates an address from a base register value and a register offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding A1

```
STRD<c> <Rt>, <Rt2>, [<Rn>,+/-<Rm>]{!}
STRD<c> <Rt>, <Rt2>, [<Rn>],+/-<Rm>
```



31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
cond	0 0 0	P	U	0	W	0	Rn	Rt	(0) (0) (0) (0)	1 1 1 1	Rm

```
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if t2 == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t || n == t2) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRD (register)* on page AppxA-4830.

Assembler syntax

`STRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>, +/-<Rm>]`	Offset: `index==TRUE, wback==FALSE`
`STRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>, +/-<Rm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`STRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>], +/-<Rm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The first source register. This register must be even-numbered and not R14.

`<Rt2>` The second source register. This register must be `<R(t+1)>`.

`<Rn>` The base register. The SP can be used. For offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`).

`<Rm>` Contains the offset that is added to the value of `<Rn>` to form the address.

The pre-UAL syntax `STR<c>D` is equivalent to `STRD<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + R[m]) else (R[n] - R[m]);
    address = if index then offset_addr else R[n];
    if address == Align(address, 8) then
        bits(64) data;
        if BigEndian() then
            data<63:32> = R[t];
            data<31:0> = R[t2];
        else
            data<31:0> = R[t];
            data<63:32> = R[t2];
        MemA[address,8] = data;
    else
        MemA[address,4] = R[t];
        MemA[address+4,4] = R[t2];
    if wback then R[n] = offset_addr;
```

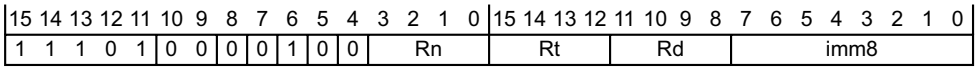
F7.1.225 STREX

Store Register Exclusive calculates an address from a base register value and an immediate offset, and stores a word from a register to memory if the executing PE has exclusive access to the memory addressed.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

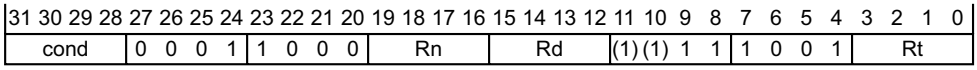
```
STREX<c> <Rd>, <Rt>, [<Rn>{, #<imm>}]
```



```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if d == n || d == t then UNPREDICTABLE;
```

Encoding A1

```
STREX <Rd>, <Rt>, [<Rn>]
```



```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);  imm32 = Zeros(32); // Zero offset
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STREX* on page AppxA-4831.

Assembler syntax

```
STREX{<c>}{<q>}  <Rd>, <Rt>, [<Rn> {, #<imm>}]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register for the returned status value. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

`<imm>` The immediate offset added to the value of `<Rn>` to form the address. Values are multiples of 4 in the range 0-1020 for encoding T1, and 0 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + imm32;
    if AArch32.ExclusiveMonitorsPass(address,4) then
        MemA[address,4] = R[t];
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Rd>` is not updated.

If SCTLR.A and SCTLR.U are both 0, a non word-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

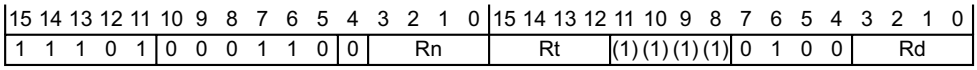
F7.1.226 STREXB

Store Register Exclusive Byte derives an address from a base register value, and stores a byte from a register to memory if the executing PE has exclusive access to the memory addressed.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

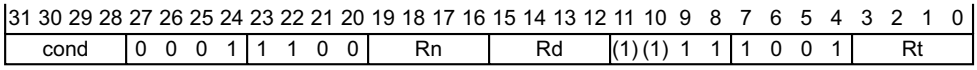
```
STREXB<c> <Rd>, <Rt>, [<Rn>]
```



```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if d == n || d == t then UNPREDICTABLE;
```

Encoding A1

```
STREXB <Rd>, <Rt>, [<Rn>]
```



```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STREXB* on page AppxA-4832.

Assembler syntax

```
STREXB{<c>}{<q>}  <Rd>, <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register for the returned status value. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,1) then
        MemA[address,1] = R[t]<7:0>;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Rd>` is not updated.

If `ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

F7.1.227 STREXD

Store Register Exclusive Doubleword derives an address from a base register value, and stores a 64-bit doubleword from two registers to memory if the executing PE has exclusive access to the memory addressed.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

```
STREXD<c> <Rd>, <Rt>, <Rt2>, [<Rn>]
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	0	1	1	0	0	Rn				Rt				Rt2				0	1	1	1	Rd			

```
d = UInt(Rd);  t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);
if d == 15 || t == 15 || t2 == 15 || n == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if d == n || d == t || d == t2 then UNPREDICTABLE;
```

Encoding A1

```
STREXD <Rd>, <Rt>, <Rt2>, [<Rn>]
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	1	0	1	0	Rn				Rd				(1)	(1)	1	1	1	0	0	1	Rt			

```
d = UInt(Rd);  t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);
if d == 15 || Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t || d == t2 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STREXD* on page AppxA-4832.

Assembler syntax

```
STREXD{<c>}{<q>}  <Rd>, <Rt>, <Rt2>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register for the returned status value. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Rd>` must not be the same as `<Rn>`, `<Rt>`, or `<Rt2>`.

`<Rt>` The first source register. For an A32 instruction, `<Rt>` must be even-numbered and not R14.

`<Rt2>` The second source register. For an A32 instruction, `<Rt2>` must be `<R(t+1)>`.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    value = if BigEndian() then R[t]:R[t2] else R[t2]:R[t];
    if AArch32.ExclusiveMonitorsPass(address,8) then
        MemA[address,8] = value;  R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Rd>` is not updated.

If SCTLR.A and SCTLR.U are both 0, a non doubleword-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non doubleword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

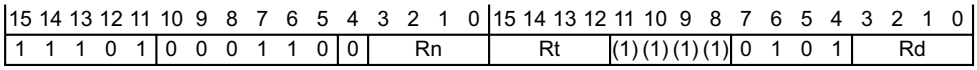
F7.1.228 STREXH

Store Register Exclusive Halfword derives an address from a base register value, and stores a halfword from a register to memory if the executing PE has exclusive access to the memory addressed.

For more information about support for shared memory see *Synchronization and semaphores* on page E2-2284. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

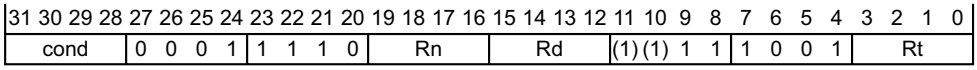
```
STREXH<c> <Rd>, <Rt>, [<Rn>]
```



```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if d == n || d == t then UNPREDICTABLE;
```

Encoding A1

```
STREXH <Rd>, <Rt>, [<Rn>]
```



```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STREXH* on page AppxA-4833.

Assembler syntax

```
STREXH{<c>}{<q>}  <Rd>, <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register for the returned status value. The value returned is:

- `0` If the operation updates memory.
- `1` If the operation fails to update memory.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,2) then
        MemA[address,2] = R[t]<15:0>;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- `<Rd>` is not updated.

If SCTLR.A and SCTLR.U are both 0, a non halfword-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

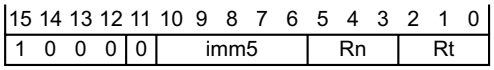
If `ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

F7.1.229 STRH (immediate), T32

Store Register Halfword (immediate) calculates an address from a base register value and an immediate offset, and stores a halfword from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

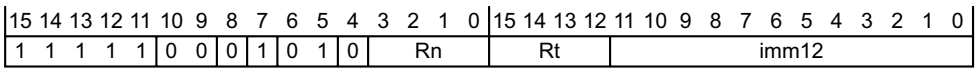
```
STRH<c> <Rt>, [<Rn>{, #<imm>}]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5:'0', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T2

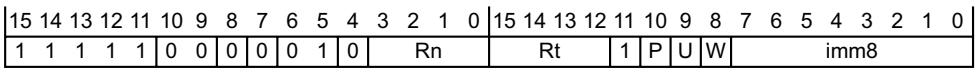
```
STRH<c>.W <Rt>, [<Rn>{, #<imm12>}]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding T3

```
STRH<c> <Rt>, [<Rn>, #-<imm8>]
STRH<c> <Rt>, [<Rn>], #+/-<imm8>
STRH<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if P == '1' && U == '1' && W == '0' then SEE STRHT;
if Rn == '1111' || (P == '0' && W == '0') then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRH (immediate, T32)* on page AppxA-4826.

Assembler syntax

`STRH{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE`, `wback==FALSE`
`STRH{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`STRH{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Values are:

Encoding T1 Multiples of 2 in the range 0-62.

Encoding T2 Any value in the range 0-4095.

Encoding T3 Any value in the range 0-255.

For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0.

The pre-UAL syntax `STR<c>H` is equivalent to `STRH<c>`.

Operation

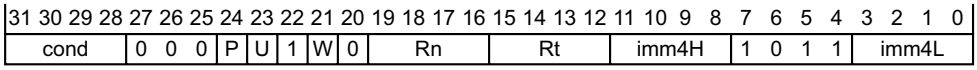
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,2] = R[t]<15:0>;
    if wback then R[n] = offset_addr;
```

F7.1.230 STRH (immediate), A32

Store Register Halfword (immediate) calculates an address from a base register value and an immediate offset, and stores a halfword from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding A1

```
STRH<c> <Rt>, [<Rn>{, #+/-<imm8>}]
STRH<c> <Rt>, [<Rn>], #+/-<imm8>
STRH<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if P == '0' && W == '1' then SEE STRHT;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRH (immediate, A32)* on page AppxA-4826.

Assembler syntax

`STRH{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`STRH{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`STRH{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used. For offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Values are 0-255. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0.

The pre-UAL syntax `STR<c>H` is equivalent to `STRH<c>`.

Operation

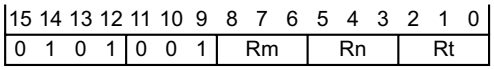
```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,2] = R[t]<15:0>;
    if wback then R[n] = offset_addr;
```

F7.1.231 STRH (register)

Store Register Halfword (register) calculates an address from a base register value and an offset register value, and stores a halfword from a register to memory. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see *Memory accesses* on page F2-2337.

Encoding T1

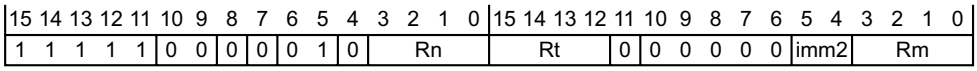
```
STRH<c> <Rt>, [<Rn>, <Rm>]
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

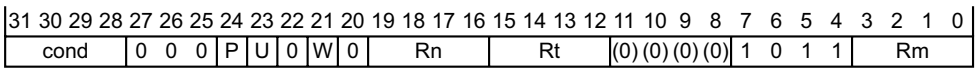
```
STRH<c>.W <Rt>, [<Rn>, <Rm>{, LSL #<imm2>}]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if t == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
STRH<c> <Rt>, [<Rn>,+/-<Rm>]{!}
STRH<c> <Rt>, [<Rn>],+/-<Rm>
```



```
if P == '0' && W == '1' then SEE STRHT;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRType_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRH (register)* on page AppxA-4827.

Assembler syntax

`STRH{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>{, LSL #<imm>}]`	Offset: `index==TRUE`, `wback==FALSE`
`STRH{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`STRH{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used. In the A32 instruction set, for offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`).

`<Rm>` Contains the offset that is optionally left shifted and added to the value of `<Rn>` to form the address.

`<imm>` If present, the size of the left shift to apply to the value from `<Rm>`, in the range 1-3. Only encoding T2 is permitted, and `<imm>` is encoded in imm2.

If absent, no shift is specified and all encodings are permitted. In encoding T2, imm2 is encoded as `0b00`.

The pre-UAL syntax `STR<c>H` is equivalent to `STRH<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    MemU[address,2] = R[t]<15:0>;
    if wback then R[n] = offset_addr;
```

F7.1.232 STRHT

Store Register Halfword Unprivileged stores a halfword from a register to memory. For information about memory accesses see *Memory accesses* on page F2-2337.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

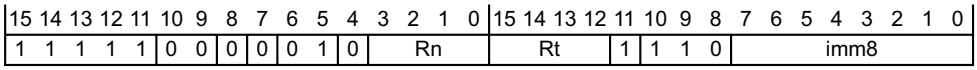
STRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

Encoding T1

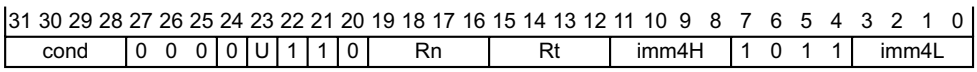
```
STRHT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

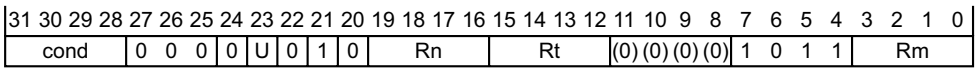
```
STRHT<c> <Rt>, [<Rn>] {, #+/-<imm8>}
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2

```
STRHT<c> <Rt>, [<Rn>], +/-<Rm>
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRHT* on page AppxA-4828.

Assembler syntax

`STRHT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: T32 only
`STRHT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: A32 only
`STRHT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: A32 only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`).

`<imm>` The immediate offset applied to the value of `<Rn>`. Any value in the range 0-255 is permitted. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is applied to the value of `<Rn>` to form the address.

Operation

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    MemU_unpriv[address,2] = R[t]<15:0>;
    if postindex then R[n] = offset_addr;
```

F7.1.233 STRT

Store Register Unprivileged stores a word from a register to memory. For information about memory accesses see *Memory accesses* on page F2-2337.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

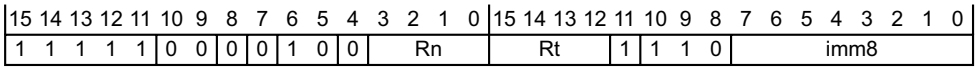
STRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

Encoding T1

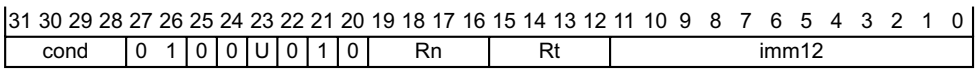
```
STRT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

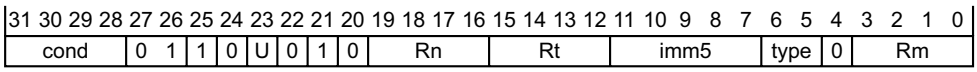
```
STRT<c> <Rt>, [<Rn>] {, +/-<imm12>}
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2

```
STRT<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;  (shift_t, shift_n) = DecodeImmShift(type, imm5);
if n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRT* on page AppxA-4829.

Assembler syntax

`STRT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: T32 only
`STRT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: A32 only
`STRT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm> {, <shift>}`	Post-indexed: A32 only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The source register. In the A32 instruction set, the PC can be used. However, ARM deprecates use of the PC.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in A32 instructions only, `add == FALSE`).

`<imm>` The immediate offset applied to the value of `<Rn>`. Values are 0-255 for encoding T1, and 0-4095 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is optionally shifted and added to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

The pre-UAL syntax `STR<c>T` is equivalent to `STRT<c>`.

Operation

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    if t == 15 then  // Only possible for encodings A1 and A2
        data = PCStoreValue();
    else
        data = R[t];
    MemU_unpriv[address,4] = data;
    if postindex then R[n] = offset_addr;
```

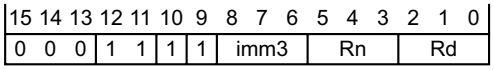
F7.1.234 SUB (immediate), T32

This instruction subtracts an immediate value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

`SUBS <Rd>, <Rn>, #<imm3>` Outside IT block.

`SUB<c> <Rd>, <Rn>, #<imm3>` Inside IT block.

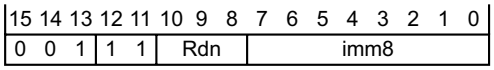


```
d = UInt(Rd);  n = UInt(Rn);  setflags = !InITBlock();  imm32 = ZeroExtend(imm3, 32);
```

Encoding T2

`SUBS <Rdn>, #<imm8>` Outside IT block.

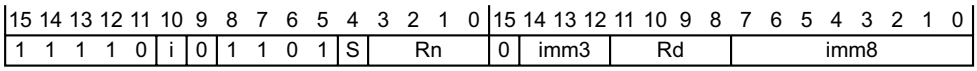
`SUB<c> <Rdn>, #<imm8>` Inside IT block.



```
d = UInt(Rdn);  n = UInt(Rdn);  setflags = !InITBlock();  imm32 = ZeroExtend(imm8, 32);
```

Encoding T3

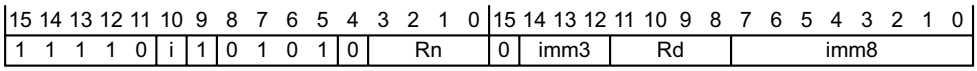
`SUB{S}<c>.W <Rd>, <Rn>, #<const>`



```
if Rd == '1111' && S == '1' then SEE CMP (immediate);
if Rn == '1101' then SEE SUB (SP minus immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = T32ExpandImm(i:imm3:imm8);
if (d == 15 && S == '0') || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding T4

`SUBW<c> <Rd>, <Rn>, #<imm12>`



```
if Rn == '1111' then SEE ADR;
if Rn == '1101' then SEE SUB (SP minus immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = FALSE;  imm32 = ZeroExtend(i:imm3:imm8, 32);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`SUB{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>`	All encodings permitted
`SUBW{<c>}{<q>}  {<Rd>,} <Rn>, #<const>`	Only encoding T4 permitted

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032.

`<Rn>` The first operand register. If the SP is specified for `<Rn>`, see *SUB (SP minus immediate)* on page F7-2887. If the PC is specified for `<Rn>`, see *ADR* on page F7-2472.

`<const>` The immediate value to be subtracted from the value obtained from `<Rn>`. The range of values is 0-7 for encoding T1, 0-255 for encoding T2 and 0-4095 for encoding T4. See *Modified immediate constants in T32 instructions* on page F3-2358 for the range of values for encoding T3.

When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4. If encoding T4 is required, use the `SUBW` syntax. Encoding T1 is preferred to encoding T2 if `<Rd>` is specified and encoding T2 is preferred to encoding T1 if `<Rd>` is omitted.

The pre-UAL syntax `SUB<c>S` is equivalent to `SUBS<c>`.

Operation

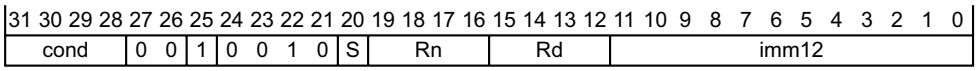
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], NOT(imm32), '1');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.235 SUB (immediate), A32

This instruction subtracts an immediate value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1

```
SUB{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rn == '1111' && S == '0' then SEE ADR;
if Rn == '1101' then SEE SUB (SP minus immediate);
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = A32ExpandImm(imm12);
```

Assembler syntax

```
SUB{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. If `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.
`<Rn>`	The first operand register. If the SP is specified for `<Rn>`, see *SUB (SP minus immediate)* on page F7-2887. If the PC is specified for `<Rn>`, see *ADR* on page F7-2472.
`<const>`	The immediate value to be subtracted from the value obtained from `<Rn>`. See *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

The pre-UAL syntax `SUB<c>S` is equivalent to `SUBS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], NOT(imm32), '1');
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

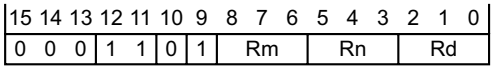
F7.1.236 SUB (register)

This instruction subtracts an optionally-shifted register value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1

`SUBS <Rd>, <Rn>, <Rm>` Outside IT block.

`SUB<c> <Rd>, <Rn>, <Rm>` Inside IT block.

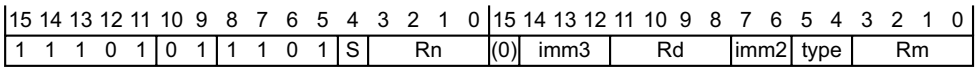


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	1	0	1	Rm			Rn			Rd		

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

`SUB{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}`



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
if Rn == '1101' then SEE SUB (SP minus register);
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SUB{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032.

In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<Rn>` The first operand register. The PC can be used in A32 instructions. If the SP is specified for `<Rn>`, see *SUB (SP minus register)* on page F7-2889.

`<Rm>` The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

The pre-UAL syntax `SUB<c>S` is equivalent to `SUBS<c>`.

Operation

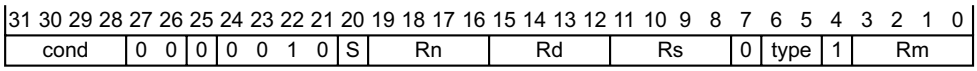
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.237 SUB (register-shifted register)

This instruction subtracts a register-shifted register value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1

```
SUB{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SUB{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax `SUB<c>S` is equivalent to `SUBS<c>`.

Operation

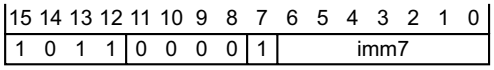
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.238 SUB (SP minus immediate)

This instruction subtracts an immediate value from the SP value, and writes the result to the destination register.

Encoding T1

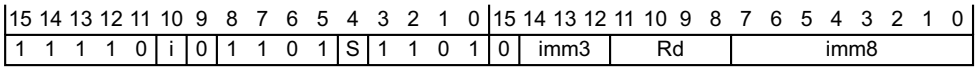
SUB<c> SP, SP, #<imm>



```
d = 13;  setflags = FALSE;  imm32 = ZeroExtend(imm7:'00', 32);
```

Encoding T2

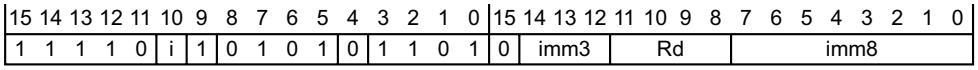
SUB{S}<c>.W <Rd>, SP, #<const>



```
if Rd == '1111' && S == '1' then SEE CMP (immediate);
d = UInt(Rd);  setflags = (S == '1');  imm32 = T32ExpandImm(i:imm3:imm8);
if d == 15 && S == '0' then UNPREDICTABLE;
```

Encoding T3

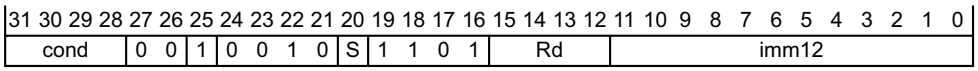
SUBW<c> <Rd>, SP, #<imm12>



```
d = UInt(Rd);  setflags = FALSE;  imm32 = ZeroExtend(i:imm3:imm8, 32);
if d == 15 then UNPREDICTABLE;
```

Encoding A1

SUB{S}<c> <Rd>, SP, #<const>



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  setflags = (S == '1');  imm32 = A32ExpandImm(imm12);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`SUB{S}{<c>}{<q>}  {<Rd>,} SP, #<const>`	All encodings permitted
`SUBW{<c>}{<q>}  {<Rd>,} SP, #<const>`	Only encoding T3 permitted

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. If omitted, `<Rd>` is SP.

In A32 instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

`<const>` The immediate value to be subtracted from the value obtained from SP. Values are multiples of 4 in the range 0-508 for encoding T1 and any value in the range 0-4095 for encoding T3. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values for encodings T2 and A1.

When both 32-bit encodings are available for an instruction, encoding T2 is preferred to encoding T3 (if encoding T3 is required, use the `SUBW` syntax).

The pre-UAL syntax `SUB<c>S` is equivalent to `SUBS<c>`.

Operation

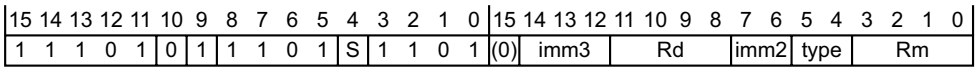
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(SP, NOT(imm32), '1');
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.239 SUB (SP minus register)

This instruction subtracts an optionally-shifted register value from the SP value, and writes the result to the destination register.

Encoding T1

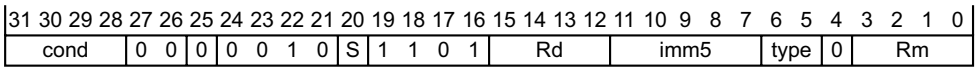
```
SUB{S}<c> <Rd>, SP, <Rm>{, <shift>}
```



```
if Rd == '1111' && S == '1' then SEE CMP (register);
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if (d == 15 && S == '0') || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SUB{S}<c> <Rd>, SP, <Rm>{, <shift>}
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SUB{S}{<c>}{<q>}  {<Rd>,} SP, <Rm> {, <shift>}
```

where:

S
: If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c><q>
: See *Standard assembler syntax fields* on page F2-2330.

<Rd>
: The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions, T32* on page F7-3030 or *SUBS PC, LR and related instructions, A32* on page F7-3032. If omitted, <Rd> is SP.

  In A32 instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on the AArch32 general-purpose registers and the PC* on page E1-2210.

<Rm>
: The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.

<shift>
: The shift to apply to the value read from <Rm>. If omitted, no shift is applied. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

  In the T32 instruction set, if <Rd> is SP or omitted, <shift> is only permitted to be omitted, LSL #1, LSL #2, or LSL #3.

The pre-UAL syntax SUB<c>S is equivalent to SUBS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(SP, NOT(shifted), '1');
    if d == 15 then          // Can only occur for A32 encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

F7.1.240 SUBS PC, LR and related instructions

These instructions are for system level use only. See *SUBS PC, LR and related instructions, T32* on page F7-3030 and *SUBS PC, LR and related instructions, A32* on page F7-3032.

F7.1.241 SVC

Supervisor Call causes a Supervisor Call exception. For more information, see *Supervisor Call (SVC) exception* on page G1-3433.

Note

SVC was previously called SWI, Software Interrupt, and this name is still found in some documentation.

Software can use this instruction as a call to an operating system to provide a service.

In the following cases, the Supervisor Call exception generated by the SVC instruction is taken to Hyp mode:

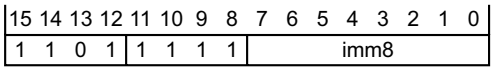
- If the SVC is executed in Hyp mode.
- If HCR.TGE is set to 1, and the SVC is executed in Non-secure User mode. For more information, see *Supervisor Call exception, when HCR.TGE is set to 1* on page G1-3410

In these cases, the HSR identifies that the exception entry was caused by a Supervisor Call exception, EC value 0x11, see *Use of the HSR* on page G4-3728. The immediate field in the HSR:

- If the SVC is unconditional:
  - For the T32 instruction, is the zero-extended value of the imm8 field.
  - For the A32 instruction, is the least-significant 16 bits the imm24 field.
- If the SVC is conditional, is UNKNOWN.

Encoding T1

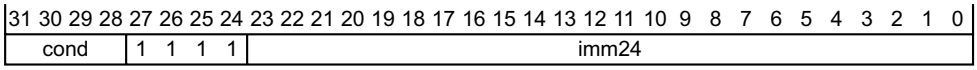
SVC<c> #<imm8>



```
imm32 = ZeroExtend(imm8, 32);
// imm32 is for assembly/disassembly. SVC handlers in some
// systems interpret imm8 in software, for example to determine the required service.
```

Encoding A1

SVC<c> #<imm24>



```
imm32 = ZeroExtend(imm24, 32);
// imm32 is for assembly/disassembly. SVC handlers in some
// systems interpret imm24 in software, for example to determine the required service.
```

Assembler syntax

```
SVC{<c>}{<q>}  {#}<imm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<imm>` Specifies an immediate constant, 8-bit in T32 instructions, or 24-bit in A32 instructions.

The pre-UAL syntax `SWI<c>` is equivalent to `SVC<c>`.

Operation

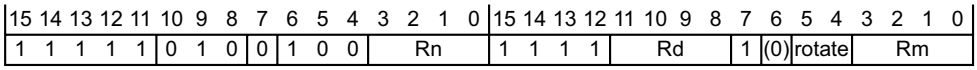
```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CallSupervisor(imm32<15:0>);
```

F7.1.242 SXTAB

Signed Extend and Add Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

Encoding T1

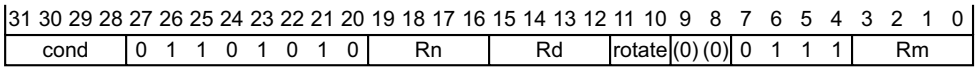
```
SXTAB<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE SXTB;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SXTAB<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE SXTB;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SXTAB{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

`<rotation>` This can be any one of:

omitted Encoded as rotate = `0b00`.

`ROR #8` Encoded as rotate = `0b01`.

`ROR #16` Encoded as rotate = `0b10`.

`ROR #24` Encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation

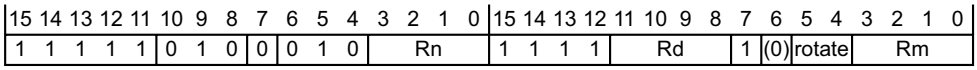
```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = R[n] + SignExtend(rotated<7:0>, 32);
```

F7.1.243 SXTAB16

Signed Extend and Add Byte 16 extracts two 8-bit values from a register, sign-extends them to 16 bits each, adds the results to two 16-bit values from another register, and writes the final results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

Encoding T1

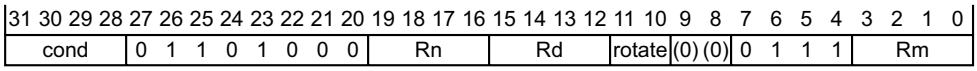
```
SXTAB16<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE SXTB16;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SXTAB16<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE SXTB16;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SXTAB16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

`<rotation>` This can be any one of:

omitted Encoded as rotate = `0b00`.

`ROR #8` Encoded as rotate = `0b01`.

`ROR #16` Encoded as rotate = `0b10`.

`ROR #24` Encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation

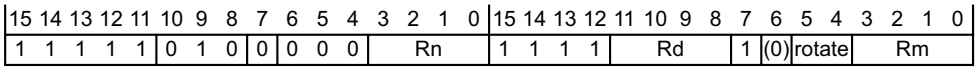
```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d]<15:0>  = R[n]<15:0> + SignExtend(rotated<7:0>, 16);
    R[d]<31:16> = R[n]<31:16> + SignExtend(rotated<23:16>, 16);
```

F7.1.244 SXTAH

Signed Extend and Add Halfword extracts a 16-bit value from a register, sign-extends it to 32 bits, adds the result to a value from another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

Encoding T1

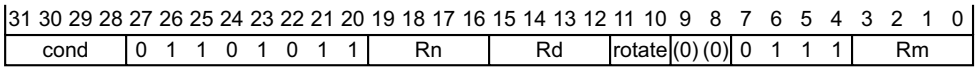
```
SXTAH<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE SXTH;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SXTAH<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE SXTH;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SXTAH{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

`<rotation>` This can be any one of:

omitted Encoded as rotate = `0b00`.

`ROR #8` Encoded as rotate = `0b01`.

`ROR #16` Encoded as rotate = `0b10`.

`ROR #24` Encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation

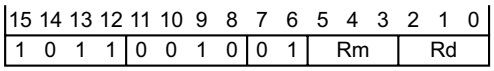
```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = R[n] + SignExtend(rotated<15:0>, 32);
```

F7.1.245 SXTB

Signed Extend Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

Encoding T1

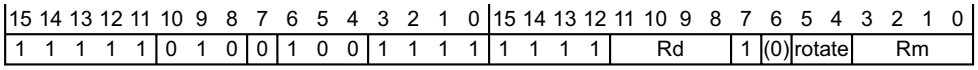
```
SXTB<c> <Rd>, <Rm>
```



```
d = UInt(Rd);  m = UInt(Rm);  rotation = 0;
```

Encoding T2

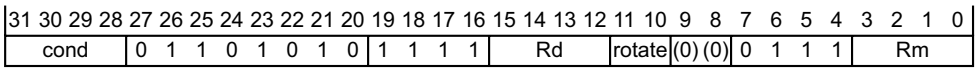
```
SXTB<c>.W <Rd>, <Rm>{, <rotation>}
```



```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SXTB<c> <Rd>, <Rm>{, <rotation>}
```



```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SXTB{<c>}{<q>}  {<Rd>,} <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rm>` The register that contains the operand.

`<rotation>` This can be any one of:

omitted Any encoding, encoded as rotate = `0b00` in encoding T2 or A1.

`ROR #8` Encoding T2 or A1, encoded as rotate = `0b01`.

`ROR #16` Encoding T2 or A1, encoded as rotate = `0b10`.

`ROR #24` Encoding T2 or A1, encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation

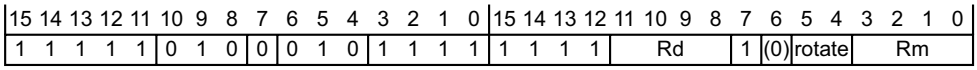
```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = SignExtend(rotated<7:0>, 32);
```

F7.1.246 SXTB16

Signed Extend Byte 16 extracts two 8-bit values from a register, sign-extends them to 16 bits each, and writes the results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

Encoding T1

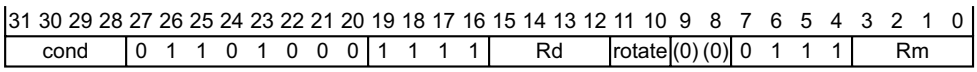
```
SXTB16<c> <Rd>, <Rm>{, <rotation>}
```



```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SXTB16<c> <Rd>, <Rm>{, <rotation>}
```



```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SXTB16{<c>}{<q>}  {<Rd>,} <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rm>` The register that contains the operand.

`<rotation>` This can be any one of:

omitted	Encoded as rotate = `0b00`.
`ROR #8`	Encoded as rotate = `0b01`.
`ROR #16`	Encoded as rotate = `0b10`.
`ROR #24`	Encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation

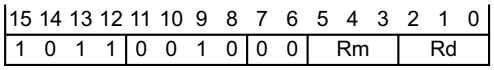
```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d]<15:0>  = SignExtend(rotated<7:0>, 16);
    R[d]<31:16> = SignExtend(rotated<23:16>, 16);
```

F7.1.247 SXTH

Signed Extend Halfword extracts a 16-bit value from a register, sign-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

Encoding T1

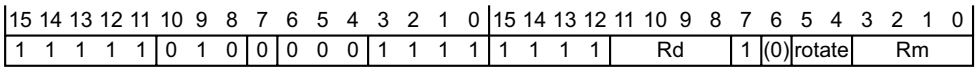
```
SXTH<c> <Rd>, <Rm>
```



```
d = UInt(Rd);  m = UInt(Rm);  rotation = 0;
```

Encoding T2

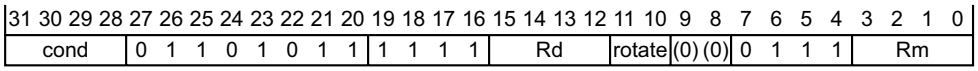
```
SXTH<c>.W <Rd>, <Rm>{, <rotation>}
```



```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
SXTH<c> <Rd>, <Rm>{, <rotation>}
```



```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SXTH{<c>}{<q>}  {<Rd>,} <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rm>` The register that contains the operand.

`<rotation>` This can be any one of:

omitted Any encoding, encoded as rotate = `0b00` in encoding T2 or A1.

`ROR #8` Encoding T2 or A1, encoded as rotate = `0b01`.

`ROR #16` Encoding T2 or A1, encoded as rotate = `0b10`.

`ROR #24` Encoding T2 or A1, encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = SignExtend(rotated<15:0>, 32);
```

F7.1.248 TBB, TBH

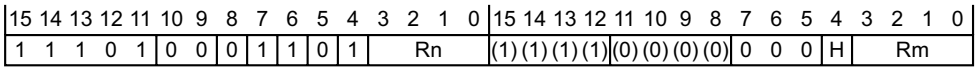
Table Branch Byte causes a PC-relative forward branch using a table of single byte offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value of the byte returned from the table.

Table Branch Halfword causes a PC-relative forward branch using a table of single halfword offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value of the halfword returned from the table.

Encoding T1

`TBB<c> [<Rn>, <Rm>]` Outside or last in IT block

`TBH<c> [<Rn>, <Rm>, LSL #1]` Outside or last in IT block



```
n = UInt(Rn);  m = UInt(Rm);  is_tbh = (H == '1');
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
TBB{<c>}{<q>}  [<Rn>, <Rm>]
TBH{<c>}{<q>}  [<Rn>, <Rm>, LSL #1]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The base register. This contains the address of the table of branch lengths. The PC can be used. If it is, the table immediately follows this instruction.

`<Rm>` The index register.

For `TBB`, this contains an integer pointing to a single byte in the table. The offset in the table is the value of the index.

For `TBH`, this contains an integer pointing to a halfword in the table. The offset in the table is twice the value of the index.

Operation

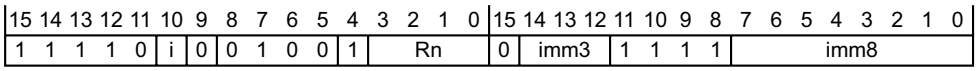
```
if ConditionPassed() then
    EncodingSpecificOperations();
    if is_tbh then
        halfwords = UInt(MemU[R[n]+LSL(R[m],1), 2]);
    else
        halfwords = UInt(MemU[R[n]+R[m], 1]);
    BranchWritePC(PC + 2*halfwords);
```

F7.1.249 TEQ (immediate)

Test Equivalence (immediate) performs a bitwise exclusive OR operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

Encoding T1

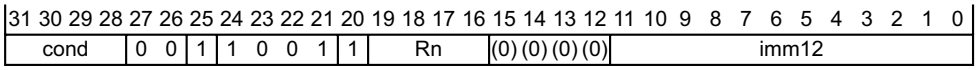
```
TEQ<c> <Rn>, #<const>
```



```
n = UInt(Rn);
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
TEQ<c> <Rn>, #<const>
```



```
n = UInt(Rn);
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
TEQ{<c>}{<q>}  <Rn>, #<const>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The operand register. The PC can be used in A32 instructions.

`<const>` The immediate value to be tested against the value obtained from `<Rn>`. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

Operation

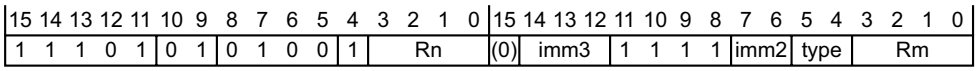
```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] EOR imm32;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

F7.1.250 TEQ (register)

Test Equivalence (register) performs a bitwise exclusive OR operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

Encoding T1

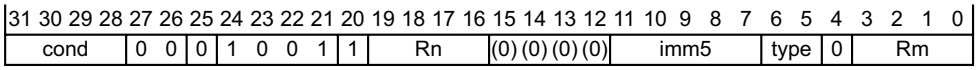
```
TEQ<c> <Rn>, <Rm>{, <shift>}
```



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
TEQ<c> <Rn>, <Rm>{, <shift>}
```



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
TEQ{<c>}{<q>}  <Rn>, <Rm> {, <shift>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The first operand register. The PC can be used in A32 instructions.

`<Rm>` The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.

`<shift>` The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

Operation

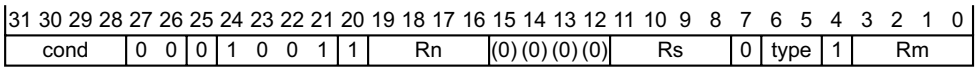
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

F7.1.251 TEQ (register-shifted register)

Test Equivalence (register-shifted register) performs a bitwise exclusive OR operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

Encoding A1

```
TEQ<c> <Rn>, <Rm>, <type> <Rs>
```



```
n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
TEQ{<c>}{<q>}  <Rn>, <Rm>, <type>  <Rs>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

Operation

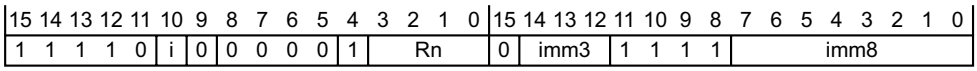
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

F7.1.252 TST (immediate)

Test (immediate) performs a bitwise AND operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

Encoding T1

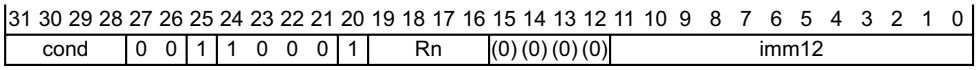
```
TST<c> <Rn>, #<const>
```



```
n = UInt(Rn);
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
TST<c> <Rn>, #<const>
```



```
n = UInt(Rn);
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
TST{<c>}{<q>}  <Rn>, #<const>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The operand register. The PC can be used in A32 instructions.

`<const>` The immediate value to be tested against the value obtained from `<Rn>`. See *Modified immediate constants in T32 instructions* on page F3-2358 or *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

Operation

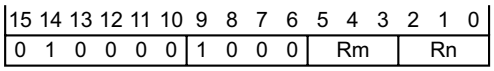
```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND imm32;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

F7.1.253 TST (register)

Test (register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

Encoding T1

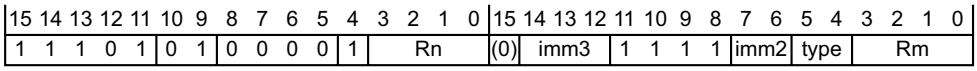
```
TST<c> <Rn>, <Rm>
```



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2

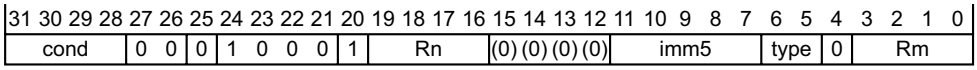
```
TST<c>.W  <Rn>, <Rm>{, <shift>}
```



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
TST<c> <Rn>, <Rm>{, <shift>}
```



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
TST{<c>}{<q>}  <Rn>, <Rm> {, <shift>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The first operand register. The PC can be used in A32 instructions.

`<Rm>` The register that is optionally shifted and used as the second operand. The PC can be used in A32 instructions.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page F2-2334 describes the shifts and how they are encoded.

Operation

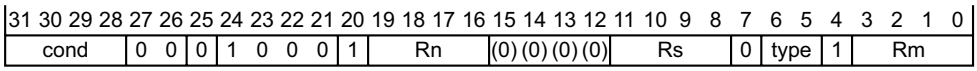
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

F7.1.254 TST (register-shifted register)

Test (register-shifted register) performs a bitwise AND operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

Encoding A1

```
TST<c> <Rn>, <Rm>, <type> <Rs>
```



```
n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
TST{<c>}{<q>}  <Rn>, <Rm>, <type>  <Rs>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

Operation

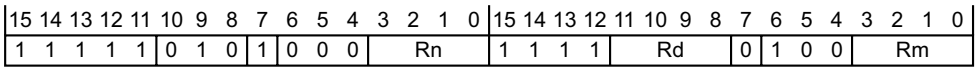
```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

F7.1.255 UADD8

Unsigned Add 8 performs four unsigned 8-bit integer additions, and writes the results to the destination register. It sets the APSR.GE bits according to the results of the additions.

Encoding T1

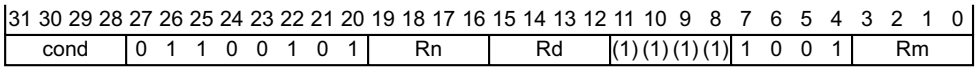
```
UADD8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m  == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UADD8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UADD8{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

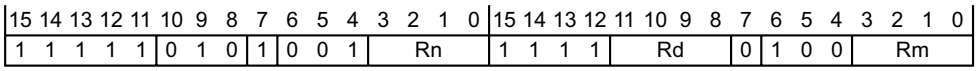
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = UInt(R[n]<7:0>) + UInt(R[m]<7:0>);
    sum2 = UInt(R[n]<15:8>) + UInt(R[m]<15:8>);
    sum3 = UInt(R[n]<23:16>) + UInt(R[m]<23:16>);
    sum4 = UInt(R[n]<31:24>) + UInt(R[m]<31:24>);
    R[d]<7:0>   = sum1<7:0>;
    R[d]<15:8>  = sum2<7:0>;
    R[d]<23:16> = sum3<7:0>;
    R[d]<31:24> = sum4<7:0>;
    PSTATE.GE<0>  = if sum1 >= 0x100 then '1' else '0';
    PSTATE.GE<1>  = if sum2 >= 0x100 then '1' else '0';
    PSTATE.GE<2>  = if sum3 >= 0x100 then '1' else '0';
    PSTATE.GE<3>  = if sum4 >= 0x100 then '1' else '0';
```

F7.1.256 UADD16

Unsigned Add 16 performs two 16-bit unsigned integer additions, and writes the results to the destination register. It sets the APSR.GE bits according to the results of the additions.

Encoding T1

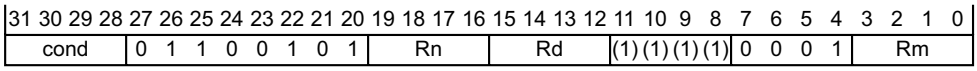
```
UADD16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UADD16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UADD16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

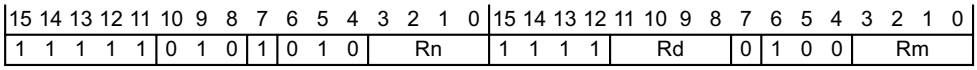
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = UInt(R[n]<15:0>) + UInt(R[m]<15:0>);
    sum2 = UInt(R[n]<31:16>) + UInt(R[m]<31:16>);
    R[d]<15:0>  = sum1<15:0>;
    R[d]<31:16> = sum2<15:0>;
    PSTATE.GE<1:0> = if sum1 >= 0x10000 then '11' else '00';
    PSTATE.GE<3:2> = if sum2 >= 0x10000 then '11' else '00';
```

F7.1.257 UASX

Unsigned Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer addition and one unsigned 16-bit subtraction, and writes the results to the destination register. It sets the APSR.GE bits according to the results.

Encoding T1

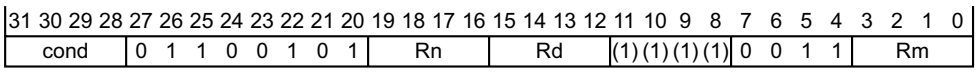
```
UASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UASX{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

The pre-UAL syntax `UADDSUBX<c>` is equivalent to `UASX<c>`.

Operation

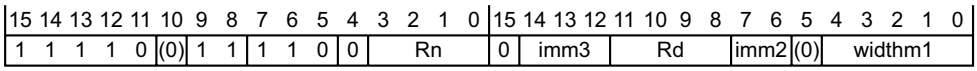
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff = UInt(R[n]<15:0>) - UInt(R[m]<31:16>);
    sum  = UInt(R[n]<31:16>) + UInt(R[m]<15:0>);
    R[d]<15:0>  = diff<15:0>;
    R[d]<31:16> = sum<15:0>;
    PSTATE.GE<1:0> = if diff >= 0 then '11' else '00';
    PSTATE.GE<3:2> = if sum  >= 0x10000 then '11' else '00';
```

F7.1.258 UBFX

Unsigned Bit Field Extract extracts any number of adjacent bits at any position from a register, zero-extends them to 32 bits, and writes the result to the destination register.

Encoding T1

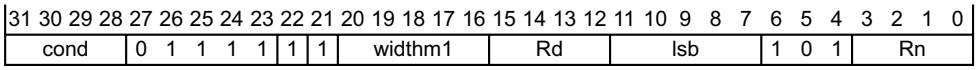
```
UBFX<c> <Rd>, <Rn>, #<lsb>, #<width>
```



```
d = UInt(Rd);  n = UInt(Rn);
lsbit = UInt(imm3:imm2);  widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UBFX<c> <Rd>, <Rn>, #<lsb>, #<width>
```



```
d = UInt(Rd);  n = UInt(Rn);
lsbit = UInt(lsb);  widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *UBFX* on page AppxA-4814.

Assembler syntax

```
UBFX{<c>}{<q>}  <Rd>, <Rn>, #<lsb>, #<width>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<lsb>`	Is the bit number of the least significant bit in the field, in the range 0-31. This determines the required value of `lsbit`.
`<width>`	Is the width of the field, in the range 1 to 32-`<lsb>`. The required value of `widthminus1` is `<width>`-1.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsbit + widthminus1;
    if msbit <= 31 then
        R[d] = ZeroExtend(R[n]<msbit:lsbit>, 32);
    else
        UNPREDICTABLE;
```

F7.1.259 UDF

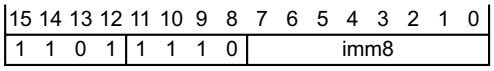
Permanently Undefined generates an Undefined Instruction exception.

The encodings for UDF used in this section are defined as permanently UNDEFINED in the ARMv8-A architecture. However:

- With the T32 instruction set, ARM deprecates using the UDF instruction in an IT block.
- In the A32 instruction set, UDF is not conditional.

Encoding T1

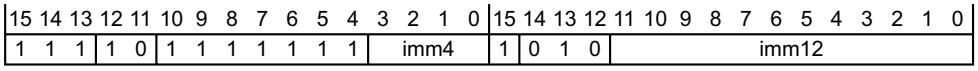
```
UDF<c> #<imm8>
```



```
imm32 = ZeroExtend(imm8, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

Encoding T2

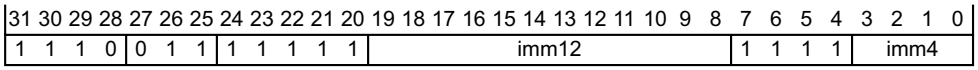
```
UDF<c>.W #<imm16>
```



```
imm32 = ZeroExtend(imm4:imm12, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

Encoding A1

```
UDF<c> #<imm16>
```



```
imm32 = ZeroExtend(imm12:imm4, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

Assembler syntax

```
UDF{<c>}{<q>} {#}<imm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

In the A32 instruction set, `<c>` must be `AL` or omitted.

In the T32 instruction set, ARM deprecates using any `<c>` value other than `AL`.

`<imm>` Specifies an immediate constant, that is 8-bit in encoding T1, and 16-bit in encodings T2 and A1. The PE ignores the value of this constant.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    UNDEFINED;
```

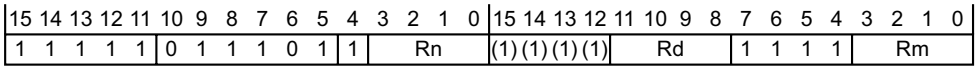
F7.1.260 UDIV

Unsigned Divide divides a 32-bit unsigned integer register value by a 32-bit unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

See *Divide instructions* on page F1-2307 for more information about this instruction.

Encoding T1

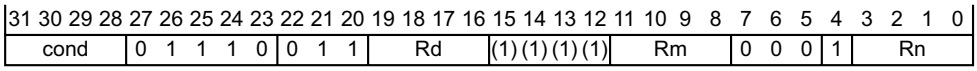
```
UDIV<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UDIV<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *UDIV* on page AppxA-4815.

Assembler syntax

```
UDIV{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The register that contains the dividend.

`<Rm>` The register that contains the divisor.

Operation

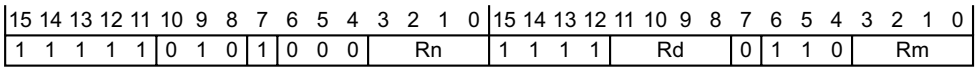
```
if ConditionPassed() then
    EncodingSpecificOperations();
    if UInt(R[m]) == 0 then
        if IntegerZeroDivideTrappingEnabled() then
            GenerateIntegerZeroDivide();
        else
            result = 0;
    else
        result = RoundTowardsZero(UInt(R[n]) / UInt(R[m]));
    R[d] = result<31:0>;
```

F7.1.261 UHADD8

Unsigned Halving Add 8 performs four unsigned 8-bit integer additions, halves the results, and writes the results to the destination register.

Encoding T1

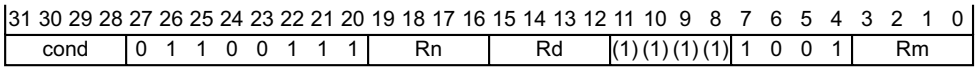
```
UHADD8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UHADD8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UHADD8{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

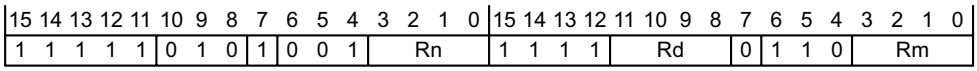
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = UInt(R[n]<7:0>) + UInt(R[m]<7:0>);
    sum2 = UInt(R[n]<15:8>) + UInt(R[m]<15:8>);
    sum3 = UInt(R[n]<23:16>) + UInt(R[m]<23:16>);
    sum4 = UInt(R[n]<31:24>) + UInt(R[m]<31:24>);
    R[d]<7:0>   = sum1<8:1>;
    R[d]<15:8>  = sum2<8:1>;
    R[d]<23:16> = sum3<8:1>;
    R[d]<31:24> = sum4<8:1>;
```

F7.1.262 UHADD16

Unsigned Halving Add 16 performs two unsigned 16-bit integer additions, halves the results, and writes the results to the destination register.

Encoding T1

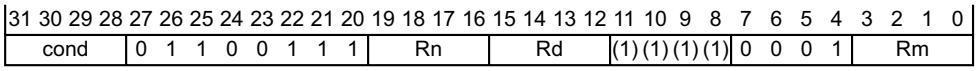
```
UHADD16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UHADD16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UHADD16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

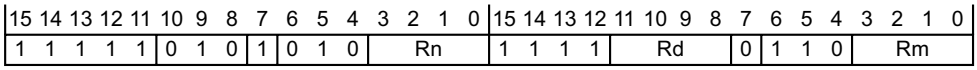
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = UInt(R[n]<15:0>) + UInt(R[m]<15:0>);
    sum2 = UInt(R[n]<31:16>) + UInt(R[m]<31:16>);
    R[d]<15:0>  = sum1<16:1>;
    R[d]<31:16> = sum2<16:1>;
```

F7.1.263 UHASX

Unsigned Halving Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer addition and one unsigned 16-bit subtraction, halves the results, and writes the results to the destination register.

Encoding T1

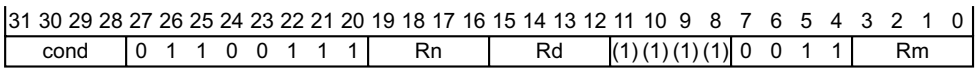
```
UHASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UHASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UHASX{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

The pre-UAL syntax `UHADDSUBX<c>` is equivalent to `UHASX<c>`.

Operation

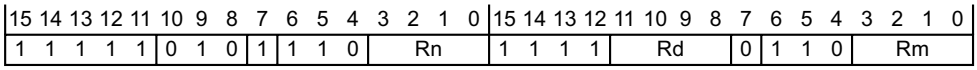
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff = UInt(R[n]<15:0>) - UInt(R[m]<31:16>);
    sum  = UInt(R[n]<31:16>) + UInt(R[m]<15:0>);
    R[d]<15:0>  = diff<16:1>;
    R[d]<31:16> = sum<16:1>;
```

F7.1.264 UHSAX

Unsigned Halving Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer subtraction and one unsigned 16-bit addition, halves the results, and writes the results to the destination register.

Encoding T1

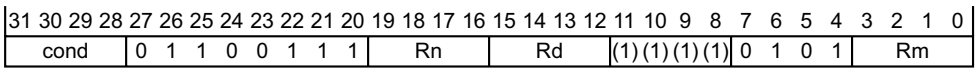
```
UHSAX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UHSAX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UHSAX{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

The pre-UAL syntax `UHSUBADDX<c>` is equivalent to `UHSAX<c>`.

Operation

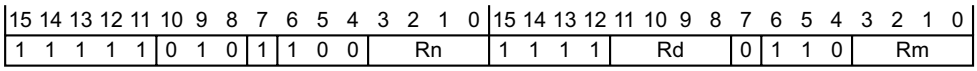
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum  = UInt(R[n]<15:0>) + UInt(R[m]<31:16>);
    diff = UInt(R[n]<31:16>) - UInt(R[m]<15:0>);
    R[d]<15:0>  = sum<16:1>;
    R[d]<31:16> = diff<16:1>;
```

F7.1.265 UHSUB8

Unsigned Halving Subtract 8 performs four unsigned 8-bit integer subtractions, halves the results, and writes the results to the destination register.

Encoding T1

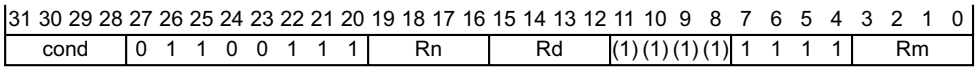
```
UHSUB8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UHSUB8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UHSUB8{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

Operation

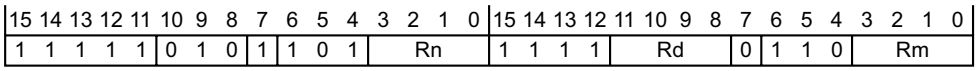
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = UInt(R[n]<7:0>) - UInt(R[m]<7:0>);
    diff2 = UInt(R[n]<15:8>) - UInt(R[m]<15:8>);
    diff3 = UInt(R[n]<23:16>) - UInt(R[m]<23:16>);
    diff4 = UInt(R[n]<31:24>) - UInt(R[m]<31:24>);
    R[d]<7:0>   = diff1<8:1>;
    R[d]<15:8>  = diff2<8:1>;
    R[d]<23:16> = diff3<8:1>;
    R[d]<31:24> = diff4<8:1>;
```

F7.1.266 UHSUB16

Unsigned Halving Subtract 16 performs two unsigned 16-bit integer subtractions, halves the results, and writes the results to the destination register.

Encoding T1

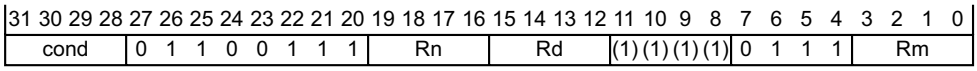
```
UHSUB16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UHSUB16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UHSUB16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

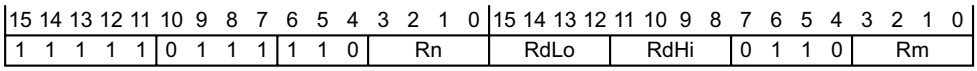
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = UInt(R[n]<15:0>) - UInt(R[m]<15:0>);
    diff2 = UInt(R[n]<31:16>) - UInt(R[m]<31:16>);
    R[d]<15:0>  = diff1<16:1>;
    R[d]<31:16> = diff2<16:1>;
```

F7.1.267 UMAAL

Unsigned Multiply Accumulate Accumulate Long multiplies two unsigned 32-bit values to produce a 64-bit value, adds two unsigned 32-bit values, and writes the 64-bit result to two registers.

Encoding T1

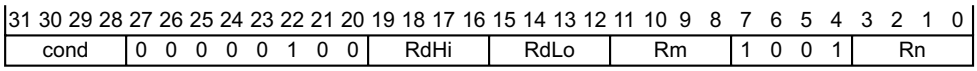
```
UMAAL<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

Encoding A1

```
UMAAL<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *UMAAL* on page AppxA-4817.

Assembler syntax

```
UMAAL{<c>}{<q>}  <RdLo>, <RdHi>, <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<RdLo>` Supplies one of the 32-bit values to be added, and is the destination register for the lower 32 bits of the result.

`<RdHi>` Supplies the other of the 32-bit values to be added, and is the destination register for the upper 32 bits of the result.

`<Rn>` The register that contains the first multiply operand.

`<Rm>` The register that contains the second multiply operand.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = UInt(R[n]) * UInt(R[m]) + UInt(R[dHi]) + UInt(R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
```

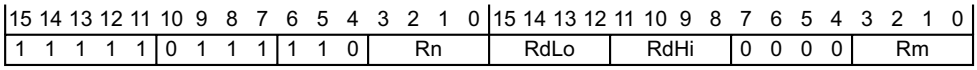
F7.1.268 UMLAL

Unsigned Multiply Accumulate Long multiplies two unsigned 32-bit values to produce a 64-bit value, and accumulates this with a 64-bit value.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

Encoding T1

```
UMLAL<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```

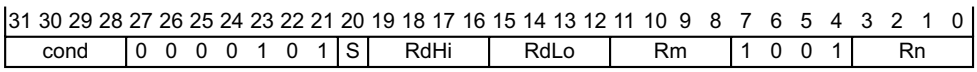


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	1	1	1	1	0	Rn				RdLo				RdHi				0	0	0	0	Rm			

```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

Encoding A1

```
UMLAL{S}<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	0	1	0	1	S	RdHi				RdLo				Rm				1	0	0	1	Rn			

```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *UMLAL* on page AppxA-4817.

Assembler syntax

```
UMLAL{S}{<c>}{<q>}  <RdLo>, <RdHi>, <Rn>, <Rm>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated. `S` can be specified only for the A32 instruction set.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<RdLo>`	Supplies the lower 32 bits of the accumulate value, and is the destination register for the lower 32 bits of the result.
`<RdHi>`	Supplies the upper 32 bits of the accumulate value, and is the destination register for the upper 32 bits of the result.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

The pre-UAL syntax `UMLAL<c>S` is equivalent to `UMLALS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = UInt(R[n]) * UInt(R[m]) + UInt(R[dHi]:R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
    if setflags then
        PSTATE.N = result<63>;
        PSTATE.Z = IsZeroBit(result<63:0>);
        // PSTATE.C, PSTATE.V unchanged
```

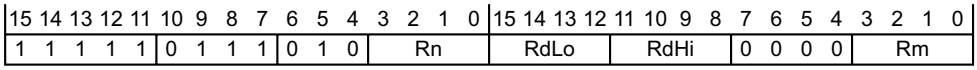
F7.1.269 UMULL

Unsigned Multiply Long multiplies two 32-bit unsigned values to produce a 64-bit result.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

Encoding T1

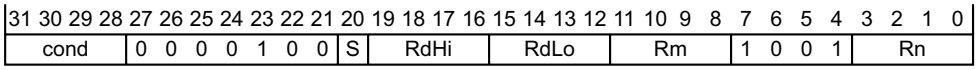
```
UMULL<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

Encoding A1

```
UMULL{S}<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *UMULL* on page AppxA-4817.

Assembler syntax

```
UMULL{S}{<c>}{<q>}  <RdLo>, <RdHi>, <Rn>, <Rm>
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated. `S` can be specified only for the A32 instruction set.
`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<RdLo>`	Stores the lower 32 bits of the result.
`<RdHi>`	Stores the upper 32 bits of the result.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

The pre-UAL syntax `UMULL<c>S` is equivalent to `UMULLS<c>`.

Operation

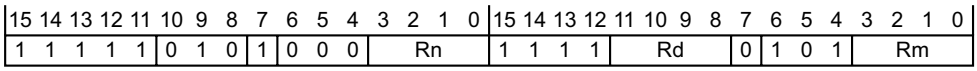
```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = UInt(R[n]) * UInt(R[m]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
    if setflags then
        PSTATE.N = result<63>;
        PSTATE.Z = IsZeroBit(result<63:0>);
        // PSTATE.C, PSTATE.V unchanged
```

F7.1.270 UQADD8

Unsigned Saturating Add 8 performs four unsigned 8-bit integer additions, saturates the results to the 8-bit unsigned integer range $0 \le x \le 2^8 - 1$, and writes the results to the destination register.

Encoding T1

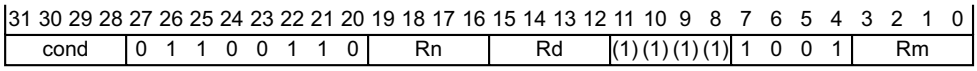
```
UQADD8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UQADD8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UQADD8{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

Operation

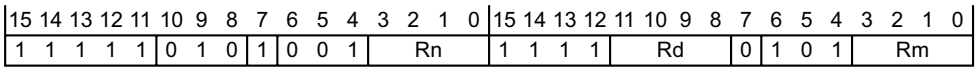
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = UInt(R[n]<7:0>) + UInt(R[m]<7:0>);
    sum2 = UInt(R[n]<15:8>) + UInt(R[m]<15:8>);
    sum3 = UInt(R[n]<23:16>) + UInt(R[m]<23:16>);
    sum4 = UInt(R[n]<31:24>) + UInt(R[m]<31:24>);
    R[d]<7:0>   = UnsignedSat(sum1, 8);
    R[d]<15:8>  = UnsignedSat(sum2, 8);
    R[d]<23:16> = UnsignedSat(sum3, 8);
    R[d]<31:24> = UnsignedSat(sum4, 8);
```

F7.1.271 UQADD16

Unsigned Saturating Add 16 performs two unsigned 16-bit integer additions, saturates the results to the 16-bit unsigned integer range $0 \le x \le 2^{16} - 1$, and writes the results to the destination register.

Encoding T1

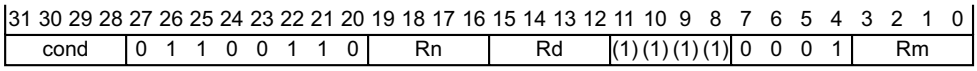
```
UQADD16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UQADD16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UQADD16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

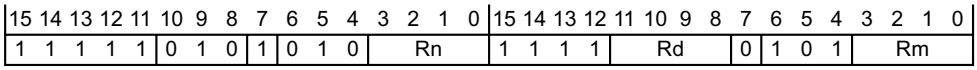
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = UInt(R[n]<15:0>) + UInt(R[m]<15:0>);
    sum2 = UInt(R[n]<31:16>) + UInt(R[m]<31:16>);
    R[d]<15:0>  = UnsignedSat(sum1, 16);
    R[d]<31:16> = UnsignedSat(sum2, 16);
```

F7.1.272 UQASX

Unsigned Saturating Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer addition and one unsigned 16-bit subtraction, saturates the results to the 16-bit unsigned integer range $0 \le x \le 2^{16} - 1$, and writes the results to the destination register.

Encoding T1

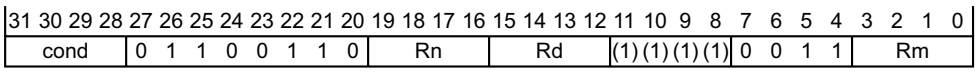
```
UQASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UQASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UQASX{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

The pre-UAL syntax `UQADDSUBX<c>` is equivalent to `UQASX<c>`.

Operation

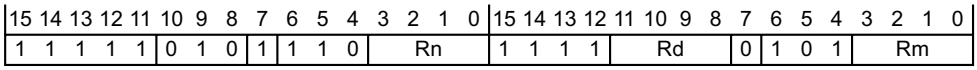
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff = UInt(R[n]<15:0>) - UInt(R[m]<31:16>);
    sum  = UInt(R[n]<31:16>) + UInt(R[m]<15:0>);
    R[d]<15:0>  = UnsignedSat(diff, 16);
    R[d]<31:16> = UnsignedSat(sum, 16);
```

F7.1.273 UQSAX

Unsigned Saturating Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer subtraction and one unsigned 16-bit addition, saturates the results to the 16-bit unsigned integer range $0 \le x \le 2^{16} - 1$, and writes the results to the destination register.

Encoding T1

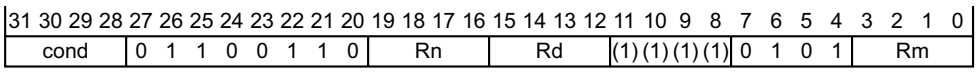
```
UQSAX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UQSAX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UQSAX{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

The pre-UAL syntax `UQSUBADDX<c>` is equivalent to `UQSAX<c>`.

Operation

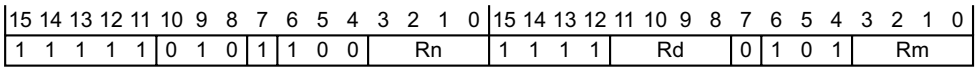
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum  = UInt(R[n]<15:0>) + UInt(R[m]<31:16>);
    diff = UInt(R[n]<31:16>) - UInt(R[m]<15:0>);
    R[d]<15:0>  = UnsignedSat(sum, 16);
    R[d]<31:16> = UnsignedSat(diff, 16);
```

F7.1.274 UQSUB8

Unsigned Saturating Subtract 8 performs four unsigned 8-bit integer subtractions, saturates the results to the 8-bit unsigned integer range $0 \le x \le 2^8 - 1$, and writes the results to the destination register.

Encoding T1

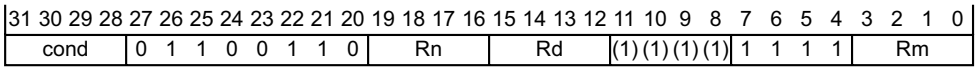
```
UQSUB8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UQSUB8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UQSUB8{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

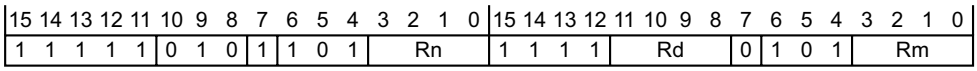
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = UInt(R[n]<7:0>) - UInt(R[m]<7:0>);
    diff2 = UInt(R[n]<15:8>) - UInt(R[m]<15:8>);
    diff3 = UInt(R[n]<23:16>) - UInt(R[m]<23:16>);
    diff4 = UInt(R[n]<31:24>) - UInt(R[m]<31:24>);
    R[d]<7:0>   = UnsignedSat(diff1, 8);
    R[d]<15:8>  = UnsignedSat(diff2, 8);
    R[d]<23:16> = UnsignedSat(diff3, 8);
    R[d]<31:24> = UnsignedSat(diff4, 8);
```

F7.1.275 UQSUB16

Unsigned Saturating Subtract 16 performs two unsigned 16-bit integer subtractions, saturates the results to the 16-bit unsigned integer range $0 \le x \le 2^{16} - 1$, and writes the results to the destination register.

Encoding T1

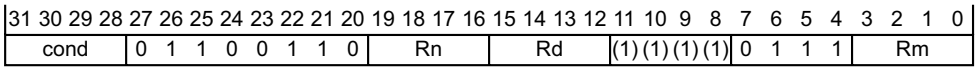
```
UQSUB16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UQSUB16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UQSUB16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

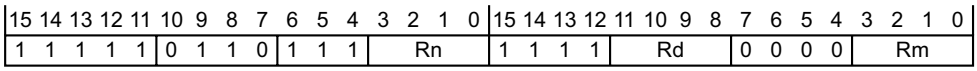
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = UInt(R[n]<15:0>) - UInt(R[m]<15:0>);
    diff2 = UInt(R[n]<31:16>) - UInt(R[m]<31:16>);
    R[d]<15:0>  = UnsignedSat(diff1, 16);
    R[d]<31:16> = UnsignedSat(diff2, 16);
```

F7.1.276 USAD8

Unsigned Sum of Absolute Differences performs four unsigned 8-bit subtractions, and adds the absolute values of the differences together.

Encoding T1

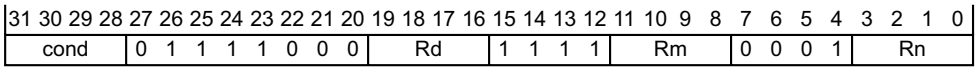
```
USAD8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
USAD8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
USAD8{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

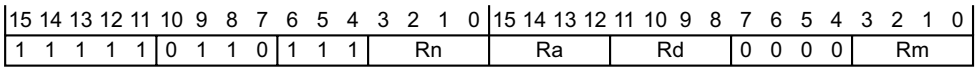
```
if ConditionPassed() then
    EncodingSpecificOperations();
    absdiff1 = Abs(UInt(R[n]<7:0>)   - UInt(R[m]<7:0>));
    absdiff2 = Abs(UInt(R[n]<15:8>)  - UInt(R[m]<15:8>));
    absdiff3 = Abs(UInt(R[n]<23:16>) - UInt(R[m]<23:16>));
    absdiff4 = Abs(UInt(R[n]<31:24>) - UInt(R[m]<31:24>));
    result = absdiff1 + absdiff2 + absdiff3 + absdiff4;
    R[d] = result<31:0>;
```

F7.1.277 USADA8

Unsigned Sum of Absolute Differences and Accumulate performs four unsigned 8-bit subtractions, and adds the absolute values of the differences to a 32-bit accumulate operand.

Encoding T1

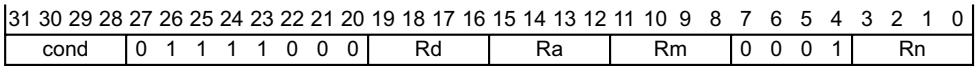
```
USADA8<c> <Rd>, <Rn>, <Rm>, <Ra>
```



```
if Ra == '1111' then SEE USAD8;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
USADA8<c> <Rd>, <Rn>, <Rm>, <Ra>
```



```
if Ra == '1111' then SEE USAD8;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
USADA8{<c>}{<q>}  <Rd>, <Rn>, <Rm>, <Ra>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.
`<Ra>`	The register that contains the accumulation value.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    absdiff1 = Abs(UInt(R[n]<7:0>)   - UInt(R[m]<7:0>));
    absdiff2 = Abs(UInt(R[n]<15:8>)  - UInt(R[m]<15:8>));
    absdiff3 = Abs(UInt(R[n]<23:16>) - UInt(R[m]<23:16>));
    absdiff4 = Abs(UInt(R[n]<31:24>) - UInt(R[m]<31:24>));
    result = UInt(R[a]) + absdiff1 + absdiff2 + absdiff3 + absdiff4;
    R[d] = result<31:0>;
```

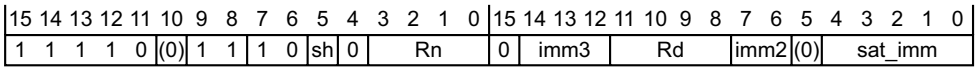
F7.1.278 USAT

Unsigned Saturate saturates an optionally-shifted signed value to a selected unsigned range.

The Q flag is set if the operation saturates.

Encoding T1

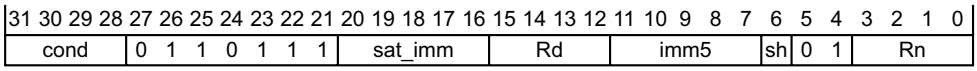
```
USAT<c> <Rd>, #<imm5>, <Rn>{, <shift>}
```



```
if sh == '1' && (imm3:imm2) == '00000' then SEE USAT16;
d = UInt(Rd);  n = UInt(Rn);  saturate_to = UInt(sat_imm);
(shift_t, shift_n) = DecodeImmShift(sh:'0', imm3:imm2);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
USAT<c> <Rd>, #<imm5>, <Rn>{, <shift>}
```



```
d = UInt(Rd);  n = UInt(Rn);  saturate_to = UInt(sat_imm);
(shift_t, shift_n) = DecodeImmShift(sh:'0', imm5);
if d == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
USAT{<c>}{<q>}  <Rd>, #<imm>, <Rn> {, <shift>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<imm>` The bit position for saturation, in the range 0 to 31. This is encoded directly in the `sat_imm` field of the instruction, meaning `sat_imm` takes the value of `<imm>`.

`<Rn>` The register that contains the value to be saturated.

`<shift>` The optional shift, encoded in the sh bit and the `immsh` field, where `immsh` is:

- `imm3:imm2` for encoding T1.
- `imm5` for encoding A1.

`<shift>` must be one of:

omitted No shift. Encoded as `sh` = 0, `immsh` = `0b00000`.

`LSL #<n>` Left shift by `<n>` bits, with `<n>` in the range 1-31.
Encoded as `sh` = 0, `immsh` = `<n>`.

`ASR #<n>` Arithmetic right shift by `<n>` bits, with `<n>` in the range 1-31.
Encoded as `sh` = 1, `immsh` = `<n>`.

`ASR #32` Arithmetic right shift by 32 bits, permitted only for encoding A1.
Encoded as `sh` = 1, `immsh` = `0b00000`.

Note

An assembler can permit `ASR #0` or `LSL #0` to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand = Shift(R[n], shift_t, shift_n, PSTATE.C);  // PSTATE.C ignored
    (result, sat) = UnsignedSatQ(SInt(operand), saturate_to);
    R[d] = ZeroExtend(result, 32);
    if sat then
        PSTATE.Q = '1';
```

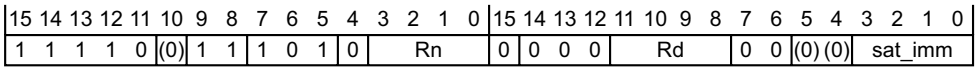
F7.1.279 USAT16

Unsigned Saturate 16 saturates two signed 16-bit values to a selected unsigned range.

The Q flag is set if the operation saturates.

Encoding T1

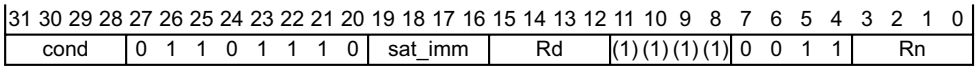
```
USAT16<c> <Rd>, #<imm4>, <Rn>
```



```
d = UInt(Rd);  n = UInt(Rn);  saturate_to = UInt(sat_imm);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
USAT16<c> <Rd>, #<imm4>, <Rn>
```



```
d = UInt(Rd);  n = UInt(Rn);  saturate_to = UInt(sat_imm);
if d == 15 || n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
USAT16{<c>}{<q>}  <Rd>, #<imm>, <Rn>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<imm>` The bit position for saturation, in the range 0 to 15. This is encoded directly in the `sat_imm` field of the instruction, meaning `sat_imm` takes the value of `<imm>`.

`<Rn>` The register that contains the values to be saturated.

Operation

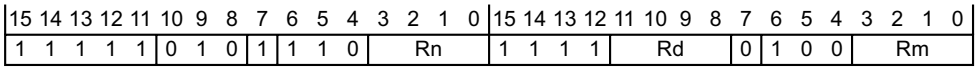
```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result1, sat1) = UnsignedSatQ(SInt(R[n]<15:0>), saturate_to);
    (result2, sat2) = UnsignedSatQ(SInt(R[n]<31:16>), saturate_to);
    R[d]<15:0> = ZeroExtend(result1, 16);
    R[d]<31:16> = ZeroExtend(result2, 16);
    if sat1 || sat2 then
        PSTATE.Q = '1';
```

F7.1.280 USAX

Unsigned Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer subtraction and one unsigned 16-bit addition, and writes the results to the destination register. It sets the APSR.GE bits according to the results.

Encoding T1

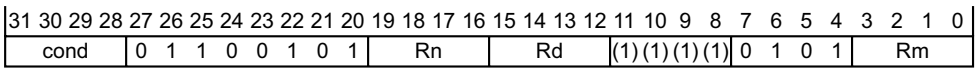
```
USAX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
USAX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
USAX{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

The pre-UAL syntax `USUBADDX<c>` is equivalent to `USAX<c>`.

Operation

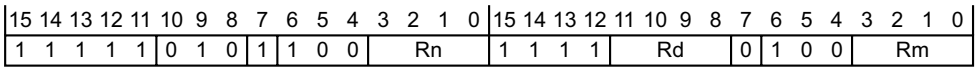
```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum  = UInt(R[n]<15:0>) + UInt(R[m]<31:16>);
    diff = UInt(R[n]<31:16>) - UInt(R[m]<15:0>);
    R[d]<15:0>  = sum<15:0>;
    R[d]<31:16> = diff<15:0>;
    PSTATE.GE<1:0> = if sum  >= 0x10000 then '11' else '00';
    PSTATE.GE<3:2> = if diff >= 0 then '11' else '00';
```

F7.1.281 USUB8

Unsigned Subtract 8 performs four 8-bit unsigned integer subtractions, and writes the results to the destination register. It sets the APSR.GE bits according to the results of the subtractions.

Encoding T1

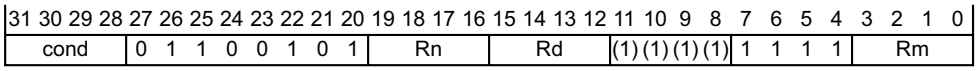
```
USUB8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
USUB8<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
USUB8{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

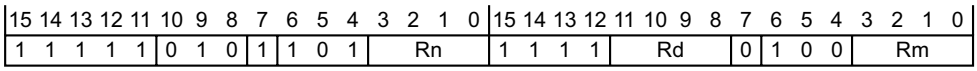
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = UInt(R[n]<7:0>) - UInt(R[m]<7:0>);
    diff2 = UInt(R[n]<15:8>) - UInt(R[m]<15:8>);
    diff3 = UInt(R[n]<23:16>) - UInt(R[m]<23:16>);
    diff4 = UInt(R[n]<31:24>) - UInt(R[m]<31:24>);
    R[d]<7:0>   = diff1<7:0>;
    R[d]<15:8>  = diff2<7:0>;
    R[d]<23:16> = diff3<7:0>;
    R[d]<31:24> = diff4<7:0>;
    PSTATE.GE<0>  = if diff1 >= 0 then '1' else '0';
    PSTATE.GE<1>  = if diff2 >= 0 then '1' else '0';
    PSTATE.GE<2>  = if diff3 >= 0 then '1' else '0';
    PSTATE.GE<3>  = if diff4 >= 0 then '1' else '0';
```

F7.1.282 USUB16

Unsigned Subtract 16 performs two 16-bit unsigned integer subtractions, and writes the results to the destination register. It sets the APSR.GE bits according to the results of the subtractions.

Encoding T1

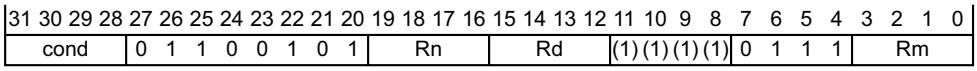
```
USUB16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
USUB16<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
USUB16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The second operand register.

Operation

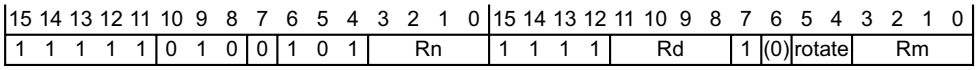
```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = UInt(R[n]<15:0>) - UInt(R[m]<15:0>);
    diff2 = UInt(R[n]<31:16>) - UInt(R[m]<31:16>);
    R[d]<15:0>  = diff1<15:0>;
    R[d]<31:16> = diff2<15:0>;
    PSTATE.GE<1:0> = if diff1 >= 0 then '11' else '00';
    PSTATE.GE<3:2> = if diff2 >= 0 then '11' else '00';
```

F7.1.283 UXTAB

Unsigned Extend and Add Byte extracts an 8-bit value from a register, zero-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

Encoding T1

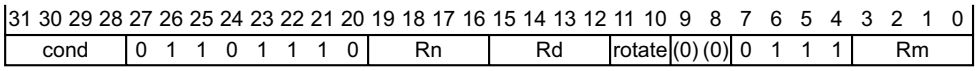
```
UXTAB<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE UXTB;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UXTAB<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE UXTB;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UXTAB{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

`<rotation>` This can be any one of:

omitted Encoded as rotate = `0b00`.

`ROR #8` Encoded as rotate = `0b01`.

`ROR #16` Encoded as rotate = `0b10`.

`ROR #24` Encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation

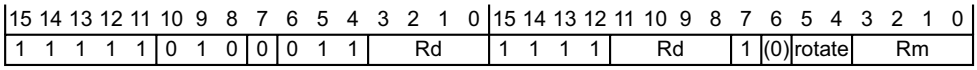
```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = R[n] + ZeroExtend(rotated<7:0>, 32);
```

F7.1.284 UXTAB16

Unsigned Extend and Add Byte 16 extracts two 8-bit values from a register, zero-extends them to 16 bits each, adds the results to two 16-bit values from another register, and writes the final results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

Encoding T1

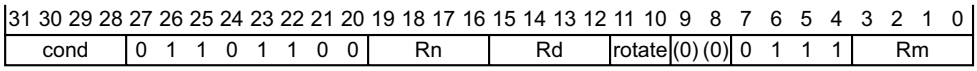
```
UXTAB16<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE UXTB16;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UXTAB16<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE UXTB16;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UXTAB16{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

`<rotation>` This can be any one of:

omitted Encoded as rotate = `0b00`.

`ROR #8` Encoded as rotate = `0b01`.

`ROR #16` Encoded as rotate = `0b10`.

`ROR #24` Encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation

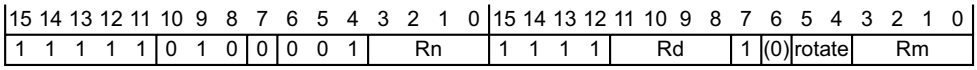
```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d]<15:0>  = R[n]<15:0> + ZeroExtend(rotated<7:0>, 16);
    R[d]<31:16> = R[n]<31:16> + ZeroExtend(rotated<23:16>, 16);
```

F7.1.285 UXTAH

Unsigned Extend and Add Halfword extracts a 16-bit value from a register, zero-extends it to 32 bits, adds the result to a value from another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

Encoding T1

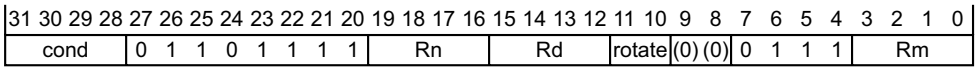
```
UXTAH<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE UXTH;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UXTAH<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE UXTH;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UXTAH{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

`<rotation>` This can be any one of:

omitted Encoded as rotate = `0b00`.

`ROR #8` Encoded as rotate = `0b01`.

`ROR #16` Encoded as rotate = `0b10`.

`ROR #24` Encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = R[n] + ZeroExtend(rotated<15:0>, 32);
```

F7.1.286 UXTB

Unsigned Extend Byte extracts an 8-bit value from a register, zero-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

Encoding T1

d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UXTB{<c>}{<q>}  {<Rd>,} <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rm>` The second operand register.

`<rotation>` This can be any one of:

omitted Any encoding, encoded as rotate = `0b00` in encoding T2 or A1.

`ROR #8` Encoding T2 or A1, encoded as rotate = `0b01`.

`ROR #16` Encoding T2 or A1, encoded as rotate = `0b10`.

`ROR #24` Encoding T2 or A1, encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

The pre-UAL syntax `UEXT8<c>` is equivalent to `UXTB<c>`.

Operation

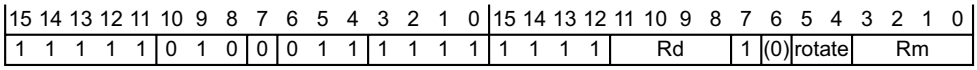
```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = ZeroExtend(rotated<7:0>, 32);
```

F7.1.287 UXTB16

Unsigned Extend Byte 16 extracts two 8-bit values from a register, zero-extends them to 16 bits each, and writes the results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

Encoding T1

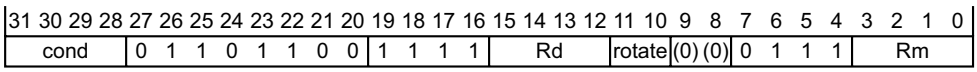
```
UXTB16<c> <Rd>, <Rm>{, <rotation>}
```



```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UXTB16<c> <Rd>, <Rm>{, <rotation>}
```



```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UXTB16{<c>}{<q>}  {<Rd>,} <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rm>` The second operand register.

`<rotation>` This can be any one of:

omitted Encoded as rotate = `0b00`.

`ROR #8` Encoded as rotate = `0b01`.

`ROR #16` Encoded as rotate = `0b10`.

`ROR #24` Encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation

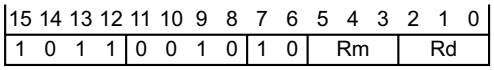
```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d]<15:0>  = ZeroExtend(rotated<7:0>, 16);
    R[d]<31:16> = ZeroExtend(rotated<23:16>, 16);
```

F7.1.288 UXTH

Unsigned Extend Halfword extracts a 16-bit value from a register, zero-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

Encoding T1

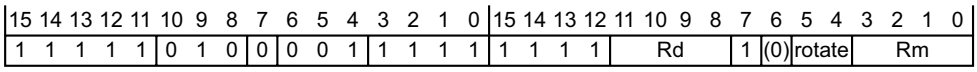
```
UXTH<c> <Rd>, <Rm>
```



```
d = UInt(Rd);  m = UInt(Rm);  rotation = 0;
```

Encoding T2

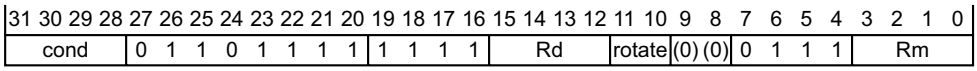
```
UXTH<c>.W <Rd>, <Rm>{, <rotation>}
```



```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
UXTH<c> <Rd>, <Rm>{, <rotation>}
```



```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
UXTH{<c>}{<q>}  {<Rd>,} <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<Rm>` The second operand register.

`<rotation>` This can be any one of:

omitted Any encoding, encoded as `rotate` = `0b00` in encoding T2 or A1.

`ROR #8` Encoding T2 or A1, encoded as `rotate` = `0b01`.

`ROR #16` Encoding T2 or A1, encoded as `rotate` = `0b10`.

`ROR #24` Encoding T2 or A1, encoded as `rotate` = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

The pre-UAL syntax `UEXT16<c>` is equivalent to `UXTH<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = ZeroExtend(rotated<15:0>, 32);
```

F7.1.289 WFE

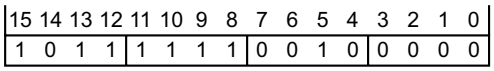
Wait For Event is a hint instruction that permits the PE to enter a low-power state until one of a number of events occurs, including events signaled by executing the SEV instruction on any PE in the multiprocessor system. For more information, see *Wait For Event and Send Event* on page G1-3457.

As described in *Wait For Event and Send Event* on page G1-3457, the execution of a WFE instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level, see:

- *Traps to Undefined mode of PL0 execution of WFE and WFI instructions* on page G1-3477.
- *Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions* on page G1-3494.
- *Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode* on page G1-3504.

Encoding T1

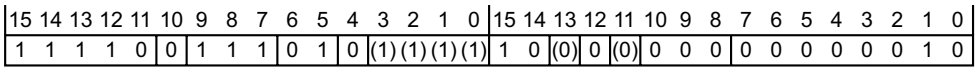
WFE<c>



```
// No additional decoding required
```

Encoding T2

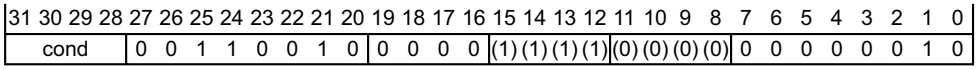
WFE<c>.W



```
// No additional decoding required
```

Encoding A1

WFE<c>



```
// No additional decoding required
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
WFE{<c>}{<q>}
```

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2330.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if EventRegistered() then
        ClearEventRegister();
    else
        if PSTATE.EL == EL0 then
            AArch32.CheckForWFxTrap(EL1, TRUE);
        if HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} then
            AArch32.CheckForWFxTrap(EL2, TRUE);
        if HaveEL(EL3) && CPSR.M != M32_Monitor then
            AArch32.CheckForWFxTrap(EL3, TRUE);
        WaitForEvent();
```

F7.1.290 WFI

Wait For Interrupt is a hint instruction that permits the PE to enter a low-power state until one of a number of asynchronous events occurs. For more information, see *Wait For Interrupt* on page G1-3460.

As described in *Wait For Interrupt* on page G1-3460, the execution of a `WFI` instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level, see:

- *Traps to Undefined mode of PL0 execution of WFE and WFI instructions* on page G1-3477.
- *Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions* on page G1-3494.
- *Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode* on page G1-3504.

            AArch32.CheckForWFxTrap(EL3, FALSE);
        WaitForInterrupt();
```

F7.1.291 YIELD

YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction see *The Yield instruction* on page F1-2312.

Assembler syntax

```
YIELD{<c>}{<q>}
```

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2330.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    Hint_Yield();
```

F7.2 General restrictions on system instructions

This section describes some restrictions that apply to a number of System instructions. The descriptions of the individual instructions refer to the following subsections when they apply:

- *Restrictions on exception return instructions*
- *Restrictions on updates to the CPSR.M field*.

F7.2.1 Restrictions on exception return instructions

A System instruction that is an exception return instruction is UNPREDICTABLE if:

- It is executed in User mode.
- For an exception return instruction other than `RFE`, it is executed in System mode.
- The SPSR value it restores to the CPSR is not permitted because of the restrictions described in *Restrictions on updates to the CPSR.M field*.

Note

An exception return instruction that is executed in Hyp mode can set CPSR.M to a value other than `'11010'`, the value for Hyp mode. However, this does not apply to the following exception return instructions, because the instructions are UNDEFINED in Hyp mode:

— `LDM` (exception return).

— `SUBS PC, LR, #<const>` with a nonzero constant.

F7.2.2 Restrictions on updates to the CPSR.M field

A System instruction that updates the CPSR.M field is UNPREDICTABLE if it attempts to change to a mode that is not accessible from the context in which the instruction is executed. This means that a System instruction is UNPREDICTABLE if it:

- Attempts to change CPSR.M to a value that does not correspond to a PE mode. Table G1-2 on page G1-3378 shows the values of M that correspond to a PE mode.
- Is executed in Non-secure state and attempts to set CPSR.M to `'10110'`, the value for Monitor mode.
- Attempts to set CPSR.M to `'11010'`, the value for Hyp mode, when any of the following applies:
  — It is executed in a Non-secure mode other than Hyp mode.
  — It is executed in a Secure mode other than Monitor mode.
  — It is executed in Monitor mode when SCR.NS is set to 0.
  — It is executed in Monitor mode and it is not an exception return instruction.
- Is not an exception return instruction, and is executed in Hyp mode, and attempts to set CPSR.M to a value other than `'11010'`, the value for Hyp mode.

F7.3 Encoding and use of Banked register transfer instructions

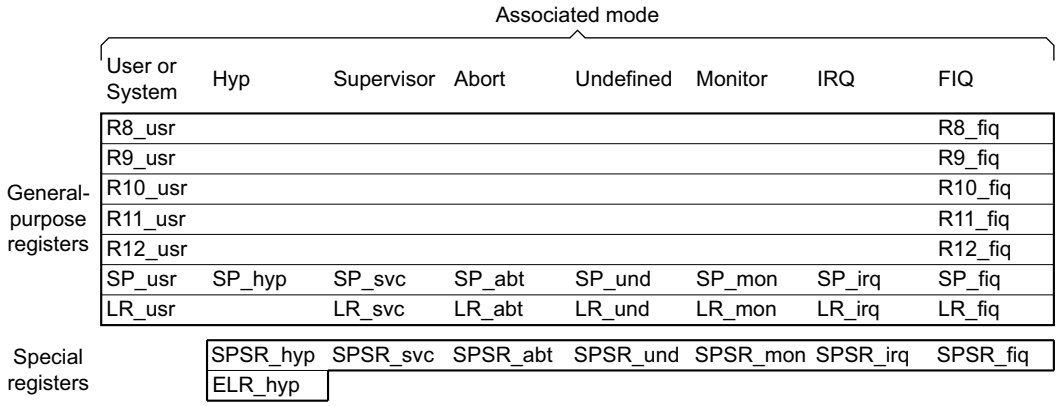
Software executing at EL1 or higher can use the MRS (Banked register) and MSR (Banked register) instructions to transfer values between the general-purpose registers and Special registers. One particular use of these instructions is for a hypervisor to save or restore the register values of a Guest OS. The following sections give more information about these instructions:

- *Register arguments in the Banked register transfer instructions*.
- *Usage restrictions on the Banked register transfer instructions* on page F7-2995.
- *Encoding the register argument in the Banked register transfer instructions* on page F7-2996.
- *Pseudocode support for the Banked register transfer instructions* on page F7-2996.

For descriptions of the instructions see *MRS (Banked register)* on page F7-3012 and *MSR (Banked register)* on page F7-3014.

F7.3.1 Register arguments in the Banked register transfer instructions

Figure F7-1 shows the Banked general-purpose registers and Special registers:



For the general-purpose registers, if no other register is shown, the *current mode register* is the _usr register. So, for example, the full set of current mode registers, including the registers that are not banked:

- For Hyp mode, is {R0_usr - R12_usr, SP_hyp, LR_usr, SPSR_hyp, ELR_hyp}.
- For Abort mode, is {R0_usr - R12_usr, SP_abt, LR_abt, SPSR_abt}.

Figure F7-1 Banking of general-purpose registers and Special registers

Figure F7-1 is based on Figure G1-2 on page G1-3381, that shows the complete set of general-purpose registers and Special registers accessible in each mode.

Note

- System mode uses the same set of registers as User mode. Neither of these modes can access an SPSR, except that System mode can use the MRS (Banked register) and MSR (Banked register) instructions to access some SPSRs, as described in *Usage restrictions on the Banked register transfer instructions* on page F7-2995.
- General-purpose registers R0-R7, that are not Banked, cannot be accessed using the MRS (Banked register) and MSR (Banked register) instructions.

Software using an MRS (Banked register) or MSR (Banked register) instruction specifies one of these registers using a name shown in Figure F7-1, or an alternative name for SP or LR. These registers can be grouped as follows:

R8-R12 Each of these registers has two Banked copies, _usr and _fiq, for example R8_usr and R8_fiq.

SP There is a Banked copy of SP for every mode except System mode. For example, SP_svc is the SP for Supervisor mode.

LR There is a Banked copy of LR for every mode except System mode and Hyp mode. For example, LR_svc is the SP for Supervisor mode.

SPSR There is a Banked copy of SPSR for every mode except System mode and User mode.

ELR_hyp Except for the operations provided by MRS (Banked register) and MSR (Banked register), ELR_hyp is accessible only from Hyp mode. It is not Banked.

F7.3.2 Usage restrictions on the Banked register transfer instructions

When software uses an MRS (Banked register) or MSR (Banked register) instruction, the current mode determines the permitted values of the register argument. This determination depends on the rules that an MRS (Banked register) or MSR (Banked register) instruction cannot access:

- A register that is not accessible from the current privilege level and security state. This means that, for example:
  - Non-secure software executing at EL1 or EL2 cannot access any Monitor mode registers.
  - Non-secure software executing at EL1 cannot access any Hyp mode registers.
  - Except in Monitor mode, Secure software cannot access any Hyp mode registers.
- A register that can be accessed, from the current mode, using a different instruction.

This means that, for each mode, the registers that cannot be accessed are as follows:

Hyp mode The current mode registers R8_usr-R12_usr, SP_hyp, LR_usr, and SPSR_hyp.

The Monitor mode registers SP_mon, LR_mon, and SPSR_mon.

Monitor mode The current mode registers R8_usr-R12_usr, SP_mon, LR_mon, and SPSR_mon.

FIQ mode The current mode registers R8_fiq-R12_fiq, SP_fiq, LR_fiq, and SPSR_fiq.

The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.

In Non-secure state, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.

System mode The current mode registers R8_usr-R12_usr, SP_usr, and LR_usr.

The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.

In Non-secure state, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.

Supervisor mode, Abort mode, Undefined mode, and IRQ mode

The current mode registers R8_usr-R12_usr, SP_<current_mode>, LR_<current_mode>, and SPSR_<current_mode>.

The Hyp mode registers SP_hyp, SPSR_hyp, and ELR_hyp.

In Non-secure state, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.

User mode MRS (Banked register) and MSR (Banked register) instructions are always UNPREDICTABLE.

If software attempts to use an MRS (Banked register) or MSR (Banked register) instruction to access a register from a state from which this section states that the register cannot be accessed, the MRS or MSR instruction is UNPREDICTABLE. For more information, see:

- *Encoding the register argument in the Banked register transfer instructions* on page F7-2996.
- *Pseudocode support for the Banked register transfer instructions* on page F7-2996.
- *MRS (Banked register)* on page F7-3012.
- *MSR (Banked register)* on page F7-3014.

Note

UNPREDICTABLE behavior must not give access to registers that are associated with a mode that cannot be entered, from the current mode, using a CPS or MSR instruction.

F7.3.3 Encoding the register argument in the Banked register transfer instructions

The MRS (Banked register) and MSR (Banked register) instructions include a 5-bit field, SYSm, and an R bit, that together encode the register argument for the instruction.

When the R bit is set to 0, the argument is a register other than a Banked copy of the SPSR, and Table F7-3 shows how the SYSm field defines the required register argument.

Table F7-3 Banked register encodings when R==0

	SYSm<4:3>			
SYSm<2:0>	0b00	0b01	0b10	0b11
0b000	R8_usr	R8_fiq	LR_irq	UNPREDICTABLE
0b001	R9_usr	R9_fiq	SP_irq	UNPREDICTABLE
0b010	R10_usr	R10_fiq	LR_svc	UNPREDICTABLE
0b011	R11_usr	R11_fiq	SP_svc	UNPREDICTABLE
0b100	R12_usr	R12_fiq	LR_abt	LR_mon
0b101	SP_usr	SP_fiq	SP_abt	SP_mon
0b110	LR_usr	LR_fiq	LR_und	ELR_hyp
0b111	UNPREDICTABLE	UNPREDICTABLE	SP_und	SP_hyp

When the R bit is set to 1, the argument is a Banked copy of the SPSR, and Table F7-4 shows how the SYSm field defines the required register argument.

Table F7-4 Banked register encodings when R==1

	SYSm<4:3>			
SYSm<2:0>	0b00	0b01	0b10	0b11
0b000	UNPREDICTABLE	UNPREDICTABLE	SPSR_irq	UNPREDICTABLE
0b001	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE
0b010	UNPREDICTABLE	UNPREDICTABLE	SPSR_svc	UNPREDICTABLE
0b011	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE
0b100	UNPREDICTABLE	UNPREDICTABLE	SPSR_abt	SPSR_mon
0b101	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE
0b110	UNPREDICTABLE	SPSR_fiq	SPSR_und	SPSR_hyp
0b111	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE	UNPREDICTABLE

F7.3.4 Pseudocode support for the Banked register transfer instructions

The pseudocode functions BankedRegisterAccessValid() and SPSRaccessValid() check the validity of MRS (Banked register) and MSR (Banked register) accesses. That is, they filter the accesses that are UNPREDICTABLE either because:

- They attempt to access a register that *Usage restrictions on the Banked register transfer instructions* on page F7-2995 shows is not accessible.

- They use an SYSm<4:0> encoding that *Encoding the register argument in the Banked register transfer instructions* on page F7-2996 shows as UNPREDICTABLE.

`BankedRegisterAccessValid()` applies to accesses to the banked general-purpose registers, or to ELR_hyp, and `SPSRaccessValid()` applies to accesses to the SPSRs.

F7.4 Alphabetical list of system instructions

This section lists every instruction in the base instruction set that behaves differently when executed at EL1 or higher, or that is only available at EL1 or higher. For more information see *Exception levels* on page G1-3367.

See also *Advanced SIMD and floating-point system instructions* on page F8-3358.

F7.4.1 CPS, T32

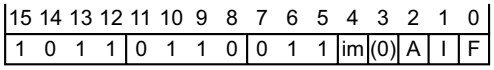
Change PE State changes one or more of the CPSR.{A, I, F} interrupt mask bits and the CPSR.M mode field, without changing the other CPSR bits.

`CPS` is treated as `NOP` if executed in User mode.

`CPS` is UNPREDICTABLE if it is attempting to change to a mode that is not permitted in the context in which it is executed, see *Restrictions on updates to the CPSR.M field* on page F7-2993.

Encoding T1

`CPS<effect> <iflags>` — Not permitted in IT block.

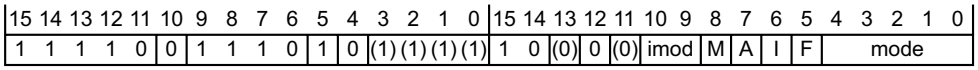


```
if A:I:F == '000' then UNPREDICTABLE;
enable = (im == '0');  disable = (im == '1');  changemode = FALSE;
affectA = (A == '1');  affectI = (I == '1');  affectF = (F == '1');
if InITBlock() then UNPREDICTABLE;
```

Encoding T2

`CPS<effect>.W <iflags>{, #<mode>}` — Not permitted in IT block.

`CPS #<mode>` — Not permitted in IT block.



```
if imod == '00' && M == '0' then SEE "Hint instructions";
if mode != '00000' && M == '0' then UNPREDICTABLE;
if (imod<1> == '1' && A:I:F == '000') || (imod<1> == '0' && A:I:F != '000') then UNPREDICTABLE;
enable = (imod == '10');  disable = (imod == '11');  changemode = (M == '1');
affectA = (A == '1');  affectI = (I == '1');  affectF = (F == '1');
if imod == '01' || InITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *CPS (T32)* on page AppxA-4836.

Hint instructions

In encoding T2, if the `imod` field is `'00'` and the `M` bit is `'0'`, a hint instruction is encoded. To determine which hint instruction, see *Change Processor State, and hints* on page F3-2362.

Assembler syntax

```
CPS<effect>{<q>}  <iflags> {, #<mode>}
CPS{<q>}  #<mode>
```

where:

<effect> The effect required on the A, I, and F bits in the CPSR. This is one of:

- IE Interrupt Enable. This sets the specified bits to 0.
- ID Interrupt Disable. This sets the specified bits to 1.

If <effect> is specified, the bits to be affected are specified by <iflags>. The mode can optionally be changed by specifying a mode number as <mode>.

If <effect> is not specified, then:

- <iflags> is not specified and interrupt settings are not changed.
- <mode> specifies the new mode number.

<q> See *Standard assembler syntax fields* on page F2-2330. A CPS instruction must be unconditional.

<iflags> Is a sequence of one or more of the following, specifying which interrupt mask bits are affected:

- a Sets the A bit in the instruction, causing the specified effect on CPSR.A, the asynchronous abort bit.
- i Sets the I bit in the instruction, causing the specified effect on CPSR.I, the IRQ interrupt bit.
- f Sets the F bit in the instruction, causing the specified effect on CPSR.F, the FIQ interrupt bit.

<mode> The number of the mode to change to. If this option is omitted, no mode change occurs.

Operation

```
EncodingSpecificOperations();
if PSTATE.EL != EL0 then
    cpsr_val = CPSR;
    if enable then
        if affectA then cpsr_val<8> = '0';
        if affectI then cpsr_val<7> = '0';
        if affectF then cpsr_val<6> = '0';
    if disable then
        if affectA then cpsr_val<8> = '1';
        if affectI then cpsr_val<7> = '1';
        if affectF then cpsr_val<6> = '1';
    if changemode then
        cpsr_val<4:0> = mode;
    // Attempts to change to an illegal mode will invoke the Illegal Execution State mechanism
    CPSR = cpsr_val;
```

F7.4.2 CPS, A32

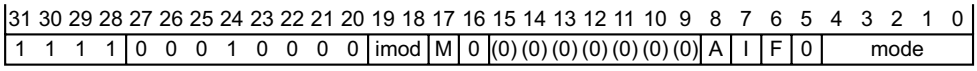
Change PE State changes one or more of the CPSR.{A, I, F} interrupt mask bits and the CPSR.M mode field, without changing the other CPSR bits.

CPS is treated as NOP if executed in User mode.

CPS is UNPREDICTABLE if it is attempting to change to a mode that is not permitted in the context in which it is executed, see *Restrictions on updates to the CPSR.M field* on page F7-2993.

Encoding A1

```
CPS<effect> <iflags>{, #<mode>}
CPS #<mode>
```



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	0	1	0	0	0	0	imod		M	0	(0)	(0)	(0)	(0)	(0)	(0)	(0)	A	I	F	0	mode				

```
if mode != '00000' && M == '0' then UNPREDICTABLE;
if (imod<1> == '1' && A:I:F == '000') || (imod<1> == '0' && A:I:F != '000') then UNPREDICTABLE;
enable = (imod == '10');  disable = (imod == '11');  changemode = (M == '1');
affectA = (A == '1');  affectI = (I == '1');  affectF = (F == '1');
if (imod == '00' && M == '0') || imod == '01' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *CPS (A32)* on page AppxA-4835.

Assembler syntax

```
CPS<effect>{<q>}  <iflags> {, #<mode>}
CPS{<q>}  #<mode>
```

where:

`<effect>` The effect required on the A, I, and F bits in the CPSR. This is one of:

- `IE` Interrupt Enable. This sets the specified bits to 0.
- `ID` Interrupt Disable. This sets the specified bits to 1.

If `<effect>` is specified, the bits to be affected are specified by `<iflags>`. The mode can optionally be changed by specifying a mode number as `<mode>`.

If `<effect>` is not specified, then:

- `<iflags>` is not specified and interrupt settings are not changed.
- `<mode>` specifies the new mode number.

`<q>` See *Standard assembler syntax fields* on page F2-2330. A `CPS` instruction must be unconditional.

`<iflags>` Is a sequence of one or more of the following, specifying which interrupt mask bits are affected:

- `a` Sets the A bit in the instruction, causing the specified effect on CPSR.A, the asynchronous abort bit.
- `i` Sets the I bit in the instruction, causing the specified effect on CPSR.I, the IRQ interrupt bit.
- `f` Sets the F bit in the instruction, causing the specified effect on CPSR.F, the FIQ interrupt bit.

`<mode>` The number of the mode to change to. If this option is omitted, no mode change occurs.

Operation

```
EncodingSpecificOperations();
if PSTATE.EL != EL0 then
    cpsr_val = CPSR;
    if enable then
        if affectA then cpsr_val<8> = '0';
        if affectI then cpsr_val<7> = '0';
        if affectF then cpsr_val<6> = '0';
    if disable then
        if affectA then cpsr_val<8> = '1';
        if affectI then cpsr_val<7> = '1';
        if affectF then cpsr_val<6> = '1';
    if changemode then
        cpsr_val<4:0> = mode;
    // Attempts to change to an illegal mode or state will invoke the Illegal Execution State
    // mechanism
    CPSR = cpsr_val;
```

F7.4.3 ERET

When executed in Hyp mode, Exception Return loads the PC from ELR_hyp and loads the CPSR from SPSR_hyp.

When executed in a Secure or Non-secure EL1 mode, ERET behaves as:

- MOVS PC, LR in the A32 instruction set, see *SUBS PC, LR and related instructions, A32* on page F7-3032.
- The equivalent SUBS PC, LR, #0 in the T32 instruction set, see *SUBS PC, LR and related instructions, T32* on page F7-3030.

In Debug state, ERET is decoded as DRPS.

ERET is CONSTRAINED UNPREDICTABLE in the cases described in *Restrictions on exception return instructions* on page F7-2993.

Note

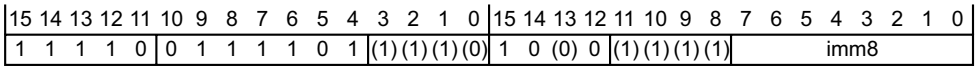
In an implementation that includes EL2:

- The T1 encoding of ERET is the preferred synonym of SUBS PC, LR, #0 in the T32 instruction set. See *SUBS PC, LR and related instructions, T32* on page F7-3030 for more information.
- Because ERET is the preferred encoding, when decoding T32 instructions, a disassembler reports an ERET where the original assembler code used SUBS PC, LR, #0.

Encoding T1

SUBS PC, LR, #0

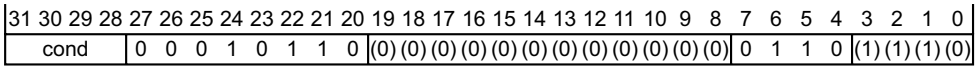
ERET<c>



```
if imm8 != '00000000' then SEE SUBS PC, LR and related instructions;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1

ERET<c>



```
// No additional decoding required
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
ERET{<c>}{<q>}
```

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2330.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;                          // UNDEFINED or NOP
    else
        new_pc_value = if PSTATE.EL == EL2 then ELR_hyp else R[14];
        AArch32.ExceptionReturn(new_pc_value, SPSR[]);
```

F7.4.4 HVC

Hypervisor Call causes a Hypervisor Call exception. For more information see *Hypervisor Call (HVC) exception* on page G1-3436. Non-secure software executing at EL1 can use this instruction to call the hypervisor to request a service.

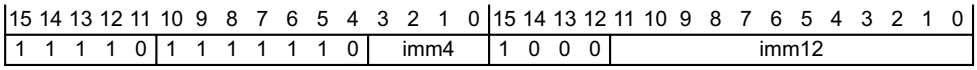
The HVC instruction is:

- UNDEFINED in Secure state, and in User mode in Non-secure state.
- When SCR.HCE is set to 0, UNDEFINED in Non-secure EL1 modes and CONSTRAINED UNPREDICTABLE in Hyp mode.

On executing an HVC instruction, the HSR reports the exception as a Hypervisor Call exception, using the EC value 0x12, and captures the value of the immediate argument, see *Use of the HSR* on page G4-3728.

Encoding T1

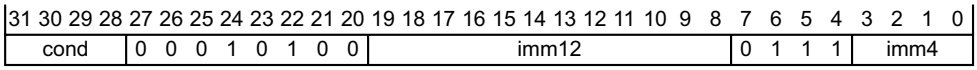
HVC #<imm>



```
// imm16 is for assembly/disassembly. It is reported in the HSR but otherwise is ignored by
// hardware. An HVC handler might interpret imm16, for example to determine the required service.
imm16 = imm4:imm12;
if InITBlock() then UNPREDICTABLE;
```

Encoding A1

HVC #<imm>



```
if cond != '1110' then UNPREDICTABLE;
imm16 = imm12:imm4;
// imm16 is for assembly/disassembly. It is reported in the HSR but otherwise is ignored by
// hardware. An HVC handler might interpret imm16, for example to determine the required service.
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*. See also *HVC* on page AppxA-4855 for information about CONSTRAINED UNPREDICTABLE behavior within virtualization.

Assembler syntax

```
HVC{<q>} {#}<imm16>
```

where:

<q> See *Standard assembler syntax fields* on page F2-2330. An HVC instruction must be unconditional.

<imm16> Specifies a 16-bit immediate constant.

Operation

```
EncodingSpecificOperations();
if !HaveEL(EL2) || PSTATE.EL == EL0 || IsSecure() then
    UNDEFINED;

hvc_enable = if HaveEL(EL3) then SCR_GEN[].HCE else NOT(HCR.HCD);
if hvc_enable == '0' then
    UNDEFINED;
else
    AArch32.CallHypervisor(imm16);
```

F7.4.5 LDM (exception return)

Load Multiple (exception return) loads multiple registers from consecutive memory locations using an address from a base register. The SPSR of the current mode is copied to the CPSR. An address adjusted by the size of the data loaded can optionally be written back to the base register.

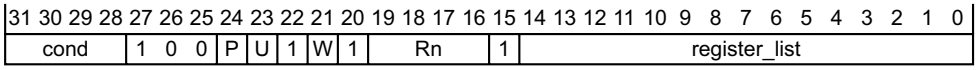
The registers loaded include the PC. The word loaded for the PC is treated as an address and a branch occurs to that address.

`LDM` (exception return) is:

- UNDEFINED in Hyp mode.
- UNPREDICTABLE in the cases described in *Restrictions on exception return instructions* on page F7-2993.

Encoding A1

```
LDM{<amode>}<c> <Rn>{!}, <registers_with_pc>^
```



```
n = UInt(Rn);  registers = register_list;
wback = (W == '1');  increment = (U == '1');  wordhigher = (P == U);
if n == 15 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDM (exception return)* on page AppxA-4837.

Assembler syntax

```
LDM{<amode>}{<c>}{<q>}  <Rn>{!}, <registers_with_pc>^
```

where:

`<amode>` is one of:

`DA`	Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
`FA`	Full Ascending. For this instruction, a synonym for `DA`.
`DB`	Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
`EA`	Empty Ascending. For this instruction, a synonym for `DB`.
`IA`	Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
`FD`	Full Descending. For this instruction, a synonym for `IA`.
`IB`	Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
`ED`	Empty Descending. For this instruction, a synonym for `IB`.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The base register. This register can be the SP.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers_with_pc>`

Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must be specified in the register list, and the instruction causes a branch to the address (data) loaded into the PC. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

The pre-UAL syntax `LDM<c>{<amode>}` is equivalent to `LDM{<amode>}<c>`.

Note

Instructions with similar syntax but without the PC included in the registers list are described in *LDM (User registers)* on page F7-3008.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elsif PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;                          // UNDEFINED or NOP
    else
        length = 4*BitCount(registers) + 4;
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;

        for i = 0 to 14
            if registers<i> == '1' then
                R[i] = MemA[address,4];  address = address + 4;
        new_pc_value = MemA[address,4];

        if wback && registers<n> == '0' then R[n] = if increment then R[n]+length else R[n]-length;
        if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;

        AArch32.ExceptionReturn(new_pc_value, SPSR[]);
```

F7.4.6 LDM (User registers)

In an EL1 mode other than System mode, Load Multiple (User registers) loads multiple User mode registers from consecutive memory locations using an address from a base register. The registers loaded cannot include the PC. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

`LDM` (user registers) is UNDEFINED in Hyp mode, and UNPREDICTABLE in User and System modes.

Encoding A1

```
LDM{<amode>}<c> <Rn>, <registers_without_pc>^
```

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15	14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
cond	1 0 0	P	U	1	(0)	1	Rn	0	register_list

```
n = UInt(Rn);  registers = register_list;  increment = (U == '1');  wordhigher = (P == U);
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDM (User registers)* on page AppxA-4837.

Assembler syntax

```
LDM{<amode>}{<c>}{<q>}  <Rn>, <registers_without_pc>^
```

where:

`<amode>` is one of:

- `DA` Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
- `FA` Full Ascending. For this instruction, a synonym for `DA`.
- `DB` Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
- `EA` Empty Ascending. For this instruction, a synonym for `DB`.
- `IA` Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
- `FD` Full Descending. For this instruction, a synonym for `IA`.
- `IB` Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
- `ED` Empty Descending. For this instruction, a synonym for `IB`.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The base register. This register can be the SP.

`<registers_without_pc>`

Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded by the `LDM` instruction. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must not be in the register list. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

The pre-UAL syntax `LDM<c>{<amode>}` is equivalent to `LDM{<amode>}<c>`.

Note

Instructions with similar syntax but with the PC included in `<registers_without_pc>` are described in *LDM (exception return)* on page F7-3006.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UNDEFINED;
    elsif PSTATE.M IN {M32_User,M32_System} then UNPREDICTABLE;
    else
        length = 4*BitCount(registers);
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;
        for i = 0 to 14
            if registers<i> == '1' then  // Load User mode register
                Rmode[i, M32_User] = MemA[address,4];  address = address + 4;
```

F7.4.7 LDRBT, LDRHT, LDRSBT, LDRSHT, and LDRT

Even when executed at EL1 or higher, loads from memory by these instructions are restricted in the same way as unprivileged loads from memory. The `MemA_unpriv[]` and `MemU_unpriv[]` pseudocode functions describe this restriction. For more information see *Alignment support* on page E2-2256.

These instructions are UNPREDICTABLE in Hyp mode.

For descriptions of the instructions see:

- *LDRBT* on page F7-2579.
- *LDRHT* on page F7-2603.
- *LDRSBT* on page F7-2611.
- *LDRSHT* on page F7-2619.
- *LDRT* on page F7-2621.

F7.4.8 MRS

Move to Register from Special register moves the value from the CPSR or SPSR of the current mode into a general-purpose register.

An `MRS` that accesses the SPSR is UNPREDICTABLE if executed in User mode or System mode.

An `MRS` that is executed in User mode and accesses the CPSR returns an UNKNOWN value for the CPSR.{E, A, I, F, M} fields.

Note

MRS on page F7-2651 describes the valid application level uses of the `MRS` instruction.

Encoding T1

```
MRS<c> <Rd>, <spec_reg>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	1	1	R	(1)	(1)	(1)	(1)	1	0	(0)	0	Rd				(0)	(0)	0	(0)	(0)	(0)	(0)	(0)

```
d = UInt(Rd);  read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Encoding A1

```
MRS<c> <Rd>, <spec_reg>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	0	R	0	0	(1)	(1)	(1)	(1)	Rd				(0)	(0)	0	(0)	0	0	0	0	(0)	(0)	(0)	(0)

```
d = UInt(Rd);  read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *MRS* on page AppxA-4838.

Assembler syntax

```
MRS{<c>}{<q>}  <Rd>, <spec_reg>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<spec_reg>` Is one of:

- `APSR`
- `CPSR`
- `SPSR`.

ARM recommends that software uses the `APSR` form when only the N, Z, C, V, Q, or GE[3:0] bits of the read value are going to be used, see *The Application Program Status Register (APSR)* on page E1-2211.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if read_spsr then
        if PSTATE.M IN {M32_User,M32_System} then
            UNPREDICTABLE;
        else
            R[d] = SPSR[];
    else
        // CPSR is read with reserved bits and execution state bits other than E masked out
        R[d] = CPSR AND '11111000 00001111 00000011 11011111';
        if PSTATE.EL == EL0 then
            // If accessed from User mode return UNKNOWN values for M, bits<4:0>,
            // and for the E, A, I, F bits, bits<9:6>
            R[d]<4:0> = bits(5) UNKNOWN;
            R[d]<9:6> = bits(4) UNKNOWN;
```

F7.4.9 MRS (Banked register)

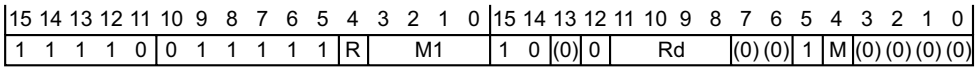
Move to Register from Banked or Special register moves the value from the Banked general-purpose register or SPSR of the specified mode, or the value of ELR_hyp, to a general-purpose register.

MRS (Banked register) is UNPREDICTABLE if executed in User mode.

The effect of using an MRS (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see *Usage restrictions on the Banked register transfer instructions* on page F7-2995.

Encoding T1

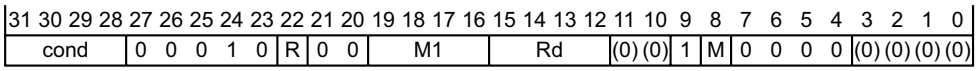
```
MRS<c> <Rd>, <banked_reg>
```



```
d = UInt(Rd);  read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
SYSm = M:M1;
```

Encoding A1

```
MRS<c> <Rd>, <banked_reg>
```



```
d = UInt(Rd);  read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE;
SYSm = M:M1;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
MRS{<c>}{<q>}  <Rd>, <banked_reg>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rd>` The destination register.

`<banked_reg>` Is one of:

- `<Rm>_<mode>`, encoded with R==0.
- `ELR_hyp`, encoded with R==0.
- `SPSR_<mode>`, encoded with R==1.

For a full description of the encoding of this field, see *Encoding and use of Banked register transfer instructions* on page F7-2994.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL0 then
       UNPREDICTABLE;
    else
        mode = PSTATE.M;
        if read_spsr then
            SPSRaccessValid(SYSm, mode);           // Check for UNPREDICTABLE cases
            case SYSm of
                when '01110'  R[d] = SPSR_fiq;
                when '10000'  R[d] = SPSR_irq;
                when '10010'  R[d] = SPSR_svc;
                when '10100'  R[d] = SPSR_abt;
                when '10110'  R[d] = SPSR_und;
                when '11100'  R[d] = SPSR_mon;
                when '11110'  R[d] = SPSR_hyp;
        else
            BankedRegisterAccessValid(SYSm, mode); // Check for UNPREDICTABLE cases

            if SYSm<4:3> == '00' then              // Access the User registers
                m = UInt(SYSm<2:0>) + 8;
                R[d] = Rmode[m,M32_User];
            elsif SYSm<4:3> == '01' then           // Access the FIQ registers
                m = UInt(SYSm<2:0>) + 8;
                R[d] = Rmode[m,M32_FIQ];
            elsif SYSm<4:3> == '11' then
                if SYSm<1> == '0' then             // Access Monitor registers
                    m = 14 - UInt(SYSm<0>);        // LR when SYSm<0> == 0, otherwise SP
                    R[d] = Rmode[m,M32_Monitor];
                else                               // Access Hyp registers
                    if SYSm<0> == '1' then         // ELR_hyp when SYSm<0> == '0', otherwise SP_hyp
                        R[d] = Rmode[13,M32_Hyp];
                    else
                        R[d] = ELR_hyp;
            else                                   // Other Banked registers
                bits(5) targetmode;                // (SYSm<4:3> == '10' case)
                targetmode<0> = SYSm<2> OR SYSm<1>;
                targetmode<1> = '1';
                targetmode<2> = SYSm<2> AND NOT SYSm<1>;
                targetmode<3> = SYSm<2> AND SYSm<1>;
                targetmode<4> = '1';
                if mode == targetmode then
                    UNPREDICTABLE;
                else
                    m = 14 - UInt(SYSm<0>);        // LR when SYSm<0> == 0, otherwise SP
                    R[d] = Rmode[m,targetmode];
```

F7.4.10 MSR (Banked register)

Move to Banked or Special register from general-purpose register moves the value of a general-purpose register to the Banked general-purpose register or SPSR of the specified mode, or to ELR_hyp.

`MSR` (Banked register) is UNPREDICTABLE if executed in User mode.

The effect of using an `MSR` (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see *Usage restrictions on the Banked register transfer instructions* on page F7-2995.

Encoding T1

`MSR<c> <banked_reg>, <Rn>`

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	0	R	Rn				1	0	(0)	0	M1				(0)	(0)	1	M	(0)	(0)	(0)	(0)

```
n = UInt(Rn);  write_spsr = (R == '1');
if n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
SYSm = M:M1;
```

Encoding A1

`MSR<c> <banked_reg>, <Rn>`

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	0	R	1	0	M1				(1)	(1)	(1)	(1)	(0)	(0)	1	M	0	0	0	0	Rn			

```
n = UInt(Rn);  write_spsr = (R == '1');
if n == 15 then UNPREDICTABLE;
SYSm = M:M1;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`MSR{<c>}{<q>}  <banked_reg>, <Rn>`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<banked_reg>` Is one of:

- `<Rm>_<mode>`, encoded with R==0.
- `ELR_hyp`, encoded with R==0.
- `SPSR_<mode>`, encoded with R==1.

For a full description of the encoding of this field, see *Encoding and use of Banked register transfer instructions* on page F7-2994.

`<Rn>` Is the general-purpose register to be transferred to `<banked_reg>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL0 then
        UNPREDICTABLE;
    else
        mode = PSTATE.M;
        if write_spsr then
            SPSRaccessValid(SYSm, mode);             // Check for UNPREDICTABLE cases
            case SYSm of
                when '01110'  SPSR_fiq = R[n];
                when '10000'  SPSR_irq = R[n];
                when '10010'  SPSR_svc = R[n];
                when '10100'  SPSR_abt = R[n];
                when '10110'  SPSR_und = R[n];
                when '11100'  SPSR_mon = R[n];
                when '11110'  SPSR_hyp = R[n];
        else
            BankedRegisterAccessValid(SYSm, mode);  // Check for UNPREDICTABLE cases

            if SYSm<4:3> == '00' then               // Access the User registers
                m = UInt(SYSm<2:0>) + 8;
                Rmode[m,M32_User] = R[n];
            elsif SYSm<4:3> == '01' then            // Access the FIQ registers
                m = UInt(SYSm<2:0>) + 8;
                Rmode[m,M32_FIQ] = R[n];
            elsif SYSm<4:3> == '11' then
                if SYSm<1> == '0' then              // Access Monitor registers
                    m = 14 - UInt(SYSm<0>);         // LR when SYSm<0> == 0, otherwise SP
                    Rmode[m,M32_Monitor] = R[n];
                else                                // Access Hyp registers
                    if SYSm<0> == '1' then          // ELR_hyp when SYSm<0> == 0, otherwise SP_hyp
                        Rmode[13,M32_Hyp] = R[n];
                    else
                        ELR_hyp = R[n];
            else                                    // Other Banked registers
                bits(5) targetmode;                 // (SYSm<4:3> == '10' case)
                targetmode<0> = SYSm<2> OR SYSm<1>;
                targetmode<1> = '1';
                targetmode<2> = SYSm<2> AND NOT SYSm<1>;
                targetmode<3> = SYSm<2> AND SYSm<1>;
                targetmode<4> = '1';
                if mode == targetmode then
                    UNPREDICTABLE;
                else
                    m = 14 - UInt(SYSm<0>);         // LR when SYSm<0> == 0, otherwise SP
                    Rmode[m,targetmode] = R[n];
```

F7.4.11 MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the CPSR or the SPSR of the current mode.

MSR (immediate) is UNPREDICTABLE if it is attempting to update the CPSR, and that update would change to a mode that is not permitted in the context in which the instruction is executed, see *Restrictions on updates to the CPSR.M field* on page F7-2993.

An MSR (immediate) executed in User mode:

- Is CONSTRAINED UNPREDICTABLE if it attempts to update the SPSR.
- Otherwise, does not update any CPSR field that is accessible only at EL1 or higher,

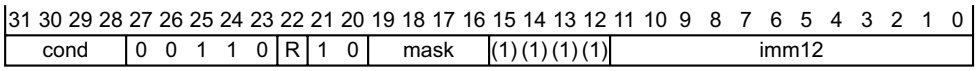
Note

MSR (immediate) on page F7-2653 describes the valid application level uses of the MSR (immediate) instruction.

An MSR (immediate) executed in System mode is CONSTRAINED UNPREDICTABLE if it attempts to update the SPSR.

Encoding A1

```
MSR<c> <spec_reg>, #<const>
```



```
if mask == '0000' && R == '0' then SEE "Related encodings";
imm32 = A32ExpandImm(imm12);  write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *MSR (immediate)* on page AppxA-4838.

Related encodings See *MSR (immediate), and hints* on page F4-2393.

Assembler syntax

```
MSR{<c>}{<q>}  <spec_reg>, #<const>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<spec_reg>` Is one of:

- `APSR_<bits>`.
- `CPSR_<fields>`.
- `SPSR_<fields>`.

ARM recommends the `APSR` forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see *The Application Program Status Register (APSR)* on page E1-2211.

`<const>` The immediate value to be transferred to `<spec_reg>`. See *Modified immediate constants in A32 instructions* on page F4-2387 for the range of values.

`<bits>` Is one of `nzcvq`, `g`, or `nzcvqg`.

In the A and R profiles:

- `APSR_nzcvq` is the same as `CPSR_f` (`mask == '1000'`).
- `APSR_g` is the same as `CPSR_s` (`mask == '0100'`).
- `APSR_nzcvqg` is the same as `CPSR_fs` (`mask == '1100'`).

`<fields>` Is a sequence of one or more of the following:

`c` mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.

`x` mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.

`s` mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.

`f` mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        SPSRWriteByInstr(imm32, mask);
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution State mechanism
        CPSRWriteByInstr(imm32, mask);       // Does not affect execution state bits other than E
```

E bit

The CPSR.E bit is writable from any mode using an `MSR` instruction. ARM deprecates using this to change its value.

F7.4.12 MSR (register)

Move to Special register from general-purpose register moves the value of a general-purpose register to the CPSR or the SPSR of the current mode.

MSR (register) is UNPREDICTABLE if it is attempting to update the CPSR, and that update would change to a mode that is not permitted in the context in which the instruction is executed, see *Restrictions on updates to the CPSR.M field* on page F7-2993.

An MSR (register) executed in User mode:

- Is UNPREDICTABLE if it attempts to update the SPSR.
- Otherwise, does not update any CPSR field that is accessible only at EL1 or higher,

Note

MSR (register) on page F7-2655 describes the valid application level uses of the MSR (register) instruction.

An MSR (register) executed in System mode is UNPREDICTABLE if it attempts to update the SPSR.

Encoding T1

```
MSR<c> <spec_reg>, <Rn>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
n = UInt(Rn);  write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *MSR (register)* on page AppxA-4838.

Assembler syntax

```
MSR{<c>}{<q>}  <spec_reg>, <Rn>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<spec_reg>` Is one of:

- `APSR_<bits>`.
- `CPSR_<fields>`.
- `SPSR_<fields>`.

ARM recommends the `APSR` forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see *The Application Program Status Register (APSR)* on page E1-2211.

`<Rn>` Is the general-purpose register to be transferred to `<spec_reg>`.

`<bits>` Is one of `nzcvq`, `g`, or `nzcvqg`.

In the A profile:

- `APSR_nzcvq` is the same as `CPSR_f` (mask == '1000').
- `APSR_g` is the same as `CPSR_s` (`mask == '0100'`).
- `APSR_nzcvqg` is the same as `CPSR_fs` (`mask == '1100'`).

`<fields>` Is a sequence of one or more of the following:

`c`	mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
`x`	mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
`s`	mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
`f`	mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        SPSRWriteByInstr(R[n], mask);
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution State mechanism
        CPSRWriteByInstr(R[n], mask);        // Does not affect execution state bits other than E
```

E bit

The CPSR.E bit is writable from any mode using an `MSR` instruction. ARM deprecates using this to change its value.

F7.4.13 RFE

Return From Exception loads the PC and the CPSR from the word at the specified address and the following word respectively. For information about memory accesses see *Memory accesses* on page F2-2337.

RFE is:

- UNDEFINED in Hyp mode.
- UNPREDICTABLE in the cases described in *Restrictions on exception return instructions* on page F7-2993.

Note

As identified in *Restrictions on exception return instructions* on page F7-2993, RFE differs from other exception return instructions in that it can be executed in System mode.

Encoding T1

RFEDB<c> <Rn>{!} Outside or last in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
n = UInt(Rn);  wback = (W == '1');  increment = TRUE;  wordhigher = FALSE;
if n == 15 then UNPREDICTABLE;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1

RFE{<amode>} <Rn>{!}

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	0	P	U	0	W	1	Rn				(0)	(0)	(0)	(0)	(1)	(0)	(1)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)

```
n = UInt(Rn);
wback = (W == '1');  increment = (U == '1');  wordhigher = (P == U);
if n == 15 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *RFE* on page AppxA-4839.

Assembler syntax

```
RFE{<amode>}{<c>}{<q>}  <Rn>{!}
```

where:

`<amode>` is one of:

- `DA` Decrement After. A32 instructions only. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0 in encoding A1.
- `DB` Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoding T1, or encoding A1 with P = 1, U = 0.
- `IA` Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoding T2, or encoding A1 with P = 0, U = 1.
- `IB` Increment Before. A32 instructions only. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1 in encoding A1.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `RFE` instruction must be unconditional.

`<Rn>` The base register.

`!` Causes the instruction to write a modified value back to `<Rn>`. If `!` is omitted, the instruction does not change `<Rn>`.

`RFEFA`, `RFEEA`, `RFEFD`, and `RFEED` are pseudo-instructions for `RFEDA`, `RFEDB`, `RFEIA`, and `RFEIB` respectively, referring to their use for popping data from Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elsif PSTATE.EL == EL0 then
        UNPREDICTABLE;                          // UNDEFINED or NOP
    else
        address = if increment then R[n] else R[n]-8;
        if wordhigher then address = address+4;
        new_pc_value = MemA[address,4];
        spsr = MemA[address+4,4];
        if wback then R[n] = if increment then R[n]+8 else R[n]-8;
        AArch32.ExceptionReturn(new_pc_value, spsr);
```

F7.4.14 SMC

Secure Monitor Call causes a Secure Monitor Call exception. For more information see *Secure Monitor Call (SMC) exception* on page G1-3435.

SMC is available only from software executing at EL1 or higher. It is UNDEFINED in User mode.

If HCR.TSC is set to 1, execution of an SMC instruction in a Non-secure EL1 mode generates a Hyp Trap exception, regardless of the value of SCR.SCD. For more information see *Traps to Hyp mode of Non-secure EL1 execution of SMC instructions* on page G1-3491.

Otherwise, when SCR.SCD is set to 1, the SMC instruction is:

- UNDEFINED in Non-secure state.
- UNPREDICTABLE if executed:
  - When EL3 is using AArch32, in a Secure EL3 mode.
  - When EL3 is using AArch32, in a Secure EL1 mode.

Encoding T1

```
SMC<c> #<imm4>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	1	1	1	1	1	1	imm4				1	0	0	0	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)

```
// imm4 is for assembly/disassembly only and is ignored by hardware
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1

```
SMC<c> #<imm4>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	0	1	1	0	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	0	1	1	1	imm4			

```
// imm4 is for assembly/disassembly only and is ignored by hardware
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SMC{<c>}{<q>}  {#}<imm4>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<imm4>` Is a 4-bit immediate value. This is ignored by the PE.

The Secure Monitor Call exception handler (Secure Monitor code) can use this value to determine what service is being requested, but ARM does not recommend this.

The pre-UAL syntax `SMI<c>` is equivalent to `SMC<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();

    if !HaveEL(EL3) || PSTATE.EL == EL0 then
        UNDEFINED;

    AArch32.CheckForSMCTrap();

    if SCR_GEN[].SCD == '1' then
        // SMC disabled
        if IsSecure() then
            // Executes either as a NOP or UNALLOCATED.
            c = ConstrainUnpredictable(Unpredictable_SMD);
            assert c IN {Constraint_NOP, Constraint_UNDEF};
            if c == Constraint_NOP then EndOfInstruction();
        UNDEFINED;
    elsif !ELUsingAArch32(EL3) then
        AArch64.CallSecureMonitor(Zeros(16));
    else
        AArch32.TakeSMCException();
```

F7.4.15 SRS, T32

Store Return State stores the LR and SPSR of the current mode to the stack of a specified mode. For information about memory accesses see *Memory accesses* on page F2-2337.

SRS is:

- UNDEFINED in Hyp mode.
- UNPREDICTABLE if:
  - It is executed in User or System mode.
  - It attempts to store the Monitor mode SP when in Non-secure state.
  - It attempts to store the Hyp mode SP.

Encoding T1

```
SRSDB<c> SP{!}, #<mode>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	0	0	0	W	0	(1)	(1)	(0)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	mode				

```
wback = (W == '1');  increment = FALSE;  wordhigher = FALSE;
```

Encoding T2

```
SRS{IA}<c> SP{!}, #<mode>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	1	1	0	W	0	(1)	(1)	(0)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	mode				

```
wback = (W == '1');  increment = TRUE;  wordhigher = FALSE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *SRS (T32)* on page AppxA-4839.

Assembler syntax

```
SRS{<amode>}{<c>}{<q>}  SP{!}, #<mode>
```

where:

`<amode>` is one of:

- `DB` Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoding T1.
- `IA` Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoding T2.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`!` Causes the instruction to write a modified value back to the base register (encoded as W = 1). If `!` is omitted, the instruction does not change the base register (encoded as W = 0).

`<mode>` The number of the mode whose Banked SP is used as the base register. For details of PE modes and their numbers see *AArch32 PE mode descriptions* on page G1-3378.

`SRSEA` is a pseudo-instruction for `SRSIA`, and `SRSFD` is a pseudo-instruction for `SRSDB`, referring to their use for pushing data onto Empty Ascending and Full Descending stacks.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elsif PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;
    elsif mode == M32_Hyp then        // Check for attempt to access Hyp mode SP
        UNPREDICTABLE;
    elsif !IsSecure() && mode == M32_Monitor then
        // In Non-secure state, check for attempts to access Monitor mode.
        // The definition of UNPREDICTABLE does not permit this to be a security hole.
        UNPREDICTABLE;
    base = Rmode[13,mode];
    address = if increment then base else base-8;
    if wordhigher then address = address+4;
    MemA[address,4]   = LR;
    MemA[address+4,4] = SPSR[];
    if wback then Rmode[13,mode] = if increment then base+8 else base-8;
```

F7.4.16 SRS, A32

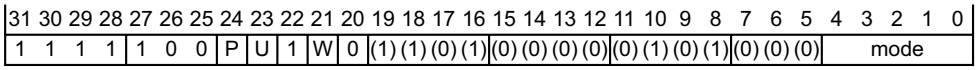
Store Return State stores the LR and SPSR of the current mode to the stack of a specified mode. For information about memory accesses see *Memory accesses* on page F2-2337.

SRS is:

- UNDEFINED in Hyp mode.
- UNPREDICTABLE if:
  - It is executed in User or System mode.
  - It attempts to store the Monitor mode SP when in Non-secure state.
  - If it attempts to store the Hyp mode SP.

Encoding A1

```
SRS{<amode>} SP{!}, #<mode>
```



```
wback = (W == '1');  increment = (U == '1');  wordhigher = (P == U);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *SRS (A32)* on page AppxA-4839.

Assembler syntax

```
SRS{<amode>}{<c>}{<q>}  SP{!}, #<mode>
```

where:

`<amode>` is one of:

- `DA` Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
- `DB` Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
- `IA` Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
- `IB` Increment Before. A32 instructions only. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. In the A32 instruction set, an `SRS` instruction must be unconditional.

`!` Causes the instruction to write a modified value back to the base register (encoded as W = 1). If `!` is omitted, the instruction does not change the base register (encoded as W = 0).

`<mode>` The number of the mode whose Banked SP is used as the base register. For details of PE modes and their numbers see *AArch32 PE mode descriptions* on page G1-3378.

`SRSFA`, `SRSEA`, `SRSFD`, and `SRSED` are pseudo-instructions for `SRSIB`, `SRSIA`, `SRSDB`, and `SRSDA` respectively, referring to their use for pushing data onto Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elsif PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;
    elsif mode == M32_Hyp then        // Check for attempt to access Hyp mode SP
        UNPREDICTABLE;
    elsif !IsSecure() && mode == M32_Monitor then
        // In Non-secure state, check for attempts to access Monitor mode.
        // The definition of UNPREDICTABLE does not permit this to be a security hole.
        UNPREDICTABLE;
    base = Rmode[13,mode];
    address = if increment then base else base-8;
    if wordhigher then address = address+4;
    MemA[address,4]   = LR;
    MemA[address+4,4] = SPSR[];
    if wback then Rmode[13,mode] = if increment then base+8 else base-8;
```

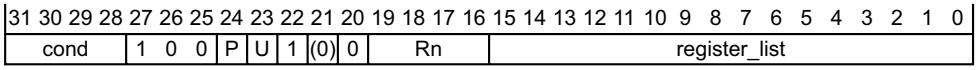
F7.4.17 STM (User registers)

In an EL1 mode other than System mode, Store Multiple (user registers) stores multiple User mode registers to consecutive memory locations using an address from a base register. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

`STM` (User registers) is UNDEFINED in Hyp mode, and CONSTRAINED UNPREDICTABLE in User or System modes.

Encoding A1

```
STM{<amode>}<c> <Rn>, <registers>^
```



```
n = UInt(Rn);  registers = register_list;  increment = (U == '1');  wordhigher = (P == U);
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STM (User registers)* on page AppxA-4840.

Assembler syntax

```
STM{<amode>}{<c>}{<q>}  <Rn>, <registers>^
```

where:

`<amode>` is one of:

- `DA` Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
- `ED` Empty Descending. For this instruction, a synonym for `DA`.
- `DB` Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
- `FD` Full Descending. For this instruction, a synonym for `DB`.
- `IA` Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
- `EA` Empty Ascending. For this instruction, a synonym for `IA`.
- `IB` Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
- `FA` Full Ascending. For this instruction, a synonym for `IB`.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rn>` The base register. This register can be the SP.

`<registers>` Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be stored by the `STM` instruction. The registers are stored with the lowest-numbered register to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC* on page F2-2341.

The pre-UAL syntax `STM<c>{<amode>}` is equivalent to `STM{<amode>}<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elsif PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;
    else
        length = 4*BitCount(registers);
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;
        for i = 0 to 14
            if registers<i> == '1' then  // Store User mode register
                MemA[address,4] = Rmode[i, M32_User];
                address = address + 4;
        if registers<15> == '1' then
            MemA[address,4] = PCStoreValue();
```

F7.4.18 STRBT, STRHT, and STRT

Even in Secure and Non-secure EL1 modes, stores to memory by these instructions are restricted in the same way as unprivilged stores to memory. The `MemA_unpriv[]` and `MemU_unpriv[]` pseudocode functions describe this restriction. For more information see *Alignment support* on page E2-2256.

These instructions are UNPREDICTABLE in Hyp mode.

For descriptions of the instructions see:

- *STRBT* on page F7-2855.
- *STRHT* on page F7-2875.
- *STRT* on page F7-2877.

F7.4.19 SUBS PC, LR and related instructions, T32

The `SUBS PC, LR, #<const>` instruction provides an exception return without the use of the stack. It subtracts the immediate constant from LR, branches to the resulting address, and also copies the SPSR to the CPSR.

Note

- The instruction `SUBS PC, LR, #0` is equivalent to `MOVS PC, LR` and `ERET`.
- For an implementation that includes EL2, `ERET` is the preferred disassembly of the T1 encoding defined in this section. Therefore, a disassembler might report an `ERET` where the original assembler code used `SUBS PC, LR, #0`.

When executing in Hyp mode:

- The encoding for `SUBS PC, LR, #0` is the encoding of the `ERET` instruction, see *ERET* on page F7-3002.
- `SUBS PC, LR, #<const>` with a nonzero constant is UNDEFINED.

`SUBS PC, LR, #<const>` is CONSTRAINED UNPREDICTABLE in the cases described in *Restrictions on exception return instructions* on page F7-2993.

Encoding T1

`SUBS<c> PC, LR, #<imm8>` Outside or last in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	1	0	1	(1)	(1)	(1)	(0)	1	0	(0)	0	(1)	(1)	(1)	(1)	imm8							

```
if IsZero(imm8) then SEE ERET;
if PSTATE.EL == EL2 then UNDEFINED;   // UNDEFINED in Hyp mode when not ERET
n = 14;  imm32 = ZeroExtend(imm8, 32);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *SUBS PC, LR and related instructions (T32)* on page AppxA-4840.

Assembler syntax

```
SUBS{<c>}{<q>}  PC, LR, #<const>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<const>` The immediate constant, in the range 0-255.

In the T32 instruction set, `MOVS{<c>}{<q>} PC, LR` is a pseudo-instruction for `SUBS{<c>}{<q>} PC, LR, #0`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;
    else
        operand2 = imm32;
        (result, -) = AddWithCarry(R[n], NOT(operand2), '1');
    AArch32.ExceptionReturn(result, SPSR[]);
```

F7.4.20 SUBS PC, LR and related instructions, A32

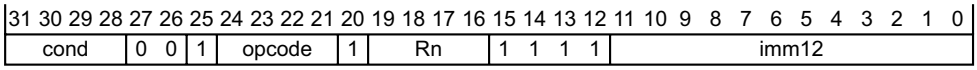
The SUBS PC, LR, #<const> instruction provides an exception return without the use of the stack. It subtracts the immediate constant from LR, branches to the resulting address, and also copies the SPSR to the CPSR. The A32 instruction set contains similar instructions based on other data-processing operations, or with a wider range of operands, or both. ARM deprecates using these other instructions, except for MOVS PC, LR.

All of these instructions are:

- UNDEFINED in Hyp mode.
- CONSTRAINED UNPREDICTABLE in the cases described in *Restrictions on exception return instructions* on page F7-2993.

Encoding A1

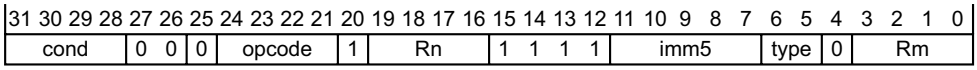
```
<opc1>S<c> PC, <Rn>, #<const>
<opc2>S<c> PC, #<const>
```



```
n = UInt(Rn);  imm32 = A32ExpandImm(imm12);  register_form = FALSE;
```

Encoding A2

```
<opc1>S<c> PC, <Rn>, <Rm>{, <shift>}
<opc2>S<c> PC, <Rm>{, <shift>}
<opc3>S<c> PC, <Rn>, #<const>
RRXS<c> PC, <Rn>
```



```
n = UInt(Rn);  m = UInt(Rm);  register_form = TRUE;
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *SUBS PC. LR and related instructions (A32)* on page AppxA-4840.

Assembler syntax

SUBS{<c>}{<q>} PC, LR, #<const>	Encoding A1
<opc1>S{<c>}{<q>} PC, <Rn>, #<const>	Encoding A1
<opc1>S{<c>}{<q>} PC, <Rn>, <Rm> {, <shift>}	Encoding A2, deprecated
<opc2>S{<c>}{<q>} PC, #<const>	Encoding A1, deprecated
<opc2>S{<c>}{<q>} PC, <Rm> {, <shift>}	Encoding A2
<opc3>S{<c>}{<q>} PC, <Rn>, #<const>	Encoding A2, deprecated
RRXS{<c>}{<q>} PC, <Rn>	Encoding A2, deprecated

where:

<c>, <q> See *Standard assembler syntax fields* on page F2-2330.

<opc1> The operation. <opc1> is one of ADC, ADD, AND, BIC, EOR, ORR, RSB, RSC, SBC, and SUB. ARM deprecates the use of all of these operations except SUB.

<opc2> The operation. <opc2> is MOV or MVN. ARM deprecates the use of MOV.

<opc3> The operation. <opc3> is ASR, LSL, LSR, or ROR. ARM deprecates the use of all of these operations.

`<Rn>` The first operand register. ARM deprecates the use of any register except `LR`.

`<const>` The immediate constant. See *Modified immediate constants in A32 instructions* on page F4-2387 for the range of available values.

`<Rm>` The optionally shifted second or only operand register. ARM deprecates the use of any register except LR.

`<shift>` The shift to apply to the value read from `<Rm>`. If absent, no shift is applied. *Constant shifts* on page F2-2334 describes the shifts and how they are encoded. ARM deprecates the use of `<shift>`.

The required operation, `<opc1>`, `<opc2>`, `<opc3>`, or `RRXS`, is encoded in the opcode field of the instruction, and in some cases in the `imm5` field of encoding T2. For the opcode values for different operations see *Operation*.

The pre-UAL syntax `<opc1><c>S` is equivalent to `<opc1>S<c>`. The pre-UAL syntax `<opc2><c>S` is equivalent to `<opc2>S<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elsif PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;                      // UNDEFINED or NOP
    else
        operand2 = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
        case opcode of
            when '0000'  result = R[n] AND operand2;                                  // AND
            when '0001'  result = R[n] EOR operand2;                                  // EOR
            when '0010'  (result, -) = AddWithCarry(R[n], NOT(operand2), '1');        // SUB
            when '0011'  (result, -) = AddWithCarry(NOT(R[n]), operand2, '1');        // RSB
            when '0100'  (result, -) = AddWithCarry(R[n], operand2, '0');             // ADD
            when '0101'  (result, -) = AddWithCarry(R[n], operand2, PSTATE.C);        // ADC
            when '0110'  (result, -) = AddWithCarry(R[n], NOT(operand2), PSTATE.C);   // SBC
            when '0111'  (result, -) = AddWithCarry(NOT(R[n]), operand2, PSTATE.C);   // RSC
            when '1100'  result = R[n] OR operand2;                                   // ORR
            when '1101'                         // MOV, if NOT(register_form)
                                                // Otherwise, ASR, LSL, LSR, ROR, or RRX, and
                                                // DecodeImmShift() decodes the different shifts
                         result = operand2;
            when '1110'  result = R[n] AND NOT(operand2);                             // BIC
            when '1111'  result = NOT(operand2);                                      // MVN

        AArch32.ExceptionReturn(result, SPSR[]);
```

Chapter F8
T32 and A32 Advanced SIMD and floating-point Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- *Alphabetical list of floating-point and Advanced SIMD instructions* on page F8-3036.
- *Advanced SIMD and floating-point system instructions* on page F8-3358.

Note

Some headings in this chapter use the term *floating-point register*. This is an abbreviated description, and means a register in the Advanced SIMD and floating-point register file.

F8.1 Alphabetical list of floating-point and Advanced SIMD instructions

This section lists every floating-point and Advanced SIMD instruction in the T32 and A32 instruction sets. For details of the format used see *Format of instruction descriptions* on page F2-2326.

This section is formatted so that a full description of an instruction uses either a single page or two facing pages.

F8.1.1 AESD

AES single round decryption.

Encoding T1 Cryptographic Extension

```
AESD.8  <Qd>, <Qm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

    Q[d>>1] = AESMixColumns(Q[m>>1]);
```

F8.1.5 F*, former floating-point instruction mnemonics

Before the introduction of UAL, the floating-point instructions had mnemonics starting with `F`. In UAL, most of these mnemonics are renamed to start with `V`. However, as this section describes, UAL does not define new mnemonics for the `FLDMX` and `FSTMX` instructions.

FLDMX, FSTMX

Encodings T1/A1 of the `VLDM`, `VPOP`, `VPUSH`, and `VSTM` instructions contain an imm8 field that is set to twice the number of doubleword registers to be transferred. ARM deprecates use of these encodings with an odd value in imm8, and there is no UAL syntax for them.

The pre-UAL mnemonics `FLDMX` and `FSTMX` result in the same instructions as `FLDMD` (`VLDM.64` or `VPOP.64`) and `FSTMD` (`VSTM.64` or `VPUSH.64`) respectively, except that imm8 is equal to twice the number of doubleword registers plus one:

- ARM deprecates use of `FLDMX` and `FSTMX`, except for disassembly purposes, and for reassembly of disassembled code.
- If an `FLDMX` or `FSTMX` instruction accesses any register in the range D16-D32, the instruction is UNPREDICTABLE.

F8.1.6 SHA1C

SHA1 hash update (choose).

Encoding T1 Cryptographic Extension

```
SHA1C.32 <Qd>, <Qn>, <Qm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	1	1	0	D	0	0	Vn				Vd				1	1	0	0	N	Q	M	0	Vm			

```
if Q != '1' then UNDEFINED;
if Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1' then UNDEFINED;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
if InITBlock() then UNPREDICTABLE;
```

Encoding A1 Cryptographic Extension

```
SHA1C.32 <Qd>, <Qn>, <Qm>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	0	0	D	0	0	Vn				Vd				1	1	0	0	N	Q	M	0	Vm			

```
if Q != '1' then UNDEFINED;
if Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1' then UNDEFINED;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
SHA1C.32 <Qd>, <Qn>, <Qm>
```

where:

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    X = Q[d>>1];
    Y = Q[n>>1]<31:0>; // Note: 32 bits wide
    W = Q[m>>1];
    for e = 0 to 3

```

F8.1.16 VABA, VABAL

Vector Absolute Difference and Accumulate {Long} subtracts the elements of one vector from the corresponding elements of another vector, and accumulates the absolute values of the results into the elements of the destination vector.

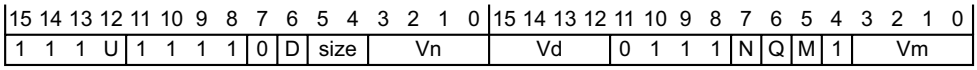
Operand and result elements are either all integers of the same length, or optionally the results can be double the length of the operands.

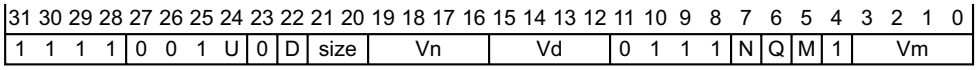
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a floating-point instruction, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VABA<c>.<dt>  <Qd>, <Qn>, <Qm>
VABA<c>.<dt>  <Dd>, <Dn>, <Dm>
```

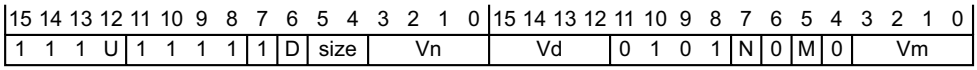


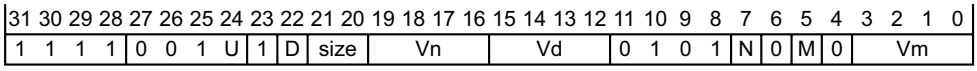


```
if size == '11' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
unsigned = (U == '1');  long_destination = FALSE;
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Encoding T2/A2

```
VABAL<c>.<dt>  <Qd>, <Dn>, <Dm>
```





```
if size == '11' then SEE "Related encodings";
if Vd<0> == '1' then UNDEFINED;
unsigned = (U == '1');  long_destination = TRUE;
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = 1;
```

Related encodings See *Advanced SIMD data-processing instructions* on page F5-2415.

Assembler syntax

`VABA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>`	Encoding T1/A1, Q = 1
`VABA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>`	Encoding T1/A1, Q = 0
`VABAL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>`	Encoding T2/A2

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VABA` or `VABAL` instruction must be unconditional. ARM strongly recommends that a T32 `VABA` or `VABAL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the operands. It must be one of:

- `S8` Encoded as size = `0b00`, U = 0.
- `S16` Encoded as size = `0b01`, U = 0.
- `S32` Encoded as size = `0b10`, U = 0.
- `U8` Encoded as size = `0b00`, U = 1.
- `U16` Encoded as size = `0b01`, U = 1.
- `U32` Encoded as size = `0b10`, U = 1.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

`<Qd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a long operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];
            op2 = Elem[Din[m+r],e,esize];
            absdiff = Abs(Int(op1,unsigned) - Int(op2,unsigned));
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = Elem[Qin[d>>1],e,2*esize] + absdiff;
            else
                Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + absdiff;
```

F8.1.17 VABD, VABDL (integer)

Vector Absolute Difference {Long} (integer) subtracts the elements of one vector from the corresponding elements of another vector, and places the absolute values of the results in the elements of the destination vector.

Operand and result elements are either all integers of the same length, or optionally the results can be double the length of the operands.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a floating-point instruction, see *Conditional execution* on page F2-2331.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

`<Qd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a long operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];
            op2 = Elem[Din[m+r],e,esize];
            absdiff = Abs(Int(op1,unsigned) - Int(op2,unsigned));
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = absdiff<2*esize-1:0>;
            else
                Elem[D[d+r],e,esize] = absdiff<esize-1:0>;
```

F8.1.18 VABD (floating-point)

Vector Absolute Difference (floating-point) subtracts the elements of one vector from the corresponding elements of another vector, and places the absolute values of the results in the elements of the destination vector.

Operand and result elements are all single-precision floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a floating-point instruction, see *Conditional execution* on page F2-2331.

                else
                    result = Abs(SInt(Elem[D[m+r],e,esize]));
                    Elem[D[d+r],e,esize] = result<esize-1:0>;
    else             // VFP instruction
        if dp_operation then
            D[d] = FPAbs(D[m]);
        else
            S[d] = FPAbs(S[m]);
```

F8.1.20 VACGE, VACGT, VACLE, VACLT

VACGE (Vector Absolute Compare Greater Than or Equal) and VACGT (Vector Absolute Compare Greater Than) take the absolute value of each element in a vector, and compare it with the absolute value of the corresponding element of a second vector. If the condition is true, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

VACLE (Vector Absolute Compare Less Than or Equal) is a pseudo-instruction, equivalent to a VACGE instruction with the operands reversed. Disassembly produces the VACGE instruction.

VACLT (Vector Absolute Compare Less Than) is a pseudo-instruction, equivalent to a VACGT instruction with the operands reversed. Disassembly produces the VACGT instruction.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements must be 32-bit floating-point numbers.

The result vector elements are 32-bit fields.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a floating-point instruction, see *Conditional execution* on page F2-2331.

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VADDHN` instruction must be unconditional.ARM strongly recommends that a T32 `VADDHN` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the operands. It must be one of:

- `I16` size = `0b00`.
- `I32` size = `0b01`.
- `I64` size = `0b10`.

`<Dd>, <Qn>, <Qm>` The destination vector, the first operand vector, and the second operand vector.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] + Elem[Qin[m>>1],e,2*esize];
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

F8.1.24 VADDL, VADDW

VADDL (Vector Add Long) adds corresponding elements in two doubleword vectors, and places the results in a quadword vector. Before adding, it sign-extends or zero-extends the elements of both operands.

VADDW (Vector Add Wide) adds corresponding elements in one quadword and one doubleword vector, and places the results in a quadword vector. Before adding, it sign-extends or zero-extends the elements of the doubleword operand.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VADDL<c>.<dt> <Qd>, <Dn>, <Dm>
VADDW<c>.<dt> <Qd>, <Qn>, <Dm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	U	1	1	1	1	1	D	size		Vn				Vd				0	0	0	op	N	0	M	0	Vm

```
if size == '11' then SEE "Related encodings";
if Vd<0> == '1' || (op == '1' && Vn<0> == '1') then UNDEFINED;
unsigned = (U == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;  is_vaddw = (op == '1');
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

Related encodings See *Advanced SIMD data-processing instructions* on page F5-2415.

Assembler syntax

`VADDL{<c>}{<q>}.<dt>  <Qd>, <Dn>, <Dm>`	Encoded as op = 0
`VADDW{<c>}{<q>}.<dt>  {<Qd>,} <Qn>, <Dm>`	Encoded as op = 1

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VADDL` or `VADDW` instruction must be unconditional. ARM strongly recommends that a T32 `VADDL` or `VADDW` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the second operand vector. It must be one of:

`S8`	Encoded as size = `0b00`, U = 0.
`S16`	Encoded as size = `0b01`, U = 0.
`S32`	Encoded as size = `0b10`, U = 0.
`U8`	Encoded as size = `0b00`, U = 1.
`U16`	Encoded as size = `0b01`, U = 1.
`U32`	Encoded as size = `0b10`, U = 1.

`<Qd>` The destination register. If this register is omitted in a `VADDW` instruction, it is the same register as `<Qn>`.

`<Qn>, <Dm>` The first and second operand registers for a `VADDW` instruction.

`<Dn>, <Dm>` The first and second operand registers for a `VADDL` instruction.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        if is_vaddw then
            op1 = Int(Elem[Qin[n>>1],e,2*esize], unsigned);
        else
            op1 = Int(Elem[Din[n],e,esize], unsigned);
        result = op1 + Int(Elem[Din[m],e,esize],unsigned);
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
```

F8.1.25 VAND (immediate)

This is a pseudo-instruction, equivalent to a VBIC (immediate) instruction with the immediate value bitwise inverted. For details see *VBIC (immediate)* on page F8-3072.

F8.1.26 VAND (register)

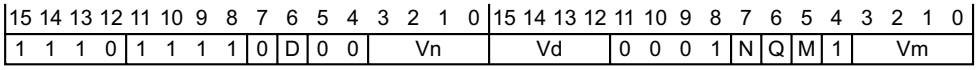
This instruction performs a bitwise AND operation between two registers, and places the result in the destination register.

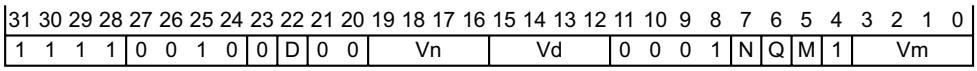
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VAND<c> <Qd>, <Qn>, <Qm>
VAND<c> <Dd>, <Dn>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VAND{<c>}{<q>}{.<dt>}  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VAND{<c>}{<q>}{.<dt>}  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330. An A32 `VAND` instruction must be unconditional. ARM strongly recommends that a T32 `VAND` instruction is unconditional, see *Conditional execution* on page F2-2331.
`<dt>`	An optional data type. It is ignored by assemblers, and does not affect the encoding.
`<Qd>, <Qn>, <Qm>`	The destination vector and the operand vectors, for a quadword operation.
`<Dd>, <Dn>, <Dm>`	The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] AND D[m+r];
```

F8.1.27 VBIC (immediate)

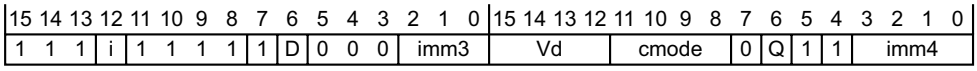
Vector Bitwise Bit Clear (immediate) performs a bitwise AND between a register value and the complement of an immediate value, and returns the result into the destination vector. For the range of constants available, see *One register and a modified immediate value* on page F5-2424.

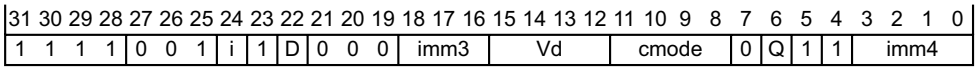
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VBIC<c>.<dt> <Qd>, #<imm>
VBIC<c>.<dt> <Dd>, #<imm>
```





```
if cmode<0> == '0' || cmode<3:2> == '11' then SEE "Related encodings";
if Q == '1' && Vd<0> == '1' then UNDEFINED;
imm64 = AdvSIMDExpandImm('1', cmode, i:imm3:imm4);
d = UInt(D:Vd);  regs = if Q == '0' then 1 else 2;
```

Related encodings See *One register and a modified immediate value* on page F5-2424.

Assembler syntax

`VBIC{<c>}{<q>}.<dt>  {<Qd>,} <Qd>, #<imm>`	Encoded as Q = 1
`VBIC{<c>}{<q>}.<dt>  {<Dd>,} <Dd>, #<imm>>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VBIC` instruction must be unconditional. ARM strongly recommends that a T32 `VBIC` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type used for `<imm>`. It can be either `I16` or `I32`.

`I8`, `I64`, and `F32` are also permitted, but the resulting syntax is a pseudo-instruction.

`<Qd>` The destination vector for a quadword operation.

`<Dd>` The destination vector for a doubleword operation.

`<imm>` A constant of the type specified by `<dt>`. This constant is replicated enough times to fill the destination register. For example, `VBIC.I32 D0, #10` ANDs the complement of `0x0000000A0000000A` with D0, and puts the result into D0.

For details of the range of constants available and the encoding of `<dt>` and `<imm>`, see *One register and a modified immediate value* on page F5-2424.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[d+r] AND NOT(imm64);
```

Pseudo-instructions

`VAND` can be used with a range of constants that are the bitwise inverse of the available constants for `VBIC`. This is assembled as the equivalent `VBIC` instruction. Disassembly produces the `VBIC` form.

One register and a modified immediate value on page F5-2424 describes pseudo-instructions with a combination of `<dt>` and `<imm>` that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.

F8.1.28 VBIC (register)

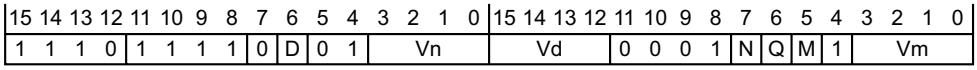
Vector Bitwise Bit Clear (register) performs a bitwise AND between a register value and the complement of a register value, and places the result in the destination register.

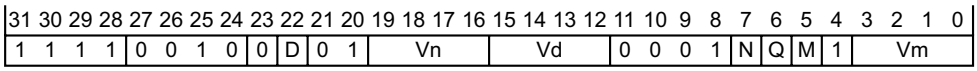
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VBIC<c> <Qd>, <Qn>, <Qm>
VBIC<c> <Dd>, <Dn>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VBIC{<c>}{<q>}{.<dt>}  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VBIC{<c>}{<q>}{.<dt>}  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330. An A32 `VBIC` instruction must be unconditional. ARM strongly recommends that a T32 `VBIC` instruction is unconditional, see *Conditional execution* on page F2-2331.
`<dt>`	An optional data type. It is ignored by assemblers, and does not affect the encoding.
`<Qd>, <Qn>, <Qm>`	The destination vector and the operand vectors, for a quadword operation.
`<Dd>, <Dn>, <Dm>`	The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] AND NOT(D[m+r]);
```

F8.1.29 VBIF, VBIT, VBSL

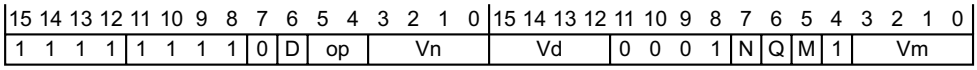
VBIF (Vector Bitwise Insert if False), VBIT (Vector Bitwise Insert if True), and VBSL (Vector Bitwise Select) perform bitwise selection under the control of a mask, and place the results in the destination register. The registers can be either quadword or doubleword, and must all be the same size.

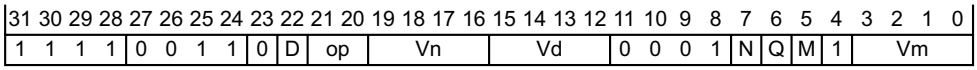
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
V<op><c> <Qd>, <Qn>, <Qm>
V<op><c> <Dd>, <Dn>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if op == '00' then SEE VEOR;
if op == '01' then operation = VBitOps_VBSL;
if op == '10' then operation = VBitOps_VBIT;
if op == '11' then operation = VBitOps_VBIF;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`V<op>{<c>}{<q>}{.<dt>}  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`V<op>{<c>}{<q>}{.<dt>}  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<op>` The operation. It must be one of:

- `BIF` Bitwise Insert if False, encoded as op = `0b11`. Inserts each bit from Vn into Vd if the corresponding bit of Vm is 0, otherwise leaves the Vd bit unchanged.
- `BIT` Bitwise Insert if True, encoded as op = `0b10`. Inserts each bit from Vn into Vd if the corresponding bit of Vm is 1, otherwise leaves the Vd bit unchanged.
- `BSL` Bitwise Select, encoded as op = `0b01`. Selects each bit from Vn into Vd if the corresponding bit of Vd is 1, otherwise selects the bit from Vm.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VBIF`, `VBIT`, or `VBSL` instruction must be unconditional. ARM strongly recommends that a T32 `VBIF`, `VBIT`, or `VBSL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` An optional data type. It is ignored by assemblers, and does not affect the encoding.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
enumeration VBitOps {VBitOps_VBIF, VBitOps_VBIT, VBitOps_VBSL};

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        case operation of
            when VBitOps_VBIF  D[d+r] = (D[d+r] AND D[m+r]) OR (D[n+r] AND NOT(D[m+r]));
            when VBitOps_VBIT  D[d+r] = (D[n+r] AND D[m+r]) OR (D[d+r] AND NOT(D[m+r]));
            when VBitOps_VBSL  D[d+r] = (D[n+r] AND D[d+r]) OR (D[m+r] AND NOT(D[d+r]));
```

F8.1.30 VCEQ (register)

VCEQ (Vector Compare Equal) takes each element in a vector, and compares it with the corresponding element of a second vector. If they are equal, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VCGE{<c>}{<q>}.<dt>  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VCGE{<c>}{<q>}.<dt>  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VCGE` instruction must be unconditional. ARM strongly recommends that a T32 `VCGE` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data types for the elements of the operands. It must be one of:

`S8`	Encoding T1/A1, encoded as size = `0b00`, U = 0.
`S16`	Encoding T1/A1, encoded as size = `0b01`, U = 0.
`S32`	Encoding T1/A1, encoded as size = `0b10`, U = 0.
`U8`	Encoding T1/A1, encoded as size = `0b00`, U = 1.
`U16`	Encoding T1/A1, encoded as size = `0b01`, U = 1.
`U32`	Encoding T1/A1, encoded as size = `0b10`, U = 1.
`F32`	Encoding T2/A2, encoded as sz = 0.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
enumeration VCGEtype {VCGEtype_signed, VCGEtype_unsigned, VCGEtype_fp};

if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[n+r],e,esize];  op2 = Elem[D[m+r],e,esize];
            case type of
                when VCGEtype_signed    test_passed = (SInt(op1) >= SInt(op2));
                when VCGEtype_unsigned  test_passed = (UInt(op1) >= UInt(op2));
                when VCGEtype_fp        test_passed = FPCompareGE(op1, op2, StandardFPSCRValue());
            Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
```

F8.1.33 VCGE (immediate #0)

`VCGE #0` (Vector Compare Greater Than or Equal to Zero) take each element in a vector, and compares it with zero. If it is greater than or equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

                test_passed = (SInt(Elem[D[m+r],e,esize]) >= 0);
            Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
```

F8.1.34 VCGT (register)

VCGT (Vector Compare Greater Than) takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is greater than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

            Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
```

F8.1.41 VCLZ

Vector Count Leading Zeros counts the number of consecutive zeros, starting from the most significant bit, in each element in a vector, and places the results in a second vector.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VCLZ<c>.<dt> <Qd>, <Qm>
VCLZ<c>.<dt> <Dd>, <Dm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	1	D	1	1	size		0	0	Vd				0	1	0	0	1	Q	M	0	Vm

```
if size == '11' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VCLZ{<c>}{<q>}.<dt>  <Qd>, <Qm>`	Encoded as Q = 1
`VCLZ{<c>}{<q>}.<dt>  <Dd>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VCLZ` instruction must be unconditional. ARM strongly recommends that a T32 `VCLZ` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data size for the elements of the operands. It must be one of:

- `I8` Encoded as size = `0b00`.
- `I16` Encoded as size = `0b01`.
- `I32` Encoded as size = `0b10`.

`<Qd>, <Qm>` The destination vector and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = CountLeadingZeroBits(Elem[D[m+r],e,esize])<esize-1:0>;
```

F8.1.42 VCMP, VCMPE

This instruction compares two floating-point registers, or one floating-point register and zero. It writes the result to the FPSCR flags. These are normally transferred to the A32 flags by a subsequent VMRS instruction.

It can optionally raise an Invalid Operation exception if either operand is any type of NaN. It always raises an Invalid Operation exception if either operand is a signaling NaN.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 summarizes these controls.

Encoding T1/A1

```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`VCMP{E}{<c>}{<q>}.F64 <Dd>, <Dm>`	Encoding T1/A1, encoded as sz = 1
`VCMP{E}{<c>}{<q>}.F32 <Sd>, <Sm>`	Encoding T1/A1, encoded as sz = 0
`VCMP{E}{<c>}{<q>}.F64 <Dd>, #0.0`	Encoding T2/A2, encoded as sz = 1
`VCMP{E}{<c>}{<q>}.F32 <Sd>, #0.0`	Encoding T2/A2, encoded as sz = 0

where:

`E` If present, any NaN operand causes an Invalid Operation exception. Encoded as E = 1.
Otherwise, only a signaling NaN causes the exception. Encoded as E = 0.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Dd>, <Dm>` The operand vectors, for a doubleword operation.

`<Sd>, <Sm>` The operand vectors, for a singleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if dp_operation then
        bits(64) op64 = if with_zero then FPZero('0') else D[m];
        FPSCR.<N,Z,C,V> = FPCompare(D[d], op64, quiet_nan_exc, FPSCR);
    else
        bits(32) op32 = if with_zero then FPZero('0') else S[m];
        FPSCR.<N,Z,C,V> = FPCompare(S[d], op32, quiet_nan_exc, FPSCR);
```

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of `<`, `==`, `>` or *unordered*. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This results in the FPSCR flags being set as N=0, Z=0, C=1 and V=1.

`VCMPE` raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for `<`, `<=`, `>`, `>=`, and other predicates that raise an exception when the operands are unordered.

F8.1.43 VCNT

This instruction counts the number of bits that are one in each element in a vector, and places the results in a second vector.

The operand vector elements must be 8-bit fields.

The result vector elements are 8-bit integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```

`VCNT{<c>}{<q>}.8  <Dd>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VCNT` instruction must be unconditional. ARM strongly recommends that a T32 `VCNT` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<Qd>, <Qm>` The destination vector and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = BitCount(Elem[D[m+r],e,esize])<esize-1:0>;
```

F8.1.44 VCVT (between floating-point and integer, Advanced SIMD)

This instruction converts each element in a vector from floating-point to integer, or from integer to floating-point, and places the results in a second vector.

The vector elements must be 32-bit floating-point numbers, or 32-bit integers. Signed and unsigned integers are distinct.

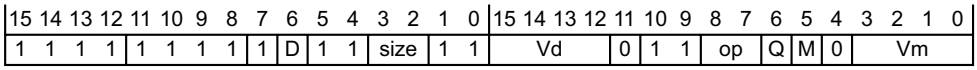
The floating-point to integer operation uses the Round towards Zero rounding mode. The integer to floating-point operation uses the Round to Nearest rounding mode.

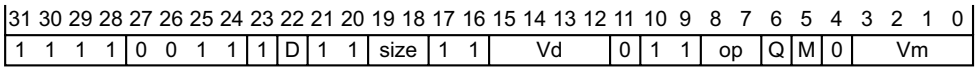
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VCVT<c>.<Td>.<Tm> <Qd>, <Qm>
VCVT<c>.<Td>.<Tm> <Dd>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size != '10' then UNDEFINED;
to_integer = (op<1> == '1');  unsigned = (op<0> == '1');
esize = 32;  elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VCVT{<c>}{<q>}.<Td>.<Tm>  <Qd>, <Qm>`	Encoded as Q = 1
`VCVT{<c>}{<q>}.<Td>.<Tm>  <Dd>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 Advanced SIMD `VCVT` instruction must be unconditional. ARM strongly recommends that a T32 Advanced SIMD `VCVT` instruction is unconditional, see *Conditional execution* on page F2-2331.

`.<Td>.<Tm>` The data types for the elements of the vectors. They must be one of:

- `.S32.F32` Encoded as op = `0b10`, size = `0b10`.
- `.U32.F32` Encoded as op = `0b11`, size = `0b10`.
- `.F32.S32` Encoded as op = `0b00`, size = `0b10`.
- `.F32.U32` Encoded as op = `0b01`, size = `0b10`.

`<Qd>, <Qm>` The destination vector and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    bits(esize) result;
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[m+r],e,esize];
            if to_integer then
                result = FPToFixed(op1, 0, unsigned, StandardFPSCRValue(), FPRounding_ZERO);
            else
                result = FixedToFP(op1, 0, unsigned, StandardFPSCRValue(), FPRounding_TIEEVEN);
            Elem[D[d+r],e,esize] = result;
```

F8.1.45 VCVT, VCVTR (between floating-point and integer, floating-point)

These instructions convert a value in a register from floating-point to a 32-bit integer, or from a 32-bit integer to floating-point, and place the result in a second register.

The floating-point to integer operation normally uses the Round towards Zero rounding mode, but can optionally use the rounding mode specified by the FPSCR. The integer to floating-point operation uses the rounding mode specified by the FPSCR.

VCVT (between floating-point and fixed-point, floating-point) on page F8-3108 describes conversions between floating-point and 16-bit integers.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 summarizes these controls.

Encoding T1/A1

to_fixed = (op == '1');  frac_bits = 64 - UInt(imm6);
unsigned = (U == '1');  esize = 32;  elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Related encodings See *One register and a modified immediate value* on page F5-2424.

Assembler syntax

`VCVT{<c>}{<q>}.<Td>.<Tm>  <Qd>, <Qm>, #<fbits>`	Encoded as Q = 1
`VCVT{<c>}{<q>}.<Td>.<Tm>  <Dd>, <Dm>, #<fbits>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 Advanced SIMD `VCVT` instruction must be unconditional. ARM strongly recommends that a T32 Advanced SIMD `VCVT` instruction is unconditional, see *Conditional execution* on page F2-2331.

`.<Td>.<Tm>` The data types for the elements of the vectors. They must be one of:

- `.S32.F32` Encoded as op = 1, U = 0.
- `.U32.F32` Encoded as op = 1, U = 1.
- `.F32.S32` Encoded as op = 0, U = 0.
- `.F32.U32` Encoded as op = 0, U = 1.

`<Qd>, <Qm>` The destination vector and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector, for a doubleword operation.

`<fbits>` The number of fraction bits in the fixed point number, in the range 1 to 32:

- (64 - `<fbits>`) is encoded in imm6.

An assembler can permit an `<fbits>` value of 0. This is encoded as floating-point to integer or integer to floating-point instruction, see *VCVT (between floating-point and integer, Advanced SIMD)* on page F8-3102.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    bits(esize) result;
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[m+r],e,esize];
            if to_fixed then
                result = FPToFixed(op1, frac_bits, unsigned, StandardFPSCRValue(),
                                   FPRounding_ZERO);
            else
                result = FixedToFP(op1, frac_bits, unsigned, StandardFPSCRValue(),
                                   FPRounding_TIEEVEN);
            Elem[D[d+r],e,esize] = result;
```

F8.1.47 VCVT (between floating-point and fixed-point, floating-point)

This instruction converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point. Software can specify the fixed-point value as either signed or unsigned.

The floating-point value can be single-precision or double-precision.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 summarizes these controls.

Encoding T1/A1

```

`<Dd>` The destination and operand register, for a double-precision operand.

`<Sd>` The destination and operand register, for a single-precision operand.

`<fbits>` The number of fraction bits in the fixed-point number:

- If `<Td>` is `S16` or `U16`, `<fbits>` must be in the range 0-16. (16 - `<fbits>`) is encoded in `[imm4, i]`
- I f `<Td>` is `S32` or `U32`, `<fbits>` must be in the range 1-32. (32 - `<fbits>`) is encoded in `[imm4, i]`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if to_fixed then
        bits(size) result;
        if dp_operation then
            result = FPToFixed(D[d], frac_bits, unsigned, FPSCR, FPRounding_ZERO);
            D[d] = Extend(result, 64, unsigned);
        else
            result = FPToFixed(S[d], frac_bits, unsigned, FPSCR, FPRounding_ZERO);
            S[d] = Extend(result, 32, unsigned);
    else
        if dp_operation then
            D[d] = FixedToFP(D[d]<size-1:0>, frac_bits, unsigned, FPSCR, FPRounding_TIEEVEN);
        else
            S[d] = FixedToFP(S[d]<size-1:0>, frac_bits, unsigned, FPSCR, FPRounding_TIEEVEN);
```

F8.1.48 VCVT (between double-precision and single-precision)

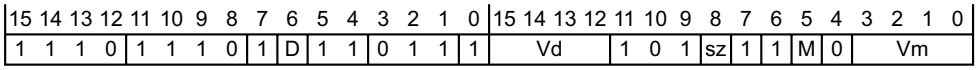
This instruction does one of the following:

- Converts the value in a double-precision register to single-precision and writes the result to a single-precision register.
- Converts the value in a single-precision register to double-precision and writes the result to a double-precision register.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 summarizes these controls.

Encoding T1/A1

```
VCVT<c>.F64.F32 <Dd>, <Sm>
VCVT<c>.F32.F64 <Sd>, <Dm>
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
double_to_single = (sz == '1');
d = if double_to_single then UInt(Vd:D) else UInt(D:Vd);
m = if double_to_single then UInt(M:Vm) else UInt(Vm:M);
```

Assembler syntax

`VCVT{<c>}{<q>}.F64.F32  <Dd>, <Sm>`	Encoded as sz = 0
`VCVT{<c>}{<q>}.F32.F64  <Sd>, <Dm>`	Encoded as sz = 1

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Dd>, <Sm>` The destination register and the operand register, for a single-precision operand.

`<Sd>, <Dm>` The destination register and the operand register, for a double-precision operand.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if double_to_single then
        S[d] = FPConvert(D[m], FPSCR);
    else
        D[d] = FPConvert(S[m], FPSCR);
```

F8.1.49 VCVT (between half-precision and single-precision, Advanced SIMD)

This instruction converts each element in a vector from single-precision to half-precision floating-point or from half-precision to single-precision, and places the results in a second vector.

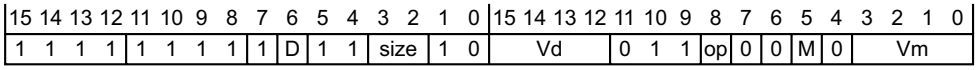
The vector elements must be 32-bit floating-point numbers, or 16-bit floating-point numbers.

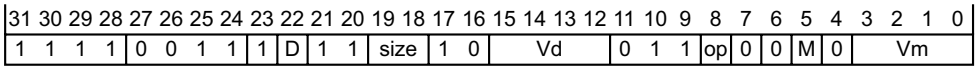
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VCVT<c>.F32.F16 <Qd>, <Dm>
VCVT<c>.F16.F32 <Dd>, <Qm>
```





```
if size != '01' then UNDEFINED;
half_to_single = (op == '1');
if half_to_single && Vd<0> == '1' then UNDEFINED;
if !half_to_single && Vm<0> == '1' then UNDEFINED;
esize = 16;  elements = 4;
m = UInt(M:Vm);  d = UInt(D:Vd);
```

Assembler syntax

`VCVT{<c>}{<q>}.F32.F16  <Qd>, <Dm>`	Encoded as op = 1
`VCVT{<c>}{<q>}.F16.F32  <Dd>, <Qm>`	Encoded as op = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VCVT` instruction must be unconditional. ARM strongly recommends that a T32 `VCVT` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<Qd>, <Dm>` The destination vector and the operand vector for a half-precision to single-precision operation.

`<Dd>, <Qm>` The destination vector and the operand vectors for a single-precision to half-precision operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        if half_to_single then
            Elem[Q[d>>1],e,32] = FPConvert(Elem[Din[m],e,16], StandardFPSCRValue());
        else
            Elem[D[d],e,16] = FPConvert(Elem[Qin[m>>1],e,32], StandardFPSCRValue());
```

F8.1.50 VCVTA, VCVTN, VCVTP, VCVTM (between floating-point and integer, Advanced SIMD)

These instructions convert each element in a vector from floating-point to integer and places the results in a second vector.

The vector elements must be 32-bit floating-point numbers, or 32-bit integers. Signed and unsigned integers are distinct.

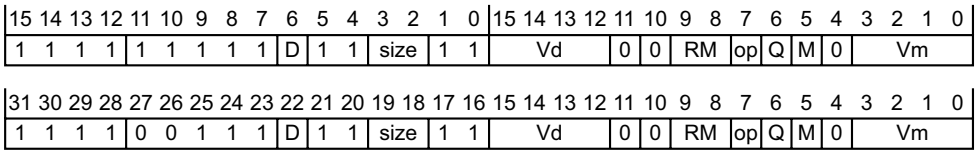
These instructions use the following rounding modes:

- `VCVTA`: Round to Nearest with Ties to Away.
- `VCVTN`: Round to Nearest with Ties to Even.
- `VCVTP`: Round toward +Infinity.
- `VCVTM`: Round toward -Infinity.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 summarizes these controls.

Encoding T1/A1

```
VCVT<r>.S32.F32 <Qd>, <Qm>
VCVT<r>.U32.F32 <Qd>, <Qm>
VCVT<r>.S32.F32 <Dd>, <Dm>
VCVT<r>.U32.F32 <Dd>, <Dm>
```



```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size != '10' then UNDEFINED;
rounding = FPDecodeRM(RM);  unsigned = (op == '1');
esize = 32;  elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
if InITBlock() then UNPREDICTABLE;
```

Assembler syntax

`VCVT<r>{<q>}.<Tm>.F32  <Qd>, <Qm>` Encoded as Q= 1

`VCVT<r>{<q>}.<Tm>.F32  <Dd>, <Dm>` Encoded as Q= 0

where:

`r` Selects the rounding mode. It must be one of:

- `A` Encoded as RM = 00.
- `N` Encoded as RM = 01.
- `P` Encoded as RM = 10.
- `M` Encoded as RM = 11.

`<q>` See *Standard assembler syntax fields* on page F2-2330.

`<Tm>` The data type for the operand. It must be one of:

- `S32` Encoded as op = 0.
- `U32` Encoded as op = 1.

`<Qd>, <Qm>` The destination vector and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector, for a doubleword operation.

Operation

```
EncodingSpecificOperations(); CheckAdvSIMDEnabled();
bits(esize) result;
for r = 0 to regs-1
    for e = 0 to elements-1
        Elem[D[d+r],e,esize] = FPToFixed(Elem[D[m+r],e,esize], 0, unsigned,
                                         StandardFPSCRValue(), rounding);
```

F8.1.51 VCVTA, VCVTN, VCVTP, VCVTM (between floating-point and integer, floating-point)

These instructions convert a value in a register from floating-point to a 32-bit integer, or from a 32-bit integer to floating-point, and place the result in a second register.

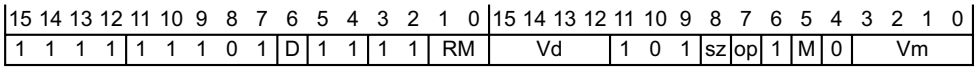
These instructions use the following rounding modes:

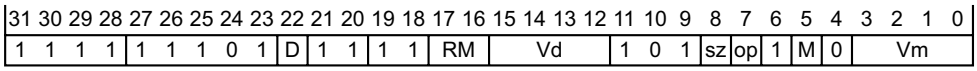
- `VCVTA`: Round to Nearest with Ties to Away.
- `VCVTN`: Round to Nearest with Ties to Even.
- `VCVTP`: Round towards +Infinity.
- `VCVTM`: Round towards -Infinity.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 summarizes these controls.

Encoding T1/A1

```
VCVT<r>.S32.F64 <Sd>, <Dm>
VCVT<r>.S32.F32 <Sd>, <Sm>
VCVT<r>.U32.F64 <Sd>, <Dm>
VCVT<r>.U32.F32 <Sd>, <Sm>
```





```
rounding = FPDecodeRM(RM);  unsigned = (op == '0');  dp_operation = (sz == '1');
d = UInt(Vd:D);  m = if dp_operation then UInt(M:Vm) else UInt(Vm:M);
if InITBlock() then UNPREDICTABLE;
```

Related encodings See *Floating-point data-processing instructions* on page F5-2427.

Assembler syntax

`VCVT<r>{<q>}.<Tm>.F64 <Sd>, <Dm>`	Encoded as sz = 1
`VCVT<r>{<q>}.<Tm>.F32 <Sd>, <Sm>`	Encoded as sz = 0

where:

`r` Selects the rounding mode. It must be one of:

- `A` Encoded as RM = 00.
- `N` Encoded as RM = 01.
- `P` Encoded as RM = 10.
- `M` Encoded as RM = 11.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Tm>` The data type for the operand. It must be one of:

- `S32` Encoded as op = 1.
- `U32` Encoded as op = 0.

`<Sd>, <Dm>` The destination register and the operand register, for a double-precision operand.

`<Sd>, <Sm>` The destination register and the operand register, for a single-precision operand or result.

Operation

```
EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
if dp_operation then
    S[d] = FPToFixed(D[m], 0, unsigned, FPSCR, rounding);
else
    S[d] = FPToFixed(S[m], 0, unsigned, FPSCR, rounding);
```

F8.1.52 VCVTB, VCVTT

Vector Convert Bottom and Vector Convert Top do one of the following:

- Convert the half-precision value in the top or bottom half of a single-precision register to single-precision and write the result to a single-precision or double-precision register.
- Convert the value in a single-precision to half-precision and write the result into the top or bottom half of a single-precision register, preserving the other half of the target register.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 summarizes these controls.

Encoding T1/A1

```

Assembler syntax

`VDIV{<c>}{<q>}.F64 {<Dd>,} <Dn>, <Dm>`	Encoded as sz = 1
`VDIV{<c>}{<q>}.F32 {<Sd>,} <Sn>, <Sm>`	Encoded as sz = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Dd>, <Dn>, <Dm>` The destination register and the operand registers, for a double-precision operation.

`<Sd>, <Sn>, <Sm>` The destination register and the operand registers, for a single-precision operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if dp_operation then
        D[d] = FPDiv(D[n], D[m], FPSCR);
    else
        S[d] = FPDiv(S[n], S[m], FPSCR);
```

F8.1.54 VDUP (scalar)

Vector Duplicate duplicates a scalar into every element of the destination vector.

The scalar, and the destination vector elements, can be any one of 8-bit, 16-bit, or 32-bit fields. There is no distinction between data types.

For more information about scalars see *Advanced SIMD scalars* on page F5-2414.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VDUP<c>.<size>  <Qd>, <Dm[x]>
VDUP<c>.<size>  <Dd>, <Dm[x]>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

case imm4 of
    when “xxx1”  esize = 8;  elements = 8;  index = UInt(imm4<3:1>);
    when “xx10”  esize = 16;  elements = 4;  index = UInt(imm4<3:2>);
    when “x100”  esize = 32;  elements = 2;  index = UInt(imm4<3>);
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == ‘0’ then 1 else 2;
```

Assembler syntax

`VDUP{<c>}{<q>}.<size>  <Qd>, <Dm[x]>`	Encoded as Q = 1
`VDUP{<c>}{<q>}.<size>  <Dd>, <Dm[x]>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VDUP` instruction must be unconditional. ARM strongly recommends that a T32 `VDUP` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as imm4<0> = '1'. imm4<3:1> encodes the index `[x]` of the scalar.
- `16` Encoded as imm4<1:0> = '10'. imm4<3:2> encodes the index `[x]` of the scalar.
- `32` Encoded as imm4<2:0> = '100'. imm4<3> encodes the index `[x]` of the scalar.

`<Qd>` The destination vector for a quadword operation.

`<Dd>` The destination vector for a doubleword operation.

`<Dm[x]>` The scalar. For details of how `[x]` is encoded, see the description of `<size>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    scalar = Elem[D[m],index,esize];
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = scalar;
```

F8.1.55 VDUP (general-purpose register)

This instruction duplicates an element from a general-purpose register into every element of the destination vector.

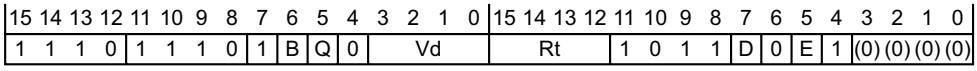
The destination vector elements can be 8-bit, 16-bit, or 32-bit fields. The source element is the least significant 8, 16, or 32 bits of the general-purpose register. There is no distinction between data types.

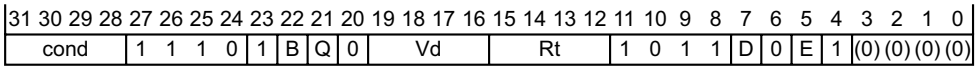
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VDUP<c>.<size>  <Qd>, <Rt>
VDUP<c>.<size>  <Dd>, <Rt>
```





```
if Q == '1' && Vd<0> == '1' then UNDEFINED;
d = UInt(D:Vd);  t = UInt(Rt);  regs = if Q == '0' then 1 else 2;
case B:E of
    when '00'  esize = 32;  elements = 2;
    when '01'  esize = 16;  elements = 4;
    when '10'  esize = 8;   elements = 8;
    when '11'  UNDEFINED;
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`VDUP{<c>}{<q>}.<size> <Qd>, <Rt>`	Encoded as Q = 1
`VDUP{<c>}{<q>}.<size> <Dd>, <Rt>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. ARM strongly recommends that any `VDUP` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size for the elements of the destination vector. It must be one of:

- `8` Encoded as [b, e] = `0b10`.
- `16` Encoded as [b, e] = `0b01`.
- `32` Encoded as [b, e] = `0b00`.

`<Qd>` The destination vector for a quadword operation.

`<Dd>` The destination vector for a doubleword operation.

`<Rt>` The ARM source register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    scalar = R[t]<esize-1:0>;
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = scalar;
```

F8.1.56 VEOR

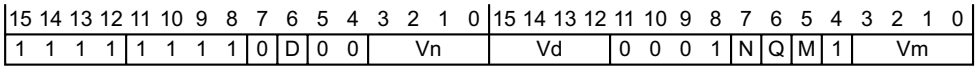
Vector Bitwise Exclusive OR performs a bitwise Exclusive OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

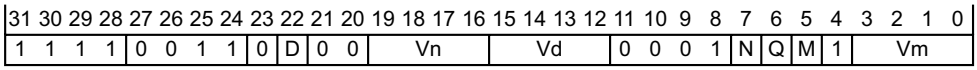
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VEOR<c> <Qd>, <Qn>, <Qm>
VEOR<c> <Dd>, <Dn>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VEOR{<c>}{<q>}{.<dt>}  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VEOR{<c>}{<q>}{.<dt>}  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330. An A32 `VEOR` instruction must be unconditional. ARM strongly recommends that a T32 `VEOR` instruction is unconditional, see *Conditional execution* on page F2-2331.
`<dt>`	An optional data type. It is ignored by assemblers, and does not affect the encoding.
`<Qd>, <Qn>, <Qm>`	The destination vector and the operand vectors, for a quadword operation.
`<Dd>, <Dn>, <Dm>`	The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] EOR D[m+r];
```

F8.1.57 VEXT

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector. See Figure F8-1 for an example.

The elements of the vectors are treated as being 8-bit fields. There is no distinction between data types.

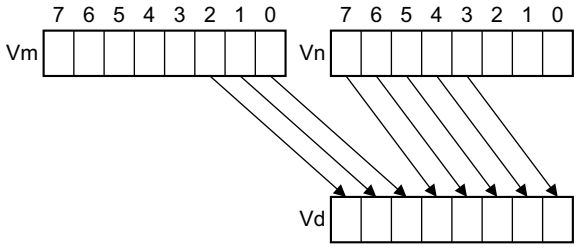


Figure F8-1 VEXT doubleword operation for imm = 3

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VEXT<c>.8 <Qd>, <Qn>, <Qm>, #<imm>
VEXT<c>.8 <Dd>, <Dn>, <Dm>, #<imm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	1	1	1	D	1	1	Vn				Vd				imm4				N	Q	M	0	Vm			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	0	1	D	1	1	Vn				Vd				imm4				N	Q	M	0	Vm			

```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if Q == '0' && imm4<3> == '1' then UNDEFINED;
quadword_operation = (Q == '1');  position = 8 * UInt(imm4);
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

Assembler syntax

```
VEXT{<c>}{<q>}.<size>  {<Qd>,} <Qn>, <Qm>, #<imm>      Encoded as Q = 1
VEXT{<c>}{<q>}.<size>  {<Dd>,} <Dn>, <Dm>, #<imm>      Encoded as Q = 0
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VEXT` instruction must be unconditional. ARM strongly recommends that a T32 `VEXT` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` Size of the operation. The value can be:

- 8, 16, or 32 for doubleword operations.
- 8, 16, 32, or 64 for quadword operations.

If the value is 16, 32, or 64, the syntax is a pseudo-instruction for a `VEXT` instruction specifying the equivalent number of bytes. The following examples show how an assembler treats values greater than 8:

`VEXT.16 D0, D1, #x` is treated as `VEXT.8 D0, D1, #(x*2)`.

`VEXT.32 D0, D1, #x` is treated as `VEXT.8 D0, D1, #(x*4)`.

`VEXT.64 Q0, Q1, #x` is treated as `VEXT.8 Q0, Q1, #(x*8)`.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

`<imm>` The location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0-7 for a doubleword operation or 0-15 for a quadword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    if quadword_operation then
        Q[d>>1] = (Q[m>>1]:Q[n>>1])<position+127:position>;
    else
        D[d] = (D[m]:D[n])<position+63:position>;
```

F8.1.58 VFMA, VFMS

Vector Fused Multiply Accumulate multiplies corresponding elements of two vectors, and accumulates the results into the elements of the destination vector. The instruction does not round the result of the multiply before the accumulation.

Vector Fused Multiply Subtract negates the elements of one vector and multiplies them with the corresponding elements of another vector, adds the products to the corresponding elements of the destination vector, and places the results in the destination vector. The instruction does not round the result of the multiply before the addition.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

- `S` Specifies `VFNMS`, encoded as op = 0.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

`<Sd>, <Sn>, <Sm>` The destination vector and the operand vectors, for a singleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    if dp_operation then
        op64 = if op1_neg then FPNeg(D[n]) else D[n];
        D[d] = FPMulAdd(FPNeg(D[d]), op64, D[m], FPSCR);
    else
        op32 = if op1_neg then FPNeg(S[n]) else S[n];
        S[d] = FPMulAdd(FPNeg(S[d]), op32, S[m], FPSCR);
```

F8.1.60 VHADD, VHSUB

Vector Halving Add adds corresponding elements in two vectors of integers, shifts each result right one bit, and places the final results in the destination vector. The results of the halving operations are truncated (for rounded results see *VRHADD* on page F8-3270).

Vector Halving Subtract subtracts the elements of the second operand from the corresponding elements of the first operand, shifts each result right one bit, and places the final results in the destination vector. The results of the halving operations are truncated (there is no rounding version).

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD1 (multiple single elements)* on page AppxA-4841.

Related encodings See *Advanced SIMD element or structure load/store instructions* on page F5-2431.

Assembler syntax

`VLD1{<c>}{<q>}.<size>  <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VLD1{<c>}{<q>}.<size>  <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VLD1{<c>}{<q>}.<size>  <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VLD1` instruction must be unconditional. ARM strongly recommends that a T32 `VLD1` instruction is unconditional, see *Conditional execution* on page F2-2331.

<size> The data size. It must be one of:

- 8 Encoded as size = 0b00.
- 16 Encoded as size = 0b01.
- 32 Encoded as size = 0b10.
- 64 Encoded as size = 0b11.

<list> The list of registers to load. It must be one of:

- {<Dd>} Encoded as D:Vd = <Dd>, type = 0b0111.
- {<Dd>, <Dd+1>} Encoded as D:Vd = <Dd>, type = 0b1010.
- {<Dd>, <Dd+1>, <Dd+2>} Encoded as D:Vd = <Dd>, type = 0b0110.
- {<Dd>, <Dd+1>, <Dd+2>, <Dd+3>} encoded as D:Vd = <Dd>, type = 0b0010.

<Rn> Contains the base address for the access.

<align> The alignment. It can be one of:

- 64 8-byte alignment, encoded as align = 0b01.
- 128 16-byte alignment, available only if <list> contains two or four registers, encoded as align = 0b10.
- 256 32-byte alignment, available only if <list> contains four registers, encoded as align = 0b11.
- **omitted** Standard alignment, see *Unaligned data access* on page E2-2256. Encoded as align = 0b00.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode* on page F5-2433.

! If present, specifies writeback.

<Rm> Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm>, see *Advanced SIMD addressing mode* on page F5-2433.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 8*regs);
    for r = 0 to regs-1
        for e = 0 to elements-1
            bits(ebytes*8) data;
            if ebytes != 8 then
                data = MemU[address,ebytes];
            else
                data<31:0> = if BigEndian() then MemU[address+4,4] else MemU[address,4];
                data<63:32> = if BigEndian() then MemU[address,4] else MemU[address+4,4];
            Elem[D[d+r],e] = data;
            address = address + ebytes;
```

F8.1.62 VLD1 (single element to one lane)

This instruction loads one element from memory into one element of a register. Elements of the register that are not loaded are unchanged. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VLD1` instruction must be unconditional. ARM strongly recommends that a T32 `VLD1` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<list>` The register containing the element to load. It must be `{<Dd[x]>}`. The register `<Dd>` is encoded in `D:Vd`.

`<Rn>` Contains the base address for the access.

`<align>` The alignment. It can be one of:

- `16` 2-byte alignment, available only if `<size>` is 16.
- `32` 4-byte alignment, available only if `<size>` is 32.
- **omitted** Standard alignment, see *Unaligned data access* on page E2-2256.

: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page F5-2433.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page F5-2433.

Table F8-1 shows the encoding of index and alignment for the different `<size>` values.

Table F8-1 Encoding of index and alignment

	`<size>` == 8	`<size>` == 16	`<size>` == 32
Index	`index_align[3:1]` = x	`index_align[3:2]` = x	`index_align[3]` = x
`<align>` omitted	`index_align[0]` = 0	`index_align[1:0]` = `'00'`	`index_align[2:0]` = `'000'`
`<align>` == 16	-	`index_align[1:0]` = `'01'`	-
`<align>` == 32	-	-	`index_align[2:0]` = `'011'`

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else ebytes);
    Elem[D[d],index] = MemU[address,ebytes];
```

F8.1.63 VLD1 (single element to all lanes)

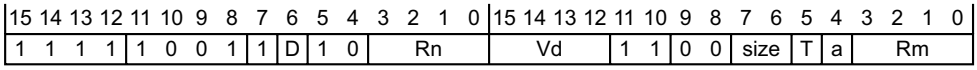
This instruction loads one element from memory into every element of one or two vectors. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

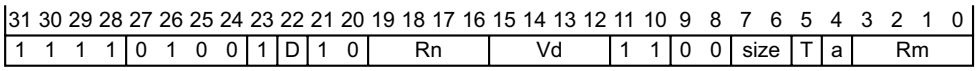
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VLD1<c>.<size> <list>, [<Rn>{:<align>}]{!}
VLD1<c>.<size> <list>, [<Rn>{:<align>}], <Rm>
```





```
if size == '11' || (size == '00' && a == '1') then UNDEFINED;
ebytes = 1 << UInt(size);  regs = if T == '0' then 1 else 2;
alignment = if a == '0' then 1 else ebytes;
d = UInt(D:Vd);  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD1 (single element to all lanes)* on page AppxA-4842.

Assembler syntax

`VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VLD1` instruction must be unconditional. ARM strongly recommends that a T32 `VLD1` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

`8`	Encoded as size = `0b00`.
`16`	Encoded as size = `0b01`.
`32`	Encoded as size = `0b10`.

`<list>` The list of registers to load. It must be one of:

`{<Dd[]>}`	Encoded as D:Vd = `<Dd>`, T = 0.
`{<Dd[]>, <Dd+1[]>}`	Encoded as D:Vd = `<Dd>`, T = 1.

`<Rn>` Contains the base address for the access.

`<align>` The alignment. It can be one of:

`16`	2-byte alignment, available only if `<size>` is 16, encoded as a = 1.
`32`	4-byte alignment, available only if `<size>` is 32, encoded as a = 1.
omitted	Standard alignment, see *Unaligned data access* on page E2-2256. Encoded as a = 0.

: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page F5-2433.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page F5-2433.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else ebytes);
    bits(64) replicated_element = Replicate(MemU[address,ebytes]);
    for r = 0 to regs-1
        D[d+r] = replicated_element;
```

F8.1.64 VLD2 (multiple 2-element structures)

This instruction loads multiple 2-element structures from memory into two or four registers, with de-interleaving. For more information, see *Element and structure load/store instructions* on page F1-2315. Every element of each register is loaded. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VLD2<c>.<size> <list>, [<Rn>{:<align>}]{!}
VLD2<c>.<size> <list>, [<Rn>{:<align>}], <Rm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d2+regs > 32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD2 (multiple 2-element structures)* on page AppxA-4842.

Related encodings See *Advanced SIMD element or structure load/store instructions* on page F5-2431.

Assembler syntax

`VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VLD2` instruction must be unconditional. ARM strongly recommends that a T32 `VLD2` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<list>` The list of registers to load. It must be one of:

- `{<Dd>, <Dd+1>}` Single-spaced registers, encoded as D:Vd = `<Dd>`, type = `0b1000`.
- `{<Dd>, <Dd+2>}` Double-spaced registers, encoded as D:Vd = `<Dd>`, type = `0b1001`.
- `{<Dd>, <Dd+1>, <Dd+2>, <Dd+3>}` Single-spaced registers, encoded as D:Vd = `<Dd>`, type = `0b0011`.

`<Rn>` Contains the base address for the access.

`<align>` The alignment. It can be one of:

- `64` 8-byte alignment, encoded as align = `0b01`.
- `128` 16-byte alignment, encoded as align = `0b10`.
- `256` 32-byte alignment, available only if `<list>` contains four registers. Encoded as align = `0b11`.
- **omitted** Standard alignment, see *Unaligned data access* on page E2-2256. Encoded as align = `0b00`.

: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page F5-2433.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page F5-2433.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 16*regs);
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r], e] = MemU[address,ebytes];
            Elem[D[d2+r],e] = MemU[address+ebytes,ebytes];
            address = address + 2*ebytes;
```

F8.1.65 VLD2 (single 2-element structure to one lane)

This instruction loads one 2-element structure from memory into corresponding elements of two registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD2 (single 2-element structure to one lane)* on page AppxA-4842.

Assembler syntax

`VLD2{<c>}{<q>}.<size>  <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VLD2{<c>}{<q>}.<size>  <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VLD2{<c>}{<q>}.<size>  <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VLD2` instruction must be unconditional. ARM strongly recommends that a T32 `VLD2` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

<list> The registers containing the structure. Encoded with D:Vd = <Dd>. It must be one of:

{<Dd[x]>, <Dd+1[x]>} Single-spaced registers, see Table F8-2.

{<Dd[x]>, <Dd+2[x]>} Double-spaced registers, see Table F8-2.
This is not available if <size> == 8.

<Rn> Contains the base address for the access.

<align> The alignment. It can be one of:

16 2-byte alignment, available only if <size> is 8.

32 4-byte alignment, available only if <size> is 16.

64 8-byte alignment, available only if <size> is 32.

omitted Standard alignment, see *Unaligned data access* on page E2-2256.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode* on page F5-2433.

! If present, specifies writeback.

<Rm> Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm> see *Advanced SIMD addressing mode* on page F5-2433.

Table F8-2 Encoding of index, alignment, and register spacing

	<size> == 8	<size> == 16	<size> == 32
Index	index_align[3:1] = x	index_align[3:2] = x	index_align[3] = x
Single-spacing	-	index_align[1] = 0	index_align[2] = 0

wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d2 > 31 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD2 (single 2-element structure to all lanes)* on page AppxA-4843.

Assembler syntax

`VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VLD2` instruction must be unconditional. ARM strongly recommends that a T32 `VLD2` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

`8`	Encoded as size = `0b00`.
`16`	Encoded as size = `0b01`.
`32`	Encoded as size = `0b10`.

`<list>` The registers containing the structure. It must be one of:

`{<Dd[]>, <Dd+1[]>}`	Single-spaced registers, encoded as D:Vd = `<Dd>`, T = 0.
`{<Dd[]>, <Dd+2[]>}`	Double-spaced registers, encoded as D:Vd = `<Dd>`, T = 1.

`<Rn>` Contains the base address for the access.

`<align>` The alignment. It can be one of:

`16`	2-byte alignment, available only if `<size>` is 8, encoded as a = 1.
`32`	4-byte alignment, available only if `<size>` is 16, encoded as a = 1.
`64`	8-byte alignment, available only if `<size>` is 32, encoded as a = 1.
omitted	Standard alignment, see *Unaligned data access* on page E2-2256. Encoded as a = 0.

: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page F5-2433.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page F5-2433.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 2*ebytes);
    D[d] = Replicate(MemU[address,ebytes]);
    D[d2] = Replicate(MemU[address+ebytes,ebytes]);
```

F8.1.67 VLD3 (multiple 3-element structures)

This instruction loads multiple 3-element structures from memory into three registers, with de-interleaving. For more information, see *Element and structure load/store instructions* on page F1-2315. Every element of each register is loaded. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

if n == 15 || d3 > 31 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD3 (multiple 3-element structures)* on page AppxA-4843.

Related encodings See *Advanced SIMD element or structure load/store instructions* on page F5-2431.

Assembler syntax

`VLD3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VLD3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VLD3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VLD3` instruction must be unconditional. ARM strongly recommends that a T32 `VLD3` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<list>` The list of registers to load. It must be one of:

- `{<Dd>, <Dd+1>, <Dd+2>}` Single-spaced registers, encoded as D:Vd = `<Dd>`, type = `0b0100`.
- `{<Dd>, <Dd+2>, <Dd+4>}` Double-spaced registers, encoded as D:Vd = `<Dd>`, type = `0b0101`.

`<Rn>` Contains the base address for the access.

`<align>` The alignment. It can be:

- `64` 8-byte alignment, encoded as align = `0b01`.
- **omitted** Standard alignment, see *Unaligned data access* on page E2-2256. Encoded as align = `0b00`.

: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page F5-2433.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page F5-2433.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 24);
    for e = 0 to elements-1
        Elem[D[d], e] = MemU[address,ebytes];
        Elem[D[d2],e] = MemU[address+ebytes,ebytes];
        Elem[D[d3],e] = MemU[address+2*ebytes,ebytes];
        address = address + 3*ebytes;
```

F8.1.68 VLD3 (single 3-element structure to one lane)

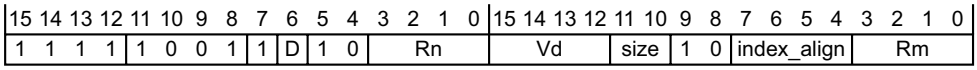
This instruction loads one 3-element structure from memory into corresponding elements of three registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

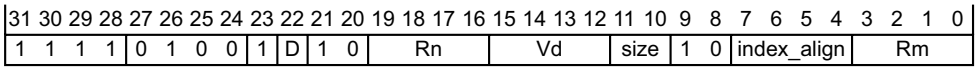
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VLD3<c>.<size> <list>, [<Rn>]{!}
VLD3<c>.<size> <list>, [<Rn>], <Rm>
```





```
if size == '11' then SEE VLD3 (single 3-element structure to all lanes);
case size of
    when '00'
        if index_align<0> != '0' then UNDEFINED;
        ebytes = 1;  index = UInt(index_align<3:1>);  inc = 1;
    when '01'
        if index_align<0> != '0' then UNDEFINED;
        ebytes = 2;  index = UInt(index_align<3:2>);
        inc = if index_align<1> == '0' then 1 else 2;
    when '10'
        if index_align<1:0> != '00' then UNDEFINED;
        ebytes = 4;  index = UInt(index_align<3>);
        inc = if index_align<2> == '0' then 1 else 2;
d = UInt(D:Vd);  d2 = d + inc;  d3 = d2 + inc;  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD3 (single 3-element structure to one lane)* on page AppxA-4844.

Assembler syntax

`VLD3{<c>}{<q>}.<size> <list>, [<Rn>]`	Encoded as Rm = `0b1111`
`VLD3{<c>}{<q>}.<size> <list>, [<Rn>]!`	Encoded as Rm = `0b1101`
`VLD3{<c>}{<q>}.<size> <list>, [<Rn>], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VLD3` instruction must be unconditional. ARM strongly recommends that a T32 `VLD3` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<list>` The registers containing the structure. Encoded with D:Vd = `<Dd>`. It must be one of:

- `{<Dd[x]>, <Dd+1[x]>, <Dd+2[x]>}` Single-spaced registers, see Table F8-3.
- `{<Dd[x]>, <Dd+2[x]>, <Dd+4[x]>}` Double-spaced registers, see Table F8-3. This is not available if `<size>` == 8.

`<Rn>` Contains the base address for the access.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page F5-2433.

Table F8-3 Encoding of index and register spacing

	`<size>` == 8	`<size>` == 16	`<size>` == 32
Index	`index_align[3:1]` = x	`index_align[3:2]` = x	`index_align[3]` = x
Single-spacing	`index_align[0]` = 0	`index_align[1:0]` = '00'	`index_align[2:0]` = '000'
Double-spacing	-	`index_align[1:0]` = '10'	`index_align[2:0]` = '100'

Alignment

Standard alignment rules apply, see *Alignment support* on page E2-2256.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];
    if wback then R[n] = R[n] + (if register_index then R[m] else 3*ebytes);
    Elem[D[d], index] = MemU[address,ebytes];
    Elem[D[d2],index] = MemU[address+ebytes,ebytes];
    Elem[D[d3],index] = MemU[address+2*ebytes,ebytes];
```

F8.1.69 VLD3 (single 3-element structure to all lanes)

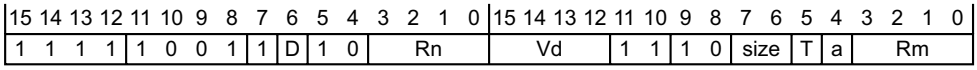
This instruction loads one 3-element structure from memory into all lanes of three registers. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

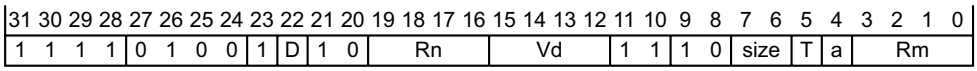
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VLD3<c>.<size> <list>, [<Rn>]{!}
VLD3<c>.<size> <list>, [<Rn>], <Rm>
```





```
if size == '11' || a == '1' then UNDEFINED;
ebytes = 1 << UInt(size);
inc = if T == '0' then 1 else 2;
d = UInt(D:Vd);  d2 = d + inc;  d3 = d2 + inc;  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD3 (single 3-element structure to all lanes)* on page AppxA-4844.

Assembler syntax

`VLD3{<c>}{<q>}.<size> <list>, [<Rn>]`	Encoded as Rm = `0b1111`
`VLD3{<c>}{<q>}.<size> <list>, [<Rn>]!`	Encoded as Rm = `0b1101`
`VLD3{<c>}{<q>}.<size> <list>, [<Rn>], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VLD3` instruction must be unconditional. ARM strongly recommends that a T32 `VLD3` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<list>` The registers containing the structures. It must be one of:

- `{<Dd[]>, <Dd+1[]>, <Dd+2[]>}` Single-spaced registers, encoded as D:Vd = `<Dd>`, T = 0.
- `{<Dd[]>, <Dd+2[]>, <Dd+4[]>}` Double-spaced registers, encoded as D:Vd = `<Dd>`, T = 1.

`<Rn>` Contains the base address for the access.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page F5-2433.

Alignment

Standard alignment rules apply, see *Alignment support* on page E2-2256.

The a bit must be encoded as 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];
    if wback then R[n] = R[n] + (if register_index then R[m] else 3*ebytes);
    D[d] = Replicate(MemU[address,ebytes]);
    D[d2] = Replicate(MemU[address+ebytes,ebytes]);
    D[d3] = Replicate(MemU[address+2*ebytes,ebytes]);
```

F8.1.70 VLD4 (multiple 4-element structures)

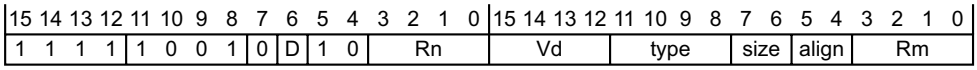
This instruction loads multiple 4-element structures from memory into four registers, with de-interleaving. For more information, see *Element and structure load/store instructions* on page F1-2315. Every element of each register is loaded. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VLD4<c>.<size> <list>, [<Rn>{:<align>}]{!}
VLD4<c>.<size> <list>, [<Rn>{:<align>}], <Rm>
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

`VLD4{<c>}{<q>}.<size> <list>, [<Rn>{ :<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VLD4` instruction must be unconditional. ARM strongly recommends that a T32 `VLD4` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`, or `0b11` for 16-byte alignment.

`<list>` The registers containing the structures. It must be one of:

- `{<Dd[]>, <Dd+1[]>, <Dd+2[]>, <Dd+3[]>}` Single-spaced registers, encoded as D:Vd = `<Dd>`, T = 0.
- `{<Dd[]>, <Dd+2[]>, <Dd+4[]>, <Dd+6[]>}` Double-spaced registers, encoded as D:Vd = `<Dd>`, T = 1.

`<Rn>` The base address for the access.

`<align>` The alignment. It can be one of:

- `32` 4-byte alignment, available only if `<size>` is 8, encoded as a = 1.
- `64` 8-byte alignment, available only if `<size>` is 16 or 32, encoded as a = 1.
- `128` 16-byte alignment, available only if `<size>` is 32, encoded as a = 1, size = `0b11`.
- **omitted** Standard alignment, see *Unaligned data access* on page E2-2256. Encoded as a = 0.

: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page F5-2433.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page F5-2433.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 4*ebytes);
    D[d] = Replicate(MemU[address,ebytes]);
    D[d2] = Replicate(MemU[address+ebytes,ebytes]);
    D[d3] = Replicate(MemU[address+2*ebytes,ebytes]);
    D[d4] = Replicate(MemU[address+3*ebytes,ebytes]);
```

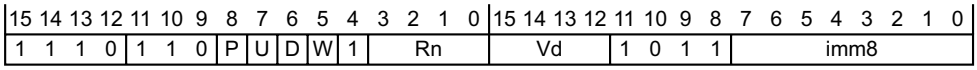
F8.1.73 VLDM

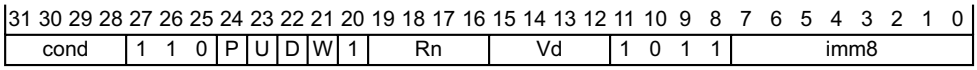
Vector Load Multiple loads multiple registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 summarizes these controls.

Encoding T1/A1

`VLDM{mode}<c> <Rn>{!}, <list>` — `<list>` is consecutive 64-bit registers

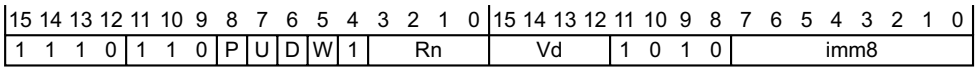


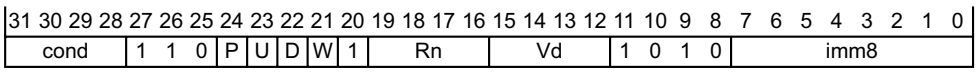


```
if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '0' && U == '1' && W == '1' && Rn == '1101' then SEE VPOP;
if P == '1' && W == '0' then SEE VLDR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE;  add = (U == '1');  wback = (W == '1');
d = UInt(D:Vd);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2;  // If UInt(imm8) is odd, see "FLDMX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
```

Encoding T2/A2

`VLDM{mode}<c> <Rn>{!}, <list>` — `<list>` is consecutive 32-bit registers





```
if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '0' && U == '1' && W == '1' && Rn == '1101' then SEE VPOP;
if P == '1' && W == '0' then SEE VLDR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = TRUE;  add = (U == '1');  wback = (W == '1');  d = UInt(Vd:D);  n = UInt(Rn);
imm32 = ZeroExtend(imm8:'00', 32);  regs = UInt(imm8);
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLDM* on page AppxA-4845.

Related encodings See *64-bit transfers accessing the SIMD and floating-point register file* on page F5-2435.

FLDMX Encoding T1/A1 behaves as described by the pseudocode if imm8 is odd. However, there is no UAL syntax for such encodings and ARM deprecates their use. For more information, see *FLDMX, FSTMX* on page F8-3040.

Assembler syntax

```
VLDM{<mode>}{<c>}{<q>}{.<size>}  <Rn>{!}, <list>
```

where:

`<mode>` The addressing mode:

- `IA` Increment After. The consecutive addresses start at the address specified in `<Rn>`. This is the default and can be omitted. Encoded as P = 0, U = 1.
- `DB` Decrement Before. The consecutive addresses end just before the address specified in `<Rn>`. Encoded as P = 1, U = 0.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<size>` An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers in `<list>`.

`<Rn>` The base register. The SP can be used. In the A32 instruction set, if `!` is not specified the PC can be used.

`!` Causes the instruction to write a modified value back to `<Rn>`. This is required if `<mode>` == `DB`, and is optional if `<mode>` == `IA`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<list>` The registers to be loaded from the Advanced SIMD and floating-point register file, as a list of consecutively numbered doubleword (encoding T1/A1) or singleword (encoding T2/A2) registers, separated by commas and surrounded by brackets. It is encoded in the instruction by setting D and Vd to specify the first register in the list, and imm8 to twice the number of registers in the list (encoding T1/A1) or the number of registers in the list (encoding T2/A2). `<list>` must contain at least one register. If it contains doubleword registers it must not contain more than 16 registers.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            S[d+r] = MemA[address,4];  address = address+4;
        else
            word1 = MemA[address,4];  word2 = MemA[address+4,4];  address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian() then word1:word2 else word2:word1;
```

F8.1.74 VLDR

This instruction loads a single register from the Advanced SIMD and floating-point register file, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

```

Assembler syntax

`VLDR{<c>}{<q>}{.64}  <Dd>, [<Rn> {, #+/-<imm>}]`	Encoding T1/A1, immediate form
`VLDR{<c>}{<q>}{.64}  <Dd>, <label>`	Encoding T1/A1, normal literal form
`VLDR{<c>}{<q>}{.64}  <Dd>, [PC, #+/-<imm>]`	Encoding T1/A1, alternative literal form
`VLDR{<c>}{<q>}{.32}  <Sd>, [<Rn> {, #+/-<imm>}]`	Encoding T2/A2, immediate form
`VLDR{<c>}{<q>}{.32}  <Sd>, <label>`	Encoding T2/A2, normal literal form
`VLDR{<c>}{<q>}{.32}  <Sd>, [PC, #+/-<imm>]`	Encoding T2/A2, alternative literal form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`.32, .64` Optional data size specifiers.

`<Dd>` The destination register for a doubleword load.

`<Sd>` The destination register for a singleword load.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. For the immediate forms of the syntax, `<imm>` can be omitted, in which case the #0 form of the instruction is assembled. Permitted values are multiples of 4 in the range 0 to 1020.

`<label>` The label of the literal data item to be loaded. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values are multiples of 4 in the range -1020 to 1020.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

For the literal forms of the instruction, the base register is encoded as `0b1111` to indicate that the PC is the base register.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page F1-2297.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    if single_reg then
        S[d] = MemA[address,4];
    else
        word1 = MemA[address,4];  word2 = MemA[address+4,4];
        // Combine the word-aligned words in the correct order for current endianness.
        D[d] = if BigEndian() then word1:word2 else word2:word1;
```

F8.1.75 VMAX, VMIN (integer)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

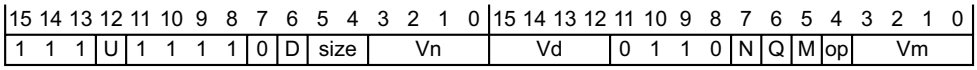
The result vector elements are the same size as the operand vector elements.

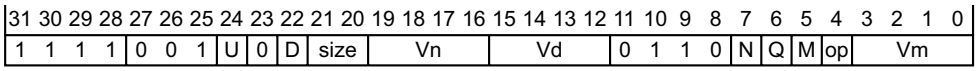
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
V<op><c>.<dt> <Qd>, <Qn>, <Qm>
V<op><c>.<dt> <Dd>, <Dn>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size == '11' then UNDEFINED;
maximum = (op == '0');  unsigned = (U == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`V<op>{<c>}{<q>}.<dt> {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`V<op>{<c>}{<q>}.<dt> {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<op>` The operation. It must be one of:

- `MAX` Encoded as op = 0.
- `MIN` Encoded as op = 1.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VMAX` or `VMIN` instruction must be unconditional. ARM strongly recommends that a T32 `VMAX` or `VMIN` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data types for the elements of the vectors. It must be one of:

- `S8` Encoded as size = `0b00`, U = 0.
- `S16` Encoded as size = `0b01`, U = 0.
- `S32` Encoded as size = `0b10`, U = 0.
- `U8` Encoded as size = `0b00`, U = 1.
- `U16` Encoded as size = `0b01`, U = 1.
- `U32` Encoded as size = `0b10`, U = 1.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Int(Elem[D[n+r],e,esize], unsigned);
            op2 = Int(Elem[D[m+r],e,esize], unsigned);
            result = if maximum then Max(op1,op2) else Min(op1,op2);
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

F8.1.76 VMAX, VMIN (floating-point)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements are 32-bit floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```

Assembler syntax

`V<op>{<c>}{<q>}.F32 {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`V<op>{<c>}{<q>}.F32 {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<op>` The operation. It must be one of:

- `MAX` Encoded as op = 0.
- `MIN` Encoded as op = 1.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VMAX` or `VMIN` instruction must be unconditional. ARM strongly recommends that a T32 `VMAX` or `VMIN` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[n+r],e,esize];  op2 = Elem[D[m+r],e,esize];
            if maximum then
                Elem[D[d+r],e,esize] = FPMax(op1, op2, StandardFPSCRValue());
            else
                Elem[D[d+r],e,esize] = FPMin(op1, op2, StandardFPSCRValue());
```

Floating-point maximum and minimum

- max(+0.0, –0.0) = +0.0
- min(+0.0, –0.0) = –0.0
- If any input is a NaN, the corresponding result element is the default NaN.

F8.1.77 VMAXNM, VMINNM

These instructions determine the floating-point maximum number and floating point minimum number accordingly.

They handle NaNs in consistence with the IEEE754-2008 specification. They return the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point `VMAX` and `VMIN`.

These instructions are not conditional.

```

F8.1.78 VMLA, VMLAL, VMLS, VMLSL (integer)

Vector Multiply Accumulate and Vector Multiply Subtract multiply corresponding elements in two vectors, and either add the products to, or subtract them from, the corresponding elements of the destination vector. Vector Multiply Accumulate Long and Vector Multiply Subtract Long do the same thing, but with destination vector elements that are twice as long as the elements that are multiplied.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Assembler syntax

`V<op>{<c>}{<q>}.<type><size>  <Qd>, <Qn>, <Qm>`	Encoding T1/A1, encoded as Q = 1
`V<op>{<c>}{<q>}.<type><size>  <Dd>, <Dn>, <Dm>`	Encoding T1/A1, encoded as Q = 0
`V<op>L{<c>}{<q>}.<type><size>  <Qd>, <Dn>, <Dm>`	Encoding T2/A2

where:

`<op>` The operation. It must be one of:

- `MLA` Vector Multiply Accumulate. Encoded as op = 0.
- `MLS` Vector Multiply Subtract. Encoded as op = 1.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 Advanced SIMD `VMLA`, `VMLAL`, `VMLS`, or `VMLSL` instruction must be unconditional. ARM strongly recommends that a T32 Advanced SIMD `VMLA`, `VMLAL`, `VMLS`, or `VMLSL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<type>` The data type for the elements of the operands. It must be one of:

- `S` Optional in encoding T1/A1. Encoded as U = 0 in encoding T2/A2.
- `U` Optional in encoding T1/A1. Encoded as U = 1 in encoding T2/A2.
- `I` Available only in encoding T1/A1.

`<size>` The data size for the elements of the operands. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

`<Qd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a long operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            product = Int(Elem[Din[n+r],e,esize],unsigned) * Int(Elem[Din[m+r],e,esize],unsigned);
            addend = if add then product else -product;
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = Elem[Qin[d>>1],e,2*esize] + addend;
            else
                Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + addend;
```

F8.1.79 VMLA, VMLS (floating-point)

Vector Multiply Accumulate multiplies corresponding elements in two vectors, and accumulates the results into the elements of the destination vector.

Vector Multiply Subtract multiplies corresponding elements in two vectors, subtracts the products from corresponding elements of the destination vector, and places the results in the destination vector.

Note

ARM recommends that software does not use the `VMLS` instruction in the *Round towards Plus Infinity* and *Round towards Minus Infinity* rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Assembler syntax

`VMOV{<c>}{<q>}.<dt>  <Qd>, #<imm>`	Encoding T1/A1, encoded as Q = 1
`VMOV{<c>}{<q>}.<dt>  <Dd>, #<imm>`	Encoding T1/A1, encoded as Q = 0
`VMOV{<c>}{<q>}.F64  <Dd>, #<imm>`	Encoding T2/A2, encoded as sz = 1
`VMOV{<c>}{<q>}.F32  <Sd>, #<imm>`	Encoding T2/A2, encoded as sz = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 Advanced SIMD `VMOV` (immediate) instruction must be unconditional. ARM strongly recommends that a T32 Advanced SIMD `VMOV` (immediate) instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type. It must be one of `I8`, `I16`, `I32`, `I64`, or `F32`.

`<Qd>` The destination register for a quadword operation.

`<Dd>` The destination register for a doubleword operation.

`<Sd>` The destination register for a singleword operation.

`<imm>` A constant of the type specified by `<dt>`. This constant is replicated enough times to fill the destination register. For example, `VMOV.I32 D0, #10` writes `0x0000000A0000000A` to D0.

For the range of constants available, and the encoding of `<dt>` and `<imm>`, see:

- *One register and a modified immediate value* on page F5-2424 for encoding T1/A1
- *Floating-point data-processing instructions* on page F5-2427 for encoding T2/A2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
    if single_register then
        S[d] = imm32;
    else
        for r = 0 to regs-1
            D[d+r] = imm64;
```

Pseudo-instructions

One register and a modified immediate value on page F5-2424 describes pseudo-instructions with a combination of `<dt>` and `<imm>` that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.

F8.1.82 VMOV (register)

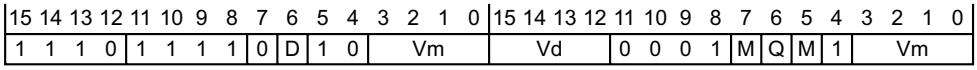
This instruction copies the contents of one register to another.

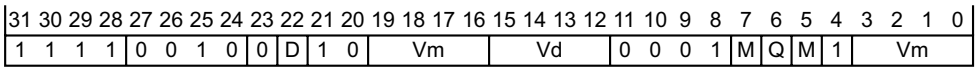
Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VMOV<c> <Qd>, <Qm>
VMOV<c> <Dd>, <Dm>
```

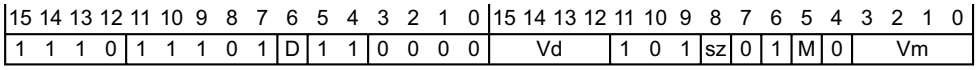


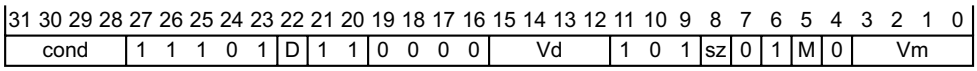


```
if !Consistent(M) || !Consistent(Vm) then SEE VORR (register);
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
single_register = FALSE;  advsimd = TRUE;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Encoding T2/A2

```
VMOV<c>.F64 <Dd>, <Dm>
VMOV<c>.F32 <Sd>, <Sm>
```





```
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
single_register = (sz == '0');  advsimd = FALSE;
if single_register then
    d = UInt(Vd:D);  m = UInt(Vm:M);
else
    d = UInt(D:Vd);  m = UInt(M:Vm);  regs = 1;
```

Assembler syntax

`VMOV{<c>}{<q>}{.<dt>}  <Qd>, <Qm>`	Encoding T1/A1, encoded as Q = 1
`VMOV{<c>}{<q>}{.<dt>}  <Dd>, <Dm>`	Encoding T1/A1, encoded as Q = 0
`VMOV{<c>}{<q>}.F64  <Dd>, <Dm>`	Encoding T2/A2, encoded as sz = 1
`VMOV{<c>}{<q>}.F32  <Sd>, <Sm>`	Encoding T2/A2, encoded as sz = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 Advanced SIMD `VMOV` (register) instruction must be unconditional. ARM strongly recommends that a T32 Advanced SIMD `VMOV` (register) instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` An optional data type. `<dt>` must not be `F64`, but it is otherwise ignored.

`<Qd>, <Qm>` The destination register and the source register, for a quadword operation.

`<Dd>, <Dm>` The destination register and the source register, for a doubleword operation.

`<Sd>, <Sm>` The destination register and the source register, for a singleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
    if single_register then
        S[d] = S[m];
    else
        for r = 0 to regs-1
            D[d+r] = D[m+r];
```

F8.1.83 VMOV (general-purpose register to scalar)

This instruction copies a byte, halfword, or word from a general-purpose register into an Advanced SIMD scalar.

On a Floating-point-only system, this instruction transfers one word to the upper or lower half of a double-precision floating-point register from a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see *Advanced SIMD scalars* on page F5-2414.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

Encoding T1/A1

```
VMOV<c>.<size> <Dd[x]>, <Rt>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

    when “1xxx”  advsimd = TRUE;  esize = 8;  index = UInt(opc1<0>:opc2);
    when “0xx1”  advsimd = TRUE;  esize = 16;  index = UInt(opc1<0>:opc2<1>);
    when “0x00”  advsimd = FALSE;  esize = 32;  index = UInt(opc1<0>);
    when “0x10”  UNDEFINED;
d = UInt(D:Vd);  t = UInt(Rt);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
VMOV{<c>}{<q>}{.<size>}  <Dd[x]>, <Rt>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<size>` The data size. It must be one of:

`8`	Encoded as `opc1<1>` = 1. `[x]` is encoded in `opc1<0>`, `opc2`.
`16`	Encoded as `opc1<1>` = 0, `opc2<0>` = 1. `[x]` is encoded in `opc1<0>`, `opc2<1>`.
`32`	Encoded as `opc1<1>` = 0, `opc2` = `0b00`. `[x]` is encoded in `opc1<0>`.
omitted	Equivalent to `32`.

`<Dd[x]>` The scalar. The register `<Dd>` is encoded in D:Vd. For details of how `[x]` is encoded, see the description of `<size>`.

`<Rt>` The source general-purpose register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
    Elem[D[d],index,esize] = R[t]<esize-1:0>;
```

F8.1.84 VMOV (scalar to general-purpose register)

This instruction copies a byte, halfword, or word from an Advanced SIMD scalar to a general-purpose register. Bytes and halfwords can be either zero-extended or sign-extended.

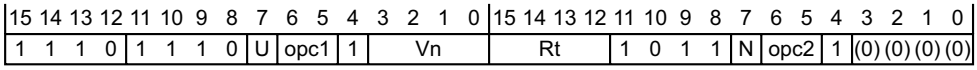
On a floating-point-only system, this instruction transfers one word from the upper or lower half of a double-precision floating-point register to a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see *Advanced SIMD scalars* on page F5-2414.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

Encoding T1/A1

```
VMOV<c>.<dt> <Rt>, <Dn[x]>
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

    when “x0x10”  UNDEFINED;
t = UInt(Rt);  n = UInt(N:Vn);  unsigned = (U == ‘1’);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
VMOV{<c>}{<q>}{.<dt>}  <Rt>, <Dn[x]>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<dt>` The data type. It must be one of:

`S8`	Encoded as U = 0, `opc1<1>` = 1. `[x]` is encoded in `opc1<0>`, `opc2`.
`S16`	Encoded as U = 0, `opc1<1>` = 0, `opc2<0>` = 1. `[x]` is encoded in `opc1<0>`, `opc2<1>`.
`U8`	Encoded as U = 1, `opc1<1>` = 1. `[x]` is encoded in `opc1<0>`, `opc2`.
`U16`	Encoded as U = 1, `opc1<1>` = 0, `opc2<0>` = 1. `[x]` is encoded in `opc1<0>`, `opc2<1>`.
`32`	Encoded as U = 0, `opc1<1>` = 0, `opc2` = `0b00`. `[x]` is encoded in `opc1<0>`.
omitted	Equivalent to `32`.

`<Dn[x]>` The scalar. For details of how `[x]` is encoded see the description of `<dt>`.

`<Rt>` The destination general-purpose register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
    if unsigned then
        R[t] = ZeroExtend(Elem[D[n],index,esize], 32);
    else
        R[t] = SignExtend(Elem[D[n],index,esize], 32);
```

F8.1.85 VMOV (between general-purpose register and single-precision register)

This instruction transfers the contents of a single-precision Floating-point register to a general-purpose register, or the contents of a general-purpose register to a single-precision Floating-point register.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 summarizes these controls.

Encoding T1/A1

```
VMOV<c> <Sn>, <Rt>
VMOV<c> <Rt>, <Sn>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	1	1	0	0	0	0	op	Vn				Rt				1	0	1	0	N	(0)	(0)	1	(0)	(0)	(0)	(0)

```
to_arm_register = (op == '1');  t = UInt(Rt);  n = UInt(Vn:N);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`VMOV{<c>}{<q>}  <Sn>, <Rt>`	Encoded as op = 0
`VMOV{<c>}{<q>}  <Rt>, <Sn>`	Encoded as op = 1

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Sn>` The single-precision floating-point register.

`<Rt>` The general-purpose register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if to_arm_register then
        R[t] = S[n];
    else
        S[n] = R[t];
```

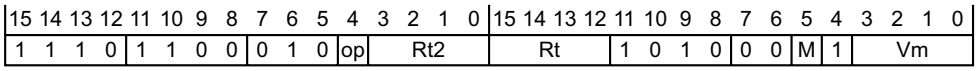
F8.1.86 VMOV (between two general-purpose registers and two single-precision registers)

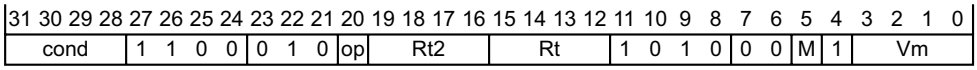
This instruction transfers the contents of two consecutively numbered single-precision Floating-point registers to two general-purpose registers, or the contents of two general-purpose registers to a pair of single-precision floating-point registers. The general-purpose registers do not have to be contiguous.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 summarizes these controls.

Encoding T1/A1

```
VMOV<c> <Sm>, <Sm1>, <Rt>, <Rt2>
VMOV<c> <Rt>, <Rt2>, <Sm>, <Sm1>
```





```
to_arm_registers = (op == '1');  t = UInt(Rt);  t2 = UInt(Rt2);  m = UInt(Vm:M);
if t == 15 || t2 == 15 || m == 31 then UNPREDICTABLE;
if CurrentInstrSet() != InstrSet_A32 && (t == 13 || t2 == 13) then UNPREDICTABLE;
if to_arm_registers && t == t2 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VMOV (between two general-purpose registers and two single-precision registers)* on page AppxA-4846.

Assembler syntax

`VMOV{<c>}{<q>}  <Sm>, <Sm1>, <Rt>, <Rt2>`	Encoded as op = 0
`VMOV{<c>}{<q>}  <Rt>, <Rt2>, <Sm>, <Sm1>`	Encoded as op = 1

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Sm>` The first single-precision floating-point register.

`<Sm1>` The second single-precision floating-point register. This is the next single-precision floating-point register after `<Sm>`.

`<Rt>` The general-purpose register that `<Sm>` is transferred to or from.

`<Rt2>` The general-purpose register that `<Sm1>` is transferred to or from.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if to_arm_registers then
        R[t] = S[m];
        R[t2] = S[m+1];
    else
        S[m] = R[t];
        S[m+1] = R[t2];
```

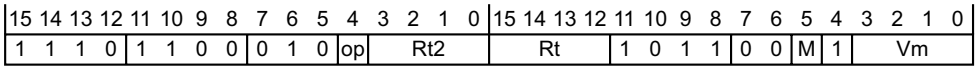
F8.1.87 VMOV (between two general-purpose registers and a doubleword floating-point register)

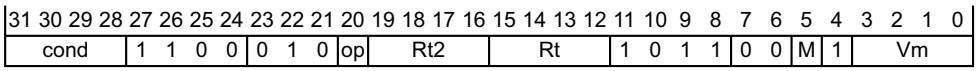
This instruction copies two words from two general-purpose registers into a doubleword register in the Advanced SIMD and floating-point register file, or from a doubleword register in the Advanced SIMD and floating-point register file to two general-purpose registers.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

Encoding T1/A1

```
VMOV<c> <Dm>, <Rt>, <Rt2>
VMOV<c> <Rt>, <Rt2>, <Dm>
```





```
to_arm_registers = (op == '1');  t = UInt(Rt);  t2 = UInt(Rt2);  m = UInt(M:Vm);
if t == 15 || t2 == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if to_arm_registers && t == t2 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VMOV (between two general-purpose registers and a doubleword floating-point register)* on page AppxA-4847.

Assembler syntax

```
VMOV{<c>}{<q>}  <Dm>, <Rt>, <Rt2>        Encoded as op = 0
VMOV{<c>}{<q>}  <Rt>, <Rt2>, <Dm>        Encoded as op = 1
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Dm>` The doubleword register in the Advanced SIMD and floating-point register file.

`<Rt>, <Rt2>` The two general-purpose registers.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if to_arm_registers then
        R[t] = D[m]<31:0>;
        R[t2] = D[m]<63:32>;
    else
        D[m]<31:0> = R[t];
        D[m]<63:32> = R[t2];
```

F8.1.88 VMOVL

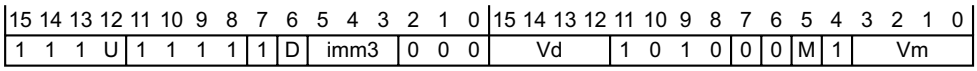
Vector Move Long takes each element in a doubleword vector, sign or zero-extends them to twice their original length, and places the results in a quadword vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VMOVL<c>.<dt> <Qd>, <Dm>
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	U	1	1	1	1	1	D	imm3			0	0	0	Vd				1	0	1	0	0	0	M	1	Vm

1	1	1	1	0	0	1	U	1	D	imm3			0	0	0	Vd				1	0	1	0	0	0	M	1	Vm			

```
if imm3 == '000' then SEE "Related encodings";
if imm3 != '001' && imm3 != '010' && imm3 != '100' then SEE VSHLL;
if Vd<0> == '1' then UNDEFINED;
esize = 8 * UInt(imm3);
unsigned = (U == '1');  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);
```

Related encodings See *One register and a modified immediate value* on page F5-2424.

Assembler syntax

```
VMOVL{<c>}{<q>}.<dt>  <Qd>, <Dm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VMOVL` instruction must be unconditional. ARM strongly recommends that a T32 `VMOVL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the operand. It must be one of:

`S8`	Encoded as U = 0, imm3 = `0b001`.
`S16`	Encoded as U = 0, imm3 = `0b010`.
`S32`	Encoded as U = 0, imm3 = `0b100`.
`U8`	Encoded as U = 1, imm3 = `0b001`.
`U16`	Encoded as U = 1, imm3 = `0b010`.
`U32`	Encoded as U = 1, imm3 = `0b100`.

`<Qd>, <Dm>` The destination vector and the operand vector.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Int(Elem[Din[m],e,esize], unsigned);
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
```

F8.1.89 VMOVN

Vector Move and Narrow copies the least significant half of each element of a quadword vector into the corresponding elements of a doubleword vector.

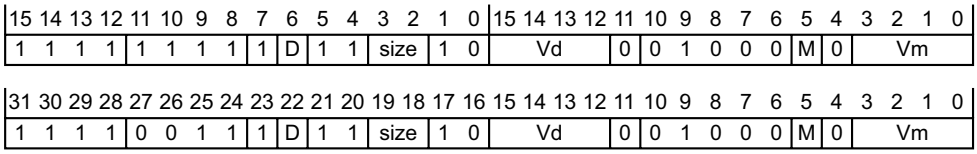
The operand vector elements can be any one of 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VMOVN<c>.<dt> <Dd>, <Qm>
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1	1	1	1	0	0	1	1	1	D	1	1	size		1	0	Vd				0	0	1	0	0	0	M	0	Vm			

```
if size == '11' then UNDEFINED;
if Vm<0> == '1' then UNDEFINED;
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);
```

Assembler syntax

```
VMOVN{<c>}{<q>}.<dt>  <Dd>, <Qm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VMOVN` instruction must be unconditional. ARM strongly recommends that a T32 `VMOVN` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the operand. It must be one of:

- `I16` Encoded as size = `0b00`.
- `I32` Encoded as size = `0b01`.
- `I64` Encoded as size = `0b10`.

`<Dd>, <Qm>` The destination vector and the operand vector.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        Elem[D[d],e,esize] = Elem[Qin[m>>1],e,2*esize]<esize-1:0>;
```

F8.1.90 VMRS

Move to general-purpose register from Advanced SIMD and floating-point System register moves the value of the FPSCR to a general-purpose register.

For details of system level use of this instruction, see *VMRS* on page F8-3358.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

Encoding T1/A1

```
VMRS<c> <Rt>, FPSCR
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
VMRS{<c>}{<q>}  <Rt>, FPSCR
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination general-purpose register. This register can be R0-R14 or APSR_nzcv. APSR_nzcv is encoded as Rt = `0b1111`, and the instruction transfers the FPSCR.{N, Z, C, V} condition flags to the APSR.{N, Z, C, V} condition flags.

The pre-UAL instruction `FMSTAT` is equivalent to `VMRS APSR_nzcv, FPSCR`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if t != 15 then
        R[t] = FPSCR;
    else
        PSTATE.<N,Z,C,V> = FPSR.<N,Z,C,V>;
```

F8.1.91 VMSR

Move to Advanced SIMD and floating-point System register from general-purpose register moves the value of a general-purpose register to the FPSCR.

For details of system level use of this instruction, see *VMSR* on page F8-3360.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

Encoding T1/A1

```
VMSR<c> FPSCR, <Rt>
```

```
t = UInt(Rt);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
VMSR{<c>}{<q>}  FPSCR, <Rt>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The general-purpose register to be transferred to the FPSCR.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    FPSCR = R[t];
```

F8.1.92 VMUL, VMULL (integer and polynomial)

Vector Multiply multiplies corresponding elements in two vectors. Vector Multiply Long does the same thing, but with destination vector elements that are twice as long as the elements that are multiplied.

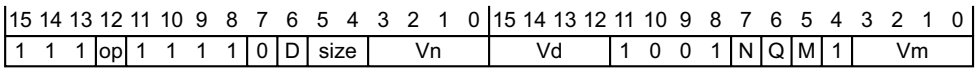
For information about multiplying polynomials see *Polynomial arithmetic over {0, 1}* on page A1-45.

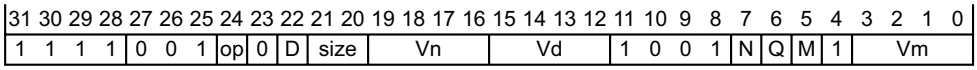
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VMUL<c>.<dt> <Qd>, <Qn>, <Qm>
VMUL<c>.<dt> <Dd>, <Dn>, <Dm>
```



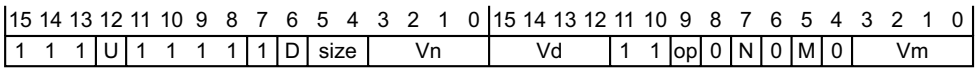


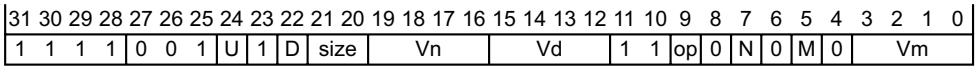
```
if size == '11' || (op == '1' && size != '00') then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
unsigned = FALSE;  // "Don't care" value: TRUE produces same functionality
polynomial = (op == '1');  long_destination = FALSE;
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Encoding T2/A2

,P64 form is Cryptographic Extension only

```
VMULL<c>.<dt> <Qd>, <Dn>, <Dm>
```





```
if size == '11' then SEE "Related encodings";
unsigned = (U == '1'); polynomial = (op == '1'); long_destination = TRUE;
esize = 8 << UInt(size); elements = 64 DIV esize;
if polynomial then
    if U == '1' || size == '01' then UNDEFINED;
    if size == '10' then    // .p64
        if !HaveCryptoExt() then UNDEFINED;
        if InITBlock() then UNPREDICTABLE;
        esize = 64; elements = 1;
if Vd<0> == '1' then UNDEFINED;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = 1;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings See *Advanced SIMD data-processing instructions* on page F5-2415.

Assembler syntax

`VMUL{<c>}{<q>}.<type><size>  {<Qd>,} <Qn>, <Qm>`	Encoding T1/A1, encoded as Q = 1
`VMUL{<c>}{<q>}.<type><size>  {<Dd>,} <Dn>, <Dm>`	Encoding T1/A1, encoded as Q = 0
`VMULL{<c>}{<q>}.<type><size>  <Qd>, <Dn>, <Dm>`	Encoding T2/A2

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 Advanced SIMD `VMUL` or `VMULL` instruction must be unconditional. ARM strongly recommends that a T32 Advanced SIMD `VMUL` or `VMULL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<type>` The data type for the elements of the operands. It must be one of:

- `S` Encoded as op = 0 in both encodings, with U = 0 in encoding T2/A2.
- `U` Encoded as op = 0 in both encodings, with U = 1 in encoding T2/A2.
- `I` Encoding T1/A1 only, encoded as op = 0.
- `P` Encoded as op = 1 in both encodings, with U= 0 in encoding T2/A2.

When `<type>` is `P`, `<size>` must be `8` or `64`.

`<size>` The data size for the elements of the operands. For integer types, it must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

For polynomial types, it must be one of:

- `8` Encoded as size = `0b00`.
- `64` Encoded as size = `0b10`.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

`<Qd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a long operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];  op1val = Int(op1, unsigned);
            op2 = Elem[Din[m+r],e,esize];  op2val = Int(op2, unsigned);
            if polynomial then
                product = PolynomialMult(op1,op2);
            else
                product = (op1val*op2val)<2*esize-1:0>;
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = product;
            else
                Elem[D[d+r],e,esize] = product<esize-1:0>;
```

F8.1.93 VMUL (floating-point)

Vector Multiply multiplies corresponding elements in two vectors, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

```

Related encodings See *Advanced SIMD data-processing instructions* on page F5-2415.

Assembler syntax

`VMUL{<c>}{<q>}.<dt>  {<Qd>,} <Qn>, <Dm[x]>`	Encoding T1/A1, encoded as Q = 1
`VMUL{<c>}{<q>}.<dt>  {<Dd>,} <Dn>, <Dm[x]>`	Encoding T1/A1, encoded as Q = 0
`VMULL{<c>}{<q>}.<dt>  <Qd>, <Dn>, <Dm[x]>`	Encoding T2/A2

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 Advanced SIMD `VMUL` or `VMULL` instruction must be unconditional. ARM strongly recommends that a T32 Advanced SIMD `VMUL` or `VMULL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the scalar, and the elements of the operand vector. It must be one of:

- `I16` Encoding T1/A1, encoded as size = `0b01`, F = 0.
- `I32` Encoding T1/A1, encoded as size = `0b10`, F = 0.
- `F32` Encoding T1/A1, encoded as size = `0b10`, F = 1.
- `S16` Encoding T2/A2, encoded as size = `0b01`, U = 0.
- `S32` Encoding T2/A2, encoded as size = `0b10`, U = 0.
- `U16` Encoding T2/A2, encoded as size = `0b01`, U = 1.
- `U32` Encoding T2/A2, encoded as size = `0b10`, U = 1.

`<Qd>, <Qn>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dn>` The destination vector, and the operand vector, for a doubleword operation.

`<Qd>, <Dn>` The destination vector, and the operand vector, for a long operation.

`<Dm[x]>` The scalar. `Dm` is restricted to D0-D7 if `<dt>` is `I16`, `S16`, or `U16`, or D0-D15 otherwise.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    op2 = Elem[Din[m],index,esize];  op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];  op1val = Int(op1, unsigned);
            if floating_point then
                Elem[D[d+r],e,esize] = FPMul(op1, op2, StandardFPSCRValue());
            else
                if long_destination then
                    Elem[Q[d>>1],e,2*esize] = (op1val*op2val)<2*esize-1:0>;
                else
                    Elem[D[d+r],e,esize] = (op1val*op2val)<esize-1:0>;
```

F8.1.95 VMVN (immediate)

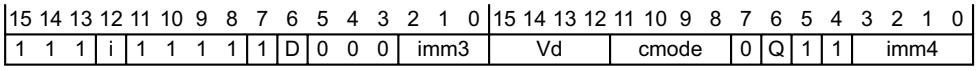
Vector Bitwise NOT (immediate) places the bitwise inverse of an immediate integer constant into every element of the destination register. For the range of constants available, see *One register and a modified immediate value* on page F5-2424.

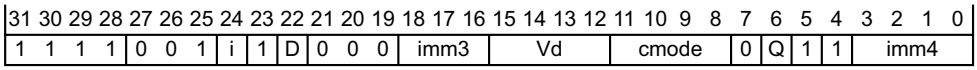
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VMVN<c>.<dt> <Qd>, #<imm>
VMVN<c>.<dt> <Dd>, #<imm>
```





```
if (cmode<0> == '1' && cmode<3:2> != '11') || cmode<3:1> == '111' then SEE "Related encodings";
if Q == '1' && Vd<0> == '1' then UNDEFINED;
imm64 = AdvSIMDExpandImm('1', cmode, i:imm3:imm4);
d = UInt(D:Vd);  regs = if Q == '0' then 1 else 2;
```

Related encodings See *One register and a modified immediate value* on page F5-2424.

Assembler syntax

`VMVN{<c>}{<q>}.<dt>  <Qd>, #<imm>`	Encoding T1/A1, encoded as Q = 1
`VMVN{<c>}{<q>}.<dt>  <Dd>, #<imm>`	Encoding T1/A1, encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VMVN` instruction must be unconditional. ARM strongly recommends that a T32 `VMVN` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type. It must be either `I16` or `I32`.

`<Qd>` The destination register for a quadword operation.

`<Dd>` The destination register for a doubleword operation.

`<imm>` A constant of the specified type.

See *One register and a modified immediate value* on page F5-2424 for the range of constants available, and the encoding of `<dt>` and `<imm>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = NOT(imm64);
```

Pseudo-instructions

One register and a modified immediate value on page F5-2424 describes pseudo-instructions with a combination of `<dt>` and `<imm>` that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.

F8.1.96 VMVN (register)

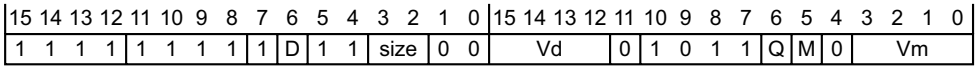
Vector Bitwise NOT (register) takes a value from a register, inverts the value of each bit, and places the result in the destination register. The registers can be either doubleword or quadword.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VMVN<c> <Qd>, <Qm>
VMVN<c> <Dd>, <Dm>
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
if size != '00' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

```
VMVN{<c>}{<q>}{.<dt>}  <Qd>, <Qm>
VMVN{<c>}{<q>}{.<dt>}  <Dd>, <Dm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VMVN` instruction must be unconditional. ARM strongly recommends that a T32 `VMVN` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` An optional data type. It is ignored by assemblers, and does not affect the encoding.

`<Qd>, <Qm>` The destination vector and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = NOT(D[m+r]);
```

F8.1.97 VNEG

Vector Negate negates each element in a vector, and places the results in a second vector. The floating-point version only inverts the sign bit.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

                    Elem[D[d+r],e,esize] = result<esize-1:0>;
    else             // VFP instruction
        if dp_operation then
            D[d] = FPNeg(D[m]);
        else
            S[d] = FPNeg(S[m]);
```

F8.1.98 VNMLA, VNMLS, VNMUL

VNMLA multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

VNMLS multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the product, and writes the result back to the destination register.

VNMUL multiplies together two floating-point register values, and writes the negation of the result to the destination register.

Note

ARM recommends that software does not use the VNMLA instruction in the *Round towards Plus Infinity* and *Round towards Minus Infinity* rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 summarizes these controls.

            when VFPNegMul_VNMUL  S[d] = FPNeg(product32);
```

F8.1.99 VORN (immediate)

VORN (immediate) is a pseudo-instruction, equivalent to a VORR (immediate) instruction with the immediate value bitwise inverted. For details see *VORR (immediate)* on page F8-3214.

F8.1.100 VORN (register)

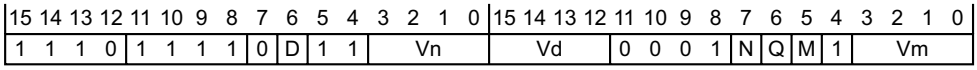
This instruction performs a bitwise OR NOT operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

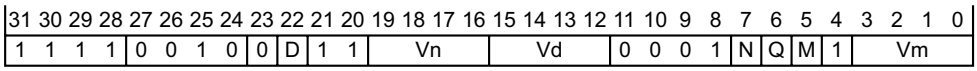
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VORN<c> <Qd>, <Qn>, <Qm>
VORN<c> <Dd>, <Dn>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VORN{<c>}{<q>}{.<dt>}  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VORN{<c>}{<q>}{.<dt>}  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page F2-2330. An A32 `VORN` instruction must be unconditional. ARM strongly recommends that a T32 `VORN` instruction is unconditional, see *Conditional execution* on page F2-2331.
`<dt>`	An optional data type. It is ignored by assemblers, and does not affect the encoding.
`<Qd>, <Qn>, <Qm>`	The destination vector and the operand vectors, for a quadword operation.
`<Dd>, <Dn>, <Dm>`	The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] OR NOT(D[m+r]);
```

F8.1.101 VORR (immediate)

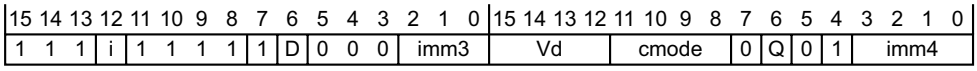
This instruction takes the contents of the destination vector, performs a bitwise OR with an immediate constant, and returns the result into the destination vector. For the range of constants available, see *One register and a modified immediate value* on page F5-2424.

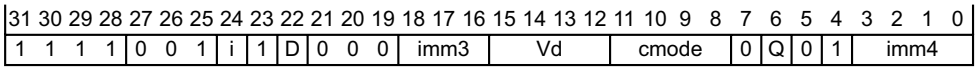
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VORR<c>.<dt> <Qd>, #<imm>
VORR<c>.<dt> <Dd>, #<imm>
```





```
if cmode<0> == '0' || cmode<3:2> == '11' then SEE VMOV (immediate);
if Q == '1' && Vd<0> == '1' then UNDEFINED;
imm64 = AdvSIMDExpandImm('0', cmode, i:imm3:imm4);
d = UInt(D:Vd);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VORR{<c>}{<q>}.<dt>  {<Qd>,} <Qd>, #<imm>`	Encoded as Q = 1
`VORR{<c>}{<q>}.<dt>  {<Dd>,} <Dd>, #<imm>>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VORR` instruction must be unconditional. ARM strongly recommends that a T32 `VORR` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type used for `<imm>`. It can be either `I16` or `I32`.

`I8`, `I64`, and `F32` are also permitted, but the resulting syntax is a pseudo-instruction.

`<Qd>` The destination vector for a quadword operation.

`<Dd>` The destination vector for a doubleword operation.

`<imm>` A constant of the type specified by `<dt>`. This constant is replicated enough times to fill the destination register. For example, `VORR.I32 D0, #10` ORs `0x0000000A0000000A` into D0.

For details of the range of constants available, and the encoding of `<dt>` and `<imm>`, see *One register and a modified immediate value* on page F5-2424.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[d+r] OR imm64;
```

Pseudo-instructions

`VORN` can be used, with a range of constants that are the bitwise inverse of the available constants for `VORR`. This is assembled as the equivalent `VORR` instruction. Disassembly produces the `VORR` form.

One register and a modified immediate value on page F5-2424 describes pseudo-instructions with a combination of `<dt>` and `<imm>` that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.

F8.1.102 VORR (register)

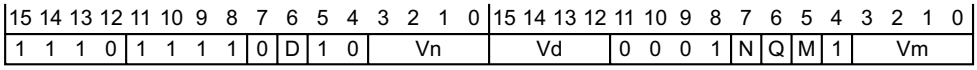
This instruction performs a bitwise OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

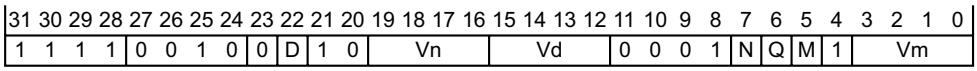
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VORR<c> <Qd>, <Qn>, <Qm>
VORR<c> <Dd>, <Dn>, <Dm>
```





```
if N == M && Vn == Vm then SEE VMOV (register);
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VORR{<c>}{<q>}{.<dt>}  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VORR{<c>}{<q>}{.<dt>}  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VORR` instruction must be unconditional. ARM strongly recommends that a T32 `VORR` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` An optional data type. It is ignored by assemblers, and does not affect the encoding.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] OR D[m+r];
```

F8.1.103 VPADAL

Vector Pairwise Add and Accumulate Long adds adjacent pairs of elements of a vector, and accumulates the results into the elements of the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

Figure F8-2 shows an example of the operation of VPADAL.

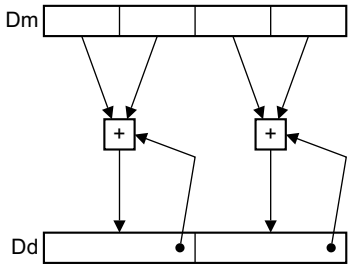


Figure F8-2 VPADAL doubleword operation for data type S16

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VPADAL{<c>}{<q>}.<dt> <Qd>, <Qm>`	Encoded as Q = 1
`VPADAL{<c>}{<q>}.<dt> <Dd>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VPADAL` instruction must be unconditional. ARM strongly recommends that a T32 `VPADAL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the vectors. It must be one of:

`S8`	Encoded as size = `0b00`, op = 0.
`S16`	Encoded as size = `0b01`, op = 0.
`S32`	Encoded as size = `0b10`, op = 0.
`U8`	Encoded as size = `0b00`, op = 1.
`U16`	Encoded as size = `0b01`, op = 1.
`U32`	Encoded as size = `0b10`, op = 1.

`<Qd>, <Qm>` The destination vector and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    h = elements DIV 2;

    for r = 0 to regs-1
        for e = 0 to h-1
            op1 = Elem[D[m+r],2*e,esize];  op2 = Elem[D[m+r],2*e+1,esize];
            result = Int(op1, unsigned) + Int(op2, unsigned);
            Elem[D[d+r],e,2*esize] = Elem[D[d+r],e,2*esize] + result;
```

F8.1.104 VPADD (integer)

Vector Pairwise Add (integer) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements must all be the same type, and can be 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

Figure F8-3 shows an example of the operation of VPADD.

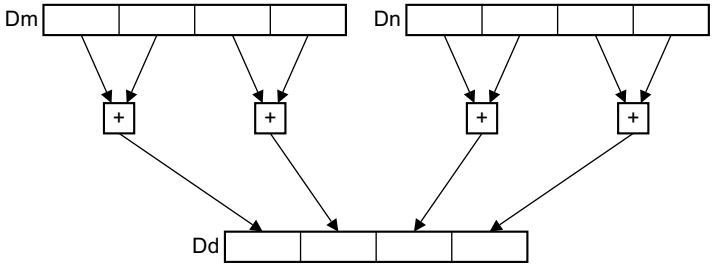

Figure F8-3 VPADD operation for data type I16

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VPADD<c>.<dt>  <Dd>, <Dn>, <Dm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

Assembler syntax

`VPADD{<c>}{<q>}.<dt>  {<Dd>,} <Dn>, <Dm>` Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VPADD` instruction must be unconditional. ARM strongly recommends that a T32 `VPADD` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the vectors. It must be one of:

- `I8` Encoding T1/A1, encoded as size = `0b00`.
- `I16` Encoding T1/A1, encoded as size = `0b01`.
- `I32` Encoding T1/A1, encoded as size = `0b10`.

`<Dd>, <Dn>, <Dm>` The destination vector, the first operand vector, and the second operand vector.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;

    for e = 0 to h-1
        Elem[dest,e,esize]   = Elem[D[n],2*e,esize] + Elem[D[n],2*e+1,esize];
        Elem[dest,e+h,esize] = Elem[D[m],2*e,esize] + Elem[D[m],2*e+1,esize];

    D[d] = dest;
```

F8.1.105 VPADD (floating-point)

Vector Pairwise Add (floating-point) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements are 32-bit floating-point numbers.

Figure F8-3 on page F8-3220 shows an example of the operation of VPADD.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VPADD<c>.F32  <Dd>, <Dn>, <Dm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

esize = 32;  elements = 2;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

Assembler syntax

`VPADD{<c>}{<q>}.F32  {<Dd>,} <Dn>, <Dm>` Encoded as Q = 0, sz = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VPADD` instruction must be unconditional. ARM strongly recommends that a T32 `VPADD` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<Dd>, <Dn>, <Dm>` The destination vector, the first operand vector, and the second operand vector.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;

    for e = 0 to h-1
        Elem[dest,e,esize]   = FPAdd(Elem[D[n],2*e,esize], Elem[D[n],2*e+1,esize], StandardFPSCRValue());
        Elem[dest,e+h,esize] = FPAdd(Elem[D[m],2*e,esize], Elem[D[m],2*e+1,esize], StandardFPSCRValue());

    D[d] = dest;
```

F8.1.106 VPADDL

Vector Pairwise Add Long adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

Figure F8-4 shows an example of the operation of VPADDL.

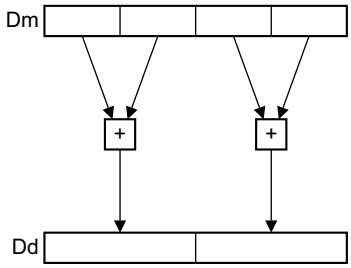

Figure F8-4 VPADDL doubleword operation for data type S16

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VPADDL<c>.<dt>  <Qd>, <Qm>
VPADDL<c>.<dt>  <Dd>, <Dm>
```

esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VPADDL{<c>}{<q>}.<dt> <Qd>, <Qm>`	Encoded as Q = 1
`VPADDL{<c>}{<q>}.<dt> <Dd>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VPADDL` instruction must be unconditional. ARM strongly recommends that a T32 `VPADDL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the vectors. It must be one of:

`S8`	Encoded as size = `0b00`, op = 0.
`S16`	Encoded as size = `0b01`, op = 0.
`S32`	Encoded as size = `0b10`, op = 0.
`U8`	Encoded as size = `0b00`, op = 1.
`U16`	Encoded as size = `0b01`, op = 1.
`U32`	Encoded as size = `0b10`, op = 1.

`<Qd>, <Qm>` The destination vector and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    h = elements DIV 2;

    for r = 0 to regs-1
        for e = 0 to h-1
            op1 = Elem[D[m+r],2*e,esize];  op2 = Elem[D[m+r],2*e+1,esize];
            result = Int(op1, unsigned) + Int(op2, unsigned);
            Elem[D[d+r],e,2*esize] = result<2*esize-1:0>;
```

F8.1.107 VPMAX, VPMIN (integer)

Vector Pairwise Maximum compares adjacent pairs of elements in two doubleword vectors, and copies the larger of each pair into the corresponding element in the destination doubleword vector.

Vector Pairwise Minimum compares adjacent pairs of elements in two doubleword vectors, and copies the smaller of each pair into the corresponding element in the destination doubleword vector.

Figure F8-5 shows an example of the operation of VPMAX.

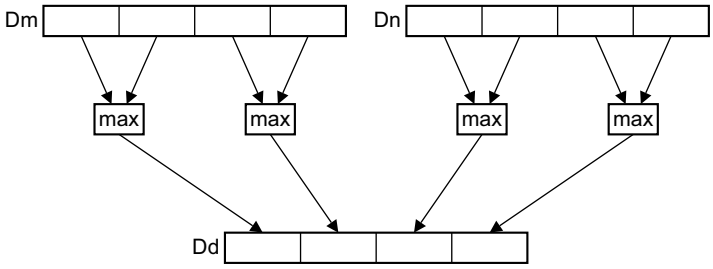

Figure F8-5 VPMAX operation for data type S16 or U16

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

```

F8.1.109 VPOP

Vector Pop loads multiple consecutive Advanced SIMD and floating-point register file registers from the stack.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

Encoding T1/A1

`VPOP <list>` `<list>` is consecutive 64-bit registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	0	0	1	D	1	1	1	1	0	1	Vd				1	0	1	1	imm8							

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	1	0	0	1	D	1	1	1	1	0	1	Vd				1	0	1	1	imm8							

```
single_regs = FALSE;  d = UInt(D:Vd);  imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2;  // If UInt(imm8) is odd, see "FLDMX".
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
```

Encoding T2/A2

`VPOP <list>` `<list>` is consecutive 32-bit registers

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	0	0	1	D	1	1	1	1	0	1	Vd				1	0	1	0	imm8							

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	1	0	0	1	D	1	1	1	1	0	1	Vd				1	0	1	0	imm8							

```
single_regs = TRUE;  d = UInt(Vd:D); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8);
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VPOP* on page AppxA-4846.

FLDMX Encoding T1/A1 behaves as described by the pseudocode if imm8 is odd. However, there is no UAL syntax for such encodings and ARM deprecates their use. For more information, see *FLDMX, FSTMX* on page F8-3040.

Assembler syntax

```
VPOP{<c>}{<q>}{.<size>}  <list>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<size>` An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers in `<list>`.

`<list>` The Advanced SIMD and floating-point register file registers to be loaded, as a list of consecutively numbered doubleword (encoding T1/A1) or singleword (encoding T2/A2) registers, separated by commas and surrounded by brackets. It is encoded in the instruction by setting D and Vd to specify the first register in the list, and imm8 to twice the number of registers in the list (encoding T1/A1) or the number of registers in the list (encoding T2/A2). `<list>` must contain at least one register, and not more than sixteen.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    address = SP;
    SP = SP + imm32;
    if single_regs then
        for r = 0 to regs-1
            S[d+r] = MemA[address,4];  address = address+4;
    else
        for r = 0 to regs-1
            word1 = MemA[address,4];  word2 = MemA[address+4,4];  address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian() then word1:word2 else word2:word1;
```

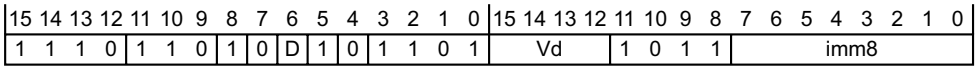
F8.1.110 VPUSH

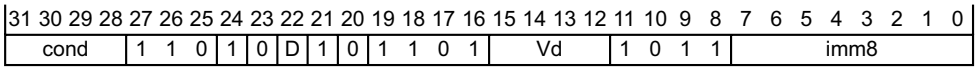
Vector Push stores multiple consecutive registers from the Advanced SIMD and floating-point register file to the stack.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

Encoding T1/A1

`VPUSH<c> <list>` — `<list>` is consecutive 64-bit registers

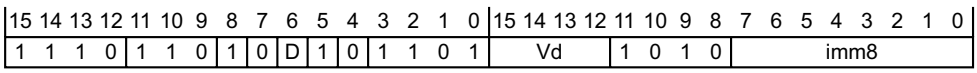


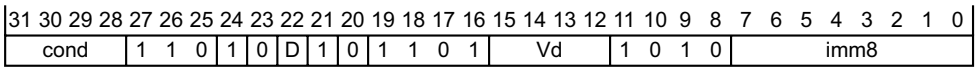


```
single_regs = FALSE;  d = UInt(D:Vd);  imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2;  // If UInt(imm8) is odd, see "FSTMX".
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
```

Encoding T2/A2

`VPUSH<c> <list>` — `<list>` is consecutive 32-bit registers





```
single_regs = TRUE;  d = UInt(Vd:D);
imm32 = ZeroExtend(imm8:'00', 32);  regs = UInt(imm8);
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VPUSH* on page AppxA-4850.

FSTMX Encoding T1/A1 behaves as described by the pseudocode if imm8 is odd. However, there is no UAL syntax for such encodings and ARM deprecates their use. For more information, see *FLDMX, FSTMX* on page F8-3040.

Assembler syntax

```
VPUSH{<c>}{<q>}{.<size>}  <list>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<size>` An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers in `<list>`.

`<list>` The registers from the Advanced SIMD and floating-point register file to be stored, as a list of consecutively numbered doubleword (encoding T1/A1) or singleword (encoding T2/A2) registers, separated by commas and surrounded by brackets. It is encoded in the instruction by setting D and Vd to specify the first register in the list, and imm8 to twice the number of registers in the list (encoding T1/A1), or the number of registers in the list (encoding T2/A2). `<list>` must contain at least one register, and not more than sixteen.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    address = SP - imm32;
    SP = SP - imm32;
    if single_regs then
        for r = 0 to regs-1
            MemA[address,4] = S[d+r];  address = address+4;
    else
        for r = 0 to regs-1
            // Store as two word-aligned words in the correct order for current endianness.
            MemA[address,4] = if BigEndian() then D[d+r]<63:32> else D[d+r]<31:0>;
            MemA[address+4,4] = if BigEndian() then D[d+r]<31:0> else D[d+r]<63:32>;
            address = address+8;
```

F8.1.111 VQABS

Vector Saturating Absolute takes the absolute value of each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode details of saturation* on page E1-2207.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VQABS<c>.<dt> <Qd>, <Qm>
VQABS<c>.<dt> <Dd>, <Dm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1	1	1	1	0	0	1	1	1	D	1	1	size		0	0	Vd				0	1	1	1	0	Q	M	0	Vm			

```
if size == '11' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VQABS{<c>}{<q>}.<dt> <Qd>, <Qm>`	Encoded as Q = 1
`VQABS{<c>}{<q>}.<dt> <Dd>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VQABS` instruction must be unconditional. ARM strongly recommends that a T32 `VQABS` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the vectors. It must be one of:

`S8`	Encoded as size = `0b00`.
`S16`	Encoded as size = `0b01`.
`S32`	Encoded as size = `0b10`.

`<Qd>, <Qm>` The destination vector and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            result = Abs(SInt(Elem[D[m+r],e,esize]));
            (Elem[D[d+r],e,esize], sat) = SignedSatQ(result, esize);
            if sat then FPSR.QC = '1';
```

F8.1.112 VQADD

Vector Saturating Add adds the values of corresponding elements of two vectors, and places the results in the destination vector.

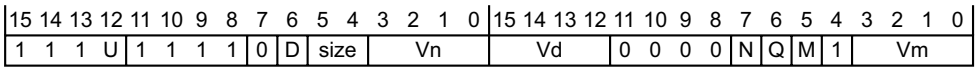
If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode details of saturation* on page E1-2207.

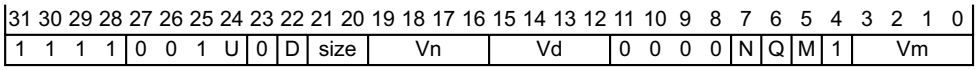
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VQADD<c>.<dt> <Qd>, <Qn>, <Qm>
VQADD<c>.<dt> <Dd>, <Dn>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
unsigned = (U == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VQADD{<c>}{<q>}.<type><size>  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VQADD{<c>}{<q>}.<type><size>  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VQADD` instruction must be unconditional. ARM strongly recommends that a T32 `VQADD` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<type>` The data type for the elements of the vectors. It must be one of:

- `S` Signed, encoded as U = 0.
- `U` Unsigned, encoded as U = 1.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.
- `64` Encoded as size = `0b11`.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            sum = Int(Elem[D[n+r],e,esize], unsigned) + Int(Elem[D[m+r],e,esize], unsigned);
            (Elem[D[d+r],e,esize], sat) = SatQ(sum, esize, unsigned);
            if sat then FPSR.QC = '1';
```

F8.1.113 VQDMLAL, VQDMLSL

Vector Saturating Doubling Multiply Accumulate Long multiplies corresponding elements in two doubleword vectors, doubles the products, and accumulates the results into the elements of a quadword vector.

Vector Saturating Doubling Multiply Subtract Long multiplies corresponding elements in two doubleword vectors, subtracts double the products from corresponding elements of a quadword vector, and places the results in the same quadword vector.

In both instructions, the second operand can be a scalar instead of a vector. For more information about scalars see *Advanced SIMD scalars* on page F5-2414.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode details of saturation* on page E1-2207.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Assembler syntax

```
VQD<op>{<c>}{<q>}.<dt>  <Qd>, <Dn>, <Dm>
VQD<op>{<c>}{<q>}.<dt>  <Qd>, <Dn>, <Dm[x]>
```

where:

`<op>` The operation. It must be one of:

- `MLAL` Encoded as op = 0.
- `MLSL` Encoded as op = 1.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VQDMLAL` or `VQDMLSL` instruction must be unconditional. ARM strongly recommends that a T32 `VQDMLAL` or `VQDMLSL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the operands. It must be one of:

- `S16` Encoded as size = `0b01`.
- `S32` Encoded as size = `0b10`.

`<Qd>, <Dn>` The destination vector and the first operand vector.

`<Dm>` The second operand vector, for an all vector operation.

`<Dm[x]>` The scalar for a scalar operation. If `<dt>` is `S16`, `Dm` is restricted to D0-D7. If `<dt>` is `S32`, `Dm` is restricted to D0-D15.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    if scalar_form then op2 = SInt(Elem[Din[m],index,esize]);
    for e = 0 to elements-1
        if !scalar_form then op2 = SInt(Elem[Din[m],e,esize]);
        op1 = SInt(Elem[Din[n],e,esize]);
        // The following only saturates if both op1 and op2 equal -(2^(esize-1))
        (product, sat1) = SignedSatQ(2*op1*op2, 2*esize);
        if add then
            result = SInt(Elem[Qin[d>>1],e,2*esize]) + SInt(product);
        else
            result = SInt(Elem[Qin[d>>1],e,2*esize]) - SInt(product);
        (Elem[Q[d>>1],e,2*esize], sat2) = SignedSatQ(result, 2*esize);
        if sat1 || sat2 then FPSR.QC = '1';
```

F8.1.114 VQDMULH

Vector Saturating Doubling Multiply Returning High Half multiplies corresponding elements in two vectors, doubles the results, and places the most significant half of the final results in the destination vector. The results are truncated, for rounded results see *VQRDMULH* on page F8-3248.

The second operand can be a scalar instead of a vector. For more information about scalars see *Advanced SIMD scalars* on page F5-2414.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode details of saturation* on page E1-2207.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

        Elem[Q[d>>1],e,2*esize] = product;
        if sat then FPSR.QC = '1';
```

F8.1.116 VQMOVN, VQMOVUN

Vector Saturating Move and Narrow copies each element of the operand vector to the corresponding element of the destination vector.

The operand is a quadword vector. The elements can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result is a doubleword vector. The elements are half the length of the operand vector elements. If the operand is unsigned, the results are unsigned. If the operand is signed, the results can be signed or unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode details of saturation* on page E1-2207.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```

Assembler syntax

```
VQMOV{U}N{<c>}{<q>}.<type><size>  <Dd>, <Qm>
```

where:

`U` If present, specifies that the operation produces unsigned results, even though the operands are signed. Encoded as op = `0b01`.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VQMOVN` or `VQMOVUN` instruction must be unconditional. ARM strongly recommends that a T32 `VQMOVN` or `VQMOVUN` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<type>` The data type for the elements of the operand. It must be one of:

- `S` Encoded as:
  - op = `0b10` for `VQMOVN`.
  - op = `0b01` for `VQMOVUN`.
- `U` Encoded as op = `0b11`. Not available for `VQMOVUN`.

`<size>` The data size for the elements of the operand. It must be one of:

- `16` Encoded as size = `0b00`.
- `32` Encoded as size = `0b01`.
- `64` Encoded as size = `0b10`.

`<Dd>, <Qm>` The destination vector and the operand vector.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        operand = Int(Elem[Qin[m>>1],e,2*esize], src_unsigned);
        (Elem[D[d],e,esize], sat) = SatQ(operand, esize, dest_unsigned);
        if sat then FPSR.QC = '1';
```

F8.1.117 VQNEG

Vector Saturating Negate negates each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode details of saturation* on page E1-2207.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

`VQRDMULH{<c>}{<q>}.<dt>  {<Qd>,} <Qn>, <Dm[x]>`	Encoding T2/A2, encoded as Q = 1
`VQRDMULH{<c>}{<q>}.<dt>  {<Dd>,} <Dn>, <Dm[x]>`	Encoding T2/A2, encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VQRDMULH` instruction must be unconditional. ARM strongly recommends that a T32 `VQRDMULH` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the operands. It must be one of:

- `S16` Encoded as size = `0b01`.
- `S32` Encoded as size = `0b10`.

`<Qd>, <Qn>` The destination vector and the first operand vector, for a quadword operation.

`<Dd>, <Dn>` The destination vector and the first operand vector, for a doubleword operation.

`<Qm>` The second operand vector, for a quadword all vector operation.

`<Dm>` The second operand vector, for a doubleword all vector operation.

`<Dm[x]>` The scalar for either a quadword or a doubleword scalar operation. If `<dt>` is `S16`, `Dm` is restricted to D0-D7. If `<dt>` is `S32`, `Dm` is restricted to D0-D15.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (esize-1);
    if scalar_form then op2 = SInt(Elem[D[m],index,esize]);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = SInt(Elem[D[n+r],e,esize]);
            if !scalar_form then op2 = SInt(Elem[D[m+r],e,esize]);
            (result, sat) = SignedSatQ((2*op1*op2 + round_const) >> esize, esize);
            Elem[D[d+r],e,esize] = result;
            if sat then FPSR.QC = '1';
```

F8.1.119 VQRSHL

Vector Saturating Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

For truncated results see *VQSHL (register)* on page F8-3254.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

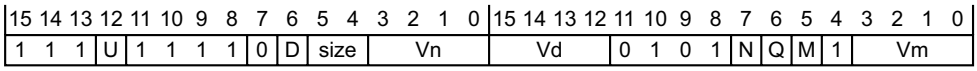
If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode details of saturation* on page E1-2207.

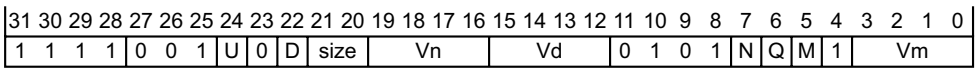
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VQRSHL<c>.<type><size> <Qd>, <Qm>, <Qn>
VQRSHL<c>.<type><size> <Dd>, <Dm>, <Dn>
```





```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1' || Vn<0> == '1') then UNDEFINED;
unsigned = (U == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  n = UInt(N:Vn);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VQRSHL{<c>}{<q>}.<type><size>  {<Qd>,} <Qm>, <Qn>`	Encoded as Q = 1
`VQRSHL{<c>}{<q>}.<type><size>  {<Dd>,} <Dm>, <Dn>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VQRSHL` instruction must be unconditional. ARM strongly recommends that a T32 `VQRSHL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<type>` The data type for the elements of the vectors. It must be one of:

- `S` Signed, encoded as U = 0.
- `U` Unsigned, encoded as U = 1.

Together with the `<size>` field, this indicates the data type and size of the first operand and the result.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.
- `64` Encoded as size = `0b11`.

`<Qd>, <Qm>, <Qn>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dm>, <Dn>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            shift = SInt(Elem[D[n+r],e,esize]<7:0>);
            round_const = 1 << (-1-shift); // 0 for left shift, 2^(n-1) for right shift
            operand = Int(Elem[D[m+r],e,esize], unsigned);
            (result, sat) = SatQ((operand + round_const) << shift, esize, unsigned);
            Elem[D[d+r],e,esize] = result;
            if sat then FPSR.QC = '1';
```

F8.1.120 VQRSHRN, VQRSHRUN

Vector Saturating Rounding Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the rounded results in a doubleword vector.

For truncated results, see *VQSHRN, VQSHRUN* on page F8-3258.

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode details of saturation* on page E1-2207.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

```

Assembler syntax

`VQSUB{<c>}{<q>}.<type><size>  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VQSUB{<c>}{<q>}.<type><size>  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VQSUB` instruction must be unconditional. ARM strongly recommends that a T32 `VQSUB` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<type>` The data type for the elements of the vectors. It must be one of:

- `S` Signed, encoded as U = 0.
- `U` Unsigned, encoded as U = 1.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.
- `64` Encoded as size = `0b11`.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            diff = Int(Elem[D[n+r],e,esize], unsigned) - Int(Elem[D[m+r],e,esize], unsigned);
            (Elem[D[d+r],e,esize], sat) = SatQ(diff, esize, unsigned);
            if sat then FPSR.QC = '1';
```

F8.1.125 VRADDHN

Vector Rounding Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are rounded. For truncated results, see *VADDHN* on page F8-3066.

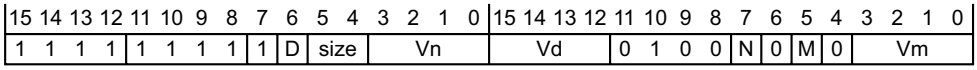
The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

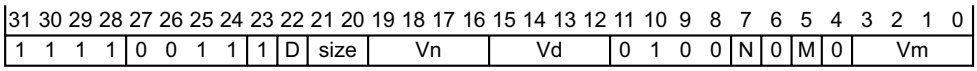
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VRADDHN<c>.<dt> <Dd>, <Qn>, <Qm>
```





```
if size == '11' then SEE "Related encodings";
if Vn<0> == '1' || Vm<0> == '1' then UNDEFINED;
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

Related encodings See *Advanced SIMD data-processing instructions* on page F5-2415.

Assembler syntax

```
VRADDHN{<c>}{<q>}.<dt>  <Dd>, <Qn>, <Qm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VRADDHN` instruction must be unconditional. ARM strongly recommends that a T32 `VRADDHN` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the operands. It must be one of:

- `I16` Encoded as size = `0b00`.
- `I32` Encoded as size = `0b01`.
- `I64` Encoded as size = `0b10`.

`<Dd>, <Qn>, <Qm>` The destination vector and the operand vectors.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (esize-1);
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] + Elem[Qin[m>>1],e,2*esize] + round_const;
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

F8.1.126 VRECPE

Vector Reciprocal Estimate finds an approximate reciprocal of each element in the operand vector, and places the results in the destination vector.

The operand and result elements are the same type, and can be 32-bit floating-point numbers, or 32-bit unsigned integers.

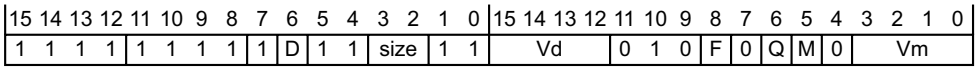
For details of the operation performed by this instruction see *Floating-point reciprocal square root estimate and step* on page E1-2238.

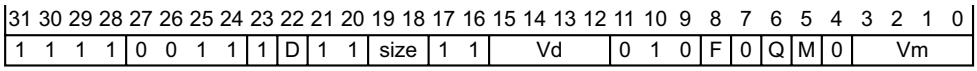
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VRECPE<c>.<dt> <Qd>, <Qm>
VRECPE<c>.<dt> <Dd>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size != '10' then UNDEFINED;
floating_point = (F == '1');  esize = 32;  elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VRECPE{<c>}{<q>}.<dt> <Qd>, <Qm>`	Encoded as Q = 1
`VRECPE{<c>}{<q>}.<dt> <Dd>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VRECPE` instruction must be unconditional. ARM strongly recommends that a T32 `VRECPE` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data types for the elements of the vectors. It must be one of:

- `U32` Encoded as F = 0, size = `0b10`.
- `F32` Encoded as F = 1, size = `0b10`.

`<Qd>, <Qm>` The destination vector and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if floating_point then
                Elem[D[d+r],e,32] = FPRecipEstimate(Elem[D[m+r],e,32], StandardFPSCRValue());
            else
                Elem[D[d+r],e,32] = UnsignedRecipEstimate(Elem[D[m+r],e,32]);
```

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of a number, see *Floating-point reciprocal estimate and step* on page E1-2235.

F8.1.127 VRECPS

Vector Reciprocal Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 2.0, and places the results into the elements of the destination vector.

The operand and result elements are 32-bit floating-point numbers.

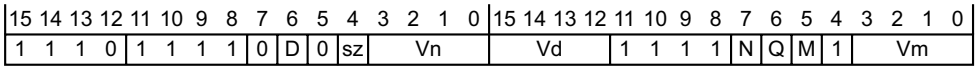
For details of the operation performed by this instruction see *Floating-point reciprocal estimate and step* on page E1-2235.

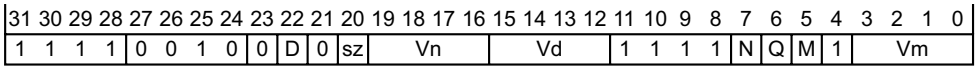
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VRECPS<c>.F32 <Qd>, <Qn>, <Qm>
VRECPS<c>.F32 <Dd>, <Dn>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' then UNDEFINED;
esize = 32;  elements = 2;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VRECPS{<c>}{<q>}.F32 {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VRECPS{<c>}{<q>}.F32 {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VRECPS` instruction must be unconditional. ARM strongly recommends that a T32 `VRECPS` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,32] = FPRecipStep(Elem[D[n+r],e,32], Elem[D[m+r],e,32]);
```

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of a number, see *Floating-point reciprocal estimate and step* on page E1-2235.

F8.1.128 VREV16, VREV32, VREV64

VREV16 (Vector Reverse in halfwords) reverses the order of 8-bit elements in each halfword of the vector, and places the result in the corresponding destination vector.

VREV32 (Vector Reverse in words) reverses the order of 8-bit or 16-bit elements in each word of the vector, and places the result in the corresponding destination vector.

VREV64 (Vector Reverse in doublewords) reverses the order of 8-bit, 16-bit, or 32-bit elements in each doubleword of the vector, and places the result in the corresponding destination vector.

There is no distinction between data types, other than size.

Figure F8-6 shows two examples of the operation of VREV.

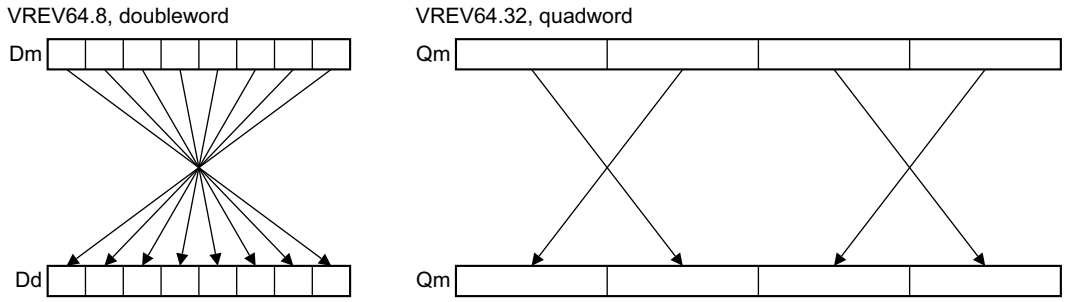


Figure F8-6 VREV operation examples

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VREV<n><c>.<size> <Qd>, <Qm>
VREV<n><c>.<size> <Dd>, <Dm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
if UInt(op)+UInt(size) >= 3 then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
esize = 8 << UInt(size);  elements = 64 DIV esize;
groupsize = (1 << (3-UInt(op)-UInt(size))); // elements per reversing group: 2, 4 or 8
reverse_mask = (groupsize-1)<esize-1:0>;    // EORing mask used for index calculations
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VREV<n>{<c>}{<q>}.<size> <Qd>, <Qm>`	Encoded as Q = 1
`VREV<n>{<c>}{<q>}.<size> <Dd>, <Dm>`	Encoded as Q = 0

where:

`<n>` The size of the regions in which the vector elements are reversed. It must be one of:

- `16` Encoded as op = `0b10`.
- `32` Encoded as op = `0b01`.
- `64` Encoded as op = `0b00`.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VREV` instruction must be unconditional. ARM strongly recommends that a T32 `VREV` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The size of the vector elements. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<size>` must specify a smaller size than `<n>`.

`<Qd>, <Qm>` The destination vector and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector, for a doubleword operation.

If op + size >= 3, the instruction is reserved.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    bits(64) dest;

    for r = 0 to regs-1
        for e = 0 to elements-1
            // Calculate destination element index by bitwise EOR on source element index:
            e_bits = e<esize-1:0>;  d_bits = e_bits EOR reverse_mask;  d = UInt(d_bits);
            Elem[dest,d,esize] = Elem[D[m+r],e,esize];
        D[d+r] = dest;
```

F8.1.129 VRHADD

Vector Rounding Halving Add adds corresponding elements in two vectors of integers, shifts each result right one bit, and places the final results in the destination vector.

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The results of the halving operations are rounded. For truncated results see *VHADD, VHSUB* on page F8-3134.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VRHADD<c> <Qd>, <Qn>, <Qm>
VRHADD<c> <Dd>, <Dn>, <Dm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Assembler syntax

`VRHADD{<c>}{<q>}.<dt>  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VRHADD{<c>}{<q>}.<dt>  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VRHADD` instruction must be unconditional. ARM strongly recommends that a T32 `VRHADD` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the vectors. It must be one of:

`S8`	Encoded as size = `0b00`, U = 0.
`S16`	Encoded as size = `0b01`, U = 0.
`S32`	Encoded as size = `0b10`, U = 0.
`U8`	Encoded as size = `0b00`, U = 1.
`U16`	Encoded as size = `0b01`, U = 1.
`U32`	Encoded as size = `0b10`, U = 1.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Int(Elem[D[n+r],e,esize], unsigned);
            op2 = Int(Elem[D[m+r],e,esize], unsigned);
            result = op1 + op2 + 1;
            Elem[D[d+r],e,esize] = result<esize:1>;
```

F8.1.130 VRINTA, VRINTN, VRINTP, VRINTM (Advanced SIMD)

These instructions round a floating-point value to an integral floating-point value of the same size. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

These instructions use the following rounding modes:

- `VRINTA`: Round to Nearest with Ties to Away.
- `VRINTN`: Round to Nearest with Ties to Even.
- `VRINTP`: Round Toward +Infinity.
- `VRINTM`: Round towards -Infinity.

Encoding T1/A1

```
VRINT<r>.F32.F32 <Qd>, <Qm>
VRINT<r>.F32.F32 <Dd>, <Dm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

if size != ‘10’ then UNDEFINED;
// Rounding encoded differently from other VCVT and VRINT instructions
rounding = FPDecodeRM(op<2>:NOT(op<1>));  exact = FALSE;
esize = 32;  elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == ‘0’ then 1 else 2;
if InITBlock() then UNPREDICTABLE;
```

Related instructions See *Two registers, miscellaneous* on page F5-2422

Assembler syntax

`VRINT<r>{<q>}.F32.F32  <Qd>, <Qm>`	Encoded as Q = 1
`VRINT<r>{<q>}.F32.F32  <Dd>, <Dm>`	Encoded as Q = 0

where:

`r` Selects the rounding direction. It must be one of:

- `A` Encoded as op = 010.
- `N` Encoded as op = 000.
- `P` Encoded as op = 111.
- `M` Encoded as op = 101.

`<q>` See *Standard assembler syntax fields* on page F2-2330.

`<Qd>, <Qm>` The destination vector and the operand vector for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector for a doubleword operation.

Operation

```
EncodingSpecificOperations(); CheckAdvSIMDEnabled();
for r = 0 to regs-1
    for e = 0 to elements-1
        op1 = Elem[D[m+r],e,esize];
        result = FPRoundInt(op1, StandardFPSCRValue(), rounding, exact);
        Elem[D[d+r],e,esize] = result;
```

F8.1.131 VRINTA, VRINTN, VRINTP, VRINTM (floating-point)

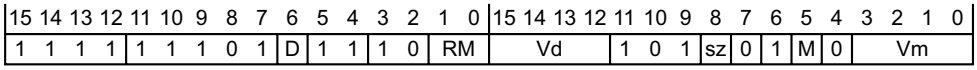
These instructions round a floating-point value to an integral floating-point value of the same size. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

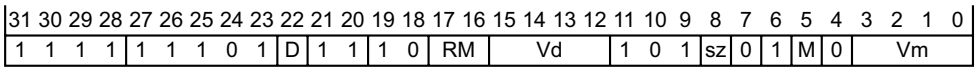
These instructions use the following rounding modes:

- `VRINTA`: Round to Nearest with Ties to Away.
- `VRINTN`: Round to Nearest with Ties to Even.
- `VRINTP`: Round toward +Infinity.
- `VRINTM`: Round toward -Infinity.

Encoding T1/A1

```
VRINT<r>.F64.F64 <Dd>, <Dm>
VRINT<r>.F32.F32 <Sd>, <Sm>
```





```
rounding = FPDecodeRM(RM);  exact = FALSE;  dp_operation = (sz == '1');
d = if dp_operation then UInt(D:Vd) else UInt(Vd:D);
m = if dp_operation then UInt(M:Vm) else UInt(Vm:M);
if InITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings See *Floating-point data-processing instructions* on page F5-2427.

Assembler syntax

`VRINT<r>{<q>}.F64.F64  <Dd>, <Dm>`	Encoded as sz = 1
`VRINT<r>{<q>}.F32.F32  <Sd>, <Sm>`	Encoded as sz = 0

where:

`r` Selects the rounding mode. It must be one of:

- `A` Encoded as RM = 00.
- `N` Encoded as RM = 01.
- `P` Encoded as RM = 10.
- `M` Encoded as RM = 11.

`<q>` See *Standard assembler syntax fields* on page F2-2330.

`<Dd>, <Dm>` The destination register and the operand register, for a double-precision operation.

`<Sd>, <Sm>` The destination register and the operand register, for a single-precision operation.

Operation

```
EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
if dp_operation then
    D[d] = FPRoundInt(D[m], FPSCR, rounding, exact);
else
    S[d] = FPRoundInt(S[m], FPSCR, rounding, exact);
```

F8.1.132 VRINTX (Advanced SIMD)

This instruction rounds a floating-point value to an integral floating-point value of the same size. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

VRINTX uses the Round to Nearest with Ties to Even rounding mode, and raises the Inexact exception when the result value is not numerically equal to the input value.

Encoding T1/A1

VRINTX.F32.F32 <Qd>, <Qm>

VRINTX.F32.F32 <Dd>, <Dm>

if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size != '10' then UNDEFINED;
rounding = FPRounding_TIEEVEN;  exact = TRUE;
esize = 32;  elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
if InITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`VRINTX{<q>}.F32.F32  <Qd>, <Qm>`	Encoded as Q = 1
`VRINTX{<q>}.F32.F32  <Dd>, <Dm>`	Encoded as Q = 0

where:

`<q>` See *Standard assembler syntax fields* on page F2-2330.

`<Qd>, <Qm>` The destination vector and the operand vector for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector for a doubleword operation.

Operation

```
EncodingSpecificOperations(); CheckAdvSIMDEnabled();
for r = 0 to regs-1
    for e = 0 to elements-1
        op1 = Elem[D[m+r],e,esize];
        result = FPRoundInt(op1, StandardFPSCRValue(), rounding, exact);
        Elem[D[d+r],e,esize] = result;
```

F8.1.133 VRINTX (floating-point)

This instruction rounds a floating-point value to an integral floating-point value of the same size. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

VRINTX uses the rounding mode specified in the FPSCR, and raises an Inexact exception when the result value is not numerically equal to the input value.

Encoding T1/A1

```
VRINTX<c>.F64.F64 <Dd>, <Dm>
VRINTX<c>.F32.F32 <Sd>, <Sm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Related encodings See *Floating-point data-processing instructions* on page F5-2427.

Assembler syntax

`VRINTX<c>{<q>}.F64.F64  <Dd>, <Dm>`	Encoded as sz= 1
`VRINTX<c>{<q>}.F32.F32  <Sd>, <Sm>`	Encoded as sz= 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Dd>, <Dm>` The destination register and the operand register, for a double-precision operation.

`<Sd>, <Sm>` The destination register and the operand register, for a single-precision operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    rounding = FPRoundingMode(FPSCR);
    if dp_operation then
        D[d] = FPRoundInt(D[m], FPSCR, rounding, exact);
    else
       S[d] = FPRoundInt(S[m], FPSCR, rounding, exact);
```

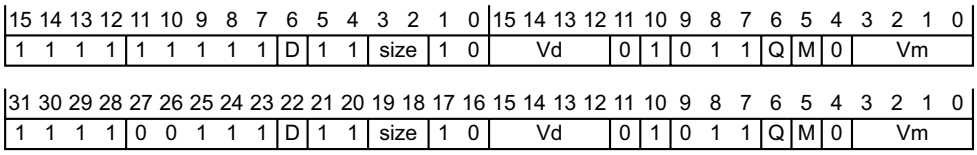
F8.1.134 VRINTZ (Advanced SIMD)

This instruction rounds a floating-point value to an integral floating-point value of the same size. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

VRINTZ uses the Round toward Zero rounding mode.

Encoding T1/A1

```
VRINTZ.F32.F32 <Qd>, <Qm>
VRINTZ.F32.F32 <Dd>, <Dm>
```



```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size != '10' then UNDEFINED;
rounding = FPRounding_ZERO;  exact = FALSE;
esize = 32;  elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
if InITBlock() then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`VRINTZ{<q>}.F32.F32  <Qd>, <Qm>`	Encoded as Q = 1
`VRINTZ{<q>}.F32.F32  <Dd>, <Dm>`	Encoded as Q = 0

where:

`<q>` See *Standard assembler syntax fields* on page F2-2330.

`<Qd>, <Qm>` The destination vector and the operand vector for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector for a doubleword operation.

Operation

```
EncodingSpecificOperations(); CheckAdvSIMDEnabled();
for r = 0 to regs-1
    for e = 0 to elements-1
        op1 = Elem[D[m+r],e,esize];
        result = FPRoundInt(op1, StandardFPSCRValue(), rounding, exact);
        Elem[D[d+r],e,esize] = result;
```

F8.1.135 VRINTZ, VRINTR (floating-point)

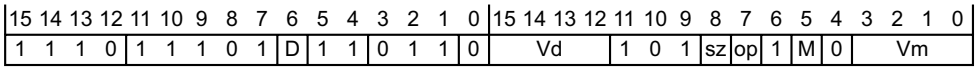
These instructions round a floating-point value to an integral floating-point value of the same size. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

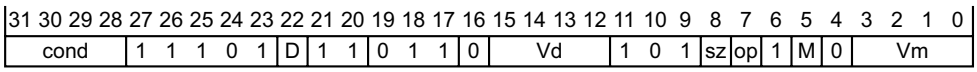
These instructions use the following rounding modes:

- `VRINTZ`: Round toward Zero.
- `VRINTR`: Round toward the rounding mode specified in the FPSCR.

Encoding T1/A1

```
VRINT<r><c>.F64.F64 <Dd>, <Dm>
VRINT<r><c>.F32.F32 <Sd>, <Sm>
```





```
rounding = if op == '1' then FPRounding_ZERO else FPRoundingMode(FPSCR);
dp_operation = (sz == '1');  exact = FALSE;
d = if dp_operation then UInt(D:Vd) else UInt(Vd:D);
m = if dp_operation then UInt(M:Vm) else UInt(Vm:M);
```

Related encodings See *Floating-point data-processing instructions* on page F5-2427.

Assembler syntax

`VRINT<r><c>{<q>}.F64.F64 <Dd>, <Dm>`	Encoded as sz= 1
`VRINT<r><c>{<q>}.F32.F32 <Sd>, <Sm>`	Encoded as sz= 0

where:

`<r>` Selects the rounding mode. It must be one of:

- `Z` Encoded as op = 1.
- `R` Encoded as op = 0.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Dd>, <Dm>` The destination register and the operand register, for a double-precision operation.

`<Sd>, <Sm>` The destination register and the operand register, for a single-precision operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    if dp_operation then
        D[d] = FPRoundInt(D[m], FPSCR, rounding, exact);
    else
        S[d] = FPRoundInt(S[m], FPSCR, rounding, exact);
```

F8.1.136 VRSHL

Vector Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see *VSHL (register)* on page F8-3302.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

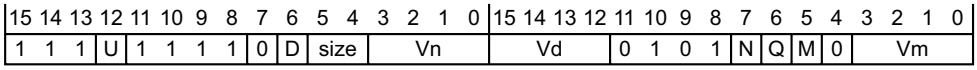
The second operand is always a signed integer of the same size.

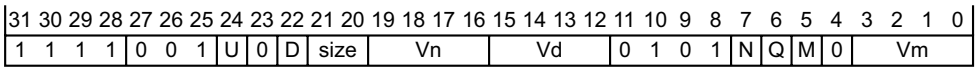
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VRSHL<c>.<type><size> <Qd>, <Qm>, <Qn>
VRSHL<c>.<type><size> <Dd>, <Dm>, <Dn>
```





```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1' || Vn<0> == '1') then UNDEFINED;
unsigned = (U == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  n = UInt(N:Vn);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VRSHL{<c>}{<q>}.<type><size>  {<Qd>,} <Qm>, <Qn>`	Encoded as Q = 1
`VRSHL{<c>}{<q>}.<type><size>  {<Dd>,} <Dm>, <Dn>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VRSHL` instruction must be unconditional. ARM strongly recommends that a T32 `VRSHL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<type>` The data type for the elements of the vectors. It must be one of:

- `S` Signed, encoded as U = 0.
- `U` Unsigned, encoded as U = 1.

Together with the `<size>` field, this indicates the data type and size of the first operand and the result.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.
- `64` Encoded as size = `0b11`.

`<Qd>, <Qm>, <Qn>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dm>, <Dn>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            shift = SInt(Elem[D[n+r],e,esize]<7:0>);
            round_const = 1 << (-shift-1); // 0 for left shift, 2^(n-1) for right shift
            result = (Int(Elem[D[m+r],e,esize], unsigned) + round_const) << shift;
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

F8.1.137 VRSHR

Vector Rounding Shift Right takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector. For truncated results, see *VSHR* on page F8-3306.

The operand and result elements must be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

VRSHR.<type><size>  <Dd>, <Dm>, #0      is a synonym for      VMOV <Dd>, <Dm>
```

For details see *VMOV (register)* on page F8-3178.

F8.1.138 VRSHRN

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector. For truncated results, see *VSHRN* on page F8-3308.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

case imm6 of
    when "001xxx"  esize = 8;  elements = 8;  shift_amount = 16 - UInt(imm6);
    when "01xxxx"  esize = 16;  elements = 4;  shift_amount = 32 - UInt(imm6);
    when "1xxxxx"  esize = 32;  elements = 2;  shift_amount = 64 - UInt(imm6);
d = UInt(D:Vd);  m = UInt(M:Vm);
```

Related encodings See *One register and a modified immediate value* on page F5-2424.

Assembler syntax

```
VRSHRN{<c>}{<q>}.I<size>  <Dd>, <Qm>, #<imm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VRSHRN` instruction must be unconditional. ARM strongly recommends that a T32 `VRSHRN` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size for the elements of the vectors. It must be one of:

- `16` Encoded as imm6<5:3> = `0b001`. (8 – `<imm>`) is encoded in imm6<2:0>.
- `32` Encoded as imm6<5:4> = `0b01`. (16 – `<imm>`) is encoded in imm6<3:0>.
- `64` Encoded as imm6<5> = `0b1`. (32 – `<imm>`) is encoded in imm6<4:0>.

`<Dd>, <Qm>` The destination vector, and the operand vector.

`<imm>` The immediate value, in the range 1 to `<size>`/2. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (shift_amount-1);
    for e = 0 to elements-1
        result = LSR(Elem[Qin[m>>1],e,2*esize] + round_const, shift_amount);
        Elem[D[d],e,esize] = result<esize-1:0>;
```

Pseudo-instructions

`VRSHRN.I<size>  <Dd>, <Qm>, #0` is a synonym for `VMOVN.I<size> <Dd>, <Qm>`

For details see *VMOVN* on page F8-3192.

F8.1.139 VRSQRTE

Vector Reciprocal Square Root Estimate finds an approximate reciprocal square root of each element in a vector, and places the results in a second vector.

The operand and result elements are the same type, and can be 32-bit floating-point numbers, or 32-bit unsigned integers.

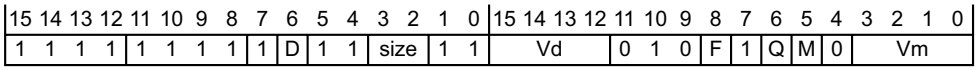
For details of the operation performed by this instruction see *Floating-point reciprocal estimate and step* on page E1-2235.

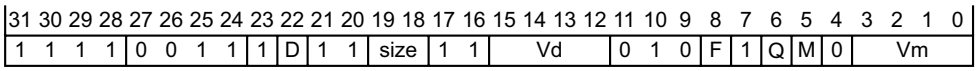
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VRSQRTE<c>.<dt> <Qd>, <Qm>
VRSQRTE<c>.<dt> <Dd>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size != '10' then UNDEFINED;
floating_point = (F == '1');  esize = 32;  elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VRSQRTE{<c>}{<q>}.<dt> <Qd>, <Qm>`	Encoded as Q = 1
`VRSQRTE{<c>}{<q>}.<dt> <Dd>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VRSQRTE` instruction must be unconditional. ARM strongly recommends that a T32 `VRSQRTE` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data types for the elements of the vectors. It must be one of:

- `U32` Encoded as F = 0, size = `0b10`.
- `F32` Encoded as F = 1, size = `0b10`.

`<Qd>, <Qm>` The destination vector and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if floating_point then
                Elem[D[d+r],e,32] = FPRSqrtEstimate(Elem[D[m+r],e,32], StandardFPSCRValue());
            else
                Elem[D[d+r],e,32] = UnsignedRSqrtEstimate(Elem[D[m+r],e,32]);
```

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of the square root of a number, see *Floating-point reciprocal estimate and step* on page E1-2235.

F8.1.140 VRSQRTS

Vector Reciprocal Square Root Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 3.0, divides these results by 2.0, and places the results into the elements of the destination vector.

The operand and result elements are 32-bit floating-point numbers.

For details of the operation performed by this instruction see *Floating-point reciprocal estimate and step* on page E1-2235.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

esize = 32;  elements = 2;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VRSQRTS{<c>}{<q>}.F32  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1, sz = 0
`VRSQRTS{<c>}{<q>}.F32  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0, sz = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VRSQRTS` instruction must be unconditional. ARM strongly recommends that a T32 `VRSQRTS` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,32] = FPRSqrtStep(Elem[D[n+r],e,32], Elem[D[m+r],e,32]);
```

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of the square root of a number, see *Floating-point reciprocal estimate and step* on page E1-2235.

F8.1.141 VRSRA

Vector Rounding Shift Right and Accumulate takes each element in a vector, right shifts them by an immediate value, and accumulates the rounded results into the destination vector. (For truncated results, see *VSRA* on page F8-3314.)

The operand and result elements must all be the same type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

Assembler syntax

```
VRSRA{<c>}{<q>}.<type><size>  {<Qd>,} <Qm>, #<imm>        Encoded as Q = 1
VRSRA{<c>}{<q>}.<type><size>  {<Dd>,} <Dm>, #<imm>        Encoded as Q = 0
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VRSRA` instruction must be unconditional. ARM strongly recommends that a T32 `VRSRA` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<type>` The data type for the elements of the vectors. It must be one of:

- `S` Signed, encoded as U = 0.
- `U` Unsigned, encoded as U = 1.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as L = 0, imm6<5:3> = `0b001`. (8 – `<imm>`) is encoded in imm6<2:0>.
- `16` Encoded as L = 0, imm6<5:4> = `0b01`. (16 – `<imm>`) is encoded in imm6<3:0>.
- `32` Encoded as L = 0, imm6<5> = `0b1`. (32 – `<imm>`) is encoded in imm6<4:0>.
- `64` Encoded as L = 1. (64 – `<imm>`) is encoded in imm6<5:0>.

`<Qd>, <Qm>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector, and the operand vector, for a doubleword operation.

`<imm>` The immediate value, in the range 1 to `<size>`. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (shift_amount - 1);
    for r = 0 to regs-1
        for e = 0 to elements-1
            result = (Int(Elem[D[m+r],e,esize], unsigned) + round_const) >> shift_amount;
            Elem[D[d+r],e,esize] = Elem[D[d+r],e,esize] + result;
```

F8.1.142 VRSUBHN

Vector Rounding Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector takes the most significant half of each result, and places the final results in a doubleword vector. The results are rounded. For truncated results, see *VSUBHN* on page F8-3342.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VRSUBHN<c>.<dt> <Dd>, <Qn>, <Qm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	1	D	size		Vn				Vd				0	1	1	0	N	0	M	0	Vm			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	D	size		Vn				Vd				0	1	1	0	N	0	M	0	Vm			

```
if size == '11' then SEE "Related encodings";
if Vn<0> == '1' || Vm<0> == '1' then UNDEFINED;
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

Related encodings See *Advanced SIMD data-processing instructions* on page F5-2415.

Assembler syntax

```
VRSUBHN{<c>}{<q>}.<dt>  <Dd>, <Qn>, <Qm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VRSUBHN` instruction must be unconditional. ARM strongly recommends that a T32 `VRSUBHN` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the operands. It must be one of:

- `I16` Encoded as size = `0b00`.
- `I32` Encoded as size = `0b01`.
- `I64` Encoded as size = `0b10`.

`<Dd>, <Qn>, <Qm>` The destination vector and the operand vectors.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (esize-1);
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] - Elem[Qin[m>>1],e,2*esize] + round_const;
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

F8.1.143 VSEL

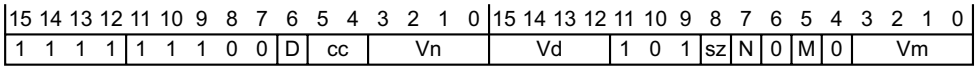
Floating-point selection allows the destination register to take the value in either one or the other source register according to the condition codes in the APSR.

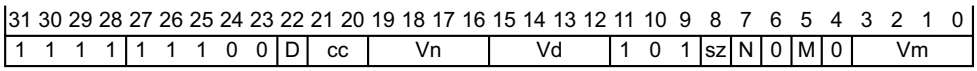
If VSEL generates an exception, it is regarded as unconditional for the purpose of reporting the condition field in the Exception Syndrome register.

VSEL cannot be made conditional using the IT mechanism in T32.

Encoding T1/A1

```
VSEL<c>.F64 <Dd>, <Dn>, <Dm>
VSEL<c>.F32 <Sd>, <Sn>, <Sm>
```





```
dp_operation = (sz == '1');
d = if dp_operation then UInt(D:Vd) else UInt(Vd:D);
n = if dp_operation then UInt(N:Vn) else UInt(Vn:N);
m = if dp_operation then UInt(M:Vm) else UInt(Vm:M);
cond = cc:(cc<1> EOR cc<0>):'0';
```

Assembler syntax

`VSEL<c>.F64 <Dd>, <Dn>, <Dm>`	Encoded as sz = 1
`VSEL<c>.F32 <Sd>, <Sn>, <Sm>`	Encoded as sz = 0

where:

`<c>` See *Standard assembler syntax fields* on page F2-2330. Must be one of `{GE, GT, EQ, VS}`, see *Conditional execution* on page F2-2331.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

`<Sd>, <Sn>, <Sm>` The destination vector and the operand vectors, for a singleword operation.

Operation

```
EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
if dp_operation then
    D[d] = if ConditionHolds(cond) then D[n] else D[m];
else
    S[d] = if ConditionHolds(cond) then S[n] else S[m];
```

F8.1.144 VSHL (immediate)

Vector Shift Left (immediate) takes each element in a vector of integers, left shifts them by an immediate value, and places the results in the destination vector.

Bits shifted out of the left of each element are lost.

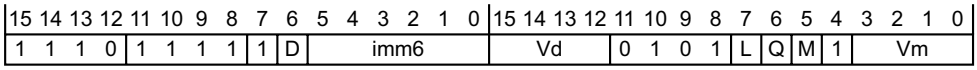
The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

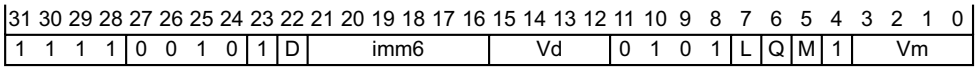
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VSHL<c>.I<size> <Qd>, <Qm>, #<imm>
VSHL<c>.I<size> <Dd>, <Dm>, #<imm>
```





```
if L:imm6 == '0000xxx' then SEE "Related encodings";
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
case L:imm6 of
    when "0001xxx"  esize = 8;  elements = 8;  shift_amount = UInt(imm6) - 8;
    when "001xxxx"  esize = 16;  elements = 4;  shift_amount = UInt(imm6) - 16;
    when "01xxxxx"  esize = 32;  elements = 2;  shift_amount = UInt(imm6) - 32;
    when "1xxxxxx"  esize = 64;  elements = 1;  shift_amount = UInt(imm6);
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Related encodings See *One register and a modified immediate value* on page F5-2424.

Assembler syntax

`VSHL{<c>}{<q>}.I<size>  {<Qd>,} <Qm>, #<imm>`	Encoded as Q = 1
`VSHL{<c>}{<q>}.I<size>  {<Dd>,} <Dm>, #<imm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VSHL` instruction must be unconditional. ARM strongly recommends that a T32 `VSHL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as L = 0, imm6<5:3> = `0b001`. `<imm>` is encoded in imm6<2:0>.
- `16` Encoded as L = 0, imm6<5:4> = `0b01`. `<imm>` is encoded in imm6<3:0>.
- `32` Encoded as L = 0, imm6<5> = `0b1`. `<imm>` is encoded in imm6<4:0>.
- `64` Encoded as L = 1. `<imm>` is encoded in imm6<5:0>.

`<Qd>, <Qm>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector, and the operand vector, for a doubleword operation.

`<imm>` The immediate value, in the range 0 to `<size>`-1. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = LSL(Elem[D[m+r],e,esize], shift_amount);
```

F8.1.145 VSHL (register)

Vector Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift.

Note

For a rounding shift, see *VRSHL* on page F8-3284.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

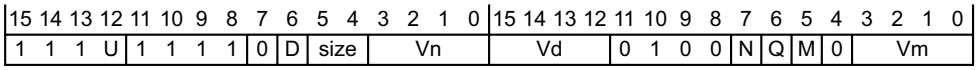
The second operand is always a signed integer of the same size.

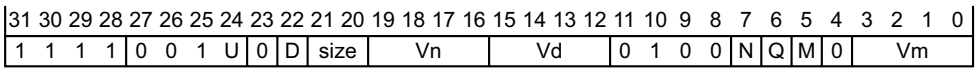
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VSHL<c>.<type><size> <Qd>, <Qm>, <Qn>
VSHL<c>.<type><size> <Dd>, <Dm>, <Dn>
```





```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1' || Vn<0> == '1') then UNDEFINED;
unsigned = (U == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  n = UInt(N:Vn);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VSHL{<c>}{<q>}.<type><size>  {<Qd>,} <Qm>, <Qn>`	Encoded as Q = 1
`VSHL{<c>}{<q>}.<type><size>  {<Dd>,} <Dm>, <Dn>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VSHL` instruction must be unconditional. ARM strongly recommends that a T32 `VSHL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<type>` The data type for the elements of the vectors. It must be one of:

- `S` Signed, encoded as U = 0.
- `U` Unsigned, encoded as U = 1.

Together with the `<size>` field, this indicates the data type and size of the first operand and the result.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.
- `64` Encoded as size = `0b11`.

`<Qd>, <Qm>, <Qn>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dm>, <Dn>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            shift = SInt(Elem[D[n+r],e,esize]<7:0>);
            result = Int(Elem[D[m+r],e,esize], unsigned) << shift;
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

F8.1.146 VSHLL

Vector Shift Left Long takes each element in a doubleword vector, left shifts them by an immediate value, and places the results in a quadword vector.

The operand elements can be:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit untyped integers, maximum shift only.

The result elements are twice the length of the operand elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VSHLL<c>.<type><size> <Qd>, <Dm>, #<imm>                    (0 < <imm> < <size>)
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
if size == '11' || Vd<0> == '1' then UNDEFINED;
esize = 8 << UInt(size);  elements = 64 DIV esize;  shift_amount = esize;
unsigned = FALSE;  // Or TRUE without change of functionality
d = UInt(D:Vd);  m = UInt(M:Vm);
```

Related encodings See *One register and a modified immediate value* on page F5-2424.

Assembler syntax

```
VSHLL{<c>}{<q>}.<type><size>  <Qd>, <Dm>, #<imm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VSHLL` instruction must be unconditional. ARM strongly recommends that a T32 `VSHLL` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<type>` The data type for the elements of the operand. It must be one of:

- `S` Signed. In encoding T1/A1, encoded as U = 0.
- `U` Unsigned. In encoding T1/A1, encoded as U = 1.
- `I` Untyped integer, Available only in encoding T2/A2.

`<size>` The data size for the elements of the operand. Table F8-5 shows the permitted values and their encodings:

Table F8-5 VSHLL <size> field encoding

<size>	Encoding T1/A1	Encoding T2/A2
8	Encoded as imm6<5:3> = 0b001	Encoded as size = 0b00
16	Encoded as imm6<5:4> = 0b01	Encoded as size = 0b01
32	Encoded as imm6<5> = 1	Encoded as size = 0b10

`<Qd>, <Dm>` The destination vector and the operand vector.

`<imm>` The immediate value. `<imm>` must lie in the range 1 to `<size>`, and:

- If `<size>` == `<imm>`, the encoding is T2/A2.
- Otherwise, the encoding is T1/A1, and:
  - If `<size>` == 8, `<imm>` is encoded in imm6<2:0>.
  - If `<size>` == 16, `<imm>` is encoded in imm6<3:0>.
  - If `<size>` == 32, `<imm>` is encoded in imm6<4:0>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Int(Elem[Din[m],e,esize], unsigned) << shift_amount;
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
```

F8.1.147 VSHR

Vector Shift Right takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector. For rounded results, see *VRSHR* on page F8-3286.

The operand and result elements must be the same size, and can be any one of:

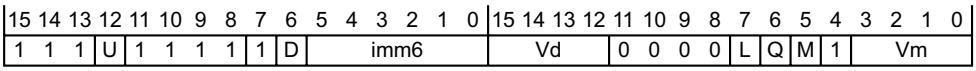
- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

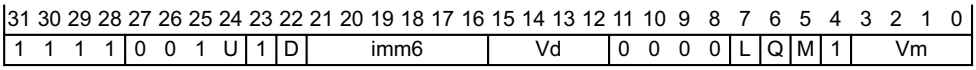
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VSHR<c>.<type><size> <Qd>, <Qm>, #<imm>
VSHR<c>.<type><size> <Dd>, <Dm>, #<imm>
```





```
if (L:imm6) == '0000xxx' then SEE "Related encodings";
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
case L:imm6 of
    when "0001xxx"  esize = 8;  elements = 8;  shift_amount = 16 - UInt(imm6);
    when "001xxxx"  esize = 16;  elements = 4;  shift_amount = 32 - UInt(imm6);
    when "01xxxxx"  esize = 32;  elements = 2;  shift_amount = 64 - UInt(imm6);
    when "1xxxxxx"  esize = 64;  elements = 1;  shift_amount = 64 - UInt(imm6);
unsigned = (U == '1');  d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Related encodings See *One register and a modified immediate value* on page F5-2424.

Assembler syntax

```
VSHR{<c>}{<q>}.<type><size>  {<Qd>,} <Qm>, #<imm>        Encoded as Q = 1
VSHR{<c>}{<q>}.<type><size>  {<Dd>,} <Dm>, #<imm>        Encoded as Q = 0
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VSHR` instruction must be unconditional. ARM strongly recommends that a T32 `VSHR` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<type>` The data type for the elements of the vectors. It must be one of:

- `S` Signed, encoded as U = 0.
- `U` Unsigned, encoded as U = 1.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as L = 0, imm6<5:3> = `0b001`. (8 – `<imm>`) is encoded in imm6<2:0>.
- `16` Encoded as L = 0, imm6<5:4> = `0b01`. (16 – `<imm>`) is encoded in imm6<3:0>.
- `32` Encoded as L = 0, imm6<5> = `0b1`. (32 – `<imm>`) is encoded in imm6<4:0>.
- `64` Encoded as L = 1. (64 – `<imm>`) is encoded in imm6<5:0>.

`<Qd>, <Qm>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector, and the operand vector, for a doubleword operation.

`<imm>` The immediate value, in the range 1 to `<size>`. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            result = Int(Elem[D[m+r],e,esize], unsigned) >> shift_amount;
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

Pseudo-instructions

```
VSHR.<type><size>  <Qd>, <Qm>, #0      is a synonym for      VMOV <Qd>, <Qm>
VSHR.<type><size>  <Dd>, <Dm>, #0      is a synonym for      VMOV <Dd>, <Dm>
```

F8.1.148 VSHRN

Vector Shift Right Narrow takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector. For rounded results, see *VRSHRN* on page F8-3288.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VSHRN<c>.I<size> <Dd>, <Qm>, #<imm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

case imm6 of
    when "001xxx"  esize = 8;  elements = 8;  shift_amount = 16 - UInt(imm6);
    when "01xxxx"  esize = 16;  elements = 4;  shift_amount = 32 - UInt(imm6);
    when "1xxxxx"  esize = 32;  elements = 2;  shift_amount = 64 - UInt(imm6);
d = UInt(D:Vd);  m = UInt(M:Vm);
```

Related encodings See *One register and a modified immediate value* on page F5-2424.

Assembler syntax

```
VSHRN{<c>}{<q>}.I<size>  <Dd>, <Qm>, #<imm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VSHRN` instruction must be unconditional. ARM strongly recommends that a T32 `VSHRN` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size for the elements of the vectors. It must be one of:

- `16` Encoded as imm6<5:3> = `0b001`. (8 – `<imm>`) is encoded in imm6<2:0>.
- `32` Encoded as imm6<5:4> = `0b01`. (16 – `<imm>`) is encoded in imm6<3:0>.
- `64` Encoded as imm6<5> = `0b1`. (32 – `<imm>`) is encoded in imm6<4:0>.

`<Dd>, <Qm>` The destination vector, and the operand vector.

`<imm>` The immediate value, in the range 1 to `<size>`/2. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = LSR(Elem[Qin[m>>1],e,2*esize], shift_amount);
        Elem[D[d],e,esize] = result<esize-1:0>;
```

Pseudo-instructions

`VSHRN.I<size>  <Dd>, <Qm>, #0` is a synonym for `VMOVN.I<size> <Dd>, <Qm>`

For details see *VMOVN* on page F8-3192.

F8.1.149 VSLI

Vector Shift Left and Insert takes each element in the operand vector, left shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the left of each element are lost.

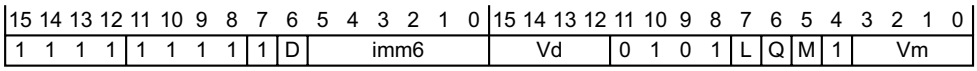
The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit. There is no distinction between data types.

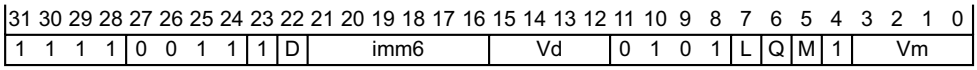
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VSLI<c>.<size> <Qd>, <Qm>, #<imm>
VSLI<c>.<size> <Dd>, <Dm>, #<imm>
```





```
if (L:imm6) == '0000xxx' then SEE "Related encodings";
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
case L:imm6 of
    when "0001xxx"  esize = 8;  elements = 8;  shift_amount = UInt(imm6) - 8;
    when "001xxxx"  esize = 16;  elements = 4;  shift_amount = UInt(imm6) - 16;
    when "01xxxxx"  esize = 32;  elements = 2;  shift_amount = UInt(imm6) - 32;
    when "1xxxxxx"  esize = 64;  elements = 1;  shift_amount = UInt(imm6);
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Related encodings See *One register and a modified immediate value* on page F5-2424.

Assembler syntax

`VSLI{<c>}{<q>}.<size>  {<Qd>,} <Qm>, #<imm>`	Encoded as Q = 1
`VSLI{<c>}{<q>}.<size>  {<Dd>,} <Dm>, #<imm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VSLI` instruction must be unconditional. ARM strongly recommends that a T32 `VSLI` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as L = 0, imm6<5:3> = `0b001`. `<imm>` is encoded in imm6<2:0>.
- `16` Encoded as L = 0, imm6<5:4> = `0b01`. `<imm>` is encoded in imm6<3:0>.
- `32` Encoded as L = 0, imm6<5> = `0b1`. `<imm>` is encoded in imm6<4:0>.
- `64` Encoded as L = 1. `<imm>` is encoded in imm6<5:0>.

`<Qd>, <Qm>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector, and the operand vector, for a doubleword operation.

`<imm>` The immediate value, in the range 0 to `<size>`-1. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    mask = LSL(Ones(esize), shift_amount);
    for r = 0 to regs-1
        for e = 0 to elements-1
            shifted_op = LSL(Elem[D[m+r],e,esize], shift_amount);
            Elem[D[d+r],e,esize] = (Elem[D[d+r],e,esize] AND NOT(mask)) OR shifted_op;
```

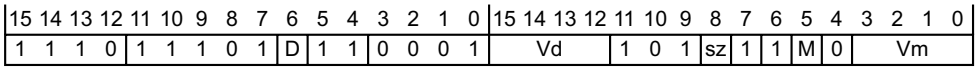
F8.1.150 VSQRT

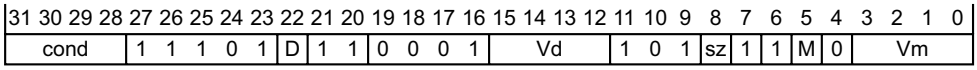
This instruction calculates the square root of the value in a floating-point register and writes the result to another floating-point register.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 summarizes these controls.

Encoding T1/A1

```
VSQRT<c>.F64 <Dd>, <Dm>
VSQRT<c>.F32 <Sd>, <Sm>
```





```
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
dp_operation = (sz == '1');
d = if dp_operation then UInt(D:Vd) else UInt(Vd:D);
m = if dp_operation then UInt(M:Vm) else UInt(Vm:M);
```

Assembler syntax

`VSQRT{<c>}{<q>}.F64 <Dd>, <Dm>`	Encoded as sz = 1
`VSQRT{<c>}{<q>}.F32 <Sd>, <Sm>`	Encoded as sz = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Dd>, <Dm>` The destination vector and the operand vector, for a double-precision operation.

`<Sd>, <Sm>` The destination vector and the operand vector, for a single-precision operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if dp_operation then
        D[d] = FPSqrt(D[m], StandardFPSCRValue());
    else
        S[d] = FPSqrt(S[m], StandardFPSCRValue());
```

F8.1.151 VSRA

Vector Shift Right and Accumulate takes each element in a vector, right shifts them by an immediate value, and accumulates the truncated results into the destination vector. For rounded results, see *VRSRA* on page F8-3294.

The operand and result elements must all be the same type, and can be any one of:

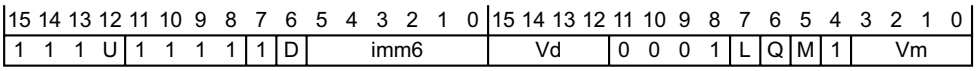
- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

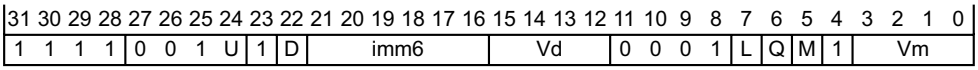
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VSRA<c>.<type><size> <Qd>, <Qm>, #<imm>
VSRA<c>.<type><size> <Dd>, <Dm>, #<imm>
```





```
if (L:imm6) == '0000xxx' then SEE "Related encodings";
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
case L:imm6 of
    when "0001xxx"  esize = 8;  elements = 8;  shift_amount = 16 - UInt(imm6);
    when "001xxxx"  esize = 16;  elements = 4;  shift_amount = 32 - UInt(imm6);
    when "01xxxxx"  esize = 32;  elements = 2;  shift_amount = 64 - UInt(imm6);
    when "1xxxxxx"  esize = 64;  elements = 1;  shift_amount = 64 - UInt(imm6);
unsigned = (U == '1');  d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Related encodings See *One register and a modified immediate value* on page F5-2424.

Assembler syntax

```
VSRA{<c>}{<q>}.<type><size>  {<Qd>,} <Qm>, #<imm>        Encoded as Q = 1
VSRA{<c>}{<q>}.<type><size>  {<Dd>,} <Dm>, #<imm>        Encoded as Q = 0
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VSRA` instruction must be unconditional. ARM strongly recommends that a T32 `VSRA` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<type>` The data type for the elements of the vectors. It must be one of:

- `S` Signed, encoded as U = 0.
- `U` Unsigned, encoded as U = 1.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as L = 0, imm6<5:3> = `0b001`. (8 – `<imm>`) is encoded in imm6<2:0>.
- `16` Encoded as L = 0, imm6<5:4> = `0b01`. (16 – `<imm>`) is encoded in imm6<3:0>.
- `32` Encoded as L = 0, imm6<5> = `0b1`. (32 – `<imm>`) is encoded in imm6<4:0>.
- `64` Encoded as L = 1. (64 – `<imm>`) is encoded in imm6<5:0>.

`<Qd>, <Qm>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector, and the operand vector, for a doubleword operation.

`<imm>` The immediate value, in the range 1 to `<size>`. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            result = Int(Elem[D[m+r],e,esize], unsigned) >> shift_amount;
            Elem[D[d+r],e,esize] = Elem[D[d+r],e,esize] + result;
```

F8.1.152 VSRI

Vector Shift Right and Insert takes each element in the operand vector, right shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the right of each element are lost.

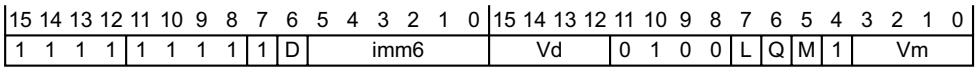
The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit. There is no distinction between data types.

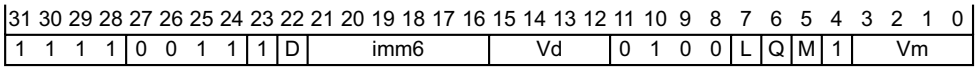
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VSRI<c>.<size> <Qd>, <Qm>, #<imm>
VSRI<c>.<size> <Dd>, <Dm>, #<imm>
```





```
if (L:imm6) == '0000xxx' then SEE "Related encodings";
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
case L:imm6 of
    when "0001xxx"  esize = 8;  elements = 8;  shift_amount = 16 - UInt(imm6);
    when "001xxxx"  esize = 16;  elements = 4;  shift_amount = 32 - UInt(imm6);
    when "01xxxxx"  esize = 32;  elements = 2;  shift_amount = 64 - UInt(imm6);
    when "1xxxxxx"  esize = 64;  elements = 1;  shift_amount = 64 - UInt(imm6);
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Related encodings See *One register and a modified immediate value* on page F5-2424.

Assembler syntax

```
VSRI{<c>}{<q>}.<size>  {<Qd>,} <Qm>, #<imm>        Encoded as Q = 1
VSRI{<c>}{<q>}.<size>  {<Dd>,} <Dm>, #<imm>        Encoded as Q = 0
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VSRI` instruction must be unconditional. ARM strongly recommends that a T32 `VSRI` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as L = 0, imm6<5:3> = `0b001`. (8 – `<imm>`) is encoded in imm6<2:0>.
- `16` Encoded as L = 0, imm6<5:4> = `0b01`. (16 – `<imm>`) is encoded in imm6<3:0>.
- `32` Encoded as L = 0, imm6<5> = `0b1`. (32 – `<imm>`) is encoded in imm6<4:0>.
- `64` Encoded as L = 1. (64 – `<imm>`) is encoded in imm6<5:0>.

`<Qd>, <Qm>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector, and the operand vector, for a doubleword operation.

`<imm>` The immediate value, in the range 1 to `<size>`. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    mask = LSR(Ones(esize), shift_amount);
    for r = 0 to regs-1
        for e = 0 to elements-1
            shifted_op = LSR(Elem[D[m+r],e,esize], shift_amount);
            Elem[D[d+r],e,esize] = (Elem[D[d+r],e,esize] AND NOT(mask)) OR shifted_op;
```

F8.1.153 VST1 (multiple single elements)

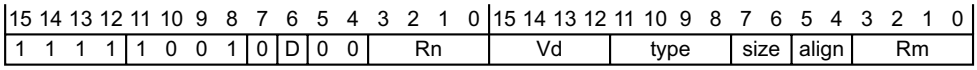
Vector Store (multiple single elements) stores elements to memory from one, two, three, or four registers, without interleaving. Every element of each register is stored. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

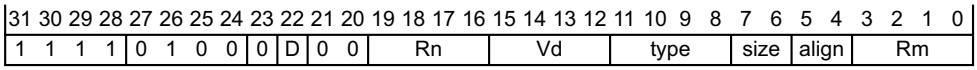
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VST1<c>.<size> <list>, [<Rn>{:<align>}]{!}
VST1<c>.<size> <list>, [<Rn>{:<align>}], <Rm>
```





```
case type of
    when ‘0111’
        regs = 1;  if align<1> == ‘1’ then UNDEFINED;
    when ‘1010’
        regs = 2;  if align == ‘11’ then UNDEFINED;
    when ‘0110’
        regs = 3;  if align<1> == ‘1’ then UNDEFINED;
    when ‘0010’
        regs = 4;
    otherwise
        SEE “Related encodings”;
alignment = if align == ‘00’ then 1 else 4 << UInt(align);
ebytes = 1 << UInt(size);  elements = 8 DIV ebytes;
d = UInt(D:Vd);  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VST1 (multiple single elements)* on page AppxA-4847.

Related encodings See *Advanced SIMD element or structure load/store instructions* on page F5-2431.

Assembler syntax

`VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VST1` instruction must be unconditional. ARM strongly recommends that a T32 `VST1` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

64 Encoded as size = 0b11.

<list> The list of registers to store. It must be one of:

{<Dd>} Encoded as D:Vd = <Dd>, type = 0b0111.

{<Dd>, <Dd+1>} Encoded as D:Vd = <Dd>, type = 0b1010.

{<Dd>, <Dd+1>, <Dd+2>}
Encoded as D:Vd = <Dd>, type = 0b0110.

{<Dd>, <Dd+1>, <Dd+2>, <Dd+3>}
Encoded as D:Vd = <Dd>, type = 0b0010.

<Rn> Contains the base address for the access.

<align> The alignment. It can be one of:

64 8-byte alignment, encoded as align = 0b01.

128 16-byte alignment, available only if <list> contains two or four registers, encoded as align = 0b10.

256 32-byte alignment, available only if <list> contains four registers, encoded as align = 0b11.

omitted Standard alignment, see *Unaligned data access* on page E2-2256. Encoded as align = 0b00.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode* on page F5-2433.

! If present, specifies writeback.

<Rm> Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm>, see *Advanced SIMD addressing mode* on page F5-2433.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 8*regs);
    for r = 0 to regs-1
        for e = 0 to elements-1
            if ebytes != 8 then
                MemU[address,ebytes] = Elem[D[d+r],e];
            else
                bits(64) data = Elem[D[d+r],e];
                MemU[address,4] = if BigEndian() then data<63:32> else data<31:0>;
                MemU[address+4,4] = if BigEndian() then data<31:0> else data<63:32>;
            address = address + ebytes;
```

F8.1.154 VST1 (single element from one lane)

This instruction stores one element to memory from one element of a register. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

`VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VST1` instruction must be unconditional. ARM strongly recommends that a T32 `VST1` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<list>` The register containing the element to store. It must be `{<Dd[x]>}`. The register `Dd` is encoded in D:Vd

`<Rn>` Contains the base address for the access.

`<align>` The alignment. It can be one of:

- `16` 2-byte alignment, available only if `<size>` is 16.
- `32` 4-byte alignment, available only if `<size>` is 32.
- **omitted** Standard alignment, see *Unaligned data access* on page E2-2256.

: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page F5-2433.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page F5-2433.

Table F8-6 shows the encoding of index and alignment for different `<size>` values.

Table F8-6 Encoding of index and alignment

	`<size>` == 8	`<size>` == 16	`<size>` == 32
Index	`index_align[3:1]` = x	`index_align[3:2]` = x	`index_align[3]` = x
`<align>` omitted	`index_align[0]` = 0	`index_align[1:0]` = '00'	`index_align[2:0]` = '000'
`<align>` == 16	-	`index_align[1:0]` = '01'	-
`<align>` == 32	-	-	`index_align[2:0]` = '011'

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else ebytes);
    MemU[address,ebytes] = Elem[D[d],index];
```

F8.1.155 VST2 (multiple 2-element structures)

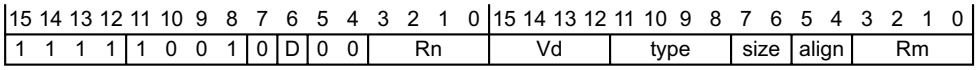
This instruction stores multiple 2-element structures from two or four registers to memory, with interleaving. For more information, see *Element and structure load/store instructions* on page F1-2315. Every element of each register is saved. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

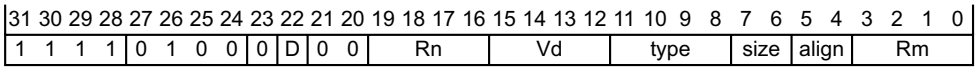
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VST2<c>.<size> <list>, [<Rn>{:<align>}]{!}
VST2<c>.<size> <list>, [<Rn>{:<align>}], <Rm>
```





```
if size == '11' then UNDEFINED;
case type of
    when '1000'
        regs = 1;  inc = 1;  if align == '11' then UNDEFINED;
    when '1001'
        regs = 1;  inc = 2;  if align == '11' then UNDEFINED;
    when '0011'
        regs = 2;  inc = 2;
    otherwise
        SEE "Related encodings";
alignment = if align == '00' then 1 else 4 << UInt(align);
ebytes = 1 << UInt(size);  elements = 8 DIV ebytes;
d = UInt(D:Vd);  d2 = d + inc;  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d2+regs > 32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VST2 (multiple 2-element structures)* on page AppxA-4847.

Related encodings See *Advanced SIMD element or structure load/store instructions* on page F5-2431.

Assembler syntax

`VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VST2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VST2` instruction must be unconditional. ARM strongly recommends that a T32 `VST2` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<list>` The list of registers to store. It must be one of:

- `{<Dd>, <Dd+1>}` Encoded as D:Vd = `<Dd>`, type = `0b1000`.
- `{<Dd>, <Dd+2>}` Encoded as D:Vd = `<Dd>`, type = `0b1001`.
- `{<Dd>, <Dd+1>, <Dd+2>, <Dd+3>}` Encoded as D:Vd = `<Dd>`, type = `0b0011`.

`<Rn>` Contains the base address for the access.

`<align>` The alignment. It can be one of:

- `64` 8-byte alignment, encoded as align = `0b01`.
- `128` 16-byte alignment, encoded as align = `0b10`.
- `256` 32-byte alignment, available only if `<list>` contains four registers, encoded as align = `0b11`.
- **omitted** Standard alignment, see *Unaligned data access* on page E2-2256. Encoded as align = `0b00`.

: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page F5-2433.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page F5-2433.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 16*regs);
    for r = 0 to regs-1
        for e = 0 to elements-1
            MemU[address,       ebytes] = Elem[D[d+r], e];
            MemU[address+ebytes,ebytes] = Elem[D[d2+r],e];
            address = address + 2*ebytes;
```

F8.1.156 VST2 (single 2-element structure from one lane)

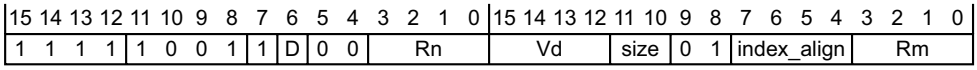
This instruction stores one 2-element structure to memory from corresponding elements of two registers. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

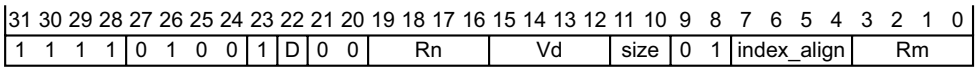
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VST2<c>.<size> <list>, [<Rn>{:<align>}]{!}
VST2<c>.<size> <list>, [<Rn>{:<align>}], <Rm>
```





```
if size == '11' then UNDEFINED;
case size of
    when '00'
        ebytes = 1;  index = UInt(index_align<3:1>);  inc = 1;
        alignment = if index_align<0> == '0' then 1 else 2;
    when '01'
        ebytes = 2;  index = UInt(index_align<3:2>);
        inc = if index_align<1> == '0' then 1 else 2;
        alignment = if index_align<0> == '0' then 1 else 4;
    when '10'
        if index_align<1> != '0' then UNDEFINED;
        ebytes = 4;  index = UInt(index_align<3>);
        inc = if index_align<2> == '0' then 1 else 2;
        alignment = if index_align<0> == '0' then 1 else 8;
d = UInt(D:Vd);  d2 = d + inc;  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d2 > 31 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VST2 (single 2-element structure from one lane)* on page AppxA-4848.

Assembler syntax

`VST2{<c>}{<q>}.<size>  <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VST2{<c>}{<q>}.<size>  <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VST2{<c>}{<q>}.<size>  <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VST2` instruction must be unconditional. ARM strongly recommends that a T32 `VST2` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<list>` The registers containing the structure. Encoded with D:Vd = `<Dd>`. It must be one of:

`{<Dd[x]>, <Dd+1[x]>}` Single-spaced registers, see Table F8-7.

`{<Dd[x]>, <Dd+2[x]>}` Double-spaced registers, see Table F8-7. This is not available if `<size>` == 8.

`<Rn>` Contains the base address for the access.

`<align>` The alignment. It can be one of:

`16` 2-byte alignment, available only if `<size>` is 8.

`32` 4-byte alignment, available only if `<size>` is 16.

`64` 8-byte alignment, available only if `<size>` is 32.

omitted Standard alignment, see *Unaligned data access* on page E2-2256.

: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page F5-2433.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page F5-2433.

Table F8-7 Encoding of index, alignment, and register spacing

	`<size>` == 8	`<size>` == 16	`<size>` == 32
Index	`index_align[3:1]` = x	`index_align[3:2]` = x	`index_align[3]` = x
Single-spacing	-	`index_align[1]` = 0	`index_align[2]` = 0
Double-spacing	-	`index_align[1]` = 1	`index_align[2]` = 1
`<align>` omitted	`index_align[0]` = 0	`index_align[0]` = 0	`index_align[1:0]` = '00'
`<align>` == 16	`index_align[0]` = 1	-	-
`<align>` == 32	-	`index_align[0]` = 1	-
`<align>` == 64	-	-	`index_align[1:0]` = '01'

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 2*ebytes);
    MemU[address,       ebytes] = Elem[D[d], index];
    MemU[address+ebytes,ebytes] = Elem[D[d2],index];
```

F8.1.157 VST3 (multiple 3-element structures)

This instruction stores multiple 3-element structures to memory from three registers, with interleaving. For more information, see *Element and structure load/store instructions* on page F1-2315. Every element of each register is saved. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

if n == 15 || d4 > 31 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VST4 (multiple 4-element structures)* on page AppxA-4849.

Related encodings See *Advanced SIMD element or structure load/store instructions* on page F5-2431.

Assembler syntax

`VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VST4` instruction must be unconditional. ARM strongly recommends that a T32 `VST4` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<list>` The list of registers to store. It must be one of:

- `{<Dd>, <Dd+1>, <Dd+2>, <Dd+3>}` Encoded as D:Vd = `<Dd>`, type = `0b0000`.
- `{<Dd>, <Dd+2>, <Dd+4>, <Dd+6>}` Encoded as D:Vd = `<Dd>`, type = `0b0001`.

`<Rn>` Contains the base address for the access.

`<align>` The alignment. It can be one of:

- `64` 8-byte alignment, encoded as align = `0b01`.
- `128` 16-byte alignment, encoded as align = `0b10`.
- `256` 32-byte alignment, encoded as align = `0b11`.
- **omitted** Standard alignment, see *Unaligned data access* on page E2-2256. Encoded as align = `0b00`.

: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page F5-2433.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page F5-2433.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 32);
    for e = 0 to elements-1
        MemU[address,         ebytes] = Elem[D[d], e];
        MemU[address+ebytes,  ebytes] = Elem[D[d2],e];
        MemU[address+2*ebytes,ebytes] = Elem[D[d3],e];
        MemU[address+3*ebytes,ebytes] = Elem[D[d4],e];
        address = address + 4*ebytes;
```

F8.1.160 VST4 (single 4-element structure from one lane)

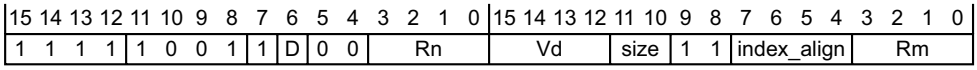
This instruction stores one 4-element structure to memory from corresponding elements of four registers. For details of the addressing mode see *Advanced SIMD addressing mode* on page F5-2433.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

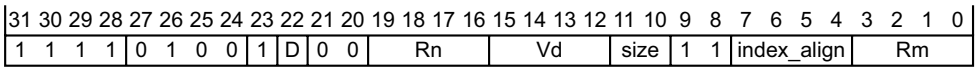
ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VST4<c>.<size> <list>, [<Rn>{:<align>}]{!}
VST4<c>.<size> <list>, [<Rn>{:<align>}], <Rm>
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	0	1	1	D	0	0	Rn				Vd				size		1	1	index_align				Rm			



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	0	1	D	0	0	Rn				Vd				size		1	1	index_align				Rm			

```
if size == '11' then UNDEFINED;
case size of
    when '00'
        ebytes = 1;  index = UInt(index_align<3:1>);  inc = 1;
        alignment = if index_align<0> == '0' then 1 else 4;
    when '01'
        ebytes = 2;  index = UInt(index_align<3:2>);
        inc = if index_align<1> == '0' then 1 else 2;
        alignment = if index_align<0> == '0' then 1 else 8;
    when '10'
        if index_align<1:0> == '11' then UNDEFINED;
        ebytes = 4;  index = UInt(index_align<3>);
        inc = if index_align<2> == '0' then 1 else 2;
        alignment = if index_align<1:0> == '00' then 1 else 4 << UInt(index_align<1:0>);
d = UInt(D:Vd);  d2 = d + inc;  d3 = d2 + inc;  d4 = d3 + inc;  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VST4 (single 4-element structure from one lane)* on page AppxA-4849.

Assembler syntax

`VST4{<c>}{<q>}.<size>  <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VST4{<c>}{<q>}.<size>  <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VST4{<c>}{<q>}.<size>  <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VST4` instruction must be unconditional. ARM strongly recommends that a T32 `VST4` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<list>` The registers containing the structure. Encoded with D:Vd = `<Dd>`. It must be one of:

`{<Dd[x]>, <Dd+1[x]>, <Dd+2[x]>, <Dd+3[x]>}`
Single-spaced registers, see Table F8-9 on page F8-3333.

`{<Dd[x]>, <Dd+2[x]>, <Dd+4[x]>, <Dd+6[x]>}`
: Double-spaced registers, see Table F8-9. This is not available if `<size>` == 8.

`<Rn>`
: The base address for the access.

`<align>`
: The alignment. It can be:

  `32` — 4-byte alignment, available only if `<size>` is 8.

  `64` — 8-byte alignment, available only if `<size>` is 16 or 32.

  `128` — 16-byte alignment, available only if `<size>` is 32.

  omitted — Standard alignment, see *Unaligned data access* on page E2-2256.

  : is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page F5-2433.

`!`
: If present, specifies writeback.

`<Rm>`
: Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page F5-2433.

Table F8-9 Encoding of index, alignment, and register spacing

	`<size>` == 8	`<size>` == 16	`<size>` == 32
Index	`index_align[3:1]` = x	`index_align[3:2]` = x	`index_align[3]` = x
Single-spacing	-	`index_align[1]` = 0	`index_align[2]` = 0
Double-spacing	-	`index_align[1]` = 1	`index_align[2]` = 1
`<align>` omitted	`index_align[0]` = 0	`index_align[0]` = 0	`index_align[1:0]` = '00'
`<align>` == 32	`index_align[0]` = 1	-	-
`<align>` == 64	-	`index_align[0]` = 1	`index_align[1:0]` = '01'
`<align>` == 128	-	-	`index_align[1:0]` = '10'

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 4*ebytes);
    MemU[address,         ebytes] = Elem[D[d], index];
    MemU[address+ebytes,  ebytes] = Elem[D[d2],index];
    MemU[address+2*ebytes,ebytes] = Elem[D[d3],index];
    MemU[address+3*ebytes,ebytes] = Elem[D[d4],index];
```

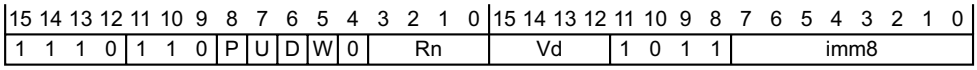
F8.1.161 VSTM

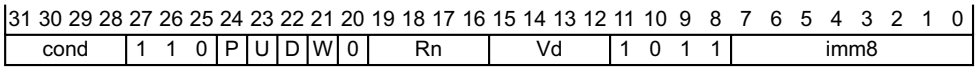
Vector Store Multiple stores multiple registers from the Advanced SIMD and floating-point register file to consecutive memory locations using an address from a general-purpose register.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

Encoding T1/A1

`VSTM{mode}<c> <Rn>{!}, <list>` — `<list>` is consecutive 64-bit registers

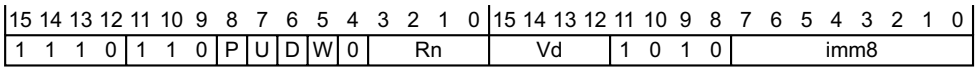


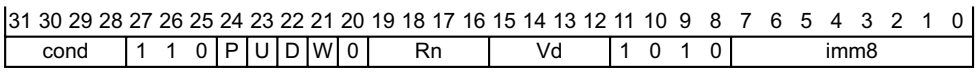


```
if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && U == '0' && W == '1' && Rn == '1101' then SEE VPUSH;
if P == '1' && W == '0' then SEE VSTR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE;  add = (U == '1');  wback = (W == '1');
d = UInt(D:Vd);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2;  // If UInt(imm8) is odd, see "FSTMX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
```

Encoding T2/A2

`VSTM{mode}<c> <Rn>{!}, <list>` — `<list>` is consecutive 32-bit registers





```
if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && U == '0' && W == '1' && Rn == '1101' then SEE VPUSH;
if P == '1' && W == '0' then SEE VSTR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = TRUE;  add = (U == '1');  wback = (W == '1');  d = UInt(Vd:D);  n = UInt(Rn);
imm32 = ZeroExtend(imm8:'00', 32);  regs = UInt(imm8);
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VSTM* on page AppxA-4850.

Related encodings See *64-bit transfers accessing the SIMD and floating-point register file* on page F5-2435.

FSTMX Encoding T1/A1 behaves as described by the pseudocode if imm8 is odd. However, there is no UAL syntax for such encodings and ARM deprecates their use. For more information, see *FLDMX, FSTMX* on page F8-3040.

Assembler syntax

```
VSTM{<mode>}{<c>}{<q>}{.<size>}  <Rn>{!}, <list>
```

where:

`<mode>` The addressing mode:

- `IA` Increment After. The consecutive addresses start at the address specified in `<Rn>`. This is the default and can be omitted. Encoded as P = 0, U = 1.
- `DB` Decrement Before. The consecutive addresses end just before the address specified in `<Rn>`. Encoded as P = 1, U = 0.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<size>` An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers in `<list>`.

`<Rn>` The base register. The SP can be used. In the A32 instruction set, if `!` is not specified the PC can be used. However, ARM deprecates use of the PC.

`!` Causes the instruction to write a modified value back to `<Rn>`. Required if <mode> == `DB`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<list>` The registers from the Advanced SIMD and floating-point register file to be stored, as a list of consecutively numbered doubleword (encoding T1/A1) or singleword (encoding T2/A2) registers, separated by commas and surrounded by brackets. It is encoded in the instruction by setting D and Vd to specify the first register in the list, and imm8 to twice the number of registers in the list (encoding T1/A1) or the number of registers (encoding T2/A2). `<list>` must contain at least one register. If it contains doubleword registers it must not contain more than 16 registers.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            MemA[address,4] = S[d+r];  address = address+4;
        else
            // Store as two word-aligned words in the correct order for current endianness.
            MemA[address,4] = if BigEndian() then D[d+r]<63:32> else D[d+r]<31:0>;
            MemA[address+4,4] = if BigEndian() then D[d+r]<31:0> else D[d+r]<63:32>;
            address = address+8;
```

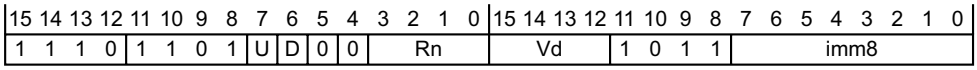
F8.1.162 VSTR

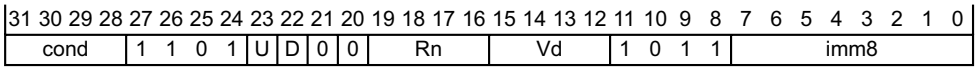
This instruction stores a single register from the Advanced SIMD and floating-point register file to memory, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, and HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

Encoding T1/A1

```
VSTR<c> <Dd>, [<Rn>{, #+/-<imm>}]
```

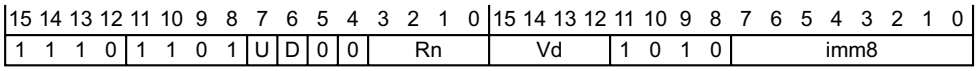


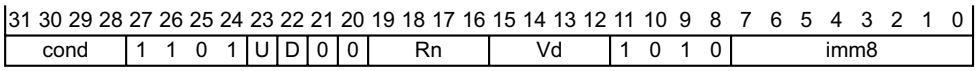


```
single_reg = FALSE;  add = (U == '1');  imm32 = ZeroExtend(imm8:'00', 32);
d = UInt(D:Vd);  n = UInt(Rn);
if n == 15 && CurrentInstrSet() != InstrSet_A32 then UNPREDICTABLE;
```

Encoding T2/A2

```
VSTR<c> <Sd>, [<Rn>{, #+/-<imm>}]
```





```
single_reg = TRUE;  add = (U == '1');  imm32 = ZeroExtend(imm8:'00', 32);
d = UInt(Vd:D);  n = UInt(Rn);
if n == 15 && CurrentInstrSet() != InstrSet_A32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler syntax

```
VSTR{<c>}{<q>}{.64}  <Dd>, [<Rn>{, #+/-<imm>}]          Encoding T1/A1
VSTR{<c>}{<q>}{.32}  <Sd>, [<Rn>{, #+/-<imm>}]          Encoding T2/A2
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`.32, .64` Optional data size specifiers.

`<Dd>` The source register for a doubleword store.

`<Sd>` The source register for a singleword store.

`<Rn>` The base register. The SP can be used. In the A32 instruction set the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Values are multiples of 4 in the range 0-1020. `<imm>` can be omitted, meaning an offset of +0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    address = if add then (R[n] + imm32) else (R[n] - imm32);
    if single_reg then
        MemA[address,4] = S[d];
    else
        // Store as two word-aligned words in the correct order for current endianness.
        MemA[address,4] = if BigEndian() then D[d]<63:32> else D[d]<31:0>;
        MemA[address+4,4] = if BigEndian() then D[d]<31:0> else D[d]<63:32>;
```

F8.1.163 VSUB (integer)

Vector Subtract subtracts the elements of one vector from the corresponding elements of another vector, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VSUB<c>.<dt> <Qd>, <Qn>, <Qm>
VSUB<c>.<dt> <Dd>, <Dn>, <Dm>
```

            S[d] = FPSub(S[n], S[m], FPSCR);
```

F8.1.165 VSUBHN

Vector Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector, takes the most significant half of each result, and places the final results in a doubleword vector. The results are truncated. For rounded results, see *VRSUBHN* on page F8-3296.

There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
if size == '11' then SEE "Related encodings";
if Vn<0> == '1' || Vm<0> == '1' then UNDEFINED;
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

Related encodings See *Advanced SIMD data-processing instructions* on page F5-2415.

Assembler syntax

```
VSUBHN{<c>}{<q>}.<dt>  <Dd>, <Qn>, <Qm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VSUBHN` instruction must be unconditional. ARM strongly recommends that a T32 `VSUBHN` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the operands. It must be one of:

- `I16` Encoded as size = `0b00`.
- `I32` Encoded as size = `0b01`.
- `I64` Encoded as size = `0b10`.

`<Dd>, <Qn>, <Qm>` The destination vector, the first operand vector, and the second operand vector.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] - Elem[Qin[m>>1],e,2*esize];
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

F8.1.166 VSUBL, VSUBW

Vector Subtract Long subtracts the elements of one doubleword vector from the corresponding elements of another doubleword vector, and places the results in a quadword vector. Before subtracting, it sign-extends or zero-extends the elements of both operands.

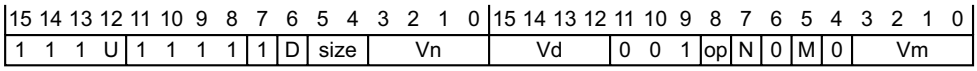
Vector Subtract Wide subtracts the elements of a doubleword vector from the corresponding elements of a quadword vector, and places the results in another quadword vector. Before subtracting, it sign-extends or zero-extends the elements of the doubleword operand.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VSUBL<c>.<dt> <Qd>, <Dn>, <Dm>
VSUBW<c>.<dt> <Qd>, <Qn>, <Dm>
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

esize = 8 << UInt(size);  elements = 64 DIV esize;  is_vsubw = (op == '1');
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

Related encodings See *Advanced SIMD data-processing instructions* on page F5-2415.

Assembler syntax

`VSUBL{<c>}{<q>}.<dt>  <Qd>, <Dn>, <Dm>`	Encoded as op = 0
`VSUBW{<c>}{<q>}.<dt>  {<Qd>,} <Qn>, <Dm>`	Encoded as op = 1

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VSUBL` or `VSUBW` instruction must be unconditional. ARM strongly recommends that a T32 `VSUBL` or `VSUBW` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` The data type for the elements of the second operand. It must be one of:

`S8`	Encoded as size = `0b00`, U = 0.
`S16`	Encoded as size = `0b01`, U = 0.
`S32`	Encoded as size = `0b10`, U = 0.
`U8`	Encoded as size = `0b00`, U = 1.
`U16`	Encoded as size = `0b01`, U = 1.
`U32`	Encoded as size = `0b10`, U = 1.

`<Qd>` The destination register.

`<Qn>, <Dm>` The first and second operand registers for a `VSUBW` instruction.

`<Dn>, <Dm>` The first and second operand registers for a `VSUBL` instruction.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        if is_vsubw then
            op1 = Int(Elem[Qin[n>>1],e,2*esize], unsigned);
        else
            op1 = Int(Elem[Din[n],e,esize], unsigned);
        result = op1 - Int(Elem[Din[m],e,esize], unsigned);
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
```

F8.1.167 VSWP

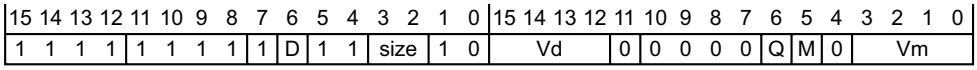
VSWP (Vector Swap) exchanges the contents of two vectors. The vectors can be either doubleword or quadword. There is no distinction between data types.

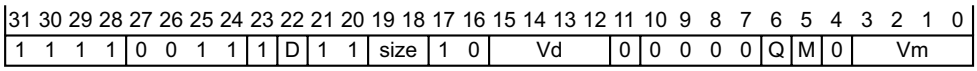
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VSWP<c> <Qd>, <Qm>
VSWP<c> <Dd>, <Dm>
```





```
if size != '00' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VSWP{<c>}{<q>}{.<dt>}  <Qd>, <Qm>`	Encoded as Q = 1, size = `0b00`
`VSWP{<c>}{<q>}{.<dt>}  <Dd>, <Dm>`	Encoded as Q = 0, size = `0b00`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VSWP` instruction must be unconditional. ARM strongly recommends that a T32 `VSWP` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<dt>` An optional data type. It is ignored by assemblers, and does not affect the encoding.

`<Qd>, <Qm>` The vectors for a quadword operation.

`<Dd>, <Dm>` The vectors for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        if d == m then
            D[d+r] = bits(64) UNKNOWN;
        else
            D[d+r] = Din[m+r];
            D[m+r] = Din[d+r];
```

F8.1.168 VTBL, VTBX

Vector Table Lookup uses byte indexes in a control vector to look up byte values in a table and generate a new vector. Indexes out of range return 0.

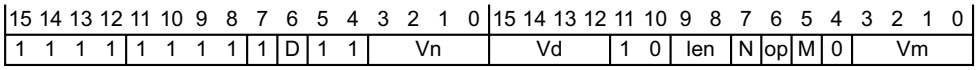
Vector Table Extension works in the same way, except that indexes out of range leave the destination element unchanged.

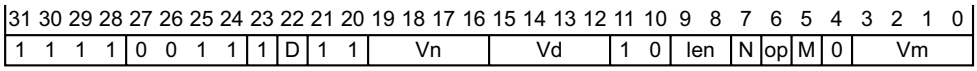
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
V<op><c>.8 <Dd>, <list>, <Dm>
```





```
is_vtbl = (op == '0');  length = UInt(len)+1;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
if n+length > 32 then UNPREDICTABLE;
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VTBL, VTBX* on page AppxA-4851.

Assembler syntax

```
V<op>{<c>}{<q>}.8  <Dd>, <list>, <Dm>
```

where:

`<op>` The operation. It must be one of:

- `TBL` Vector Table Lookup. Encoded as op = 0.
- `TBX` Vector Table Extension. Encoded as op = 1.

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VTBL` or `VTBX` instruction must be unconditional. ARM strongly recommends that a T32 `VTBL` or `VTBX` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<Dd>` The destination vector.

`<list>` The vectors containing the table. It must be one of:

- `{<Dn>}` Encoded as len = `0b00`.
- `{<Dn>, <Dn+1>}` Encoded as len = `0b01`.
- `{<Dn>, <Dn+1>, <Dn+2>}` Encoded as len = `0b10`.
- `{<Dn>, <Dn+1>, <Dn+2>, <Dn+3>}` Encoded as len = `0b11`.

`<Dm>` The index vector.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();

    // Create 256-bit = 32-byte table variable, with zeros in entries that will not be used.
    table3 = if length == 4 then D[n+3] else Zeros(64);
    table2 = if length >= 3 then D[n+2] else Zeros(64);
    table1 = if length >= 2 then D[n+1] else Zeros(64);
    table = table3 : table2 : table1 : D[n];

    for i = 0 to 7
        index = UInt(Elem[D[m],i,8]);
        if index < 8*length then
            Elem[D[d],i,8] = Elem[table,index,8];
        else
            if is_vtbl then
                Elem[D[d],i,8] = Zeros(8);
            // else Elem[D[d],i,8] unchanged
```

F8.1.169 VTRN

Vector Transpose treats the elements of its operand vectors as elements of 2 × 2 matrices, and transposes the matrices.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

Figure F8-7 shows the operation of doubleword VTRN. Quadword VTRN performs the same operation as doubleword VTRN twice, once on the upper halves of the quadword vectors, and once on the lower halves

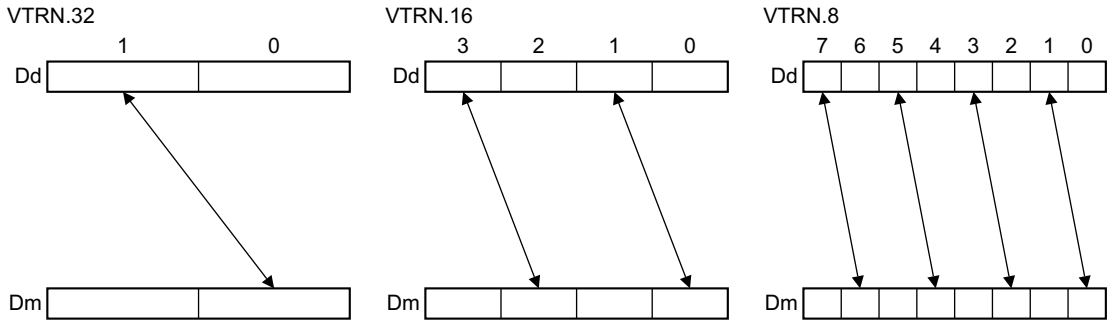


Figure F8-7 VTRN doubleword operation

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VTRN<c>.<size>  <Qd>, <Qm>
VTRN<c>.<size>  <Dd>, <Dm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
if size == '11' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VTRN{<c>}{<q>}.<size>  <Qd>, <Qm>`	Encoded as Q = 1
`VTRN{<c>}{<q>}.<size>  <Dd>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VTRN` instruction must be unconditional. ARM strongly recommends that a T32 `VTRN` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<Qd>, <Qm>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector, and the operand vector, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    h = elements DIV 2;

    for r = 0 to regs-1
        if d == m then
            D[d+r] = bits(64) UNKNOWN;
        else
            for e = 0 to h-1
                Elem[D[d+r],2*e+1,esize] = Elem[Din[m+r],2*e,esize];
                Elem[D[m+r],2*e,esize] = Elem[Din[d+r],2*e+1,esize];
```

F8.1.170 VTST

Vector Test Bits takes each element in a vector, and bitwise ANDs it with the corresponding element of a second vector. If the result is not zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit fields.

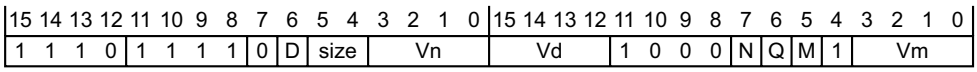
The result vector elements are fields the same size as the operand vector elements.

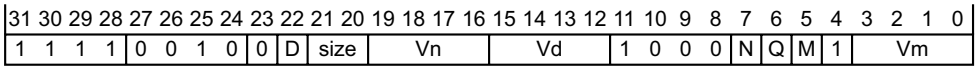
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VTST<c>.<size> <Qd>, <Qn>, <Qm>
VTST<c>.<size> <Dd>, <Dn>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size == '11' then UNDEFINED;
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VTST{<c>}{<q>}.<size>  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VTST{<c>}{<q>}.<size>  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VTST` instruction must be unconditional. ARM strongly recommends that a T32 `VTST` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size for the elements of the operands. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if !IsZero(Elem[D[n+r],e,esize] AND Elem[D[m+r],e,esize]) then
                Elem[D[d+r],e,esize] = Ones(esize);
            else
                Elem[D[d+r],e,esize] = Zeros(esize);
```

F8.1.171 VUZP

Vector Unzip de-interleaves the elements of two vectors. See Table F8-10 and Table F8-11 for examples of the operation.

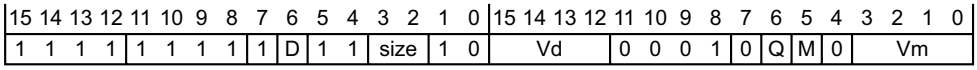
The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

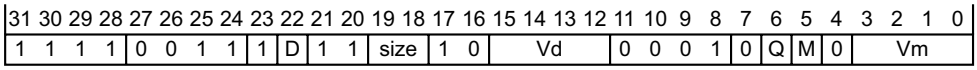
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VUZP<c>.<size>  <Qd>, <Qm>
VUZP<c>.<size>  <Dd>, <Dm>
```





```
if size == '11' || (Q == '0' && size == '10') then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
quadword_operation = (Q == '1');  esize = 8 << UInt(size);
d = UInt(D:Vd);  m = UInt(M:Vm);
```

Table F8-10 shows the operation of a doubleword `VUZP.8` instruction, and Table F8-11 shows the operation of a quadword `VUZP.32` instruction, and

Table F8-10 Operation of doubleword VUZP.8

	Register state before operation								Register state after operation							
Dd	A_7	A_6	A_5	A_4	A_3	A_2	A_1	A_0	B_6	B_4	B_2	B_0	A_6	A_4	A_2	A_0

Assembler syntax

`VUZP{<c>}{<q>}.<size>  <Qd>, <Qm>`	Encoded as Q = 1
`VUZP{<c>}{<q>}.<size>  <Dd>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VUZP` instruction must be unconditional. ARM strongly recommends that a T32 `VUZP` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10` for a quadword operation.
  Doubleword operation with `<size>` = 32 is a pseudo-instruction.

`<Qd>, <Qm>` The vectors for a quadword operation.

`<Dd>, <Dm>` The vectors for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    if quadword_operation then
        if d == m then
            Q[d>>1] = bits(128) UNKNOWN;  Q[m>>1] = bits(128) UNKNOWN;
        else
            zipped_q = Q[m>>1]:Q[d>>1];
            for e = 0 to (128 DIV esize) - 1
                Elem[Q[d>>1],e,esize] = Elem[zipped_q,2*e,esize];
                Elem[Q[m>>1],e,esize] = Elem[zipped_q,2*e+1,esize];
    else
        if d == m then
            D[d] = bits(64) UNKNOWN;  D[m] = bits(64) UNKNOWN;
        else
            zipped_d = D[m]:D[d];
            for e = 0 to (64 DIV esize) - 1
                Elem[D[d],e,esize] = Elem[zipped_d,2*e,esize];
                Elem[D[m],e,esize] = Elem[zipped_d,2*e+1,esize];
```

Pseudo-instruction

`VUZP.32 <Dd>, <Dm>` is a synonym for `VTRN.32 <Dd>, <Dm>`. For details see *VTRN* on page F8-3350.

F8.1.172 VZIP

Vector Zip interleaves the elements of two vectors. See Table F8-12 and Table F8-13 for examples of the operation.

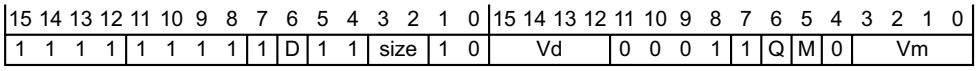
The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

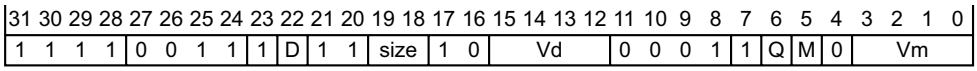
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a floating-point instruction encoding, see *Conditional execution* on page F2-2331.

Encoding T1/A1

```
VZIP<c>.<size>  <Qd>, <Qm>
VZIP<c>.<size>  <Dd>, <Dm>
```





```
if size == '11' || (Q == '0' && size == '10') then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
quadword_operation = (Q == '1');  esize = 8 << UInt(size);
d = UInt(D:Vd);  m = UInt(M:Vm);
```

Table F8-12 shows the operation of a doubleword `VZIP.8` instruction, and Table F8-13 shows the operation of a quadword `VZIP.32` instruction.

Table F8-12 Operation of doubleword VZIP.8

	Register state before operation								Register state after operation							
Dd	A_7	A_6	A_5	A_4	A_3	A_2	A_1	A_0	B_3	A_3	B_2	A_2	B_1	A_1	B_0	A_0
Dm	B_7	B_6	B_5	B_4	B_3	B_2	B_1	B_0	B_7	A_7	B_6	A_6	B_5	A_5	B_4	A_4

Table F8-13 Operation of quadword VZIP.32

	Register state before operation				Register state after operation			
Qd	A_3	A_2	A_1	A_0	B_1	A_1	B_0	A_0
Qm	B_3	B_2	B_1	B_0	B_3	A_3	B_2	A_2

Assembler syntax

`VZIP{<c>}{<q>}.<size>  <Qd>, <Qm>`	Encoded as Q = 1
`VZIP{<c>}{<q>}.<size>  <Dd>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330. An A32 `VZIP` instruction must be unconditional. ARM strongly recommends that a T32 `VZIP` instruction is unconditional, see *Conditional execution* on page F2-2331.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10` for a quadword operation.

  Doubleword operation with `<size>` = 32 is a pseudo-instruction.

`<Qd>, <Qm>` The vectors for a quadword operation.

`<Dd>, <Dm>` The vectors for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    if quadword_operation then
        if d == m then
            Q[d>>1] = bits(128) UNKNOWN;  Q[m>>1] = bits(128) UNKNOWN;
        else
            bits(256) zipped_q;
            for e = 0 to (128 DIV esize) - 1
                Elem[zipped_q,2*e,esize] = Elem[Q[d>>1],e,esize];
                Elem[zipped_q,2*e+1,esize] = Elem[Q[m>>1],e,esize];
            Q[d>>1] = zipped_q<127:0>;  Q[m>>1] = zipped_q<255:128>;
    else
        if d == m then
            D[d] = bits(64) UNKNOWN;  D[m] = bits(64) UNKNOWN;
        else
            bits(128) zipped_d;
            for e = 0 to (64 DIV esize) - 1
                Elem[zipped_d,2*e,esize] = Elem[D[d],e,esize];
                Elem[zipped_d,2*e+1,esize] = Elem[D[m],e,esize];
            D[d] = zipped_d<63:0>;  D[m] = zipped_d<127:64>;
```

Pseudo-instructions

`VZIP.32 <Dd>, <Dm>` is a synonym for `VTRN.32 <Dd>, <Dm>`. For details see *VTRN* on page F8-3350.

F8.2 Advanced SIMD and floating-point system instructions

This section lists the Advanced SIMD and floating-point instructions that behave differently when executed at EL1 or higher, or that are only available at EL1 or higher. For more information see *Exception levels* on page G1-3367.

For the system instructions in the base instruction set see *Alphabetical list of system instructions* on page F7-2998.

F8.2.1 VMRS

Move to general-purpose register from Advanced SIMD and floating-point System register moves the value of an Advanced SIMD and floating-point system register to a general-purpose register. When the specified System register is the FPSCR, a form of the instruction transfers the FPSCR.{N, Z, C, V} condition flags to the APSR.{N, Z, C, V} condition flags.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute a VMRS instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

When these settings permit the execution of floating-point and Advanced SIMD instructions, if the specified floating-point System register is not the FPSCR, the instruction is UNDEFINED if executed in User mode.

In an implementation that includes EL2, when HCR.TID0 is set to 1, any VMRS access to FPSID, from a Non-secure EL1 mode, that would be permitted if HCR.TID0 was set to 0, generates a Hyp Trap exception. For more information, see *ID group 0, Primary device identification registers* on page G1-3492.

Note

- *VMRS* on page F8-3194 describes the valid application level uses of the VMRS instruction
- For simplicity, the VMRS pseudocode does not show the possible trap to Hyp mode.

Encoding T1/A1

```
VMRS<c> <Rt>, <spec_reg>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	1	0	1	1	1	1	reg				Rt				1	0	1	0	(0)	(0)	(0)	1	(0)	(0)	(0)	(0)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	1	1	0	1	1	1	1	reg				Rt				1	0	1	0	(0)	(0)	(0)	1	(0)	(0)	(0)	(0)

```
t = UInt(Rt);
if !(reg IN {‘000x’, ‘0101’, ‘011x’, ‘1000’}) then UNPREDICTABLE;
if t == 15 && reg != ‘0001’ then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VMRS* on page AppxA-4851.

Assembler syntax

```
VMRS{<c>}{<q>}  <Rt>, <spec_reg>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<Rt>` The destination general-purpose register. This register can be R0-R14.

If `<spec_reg>` is `FPSCR`, it is also permitted to be `APSR_nzcv`, encoded as Rt = '1111'. This instruction transfers the FPSCR.{N, Z, C, V} condition flags to the APSR.{N, Z, C, V} condition flags.

`<spec_reg>` Is one of:

`FPSID`	reg = '0000'.
`FPSCR`	reg = '0001'.
`MVFR2`	reg = '0101'.
`MVFR1`	reg = '0110'.
`MVFR0`	reg = '0111'.
`FPEXC`	reg = '1000'.

The pre-UAL instruction `FMSTAT` is equivalent to `VMRS APSR_nzcv, FPSCR`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if reg == '0001' then                 // FPSCR
        CheckVFPEnabled(TRUE);
        if t == 15 then
            PSTATE.<N,Z,C,V> = FPSR.<N,Z,C,V>;
        else
            R[t] = FPSCR;
    elsif PSTATE.EL == EL0 then
        UNDEFINED;                        // Non-FPSCR registers accessible only at PL1 or above
    else
        CheckVFPEnabled(FALSE);           // Non-FPSCR registers are not affected by FPEXC.EN
        case reg of
            // Pseudocode does not consider possible HCR.TIDn Hyp Traps of Non-secure register reads
            when '0000'  R[t] = FPSID;
            when '0101'  R[t] = MVFR2;
            when '0110'  R[t] = MVFR1;
            when '0111'  R[t] = MVFR0;
            when '1000'  R[t] = FPEXC;
            otherwise    Unreachable();   // Dealt with above or in encoding-specific pseudocode
```

F8.2.2 VMSR

Move to Advanced SIMD and floating-point System register from general-purpose register moves the value of a general-purpose register to a floating-point System register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute a VMSR instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 and *Summary of access controls for Advanced SIMD functionality* on page G1-3470 summarize these controls.

When these settings permit the execution of floating-point and Advanced SIMD instructions, if the specified floating-point System register is not the FPSCR, the instruction is UNDEFINED if executed in User mode.

Note

VMSR on page F8-3196 describes the valid application level uses of the VMSR instruction.

Encoding T1/A1

```
VMSR<c> <spec_reg>, <Rt>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	1	0	1	1	1	0	reg				Rt				1	0	1	0	(0)	(0)	(0)	1	(0)	(0)	(0)	(0)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	1	1	0	1	1	1	0	reg				Rt				1	0	1	0	(0)	(0)	(0)	1	(0)	(0)	(0)	(0)

```
t = UInt(Rt);
if reg != ‘000x’ && reg != ‘1000’ then UNPREDICTABLE;
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VMSR* on page AppxA-4851.

Assembler syntax

```
VMSR{<c>}{<q>}  <spec_reg>, <Rt>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page F2-2330.

`<spec_reg>` Is one of:

FPSID	reg = '0000'.
FPSCR	reg = '0001'.
FPEXC	reg = '1000'.

`<Rt>` The general-purpose register to be transferred to `<spec_reg>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if reg == '0001' then                 // FPSCR
        CheckVFPEnabled(TRUE);
        FPSCR = R[t];
    elsif PSTATE.EL == EL0 then
        UNDEFINED;                        // Non-FPSCR registers accessible only at PL1 or above
    else
        CheckVFPEnabled(FALSE);           // Non-FPSCR registers are not affected by FPEXC.EN
        case reg of
            when '0000'                   // FPSID is read-only, do nothing
            when '1000'  FPEXC = R[t];
            otherwise    Unreachable();   // Dealt with above or in encoding-specific pseudocode
```

Part G

The AArch32 System Level Architecture

Chapter G1
The AArch32 System Level Programmers' Model

This chapter gives a system level description of the programmers' model for execution in AArch32 state. It contains the following sections:

G1.1 About the AArch32 System level programmers' model

An application programmer has only a restricted view of the system. The System level programmers' model supports this application level view of the system, and includes features required for one or both of an operating system (OS) and a hypervisor to provide the programming environment seen by an application. This chapter describes the System level programmers' model when executing at EL1 or higher in an Exception level that is using AArch32.

The system level programmers' model includes all of the system features required to support operating systems and to handle hardware events.

The sections listed below give a system level introduction to the basic concepts of the ARM architecture AArch32 state, and the terminology used for describing the architecture when executing in this state:

- *Exception levels* on page G1-3367.
- *Exception terminology* on page G1-3368.
- *Execution state* on page G1-3370.
- *Instruction Set state* on page G1-3372.
- *Security state* on page G1-3373.
- *Virtualization* on page G1-3376.

The rest of this chapter describes the system level programmers' model when executing in AArch32 state.

The other chapters in this part describe:

- The memory system architecture, as seen when executing in an Exception level that is using AArch32:
  - Chapter G3 *The AArch32 System Level Memory Model* describes the general features of the ARMv8 memory model, when executing in AArch32 state, that are not visible at the application level.

    Note

    Chapter E2 *The AArch32 Application Level Memory Model* describes the application level view of the memory model.

  - Chapter G4 *The AArch32 Virtual Memory System Architecture* describes the Virtual Memory System Architecture (VMSA) used in AArch32 state.
- The AArch32 System Registers, see Chapter G5 *AArch32 System Register Descriptions*.

Note

The T32 and A32 instruction sets include instructions that provide system level functionality, such as returning from an exception. See *Alphabetical list of system instructions* on page F7-2998.

G1.2 Exception levels

The ARMv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If ELn is the Exception level, increased values of *n* indicate increased software execution privilege.
- Execution at EL0 is called *unprivileged execution*.
- EL2 provides support for virtualization of Non-secure operation.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

Note

A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

Supported configurations on page D1-1524 provides information on implementations.

When executing in AArch32 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the *target Exception level* of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the system control registers.

An exception cannot target EL0.

Exception levels exist within *Security states*. *The ARMv8-A security model* on page G1-3373 describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then because EL3 is only implemented in Secure state, execution at EL3 can access all resources available at all Exception levels, for both Security states.

Each exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see Chapter G4 *The AArch32 Virtual Memory System Architecture*.

G1.2.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

EL0 Applications.

EL1 OS kernel and associated functions that are typically described as *privileged*.

EL2 Hypervisor.

EL3 Secure monitor.

G1.3 Exception terminology

The following subsections define the terms used when describing exceptions:

- *Terminology for taking an exception*.
- *Terminology for returning from an exception*.
- *Exception levels*.
- *Definition of a precise exception*.
- *Definitions of synchronous and asynchronous exceptions* on page G1-3369.

G1.3.1 Terminology for taking an exception

An exception is *generated* when the PE first responds to an exceptional condition.The PE state at this time is the state the exception is *taken from*. The PE state immediately after taking the exception is the state the exception is *taken to*.

G1.3.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction.The PE state when an exception return instruction is committed for execution is the state the exception *returns from*. The PE state immediately after the execution of that instruction is the state the exception *returns to*.

G1.3.3 Exception levels

An Exception level, EL*n*, with a larger value of *n* than another Exception level, is described as being a *higher* Exception level than the other Exception level. For example, EL3 is a higher Exception level than EL1.

An Exception level with a smaller value of *n* than another Exception level is described as being a *lower* Exception level than the other Exception level. For example, EL0 is a lower Exception level than EL1.

An Exception level is described as:

- *Using AArch64* when execution in that Exception level is in the AArch64 Execution state.
- *Using AArch32* when execution in that Exception level is in the AArch32 Execution state.

G1.3.4 Definition of a precise exception

An exception is described as *precise* when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Other than the *Asynchronous Data Abort*, sometimes referred to as an *external interrupt*, all exceptions taken to AArch32 state are required to be precise. For each occurrence of an Asynchronous Data Abort, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

Where a synchronous exception that is taken to AArch32 state is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by those instructions can be UNKNOWN, provided that:

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
- The registers are not involved in the calculation of the memory address used by the instruction.

In AArch32 state, examples of instructions that perform more than one single-copy atomic memory access are the `LDM` and `STM` instructions.

Note

- For the definition of a single-copy atomic access, see *Single-copy atomicity* on page E2-2261.
- Asynchronous Data Aborts are known as SError interrupts in AArch64 state.
- By definition, all synchronous aborts are precise.

G1.3.5 Definitions of synchronous and asynchronous exceptions

An exception is described as *synchronous* if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

An exception is described as *asynchronous* if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about exceptions, see *Handling exceptions that are taken to an Exception level using AArch32* on page G1-3396.

G1.4 Execution state

The Execution states are:

AArch64 The 64-bit Execution state.

AArch32 The 32-bit Execution state. Operation in this state is compatible with ARMv7-A operation.

Execution state on page A1-33 gives more information about them.

Exception levels *use* Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.
- The PE can change Execution states only either:
  - At reset.
  - On a change of Exception level.

Note

- *Typical Exception level usage model* on page G1-3367 shows which Exception levels different software layers might typically use.
- *Supported configurations* on page D1-1524 gives information on supported configurations of Exception levels and Execution states.

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. *Interprocessing* on page D1-1512 describes this.

G1.4.1 About the AArch32 PE modes

AArch32 state provides a set of *PE modes* that support normal software execution and handle exceptions. The current mode determines the set of registers that are available, as described in *AArch32 general-purpose registers, and the PC* on page G1-3383.

The AArch32 modes are:

- Monitor mode. This mode always executes at Secure EL3.
- Hyp mode. This mode always executes at Non-secure EL2.
- System, Supervisor, Abort, Undefined, IRQ and FIQ modes. The Exception level these modes execute at depends on the Security state, as described in *Security state* on page G1-3373.
- User mode. This mode always executes at EL0.

Note

AArch64 state does not support modes. Modes are a concept that is specific to AArch32 state. Modes that execute at a particular Exception level are only implemented if that Exception level supports using AArch32.

For more information on modes see *AArch32 PE mode descriptions* on page G1-3378.

The mode in use immediately before an exception is taken is described as the mode the exception is *taken from*. The mode that is used on taking the exception is described as the mode the exception is *taken to*.

All of the following define the mode that an exception is taken to:

- The type of exception.
- The mode the exception is taken from.

- Configuration settings defined at EL2 and EL3.

Monitor mode and Hyp mode can create system traps that cause exceptions to EL3 or EL2 respectively. There is an architected hierarchy where EL2 and EL3 configuration settings affect a common condition, for example interrupt routing. When no traps are enabled for a particular condition, the AArch32 mode an exception is taken to is called the *default mode* for that exception.

In AArch32 state, a number of different modes can exist at the same *Privilege level* (PL), All modes at a particular privilege level have the same access rights for accesses to memory and to System registers. The mapping of PE modes to Exception levels depends on the Security state, as described in *Security state* on page G1-3373.

Execution privilege, Exception levels, and AArch32 Privilege levels on page G4-3616 gives more information about the PE modes, their associated Privilege levels, and how these map onto the Exception levels.

G1.5 Instruction Set state

In AArch32 state, the *Instruction Set state* determines the instruction set that the PE is executing. In an implementation that follows the ARM recommendations, the available Instruction Set states are:

T32 state The PE is executing T32 instructions.

A32 state The PE is executing A32 instructions.

Note

In previous versions of the ARM architecture:

- The T32 instruction set was called the Thumb instruction set.
- The A32 instruction set was called the ARM instruction set.

For more information, see *Instruction set state register, ISETSTATE* on page E1-2212.

G1.6 Security state

The ARMv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

Secure state When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space.

Non-secure state When in this state, the PE:

- Can access only the Non-secure physical address space.
- Cannot access the Secure system control resources.

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see *About VMSAv8-32* on page G4-3618.

G1.6.1 The ARMv8-A security model

The general principles of the ARMv8-A security model are:

- If the implementation includes EL3 then it has two Security states, Secure and Non-secure, and:
  - EL3 exists only in Secure state.
  - A change from Non-secure state to Secure state can only occur on taking an exception to EL3.
  - A change from Secure state to Non-secure state can only occur on an exception return from EL3.
  - If EL2 is implemented, it exists only in Non-secure state.
- If the implementation does not include EL3 it has one Security state, that is:
  - IMPLEMENTATION DEFINED, if the implementation does not include EL2.
  - Non-secure state if the implementation includes EL2.

The AArch32 security model, and execution privilege

The Exception level hierarchy of four Exception levels, EL0, EL1, EL2, and EL3, applies to execution in both Execution states. This section describes the mapping between Exception levels, AArch32 modes, and Privilege levels.

The AArch32 modes Monitor, System, Supervisor, Abort, Undefined, IRQ, and FIQ all have the same privilege. In the AArch32 Privilege model this is PL1.

In Secure state:

- Monitor mode executes only at EL3, and is accessible only when EL3 is using AArch32.
- System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode all:
  - Execute at EL1 when EL3 is using AArch64.
  - Execute at EL3 when EL3 is using AArch32.

This means that there is a difference in the Secure state hierarchy that the PE is using, depending on which Execution state EL3 is using:

- If EL3 is using AArch64:
  - There is no support for Monitor mode.
  - If EL1 is using AArch32, System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL1.
- If EL3 is using AArch32:
  - Monitor mode is supported, and executes at Secure EL3
  - System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL3.
  - There is no support for a Secure EL1 Exception level.

See *Security behavior in Exception levels using AArch32 when EL3 is using AArch64* on page G1-3406 for more information about operation in a Secure EL1 mode when EL3 is using AArch64.

In Non-secure state, the PL1 modes System, Supervisor, Abort, Undefined, IRQ, and FIQ always execute at EL1.

User mode always executes at EL0 and has Privilege level PL0. Hyp mode always executes at EL2 and has Privilege level PL2. See *About the AArch32 PE modes* on page G1-3370.

Note

For more information about the Privilege level terminology, see *Execution privilege, Exception levels, and AArch32 Privilege levels* on page G4-3616.

Figure G1-1 shows the security model when EL3 is using AArch32, and shows the expected use of the different Exception levels, and which modes execute at which Exception levels.

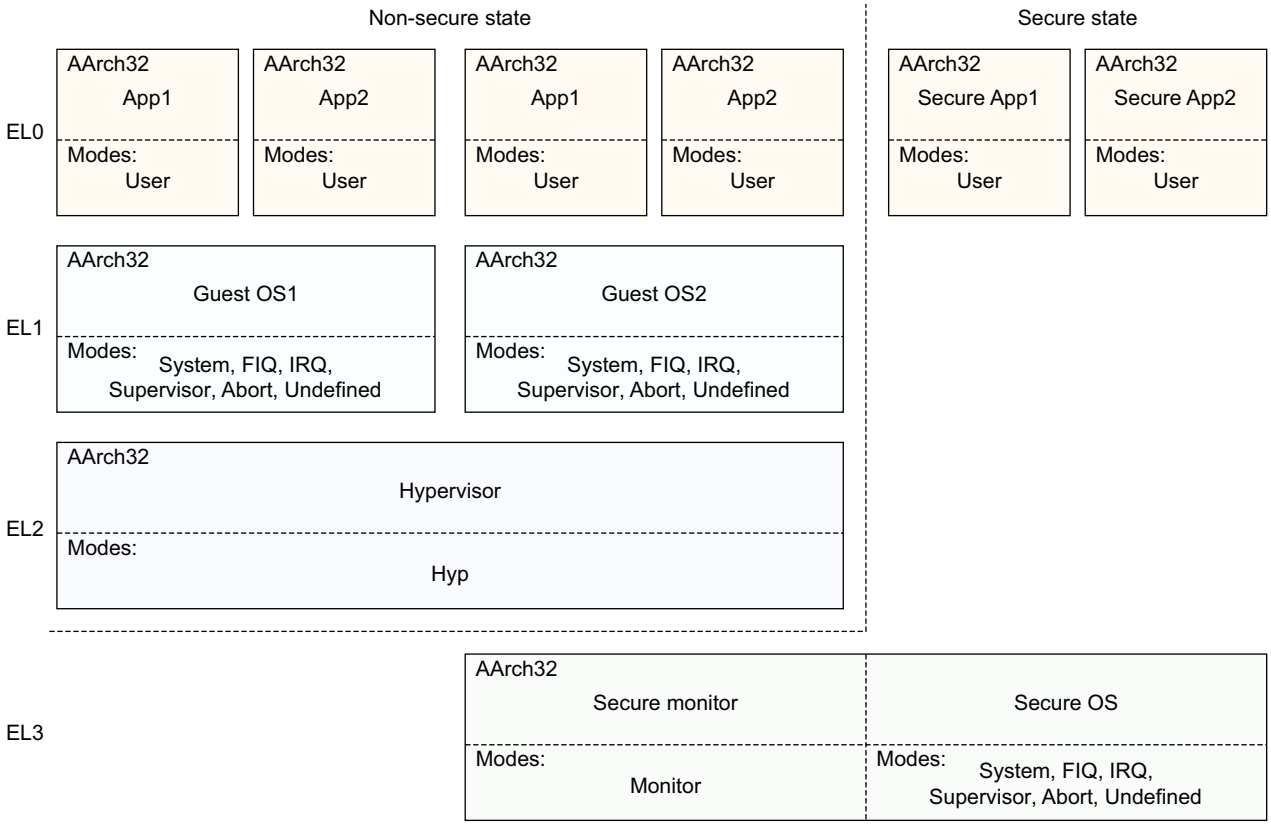


Figure G1-1 ARMv8-A Security model when EL3 is using AArch32

Note

For an overview of the Security models when EL3 is using AArch64:

- See Figure G1-2 on page G1-3381 for the case where EL2, EL1, and EL0 are all using AArch32. This figure shows the implementation of the PE modes.
- See Figure D1-1 on page D1-1405 for an overview of the set of possible implementations.

Figure G1-1 on page G1-3374 shows that when EL3 is using AArch32, the Exception levels and modes available in each Security state are as follows:

Secure state

EL0 User mode.

EL3 Any mode that is available in Secure state, other than User mode.

Non-secure state

EL0 User mode.

EL1 Any mode that is available in Non-secure state, other than Hyp mode and User mode.

EL2 Hyp mode.

Execution at EL0 is described as *unprivileged execution*.

A mode associated with a particular Exception level, EL*n*, is described as an EL*n* mode.

Note

The Exception level defines the ability to access resources in the current Security state, and does not imply anything about the ability to access resources in the other Security state.

When EL3 is using AArch32, many AArch32 system registers accessible at PL1 are *banked* between the Secure and Non-secure states.

When EL3 is using AArch64 and Secure EL1 is using AArch32, system registers accessible at PL1 are not banked between the Non-secure and Secure states. Software running at EL3 is expected to switch the content of the PL1 accessible system registers between the Secure and Non-secure context, in a similar manner to switching the contents of general purpose registers. For information on the relationship between AArch64 and AArch32 system registers in an interprocessing environment, see *Mapping of the System registers between the Execution states* on page D1-1515.

For more information on the system registers, see *The conceptual coprocessor interface and system control* on page G1-3463.

The *Secure Monitor Call* (`SMC`) instruction provides software with a system call to EL3. When executing at a privileged Exception level, `SMC` instructions generates exceptions. For more information, see *Secure Monitor Call (SMC) exception* on page G1-3435 and *SMC* on page F7-3022.

Note

For more information about the Privilege level terminology, see *Execution privilege, Exception levels, and AArch32 Privilege levels* on page G4-3616.

Changing from Secure state to Non-secure state

Monitor mode is provided to support switching between Secure and Non-secure states. When executing in an Exception level that is using AArch32, except in Monitor mode and Hyp mode, the Security state is controlled:

- By the SCR.NS bit, when EL3 is using AArch32.
- By the SCR_EL3.NS bit, when EL3 is using AArch64.

The mapping of AArch32 privileged modes to the exception hierarchy means that it is possible when EL3 is using AArch32 to change from EL3 to non-secure EL1 without an exception return. This can occur in one of the following ways:

- Using an `MSR` or `CPS` instruction to switch from Monitor mode to another privileged mode while SCR.NS is 1.
- Using an `MCR` instruction that writes SCR.NS to change from Secure to Non-secure state when in a privileged mode other than Monitor mode.

ARM strongly recommends that software executing at EL3 using AArch32 does not use either of these mechanisms to change from EL3 to non-secure EL1 without an exception return. The use of both of these mechanisms is deprecated.

G1.7 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2. A PE is in *Hyp mode* when it is executing at EL2 in the AArch32 state. An exception return from Hyp mode to software running at EL1 or EL0 is performed using the `ERET` instruction.

EL2 provides a set of features that support virtualizing the Non-secure state of an ARMv8-A implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between *virtual machines*. A virtual machine is comprised of Non-secure EL1 and Non-secure EL0.
- A number of Guest operating systems, that each run in Non-secure EL1, on a virtual machine.
- For each Guest operating system, applications, that usually run in Non-secure EL0, on a virtual machine.

Note

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The ARMv8-A architecture supports both of these models.

The hypervisor assigns a *virtual machine identifier* (VMID) to each virtual machine.

EL2 is implemented only in Non-secure state, to support Guest OS management. EL2 provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.
- *Trap* various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2.
- Route interrupts to the appropriate one of:
  - The current Guest OS.
  - A Guest OS that is not currently running.
  - The hypervisor.

In Non-secure state:

- The implementation provides an independent *translation regime* for memory accesses from EL2.
- For the PL1&0 translation regime, address translation occurs in two stages:
  - Stage 1 maps the *Virtual Address* (VA) to an *Intermediate Physical Address* (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the *Physical Address* (PA).
  - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

For more information on the translation regimes, see Chapter G4 *The AArch32 Virtual Memory System Architecture*.

G1.7.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- Hypervisor Call (HVC) exception.
- Traps to EL2. *EL2 configurable instruction enables, disables, and traps* on page G1-3482, describes these.
- All of the virtual interrupts:
  - Virtual External interrupt.
  - Virtual IRQ.
  - Virtual FIQ.

HVC exceptions are always taken to EL2. All virtual interrupts are always taken to EL1, and can only be taken from Non-secure EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See *Virtual interrupts*.

When a virtual interrupt is enabled, its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3. For more information, see *Asynchronous exception behavior for exceptions taken from AArch32 state* on page G1-3418.

An implementation that includes EL2 also:

- Provides controls that can be used to route some synchronous exceptions, taken from Non-secure state, to EL2. For more information see:
  - *Routing general exceptions to EL2* on page G1-3410.
  - *Routing debug exceptions to EL2* on page G1-3411.
- Provides mechanisms to trap PE operations to EL2. See *EL2 configurable instruction enables, disables, and traps* on page G1-3482.

  When an operation is trapped to EL2, the hypervisor typically either:
  - Emulates the required operation. The application running in the Guest OS is unaware of the trap.
  - Returns an error to the Guest OS.

Virtual interrupts

The virtual interrupts have names that correspond to the physical interrupts, as shown in Table G1-1.

Table G1-1 The virtual interrupts

Physical interrupt	Corresponding virtual interrupt
External abort	Virtual External Abort
IRQ	Virtual IRQ
FIQ	Virtual FIQ

Software executing at EL2 can use virtual interrupts to signal physical interrupts to Non-secure EL1 and Non-secure EL0. Example G1-1 shows a usage model for virtual interrupts.

Example G1-1 Virtual interrupt usage model

A usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.
2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
   - If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
   - If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

Non-secure EL1 and Non-secure EL0 modes cannot distinguish a virtual interrupt from the corresponding physical interrupt.

For more information see *Virtual exceptions when an implementation includes EL2* on page G1-3418.

G1.8 AArch32 PE modes, general-purpose registers, and the PC

The following sections describe the AArch32 PE modes and the general-purpose registers and the PC:

- *AArch32 PE mode descriptions*.
- *AArch32 general-purpose registers, and the PC* on page G1-3383.
- *Program Status Registers (PSRs)* on page G1-3387.
- *ELR_hyp* on page G1-3393.

Note

The PC is included in the scope of this section because, in AArch32 state, it is defined as being part of the same register file as the general-purpose registers. That is, the AArch32 register file R0-R15 comprises:

- The general-purpose registers R0-R14.
- The PC, that can be described as R15.

G1.8.1 AArch32 PE mode descriptions

Table G1-2 shows the PE modes defined by the ARM architecture, for execution in AArch32 state. In this table:

- The *PE mode* column gives the name of each mode and the abbreviation used, for example, in the general-purpose register name suffixes used in *AArch32 general-purpose registers, and the PC* on page G1-3383.
- The *Encoding* column gives the corresponding CPSR.M field.
- The *Exception level* column gives the Exception level at which the mode is implemented, including dependencies on the current Security state and on whether EL3 is using AArch32, see *Exception levels* on page G1-3367.

Table G1-2 AArch32 PE modes

PE mode		Encoding	Security state	Exception level	Implemented
User	usr	10000	Both	EL0	Always
FIQ	fiq	10001	Non-secure Secure	EL1 EL1 or EL3[a]	Always
IRQ	irq	10010	Non-secure Secure	EL1 EL1 or EL3[a]	Always
Supervisor	svc	10011	Non-secure Secure	EL1 EL1 or EL3[a]	Always
Monitor	mon	10110	Secure	EL3	If EL3 implemented and using AArch32
Abort	abt	10111	Non-secure Secure	EL1 EL1 or EL3[a]	Always
Hyp	hyp	11010	Non-secure	EL2	If EL2 implemented and using AArch32
Undefined	und	11011	Non-secure Secure	EL1 EL1 or EL3[a]	Always
System	sys	11111	Non-secure Secure	EL1 EL1 or EL3[a]	Always

a. EL3 if EL3 is using AArch32. EL1 if EL3 is using AArch64 and EL1 is using AArch32.

Mode changes can be made under software control, or can be caused by an external or internal exception.

Notes on the AArch32 PE modes

PE modes are defined only in AArch32. Because each mode is implemented as part of a particular Exception level that is using AArch32, the set of available modes depends on which Exception levels are implemented and using AArch32, as described in *Effect of the EL3 Execution state on the PE modes and Exception levels* on page G1-3381.

This section gives more information about each of the modes, when it is implemented.

User mode Software executing in User mode executes at EL0. Execution in User mode is sometimes described as unprivileged execution. Application programs normally execute in User mode, and any program executed in User mode:

- Makes only unprivileged accesses to system resources, meaning it cannot access protected system resources.
- Makes only unprivileged access to memory.
- Cannot change mode except by causing an exception, see *Handling exceptions that are taken to an Exception level using AArch32* on page G1-3396.

System mode System mode is implemented at EL1 or EL3, see *Effect of the EL3 Execution state on the PE modes and Exception levels* on page G1-3381.

System mode has the same registers available as User mode, and is not entered by any exception.

Supervisor mode

Supervisor mode is implemented at EL1 or EL3, see *Effect of the EL3 Execution state on the PE modes and Exception levels* on page G1-3381.

Supervisor mode is the default mode to which a Supervisor Call exception is taken. Executing a `SVC` (Supervisor Call) instruction generates an Supervisor Call exception.

In an implementation where the highest implemented Exception level is using AArch32, if that Exception level is EL3 or EL1, a PE enters Supervisor mode on Reset.

Abort mode Abort mode is implemented at EL1 or EL3, see *Effect of the EL3 Execution state on the PE modes and Exception levels* on page G1-3381.

Abort mode is the default mode to which a Data Abort exception or Prefetch Abort exception is taken.

Undefined mode

Undefined mode is implemented at EL1 or EL3, see *Effect of the EL3 Execution state on the PE modes and Exception levels* on page G1-3381.

Undefined mode is the default mode to which an instruction-related exception, including any attempt to execute an UNDEFINED instruction, is taken.

FIQ mode FIQ mode is implemented at EL1 or EL3, see *Effect of the EL3 Execution state on the PE modes and Exception levels* on page G1-3381.

FIQ mode is the default mode to which an FIQ interrupt is taken.

IRQ mode IRQ mode is implemented at EL1 or EL3, see *Effect of the EL3 Execution state on the PE modes and Exception levels* on page G1-3381.

IRQ mode is the default mode to which an IRQ interrupt is taken.

Hyp mode Hyp mode is the Non-secure EL2 mode.

Hyp mode is entered on taking an exception from Non-secure state that must be taken to EL2.

In an implementation where the highest implemented Exception level is EL2 and EL2 uses AArch32 on reset, a PE enters Hyp mode on Reset.

The Hypervisor Call exception and Hyp Trap exception are implemented as part of EL2 and are always taken to Hyp mode.

Note

This means that Hypervisor Call and Hyp Trap exceptions cannot be taken from Secure state.

When the value of the Hypervisor Call enable bit, SCR.HCE, is 1, executing a `HVC` (Hypervisor Call) instruction in a Non-secure EL1 mode generates a Hypervisor Call exception.

For more information, see *Hyp mode* on page G1-3382.

Monitor mode

Monitor mode is the Secure EL3 mode. This means it is always in the Secure state, regardless of the value of the SCR.NS bit.

Monitor mode is the mode to which a Secure Monitor Call exception is taken. In a Non-secure EL1 mode, or a Secure EL3 mode, executing an `SMC` (Secure Monitor Call) instruction generates a Secure Monitor Call exception.

When EL3 is using AArch32, some exceptions that are taken to a different mode by default can be configured to be taken to EL3, see *PE mode for taking exceptions* on page G1-3404.

When EL3 is using AArch32, software executing in Monitor mode:

- Has access to both the Secure and Non-secure copies of System registers.
- Can perform an exception return to Secure state, or to Non-secure state.

This means that, when EL3 is using AArch32, Monitor mode provides the only recommended method of changing between the Secure and Non-secure Security states.

Secure and Non-secure modes

In an implementation that includes EL3, the names of most implemented modes can be qualified as Secure or Non-secure, to indicate whether the PE is also in Secure state or Non-secure state. For example:

- If a PE is in Supervisor mode and Secure state, it is in *Secure Supervisor mode*.
- If a PE is in User mode and Non-secure state, it is in *Non-secure User mode*.

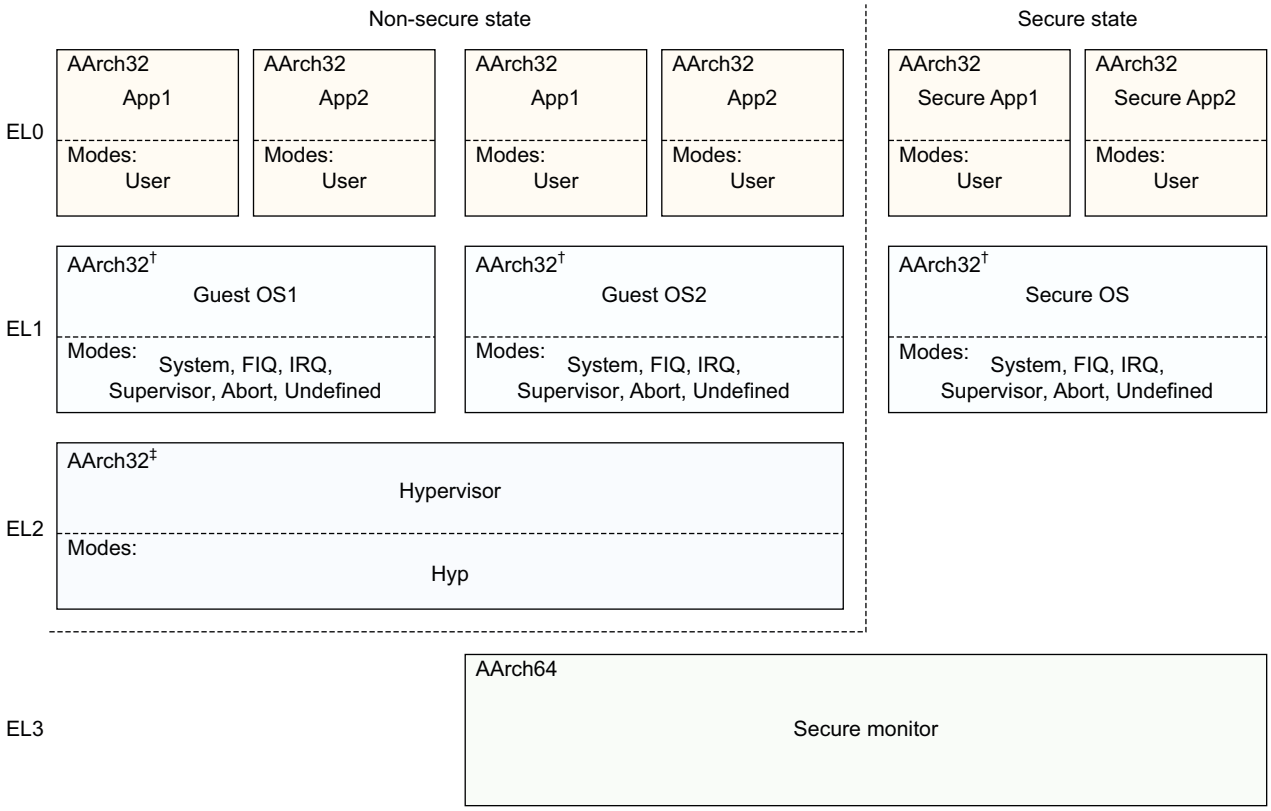
Note

As indicated in the appropriate Mode descriptions:

- Monitor mode is a Secure mode, meaning it is always in the Secure state.
- Hyp mode is a Non-secure mode, meaning it is accessible only in Non-secure state.

Effect of the EL3 Execution state on the PE modes and Exception levels

Figure G1-1 on page G1-3374 shows the PE modes, Exception levels, and Security states, for an implementation that includes all of the Exception levels, when EL3 is using AArch32. Figure G1-2 shows how the implemented modes change when EL3 is using AArch64.



† When EL1 is using AArch64, System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are not implemented
‡ When EL2 is using AArch64, Hyp mode is not implemented

Figure G1-2 ARMv8 Exception levels, and PE modes, when EL3 is using AArch64

Comparing Figure G1-1 on page G1-3374 and Figure G1-2 shows how, in Secure state only, the implementation of System, FIQ, IRQ, Supervisor, Abort, and Undefined mode depends on the Execution state that EL3 is using. That is, these modes are implemented as follows:

Non-secure state

If Non-secure EL1 is using AArch32 then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Non-secure state.

Secure state The implementation of these modes depends on the Execution state that EL3 is using, as follows:

EL3 using AArch64 If Secure EL1 is using AArch32 then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Secure state.

EL3 using AArch32 In Secure state, System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL3, see Figure G1-1 on page G1-3374.

Hyp mode

Hyp mode is the Non-secure EL2 mode. When EL2 is using AArch32, it provides the usual method of controlling the virtualization of Non-secure execution at EL1 and EL0.

Note

The alternative method of controlling this functionality is by accessing the EL2 controls from EL3 with the SCR_EL3.NS or SCR.NS bit set to 1.

This section summarizes how Hyp mode differs from the other modes, and references where this part of the manual describes the features of Hyp mode in more detail:

- Software executing in Hyp mode executes at EL2, see Figure G1-1 on page G1-3374.
- Hyp mode is accessible only in Non-secure state. When the PE is in Secure state, setting CPSR.M to `0b11010`, the encoding for Hyp mode, has no meaning. Therefore, in Secure state, the effect of attempting to set CPSR.M to `0b11010` is UNPREDICTABLE. For more information see *The Current Program Status Register (CPSR)* on page G1-3387.
- In Non-debug state, the only mechanisms for changing to Hyp mode are:
  - An exception taken from a Non-secure EL1 or EL0 mode.
  - When EL3 is using AArch32, an exception return from Secure Monitor mode.
  - When EL3 is using AArch64, an exception return from EL3.
- In Hyp mode, the only exception return is execution of an `ERET` instruction, see *ERET* on page F7-3002.
- In Hyp mode, the CPACR has no effect on the execution of coprocessor, floating-point, or Advanced SIMD instructions. The HCPTR controls execution of these instructions in Hyp mode.
- If software running in Hyp mode executes an `SVC` instruction, the Supervisor Call exception generated by the instruction is taken to Hyp mode, see *SVC* on page F7-2891.
- The effect of an exception return with the restored CPSR specifying Hyp mode is UNPREDICTABLE if any of the following applies:
  - EL3 is using AArch64 and the value of SCR_EL3.NS is 0.
  - EL3 is using AArch32 and the value of SCR.NS is 0.
  - The return is from a Non-secure EL1 mode.
- The instructions described in the following sections are UNDEFINED if executed in Hyp mode:
  - *SRS, T32* on page F7-3024.
  - *SRS, A32* on page F7-3026.
  - *RFE* on page F7-3020.
  - *LDM (exception return)* on page F7-3006.
  - *LDM (User registers)* on page F7-3008.
  - *STM (User registers)* on page F7-3028.
  - *SUBS PC, LR and related instructions, A32* on page F7-3032.
  - *SUBS PC, LR and related instructions, T32* on page F7-3030, when executed with a nonzero constant.

    Note

    In T32 state, `ERET` is encoded as `SUBS PC, LR, #0`, and therefore this is a valid instruction.
- The unprivileged Load unprivileged and Store unprivileged instructions `LDRT`, `LDRSHT`, `LDRHT`, `LDRBT`, `STRT`, `STRHT`, and `STRBT`, are UNPREDICTABLE if executed in Hyp mode.

In an implementation that includes EL3, from reset, the HVC instruction is UNDEFINED in Non-secure EL1 modes, meaning entry to Hyp mode is disabled by default. To permit entry to Hyp mode using the Hypervisor Call exception, Secure software must enable use of the HVC instruction:

- By setting the SCR_EL3.HCE bit to1, if EL3 is using AArch64.
- By setting the SCR.HCE bit to 1, if EL3 is using AArch32.

When the HVC instruction is UNDEFINED in Non-secure EL1 modes because of the value of the SCR_EL3.HCE or SCR.HCE bit, HVC is UNPREDICTABLE in Hyp mode.

Pseudocode details of mode operations

The BadMode() function tests whether a 5-bit mode number corresponds to one of the permitted modes:

```
// BadMode()
// =========

boolean BadMode(bits(5) mode)
    case mode of
        when M32_User    result = FALSE;
        when M32_FIQ     result = FALSE;
        when M32_IRQ     result = FALSE;
        when M32_Svc     result = FALSE;
        when M32_Monitor result = !HaveEL(EL3);
        when M32_Abort   result = FALSE;
        when M32_Hyp     result = !HaveEL(EL2);
        when M32_Undef   result = FALSE;
        when M32_System  result = FALSE;
        otherwise     result = TRUE;
    return result;
```

G1.8.2 AArch32 general-purpose registers, and the PC

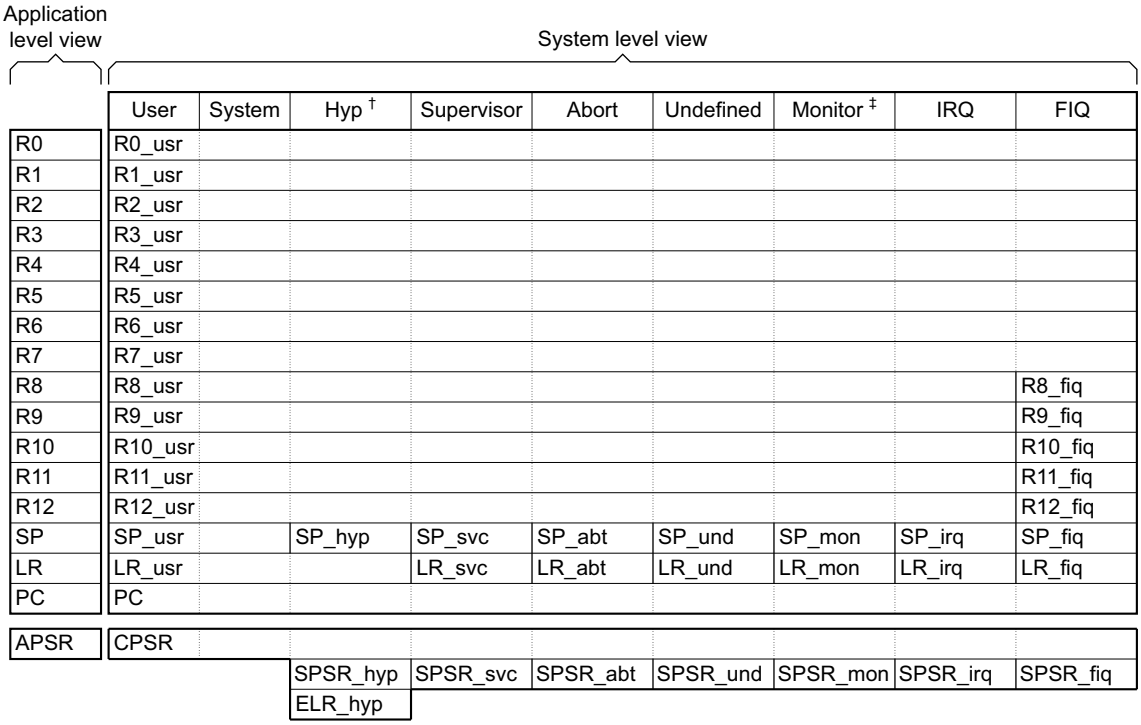
The general-purpose registers, and the PC, in AArch32 state on page E1-2208 describes the application level view of the general-purpose registers, and the PC. This view provides:

- The general-purpose registers R0-R14, of which:
  - The preferred name for R13 is SP (*stack pointer*).
  - The preferred name for R14 is LR (*link register*).
- The PC (*program counter*), that can be described as R15.

These registers are selected from a larger set of registers, that includes *Banked* copies of some registers, with the current register selected by the execution mode. The implementation and banking of the general-purpose registers depends on whether or not the implementation includes EL2 and EL3, and whether those exception levels are using AArch32. Figure G1-3 on page G1-3384 shows the full set of Banked general-purpose registers, the Program Status Registers CPSR and SPSR, and the ELR_hyp Special register.

Note

The architecture uses system level register names, such as R0_usr, R8_usr, and R8_fiq, when it must identify a specific register. The application level names refer to the registers for the current mode, and usually are sufficient to identify a register.



‡ Part of EL3. Exists only in Secure state, and only when EL3 is using AArch32.
† Part of EL2. Exists only in Non-secure state, and only when EL2 is using AArch32.
Cells with no entry indicate that the User mode register is used.

Figure G1-3 AArch32 general-purpose registers, the PC, PSRs, and ELR_hyp, showing register banking

As described in *PE mode for taking exceptions* on page G1-3404, on taking an exception the PE changes mode, unless it is already in the mode to which it must take the exception. Each mode that the PE might enter in this way has:

- A Banked copy of the stack pointer, for example SP_irq and SP_hyp.
- A register that holds a preferred return address for the exception. This is:
  - For the EL2 mode, Hyp mode, the special register ELR_hyp.
  - For the other privileged modes to which exceptions can be taken, a Banked copy of the link register, for example LR_und and LR_mon.
- A saved copy of the CPSR, made on exception entry, for example SPSR_irq and SPSR_hyp.

In addition FIQ mode has Banked copies of the general-purpose registers R8 to R12.

User mode and System mode share the same general-purpose registers.

User mode, System mode, and Hyp mode share the same LR.

For more information about the application level view of the SP, LR, and PC, and the alternative descriptions of them as R13, R14 and R15, see *The general-purpose registers, and the PC, in AArch32 state* on page E1-2208.

Pseudocode details of general-purpose register and PC operations

The following pseudocode gives access to the general-purpose registers and the PC,

_R is the array of general-purpose registers. This array is common to AArch32 and AArch64 operation and therefore contains 31 64-bit registers. _PC is the program counter, and its definition is common to AArch32 and AArch64 operation and therefore its size is 64-bit.

```
array bits(64) _R[0..30];

bits(64) _PC;
```

LookUpRIndex() looks up the _R entry for the specified register number and PE mode, using RBankSelect() to evaluates the result.

```
// LookUpRIndex()
// ==============

integer LookUpRIndex(integer n, bits(5) mode)
    assert n >= 0 && n <= 14;

    case n of  // Select  index by mode:     usr fiq irq svc abt und hyp
        when 8     result = RBankSelect(mode,  8, 24,  8,  8,  8,  8,  8);
        when 9     result = RBankSelect(mode,  9, 25,  9,  9,  9,  9,  9);
        when 10    result = RBankSelect(mode, 10, 26, 10, 10, 10, 10, 10);
        when 11    result = RBankSelect(mode, 11, 27, 11, 11, 11, 11, 11);
        when 12    result = RBankSelect(mode, 12, 28, 12, 12, 12, 12, 12);
        when 13    result = RBankSelect(mode, 13, 29, 17, 19, 21, 23, 15);
        when 14    result = RBankSelect(mode, 14, 30, 16, 18, 20, 22, 14);
        otherwise  result = n;

    return result;

// RBankSelect()
// =============

integer RBankSelect(bits(5) mode, integer usr, integer fiq, integer irq,
                    integer svc, integer abt, integer und, integer hyp)

    case mode of
        when M32_User    result = usr;  // User mode
        when M32_FIQ     result = fiq;  // FIQ mode
        when M32_IRQ     result = irq;  // IRQ mode
        when M32_Svc     result = svc;  // Supervisor mode
        when M32_Abort   result = abt;  // Abort mode
        when M32_Hyp     result = hyp;  // Hyp mode
        when M32_Undef   result = und;  // Undefined mode
        when M32_System  result = usr;  // System mode uses User mode registers
        otherwise        Unreachable(); // Monitor mode

    return result;
```

R[] accesses the specified general-purpose register in the current PE mode, using Rmode[] to accesses the register, accessing _R if necessary. SP accesses the stack pointer, LR accesses the link register, and PC accesses the program counter. Each function has a non-assignment form for register reads and an assignment form for register writes, other than PC, which has only a non-assignment form.

```
// R[] - assignment form
// =====================

R[integer n] = bits(32) value
    Rmode[n, PSTATE.M] = value;
    return;

// R[] - non-assignment form
// =========================

bits(32) R[integer n]
    if n == 15 then
        offset = (if CurrentInstrSet() == InstrSet_A32 then 8 else 4);
        return _PC<31:0> + offset;
    else
        return Rmode[n, PSTATE.M];

// Rmode[] - non-assignment form
// =============================

bits(32) Rmode[integer n, bits(5) mode]
    assert n >= 0 && n <= 14;
```

```
    // Check for attempted use of Monitor mode in Non-secure state.
    if !IsSecure() then assert mode != M32_Monitor;
    assert !BadMode(mode);

    if mode == M32_Monitor && n == 13 then
        return SP_mon;
    elsif mode == M32_Monitor && n == 14 then
        return LR_mon;
    else
        return _R[LookUpRIndex(n, mode)]<31:0>;

// Rmode[] - assignment form
// =========================

Rmode[integer n, bits(5) mode] = bits(32) value
    assert n >= 0 && n <= 14;

    // Check for attempted use of Monitor mode in Non-secure state.
    if !IsSecure() then assert mode != M32_Monitor;
    assert !BadMode(mode);

    if mode == M32_Monitor && n == 13 then
        SP_mon = value;
    elsif mode == M32_Monitor && n == 14 then
        LR_mon = value;
    else
        // It is CONSTRAINED UNPREDICTABLE whether the upper 32 bits of the X
        // register are unchanged or set to zero. This is also tested for on
        // exception entry, as this applies to all AArch32 registers.
        if ConstrainUnpredictableBool() then
            _R[LookUpRIndex(n, mode)] = ZeroExtend(value);
        else
            _R[LookUpRIndex(n, mode)]<31:0> = value;

    return;

// SP - assignment form
// ====================

SP = bits(32) value
    R[13] = value;
    return;

// SP - non-assignment form
// ========================

bits(32) SP
    return R[13];

// LR - assignment form
// ====================

LR = bits(32) value
    R[14] = value;
    return;

// LR - non-assignment form
// ========================

bits(32) LR
    return R[14];

// PC - non-assignment form
// ========================

bits(32) PC
    return R[15];               // This includes the offset from AArch32 state
```

`BranchTo()` performs a branch to the specified address.

```
// BranchTo()
// ==========

// Set program counter to a new address, with a branch reason hint
// for possible use by hardware fetching the next instruction.

BranchTo(bits(N) target, BranchType branch_type)
    HintBranch(branch_type);
    if N == 32 then
        assert UsingAArch32();
        _PC = ZeroExtend(target);
    else
        assert N == 64 && !UsingAArch32();
        // Remove the tag bits from a tagged target
        case PSTATE.EL of
            when EL0, EL1
                if target<55> == '1' && TCR_EL1.TBI1 == '1' then
                    target<63:56> = '11111111';
                if target<55> == '0' && TCR_EL1.TBI0 == '1' then
                    target<63:56> = '00000000';
            when EL2
                if TCR_EL2.TBI == '1' then
                    target<63:56> = '00000000';
            when EL3
                if TCR_EL3.TBI == '1' then
                    target<63:56> = '00000000';
        _PC = target<63:0>;
    return;
```

G1.8.3 Program Status Registers (PSRs)

In AArch32 state, the Application level programmers' model provides the Application Program Status Register, see *The Application Program Status Register (APSR)* on page E1-2211. This is an application level alias for the *Current Program Status Register* (CPSR). The system level view of the CPSR extends the register, adding system level information.

Every mode that an exception can be taken to has its own saved copy of the CPSR, the *Saved Program Status Register* (SPSR), as shown in Figure G1-3 on page G1-3384. For example, the SPSR for Monitor mode is called SPSR_mon.

Note

The information held in the APSR and CPSR is part of the ARMv8 PSTATE information, described in *Process state, PSTATE* on page D1-1413. Unlike the AArch32 CPSR, AArch64 state supports instructions that operate on elements of PSTATE, but its programmers' model does not include a register that gives access to all of PSTATE.

The Current Program Status Register (CPSR)

In AArch32 state, the *Current Program Status Register* (CPSR) holds PE status and control information. This means it holds:

- The APSR, see *The Application Program Status Register (APSR)* on page E1-2211.
- The current instruction set state, see *Instruction set state register, ISETSTATE* on page E1-2212.
- The Execution State bits for the T32 If-Then instruction, see *IT block state register, ITSTATE* on page E1-2213.
- The current endianness, see *Endianness mapping register, ENDIANSTATE* on page E1-2215.
- The current PE mode.
- Interrupt and asynchronous abort disable bits.

The non-APSR bits of the CPSR have defined reset values. These are shown in the `TakeReset()` pseudocode function, see *Reset into AArch32 state* on page G1-3454.

Writes to the CPSR have side-effects on various aspects of PE operation. All of these side-effects, except for those on memory accesses associated with fetching instructions, are synchronous to the CPSR write. This means they are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

The privilege level and address space of memory accesses associated with fetching instructions depend on the current Exception level and Security state. Writes to CPSR.M can change one or both of the Exception level and Security state. The effect, on memory accesses associated with fetching instructions, of a change of Exception level or Security state is:

- Synchronous to the change of Exception level or Security state, if that change is caused by an exception entry or exception return.
- Guaranteed not to be visible to any memory access caused by fetching an earlier instruction in the execution stream.
- Guaranteed to be visible to any memory access caused by fetching any instruction after the next context synchronization operation in the execution stream.

  Note

  See *Context synchronization operation* for the definition of this term.

- Might or might not affect memory accesses caused by fetching instructions between the mode change instruction and the point where the mode change is guaranteed to be visible.

See *Exception return to an Exception level using AArch32* on page G1-3412 for the definition of exception return instructions.

The Saved Program Status Registers (SPSRs)

The purpose of an SPSR is to record the pre-exception value of the CPSR. On taking an exception, the CPSR is copied to the SPSR of the mode to which the exception is taken. Saving this value means the exception handler can:

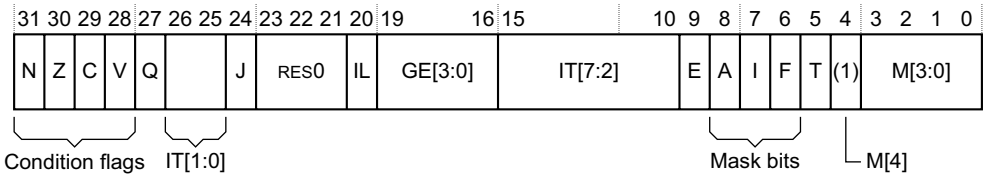
- On exception return, restore the CPSR to the value it had immediately before the exception was taken.
- Examine the value that the CPSR had when the exception was taken, for example to determine the instruction set state and privilege level in which the instruction that caused an Undefined Instruction exception was executed.

Figure G1-3 on page G1-3384 shows the banking of the SPSRs.

The SPSRs are UNKNOWN on reset. Any operation in a Non-secure EL1 or EL0 mode makes SPSR_hyp UNKNOWN.

Format of the CPSR and SPSRs

The CPSR and SPSR bit assignments are:



Condition flags, bits[31:28]

Set on the result of instruction execution. The flags are:

N, bit[31] Negative condition flag.

Z, bit[30] Zero condition flag.

C, bit[29] Carry condition flag.

V, bit[28] Overflow condition flag.

The condition flags can be read or written in any mode, and are described in *IT block state register, ITSTATE* on page E1-2213.

Q, bit[27] Cumulative saturation bit. This bit can be read or written in any mode, and is described in *IT block state register, ITSTATE* on page E1-2213.

IT[7:0], bits[15:10, 26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. *IT block state register, ITSTATE* on page E1-2213 describes the encoding of these bits. CPSR.IT[7:0] are the IT[7:0] bits described there. For more information, see *IT* on page F7-2533.

For details of how these bits can be accessed see *Accessing the Execution State bits* on page G1-3390.

J, bit[24] J bit, this is the same bit as ISETSTATE.J.

This bit is RES0.

Bits[23:21] Reserved. RAZ/SBZP.

IL, bit[20] Illegal state Execution State bit. In an SPSR, the IL bit shows the value of PSTATE.IL immediately before the exception was taken. In AArch32 state, PSTATE.IL is set to 1 to indicate that, on exception return or as a result of an explicit change of the CPSR.M field, an illegal state or mode was indicated.

This bit is RES0 in the CPSR.

For more information see *Illegal exception returns to AArch32 state* on page G1-3413.

GE[3:0], bits[19:16]

Greater than or Equal flags, for the parallel addition and subtraction instructions described in *Parallel addition and subtraction instructions* on page F1-2306.

The GE[3:0] field can be read or written in any mode, and is described in *The Application Program Status Register (APSR)* on page E1-2211.

E, bit[9] Endianness Execution State bit. Controls the load and store endianness for data accesses:

0 Little-endian operation.

1 Big-endian operation.

Instruction fetches ignore this bit.

Endianness mapping register, ENDIANSTATE on page E1-2215 describes the encoding of this bit. CPSR.E is the ENDIANSTATE bit described there.

For details of how this bit can be accessed see *Accessing the Execution State bits* on page G1-3390.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

Mask bits, bits[8:6]

These bits are:

A, bit[8] Asynchronous abort mask bit.

I, bit[7] IRQ mask bit.

F, bit[6] FIQ mask bit.

The possible values of each bit are:

0 Exception not masked.

1 Exception masked.

The A bit has no effect on any Data Abort exception generated by a watchpoint. For more information see *Watchpoint exceptions* on page G2-3550.

In an implementation that does not include EL3, setting a mask bit masks the corresponding exception, meaning it cannot be taken. However, the implementation of EL3 and EL2 significantly alters the behavior and effect of these bits, see *Effects of EL3 and EL2 on the CPSR.{A, F} bits* on page G1-3391 and *Asynchronous exception masking controls* on page G1-3421.

The mask bits can be written only at EL1 or higher. Their values can be read in any mode, but ARM deprecates any use of their values, or attempt to change them, by software executing at EL0.

T, bit[5] T32 Execution State bit. This bit determines the instruction set state of the PE, A32 or T32. *Instruction set state register, ISETSTATE* on page E1-2212 describes the encoding of this bit. CPSR.T is the same bit as ISETSTATE.T. For more information, see *Instruction set states* on page G1-3394.

For details of how this bit can be accessed see *Accessing the Execution State bits*.

M[4:0], bits[4:0]

Mode field. This field determines the current mode of the PE. The permitted values of this field are listed in Table G1-2 on page G1-3378. All other values of M[4:0] are reserved. *Illegal changes to the CPSR.M field* on page G1-3415 describes the effect of setting M[4:0] to a reserved value.

ARMv8 redefines M[4] as follows:

M[4], Execution state This bit indicates the Execution state of the PE, as follows:

0 AArch64 state.

1 AArch32 state.

Note

This is consistent with the use of the M[4:0] field in previous versions of the architecture. All of the PE modes have M[4:0] values in which the value of the most significant bit is 1.

For more information about the PE modes see *AArch32 PE mode descriptions* on page G1-3378. Figure G1-3 on page G1-3384 shows the registers that can be accessed in each mode.

This field can be written only at EL1 or higher. Its value can be read in any mode, but ARM deprecates software executing at EL0 making any use of its value, or attempting to change it.

Accessing the Execution State bits

The Execution State bits are the IL, IT[7:0], J, E, and T bits. Software can read or write these bits in an SPSR.

In the CPSR:

- The Execution State bits, other than the E bit, are RAZ when read by an `MRS` instruction.
- Writes to the Execution State bits, other than the E bit, by an `MSR` instruction are ignored in all modes.

Instructions other than `MRS` and `MSR` that access the Execution State bits can read and write them in any mode.

Unlike the other Execution State bits in the CPSR, CPSR.E can be read by an `MRS` instruction and might be written by an `MSR` instruction. However, ARM deprecates CPSR.E having a different value from the equivalent System control register EE bit, see *Mixed-endian support* on page G3-3578.

Note

To determine the current endianness, software can use an `LDR` instruction to load a word of memory with a known value that differs if the endianness is reversed. For example, using an `LDR` (literal) instruction to load a word whose four bytes are `0x01`, `0x00`, `0x00`, and `0x00` in ascending order of memory address loads the destination register with:

- `0x00000001` if the current endianness is little-endian.
- `0x01000000` if the current endianness is big-endian.

Effects of EL3 and EL2 on the CPSR.{A, F} bits

In an implementation that includes EL3, the SCR.{AW, FW} bits modify the effect of the CPSR.{A, F} bits on exceptions taken from Non-secure state.

In an implementation that includes EL2, the HCR.{AMO, IMO, FMO} bits modify the effect of the CPSR.{A, I, F} bits on exceptions taken from Non-secure state.

For more information see *Asynchronous exception masking controls* on page G1-3421.

Privileged software can change the CPSR.{A, F} and SPSR.{A, F} bits. In an implementation that includes EL3, this is true regardless of the value of the corresponding SCR.{AW, FW} bits. However, when the SPSR is copied to the CPSR, a CPSR.{A. F} bit is not updated if the value of the corresponding SCR.{AW, FW} bit is 0.

Note

In early ARMv7 implementations, the SCR.{AW, FW} bits control whether the CPSR.{A, F} bits are writable in Non-secure state. In ARMv8, the SCR.{AW, FW} bits never have this effect.

Pseudocode details of PSR operations

The following pseudocode gives access to the PSRs. The `SPSR[]` function accesses the current SPSR, and is common to AArch32 and AArch64 operation. The `CPSR[]` function accesses the CPSR. Each of these functions has non-assignment form for reads and an assignment form for writes.

```
bits(32) CPSR, SPSR_fiq, SPSR_irq, SPSR_svc, SPSR_mon, SPSR_abt, SPSR_und, SPSR_hyp;

// SPSR[] - non-assignment form
// ============================

bits(32) SPSR[]
    bits(32) result;
    if UsingAArch32() then
        case PSTATE.M of
            when M32_FIQ      result = SPSR_fiq;
            when M32_IRQ      result = SPSR_irq;
            when M32_Svc      result = SPSR_svc;
            when M32_Monitor  result = SPSR_mon;
            when M32_Abort    result = SPSR_abt;
            when M32_Hyp      result = SPSR_hyp;
            when M32_Undef    result = SPSR_und;
            otherwise         Unreachable();
    else
        case PSTATE.EL of
            when EL1          result = SPSR_EL1;
            when EL2          result = SPSR_EL2;
            when EL3          result = SPSR_EL3;
            otherwise         Unreachable();

    return result;

// SPSR[] - assignment form
// ========================

SPSR[] = bits(32) value
    if UsingAArch32() then
        case PSTATE.M of
            when M32_FIQ      SPSR_fiq = value;
            when M32_IRQ      SPSR_irq = value;
            when M32_Svc      SPSR_svc = value;
            when M32_Monitor  SPSR_mon = value;
            when M32_Abort    SPSR_abt = value;
            when M32_Hyp      SPSR_hyp = value;
            when M32_Undef    SPSR_und = value;
            otherwise         Unreachable();
    else
```

```
        case PSTATE.EL of
            when EL1          SPSR_EL1 = value;
            when EL2          SPSR_EL2 = value;
            when EL3          SPSR_EL3 = value;
            otherwise         Unreachable();

    return;

// CPSR - non-assignment form
// ==========================

    if bytemask<0> == '1' then
        if privileged then
            new_cpsr<7> = value<7>;             // I interrupt mask
            new_cpsr<6> = value<6>;             // F interrupt mask
            new_cpsr<4:0> = value<4:0>;         // Mode bits

    // Attempts to change to an illegal mode will invoke the Illegal Execution State mechanism
    CPSR = new_cpsr;                            // Assign new CPSR value

    return;

// SPSRWriteByInstr()
// ==================

SPSRWriteByInstr(bits(32) value, bits(4) bytemask)

    new_spsr = SPSR[];

    if bytemask<3> == '1' then
        new_spsr<31:24> = value<31:24>;  // N,Z,C,V,Q flags, IT[1:0],J execution state bits

    if bytemask<2> == '1' then
        new_spsr<23:16> = value<23:16>;  // IL execution state bit, GE[3:0] flags

    if bytemask<1> == '1' then
```

```
        new_spsr<15:8> = value<15:8>;    // IT[7:2] execution state bits, E bit, A interrupt mask

    if bytemask<0> == '1' then
        new_spsr<7:0> = value<7:0>;      // I,F interrupt masks, T execution state bit, Mode bits

    SPSR[] = new_spsr;                   // UNPREDICTABLE if User or System mode

    return;
```

G1.8.4 ELR_hyp

Hyp mode does not provide its own Banked copy of LR. Instead, on taking an exception to Hyp mode, the preferred return address is stored in ELR_hyp, a 32-bit Special register implemented for this purpose.

ELR_hyp can be accessed explicitly only by executing:

- An MRS or MSR instruction that targets ELR_hyp, see:
  - *MRS (Banked register)* on page F7-2653.
  - *MSR (Banked register)* on page F7-2657.

The ERET instruction uses the value in ELR_hyp as the return address for the exception. For more information, see *ERET* on page F7-2530.

Software execution in any Non-secure EL1 or EL0 mode makes ELR_hyp UNKNOWN.

G1.9 Instruction set states

The instruction set states are described in Chapter E2 *The AArch32 Application Level Memory Model* and application level operations on them are described there. This section supplies more information about how they interact with system level functionality, in the sections:

- *Exceptions and instruction set state*.
- *Unimplemented instruction sets*.

G1.9.1 Exceptions and instruction set state

If an exception is taken to a EL1 mode, the SCTLR.TE bit for the Security state the exception is taken to determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

If the exception is taken to Hyp mode, the HSCTLR.TE bit determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

On coming out of reset, if the highest implemented Exception level is using AArch32:

- If the highest implemented Exception level is EL2, the PE starts execution in Hyp mode, in the instruction set state determined by the reset value of HSCTLR.TE.
- Otherwise, the PE starts execution in Supervisor mode, in the instruction set state determined by the reset value of SCTLR.TE. If the implementation includes EL3, this execution is in Secure Supervisor mode.

For more information about exception entry see *Overview of exception entry* on page G1-3401.

G1.9.2 Unimplemented instruction sets

The CPSR.J and CPSR.T bits define the current instruction set state, see *Instruction set state register, ISETSTATE* on page E1-2212.

In the ARMv8 architecture there is no support for the hardware acceleration of Java bytecodes, and the Jazelle Instruction set state is obsolete. Every AArch32 implementation must support the Trivial Jazelle implementation described in *Trivial implementation of the Jazelle extension*:

Some system instructions permit setting CPSR.{J, T} to values that select an unimplemented instruction set state, for example setting CPSR.J to 1 and CPSR.T to 0 on an PE that does not implement the Jazelle state. If such values are written to CPSR.{J, T}, the implementation behaves in one of these ways:

- Sets CPSR.{J, T} to the requested values and causes the next instruction to generate an Undefined Instruction exception, as described in *Exception return to an unimplemented instruction set state* on page G1-3415.
- Does not set CPSR.{J, T} to the requested values. The PE might change the value of one or both of the bits in such a way that the new values correspond to an implemented instruction set state. If this is done then the instruction set state changes to this new state. The detailed behavior of the attempt to change to an unimplemented state is IMPLEMENTATION DEFINED.

Trivial implementation of the Jazelle extension

ARMv8 requires that the implementation of AArch32 state includes the trivial Jazelle implementation.

A trivial implementation of the Jazelle extension must:

- Implement the JIDR with the implementer and subarchitecture fields set to zero. The register can be implemented so that the whole register is RAZ.
- Implement the JMCR as RAZ/WI.
- Implement the JOSCR either:
  - So that it can be read and written, but its effects are ignored.
  - As RAZ/WI.

This ensures that operating systems that support an EJVM execute correctly.

- Implement the `BXJ` instruction to behave identically to the `BX` instruction in all circumstances, as required by the fact that the JMCR.JE bit is always zero. This means that, with a trivial implementation of the Jazelle extension, Jazelle state can never be entered normally.
- Treat Jazelle state as an unimplemented instruction set state, as described in *Exception return to an unimplemented instruction set state* on page G1-3415.

A trivial implementation does not have to extend the PC to 32 bits, that is, it can implement PC[0] as RAZ/WI. This is because the only way that PC[0] is visible in A32 or T32 state is as a result of an exception occurring during Jazelle state execution, and Jazelle state execution cannot occur on a trivial implementation.

G1.10 Handling exceptions that are taken to an Exception level using AArch32

An exception causes the PE to suspend program execution to handle an event, such as an externally generated interrupt or an attempt to execute an undefined instruction. Exceptions can be generated by internal and external sources.

Normally, when an exception is taken the PE state is preserved immediately, before handling the exception. This means that, when the event has been handled, the original state can be restored and program execution resumed from the point where the exception was taken.

More than one exception might be generated at the same time, and a new exception can be generated while the PE is handling an exception.

The following sections describe exception handling:

- *Exception vectors and the exception base address*.
- *Exception priority order* on page G1-3400.
- *Overview of exception entry* on page G1-3401.
- *PE mode for taking exceptions* on page G1-3404.
- *PE state on exception entry* on page G1-3408.
- *Routing general exceptions to EL2* on page G1-3410.
- *Routing debug exceptions to EL2* on page G1-3411.
- *Exception return to an Exception level using AArch32* on page G1-3412.

Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3418 gives a full description of asynchronous exception handling, for exceptions taken asynchronously from AArch32 state.

Note

Because of the common model for handling exceptions, the current section requires some understanding of the asynchronous exception behaviors described in *Asynchronous exception behavior for exceptions taken from AArch32 state* on page G1-3418.

AArch32 state exception descriptions on page G1-3428 then describes each exception.

G1.10.1 Exception vectors and the exception base address

When an exception is taken, PE execution is forced to an address that corresponds to the type of exception. This address is called the *exception vector* for that exception. The vectors for the different types of exception form a *vector table*.

Note

There are significant differences in the sets of exception vectors for exceptions taken to an Exception level that is using AArch32 and for exceptions taken to an Exception level that is using AArch64. This part of this manual describes only how exceptions are taken to an Exception level that is using AArch32. So, for example, when executing at EL1 or EL0, an exception might be generated that must be taken to EL3. In this case:

- If EL3 is using AArch32 then the exception is taken as described in this chapter, using the exception vectors described in this section.
- If EL3 is using AArch64 then the exception is taken as described in Chapter D1 *The AArch64 System Level Programmers' Model*using the exception vectors described in *Exception vectors* on page D1-1423.

AArch32 state defines exception vector tables for exceptions taken to EL2 and EL3 when those Exception levels are using AArch32. Those vector tables are not used when the corresponding Exception levels are using AArch64.

A set of exception vectors for an Exception level that is using AArch32 comprises eight consecutive word-aligned memory addresses, starting at an *exception base address*. These eight vectors form an AArch32 *vector table*.

The number of possible exception base addresses, and therefore the number of vector tables, depends on the implemented Exception levels, as follows:

Implementation that does not include EL3

Any implementation that does not include EL3 must include the following AArch32 vector table if EL1 can use AArch32:

- An exception table for exceptions taken to EL1 modes other than System mode. This is the EL1 vector table, and is in the address space of the PL1&0 translation regime.

  Note

  Exceptions cannot be taken to System mode.

  For this vector table, the VBAR holds the exception base address.

Implementation that includes EL2

Any implementation that includes EL2 must include the following additional AArch32 vector table if EL2 can use AArch32:

- An exception table for exceptions taken to Hyp mode. This is the Hyp vector table, and is in the address space of the Non-secure PL2 translation regime.

  For this vector table, HVBAR holds the exception base address.

Implementation that includes EL3

Any implementation that includes EL3 must include the following AArch32 vector tables:

- If EL3 can use AArch32, a vector table for exceptions taken to Secure Monitor mode. This is the Monitor vector table, and is in the address space of the Secure PL1&0 translation regime.

  For this vector table, MVBAR holds the exception base address.

- If Secure EL1 can use AArch32, a vector table for exceptions taken to Secure privileged modes other than Monitor mode and System mode. This is the Secure vector table, and is in the address space of the Secure PL1&0 translation regime.

  For this vector table, the Secure VBAR holds the exception base address.

- If Non-secure EL1 can use AArch32, a vector table for exceptions taken to Non-secure PL1 modes. This is the Non-secure vector table, and is in the address space of the Non-secure PL1&0 translation regime.

  For this vector table, the Non-secure VBAR holds the exception base address.

The following subsections give more information:

- *The vector tables and exception offsets*.
- *Pseudocode determination of the exception base address* on page G1-3399.

The vector tables and exception offsets

Table G1-3 on page G1-3398 defines the AArch32 vector table entries. In this table:

- The *Hyp mode* column defines the vector table entries for exceptions taken to Hyp mode.
- The *Monitor mode* column defines the vector table entries for exceptions taken to Monitor mode.
- The *Secure* and *Non-secure* columns define the Secure and Non-secure vector table entries, that are used for exceptions taken to modes other than Monitor mode, Hyp mode, System mode, and User mode. Table G1-4 on page G1-3398 shows the mode to which each of these exceptions is taken. Each of these modes is described as the *default* mode for taking the corresponding exception.

  Note

  Exceptions cannot be taken to System mode or User mode.

For more information about determining the mode to which an exception is taken, see *PE mode for taking exceptions* on page G1-3404.

When EL2 is using AArch3, it provides a number of additional exceptions, some of which are not shown explicitly in the vector tables. For more information, see *Offsets of AArch32 exceptions provided by EL2* on page G1-3399.

Table G1-3 The AArch32 vector tables

Offset	Vector tables			
	Hyp[a]	Monitor[b]	Secure[c]	Non-secure[c]
0x00	Not used	Not used	Not used[d]	Not used
0x04	Undefined Instruction, from Hyp mode	Monitor Trap	Undefined Instruction	Undefined Instruction
0x08	Hypervisor Call, from Hyp mode	Secure Monitor Call	Supervisor Call	Supervisor Call
0x0C	Prefetch Abort, from Hyp mode	Prefetch Abort	Prefetch Abort	Prefetch Abort
0x10	Data Abort, from Hyp mode	Data Abort	Data Abort	Data Abort
0x14	Hyp Trap, or Hyp mode entry[e]	Not used	Not used	Not used
0x18	IRQ interrupt	IRQ interrupt	IRQ interrupt	IRQ interrupt
0x1C	FIQ interrupt	FIQ interrupt	FIQ interrupt	FIQ interrupt

a. Non-secure state only. Implemented only if the implementation includes EL2 and EL2 can use AArch32.
b. Secure state only. Implemented only if the implementation includes EL3 and EL3 can use AArch32.
c. If the implementation does not include EL3 then there is a single vector table for exceptions taken to EL1 when EL1 is using AArch32. That table holds the vectors shown in the Secure column of this table
d. In previous versions of the architecture, this entry has been used for the Reset vector, meaning the address at which execution starts on coming out of reset. In ARMv8, the AArch32 Reset vector is IMPLEMENTATION DEFINED. An implementation might use this vector table entry to hold the Reset vector.
e. See *Use of offset 0x14 in the Hyp vector table* on page G1-3399.

Table G1-4 Modes for taking the exceptions shown in the Secure or Non-secure vector table

Exception	Mode taken to
Undefined Instruction	Undefined
Supervisor Call	Supervisor
Prefetch Abort	Abort
Data Abort	Abort
IRQ interrupt	IRQ
FIQ interrupt	FIQ

For more information about use of the vector tables see *Overview of exception entry* on page G1-3401.

Offsets of AArch32 exceptions provided by EL2

EL2 provides the following exceptions. When EL2 is using AArch32, these exceptions are taken to Hyp mode, and the PE enters the handlers for these exceptions using the following vector table entries shown in Table G1-3 on page G1-3398:

Hypervisor Call
: If taken from Hyp mode, shown explicitly in the Hyp mode vector table. Otherwise, see *Use of offset 0x14 in the Hyp vector table*.

Hyp Trap
: Shown explicitly in the Hyp mode vector table.

Virtual Abort
: Entered through the Data Abort vector in the Non-secure vector table.

Virtual IRQ
: Entered through the IRQ vector in the Non-secure vector table.

Virtual FIQ
: Entered through the FIQ vector in the Non-secure vector table.

Note

Virtual exceptions when an implementation includes EL2 on page G1-3418 gives more information about the virtual exceptions.

Use of offset `0x14` in the Hyp vector table

The vector at offset `0x14` in the Hyp vector table is used for exceptions that cause entry to Hyp mode. This means it is:

- Always used for the Hyp Trap exception.
- Used for any Hypervisor Call exception that is taken from a mode other than Hyp mode.
- Used for any Supervisor Call exception that is taken from Non-secure User mode when the value of HCR.TGE is 1.
- Used for any Undefined Instruction that is taken from Hyp mode, or is taken from Non-secure User mode when the value of HCR.TGE is 1.
- Used for any Prefetch Abort exception that is:
  - Taken from Non-secure User mode when the value of HCR.TGE is 1.
  - Generated by a Debug exception from Non-secure state when the value of HDCR.TDE is 1.
  - Generated by a stage 2 abort on an address translation instruction.
- Used for any Data Abort exception that is:
  - Taken from Non-secure User mode when the value of HCR.TGE is 1.
  - Generated by an asynchronous External abort from Non-secure state when the value of HCR.AMO is 1.
  - Generated by a Watchpoint exception from Non-secure state when the value of HDCR.TDE is 1.
  - Generated by a stage 2 abort on an address translation operation.

Note

Offset `0x14` is never used for IRQ exceptions, Virtual IRQ exceptions, FIQ exceptions, or Virtual FIQ exceptions.

For more information, see *PE mode for taking exceptions* on page G1-3404.

Pseudocode determination of the exception base address

For an exception taken to a PL1 mode, the `ExcVectorBase()` function determines the exception base address:

```
// ExcVectorBase()
// ===============
```

```
bits(32) ExcVectorBase()
    if SCTLR.V == '1' then  // Hivecs selected, base = 0xFFFF0000
        return Ones(16):Zeros(16);
    else
        return VBAR;
```

Note

The PL1 modes to which exceptions can be taken are Supervisor mode, Undefined mode, Abort mode, IRQ mode, and FIQ mode.In Non-secure state, and in Secure state when EL3 is using AArch64, these are EL1 modes. However, in Secure state when EL3 is using AArch32, these are EL3 modes. For more information see *Execution privilege, Exception levels, and AArch32 Privilege levels* on page G4-3616.

G1.10.2 Exception priority order

An instruction is not valid if it generates a synchronous Prefetch Abort exception. Therefore, if an instruction generates a synchronous Prefetch Abort exception, no other synchronous exception is generated on that instruction.

Note

This includes Prefetch Aborts generated by Debug exceptions other than Exception Trapping Vector Catch and Watchpoint exceptions. An Exception Trapping Vector Catch exception is generated as a result of trapping an exception that has been prioritized as described in this section. This means that it is outside the scope of the description of this section. For more information, see *Vector Catch exceptions* on page G2-3564.

Otherwise:

- An instruction that generates an Undefined Instruction exception, Hyp Trap exception or a Monitor Trap exception cannot cause any memory access, and therefore cannot cause a Data Abort exception.
- If an instruction generates both an Undefined Instruction exception and a Hyp Trap or a Monitor Trap exception then, unless this manual explicitly states otherwise, the Undefined Instruction exception has priority.
- If an instruction generates both a Hyp Trap exception and a Monitor Trap exception then, unless this manual explicitly states otherwise, the Hyp Trap exception has priority.
- If a system call is configured to generate an Undefined Instruction exception or a Hyp Trap exception, then the Undefined Instruction exception or the Hyp Trap exception has priority over the system call.

  The system calls are the `SVC`, `HVC`, and `SMC` instructions.
- All other synchronous exceptions are mutually exclusive and are derived from a decode of the instruction.

For more information, see:

- *Prioritization of aborts* on page G4-3714, for information about:
  - The prioritization of aborts on a single memory access in a VMSA implementation.
  - The prioritization of exceptions generated during address translation
- *Debug state entry and debug event prioritization* on page H2-4397 for information about the relative prioritization of exceptions and the debug events that cause entry to Debug state.

Architectural requirements for taking asynchronous exceptions

The ARM architecture does not define when asynchronous exceptions are taken, but sets the following limits on when they are taken:

- An asynchronous exception that is pending before one of the following context synchronizing events is taken before the first instruction after the context synchronizing event completes its execution, provided that the pending asynchronous event is not masked after the context synchronizing event. The context synchronizing events are:
  - Execution of an `ISB` instruction.
  - Taking an exception.
  - Return from an exception.
  - Exit from Debug state.

  The ISR identifies any pending asynchronous exceptions.

  Note

  If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define the order in which that synchronous exception and the asynchronous exception are taken.

- In the absence of a specific requirement to take an asynchronous exception because of a context synchronizing event, the only requirement of the architecture is that an unmasked asynchronous exception is taken in finite time.

  Note

  The taking of an unmasked asynchronous exception in finite time must occur with all code sequences, including with a sequence that consists of unconditional loops.

Within these limits, the prioritization of asynchronous exceptions relative to other exceptions, both synchronous and asynchronous, is IMPLEMENTATION DEFINED.

The CPSR includes a mask bit for each type of asynchronous exception. Setting one of these bits to 1 can prevent the corresponding asynchronous exception from being taken, although when the PE is in Non-secure state other controls can modify the effect of these bits. For more information, see *Asynchronous exception behavior for exceptions taken from AArch32 state* on page G1-3418.

Taking an exception sets an exception-dependent subset of these mask bits.

Note

In some contexts. the CPSR.{A, I, F} bits mask the taking of asynchronous exceptions. The way these are set on exception entry, described in *CPSR.{A, I, F, M} values on exception entry* on page G1-3409, can prevent an exception handler being interrupted by an asynchronous exception.

G1.10.3 Overview of exception entry

There are some significant differences between the handling of exceptions taken to Hyp mode and exceptions taken to other modes. Because Hyp mode is the EL2 mode, this means the following descriptions sometimes distinguish between the *EL2 mode* and the *non-EL2 modes*.

On taking an exception to an Exception level that is using AArch32:

1. The hardware determines the mode to which the exception must be taken, see *PE mode for taking exceptions* on page G1-3404.

2. A link value, indicating the *preferred return address* for the exception, is saved. This is a possible return address for the exception handler, and depends on:
   - The exception type.
   - Whether the exception is taken to the EL2 mode or to a non-EL2 mode.
   - For some exceptions taken to non-EL2 modes, the instruction set state when the exception was taken.

   Where the link value is saved depends on whether the exception is taken to the EL2 mode.

   For more information see *Link values saved on exception entry* on page G1-3403.

3. The value of the CPSR is saved in the SPSR for the mode to which the exception must be taken. The value saved in SPSR.IT[7:0] is always correct for the preferred return address.

4. In an implementation that includes EL3, when EL3 is using AArch32:
   - If the exception is taken from Monitor mode, SCR.NS is cleared to 0.
   - Otherwise, taking the exception leaves SCR.NS unchanged.

   When EL3 is using AArch64, Monitor mode is not available.

5. The CPSR is updated with new context information for the exception handler. This includes:
   - Setting CPSR.M to the PE mode to which the exception is taken.
   - Setting the appropriate CPSR mask bits. This can disable the corresponding exceptions, preventing uncontrolled nesting of exception handlers.
   - Setting the instruction set state to the state required for exception entry.
   - Setting the endianness to the required value for exception entry.
   - Clearing the CPSR.IT[7:0] bits to 0.

   For more information, see *PE state on exception entry* on page G1-3408.

6. The appropriate exception vector is loaded into the PC, see *Exception vectors and the exception base address* on page G1-3396.

7. Execution continues from the address held in the PC.

For an exception taken to a non-EL2 mode, on exception entry, the exception handler can use the SRS instruction to store the return state onto the stack of any mode at the same Exception level and in the same Security state, and can use the CPS instruction to change mode. For more information about the instructions, see *SRS, T32* on page F7-3024, *SRS, A32* on page F7-3026, *CPS, T32* on page F7-2998, and *CPS, A32* on page F7-3000.

Later sections of this chapter describe each of the possible exceptions, and each of these descriptions includes a pseudocode description of the PE state changes on taking that exception. Table G1-5 gives an index to these descriptions:

Table G1-5 Pseudocode descriptions of exception entry for exceptions taken to AArch32 state

Exception	Description of exception entry
Reset	*Pseudocode description of Reset* on page G1-3454
Undefined Instruction	*Pseudocode description of taking the Undefined Instruction exception* on page G1-3429
Hyp Trap	*Pseudocode description of taking the Hyp Trap exception* on page G1-3432
Monitor Trap	*Pseudocode description of taking the Monitor Trap exception* on page G1-3432
Supervisor Call	*Pseudocode description of taking the Supervisor Call exception* on page G1-3434
Secure Monitor Call	*Pseudocode description of taking the Secure Monitor Call exception* on page G1-3435
Hypervisor Call	*Pseudocode description of taking the Hypervisor Call exception* on page G1-3436
Prefetch Abort	*Pseudocode description of taking the Prefetch Abort exception* on page G1-3438

Table G1-5 Pseudocode descriptions of exception entry for exceptions taken to AArch32 state (continued)

Exception	Description of exception entry
Data Abort	*Pseudocode description of taking the Data Abort exception* on page G1-3442
Virtual Abort	*Pseudocode description of taking the Virtual Asynchronous Abort exception* on page G1-3444
IRQ	*Pseudocode description of taking the IRQ exception* on page G1-3447
Virtual IRQ	*Pseudocode description of taking the Virtual IRQ exception* on page G1-3449
FIQ	*Pseudocode description of taking the FIQ exception* on page G1-3450
Virtual FIQ	*Pseudocode description of taking the Virtual FIQ exception* on page G1-3451

The following sections give more information about the PE state changes, for different architecture implementations. However, you must refer to the pseudocode for a full description of the state changes:

- *PE mode for taking exceptions* on page G1-3404.
- *PE state on exception entry* on page G1-3408.

Link values saved on exception entry

On exception entry, a link value for use on return from the exception, is saved. This link value is based on the *preferred return address for the exception*, as shown in Table G1-6:

Table G1-6 Exception return addresses for exceptions taken to AArch32 state

Exception	Preferred return address	Taken to a mode at
Undefined Instruction	Address of the UNDEFINED instruction	Non-EL2[a], or EL2[c]
Hyp Trap	Address of the trapped instruction	EL2 only[c]
Monitor Trap	Address of the trapped instruction	EL3 only
Supervisor Call	Address of the instruction after the `SVC` instruction	Non-EL2[a] or EL2[c]
Secure Monitor Call	Address of the instruction after the `SMC` instruction	EL3[b], and only in Secure state
Hypervisor Call	Address of the instruction after the `HVC` instruction	EL2 only[c]
Prefetch Abort	Address of aborted instruction fetch	Non-EL2[a] or EL2[c]
Data Abort	Address of instruction that generated the abort	Non-EL2[a] or EL2[c]
Virtual Abort	Address of next instruction to execute	EL1, and only in Non-secure state
IRQ or FIQ	Address of next instruction to execute	Non-EL2[a] or EL2[c]
Virtual IRQ or Virtual FIQ	Address of next instruction to execute	EL1, and only in Non-secure state

a. EL1 if the exception is taken to a Non-secure mode, or is taken to a Secure mode when EL3 is using AArch64. EL3 if the exception is taken to a Secure mode when EL3 is using AArch64.

b. A Secure Monitor Call exception is taken to EL3, and therefore is taken to AArch32 state only if EL3 is using AArch32, in which case it is taken to Monitor mode.

c. EL2 is implemented only in Non-secure state. Therefore, an exception can be taken to EL2 mode only if it is taken from Non-secure state.

Note

- Although Reset is described as an exception, it differs significantly from other exceptions. The architecture has no concept of a return from a Reset and therefore it is not listed in this section.
- For each exception, the preferred return address is not affected by the Exception level from which the exception was taken.

The link value saved, and where it is saved, depend on whether the exception is taken to a non-EL2 mode, or to an EL2 mode, as follows:

Exception taken to a non-EL2 mode

The link value is saved in the LR for the mode to which the exception is taken.

The saved link value is the preferred return address for the exception, plus an offset that depends on the instruction set state when the exception was taken, as Table G1-7 shows:

Table G1-7 Offsets applied to Link value for exceptions taken to non-EL2 modes

Exception	Offset, for PE state of:	
	A32	T32
Undefined Instruction	+4	+2
Monitor Trap	+4	+2
Supervisor Call	None	None
Secure Monitor Call	None	None
Prefetch Abort	+4	+4
Data Abort	+8	+8
Virtual Abort	+8	+8
IRQ or FIQ	+4	+4
Virtual IRQ or Virtual FIQ	+4	+4

Exception taken to an EL2 mode

The link value is saved in the ELR_hyp Special register.

The saved link value is the preferred return address for the exception, as shown in Table G1-6 on page G1-3403, with no offset.

G1.10.4 PE mode for taking exceptions

The following principles determine the Exception level to which an exception is taken, and if that Exception level is using AArch32, the PE mode to which the exception is taken:

- An exception cannot be taken to the EL0 mode.
- An exception is taken either:
  - To the Exception level at which the PE was executing when it took the exception.
  - To a higher Exception level.

  This means that, in Secure state:
  - When EL3 is using AArch32, an exception is always taken to an EL3 mode.
  - When EL3 is using AArch64, an exception that is taken to AArch32 state is taken to an EL1 mode.

- Configuration options and other features provided by EL2 and EL3 can determine the mode to which some exceptions are taken, as follows:

  In an implementation that does not include EL2 or EL3

  An exception is always taken to the default mode for that exception.

  In an implementation that includes EL3

  A Secure Monitor Call exception is always taken to EL3. This means:

  - If EL3 is using AArch32 the exception is taken to Secure Monitor mode.
  - If EL3 is using AArch64 then executing the instruction generates an exception that is taken to EL3, see *Execution of an SMC instruction from a privileged Exception level that is using AArch32* on page G1-3406.

  IRQ, FIQ, and External abort exceptions can be configured to be taken to EL3. Therefore, if EL3 is using AArch32 the exceptions are taken to Secure Monitor mode.

  When EL3 is using AArch32, a Monitor Trap exception is taken to Secure Monitor mode.

  Any exception taken from Secure state that is not taken to Secure Monitor mode is taken to Secure state in the default mode for that exception. As described in *Execution privilege, Exception levels, and AArch32 Privilege levels* on page G4-3616, this means it is taken to:

  - An EL3 mode other than Monitor mode if EL3 is using AArch32.
  - An EL1 mode if EL3 is using AArch64.

  If the implementation does not include EL2, any exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state to the default mode for that exception. The default mode will be an EL1 mode.

  In an implementation that includes EL2

  An exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state and:

  - If the exception is taken from Hyp mode then it is taken to Hyp mode.
  - Otherwise, the exception is either taken to Hyp mode, as described in *Exceptions taken to Hyp mode* on page G1-3406, or taken to the default mode for the exception.

  Note

  - Hyp mode is the EL2 mode. The other modes to which an exception can be taken in Non-secure state are EL1 modes.
  - EL2 has no effect on the handling of exceptions taken from Secure state.

Table G1-4 on page G1-3398 shows the default mode to which each exception is taken.

Asynchronous exception routing controls on page G1-3420 describes the exception routing controls provided by EL2 and EL3.

Routing of aborts taken to AArch32 state on page G4-3703 gives more information about the modes to which memory aborts are taken.

The possible modes for taking each exception on page G1-3407 shows all modes to which each exception might be taken, in any implementation. That is, it applies to implementations:

- That include neither EL2 nor EL3.
- That include EL2 but not EL3
- That do not include EL2 but include EL3
- That include both EL2 and EL3.

Exceptions taken to Hyp mode

In an implementation that includes EL2 and EL3, when EL2 is using AArch32:

- Any exception taken from Hyp mode, that is not routed to EL3 by the controls described in *Asynchronous exception routing controls* on page G1-3420, is taken to Hyp mode.
- The following exceptions, if taken from Non-secure state, are taken to Hyp mode:
  - An abort that *Routing of aborts taken to AArch32 state* on page G4-3703 identifies as taken to Hyp mode.
  - A Hyp Trap exception, see *EL2 configurable instruction enables, disables, and traps* on page G1-3482.
  - A Hypervisor Call exception. This is generated by executing a `HVC` instruction in a Non-secure mode.
  - An asynchronous abort, IRQ exception or FIQ exception that is not routed to EL3 but is explicitly routed to Hyp mode, as described in *Asynchronous exception routing controls* on page G1-3420.
  - A synchronous external abort, Alignment fault, Undefined Instruction exception, or Supervisor Call exception taken from the Non-secure EL0 mode and explicitly routed to Hyp mode, as described in *Routing general exceptions to EL2* on page G1-3410.

    Note

    A synchronous external abort can be routed to Hyp mode only if it is not routed to EL3.

  - A debug exception that is explicitly routed to Hyp mode as described in *Routing debug exceptions to EL2* on page G1-3411.

Note

The virtual exceptions cannot be taken to Hyp mode. They are always taken to a Non-secure EL1 mode.

Security behavior in Exception levels using AArch32 when EL3 is using AArch64

As described in *The ARMv8-A security model* on page G1-3373, when EL3 is using AArch64, lower Exception levels, in either Security state, can be using AArch32. This means software executing in those Exception levels might try to access AArch32 security features that are not available. The following subsections describe the associated behaviors:

- *Execution of an SMC instruction from a privileged Exception level that is using AArch32*
- *Non-secure reads of the NSACR*
- *Secure EL1 operations when Secure EL1 is using AArch32* on page G1-3407

Execution of an SMC instruction from a privileged Exception level that is using AArch32

When EL3 is using AArch64, an `SMC` instruction executed from Secure or Non-secure EL1 using AArch32, or from Non-secure EL2 using AArch32 when the value of HCR.TSC is 0, generates an exception that is taken to EL3. The exception syndrome is reported with an EC value of `0x13`, `SMC` instruction executed in AArch32 state, see *ISS encoding for an exception from SMC instruction execution in AArch32 state* on page D7-1846.

Non-secure reads of the NSACR

The NSACR is defined as being RO from Non-secure PE modes other than User mode. When EL3 is using AArch64, a read of the NSACR returns a fixed value of `0x00000C00` in the following cases:

- If the read is from a Non-secure EL1 mode when EL1 is using AArch32.
- If the read is from Hyp mode when EL2 is using AArch32.

Secure EL1 operations when Secure EL1 is using AArch32

When Secure EL1 is using AArch32 and EL3 is using AArch64:

- Any of the following operations performed in a Secure EL1 mode is trapped to Secure EL3:
  - A read or write of any of the SCR, NSACR, MVBAR, and SDCR.
  - Performing any of the ATS12NSO** operations described in *Address translation stages 1 and 2, Non-secure state only* on page G4-3738.
  - Executing an `SRS` instruction that would use SP_mon, see *SRS, T32* on page F7-3024 and *SRS, T32* on page F7-3024.
  - Executing a `MRS` (Banked register) or `MSR` (Banked register) instruction that would access SPSR_mon, SP_mon, or LR_mon, see *MRS (Banked register)* on page F7-3012 and *MSR (Banked register)* on page F7-3014.

  For more information about these traps, including the associated exception syndromes, see *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32* on page D1-1490.
- Writes to the CNTFRQ register are UNDEFINED.
- Any attempt to move into Monitor mode, either by an exception return or by executing a `CPS` or `MSR` instruction, is treated as an illegal operation and is handled as described in *Illegal exception returns to AArch32 state* on page G1-3413.

Note

This functionality supports a usage model where:

- EL3 uses AArch64.
- Secure software executed in Secure EL1 using AArch32 and Secure EL0 using AArch32.
- The Non-secure state uses AArch64.

The possible modes for taking each exception

Each of the exception descriptions in *AArch32 state exception descriptions* on page G1-3428 includes a subsection that describes the modes to which each exception can be taken. Those subsections are:

- *The PE mode to which the Undefined Instruction exception is taken* on page G1-3429.
- *The PE mode to which the Hyp Trap exception is taken* on page G1-3432.
- *The PE mode to which the Monitor Trap exception is taken* on page G1-3432.
- *The PE mode to which the Supervisor Call exception is taken* on page G1-3433.
- *The PE mode to which the Secure Monitor Call exception is taken* on page G1-3435.
- *The PE mode to which the Hypervisor Call exception is taken* on page G1-3436.
- *The PE mode to which the Prefetch Abort exception is taken* on page G1-3437.
- *The PE mode to which the Data Abort exception is taken* on page G1-3441.
- *The PE mode to which the Virtual Abort exception is taken* on page G1-3444.
- *The PE mode to which the physical IRQ exception is taken* on page G1-3445.
- *The PE mode to which the Virtual IRQ exception is taken* on page G1-3448.
- *The PE mode to which the physical FIQ exception is taken* on page G1-3450.
- *The PE mode to which the Virtual FIQ exception is taken* on page G1-3451.

These descriptions also show the vector offset for the exception entry for each mode. These descriptions assume that all Exception levels are using AArch32, meaning:

- HCR, rather than HCR_EL2, controls the routing of exceptions to EL2.
- SCR, rather than SCR_EL3, controls the routing of exceptions to EL3.

For more information about:

- Vector offsets, see *Exception vectors and the exception base address* on page G1-3396.
- The routing of external aborts, IRQ and FIQ exceptions, and the virtual exceptions, see *Asynchronous exception routing controls* on page G1-3420.

UNPREDICTABLE cases when the value of HCR.TGE is 1

When the value of HCR.TGE is 1, exceptions that would otherwise be taken to EL1 are, instead, routed to EL2, see *Routing general exceptions to EL2* on page G1-3410. Related to this, when the value of HCR.TGE is 1, execution in a Non-secure EL1 mode is UNPREDICTABLE. ARMv8 does not constrain this UNPREDICTABLE behavior, but in ARMv8 software that follows the ARM recommendations cannot get to this state. When following the ARM recommendations, any attempt to move to a Non-secure EL1 mode when the value of HCR.TGE is 1 is either:

- An illegal exception return, see *Illegal exception returns to AArch32 state* on page G1-3413.
- An illegal PE mode change, see *Illegal changes to the CPSR.M field* on page G1-3415.

G1.10.5 PE state on exception entry

The description of each exception includes a pseudocode description of entry to that exception, as Table G1-5 on page G1-3402 shows. The following sections describe the PE state changes on entering an exception, for different implementations and operating states. However, you must always see the exception entry pseudocode for a full description of the state changes on exception entry:

- *Instruction set state on exception entry*.
- *CPSR.E bit value on exception entry* on page G1-3409.
- *CPSR.{A, I, F, M} values on exception entry* on page G1-3409.

Note

The descriptions in these sections assume that EL2 and EL3, that control some aspects of the routing of exceptions taken from EL1 or EL0, are both using AArch32. If this is not the case:

- If EL2 is using AArch64:
  - Controls shown as provided by the HSCTLR are provided by the SCTLR_EL2.
  - Controls shown as provided by the HCR are provided by the HCR_EL2.
- If EL3 is using AArch64, controls shown as provided by the SCR are provided by the SCR_EL3.

Instruction set state on exception entry

Exception handlers can execute in either T32 state or A32 state. On exception entry, the CPSR.{T, J} are set to the required values, with the CPSR.T value determined by SCTLR.TE or HSCTLR.TE, depending on the mode the exception is taken to. Table G1-8 shows this:

Table G1-8 CPSR.{J, T} bit values on exception entry

Exception mode	HSCTLR.TE	SCTLR.TE	CPSR.J	CPSR.T	Exception handler state
Not Hyp	x	0	0	0	A32
		1	0	1	T32
Hyp	0	x	0	0	A32
	1	x	0	1	T32

When an implementation includes EL3 and EL3 is using AArch32, SCTLR is Banked for Secure and Non-secure states, and therefore the TE bit value might be different for Secure and Non-secure states. For an exception taken to a Secure or Non-secure non-Hyp mode, the SCTLR.TE bit for the Security state to which the exception is taken determines the instruction set state for the exception handler. This means the non-Hyp mode exception handlers might run in different instruction set states, depending on the Security state.

CPSR.E bit value on exception entry

The CPSR.E bit controls the load and store endianness for data handling. Table G1-9 show the value to which this bit is set on exception entry:

Table G1-9 CPSR.E bit value on exception entry

Exception mode	HSCTLR.EE	SCTLR.EE	Endianness for data loads and stores	CPSR.E
Secure or Non-secure EL1	x	0	Little-endian	0
		1	Big-endian	1
Hyp	0	x	Little-endian	0
	1	x	Big-endian	1

For more information, see the bit description in *Format of the CPSR and SPSRs* on page G1-3388.

CPSR.{A, I, F, M} values on exception entry

On exception entry, CPSR.M is set to the value for the mode to which the exception is taken, as described in *PE mode for taking exceptions* on page G1-3404.

Table G1-10 shows the cases where CPSR.{A, I, F} bits are set to 1 on an exception entry, and how this depends on the mode and Security state to which an exception is taken. If the table entry for a particular mode and Security state does not define a value for a CPSR.{A, I, F} bit then that bit is unchanged by the exception entry. In this table:

- The *Exception mode* column is the mode to which the exception is taken.
- The *Non-secure, EL2 not implemented* column applies to exceptions taken to Non-secure state in an implementation that includes EL3 but does not include EL2.
- The *All others* column applies to:
  - Exceptions taken to Secure state.
  - Implementations that do not include the EL3.
  - Exceptions taken to Non-secure state in an implementation that includes EL2.

Table G1-10 CPSR.{A, I, F} values on exception entry

PE mode exception is taken to	Security state	
	Non-secure	Secure
Hyp	If SCR.EA==0 then CPSR.A is set to 1 If SCR.IRQ==0 then CPSR.I is set to 1 If SCR.FIQ==0 then CPSR.F is set to 1	-
Monitor	-	CPSR.A is set to 1 CPSR.I is set to 1 CPSR.F is set to 1
FIQ	CPSR.A is set to 1 CPSR.I is set to 1 CPSR.F is set to 1	CPSR.A is set to 1 CPSR.I is set to 1 CPSR.F is set to 1
IRQ, Abort	CPSR.A is set to 1 CPSR.I is set to 1	CPSR.A is set to 1 CPSR.I is set to 1
Undefined, Supervisor	CPSR.I is set to 1	CPSR.I is set to 1

Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3418 describes how, in some situations, the CPSR.{A, I, F} bits mask the taking of asynchronous aborts, IRQ interrupts, and FIQ interrupts.

G1.10.6 Routing general exceptions to EL2

Note

The routing provided when the value of HCR.TGE is 1 permits a usage model where applications execute in User mode under a hypervisor, that executes in Hyp mode, without a Guest OS running in a Non-secure EL1 mode.

When the value of HCR.TGE is 1, and the PE is in Non-secure User mode, any exception that would otherwise be taken to Non-secure EL1 is taken to EL2. If EL2 is using AArch32 this means it is taken to Hyp mode, instead of to the default Non-secure mode for handling the exception. Any exception that is routed to Secure Monitor mode or to EL3 using AArch64 is unaffected.

The following sections give more information about the behavior of synchronous exceptions that are routed this way:

- *Undefined Instruction exception, when HCR.TGE is set to 1*.
- *Supervisor Call exception, when HCR.TGE is set to 1*.
- *Abort exceptions, when HCR.TGE is set to 1* on page G1-3411.

When the value of HCR.TGE is 1, and the value of SCR.NS is 1:

- The SCTLR.M bit is treated as 0 for all purposes other than reading the SCTLR register.
- Each of the HCR.{FMO, IMO, AMO} bits is treated as 1 for all purposes other than reading the HCR register
- Each of the HDCR.{TDE, TDA, TDRA, TDOSA} bits is treated as 1 for all purposes other than reading the HDCR register.
- An exception return to EL1 is treated as an illegal exception return, see *Illegal exception returns to AArch32 state* on page G1-3413.
- All virtual interrupts, including any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts, are disabled.

Undefined Instruction exception, when HCR.TGE is set to 1

When HCR.TGE is set to 1, if the PE is executing in Non-secure User mode and attempts to execute an UNDEFINED instruction, it takes the Hyp Trap exception, instead of an Undefined Instruction exception. On taking the Hyp Trap exception, the HSR reports an unknown reason for the exception, using the EC value `0x00`. For more information see *Use of the HSR* on page G4-3728.

Supervisor Call exception, when HCR.TGE is set to 1

When HCR.TGE is set to 1, if the PE executes an `SVC` instruction in Non-secure User mode, the Supervisor Call exception generated by the instruction is taken to Hyp mode.

The HSR reports that entry to Hyp mode was because of a Supervisor Call exception, and:

- If the `SVC` is unconditional, takes for the `imm16` value in the HSR:
  - A zero-extended 8-bit immediate value for the T32 `SVC` instruction.

    Note

    The only T32 encoding for `SVC` is a 16-bit instruction encoding.

  - The bottom16 bits of the immediate value for the A32 `SVC` instruction.
- If the `SVC` is conditional, the `imm16` value in the HSR is UNKNOWN.

If the `SVC` is conditional, the PE takes the exception only if the instruction passes its condition code check.

The HSR reports the exception as a Supervisor Call exception taken to Hyp mode, using the EC value 0x11. For more information, see *Use of the HSR* on page G4-3728.

Note

The effect of setting HCR.TGE to 1 is to route the Supervisor Call exception to Hyp mode, not to trap the execution of the SVC instruction. This means that the preferred return address for the exception, when routed to Hyp mode in this way, is the instruction after the SVC instruction.

Abort exceptions, when HCR.TGE is set to 1

When the value of HCR.TGE is 1, if the PE is executing in Non-secure User mode then any abort exception that is not routed to Secure Monitor mode or EL using AArch64 generates an exception that is taken as a Hyp Trap exception. Where an attempt to execute an instruction causes an abort, on taking the Hyp Trap exception, the HSR indicates whether a Data Abort exception or a Prefetch Abort exception caused the Hyp Trap exception entry, and presents a valid syndrome in the HSR.

Note

- When SCR.EA is set to 1, external aborts are routed to Secure Monitor mode, and this takes priority over the HCR.TGE routing. For more information, see *Asynchronous exception routing controls* on page G1-3420. The SCR.EA control described in that section applies to both synchronous and asynchronous external aborts.
- Any asynchronous external abort generates a Data Abort exception. Therefore, if an asynchronous external abort is routed to Hyp mode because the value of HCR.TGE is 1 the exception is reported as a Data Abort exception routed to Hyp mode.

The HSR reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
- As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information about the exception reporting, see *Use of the HSR* on page G4-3728.

G1.10.7 Routing debug exceptions to EL2

When the value of HDCR.TDE is 1, if the PE is executing in a Non-secure mode other than Hyp mode, any Debug exception is routed to Hyp mode. This means it generates a Hyp Trap exception. This applies to:

- Debug exceptions associated with an instruction fetch, that would otherwise generate a Prefetch Abort exception. These are the Breakpoint, Software Breakpoint Instruction, and Vector Catch exception, see Chapter G2 *AArch32 Self-hosted Debug*.
- Watchpoint exceptions associated with data accesses, that would otherwise generate a Data Abort exception. See *Watchpoint exceptions* on page G2-3550.

When the value of HDCR.TDE is 1, each of the HDCR.{TDRA, TDOSA, TDA} bits is treated as 1 for all purposes other than reading the HDCR register.

Note

- A Breakpoint or Watchpoint debug event that generates entry to Debug state cannot be trapped to Hyp mode. See *Breakpoint and Watchpoint debug events* on page H2-4396.
- When HDCR.TDE is set to 1, the Hyp Trap exception is generated instead of the Prefetch Abort exception or Data Abort exception that is otherwise generated by the Debug exception.
- Debug exceptions, other than Software Breakpoint Instruction exceptions, are never generated in Hyp mode.

When a Hyp Trap exception is generated because HDCR.TDE is set to 1, The HSR reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
- As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information see *Use of the HSR* on page G4-3728.

G1.10.8 Exception return to an Exception level using AArch32

In the ARM architecture, *exception return* to an Exception level that is using AArch32 requires the simultaneous restoration of the PC and CPSR to values that are consistent with the desired state of execution on returning from the exception. Typically, exception return involves returning to one of:

- The instruction after the instruction boundary at which an asynchronous exception was taken.
- The instruction following an `SVC`, `SMC`, or `HMC` instruction, for an exception generated by one of those instructions.
- The instruction that caused the exception, after the reason for the exception has been removed.
- The subsequent instruction, if the instruction that caused the exception has been emulated in the exception handler.

The ARM architecture defines a *preferred return address* for each exception other than Reset, see *Link values saved on exception entry* on page G1-3403. The values of the SPSR.IT[7:0] bits generated on exception entry are always correct for this preferred return address, but might require adjustment by the exception handler if returning elsewhere.

In some cases, to calculate the appropriate preferred return address for a return to an Exception level that is using AArch32, a subtraction must be performed on the link value saved on taking the exception. The description of each exception includes any value that must be subtracted from the link value, and other information about the required exception return.

On an exception return, the CPSR takes either:

- The value loaded by the `RFE` instruction.
- If the exception return is not performed by executing an `RFE` instruction, the value of the current SPSR at the time of the exception return.

Illegal exception returns to AArch32 state on page G1-3413 describes the behavior if the restored PE state would not be valid for the Exception level, PE mode, and Security state targeted by the exception return.

Exception return instructions

The instructions that an exception handler can use to return from an exception depend on whether the exception was taken to a EL1 mode, or in an EL2 mode, see:

- *Return from an exception taken to a PE mode other than Hyp mode*.
- *Return from an exception taken to Hyp mode* on page G1-3413.

Return from an exception taken to a PE mode other than Hyp mode

For an exception taken to a PE mode other than Hyp mode, the ARM AArch32 architecture provides the following *exception return instructions*:

- Data-processing instructions with the S bit set and the PC as a destination, see *SUBS PC, LR and related instructions, T32* on page F7-3030 and *SUBS PC, LR and related instructions, A32* on page F7-3032.

  Typically:

  — A return where no subtraction is required uses `SUBS` with an operand of 0, or the equivalent `MOVS` instruction.

  — A return requiring subtraction uses `SUBS` with a nonzero operand.

- The `RFE` instruction, see *RFE* on page F7-3020. If a subtraction is required, typically it is performed before saving the LR value to memory.
- In A32 state, a form of the `LDM` instruction, see *LDM (exception return)* on page F7-3006. If a subtraction is required, typically it is performed before saving the LR value to memory.

Return from an exception taken to Hyp mode

For an exception taken to Hyp mode, the ARM architecture provides the ERET instruction, see *ERET* on page F7-3002. An exception handler executing in Hyp mode must return using the ERET instruction.

Both Hyp mode and the ERET instruction are implemented only as part of EL2.

Alignment of exception returns

The {J, T} bits of the value transferred to the CPSR by an exception return control the target instruction set of that return. The behavior of the hardware for exception returns for different values of the {J, T} bits is as follows:

{J, T} == 00 The target instruction set state is A32 state. Bits[1:0] of the address transferred to the PC are ignored by the hardware.

{J, T} == 01 The target instruction set state is T32 state:

- Bit[0] of the address transferred to the PC is ignored by the hardware.
- Bit[1] of the address transferred to the PC is part of the instruction address.

{J, T} == 1x Reserved, see *Exception return to an unimplemented instruction set state* on page G1-3415.

Note

Before ARMv8, 0b10 indicated Jazelle state as the target instruction set state. However, ARMv8 requires a trivial implementation of the Jazelle extension, and therefore Jazelle state is not implemented. For a description of the trivial Jazelle implementation see *Trivial implementation of the Jazelle extension* on page G1-3394. Similarly, 0b11 indicated T32EE state, which ARM does not support.

ARM deprecates any dependence on the requirements that the hardware ignores bits of the address. ARM recommends that the address transferred to the PC for an exception return is correctly aligned for the target instruction set.

After an exception entry other than Reset, the LR value has the correct alignment for the instruction set indicated by the SPSR.{J, T} bits. This means that if exception return instructions are used with the LR and SPSR values produced by such an exception entry, the only precaution software needs to take to ensure correct alignment is that any subtraction is of a multiple of four if returning to A32 state, or a multiple of two if returning to T32 state.

Illegal exception returns to AArch32 state

Throughout this section:

Saved process state

Refers to any of:

- The state held in the SPSR for any exception return other than an exception return made by executing an RFE instruction in AArch32 state.
- The state held in memory that is to be restored to the CPSR by the execution of an RFE instruction in AArch32 state.
- The state held in the DSPSR on a Debug state exit.

Exception or debug return

Refers to any of:

- An exception return.
- Execution of a DRPS instruction in Debug state
- Exit from Debug state.

Configured from reset

Indicates state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The ARMv8 architecture has a generic mechanism for handling exception returns to a mode or state that is illegal. This can occur as a result of any of the following situations:

- An exception or debug return where the Exception level being returned to is higher than the current Exception level.
- An exception or debug return to EL1, EL2 or EL3 where the Execution state specified in the saved process state is different from the Execution state used in the exception level being returned to, as determined by the SCR_EL3.RW or HCR_EL2_EL2.RW bits, or as configured from reset.
- An exception or debug return to EL0 where the Execution state specified in the saved process state is AArch64 and the target Execution state for EL1, as determined by the SCR_EL3.RW or HCR_EL2_EL2.RW bits or as configured from reset, is AArch32.
- An exception or debug return to an Exception level that is not implemented or not accessible, for example:
  - A return to EL2 when the value of SCR.NS for the Exception level being returned to is 0.
  - Any return to an Exception level that is not implemented.
- An exception or debug return from AArch32 state when the saved process state indicates a return to AArch64 EL0 execution.
- An exception or debug return to Non-secure EL1 when the value of the HCR.TGE bit is 1.
- It is IMPLEMENTATION DEFINED whether:
  - An exception or debug return to an Exception level using AArch32 when the values of the saved process state {T, J} bits are {1, 1} is an illegal exception return.
  - The saved process state J bit is treated as 0.

  See also *Exception return to an unimplemented instruction set state* on page G1-3415.
- An exception or debug return to an Exception level using AArch64 when the value of the saved process state M[1] bit is 1.
- An exception or debug return to an Exception level using AArch32 when the value of the saved process state M field value is not a valid mode. Table G1-2 on page G1-3378 shows the M value for each of the AArch32 PE modes.
- Debug state exit from EL0 using AArch64 to EL0 using AArch32.

In these cases:

- PSTATE.IL is set to 1, to indicate an illegal exception or debug return.
- If the exception or debug return is from an Exception level that is using AArch32, the attempted exception or debug return does not change the PE mode. This means the CPSR.M field is unchanged.
- If the exception or debug return is from an Exception level that is using AArch64, the attempted exception or debug return does not change any of the Exception level, the Execution state, and the current stack pointer selection.
- The SS bit is handled in the same way as any other exception or debug return, see *Software Step exceptions* on page D2-1579.
- The CPSR.{GE, N, Z, C, V, Q, A, I, F, E} fields are copied from the saved process state in the SPSR for the PE mode in which the exception is handled.
- The CPSR.{IT, T, J} bits are each either:
  - Set to 0
  - Copied from the saved process state in the SPSR for the PE mode in which the exception is handled.

The choice between these two options is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

Note

An illegal exception return from an Exception level that is using AArch64 is handled in AArch64 state and therefore is not considered here.

All aspects of the illegal exception or debug return, other than the effects described in this section, occur as they do for a legal exception return.

Exception return to an unimplemented instruction set state

In AArch32 state, the CPSR.{J. T} bits identify the current Instruction set state. In an ARMv8 implementation:

Jazelle state Corresponds to the {J, T} values {1, 0}, and is never implemented, because ARMv8 requires a trivial Jazelle implementation.

T32EE state Corresponds to the {J, T} values {1, 1}. ARM does not support T32EE state.

An ARMv8 implementation does not normally attempt to enter an unimplemented instruction set state, because:

- The trivial Jazelle implementation means the `BXJ` instruction acts as a `BX` instruction.
- Normal exception entry and return preserves the instruction set state.

However, an exception return instruction might set CPSR.{J. T} to the values corresponding to an unimplemented instruction set state, see *Unimplemented instruction sets* on page G1-3394. This is most likely to happen because a faulty exception handler restores the wrong value to the CPSR.

If the PE attempts to execute an instruction while the CPSR.{J, T} bits indicate an unimplemented instruction set state, an Undefined Instruction exception is taken. This happens if either:

- The value of CPSR.{J, T} is {1, 0}, the encoding for Jazelle state in previous versions of the architecture.
- The value of CPSR.{J, T} is {1, 1}, the encoding for T32EE state in previous versions of the architecture.

The Undefined Instruction exception handler can detect the cause of this exception because on entry to the handler the SPSR.{J, T} bits indicate the unimplemented instruction set state. If the Undefined Instruction exception handler wants to return to a valid instruction set state it can change the values its exception return instruction writes to the CPSR.{J, T} bits.

If an exception return writes CPSR.{J, T} values that correspond to an unimplemented instruction set state, and also writes the address of an aborting memory location to the PC, it is IMPLEMENTATION DEFINED whether:

- The instruction fetch is attempted, and a Prefetch Abort exception is taken because the memory access aborts.
- An Undefined Instruction exception is taken, without the instruction being fetched.

If an exception return writes CPSR.{J, T} values that correspond to an unimplemented instruction set, the width of the instruction fetch is an IMPLEMENTATION DEFINED value that is 2 or 4 bytes.

On ARMv8 implementations, the J bits of the PSRs are RES0. On such an implementation, a return to an unimplemented instruction set state cannot occur.

Illegal changes to the CPSR.M field

The CPSR.M field can be changed explicitly using an `MSR` or `CPS` instruction. Changing the M field to any of the following values is an illegal change to the CPSR.M field:

- Changing M to a value that Table G1-2 on page G1-3378 does not show as allocated.
- Changing M to the value that corresponds to a PE mode that is not implemented or not accessible.

  This includes:

  — When executing in Secure EL1, changing M to the value for Monitor mode when EL3 is using AArch64.

  - In an implementation that includes EL2, writing the value for Hyp mode to the M field from any PE mode other than Hyp mode.
  - In an implementation that includes EL2, when EL2 is using AArch32 and the PE is in Hyp mode, changing M to the value for any mode other than Hyp mode.

- Changing M to a value that would cause an increase in Exception level.
- When executing in Non-secure state, changing M to the value for Monitor mode.

In the ARMv8 Architecture, in AArch32 state, the IL process state bit catches any illegal explicit change to the CPSR.M field using an `MSR` or `CPS` instruction. The effect of such an illegal change to the CPSR.M field is that:

1. The current PE mode remains unchanged.
2. The PSTATE.IL bit is set to 1.
3. Any attempt to execute any instruction generates an Illegal Execution State exception.

The Illegal Execution State exception is handled as described in *Illegal exception returns to AArch32 state* on page G1-3413.

Note

In ARMv7, the effect of an illegal change to the CPSR.M field is UNPREDICTABLE.

Legal exception returns that set PSTATE.IL to 1

When a legal exception return to AArch32 would set the PSTATE.IL bit to 1, either by copying this value from an SPSR, or by loading it from memory if the exception return was performed by executing an `RFE` instruction, then the CPSR.{IT, T, J} bits are each either:

- Set to 0.
- Copied from the SPSR, or loaded from memory if the exception return was performed by executing an `RFE` instruction.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. This means software must regard each value as being an UNKNOWN choice between the two permitted values.

Because the exception return sets the PSTATE.IL bit to 1, any attempt to execute any instruction generates an Illegal Execution State exception. This is handled as described in *Illegal exception returns to AArch32 state* on page G1-3413.

The Illegal Execution State exception

When the value of PSTATE.IL is 1, any attempt to execute any instruction generates an Illegal Execution State exception. In AArch32 state, the PSTATE.IL bit can be set to 1 by any of:

- An illegal exception return, as described in *Illegal exception returns to AArch32 state* on page G1-3413.
- An illegal change to CPSR.M, as described in *Illegal changes to the CPSR.M field* on page G1-3415.
- A legal exception return that would set PSTATE.IL to 1, as described in *Legal exception returns that set PSTATE.IL to 1*.

An Illegal Execution State exception is taken in the same way as an Undefined Instruction exception in the current Exception level. If the current Exception level is EL2 using AArch32, the HSR provides a syndrome for the exception, as follows:

- HSR.EC has the value `0xE`.
- The HSR.IL bit is invalid, and is RES1.
- The HSR.ISS field is RES0.

An Illegal Execution State exception has priority over any other Undefined Instruction exception that might arise from instruction execution.

Note

This section only describes the handling of an Illegal Execution State exception that is taken to an Exception level that is using AArch32. *Illegal return events* on page D1-1438 describes the cases where an Illegal Execution State exception is taken to an Exception level that is using AArch64.

On taking an Illegal Execution State exception to an Exception level that is using AArch32:

1. The value of the PSTATE.IL bit, 1, is copied to the SPSR.IL bit for the PE mode to which the exception is taken.
2. The PSTATE.IL bit is cleared to 0.

G1.11 Asynchronous exception behavior for exceptions taken from AArch32 state

In an implementation that does not include EL2 or EL3, the asynchronous exceptions behave as follows when EL1 and EL0 are both using AArch32:

- An asynchronous abort is taken to Abort mode.
- An IRQ exception is taken to IRQ mode.
- An FIQ exception is taken to FIQ mode.

These are the *default PE modes* for taking these exceptions.

However, the CPSR.{A, I, F} bits *mask* the asynchronous exceptions, meaning that when the value of one of these CPSR bits is 1, the corresponding exception is not taken.

If a masked asynchronous exceptions remains signalled, then the exception remains pending unless the value of the CPSR bit is changed to 0.

EL2 and EL3 provide controls that affect:

- The routing of these exceptions, see *Asynchronous exception routing controls* on page G1-3420
- Masking of these exceptions in Non-secure state, see *Asynchronous exception masking controls* on page G1-3421.

Similar register control bits are provided regardless of whether EL2 and EL3 are using AArch32 or AArch64:

- The EL2 controls are provided by the HCR when EL2 is using AArch32, and by the HCR_EL2 when EL2 is using AArch64.
- The EL3 controls are provided by the SCR when EL3 is using AArch32, and by the SCR_EL3 when EL3 is using AArch64.

Therefore, most references to the HCR or SCR in this section are to entries in Table J-1 on page AppxJ-5170, that disambiguates between AArch32 registers and AArch64 registers. However, the Execution states used by EL2 and EL3 do affect some aspects of the routing and masking of the asynchronous exceptions, see *Asynchronous exception routing and masking with higher Exception levels using AArch64* on page G1-3423.

G1.11.1 Virtual exceptions when an implementation includes EL2

When implemented, EL2 provides the following virtual exceptions, that correspond to the physical asynchronous exceptions:

- Virtual Abort, that corresponds to a physical external asynchronous abort.
- Virtual IRQ, that corresponds to a physical IRQ.
- Virtual FIQ, that corresponds to a physical FIQ.

When the value of the corresponding HCR.{AMO, IMO, FMO} bit is 1, a virtual exception is generated either:

- By setting a virtual interrupt pending bit, HCR.{VA, VI, VF}, to 1.
- For a Virtual IRQ or Virtual FIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller, for example from a Virtual GIC, as defined by the *ARM Generic Interrupt Controller Architecture Specification*.

In AArch32 state, a virtual exception is taken only from a Non-secure EL1 or EL0 mode. In any other mode, if the exception is generated it is not taken.

A virtual exception is taken in Non-secure state to the default mode for the corresponding physical exception. This means:

- A Virtual Abort is taken to Non-secure Abort mode.
- A Virtual IRQ is taken to Non-secure IRQ mode.
- A Virtual FIQ is taken to Non-secure FIQ mode.

Table G1-11 summarizes the HCR bits that route asynchronous exceptions to EL2, and the bits that generate the virtual exceptions.

Table G1-11 HCR bits controlling asynchronous exceptions

Exception	Routing the physical exception to EL2	Generating the virtual exception
Asynchronous abort	HCR.AMO	HCR.VA
IRQ	HCR.IMO	HCR.VI
FIQ	HCR.FMO	HCR.VF

The HCR.{VA, VI, VF} bits generate a virtual exception only if set to 1 when the value of the corresponding HCR.{AMO, IMO, FMO} is 1.

Similarly, if the implementation also includes EL3, the HCR.{AMO, IMO, FMO} bits route the corresponding physical exception to Hyp mode only if the physical exception is not routed to Monitor mode by the SCR.{EA, IRQ, FIQ} bit. For more information, see *Asynchronous exception routing controls* on page G1-3420.

When the value of an HCR.{AMO, IMO, FMO} control bit is 1, the corresponding mask bit in the CPSR:

- Does not mask the physical exception.
- Masks the virtual exception when the PE is executing in a Non-secure EL1 or EL0 mode.

Taking a Virtual Abort exception clears HCR.VA to zero. Taking a Virtual IRQ exception or a Virtual FIQ exception does not affect the value of HCR.VI or HCR.VF.

Note

This means that the exception handler for a Virtual IRQ exception or a Virtual FIQ exception must cause software that is executing at EL2 or EL3 to update the HCR to clear the appropriate virtual exception bit to 0.

See *WFE wake-up events* on page G1-3458 and *Wait For Interrupt* on page G1-3460 for information about how virtual exceptions affect wake up from power-saving states.

Note

A hypervisor can use virtual exceptions to signal exceptions to the current Guest OS. The Guest OS takes a virtual exception exactly as it would take the corresponding physical exception, and is unaware of any distinction between virtual exception and the corresponding physical exception.

Effects of the HCR.{AMO, IMO, FMO} bits

As described in this section, the HCR.{AMO, IMO, FMO} bits are part of the mechanism for enabling the virtual exceptions. In addition, for exceptions generated in Non-secure state:

- As mentioned in this section, affect the routing of the exceptions. See *Asynchronous exception routing controls* on page G1-3420.
- Affect the masking of the exceptions. See *Asynchronous exception masking controls* on page G1-3421.

G1.11.2 Asynchronous exception routing controls

Note

This section describes the behavior when all exception levels are using AArch32. For the differences when this is not the case see *Asynchronous exception routing and masking with higher Exception levels using AArch64* on page G1-3423

In an implementation that includes EL3 the following bits in the SCR control the routing of asynchronous exceptions, and also the routing of synchronous external aborts:

SCR.EA When the value of this bit is 1, any external abort is taken to EL3.

Note

- Although this section describes the asynchronous exception routing controls, SCR.EA controls the routing of both synchronous and asynchronous external aborts.
- The other classes of abort cannot be routed to EL3. For more information about the classification of aborts, see *VMSAv8-32 memory aborts* on page G4-3703.

SCR.FIQ When the value of this bit is 1, any FIQ exception is taken to EL3.

SCR.IRQ When the value of this bit is 1, any IRQ exception is taken to EL3.

When EL3 is using AArch32 and the value of one of the SCR.{EA, FIQ, IRQ} bits is 1, the exception is taken to Monitor mode.

Only Secure software can change the values of these bits.

In an implementation that includes EL2, the following bits in the HCR route asynchronous exceptions to EL2, for exceptions that are both:

- Taken from a Non-secure EL1 or EL0 mode.
- If the implementation also includes EL3, not configured, by the SCR.{EA, FIQ, IRQ} controls, to be taken to EL3.

HCR.AMO When the value of this bit is 1, an asynchronous external abort taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure Abort mode. If the implementation also includes EL3, this control applies only if the value of SCR.EA is 0. When the value of SCR.EA is 1, the value of the AMO bit is ignored.

Note

Figure G1-8 on page G1-3441 also shows how synchronous external aborts are handled.

HCR.FMO When the value of this bit is 1, an FIQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure FIQ mode. If the implementation also includes EL3, this control applies only if the value of SCR.FIQ is 0. When the value of SCR.FIQ is 1, the value of the FMO bit is ignored.

HCR.IMO When the value of this bit is 1, an IRQ exceptions taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure IRQ mode. If the implementation also includes EL3, this control applies only if the value of SCR.IRQ is 0. When the value of SCR.IRQ is 1, the value of the IMO bit is ignored.

When EL2 is using AArch32 and the value of one of the HCR.{AMO, FMO, IMO} bits is 1, the exception is taken to Hyp mode.

Only software executing in Hyp mode, or Secure software executing at EL3 with SCR.NS set to 1, can change the values of these bits. If EL3 is using AArch32, this requires the Secure software to be executing in Monitor mode.

The HCR.{AMO, FMO, IMO} bits also affect the masking of asynchronous exceptions in Non-secure state, as described in *Asynchronous exception masking controls* on page G1-3421.

The SCR.{EA, FIQ, IRQ} and HCR.{AMO, FMO, IMO} bits have no effect on the routing of Virtual Abort, Virtual FIQ, and Virtual IRQ exceptions.

Note

When the PE is in Hyp mode:

- Physical asynchronous exceptions that are not routed to Monitor mode are taken to Hyp mode.
- Virtual exceptions are not signaled to the PE.

See also *Asynchronous exception behavior for exceptions taken from AArch32 state* on page G1-3418.

G1.11.3 Asynchronous exception masking controls

Note

This section describes the behavior when all exception levels are using AArch32. For the differences when this is not the case see *Asynchronous exception routing and masking with higher Exception levels using AArch64* on page G1-3423

The CPSR.{A, I, F} bits can mask the taking of the corresponding exceptions from AArch32 state, as follows:

- CPSR.A can mask asynchronous aborts.
- CPSR.I can mask IRQ exceptions.
- CPSR.F can mask FIQ exceptions.

In an implementation that does not include either of EL2 and EL3, setting one of these bits to 1 masks the corresponding exception, meaning the exception cannot be taken.

In an implementation that includes EL2, the HCR.{AMO, IMO, FMO} bits modify the masking of exceptions taken from Non-secure state.

Similarly, in an implementation that includes EL3, the SCR.{AW, FW} bits modify the masking of exceptions taken from Non-secure state by the CPSR.{A, F} bits.

An implementation that includes only EL1 and EL0 does not provide any masking of the CPSR.{A, I, F} bits. The following subsections describe the masking of these bits in other implementations:

- *Asynchronous exception masking in an implementation that includes EL2 but not EL3*.
- *Asynchronous exception masking in an implementation that includes EL3 but not EL2*.
- *Asynchronous exception masking in an implementation that includes both EL2 and EL3* on page G1-3422.
- *Summary of the asynchronous exception masking controls* on page G1-3422.

Asynchronous exception masking in an implementation that includes EL2 but not EL3

The HCR.{AMO, IMO, FMO} bits modify the effect of the CPSR.{A, I, F} bits. When the value of an HCR.{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding CPSR.{A, I, F} bit is ignored when the exception is taken from a Non-secure mode other than Hyp mode.

Asynchronous exception masking in an implementation that includes EL3 but not EL2

The SCR.{AW, FW} bits modify the effect of the CPSR.{A, F} bits. When the value of one of the SCR.{AW, FW} bits is 0, the corresponding CPSR bit is ignored when both of the follow apply:

- The corresponding exception is taken from Non-secure state.
- The value of the corresponding SCR.{EA, FIQ} bit is 1, routing the exception to EL3. This means the exception is routed to Monitor mode if EL3 is using AArch32.

Note

Whenever the value of CPSR.I is 1, IRQ exceptions are masked and cannot be taken.

Asynchronous exception masking in an implementation that includes both EL2 and EL3

When the value of an HCR.{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding CPSR.{A, I, F} bit is ignored when both of the following apply:

- The exception is taken from Non-secure state.
- Either:
  - The corresponding SCR.{EA, IRQ, FIQ} bit routes the exception to Monitor mode.
  - The exception is taken from a Non-secure mode other than Hyp mode.

In addition, when the value of an SCR.{AW, FW} bit is 0, the value of the corresponding CPSR.{A, F} bit is ignored when all of the following apply:

- The exception is taken from Non-secure state.
- The corresponding SCR.{EA, FIQ} bit routes the exception to Monitor mode.
- The corresponding HCR.{AMO, FMO} mask override bit is set to 0.

Summary of the asynchronous exception masking controls

The tables in this section show the masking controls for each of the CPSR.{A, I, F} bits. For an implementation that does not include all of the exception levels:

If the implementation includes only EL1 and EL0

The CPSR bits cannot be masked. The behavior is as shown in the *Secure* row of the tables.

If the implementation includes EL2 but not EL3

The behavior is as shown in the *Non-secure* table rows when the control bits in the SCR are both 0.

If the implementation includes EL3 but not EL2

The behavior is as shown in the table rows where the control bit in the HCR is 0.

Table G1-12 shows the controls of the masking of asynchronous exceptions by CPSR.A.

Table G1-12 Control of masking by CPSR.A

Security state	HCR.AMO	SCR.EA	SCR.AW	Mode	CPSR.A
Secure	x	x	x	x	Masks asynchronous aborts, when set to 1
Non-secure	0	0	x	x	Masks asynchronous aborts, when set to 1
		1	0	x	Ignored
			1	x	Masks asynchronous aborts, when set to 1
	1	x	x	Not Hyp	Ignored
		0	x	Hyp	Masks asynchronous aborts, when set to 1
		1	x	x	Ignored

Table G1-13 shows the controls of the masking of FIQ exceptions by CPSR.F:

Table G1-13 Control of masking by CPSR.I

Security state	HCR.IMO	SCR.IRQ	Mode	CPSR.I
Secure	x	x	x	Masks IRQs, when set to 1
Non-secure	0	x	x	Masks IRQs, when set to 1
	1	x	Not Hyp	Ignored
		0	Hyp	Masks IRQs, when set to 1
		1	x	Ignored

Table G1-14 shows the controls of the masking of FIQ exceptions by CPSR.F:

Table G1-14 Control of masking by CPSR.F

Security state	HCR.FMO	SCR.FIQ	SCR.FW	Mode	CPSR.F
Secure	x	x	x	x	Masks FIQs, when set to 1
Non-secure	0	0	x	x	Masks FIQs, when set to 1
		1	0	x	Ignored
			1	x	Masks FIQs, when set to 1
	1	x	x	Not Hyp	Ignored
		0	x	Hyp	Masks FIQs, when set to 1
		1	x	x	Ignored

G1.11.4 Asynchronous exception routing and masking with higher Exception levels using AArch64

Asynchronous exception routing controls on page G1-3420 and *Asynchronous exception masking controls* on page G1-3421 give full descriptions of the routing and masking of the asynchronous exceptions when all Exception levels are using AArch32. However, when EL0 and EL1 are using AArch32:

- As already described, the SCR and HCR controls might be from Exception levels that are using AArch64.
- If EL3 is using AArch64, or EL2 is using AArch64, there are some changes to the asynchronous exception behaviors.

Therefore, the following sections summarize the asynchronous exception behaviors, taking account of the Execution state being used at EL2 and EL3:

- *Summary of physical interrupt routing*.
- *Summary of physical interrupt masking* on page G1-3425.

Summary of physical interrupt routing

The following tables show the routing of physical interrupts. Table G1-15 on page G1-3424 shows the routing of physical FIQ interrupts, Table G1-16 on page G1-3424 shows the routing of physical IRQ interrupts, and Table G1-17 on page G1-3425 shows the routing of physical asynchronous aborts.

In these tables, for exceptions that must be taken to an Exception level that is using AArch32, the table shows the target Exception level and PE mode. In these entries, *Mon* indicates Monitor mode, and *Abt* indicates Abort mode.

Table G1-15 Routing of physical FIQ exceptions

EL3 Execution state	Control bits: SCR		Control bits: HCR	Target when take from: Non-secure			Target when take from: Secure		
	FIQ	RW[a]	FMO[b]	EL0	EL1	EL2	EL0	EL1[c]	EL3
AArch32	0	x	0	EL1 FIQ	EL1 FIQ	EL2 Hyp	EL3 FIQ	-	EL3 FIQ
			1	EL2 Hyp	EL2 Hyp	EL2 Hyp	EL3 FIQ	-	EL3 FIQ
	1	x	x	EL3 Mon	EL3 Mon	EL3 Mon	EL3 Mon	-	EL3 Mon
AArch64	0	0	0	EL1 FIQ	EL1 FIQ	EL2 Hyp	EL1 FIQ	EL1 FIQ	P[d]
		x	1	EL2[e]	EL2[e]	EL2[e]	EL1[f]	EL1[f]	P[d]
		1	0	EL1	EL1	P[d]	EL1	EL1	P[d]
	1	x	x	EL3	EL3	EL3	EL3	EL3	EL3

a. SCR_EL3.RW. When 1, the next lower Exception level is using AArch64. This control is not present when EL3 is using AArch32.
b. When the value of HCR.TGE is 1, the effective value of this bit is 1.
c. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.
d. Interrupt is not taken, but remains pending.
e. If EL2 is using AArch32, taken to Hyp mode.
f. If EL1 is using AArch32.taken to Abort mode.

Table G1-16 Routing of physical IRQ exceptions

EL3 Execution state	Control bits: SCR		Control bits: HCR	Target when take from: Non-secure			Target when take from: Secure		
	IRQ	RW[a]	IMO[b]	EL0	EL1	EL2	EL0	EL1[c]	EL3
AArch32	0	x	0	EL1 IRQ	EL1 IRQ	EL2 Hyp	EL3 IRQ	-	EL3 IRQ
			1	EL2 Hyp	EL2 Hyp	EL2 Hyp	EL3 IRQ	-	EL3 IRQ
	1	x	x	EL3 Mon	EL3 Mon	EL3 Mon	EL3 Mon	-	EL3 Mon
AArch64	0	0	0	EL1 IRQ	EL1 IRQ	EL2 Hyp	EL1 IRQ	EL1 IRQ	P[d]
		x	1	EL2[e]	EL2[e]	EL2[e]	EL1[f]	EL1[f]	P[d]
		1	0	EL1	EL1	P[d]	EL1	EL1	P[d]
	1	x	x	EL3	EL3	EL3	EL3	EL3	EL3

a. SCR_EL3.RW. When 1, the next lower Exception level is using AArch64. This control is not present when EL3 is using AArch32.
b. When the value of HCR.TGE is 1, the effective value of this bit is 1.
c. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.
d. Interrupt is not taken, but remains pending.
e. If EL2 is using AArch32, taken to Hyp mode.
f. If EL1 is using AArch32.taken to Abort mode.

Table G1-17 Routing of physical Asynchronous aborts

EL3 Execution state	Control bits: SCR EA	Control bits: SCR RW[a]	Control bits: HCR AMO[b]	Target when take from: Non-secure EL0	Non-secure EL1	Non-secure EL2	Secure EL0	Secure EL1[c]	Secure EL3
AArch32	0	x	0	EL1 Abt	EL1 Abt	EL2 Hyp	EL3 Abt	-	EL3 Abt
			1	EL2 Hyp	EL2 Hyp	EL2 Hyp	EL3 Abt	-	EL3 Abt
	1	x	x	EL3 Mon	EL3 Mon	EL3 Mon	EL3 Mon	-	EL3 Mon
AArch64	0	0	0	EL1 Abt	EL1 Abt	EL2 Hyp	EL1 Abt	EL1Abt	P[d]
		x	1	EL2[e]	EL2[e]	EL2[e]	EL1[f]	EL1[f]	P[d]
		1	0	EL1	EL1	P[d]	EL1	EL1	P[d]
	1	x	x	EL3	EL3	EL3	EL3	EL3	EL3

a. SCR_EL3.RW. When 1, the next lower Exception level is using AArch64. This control is not present when EL3 is using AArch32.
b. When the value of HCR.TGE is 1, the effective value of this bit is 1.
c. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.
d. Interrupt is not taken, but remains pending.
e. If EL2 is using AArch32, taken to Hyp mode.
f. If EL1 is using AArch32.taken to Abort mode.

Summary of physical interrupt masking

The following tables show the masking of physical interrupts. Table G1-18 shows the masking of physical FIQ interrupts, Table G1-19 on page G1-3426 shows the masking of physical IRQ interrupts, and Table G1-20 on page G1-3427 shows the masking of physical asynchronous aborts. In these tables:

M Indicates that the exception is masked when the value of the CPSR mask bit is 1.

T Indicates that the exception is taken, regardless of the value of the CPSR mask bit.

P Indicates that the exception is not taken but remains pending. The value of the CPSR mask bit has no effect on this behavior.

Table G1-18 Masking of physical FIQ exceptions

EL3 Execution state	Control bits: SCR FIQ	Control bits: SCR FW	Control bits: SCR RW[b]	Control bits: HCR FMO[c]	Effect of CPSR.F[a] mask in Exception level: Non-secure EL0	Non-secure EL1	Non-secure EL2	Secure EL0	Secure EL1[d]	Secure EL3
AArch32	0	x	x	0	M	M	M	M	-	M
				1	T	T	M	M	-	M
	1	0	x	0	T	T	T	M	-	M
		1	x	0	M	M	M	M	-	M
		x	x	1	T	T	T	M	-	M

Table G1-18 Masking of physical FIQ exceptions (continued)

EL3 Execution state	Control bits: SCR			HCR	Effect of CPSR.F[a] mask in Exception level: Non-secure			Secure		
	FIQ	FW	RW[b]	FMO[c]	EL0	EL1	EL2	EL0	EL1[d]	EL3
AArch64	0	x	0	0	M	M	M	M	M	P
				1	T	T	M	M	M	P
			1	0	M	M	P	M	M	P
				1	T	T	M	M	M	P
	1	x	x	x	T	T	T	T	T	M

a. Or the PSTATE.F mask in an Exception level that is using AArch64.
b. SCR_EL3 only, this control is not present when EL3 is using AArch32. When the value of RW is 1, the next lower Exception level is using AArch64.
c. When the value of HCR.TGE is 1, the effective value of this bit is 1.
d. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.

Table G1-19 Masking of physical IRQ exceptions

EL3 Execution state	Control bits: SCR		HCR	Effect of CPSR.I[a] mask in Exception level: Non-secure			Secure		
	IRQ	RW[b]	IMO[c]	EL0	EL1	EL2	EL0	EL1[d]	EL3
AArch32	0	x	0	M	M	M	M	-	M
			1	T	T	M	M	-	M
	1	x	0	M	M	M	M	-	M
			1	T	T	T	M	-	M
AArch64	0	0	0	M	M	M	M	M	P
			1	T	T	M	M	M	P
		1	0	M	M	P	M	M	P
			1	T	T	M	M	M	P
	1	x	x	T	T	T	T	T	M

a. Or the PSTATE.I mask in an Exception level that is using AArch64.
b. SCR_EL3 only, this control is not present when EL3 is using AArch32. When the value of RW is 1, the next lower Exception level is using AArch64.
c. When the value of HCR.TGE is 1, the effective value of this bit is 1.
d. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.

Table G1-20 Masking of physical Asynchronous aborts

EL3 Execution state	Control bits: SCR			Control bits: HCR	Effect of CPSR.A[a] mask in Exception level: Non-secure			Secure		
	EA	AW	RW[b]	AMO[c]	EL0	EL1	EL2	EL0	EL1[d]	EL3
AArch32	0	x	x	0	M	M	M	M	-	M
				1	T	T	M	M	-	M
	1	0	x	0	T	T	T	M	-	M
		1	x	0	M	M	M	M	-	M
		x	x	1	T	T	T	M	-	M
AArch64	0	x	0	0	M	M	M	M	M	P
				1	T	T	M	M	M	P
			1	0	M	M	P	M	M	P
				1	T	T	M	M	M	P
	1	x	x	x	T	T	T	T	T	M

a. Or the PSTATE.A mask in an Exception level that is using AArch64.

b. SCR_EL3 only, this control is not present when EL3 is using AArch32. When the value of RW is 1, the next lower Exception level is using AArch64.

c. When the value of HCR.TGE is 1, the effective value of this bit is 1.

d. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.

G1.12 AArch32 state exception descriptions

Handling exceptions that are taken to an Exception level using AArch32 on page G1-3396 gives general information about exception handling. This section describes each of the exceptions, in the following subsections:

- *Undefined Instruction exception*.
- *Hyp Trap exception* on page G1-3430.
- *Monitor Trap exception* on page G1-3432.
- *Supervisor Call (SVC) exception* on page G1-3433.
- *Secure Monitor Call (SMC) exception* on page G1-3435.
- *Hypervisor Call (HVC) exception* on page G1-3436.
- *Prefetch Abort exception* on page G1-3437.
- *Data Abort exception* on page G1-3439.
- *Virtual Abort exception* on page G1-3443.
- *IRQ exception* on page G1-3444.
- *Virtual IRQ exception* on page G1-3447.
- *FIQ exception* on page G1-3449.
- *Virtual FIQ exception* on page G1-3451.

Additional pseudocode functions for exception handling on page G1-3452 gives additional pseudocode that is used in the pseudocode descriptions of a number of the exceptions.

G1.12.1 Undefined Instruction exception

An Undefined Instruction exception might be caused by:

- A coprocessor instruction that is not accessible because of the settings in one or more of the CPACR, NSACR, HCPTR, and DBGDSCRext.
- A coprocessor instruction that is not implemented.
- A coprocessor instruction that causes an exception during execution, for example a trapped floating-point exception on a floating-point instruction, see *Floating-point exceptions* on page E1-2220.
- An instruction that is UNDEFINED.
- An attempt to execute an instruction in an unimplemented instruction set state, see *Exception return to an unimplemented instruction set state* on page G1-3415.
- Division by zero in an `SDIV` or `UDIV` instruction.

By default, an Undefined Instruction exception is taken to Undefined mode, but an Undefined Instruction exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see *The PE mode to which the Undefined Instruction exception is taken* on page G1-3429.

The Undefined Instruction exception can provide:

- Signaling of an illegal instruction execution.
- *Lazy context switching* of coprocessor registers.

The preferred return address for an Undefined Instruction exception is the address of the instruction that generated the exception. This return is performed as follows:

- If returning from Secure or Non-secure Undefined mode, the exception return uses the SPSR and LR_und values generated by the exception entry, as follows:
  - If SPSR.{J, T} are both 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
  - If SPSR.T is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.
- If returning from Hyp mode, the exception return is performed by an `ERET` instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see *Exception return to an Exception level using AArch32* on page G1-3412.

Note

If handling the Undefined Instruction exception requires instruction emulation, followed by return to the next instruction after the instruction that caused the exception, the instruction emulator must use the instruction length to calculate the correct return address, and to calculate the updated values of the IT bits if necessary.

The PE mode to which the Undefined Instruction exception is taken

Figure G1-4 shows how the implementation, state, and configuration options determine the PE mode to which an Undefined Instruction exception is taken.

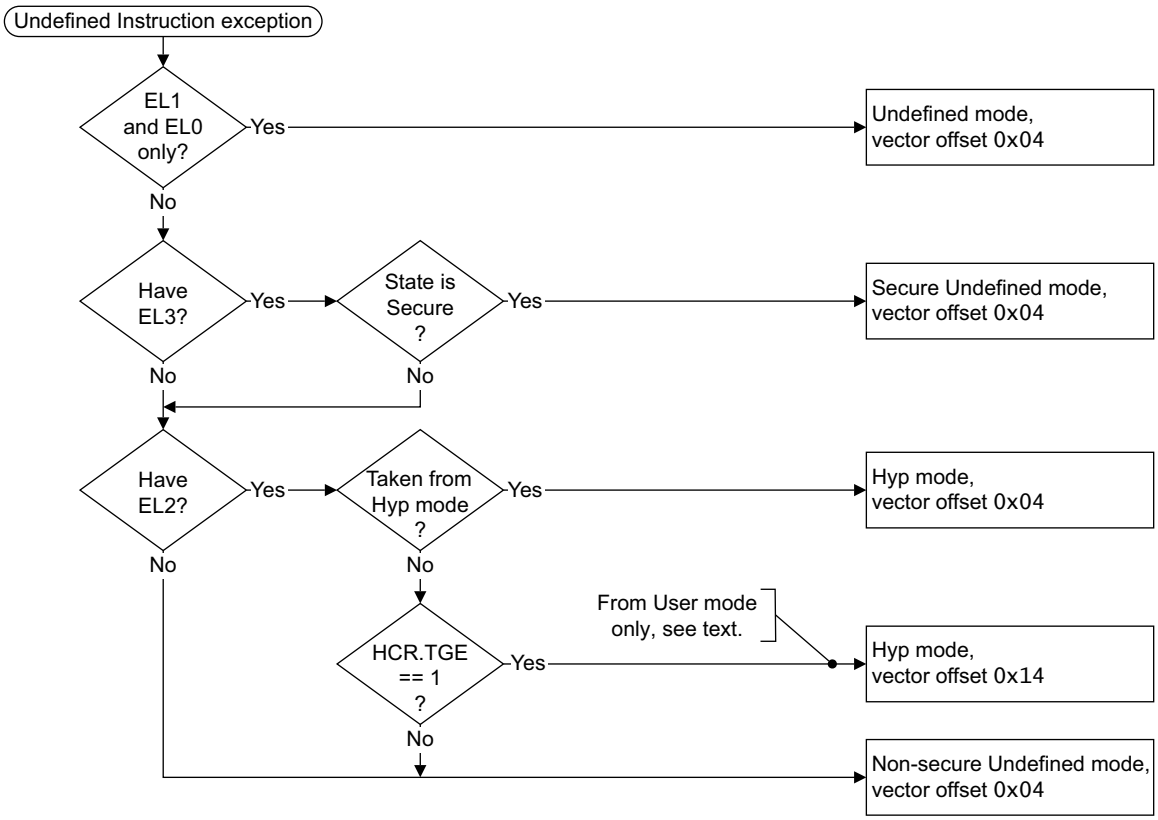

Figure G1-4 The PE mode the Undefined Instruction exception is taken to

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-3408.

Pseudocode description of taking the Undefined Instruction exception

The `TakeUndefInstrException()` pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeUndefInstrException()
// =================================

AArch32.TakeUndefInstrException()

    route_to_hyp = HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} && HCR.TGE == '1';

    bits(32) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x04;
    lr_offset = if CurrentInstrSet() == InstrSet_A32 then 4 else 2;
```

```
if PSTATE.EL == EL2 || route_to_hyp then
    exception = ExceptionSyndrome(Exception_Uncategorized);
    if PSTATE.EL == EL2 then
        AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
    else
        AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
else
    AArch32.EnterMode(M32_Undef, preferred_exception_return, lr_offset, vect_offset);
```

Additional pseudocode functions for exception handling on page G1-3452 defines the `EnterHypMode()` pseudocode procedure.

Conditional execution of undefined instructions

The conditional execution rules described in *Conditional execution* on page F2-2331 apply to all instructions. This includes undefined instructions and other instructions that would cause entry to the Undefined Instruction exception.

If such an instruction fails its condition check, the behavior depends on the architecture profile and the potential cause of entry to the Undefined Instruction exception, as follows:

- If the potential cause is the execution of the instruction itself and depends on data values used by the instruction, the instruction executes as a `NOP` and does not cause an Undefined Instruction exception.
- If the potential cause is the execution of an earlier coprocessor instruction, or the execution of the instruction itself without dependence on the data values used by the instruction, it is IMPLEMENTATION DEFINED whether the instruction executes as a `NOP` or causes an Undefined Instruction exception.

  An implementation must handle all such cases in the same way.

Note

Before ARMv7, all implementations executed any instruction that failed its condition check as a `NOP`, even if it would otherwise have caused an Undefined Instruction exception. An Undefined Instruction handler written for these implementations might assume without checking that the undefined instruction passed its condition check. Such an Undefined Instruction handler is likely to need rewriting, to check the condition is passed, before it functions correctly on all AArch32 implementations.

Interaction of UNPREDICTABLE and UNDEFINED instruction behavior

If this manual describes an instruction as both UNPREDICTABLE and UNDEFINED then the instruction is UNPREDICTABLE.

Note

An example of this is where both:

- An instruction, or instruction class, is made UNDEFINED by some general principle, or by a configuration field.
- A particular encoding of that instruction or instruction class is specified as UNPREDICTABLE.

G1.12.2 Hyp Trap exception

The Hyp Trap exception is implemented only as part of EL2 and can be generated only if EL2 is using AArch32.

A Hyp Trap exception is generated if the PE is running in a Non-secure mode other than Hyp mode, and commits for execution an instruction that is trapped to Hyp mode. Instruction traps are enabled by setting bits to 1 in the HCR, HCPTR, HDCR, or HSTR. For more information see *EL2 configurable instruction enables, disables, and traps* on page G1-3482.

A Hyp Trap exception is taken to Hyp mode.

The preferred return address for a Hyp Trap exception is the address of the trapped instruction. The exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

Note

The SPSR and ELR_hyp values generated on exception entry can be used, without modification, for an exception return to re-execute the trapped instruction. If the exception handler emulates the trapped instruction, and must return to the following instruction, the emulation of the instruction must include modifying ELR_hyp, and possibly updating SPSR_hyp.

General information about traps to the hypervisor

The Hyp Trap exception provides the standard mechanism for trapping Guest OS functions to the hypervisor. When EL2 is using AArch32, the PE always takes a Hyp Trap exception to Hyp mode, and enters the exception handler using the vector at offset 0x14 from the Hyp vector base address. For more information see *Handling exceptions that are taken to an Exception level using AArch32* on page G1-3396.

When the PE enters the handler for a Hyp Trap exception, the HSR holds syndrome information for the exception. For more information see *Use of the HSR* on page G4-3728.

A Hyp Trap exception can be generated only when all of the following apply:

- The PE is in a Non-secure EL1 or EL0 mode.
- The trapped instruction is not UNPREDICTABLE in the mode in which it is executed. UNPREDICTABLE instructions can generate a Hyp Trap exception, but the architecture does not require them to do so, see UNPREDICTABLE.
- The trapped instruction is not UNDEFINED in the mode in which it is executed, except for the following cases in which an UNDEFINED instruction might cause a Hyp Trap exception:
  - A trapped conditional UNDEFINED instruction that, if it was not trapped, would generate an Undefined Instruction exception, see *Hyp traps on instructions that fail their condition code check* on page G1-3483.
  - A EL0 mode access to IMPLEMENTATION DEFINED CP15 features in primary CP15 register c9-c11, see *Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations* on page G1-3490.
  - A EL0 mode access to an IMPLEMENTATION DEFINED CP15 register for which there is a generic Hyp trap, see *General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to CP15 System registers* on page G1-3497.
  - When HCR.TGE is set to 1, any instruction executed in Non-secure User mode that generates an Undefined Instruction exception, see *Undefined Instruction exception, when HCR.TGE is set to 1* on page G1-3410.

Note

- These rules mean that, for traps on system control register accesses, unless the specific trap description states otherwise:
  - If the register description in this manual describes the register as not being accessible from User mode in Non-secure state, the implementation of EL2 does not change this behavior. User mode accesses to the register cannot be trapped.
  - If the register description in this manual describes the register as being accessible from User mode in Non-secure state, when accesses to the register are trapped to Hyp mode the trap applies to accesses from both Non-secure EL1 modes and from the Non-secure EL0 mode.
- Traps to Hyp mode never apply in Secure state, regardless of the value of the SCR.NS bit.
- Although a Hyp Trap exception cannot be generated when the PE is in Hyp mode, the HCPTR restricts coprocessor accesses in Hyp mode, as well as in the Non-secure EL1 modes. If the HCPTR settings generate an exception when the PE is in Hyp mode, that exception is taken using the Hyp mode Undefined Instruction vector, not the Hyp Trap vector.

- EL0 mode is a synonym for User mode.

Many instructions that can be trapped by a Hyp trap are UNDEFINED in User mode. For these instructions, enabling a Hyp trap on the instruction has no effect on operation in Non-secure User mode. A small number of traps also apply to operations in Non-secure User mode. This means they trap operations at EL0 and at EL1.

The PE mode to which the Hyp Trap exception is taken

The Hyp Trap exception is supported only as part of EL2, and only when EL2 is using AArch32. A Hyp Trap exception is taken to Hyp mode, using a vector offset of `0x14` from the Hyp exception base address.

Pseudocode description of taking the Hyp Trap exception

The `TakeHypTrapException()` pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeHypTrapException()
// ==============================
// Exceptions routed to Hyp mode as a Hyp Trap exception.

AArch32.TakeHypTrapException(ExceptionRecord exception)
    assert HaveEL(EL2) && !IsSecure() && ELUsingAArch32(EL2);

    bits(32) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x14;

    AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
```

Additional pseudocode functions for exception handling on page G1-3452 defines the `EnterHypMode()` pseudocode procedure.

G1.12.3 Monitor Trap exception

The Monitor Trap exception is implemented only as part of EL3, and can be generated only if EL3 is using AArch32.

A Monitor Trap exception is generated if the PE is running in a mode other than Monitor mode, and commits for execution a `WFI` or `WFE` instruction that would otherwise cause suspension of execution when:

- In the case of the `WFI` instruction, the value of the SCR.TWI bit is 1.
- In the case of the `WFE` instruction, the value of the SCR.TWE bit is 1.

A Monitor Trap exception is taken to Monitor mode.

The preferred return address for a Monitor Trap exception is the address of the instruction that generated the exception. The exception return uses the SPSR and LR_mon values generated by the exception entry, as follows:

- If SPSR.{J, T} are both 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
- If SPSR.T is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.

For more information, see *Exception return to an Exception level using AArch32* on page G1-3412.

The PE mode to which the Monitor Trap exception is taken

The Monitor Trap exception is supported only as part of EL3. When EL3 is using AArch32, a Monitor Trap exception is taken to Monitor mode, using a vector offset of `0x04` from the Monitor exception base address.

Pseudocode description of taking the Monitor Trap exception

The `TakeMonitorTrapException()` pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeMonitorTrapException()
// ==================================
// Exceptions routed to Monitor mode as a Monitor Trap exception.

AArch32.TakeMonitorTrapException()
    assert HaveEL(EL3) && ELUsingAArch32(EL3);

    bits(32) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x04;
    lr_offset = if CurrentInstrSet() == InstrSet_A32 then 4 else 2;

    AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);
```

Additional pseudocode functions for exception handling on page G1-3452 defines the `EnterMonitorMode()` pseudocode procedure.

G1.12.4 Supervisor Call (SVC) exception

The Supervisor Call instruction, `SVC`, requests a supervisor function, typically to request an operating system function. When EL1 is using AArch32, executing an `SVC` instruction causes the PE to enter Supervisor mode. For more information, see *SVC* on page F7-2891.

Note

In an implementation that includes EL2:

- When an `SVC` instruction is executed in Hyp mode, the Supervisor Call exception is taken to Hyp mode. For more information see *SVC* on page F7-2891.
- When the HCR.TGE bit is set to 1, the Supervisor Call exception generated by execution of an `SVC` instruction in Non-secure User mode is routed to Hyp mode. For more information, see *Supervisor Call exception, when HCR.TGE is set to 1* on page G1-3410.

By default, a Supervisor Call exception is taken to Supervisor mode, but a Supervisor Call exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see *The PE mode to which the Supervisor Call exception is taken*.

The preferred return address for a Supervisor Call exception is the address of the next instruction after the `SVC` instruction. This return is performed as follows:

- If returning from Secure or Non-secure Supervisor mode, the exception return uses the SPSR and LR_svc values generated by the exception entry, in an exception return instruction without subtraction.
- If returning from Hyp mode, the exception return is performed by an `ERET` instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see *Exception return to an Exception level using AArch32* on page G1-3412.

The PE mode to which the Supervisor Call exception is taken

Figure G1-5 on page G1-3434 shows how the implementation, state, and configuration options determine the PE mode to which a Supervisor Call exception is taken.

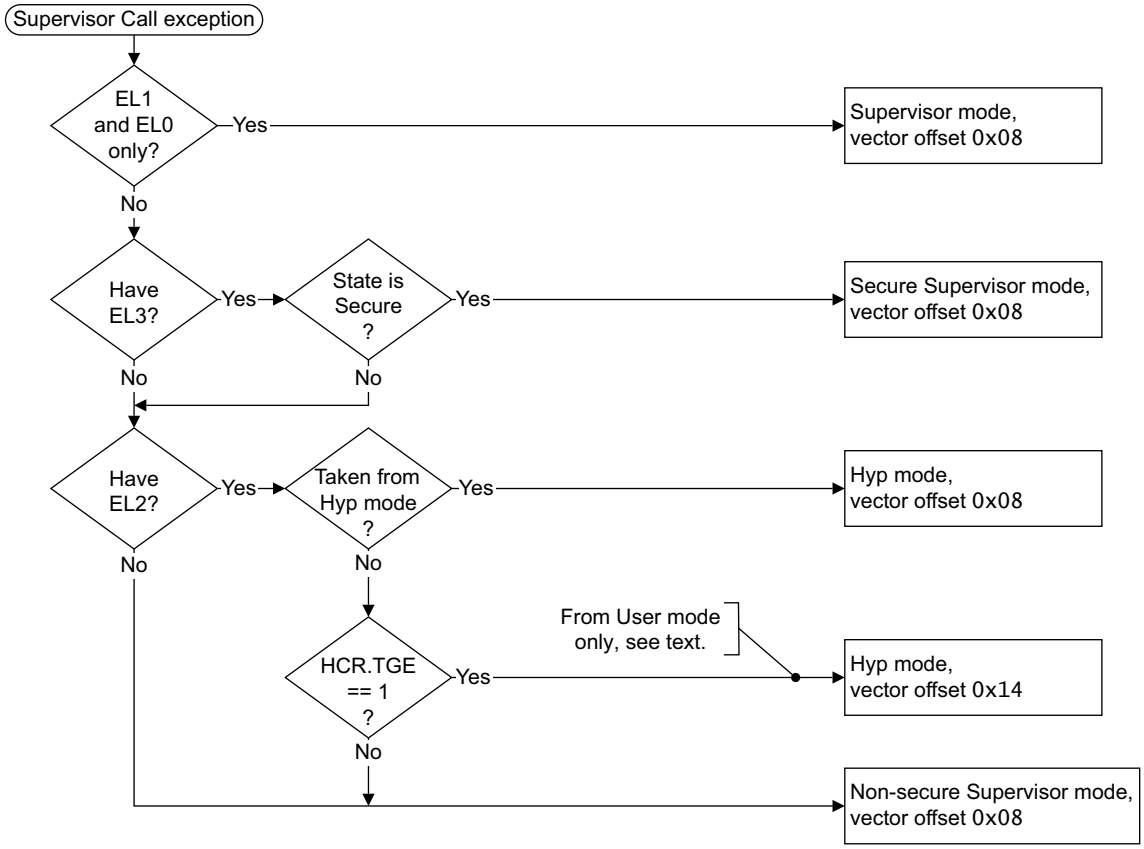

Figure G1-5 The PE mode the Supervisor Call exception is taken to

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-3408.

Pseudocode description of taking the Supervisor Call exception

The `TakeSVCException()` pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeSVCException()
// ==========================

AArch32.TakeSVCException(bits(16) immediate)

    AArch32.ITAdvance();
    SSAdvance();

    route_to_hyp = HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} && HCR.TGE == '1';

    bits(32) preferred_exception_return = NextInstrAddr();
    vect_offset = 0x08;
    lr_offset = 0;

    if PSTATE.EL == EL2 || route_to_hyp then
        exception = ExceptionSyndrome(Exception_SupervisorCall);
        exception.syndrome<15:0> = immediate;
        if PSTATE.EL == EL2 then
            AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
        else
            AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
    else
        AArch32.EnterMode(M32_Svc, preferred_exception_return, lr_offset, vect_offset);
```

Additional pseudocode functions for exception handling on page G1-3452 defines the `EnterHypMode()` pseudocode procedure.

G1.12.5 Secure Monitor Call (SMC) exception

The Secure Monitor Call exception is implemented only as part of EL3. When EL3 is using AArch32, the exception is taken to Monitor mode.

The Secure Monitor Call instruction, `SMC`, requests a Secure Monitor function. When EL3 is using AArch32, executing an `SMC` instruction causes the PE to enter Monitor mode. For more information, see *SMC* on page F7-3022.

Note

In an implementation that includes EL2, execution of an `SMC` instruction in a Non-secure EL1 mode can be trapped to EL2. When EL2 is using AArch32, this means that when the value of the HCR.TSC bit is 1, execution of an `SMC` instruction in a Non-secure EL1 mode generates a Hyp Trap Exception that is taken to Hyp mode. For more information see *Traps to Hyp mode of Non-secure EL1 execution of SMC instructions* on page G1-3491.

The preferred return address for a Secure Monitor Call exception is the address of the next instruction after the `SMC` instruction. This return is performed using the SPSR and LR_mon values generated by the exception entry, using an exception return instruction without a subtraction.

For more information, see *Exception return to an Exception level using AArch32* on page G1-3412.

Note

The exception handler can return to the `SMC` instruction itself by returning using a subtraction of 4, without any adjustment to the SPSR.IT[7:0] bits. If it does this, the return occurs, then interrupts or external aborts might occur and be handled, then the `SMC` instruction is re-executed and another Secure Monitor Call exception occurs.

This relies on:

- The `SMC` instruction being used correctly, either outside an IT block or as the last instruction in an IT block, so that the SPSR.IT[7:0] bits indicate unconditional execution.
- The Secure Monitor Call handler not changing the result of the original conditional execution test for the `SMC` instruction.

The PE mode to which the Secure Monitor Call exception is taken

The Secure Monitor Call exception is supported only as part of EL3. When EL3 is using AArch32, a Secure Monitor Call exception is taken to Monitor mode, using vector offset `0x08` from the Monitor exception base address.

Note

- An `SMC` instruction that is trapped to Hyp mode because HCR.TSC is set to 1 generates a Hyp Trap exception, see *The PE mode to which the Hyp Trap exception is taken* on page G1-3432.
- If EL3 is using AArch64 then *Security behavior in Exception levels using AArch32 when EL3 is using AArch64* on page G1-3406 describes the effect of executing an `SMC` instruction in a mode that is part of an Exception level that is using EL1.

Pseudocode description of taking the Secure Monitor Call exception

The `TakeSMCException()` pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeSMCException()
// ==========================

AArch32.TakeSMCException()
    assert HaveEL(EL3) && ELUsingAArch32(EL3);
```

```
    AArch32.ITAdvance();
    SSAdvance();

    bits(32) preferred_exception_return = NextInstrAddr();
    vect_offset = 0x08;
    lr_offset = 0;

    AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);
```

Additional pseudocode functions for exception handling on page G1-3452 defines the EnterMonitorMode() pseudocode procedure.

G1.12.6 Hypervisor Call (HVC) exception

The Hypervisor Call exception is implemented only as part of EL2.

The Hypervisor Call instruction, HVC, requests a hypervisor function. When EL2 is using AArch32, executing an HVC instruction generates a Hypervisor Call exception that is taken to Hyp mode. For more information, see *HVC* on page F7-3004.

The preferred return address for a Hypervisor Call exception is the address of the next instruction after the HVC instruction. The exception return is performed by an ERET instruction, using the SPSR and ELR_hyp values generated by the exception entry.

For more information, see *Exception return to an Exception level using AArch32* on page G1-3412.

When EL2 is using AArch32, executing an HVC instruction transfers the immediate argument of the instruction to the HSR. The exception handler retrieves the argument from the HSR, and therefore does not have to access the original HVC instruction. For more information see *Use of the HSR* on page G4-3728.

The PE mode to which the Hypervisor Call exception is taken

The Hypervisor Call exception is supported only as part of EL2. When EL2 is using AArch32, a Hypervisor Call exception is taken to Hyp mode, using a vector offset that depends on the mode from which the exception is taken, as Figure G1-6 shows. This offset is from the Hyp exception base address.

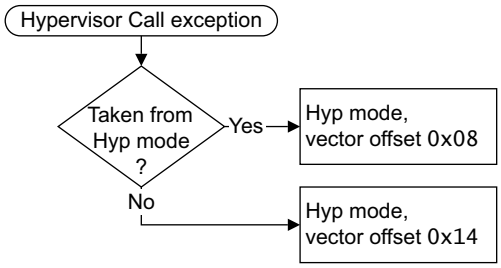

Figure G1-6 The PE mode the Hypervisor Call exception is taken to

Pseudocode description of taking the Hypervisor Call exception

The TakeHVCException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeHVCException()
// ==========================

AArch32.TakeHVCException(bits(16) immediate)
    assert HaveEL(EL2) && ELUsingAArch32(EL2);

    AArch32.ITAdvance();
    SSAdvance();

    bits(32) preferred_exception_return = NextInstrAddr();
    vect_offset = 0x08;
```

```
exception = ExceptionSyndrome(Exception_HypervisorCall);
exception.syndrome<15:0> = immediate;

if PSTATE.EL == EL2 then
    AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
else
    AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
```

Additional pseudocode functions for exception handling on page G1-3452 defines the `EnterHypMode()` pseudocode procedure.

G1.12.7 Prefetch Abort exception

A Prefetch Abort exception can be generated by:

- A synchronous memory abort on an instruction fetch.

  Note

  Asynchronous aborts on instruction fetches are reported using the Data Abort exception, see *Data Abort exception* on page G1-3439.

  A Prefetch Abort exception entry is synchronous to the instruction whose fetch aborted.

  For more information about memory aborts see *VMSAv8-32 memory aborts* on page G4-3703.

- A Breakpoint, Vector Catch or Software Breakpoint Instruction exception, see Chapter G2 *AArch32 Self-hosted Debug*.

Note

If an implementation fetches instructions speculatively, it must handle a synchronous abort on such an instruction fetch by:

- Generating a Prefetch Abort exception only if the instruction would be executed in a simple sequential execution of the program.
- Ignoring the abort if the instruction would not be executed in a simple sequential execution of the program.

By default, when EL1 is using AArch32, a Prefetch Abort exception is taken to Abort mode, but a Prefetch Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information, see *The PE mode to which the Prefetch Abort exception is taken*.

The preferred return address for a Prefetch Abort exception is the address of the aborted instruction. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - SPSR_abt and LR_abt if returning from Abort mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.
- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an `ERET` instruction.

For more information, see *Exception return to an Exception level using AArch32* on page G1-3412.

The PE mode to which the Prefetch Abort exception is taken

Figure G1-7 on page G1-3438 shows how the implementation, state, and configuration options determine the PE mode to which a Prefetch Abort exception is taken.

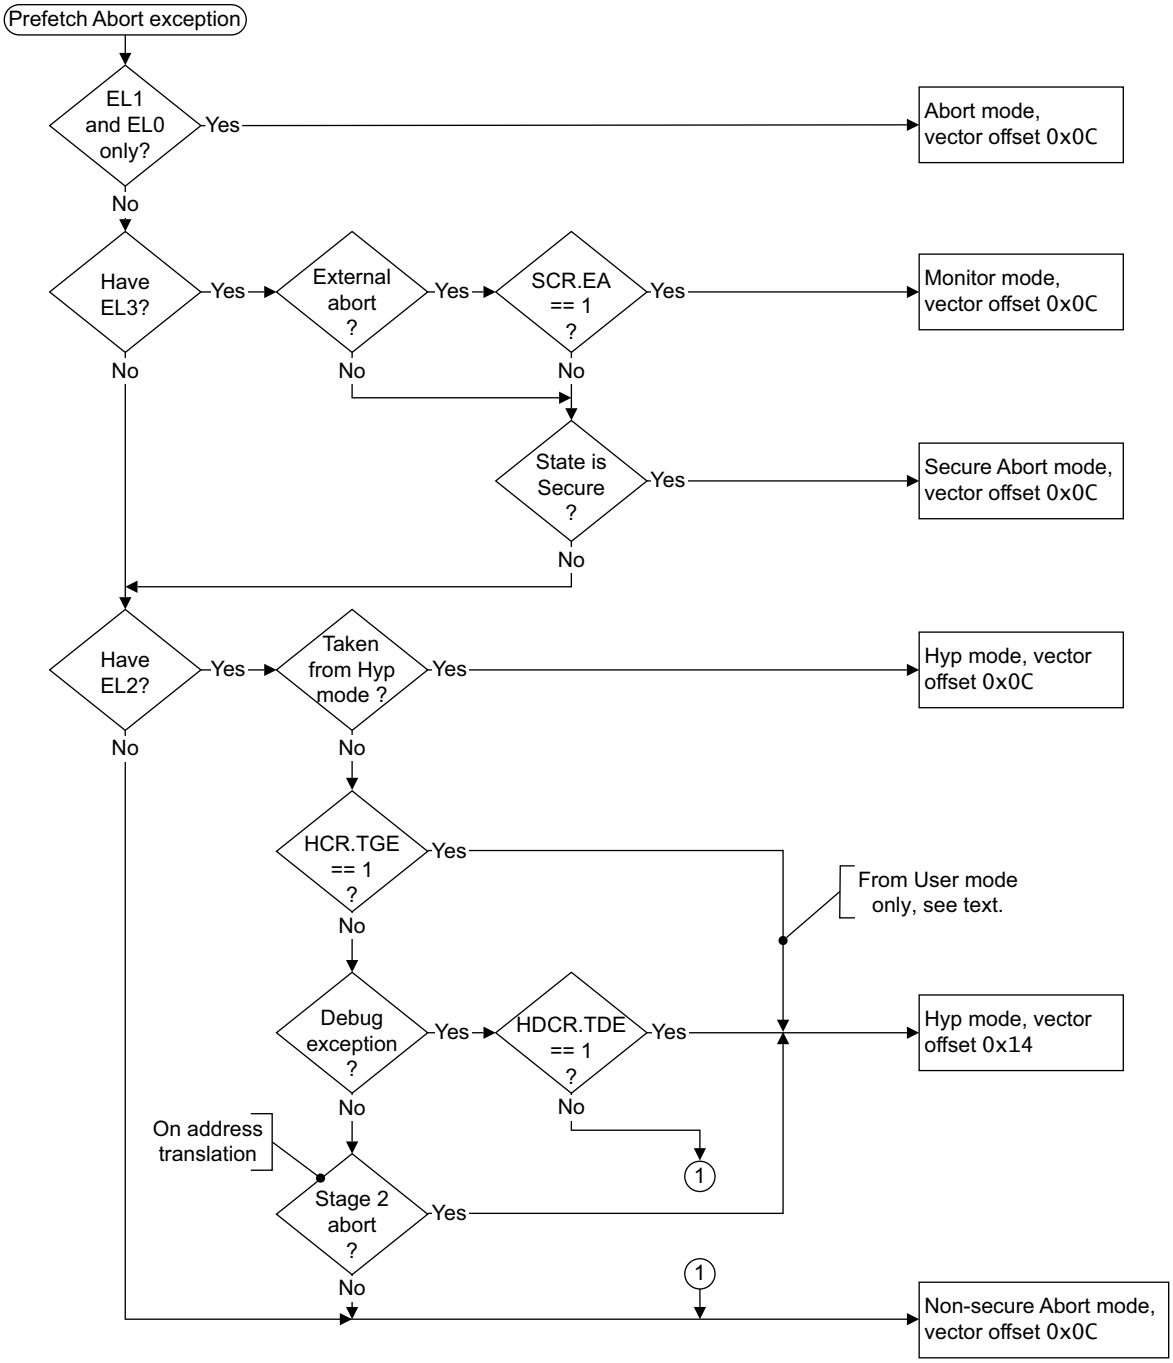

Figure G1-7 The PE mode the Prefetch Abort exception is taken to

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-3408.

Pseudocode description of taking the Prefetch Abort exception

The `TakePrefetchAbortException()` pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakePrefetchAbortException()
// ====================================

AArch32.TakePrefetchAbortException(bits(32) vaddress, FaultRecord fault)
```

```
route_to_monitor = HaveEL(EL3) && SCR.EA == '1' && IsExternalAbort(fault);
route_to_hyp = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                (HCR.TGE == '1' || IsSecondStage(fault) ||
                 (IsDebugException(fault) && HDCR.TDE == '1')));

bits(32) preferred_exception_return = ThisInstrAddr();
vect_offset = 0x0C;
lr_offset = 4;

secure = route_to_monitor || IsSecure();

if IsDebugException(fault) then DBGDSCRext.MOE = fault.debugmoe;

if route_to_monitor then
    AArch32.ReportPrefetchAbort(secure, fault, vaddress);
    AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);
elsif PSTATE.EL == EL2 || route_to_hyp then
    if fault.type == Fault_Alignment then             // PC Alignment fault
        exception = ExceptionSyndrome(Exception_PCAlignment);
    else
        exception = AArch32.AbortSyndrome(Exception_InstructionAbort, fault, vaddress);
    if PSTATE.EL == EL2 then
        AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
    else
        AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
else
    AArch32.ReportPrefetchAbort(secure, fault, vaddress);
    AArch32.EnterMode(M32_Abort, preferred_exception_return, lr_offset, vect_offset);
```

Additional pseudocode functions for exception handling on page G1-3452 defines the `EnterMonitorMode()` and `EnterHypMode()` pseudocode procedures.

G1.12.8 Data Abort exception

A Data Abort exception can be generated by:

- A synchronous abort on a data read or write memory access. Exception entry is synchronous to the instruction that generated the memory access.
- An asynchronous abort. The memory access that caused the abort can be any of:
  - A data read or write access.
  - An instruction fetch.
  - In a VMSA memory system, a translation table access.

  Exception entry occurs asynchronously, and is similar to an interrupt.

  As described in *Asynchronous exception masking controls* on page G1-3421, asynchronous aborts can be masked. When this happens, a generated asynchronous abort is not taken until it is not masked.

  Note

  There are no asynchronous internal aborts in the ARM architecture, so asynchronous aborts are always asynchronous external aborts.
- A watchpoint, see *Watchpoint exceptions* on page G2-3550.

By default, when EL1 is using AArch32 a Data Abort exception is taken to Abort mode, but a Data Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information see *The PE mode to which the Data Abort exception is taken* on page G1-3441.

For more information about memory aborts see *VMSAv8-32 memory aborts* on page G4-3703.

The preferred return address for a Data Abort exception is the address of the instruction that generated the aborting memory access, or the address of the instruction following the instruction boundary at which an asynchronous Data Abort exception was taken. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 8. This means using:
  - SPSR_abt and LR_abt if returning from Abort mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.
- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an `ERET` instruction.

For more information, see *Exception return to an Exception level using AArch32* on page G1-3412.

The PE mode to which the Data Abort exception is taken

Figure G1-8 shows the determination of the mode to which a Data Abort exception is taken.

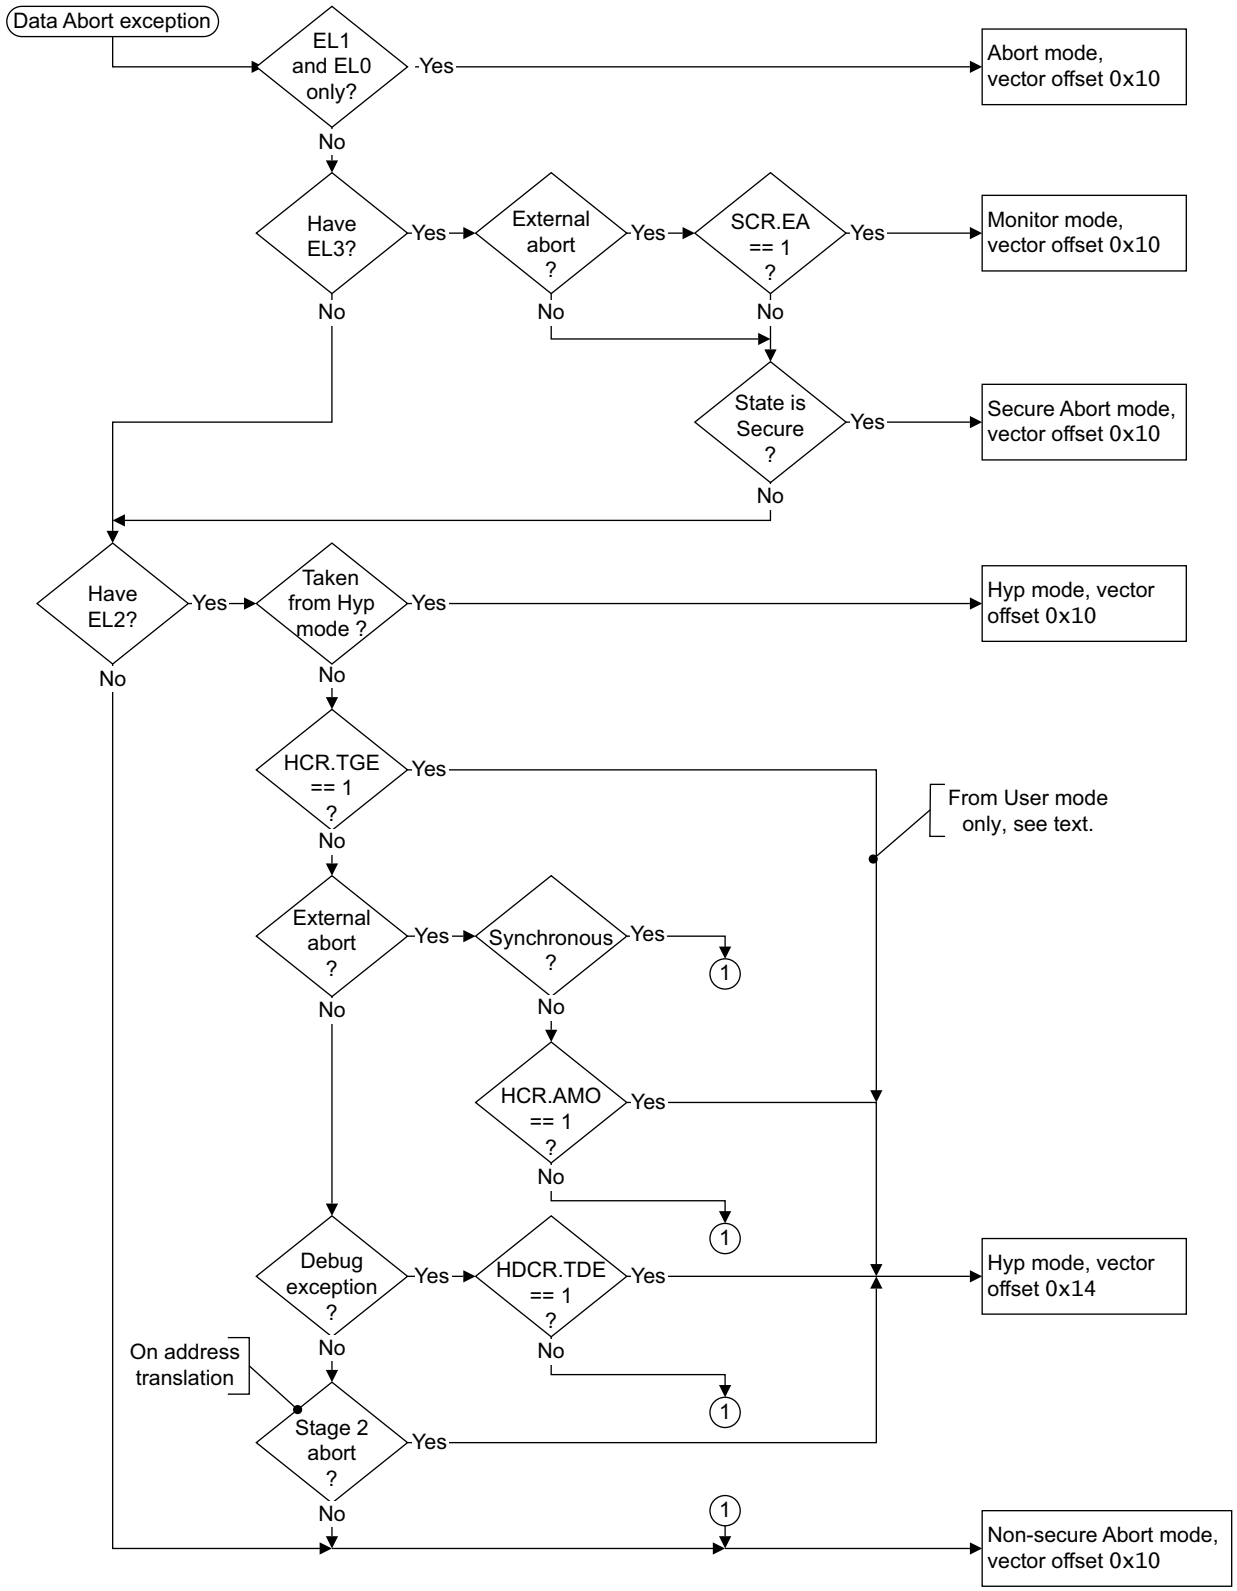

Figure G1-8 The PE mode the Data Abort exception is taken to

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-3408.

Pseudocode description of taking the Data Abort exception

The TakeDataAbortException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeDataAbortException()
// ================================

AArch32.TakeDataAbortException(bits(32) vaddress, FaultRecord fault)

    route_to_monitor = HaveEL(EL3) && SCR.EA == '1' && IsExternalAbort(fault);
    route_to_hyp = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                    (HCR.TGE == '1' || IsSecondStage(fault) ||
                     (IsDebugException(fault) && HDCR.TDE == '1')));

    bits(32) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x10;
    lr_offset = 8;

    secure = route_to_monitor || IsSecure();

    if IsDebugException(fault) then DBGDSCRext.MOE = fault.debugmoe;

    if route_to_monitor then
        AArch32.ReportDataAbort(secure, fault, vaddress);
        AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);
    elsif PSTATE.EL == EL2 || route_to_hyp then
        exception = AArch32.AbortSyndrome(Exception_DataAbort, fault, vaddress);
        if PSTATE.EL == EL2 then
            AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
        else
            AArch32.EnterHypMode(exception, preferred_exception_return, 0x14);
    else
        AArch32.ReportDataAbort(secure, fault, vaddress);
        AArch32.EnterMode(M32_Abort, preferred_exception_return, lr_offset, vect_offset);
```

Additional pseudocode functions for exception handling on page G1-3452 defines the EnterMonitorMode() and EnterHypMode() pseudocode procedures.

Effects of data-aborted instructions

An instruction that accesses data memory can modify memory by storing one or more values. If the execution of such an instruction generates a Data Abort exception, or causes Debug state entry because of a watchpoint set on the instruction, the value of each memory location that the instruction stores to is:

- Unchanged for any location for which one of the following applies:
  - A stage of address translation fault is generated.
  - A Watchpoint is generated.
  - An external abort is generated, if that external abort is taken synchronously.
- UNKNOWN for any location for which no exception is generated.

If the access to a memory location generates an external abort that is taken asynchronously, it is outside the scope of the architecture to define the effect of the store on that memory location, because this depends on the system-specific nature of the external abort. However, in general, ARM recommends that such locations are unchanged.

For external aborts and Watchpoints, where in principle faulting could be identified at byte or halfword granularity, the size of a location in this definition is the size for which a memory access is single-copy atomic.

In AArch32 state, instructions that access data memory can modify registers in the following ways:

- By loading values into one or more of the general-purpose registers. The registers loaded can include the PC.
- By loading values into one or more of the registers in the Advanced SIMD and floating-point register file.

- By specifying *base register writeback*, in which the base register used in the address calculation has a modified value written to it. All instructions that support base register writeback have UNPREDICTABLE results if base register writeback is specified with the PC as the base register. Only general-purpose registers can be modified reliably in this way.
- By a direct or indirect write to one or more coprocessor registers, for example:
  - An LDC instruction is a *direct write* to a coprocessor register with a value read from memory.
  - An STC instruction that reads DBGDTRTXint makes an *indirect write* to DBGDSCRint.RXfull.
- By modifying the CPSR.

If the execution of such an instruction generates a synchronous Data Abort exception, the following rules determine the values left in these registers:

- On entry to the Data Abort exception handler:
  - The PC value is the Data Abort vector address, see *Exception vectors and the exception base address on page G1-3396*.
  - The LR_abt value is determined from the address of the aborted instruction.

  Neither value is affected by the results of any load specified by the instruction.
- The base register is restored to its original value if either:
  - The aborted instruction is a load and the list of registers to be loaded includes the base register.
  - The base register is being written back.
- If the instruction only loads one general-purpose register the value in that register is unchanged.
- If the instruction loads more than one general-purpose register, UNKNOWN values are left in destination registers other than the PC and the base register of the instruction.
- If the instruction affects any registers in the Advanced SIMD and floating-point register file, UNKNOWN values are left in the registers that are affected.
- CPSR bits that are not defined as updated on exception entry retain their current value.
- If the instruction is a STREX, STREXB, STREXH, or STREXD, <Rd> is not updated.

After taking a Data Abort exception, the state of the exclusive monitors is UNKNOWN. Therefore, ARM strongly recommends that the abort handler performs a CLREX instruction, or a dummy STREX instruction, to clear the exclusive monitor state.

The ARM abort model

The abort model used by an ARM PE is described as a *Base Restored Abort Model*. This means that if a synchronous Data Abort exception is generated by executing an instruction that specifies base register writeback, the value in the base register is unchanged.

The abort model applies uniformly across all instructions.

G1.12.9 Virtual Abort exception

The Virtual Abort exception is implemented only as part of EL2.

A Virtual Abort exception is generated if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of CPSR.A is 0.
- Either:
  - EL2 is using AArch32 and the values of the HCR.{AMO, VA} bits are {1, 1}.
  - EL2 is using AArch64 and the values of the HCR_EL2.{AMO, VA} bits are {1, 1}.

The conditions for generating a Virtual Abort exception mean the exception is always:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure Abort mode.

For more information see *Virtual exceptions when an implementation includes EL2* on page G1-3418.

Note

Because the Virtual Abort exception is always taken to Non-secure Abort mode, on exception entry the preferred return address is always saved to LR_abt.

The preferred return address for a Virtual Abort exception is the address of the instruction immediately after the instruction boundary where the exception was taken. This return is performed using the SPSR and LR_abt values generated by the exception entry, using an exception return instruction without subtraction.

The PE mode to which the Virtual Abort exception is taken

The Virtual Abort exception is supported only as part of EL2. A Virtual Abort exception is taken from a Non-secure EL1 or EL0 mode, and is taken to Non-secure Abort mode, using a vector offset of `0x10` from the Non-secure exception base address.

For more information about this exception see *Virtual exceptions when an implementation includes EL2* on page G1-3418.

Pseudocode description of taking the Virtual Asynchronous Abort exception

The `TakeVirtualAsyncAbortException()` pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeVirtualAsynchAbortException()
// =========================================

AArch32.TakeVirtualAsynchAbortException()
    assert HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1};
    if ELUsingAArch32(EL2) then   // Virtual Asynchronous Abort enabled if TGE==0 and AMO==1
        assert HCR.TGE == '0' && HCR.AMO == '1';
    else
        assert HCR_EL2.TGE == '0' && HCR_EL2.AMO == '1';

    // Check if routed to AArch64 state
    if PSTATE.EL == EL0 && !ELUsingAArch32(EL1) then AArch64.TakeVirtualSystemErrorException();

    bits(32) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x10;
    lr_offset = 8;

    vaddress = bits(32) UNKNOWN;
    secure = FALSE;
    parity = FALSE;
    extflag = bit IMPLEMENTATION_DEFINED "Virtual Asynchronous Abort ExT bit";
    fault = AArch32.AsynchExternalAbort(parity, extflag);

    if ELUsingAArch32(EL2) then HCR.VA = '0'; else HCR_EL2.VSE = '0';

    AArch32.ReportDataAbort(secure, fault, vaddress);
    AArch32.EnterMode(M32_Abort, preferred_exception_return, lr_offset, vect_offset);
```

G1.12.10 IRQ exception

The IRQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an IRQ interrupt request input to the PE.

When an IRQ exception is taken, exception entry is precise to an instruction boundary.

As described in *Asynchronous exception masking controls* on page G1-3421, IRQ exceptions can be masked. When this happens, a generated IRQ exception is not taken until it is not masked.

By default, when EL1 is using AArch32, an IRQ exception is taken to IRQ mode, but an IRQ exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information, see *The PE mode to which the physical IRQ exception is taken*.

The preferred return address for an IRQ exception is the address of the instruction following the instruction boundary at which the exception was taken. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - SPSR_irq and LR_irq if returning from IRQ mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.
- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an `ERET` instruction.

For more information, see *Exception return to an Exception level using AArch32* on page G1-3412.

The PE mode to which the physical IRQ exception is taken

Figure G1-9 on page G1-3446 shows how the implementation, state, and configuration options determine the mode to which an IRQ exception is taken.

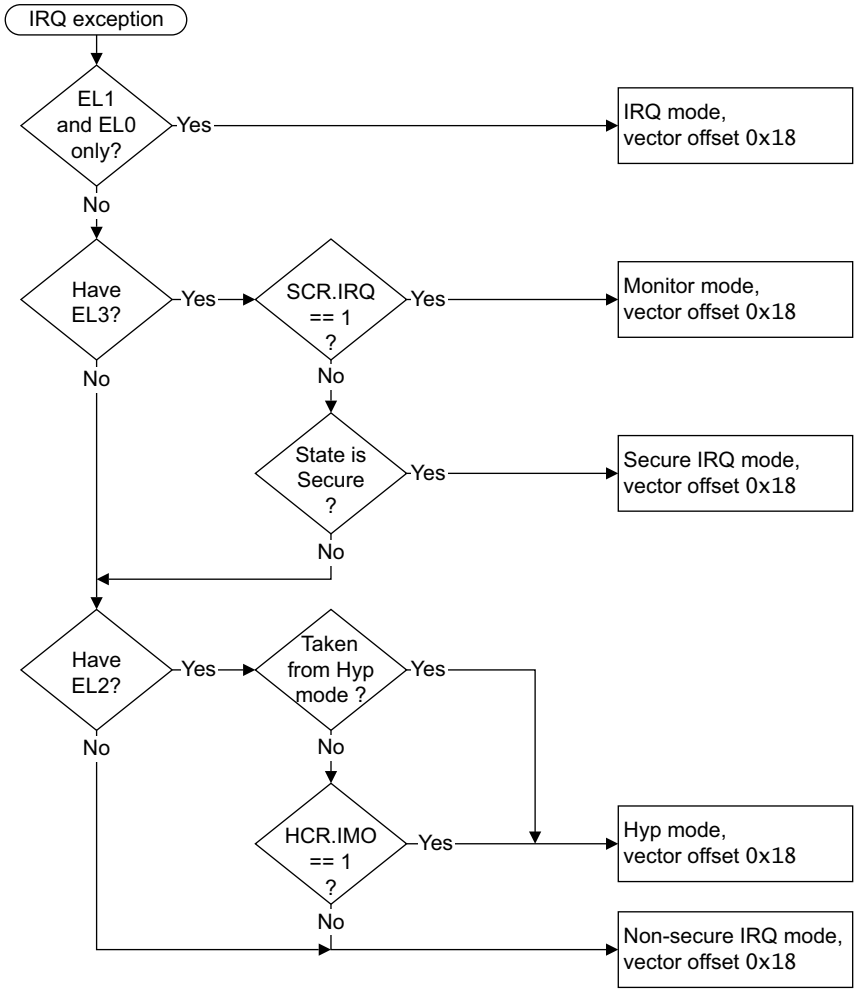

Figure G1-9 The PE mode the IRQ exception is taken to

Pseudocode description of taking the IRQ exception

The TakePhysicalIRQException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakePhysicalIRQException()
// ==================================
// Take an enabled physical IRQ exception.

AArch32.TakePhysicalIRQException()

    // Check if routed to AArch64 state
    route_to_aarch64 = PSTATE.EL == EL0 && !ELUsingAArch32(EL1);

    if !route_to_aarch64 && HaveEL(EL2) && !IsSecure() && !ELUsingAArch32(EL2) then
        route_to_aarch64 = HCR_EL2.TGE == '1' || HCR_EL2.IMO == '1';

    if !route_to_aarch64 && HaveEL(EL3) && !ELUsingAArch32(EL3) then
        route_to_aarch64 = SCR_EL3.IRQ == '1';

    if route_to_aarch64 then AArch64.TakePhysicalIRQException();

    route_to_monitor = HaveEL(EL3) && SCR.IRQ == '1';
    route_to_hyp = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                    (HCR.TGE == '1' || HCR.IMO == '1'));

    bits(32) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x18;
    lr_offset = 4;

    if route_to_monitor then
        AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);
    elsif PSTATE.EL == EL2 || route_to_hyp then
        exception = ExceptionSyndrome(Exception_IRQ);
        AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
    else
        AArch32.EnterMode(M32_IRQ, preferred_exception_return, lr_offset, vect_offset);
```

Additional pseudocode functions for exception handling on page G1-3452 defines the EnterMonitorMode() and EnterHypMode() pseudocode procedures.

G1.12.11 Virtual IRQ exception

The Virtual IRQ exception is implemented only as part of EL2.

A Virtual IRQ exception is generated if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of CPSR.I is 0.
- Either:
  - EL2 is using AArch32 and the value of HCR.IMO is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.IMO is 1.
- One of the following applies:
  - EL2 is using AArch32 and the value of HCR.VI is 1.
  - EL2 is using AArch64 and the value of HCR_EL2.VI is 1.
  - A Virtual IRQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The conditions for generating a Virtual IRQ exception mean the exception is always:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure IRQ mode.

For more information see *Virtual exceptions when an implementation includes EL2* on page G1-3418

The preferred return address for a Virtual IRQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. This return is performed using the SPSR and LR_irq values generated by the exception entry, using an exception return instruction with a subtraction of 4.

The PE mode to which the Virtual IRQ exception is taken

The Virtual IRQ exception is supported only as part of EL2. A Virtual IRQ exception is taken from a Non-secure EL1 or EL0 mode, and is taken to Non-secure IRQ mode, using a vector offset of `0x18` from the Non-secure exception base address.

For more information about this exception see *Virtual exceptions when an implementation includes EL2* on page G1-3418.

Pseudocode description of taking the Virtual IRQ exception

The TakeVirtualIRQException() pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeVirtualIRQException()
// =================================

AArch32.TakeVirtualIRQException()
    assert HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1};
    if ELUsingAArch32(EL2) then   // Virtual IRQs enabled if TGE==0 and IMO==1
        assert HCR.TGE == '0' && HCR.IMO == '1';
    else
        assert HCR_EL2.TGE == '0' && HCR_EL2.IMO == '1';

    // Check if routed to AArch64 state
    if PSTATE.EL == EL0 && !ELUsingAArch32(EL1) then AArch64.TakeVirtualIRQException();

    bits(32) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x18;
    lr_offset = 4;

    AArch32.EnterMode(M32_IRQ, preferred_exception_return, lr_offset, vect_offset);
```

G1.12.12 FIQ exception

The FIQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an FIQ interrupt request input to the PE.

When an FIQ exception is taken, exception entry is precise to an instruction boundary.

As described in *Asynchronous exception masking controls* on page G1-3421, FIQ exceptions can be masked. When this happens, a generated FIQ exception is not taken until it is not masked.

By default, an FIQ exception is taken to FIQ mode, but an FIQ exception can be taken:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information, see *The PE mode to which the physical FIQ exception is taken* on page G1-3450.

The preferred return address for an FIQ exception is the address of the instruction following the instruction boundary at which the exception was taken. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the SPSR and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
  - SPSR_fiq and LR_fiq if returning from FIQ mode.
  - SPSR_mon and LR_mon if returning from Monitor mode.
- If returning from Hyp mode, using the SPSR_hyp and ELR_hyp values generated by the exception entry, using an ERET instruction.

For more information, see *Exception return to an Exception level using AArch32* on page G1-3412.

The PE mode to which the physical FIQ exception is taken

Figure G1-9 on page G1-3446 shows how the implementation, state, and configuration options determine the PE mode to which an FIQ exception is taken.

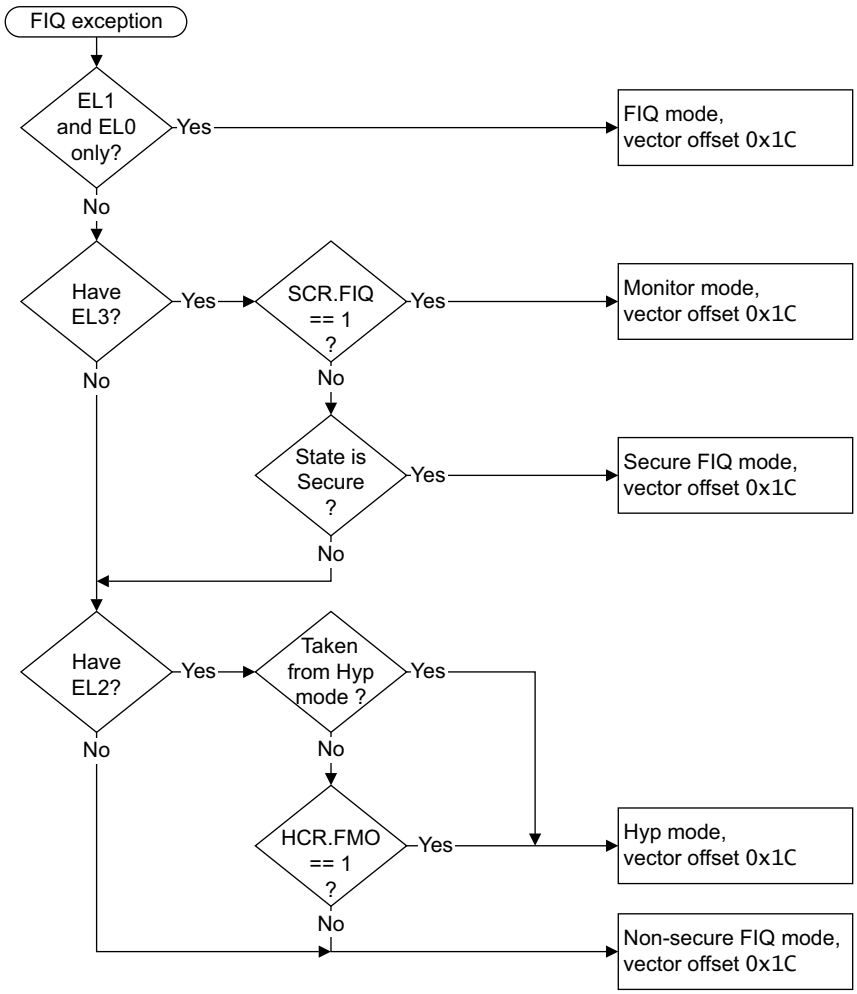

Figure G1-10 The PE mode the FIQ exception is taken to

Pseudocode description of taking the FIQ exception

The `TakePhysicalFIQException()` pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakePhysicalFIQException()
// ==================================

AArch32.TakePhysicalFIQException()

    // Check if routed to AArch64 state
    route_to_aarch64 = PSTATE.EL == EL0 && !ELUsingAArch32(EL1);

    if !route_to_aarch64 && HaveEL(EL2) && !IsSecure() && !ELUsingAArch32(EL2) then
        route_to_aarch64 = HCR_EL2.TGE == '1' || HCR_EL2.FMO == '1';

    if !route_to_aarch64 && HaveEL(EL3) && !ELUsingAArch32(EL3) then
        route_to_aarch64 = SCR_EL3.FIQ == '1';

    if route_to_aarch64 then AArch64.TakePhysicalFIQException();
```

```
route_to_monitor = HaveEL(EL3) && SCR.FIQ == '1';
route_to_hyp = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} &&
                (HCR.TGE == '1' || HCR.FMO == '1'));

bits(32) preferred_exception_return = ThisInstrAddr();
vect_offset = 0x1C;
lr_offset = 4;

if route_to_monitor then
    AArch32.EnterMonitorMode(preferred_exception_return, lr_offset, vect_offset);
elsif PSTATE.EL == EL2 || route_to_hyp then
    exception = ExceptionSyndrome(Exception_FIQ);
    AArch32.EnterHypMode(exception, preferred_exception_return, vect_offset);
else
    AArch32.EnterMode(M32_FIQ, preferred_exception_return, lr_offset, vect_offset);
```

Additional pseudocode functions for exception handling on page G1-3452 defines the `EnterMonitorMode()` and `EnterHypMode()` pseudocode procedures.

G1.12.13 Virtual FIQ exception

The Virtual FIQ exception is implemented only as part of EL2.

A Virtual FIQ exception is generated if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of CPSR.F is 0.
- Either:
  - EL2 is using AArch32, the value of HCR.FMO is 1, and the value of HCR.VF is 1, or a Virtual FIQ exception is generated by an IMPLEMENTATION DEFINED mechanism.
  - EL2 is using AArch64, the value of HCR_EL2.FMO is 1, and the value of HCR_EL2.VF is 1 or a Virtual FIQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The conditions for generating a Virtual FIQ exception mean the exception is always:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure FIQ mode.

For more information see *Virtual exceptions when an implementation includes EL2* on page G1-3418.

The preferred return address for a Virtual FIQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. This return is performed using the SPSR and LR_irq values generated by the exception entry, using an exception return instruction with a subtraction of 4.

The PE mode to which the Virtual FIQ exception is taken

The Virtual FIQ exception is supported only as part of EL2. A Virtual FIQ exception is taken from a Non-secure EL1 or EL0 mode, and is taken to Non-secure FIQ mode, using a vector offset of `0x1C` from the Non-secure exception base address.

For more information about this exception see *Virtual exceptions when an implementation includes EL2* on page G1-3418.

Pseudocode description of taking the Virtual FIQ exception

The `TakeVirtualFIQException()` pseudocode procedure describes how the PE takes the exception:

```
// AArch32.TakeVirtualFIQException()
// =================================

AArch32.TakeVirtualFIQException()
    assert HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1};
    if ELUsingAArch32(EL2) then  // Virtual IRQ enabled if TGE==0 and FMO==1
        assert HCR.TGE == '0' && HCR.FMO == '1';
    else
```

```
        assert HCR_EL2.TGE == '0' && HCR_EL2.FMO == '1';

    // Check if routed to AArch64 state
    if PSTATE.EL == EL0 && !ELUsingAArch32(EL1) then AArch64.TakeVirtualFIQException();

    bits(32) preferred_exception_return = ThisInstrAddr();
    vect_offset = 0x1C;
    lr_offset = 4;

    AArch32.EnterMode(M32_FIQ, preferred_exception_return, lr_offset, vect_offset);
```

G1.12.14 Additional pseudocode functions for exception handling

The `EnterMonitorMode()` pseudocode function changes the PE mode to Monitor mode, with the required state changes:

```
// AArch32.EnterMonitorMode()
// ==========================
// Take an exception to Monitor mode.

AArch32.EnterMonitorMode(bits(32) preferred_exception_return, integer lr_offset, integer vect_offset)
    assert HaveEL(EL3) && ELUsingAArch32(EL3);

    spsr = GetPSRFromPSTATE();
    if PSTATE.M == M32_Monitor then SCR.NS = '0';
    AArch32.WriteMode(M32_Monitor);
    SPSR[] = spsr;
    R[14] = preferred_exception_return + lr_offset;
    PSTATE.J = '0';  PSTATE.T = SCTLR.TE;
    PSTATE.SS = '0';
    PSTATE.<A,I,F> = '111';
    PSTATE.E = SCTLR.EE;
    PSTATE.IL = '0';
    PSTATE.IT = '00000000';
    BranchTo(MVBAR + vect_offset, BranchType_UNKNOWN);
    EndOfInstruction();
```

The `EnterHypMode()` pseudocode function changes the PE mode to Hyp mode, with the required state changes:

```
// AArch32.EnterHypMode()
// ======================
// Take an exception to Hyp mode.

AArch32.EnterHypMode(ExceptionRecord exception, bits(32) preferred_exception_return,
                     integer vect_offset)
    assert HaveEL(EL2) && !IsSecure() && ELUsingAArch32(EL2);

    spsr = GetPSRFromPSTATE();
    AArch32.WriteMode(M32_Hyp);
    if !(exception.type IN {Exception_IRQ, Exception_FIQ}) then
        AArch32.ReportHypEntry(exception);
    SPSR[] = spsr;
    R[14] = preferred_exception_return;
    PSTATE.J = '0';  PSTATE.T = HSCTLR.TE;
    PSTATE.SS = '0';
    if !HaveEL(EL3) || SCR_GEN[].EA == '0' then PSTATE.A = '1';
    if !HaveEL(EL3) || SCR_GEN[].IRQ == '0' then PSTATE.I = '1';
    if !HaveEL(EL3) || SCR_GEN[].FIQ == '0' then PSTATE.F = '1';
    PSTATE.E = HSCTLR.EE;
    PSTATE.IL = '0';
    PSTATE.IT = '00000000';
    BranchTo(HVBAR + vect_offset, BranchType_UNKNOWN);
    EndOfInstruction();
```

The `EnterMode()` pseudocode function changes the PE mode to a PL1 mode, with the required state changes. It is used for all exceptions that are not routed to Hyp mode or Monitor mode.

```
// AArch32.EnterMode()
// ===================
// Take an exception to a mode other than Monitor and Hyp mode.

AArch32.EnterMode(bits(5) target_mode, bits(32) preferred_exception_return, integer lr_offset,
                  integer vect_offset)
    assert ELUsingAArch32(EL1) && PSTATE.EL != EL2;

    spsr = GetPSRFromPSTATE();
    if PSTATE.M == M32_Monitor then SCR.NS = '0';
    AArch32.WriteMode(target_mode);
    SPSR[] = spsr;
    R[14] = preferred_exception_return + lr_offset;
    PSTATE.J = '0';  PSTATE.T = SCTLR.TE;
    if target_mode == M32_FIQ then
        PSTATE.<A,I,F> = '111';
    elsif target_mode IN {M32_Abort, M32_IRQ} then
        PSTATE.<A,I> = '11';
    else
        PSTATE.I = '1';
    PSTATE.E = SCTLR.EE;
    PSTATE.IL = '0';
    PSTATE.IT = '00000000';
    BranchTo(ExcVectorBase() + vect_offset, BranchType_UNKNOWN);
    EndOfInstruction();
```

G1.13 Reset into AArch32 state

On an ARM PE, when the Reset input is asserted the PE stops execution. When Reset is deasserted, the PE then starts executing instructions in the highest implemented Exception level. If that Exception level is using AArch32, then it starts execution:

- In Secure state, if the implementation includes EL3.
- With interrupts disabled:
  - In Hyp mode, if the highest implemented Exception level is EL2.
  - In Supervisor mode, otherwise.

Reset returns some PE state to architecturally-defined or IMPLEMENTATION DEFINED values, and makes other state UNKNOWN. For more information see:

- *Behavior of caches at reset* on page G3-3583.
- *Enabling stages of address translation* on page G4-3628.
- *TLB behavior at reset* on page G4-3687.
- *Reset behavior of CP14 and CP15 registers* on page G4-3747.

When reset is deasserted, execution starts either:

- From an IMPLEMENTATION DEFINED address.

  Software might be able to identify this address:

  - If reset is into EL3, by reading the reset value of MVBAR. That is, after coming out of reset, by reading MVBAR before the boot software has updated it.
  - If reset is into EL2 or EL1, by reading RVBAR.

  It is IMPLEMENTATION DEFINED whether this discovery mechanism is supported. RVBAR can only be implemented at the highest implemented Exception level, and only if that Exception level is not EL3. If RVBAR is not implemented, and at all Exception levels other than the highest implemented Exception level, the encoding for RVBAR is UNDEFINED.

- If reset is into EL3 or EL1, from the low or high reset vector address, `0x00000000` or `0xFFFF0000`, as determined by the reset value of the SCTLR.V bit. This reset value can be determined by an IMPLEMENTATION DEFINED configuration input signal.

When executions starts, system behavior depends on the reset value of the CPSR, as defined by the `TakeReset()` pseudocode function that is defined later in this section. See also *The Current Program Status Register (CPSR)* on page G1-3387.

The ARM architecture does not define any way of returning to a previous execution state from a reset.

Note

- A reset does not reset the value of all of the debug registers. For more information see *Reset and debug* on page H8-4535.
- The ARM architecture does not distinguish between multiple levels of reset. A system can provide multiple distinct levels of reset that reset different parts of the system. These all correspond to this single reset description.

G1.13.1 Pseudocode description of Reset

The `TakeReset()` pseudocode procedure describes how the PE behaves when reset is deasserted:

```
// AArch32.TakeReset()
// ===================
// Reset into AArch32 state

AArch32.TakeReset(boolean cold_reset)
    assert HighestELUsingAArch32();

    // Enter the highest implemented Exception level in AArch32 state
```

```
    if HaveEL(EL3) then
        AArch32.WriteMode(M32_Svc);
        SCR.NS = '0';                       // Secure state
    elsif HaveEL(EL2) then
        AArch32.WriteMode(M32_Hyp);
    else
        AArch32.WriteMode(M32_Svc);

    // Reset the CP14 and CP15 registers and other system components
    AArch32.ResetControlRegisters(cold_reset);
    FPEXC.EN = '0';

    // Reset all other PSTATE fields, including instruction set and endianness according to the SCTLR
    // values produced by the above call to ResetControlRegisters()
    PSTATE.<A,I,F> = '111';               // All asynchronous exceptions masked
    PSTATE.IT = '00000000';               // IT block state reset
    PSTATE.J = '0';  PSTATE.T = SCTLR.TE; // Instruction set: TE=0: A32, TE=1: T32
    PSTATE.E = SCTLR.EE;                  // Endianness: EE=0: little-endian, EE=1: big-endian
    PSTATE.IL = '0';                      // Clear illegal execution state bit

    // All registers, bits and fields not reset by the above pseudocode or by the BranchTo() call
    // below are UNKNOWN bitstrings after reset. In particular, the return information registers
    // R14 or ELR_hyp and SPSR have UNKNOWN values, so that it is impossible to return from a reset
    // in an architecturally defined way.
    AArch32.ResetGeneralRegisters();
    AArch32.ResetSIMDFPRegisters();
    AArch32.ResetSpecialRegisters();
    ResetExternalDebugRegisters(cold_reset);

    bits(32) rv;                          // IMPLEMENTATION DEFINED reset vector
    if HaveEL(EL3) then
        if MVBAR<0> == '1' then           // Reset vector in MVBAR
            rv = MVBAR<31:1>:'0';
        else
            rv = bits(32) IMPLEMENTATION_DEFINED "reset vector address";
    else
        rv = RVBAR;

    // The reset vector must be correctly aligned
    assert rv<0> == '0' && (PSTATE.T == '1' || rv<1> == '0');

    BranchTo(rv, BranchType_UNKNOWN);
```

The `ResetGeneralRegisters()` function resets the general-purpose registers.

```
// AArch32.ResetGeneralRegisters()
// ===============================

AArch32.ResetGeneralRegisters()

    for i = 0 to 7
        R[i] = bits(32) UNKNOWN;
    for i = 8 to 12
        Rmode[i, M32_User] = bits(32) UNKNOWN;
        Rmode[i, M32_FIQ] = bits(32) UNKNOWN;
    if HaveEL(EL2) then Rmode[13, M32_Hyp] = bits(32) UNKNOWN;   // No R14_hyp
    for i = 13 to 14
        Rmode[i, M32_User] = bits(32) UNKNOWN;
        Rmode[i, M32_FIQ] = bits(32) UNKNOWN;
        Rmode[i, M32_IRQ] = bits(32) UNKNOWN;
        Rmode[i, M32_Svc] = bits(32) UNKNOWN;
        Rmode[i, M32_Abort] = bits(32) UNKNOWN;
        Rmode[i, M32_Undef] = bits(32) UNKNOWN;
        if HaveEL(EL3) then Rmode[i, M32_Monitor] = bits(32) UNKNOWN;

    return;
```

The ResetSIMDFPRegisters() function resets the SIMD and floating-point registers.

```
// AArch32.ResetSIMDFPRegisters()
// ==============================

AArch32.ResetSIMDFPRegisters()

    for i = 0 to 15
        Q[i] = bits(128) UNKNOWN;

    return;
```

The ResetSpecialRegisters() function resets the special registers.

```
// AArch32.ResetSpecialRegisters()
// ===============================

AArch32.ResetSpecialRegisters()

    // AArch32 special registers
    SPSR_fiq = bits(32) UNKNOWN;
    SPSR_irq = bits(32) UNKNOWN;
    SPSR_svc = bits(32) UNKNOWN;
    SPSR_abt = bits(32) UNKNOWN;
    SPSR_und = bits(32) UNKNOWN;
    if HaveEL(EL2) then
        SPSR_hyp = bits(32) UNKNOWN;
        ELR_hyp = bits(32) UNKNOWN;
    if HaveEL(EL3) then
        SPSR_mon = bits(32) UNKNOWN;

    // External debug special registers
    DLR = bits(32) UNKNOWN;
    DSPSR = bits(32) UNKNOWN;

    return;
```

The ResetSystemRegisters() function resets all CP14 and CP15 to their reset state as defined in the register descriptions in Chapter G5 *AArch32 System Register Descriptions*.

Note

The ResetSystemRegisters() function only resets the System registers.

```
AArch32.ResetSystemRegisters(boolean cold_reset);
```

The ResetExternalDebugRegisters() function resets all external debug registers to their reset state as defined in the register descriptions in Chapter H9 *External Debug Register Descriptions*.

```
ResetExternalDebugRegisters(boolean cold_reset);
```

G1.14 Mechanisms for entering a low-power state

The following sections describe the architectural mechanisms that a PE can use to request entry to a low-power state:

- *Wait For Event and Send Event*.
- *Wait For Interrupt* on page G1-3460.

G1.14.1 Wait For Event and Send Event

The Wait For Event (WFE) mechanism permits a PE to request entry to a low-power state, and, if the request succeeds, to remain in that state until an event is generated by a Send Event operation, or another WFE wake-up event occurs. Example G1-2 describes how a spinlock implementation might use this mechanism to save energy.

Example G1-2 Spinlock as an example of using Wait For Event and Send Event

---

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device it might need to add data received from the device to a queue. If another PE is removing data from the queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the lock has been released. It cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in *Synchronization and semaphores* on page E2-2284.
- If the PE obtains the lock it performs its memory operation and releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. At this point it again attempts to obtain the lock.

A spin-lock mechanism is not ideal for all situations:

- In a low-power system the tight read loop is undesirable because it uses energy to no effect.
- In a multi-threaded implementation the execution of spin-locks by waiting threads can significantly degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock. In this situation, a PE that fails to obtain a lock can execute a Wait For Event instruction, `WFE`, to request entry to a low-power state. When a PE releases a lock, it must execute a Send Event instruction, `SEV`, causing any waiting PEs to wake up. Then, these PEs can attempt to gain the lock again.

The execution in AArch32 state of a `WFE` instruction that would otherwise cause suspension of execution can be trapped, see:

- *Traps to Undefined mode of PL0 execution of WFE and WFI instructions* on page G1-3477.
- *Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions* on page G1-3494.
- *Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode* on page G1-3504.

The execution of a `WFE` instruction can cause suspension of execution only if all of the following are true:

- The instruction does not cause any other exception.
- When the instruction is executed:
  - The Event Register is not set.

— There is not a pending WFI wakeup event.

For more information about the trap to EL2 see *Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions* on page G1-3494.

The architecture does not define the exact nature of the low power state entered as a result of executing a `WFE` instruction, but the execution of a `WFE` instruction must not cause a loss of memory coherency.

Note

Although a complex operating system can contain thousands of distinct locks, the event sent by this mechanism does not indicate which lock has been released. If the event relates to a different lock, or if another PE acquires the lock more quickly, the PE fails to acquire the lock and can re-enter the low-power state waiting for the next event.

The Wait For Event system relies on hardware and software working together to achieve energy saving:

- The hardware provides the mechanism to enter the Wait For Event low-power state.
- The operating system software is responsible for issuing:
  - A Wait For Event instruction, to request entry to the low-power state, used in the example when waiting for a spin-lock.
  - A Send Event instruction, required in the example when releasing a spin-lock.

The mechanism depends on the interaction of:
- WFE wake-up events, see *WFE wake-up events*.
- The Event Register, see *The Event Register* on page G1-3459.
- The Send Event instructions, see *The Send Event instructions* on page G1-3459.
- The Wait For Event instruction, see *The Wait For Event instruction* on page G1-3460.

WFE wake-up events

The following events are *WFE wake-up events*:
- The execution of an `SEV` instruction on any PE in the system.
- The execution of an `SEVL` instruction on the PE.
- A physical IRQ interrupt, unless masked by the CPSR.I bit.
- A physical FIQ interrupt, unless masked by the CPSR.F bit.
- A physical asynchronous abort, unless masked by the CPSR.A bit.
- In Non-secure state in any mode other than Hyp mode:
  - When HCR.IMO is set to 1, a virtual IRQ interrupt, unless masked by the CPSR.I bit.
  - When HCR.FMO is set to 1, a virtual FIQ interrupt, unless masked by the CPSR.F bit.
  - When HCR.AMO is set to 1, a virtual asynchronous abort, unless masked by the CPSR.A bit.
- An asynchronous debug event, if invasive debug is enabled and the debug event is permitted.
- An event sent by the timer event stream, see *Event streams* on page D6-1787.
- An event sent by some IMPLEMENTATION DEFINED mechanism.
- An event caused by the clearing of the global monitor associated with the PE.

In addition to the possible masking of WFE wake-up events shown in this list, when invasive debug is enabled and EDSCR.HDE is set to 1, EDSCR.INTdis can mask interrupts, including masking them acting as WFE wake-up events. For more information, see *EDSCR, External Debug Status and Control Register* on page H9-4603.

As shown in the list of wake-up events, an implementation can include IMPLEMENTATION DEFINED hardware mechanisms to generate wake-up events.

Note

For more information about CPSR masking see *Asynchronous exception masking controls* on page G1-3421. If the configuration of the masking controls provided by EL2 and EL3 mean that a CPSR mask bit cannot mask the corresponding exception, then the physical exception is a WFE wake-up event, regardless of the value of the CPSR mask bit.

The Event Register

The Event Register is a single bit register for each PE. When set, an event register indicates that an event has occurred, since the register was last cleared, that might require some action by the PE. Therefore, the PE must not suspend operation on issuing a WFE instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register for a PE is set by:

- The execution of an SEV instruction on any PE in the multiprocessor system.
- The execution of an SEVL instruction by the PE.
- An event sent by some IMPLEMENTATION DEFINED mechanism.
- An exception return.

As shown in this list, the Event Register might be set by IMPLEMENTATION DEFINED mechanisms.

The Event Register is cleared only by a Wait For Event instruction.

Software cannot read or write the value of the Event Register directly.

The Send Event instructions

The Send Event instruction, SEV, causes an event to be signaled to all PEs in the system. The mechanism that signals the event to the PEs is IMPLEMENTATION DEFINED. Hardware does not guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the SEV instruction. Therefore, ARM recommends that software includes a DSB instruction before an SEV instruction.

The Send Event instructions are:

SEV, Send Event This causes an event to be signaled to all PEs in the multiprocessor system.

SEVL, Send Event Local
This must set the local Event Register. It might signal an event to other PEs, but is not required to do so.

The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED. The PE is not required to guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the SEV instruction. Therefore, ARM recommends that software includes a DSB instruction before any SEV instruction.

Note

A DSB instruction ensures that no instruction, including any SEV instruction, that appears in program order after the DSB instruction, can execute until the DSB instruction has completed. For more information, see *Data Synchronization Barrier (DSB)* on page E2-2270.

The SEVL instruction appears to execute in program order relative to any subsequent WFE instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.

Execution of the Send Event instruction sets the Event Register.

The Send Event instructions are available at all privilege levels.

The Wait For Event instruction

The action of the Wait For Event instruction depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately. Normally, if this happens the software makes another attempt to claim the lock.
- If the Event Register is clear the PE can suspend execution, and hardware might enter a low-power state. The PE can remain suspended until a WFE wake-up event or a reset occurs. When a WFE wake-up event occurs, or earlier if the implementation chooses, the `WFE` instruction completes.

The Wait For Event instruction, `WFE`, is available at all privilege levels, see *WFE* on page F7-2987.

Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake ups.

EL2 provides a bit that traps to EL2 any attempt to enter a low-power state from a Non-secure EL1 or EL0 mode. For more information see *Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions* on page G1-3494.

Pseudocode details of the Wait For Event lock mechanism

This section defines pseudocode functions that describe the operation of the Wait For Event mechanism.

The `ClearEventRegister()` pseudocode procedure clears the Event Register of the current PE.

The `EventRegistered()` pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear:

```
boolean EventRegistered();
```

The `WaitForEvent()` pseudocode procedure optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes a `ClearEventRegister()` to occur.

The `SendEvent()` pseudocode procedure sets the Event Register of every PE in the system.

G1.14.2 Wait For Interrupt

AArch32 state supports Wait For Interrupt through an instruction, `WFI`, that is provided in the A32 and T32 instruction sets. For more information, see *WFI* on page F7-2989.

When a PE issues a `WFI` instruction, its execution can be suspended, and a low-power state can be entered.

The execution in AArch32 state of a `WFI` instruction that would otherwise cause suspension of execution can be trapped, see:

- *Traps to Undefined mode of PL0 execution of WFE and WFI instructions* on page G1-3477.
- *Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions* on page G1-3494.
- *Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode* on page G1-3504.

The execution of a `WFI` instruction can cause suspension of execution only if both:

- The instruction does not cause any other exception.
- When the instruction is executed, there is not a pending WFI wakeup event.

For more information about the trap to EL2 see *Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions* on page G1-3494.

The PE can remain suspended in its WFI state until it is reset, or one of the following *WFI wake-up events* occurs:

- A physical IRQ interrupt, regardless of the value of the CPSR.I bit.
- A physical FIQ interrupt, regardless of the value of the CPSR.F bit.
- A physical asynchronous abort, regardless of the value of the CPSR.A bit.
- In Non-secure state in any mode other than Hyp mode:
  - When HCR.IMO is set to 1, a virtual IRQ interrupt, regardless of the value of the CPSR.I bit.

  - When HCR.FMO is set to 1, a virtual FIQ interrupt, regardless of the value of the CPSR.F bit.
  - When HCR.AMO is set to 1, a virtual asynchronous abort, regardless of the value of the CPSR.A bit.
- An asynchronous debug event, when invasive debug is enabled and the debug event is permitted.

An implementation can include other IMPLEMENTATION DEFINED hardware mechanisms to generate WFI wake-up events.

When a WFI wake-up event is detected, or earlier if the implementation chooses, the `WFI` instruction completes.

WFI wake-up events cannot be masked by the mask bits in the CPSR.

The architecture does not define the exact nature of the low power state, but the execution of a `WFI` instruction must not cause a loss of memory coherency.

Note

- Because debug events are WFI wake-up events, ARM strongly recommends that Wait For Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures the intervention of debug while waiting does not significantly change the function of the program being debugged.
- In some previous implementations of Wait For Interrupt, the idle loop is followed by exit functions that must be executed before taking the interrupt. The operation of Wait For Interrupt remains consistent with this model, and therefore differs from the operation of Wait For Event.
- Some implementations of Wait For Interrupt drain down any pending memory activity before suspending execution. The ARM architecture does not require this operation, and software must not rely on Wait For Interrupt operating in this way.

Using WFI to indicate an idle state on bus interfaces

A common implementation practice is to complete any entry into powerdown routines with a `WFI` instruction. Typically, the `WFI` instruction:

1. Forces the completion of execution of any instructions that are in progress, and of all associated bus activity.
2. Suspends the execution of instructions by the PE.

The control logic required to do this tracks the activity of the bus interfaces used by the PE. This means it can signal to an external power controller when there is no ongoing bus activity.

However, memory-mapped and external debug interface accesses to debug registers must continue to be processed while the PE is in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

When the value of DBGOSDLR.DLK, the OS Double Lock status bit, is set to 1, this idle state must not be signaled to the PE unless the system can guarantee, also, that the debug interface is idle.

Note

When separate core and debug power domains are implemented, the debug interface referred to in this section is the interface between the core and debug power domains, since the signal to the power controller indicates that the core power domain is idle. For more information about the power domains see *Power domains and debug* on page H6-4497.

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

Pseudocode details of Wait For Interrupt

The `WaitForInterrupt()` pseudocode procedure optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.

G1.14.3 Pseudocode details for trapping WFE and WFI instructions

The AArch32.CheckForWFxTrap() pseudocode function is as follows:

```
// AArch32.CheckForWFxTrap()
// =========================
// Check for trap on WFE or WFI instruction

AArch32.CheckForWFxTrap(bits(2) target_el, boolean is_wfe)
    assert HaveEL(target_el);

    // Check for routing to AArch64
    if !ELUsingAArch32(target_el) then
        AArch64.CheckForWFxTrap(target_el, is_wfe);

    case target_el of
        when EL1  trap = (if is_wfe then SCTLR.nTWE else SCTLR.nTWI) == '0';
        when EL2  trap = (if is_wfe then HCR.TWE else HCR.TWI) == '1';
        when EL3  trap = (if is_wfe then SCR.TWE else SCR.TWI) == '1';

    if trap then
        if (target_el == EL1 && HaveEL(EL2) && !IsSecure() && !ELUsingAArch32(EL2) &&
            HCR_EL2.TGE == '1') then
            AArch64.WFxTrap(target_el, is_wfe);

        if target_el == EL3 then
            AArch32.TakeMonitorTrapException();
        elsif target_el == EL2 then
            exception = ExceptionSyndrome(Exception_WFxTrap);
            exception.syndrome<0> = if is_wfe then '1' else '0';
            AArch32.TakeHypTrapException(exception);
        else
            AArch32.TakeUndefInstrException();
```

G1.15 The conceptual coprocessor interface and system control

AArch32 state includes a coprocessor interface that can access sixteen coprocessors, CP0 to CP15. *Coprocessor support* on page E1-2244 introduces this interface. Part of this interface is reserved for conceptual coprocessors, as follows:

- CP10 and CP11 provide Advanced SIMD and floating-point functionality.
- CP14 and CP15 provide configuration and control related to the architecture:

In ARMv8, AArch32 has no support for coprocessors other than CP10, CP11, CP14, and CP15.

This section gives:

- An introduction to the CP14 and CP15 registers, see *CP14 and CP15 system control registers*.
- Information about access controls for the other coprocessors, see *Access controls on CP10 and CP11*.

G1.15.1 CP14 and CP15 system control registers

In AArch32 state:

- CP14 is reserved for the configuration and control of:
  - Debug features, see *Debug registers* on page G5-4158.
  - Trace features, see the *Embedded Trace Macrocell Architecture Specification* and the *CoreSight Program Flow Trace Architecture Specification*.
  - Identification registers for the Trivial Jazelle implementation, see *Trivial implementation of the Jazelle extension* on page G1-3394.
- CP15 is called the System Control coprocessor, and is reserved for the control and configuration of the PE, including architecture and feature identification. This means CP15 provides access to the System registers that control and return status information for PE operation.

See Chapter G5 *AArch32 System Register Descriptions*.

Access to CP14 and CP15 registers

Most CP14 and CP15 registers are accessible only from EL1 or higher. For possible accesses from EL0:

- The register descriptions in Chapter G5 *AArch32 System Register Descriptions* indicate whether a register is accessible from EL0.
- The descriptions of the CP14 interface in *Debug registers* on page G5-4158 include the permitted accesses to the debug registers from EL0.
- *EL0 views of the CP15 registers* on page G4-3783 summarizes the permitted accesses to CP15 registers from EL0.

G1.15.2 Access controls on CP10 and CP11

The CP10 and CP11 part of the coprocessor interface supports the Advanced SIMD and floating-point instructions, providing access to System registers relating to the use of these instructions, and some instruction encodings. See also *Advanced SIMD and floating-point support* on page G1-3466.

In ARMv8, the CPACR controls access to CP10 and CP11 from software executing at EL1 or EL0 in AArch32 state.

Initially on powerup or reset into AArch32 state, access to coprocessors CP10 and CP11 is disabled.

Note

The CPACR has no effect on accesses from Hyp mode.

If an implementation includes EL3, the NSACR determines whether CP10 and CP11 can be accessed from the Non-secure state.

If an implementation includes EL2, the HCPTR provides additional controls on Non-secure accesses to CP10 and CP11. For accesses that are otherwise permitted by the CPACR and NSACR settings, setting HCPTR bits to 1:

- Traps otherwise-permitted accesses from EL1 or EL0 to EL2. When EL2 is using AArch32, these accesses are trapped to Hyp mode.
- Makes accesses from EL2 mode UNDEFINED. When EL2 is using AArch32, this makes accesses from Hyp mode UNDEFINED.

For more information, see *General trapping to Hyp mode of Non-secure accesses to the Advanced SIMD and floating-point registers* on page G1-3495.

Note

The access settings for CP10 and CP11 must be identical. If these settings are not identical the behavior of the Advanced SIMD and floating-point functionality is CONSTRAINED UNPREDICTABLE. ARMv8 constrains the UNPREDICTABLE behavior to be that, for all purposes other than reading the value of the CP11 control bit field, behavior is as if the access control field for CP11 has the same value as the access control field for CP10.

G1.15.3 Pseudocode details for Coproc_Accepted()

The `Coproc_Accepted()` function determines whether the CP14 or CP15 coprocessor instruction is accepted.

```
// Coproc_Accepted()
// =================
// Determines whether the AArch32 CP14 or CP15 coprocessor instruction is accepted.

boolean Coproc_Accepted(integer cp_num, bits(32) instr)
    assert UsingAArch32();
    assert !(cp_num IN {10,11});
    assert cp_num == UInt(instr<11:8>);

    if instr<27:24> == '1110' && instr<4> == '1' && instr<31:28> != '1111' then
        // MRC/MCR
        nreg = 1;
        opc1 = UInt(instr<23:21>);
        opc2 = UInt(instr<7:5>);
        CRn  = UInt(instr<19:16>);
        CRm  = UInt(instr<3:0>);
    elsif instr<27:21> == '1100010' && instr<31:28> != '1111' then
        // MRRC/MCRR
        nreg = 2;
        opc1 = UInt(instr<7:4>);
        CRm  = UInt(instr<3:0>);
    elsif instr<27:25> == '110' && instr<31:28> != '1111' then
        // LDC/STC
        nreg = 0;
        CRn  = UInt(instr<15:12>);
    else
        Unreachable();

    case cp_num of
        when 14
            if Coproc_UnallocatedAtEL(PSTATE.EL, instr) then UNDEFINED;
            // Coarse-grained decode of CP14 based on opc1 field
            case opc1 of
                when 0  accepted = CP14DebugInstrDecode(instr);
                when 1  accepted = CP14TraceInstrDecode(instr);
                when 6  accepted = CP14TEEInstrDecode(instr);
                otherwise
                    Unreachable();              // All other codes are UNDEFINED

        when 15
            // Check for coarse-grained Hyp traps
            if HaveEL(EL2) && !IsSecure() then
```

```
                // Disabled in HSTR
                if !(CRn IN {4,14}) && HSTR<CRn> == '1' then
                    if (PSTATE.EL == EL0 && Coproc_UnallocatedAtEL(EL0, instr) &&
                        boolean IMPLEMENTATION_DEFINED "choice to be UNDEFINED") then
                        UNDEFINED;
                    AArch32.CPRegTrap(EL2, instr);

                // Check for TIDCP as a coarse-grain check for PL1 accesses
                if (HCR.TIDCP == '1' && nreg == 1 &&
                    ((CRn == 9  && CRm IN {0,  2,    5,6,7,8   }) ||
                     (CRn == 10 && CRm IN {0,1,    4,      8   }) ||
                     (CRn == 11 && CRm IN {0,1,2,3,4,5,6,7,8,15}))) then
                    if (PSTATE.EL == EL0 && Coproc_UnallocatedAtEL(EL0, instr) &&
                        boolean IMPLEMENTATION_DEFINED "choice to be UNDEFINED") then
                        UNDEFINED;
                    AArch32.CPRegTrap(EL2, instr);

            if Coproc_UnallocatedAtEL(PSTATE.EL, instr) then
                UNDEFINED;
            else
                accepted = CP15InstrDecode(instr);

        otherwise
            // In ARMv8 this case should be Unreachable()
            Unreachable();

    return accepted;
```

G1.16 Advanced SIMD and floating-point support

Advanced SIMD and floating-point instructions on page E1-2216 introduces:

- The scalar floating-point instructions in the A32 and T32 instruction sets.
- The Advanced SIMD integer and floating-point vector instructions in the A32 and T32 instruction sets.
- The SIMD and floating-point register file, that can be viewed as:
  - Singleword registers S0 - S31.
  - Doubleword registers D0 - D31.
  - Quadword registers Q0 - Q15.
- The *Floating-Point Status and Control Register* (FPSCR).

For more information about the system registers for the Advanced SIMD and floating-point operation see *Advanced SIMD and floating-point system registers* on page G1-3472. Software can interrogate these registers to discover the implemented Advanced SIMD and floating-point support.

The following subsections give more information about the Advanced SIMD and Floating-point support:

- *Enabling Advanced SIMD and floating-point support*.
- *Advanced SIMD and floating-point system registers* on page G1-3472.
- *Context switching when using Advanced SIMD and floating-point functionality* on page G1-3473.
- *Floating-point exception traps, serialization, and floating-point exception barriers* on page G1-3473.

G1.16.1 Enabling Advanced SIMD and floating-point support

Software must ensure that the required access to the Advanced SIMD and floating-point features is enabled:

- Any use of Advanced SIMD or floating-point features requires access to CP10 and CP11.
- Additional controls apply to the use of Advanced SIMD features, see *Additional controls on Advanced SIMD functionality* on page G1-3470.

Note

This section describes the controls when the controlling Exception levels are using AArch32. Similar controls are provided when the Exception levels are using AArch64, and then apply to lower Exception levels that are using AArch32.

The controls of access to CP10 and CP11 are:

- CPACR.{cp10, cp11} control access from PE modes other than Hyp mode. The permitted values of these fields are:

  0b00 No access. Any access to the Advanced SIMD and floating-point features is UNDEFINED.

  0b01 Accessible from privileged modes only. Any access to the Advanced SIMD and floating-point features from User mode is UNDEFINED.

  0b11 Accessible from privileged and unprivileged modes.

  These fields reset to `0b00`, no access.

  These fields have no effect on accesses to CP10 and CP11 from Hyp mode.

- In an implementation that includes EL3, NSACR.{cp10, cp11} control access from Non-secure state. The permitted values of these bits are:

  0 Accessible from Secure state only. Any access to the Advanced SIMD and floating-point features from Non-secure state is UNDEFINED.

  1 Accessible from both Security states, subject to any other access controls that apply. These include:

  - For accesses from any PE mode other than Hyp mode, the CPACR.{cp10, cp11} controls.
  - If the implementation includes EL2, the HCPTR.{TCP10, TCP11} control. This applies to accesses from all PE modes in Non-secure state.

- In an implementation that includes EL2, when NSACR.{cp10, cp11} are set to 1, to permit Non-secure accesses, HCPTR.{TCP10, TCP11} provide an additional control on those accesses. The permitted values of these bits are:

  0 Advanced SIMD and floating-point features are accessible from Non-secure state, subject to any other access controls that apply. The CPACR.{cp10, cp11} controls:
  - Have no effect on accesses from Hyp mode.
  - Apply to accesses from all other PE modes.

  1 Trap coprocessor accesses:
  - Any access from a Non-secure PE mode other than Hyp mode that is permitted by other controls, including the CPACR.{cp10, cp11} controls, generates an exception that is taken to Hyp mode.
  - Any access to Advanced SIMD and floating-point features from Hyp mode is UNDEFINED.

  When NSACR.{cp10, cp11} are set to 0, all accesses to Advanced SIMD and floating-point features from Non-secure state are UNDEFINED.

  Note

  The HCPTR can also trap to Hyp mode otherwise-permitted Non-secure EL1 and EL0 accesses to Advanced SIMD and floating-point functionality. At reset, those traps are disabled.

Access control bits for CP10 and CP11 must be programmed with the same values, otherwise operation of the controlled Advanced SIMD and floating-point features is CONSTRAINED UNPREDICTABLE. This means that operation is CONSTRAINED UNPREDICTABLE:

- In any implementation, if the values of CPACR.cp10 and CPACR.cp11 are different.
- In an implementation that includes EL3, in Non-secure state, if the values of NSACR.cp10 and NSACR.cp11 are different.
- In an implementation that includes EL2, in Non-secure state, if the values of HCPTR.TCP10 and HCPTR.TCP11 are different.

In ARMv8, the CONSTRAINED UNPREDICTABLE behavior is that, for all purposes other than reading the value of the register field, behavior is as if the access control field for CP11 has the same value as the access control field for CP10.

In addition, FPEXC.EN is an enable bit for most Advanced SIMD and floating-point operations. When FPEXC.EN is 0, all Advanced SIMD and floating-point instructions are treated as UNDEFINED except for:

- A `VMSR` to the FPEXC or FPSID register.
- A `VMRS` from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2 register.

These instructions can be executed only at EL1 or higher.

Note

- Although FPSID is a read-only register, software can perform a `VMSR` to the FPSID to force Floating-point serialization, as described in *Floating-point exception traps, serialization, and floating-point exception barriers* on page G1-3473.
- When FPEXC.EN is 0, these operations are treated as UNDEFINED:
  - A `VMSR` to the FPSCR.
  - A `VMRS` from the FPSCR.

These controls, summarized in *Summary of general controls of CP10 and CP11 functionality* on page G1-3468, apply to all functionality that depends on access to CP10 and CP11. That is, they apply equally to all implemented Advanced SIMD and floating-point functionality.

Additional controls apply to any implemented Advanced SIMD functionality, see *Additional controls on Advanced SIMD functionality* on page G1-3470.

Pseudocode details of enabling Advanced SIMD and floating-point functionality on page G1-3471 gives a pseudocode description of both sets of controls.

Summary of general controls of CP10 and CP11 functionality

Table G1-21 summarizes the access controls for the implemented Advanced SIMD and floating-point functionality, that are based on controlling access to coprocessors CP10 and CP11, and on the FPEXC.EN enable bit. The following subsections give more information about the entries in this table:

- *Information about the general controls of CP10 and CP11 functionality* on page G1-3469.
- *EL0 access to Advanced SIMD and floating-point functionality* on page G1-3469.

In this table, and in Table G1-22 on page G1-3470, an entry of:

- UND indicates that the Advanced SIMD or floating-point access generates an Undefined Instruction exception. For an access made from Hyp mode this exception is taken to Hyp mode, otherwise it is taken to Secure or Non-secure Undefined mode.
- Trapped indicates that accesses generate a Hyp Trap exception, that is taken to Hyp mode.

Table G1-21 Summary of access controls for all CP10 and CP11 functionality

Controls				Secure		Non-secure		
CPACR.cp*n*[a]	NSACR.cp*n*	HCPTR.TCP*n*	FPEXC.EN	EL3[b]	EL0	EL2	EL1	EL0
00	0	x[c]	x	UND	UND	UND	UND	UND
	1	0	0	UND	UND	UND[d]	UND	UND
			1	UND	UND	Enabled	UND	UND
		1	x	UND	UND	UND	UND	UND
01	0	x[c]	0	UND[d]	UND	UND	UND	UND
			1	Enabled	UND	UND	UND	UND
	1	0	0	UND[d]	UND	UND[d]	UND[d]	UND
			1	Enabled	UND	Enabled	Enabled	UND
		1	0	UND[d]	UND	UND	UND[e]	UND

			1	Enabled	Enabled	Enabled	Enabled	Enabled
		1	0	UND[d]	UND	UND	UND[e]	UND
			1	Enabled	Enabled	UND	Trapped	Trapped

a. When the corresponding NSACR bit is set to 0, for Non-secure accesses the CPACR field behaves as RAZ/WI. That is, when NSACR.cp10 is set to 0, for Non-secure accesses CPACR.cp10 ignores writes, and reads as `0b00`, regardless of its actual value.

b. When EL3 is implemented and is using AArch64, Monitor mode is not available, and all Secure modes other than User mode are Secure EL1 modes.

c. When the NSACR control bits are set to 0, for Non-secure accesses the HCPTR control bits behave as RAO/WI.

d. Except for `VMSR` to the FPEXC or FPSID register, or a `VMRS` from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2 register.

e. Except for VMSR to the FPEXC or FPSID register, or a VMRS from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2 register, that are Trapped.

Note

In Table G1-21 on page G1-3468:

- The behavior of Secure accesses depends only on the CPACR and FPEXC control values.
- The behavior of accesses from Hyp mode depends only on the NSACR, HCPTR, and FPEXC control values.

Information about the general controls of CP10 and CP11 functionality

In Table G1-21 on page G1-3468, the values for each of the registers shown in the *Controls* columns are:

CPACR The value of the CPACR.{cp10, cp11} fields. These fields must be programmed to the same value, otherwise behavior is CONSTRAINED UNPREDICTABLE. The table does not show the reserved value of 0b10.

NSACR The value of the NSACR.{cp10, cp11} bits. These bits must be programmed to the same value, otherwise behavior is CONSTRAINED UNPREDICTABLE.

These controls are implemented only as part of EL3. For the access controls for an implementation that does not include EL3, consider only:

- The Secure EL3 and EL0 columns. When EL3 is not implemented:
  - Monitor mode is not available.
  - There is only a single Security state, and all AArch32 modes other than User mode and Hyp mode are always EL1 modes.
- The rows for which NSACR is 0, and HCPTR is 0 or x.

HCPTR The value of the HCPTR.{TCP10, TCP11} bits. These bits must be programmed to the same value, otherwise behavior is CONSTRAINED UNPREDICTABLE.

These controls are implemented only as part of EL2. For the access controls for an implementation that does not include EL2:

- Ignore the Non-secure EL2 column.
- Consider only the rows for which HCPTR is 0 or x.

FPEXC.EN The value of FPEXC.EN. As indicated in this section, and in the table footnote, when this bit is set to 0:

- Most Advanced SIMD and floating-point functionality is disabled.
- A limited number of register accesses are permitted at EL1 or higher.

When this bit is set to 1, Advanced SIMD and floating-point functionality is enabled, but subject to:

- The other access controls shown in the table.
- The restrictions described in *EL0 access to Advanced SIMD and floating-point functionality*.

In ARMv8, the CONSTRAINED UNPREDICTABLE behavior when the access control fields for CP10 and CP11 have different values is that, for all purposes other than reading the value of the CP11 control bit, behavior is as if the access control field for CP11 has the same value as the access control field for CP10.

EL0 access to Advanced SIMD and floating-point functionality

When Table G1-21 on page G1-3468 shows that EL0 access to the Advanced SIMD and floating-point functionality is enabled, this applies only to the subset of functionality that is available at EL0. In particular, the only Advanced SIMD and Floating-point system register that is accessible is the FPSCR. However, the Advanced SIMD and floating-point instructions are available. Execution at EL0 corresponds to the application level view of the Advanced SIMD and floating-point functionality, as described in *Advanced SIMD and floating-point system registers* on page E1-2219.

Additional controls on Advanced SIMD functionality

If the general controls summarized in *Summary of general controls of CP10 and CP11 functionality* on page G1-3468 permit access to CP10 and CP11 functionality, additional controls apply to any implemented Advanced SIMD functionality. The following controls apply to all Advanced SIMD instructions, that is, to all instruction encodings in *Alphabetical list of T32 and A32 base instruction set instructions* on page F7-2450 that are identified as Advanced SIMD encodings and are not also floating-point encodings:

- When the value of CPACR.ASEDIS is 1, all Advanced SIMD instructions are UNDEFINED.
- In an implementation that includes EL3, when the value of CPACR.ASEDIS is 0, if the value of NSACR.NSASEDIS is 1 and the PE is in Non-secure state, CPACR.ASEDIS appears as RAO/WI and all Advanced SIMD instructions are UNDEFINED.
- In an implementation that includes EL2, when the CPACR and NSACR settings permit Non-secure use of the Advanced SIMD instructions, if HCPTR.TASE is set to 1 any use of an Advanced SIMD instruction from:
  - A Non-secure EL1 or EL0 mode is trapped to Hyp mode.
  - Hyp mode generates an Undefined Instruction exception that is taken to Hyp mode.

Table G1-22 references the descriptions of the registers that control this functionality, and *Summary of access controls for Advanced SIMD functionality* shows these controls.

Summary of access controls for Advanced SIMD functionality

Table G1-22 summarizes the additional access controls for the use of Advanced SIMD instructions.

- In this table, entries of UND and Enabled have the meanings defined in *Summary of general controls of CP10 and CP11 functionality* on page G1-3468
- The entries shown in this table must be combined with the information shown in Table G1-21 on page G1-3468 as follows:
  - If at least one table shows the access as UND then the access is UNDEFINED.
  - Otherwise, if at least one table shows the access as Trapped then the access generates a Hyp Trap exception.
  - Otherwise, both tables show the access as Enabled, meaning the access is permitted.

Table G1-22 Summary of additional access controls for Advanced SIMD functionality

Controls			Secure		Non-secure		
CPACR.ASEDIS	NSACR.NSASEDIS	HCPTR.TASE	EL3[a]	EL0	EL2	EL1	EL0
0[b]	0	0	Enabled	Enabled	Enabled	Enabled	Enabled
		1	Enabled	Enabled	UND	Trapped	Trapped
	1	x[b]	Enabled	Enabled	UND	UND	UND
1	0	0	UND	UND	Enabled	UND	UND
		1	UND	UND	UND	UND	UND
	1	x[b]	UND	UND	UND	UND	UND

a. When EL3 is implemented and is using AArch64, Monitor mode is not available, and all Secure modes other than User mode are Secure EL1 modes.

b. When the value of the NSACR.NSASEDIS is 1, for Non-secure accesses:
– To CPACR, the ASEDIS bit behaves as RAO/WI.
– To HCPTR, the TASE bit behaves as RAO/WI.

When interpreting Table G1-22 on page G1-3470:

- The NSACR is implemented only as part of EL3. For an implementation that does not include EL3, use of the Advanced SIMD instructions:
  - Is enabled when CPACR.ASEDIS is set to 0.
  - Is disabled when CPACR.ASEDIS is set to 1.
- The HCPTR is implemented only as part of EL2. For an implementation that does not include EL2, when the controls shown in Table G1-21 on page G1-3468 permit Non-secure use of the CP10 and CP11 functionality, use of the Advanced SIMD instructions from Non-secure state:
  - Is enabled when CPACR.ASEDIS and NSACR.NSASEDIS are both set to 0.
  - Is disabled otherwise.

Pseudocode details of enabling Advanced SIMD and floating-point functionality

The following pseudocode functions take appropriate action if an Advanced SIMD or Floating-point instruction is used when the Advanced SIMD and floating-point functionality is not enabled:

```
// AArch32.CheckAdvSIMDOrFPEnabled()
// =================================
// Check against CPACR, FPEXC, HCPTR, NSACR, and CPTR_EL3.

AArch32.CheckAdvSIMDOrFPEnabled(boolean fpexc_check, boolean advsimd)

    if PSTATE.EL == EL0 && !ELUsingAArch32(EL1) then
        AArch64.CheckFPAdvSIMDEnabled();
    else
        cpacr_asedis = CPACR.ASEDIS;
        cpacr_cp10 = CPACR.cp10;

        if HaveEL(EL3) && ELUsingAArch32(EL3) && !IsSecure() then
            // Check if access disabled in NSACR
            if NSACR.NSASEDIS == '1' then cpacr_asedis = '1';
            if NSACR.cp10 == '0' then cpacr_cp10 = '00';

        if PSTATE.EL != EL2 then
            // Check if Advanced SIMD disabled in CPACR
            if advsimd && cpacr_asedis == '1' then UNDEFINED;

            // Check if access disabled in CPACR
            case cpacr_cp10 of
                when 'x0'  disabled = TRUE;
                when '01'  disabled = PSTATE.EL == EL0;
                when '11'  disabled = FALSE;
            if disabled then UNDEFINED;

        // If required, check FPEXC enabled bit. If EL1 is using AArch64, then do not
        // make this check
        if fpexc_check && FPEXC.EN == '0' then UNDEFINED;

        AArch32.CheckFPAdvSIMDTrap(advsimd);            // Also check against HCPTR and CPTR_EL3

// AArch32.CheckFPAdvSIMDTrap()
// ============================
// Check against CPTR_EL2 and CPTR_EL3.

AArch32.CheckFPAdvSIMDTrap(boolean advsimd)

    if HaveEL(EL2) && !IsSecure() && !ELUsingAArch32(EL2) then
        AArch64.CheckFPAdvSIMDTrap();
    else
        if HaveEL(EL2) && !IsSecure() then
            hcptr_tase = HCPTR.TASE;
            hcptr_cp10 = HCPTR.TCP10;
```

```
            if HaveEL(EL3) && ELUsingAArch32(EL3) && !IsSecure() then
                // Check if access disabled in NSACR
                if NSACR.NSASEDIS == '1' then hcptr_tase = '1';
                if NSACR.cp10 == '0' then hcptr_cp10 = '1';

            // Check if access disabled in HCPTR
            if (advsimd && hcptr_tase == '1') || hcptr_cp10 == '1' then
                exception = ExceptionSyndrome(Exception_AdvSIMDFPAccessTrap);
                if advsimd then
                    exception.syndrome<5> = '1';
                else
                    exception.syndrome<5> = '0';
                    exception.syndrome<3:0> = '1010';         // coproc field, always 0xA
                AArch32.TakeHypTrapException(exception);

        if HaveEL(EL3) && !ELUsingAArch32(EL3) then
            // Check if access disabled in CPTR_EL3
            if CPTR_EL3.TFP == '1' then AArch64.AdvSIMDFPAccessTrap(EL3);

    return;
```

The CheckAdvSIMDOrVFPEnabled(), CheckAdvSIMDEnabled(), and CheckVFPEnabled() wrapper functions support the CheckAdvSIMDOrFPEnabled() and CheckFPAdvSIMDTrap() functions.

```
// CheckAdvSIMDOrVFPEnabled()
// ==========================

CheckAdvSIMDOrVFPEnabled(boolean include_fpexc_check, boolean advsimd)
    AArch32.CheckAdvSIMDOrFPEnabled(include_fpexc_check, advsimd);
    // Return from CheckAdvSIMDOrFPEnabled() occurs only if VFP access is permitted
    return;

// CheckAdvSIMDEnabled()
// =====================

CheckAdvSIMDEnabled()

    fpexc_check = TRUE;
    advsimd = TRUE;

    AArch32.CheckAdvSIMDOrFPEnabled(fpexc_check, advsimd);
    // Return from CheckAdvSIMDOrFPEnabled() occurs only if Advanced SIMD access is permitted

    // Make temporary copy of D registers
    // _Dclone[] is used as input data for instruction pseudocode
    for i = 0 to 31
        _Dclone[i] = D[i];

    return;

// CheckVFPEnabled()
// =================

CheckVFPEnabled(boolean include_fpexc_check)
    advsimd = FALSE;
    AArch32.CheckAdvSIMDOrFPEnabled(include_fpexc_check, advsimd);
    // Return from CheckAdvSIMDOrFPEnabled() occurs only if VFP access is permitted
    return;
```

G1.16.2 Advanced SIMD and floating-point system registers

AArch32 state provides a common set of System registers for the Advanced SIMD and floating-point functionality. This section gives general information about this set of registers, and indicates where each register is described in detail. It contains the following subsections:

- *Register map of the Advanced SIMD and floating-point System registers* on page G1-3473.
- *Accessing the Advanced SIMD and floating-point System registers* on page G1-3473.

Register map of the Advanced SIMD and floating-point System registers

Table G1-45 on page G1-3492 shows the register map of the Advanced SIMD and Floating-point registers. Each register is 32 bits wide. In an implementation that includes EL3, the Advanced SIMD and Floating-point registers are common registers, see *Common System registers* on page G4-3754.

Accessing the Advanced SIMD and floating-point System registers

Software accesses the Advanced SIMD and floating-point System registers using the `VMRS` and `VMSR` instructions, see:

- *VMRS* on page F8-3358.
- *VMSR* on page F8-3360.

For example:

```
VMRS <Rt>, FPSID    ; Read  Floating-Point System ID Register
VMRS <Rt>, MVFR1    ; Read  Media and VFP Feature Register 1
VMSR FPSCR, <Rt>    ; Write Floating-Point System Control Register
```

Software can access the Advanced SIMD and floating-point System registers only if the access controls permit the access, see *Enabling Advanced SIMD and floating-point support* on page G1-3466.

Note

All hardware ID information can be accessed only from EL1 or higher. This means:

The FPSID is accessible only from EL1 or higher.

This is a change introduced from VFPv3. Previously, the FPSID register can be accessed in all modes.

The MVFR registers are accessible only from EL1 or higher.

Unprivileged software must issue a system call to determine what features are supported.

G1.16.3 Context switching when using Advanced SIMD and floating-point functionality

When the Advanced SIMD and floating-point functionality is used by only a subset of processes, the operating system might implement lazy context switching of the Advanced SIMD and floating-point register file and System registers.

In the simplest lazy context switch implementation, the primary context switch software disables the Advanced SIMD and floating-point functionality, by disabling access to coprocessors CP10 and CP11 in the CPACR, see *Enabling Advanced SIMD and floating-point support* on page G1-3466. Subsequently, when a process or thread attempts to use an Advanced SIMD or Floating-point instruction, it triggers an Undefined Instruction exception. The operating system responds by saving and restoring the Advanced SIMD and floating-point register file and System registers. Typically, it then re-executes the Advanced SIMD or floating-point instruction that generated the Undefined Instruction exception.

G1.16.4 Floating-point exception traps, serialization, and floating-point exception barriers

Execution of a floating-point instruction can generate an exceptional condition, called a *floating-point exception*.

Note

Do not confuse floating-point exceptions with the AArch32 architectural exceptions summarized in *AArch32 state exception descriptions* on page G1-3428.

An Advanced SIMD and floating-point implementation can support floating-point exception *traps*, meaning floating-point exceptions are passed back to application software to resolve, see *Floating-point exceptions* on page E1-2220.

VMRS and VMSR instructions that access the FPSID, FPSCR, or FPEXC registers are *serializing* instructions. This means that, before they perform any required register transfer, they ensure that any exceptional condition that requires support code processing, from any preceding Floating-point instruction, has been detected and reflected in the Advanced SIMD and floating-point system registers. A VMSR instruction to the read-only FPSID register is a serializing NOP.

In addition, a VMRS or VMSR instruction that accesses the FPSCR acts as a *Floating-point exception barrier*. This means that, before it performs the register transfer, it ensures that any outstanding exceptional conditions in preceding Floating-point instructions have been detected and processed by the support code. If necessary, the VMRS or VMSR instruction takes an asynchronous bounce to force the processing of any outstanding exceptional conditions.

In pseudocode, Floating-point serialization and the Floating-point exception barriers are described by the SerializeVFP() and VFPExcBarrier() functions respectively.

G1.17 Configurable instruction enables, disables, and traps

Trapping refers to a configuration that causes an instruction to generate an exception rather than complete normally. Typically, this means that an instruction that would normally be executed at a lower Exception level instead generates an exception that is taken to a higher Exception level. The instruction is said to be *trapped* to the higher Exception level. However, some instructions are trapped to the same Exception level, rather than to a higher Exception level.

Enable and *disable* controls refer to configurations that cause an instruction to generate an Undefined Instruction exception when executed at a lower Exception level, rather than completing normally.

In AArch32 state, only instructions that are trapped directly to Hyp mode are reported in a syndrome register, and software can use this information to determine which instruction type was trapped.

Note

Routing exceptions is described elsewhere in this chapter:

- *Asynchronous exception behavior for exceptions taken from AArch32 state* on page G1-3418 describes the routing options for asynchronous exceptions.
- *Routing general exceptions to EL2* on page G1-3410 describes a control that routes exceptions from Non-secure EL0 to EL2.

This section is organized as follows:

- *PL1 instruction enables, disables, and traps configurable*.
- *EL2 configurable instruction enables, disables, and traps* on page G1-3482.
- *EL3 configurable instruction enables, disables, and traps* on page G1-3503.

Note

An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide finer-grained control of control of trapping of IMPLEMENTATION DEFINED features.

G1.17.1 PL1 instruction enables, disables, and traps configurable

Software configures enables, disables, and traps for instructions executed at PL0 and PL1 using AArch32 System registers. Some controls apply only to instructions executed at PL0. Some controls apply only to instructions executed at PL1, because the instructions are always UNDEFINED at PL0.

The disabled or trapped instruction generates an Undefined Instruction exception taken from AArch32 state.

There is no distinction between traps, enables, and disables if these are taken to Undefined mode. However:

- If they are routed to EL2 using AArch32, then the exception is reported using EC value `0x00`.
- If they are routed to EL2 using AArch64 because HCR_EL2.TGE is set to 1, then:
  - A trap is reported as a trap to EL2.
  - Enables and disables are reported using EC value `0x00`.

The exception is only generated when the instruction does not also generate a higher priority exception. *Exception priority order* on page G1-3400 defines the prioritization of different exceptions on the same instruction.

Table G1-23 shows the AArch32 System registers that contain controls that control trapping to Undefined mode.

Table G1-23 Summary of the registers that control trapping to Undefined mode using AArch32

Register description	Register name
System Control Register	SCTLR
Floating-point Exception Control Register	FPEXC
Architectural Feature Access Control Register	CPACR
Monitor System Debug Control Register	DBGDSCRext
Performance Monitors User Enable Register	PMUSERENR

Table G1-24 summarizes the controls that control trapping to Undefined mode using AArch32.

Table G1-24 Summary of the EL1 controls that control trapping to Undefined mode using AArch32

Control	Type of control	Trap
SCTLR.{nTWE, nTWI}	Trap	*Traps to Undefined mode of PL0 execution of WFE and WFI instructions* on page G1-3477
SCTLR.{SED, ITD}	Disable	*Enable and disable controls for AArch32 deprecated functionality* on page G1-3478
SCTLR.CP15BEN	Enable	
CPACR.TRCDIS	Trap	*Traps to Undefined mode of PL0 and PL1 CP14 accesses to the trace registers* on page G1-3478
CPACR.{cp11, cp10}	Enable	*Enabling PL0 and PL1 accesses to Advanced SIMD and floating-point registers* on page G1-3478
FPEXC.EN	Enable	
CPACR.ASEDIS	Disable	*Disabling PL0 and PL1 access to Advanced SIMD functionality* on page G1-3479
DBGDSCRext.UDCCdis	Trap	*Traps to Undefined mode of PL0 accesses to the Debug Communications Channel (DCC) registers* on page G1-3479
PMUSERENR.{ER, CR, SW, EN}	Trap	*Traps to Undefined mode of PL0 accesses to Performance Monitors registers* on page G1-3481

Undefined mode traps on instructions that fail their condition code check

See *Conditional execution of undefined instructions* on page G1-3430

Undefined mode traps on instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE, but is in a class that has an Undefined mode trap, the behavior of the instruction when the Undefined mode trap is enabled is UNPREDICTABLE. The architecture permits such an instruction to generate an Undefined Instruction exception, but does not require it to do so.

Note

UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE. This means that setting an Undefined mode trap on an instruction changes the set of instructions that might be executed in Non-secure state at EL0 or EL1. This indirectly affects the permitted behavior of UNPREDICTABLE instructions.

If no instructions are configured to generate Undefined mode traps, then the attempted execution of an UNPREDICTABLE instruction in a Non-secure EL0 or EL1 mode cannot generate an Undefined Instruction exception.

Traps of register access instructions

When an attempt to execute an instruction is trapped to Undefined mode, the trap is taken before execution of the instruction. This means that, if the trapped instruction is a register access instruction, before taking the exception:

- No register access is made.
- No side-effects normally associated with the register access occur.

Traps to Undefined mode of PL0 execution of `WFE` and `WFI` instructions

SCTLR provides the following controls to enable `WFE` and `WFI` instruction execution at PL0:

SCTLR.nTWE

1 `WFE` instruction execution is enabled at PL0.

0 Any attempt to execute a `WFE` instruction at PL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

SCTLR.nTWI

1 `WFI` instruction execution is enabled at PL0.

0 Any attempt to execute a `WFI` instruction at PL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

Table G1-25 shows the instructions trapped to Undefined mode when SCTLR.{TWE, TWI} are 0.

Table G1-25 Instructions trapped to Undefined mode when SCTLR.{TWE, TWI} are 0

Enable control	Traps from	Trapped instructions
SCTLR.nTWE	PL0 using AArch32	`WFE`
SCTLR.nTWI		`WFI`

The traps that SCTLR.{TWE, TWI} enable trap the attempted execution of conditional `WFE` or `WFI` instructions only if the instructions pass their condition code check.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- *Wait For Event and Send Event* on page G1-3457.
- *Wait For Interrupt* on page G1-3460.

Enable and disable controls for AArch32 deprecated functionality

When a particular functionality shown in Table G1-26 is disabled, any attempt to access that functionality at PL0 and PL1 using AArch32 is trapped to Undefined mode.

Table G1-26 Traps to Undefined mode on EL0 accesses to deprecated functionality

Deprecated AArch32 functionality	Enable or disable control in the SCTLR	Trapped instructions, or trapped accesses
SETEND instructions	SED	SETEND instructions
Some uses of IT instructions	ITD	See *The effect of setting SCTLR.ITD to 1*.
Accesses to the CP15 DMB, DSB, and ISB barrier operations.	CP15BEN	MCR accesses to the CP15DMB, CP15DSB, and CP15ISB

The effect of setting SCTLR.ITD to 1

When the value of the SCTLR.ITD bit is 1, the IT instruction functionality is disabled for when executing at EL1 or EL0. For more information see the bit description.

Traps to Undefined mode of PL0 and PL1 CP14 accesses to the trace registers

CPACR.TRCDIS enables a trap to Undefined mode of PL0 and PL1 CP14 accesses to the trace registers:

1 PL0 and PL1 CP14 accesses to the trace registers, except for accesses that the appropriate Trace Architecture Specification describes as UNPREDICTABLE or as UNDEFINED, are trapped to Undefined mode

0 PL0 and PL1 CP14 accesses to the trace registers are not trapped to Undefined mode.

Note

- CPACR.TRCDIS might be implemented as RAZ/WI. See the register description for more information.
- The ETMv4 architecture does not permit PL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, PL0 accesses to the trace registers are UNDEFINED.
- PL1 does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

CP14 accesses to the trace registers can have side-effects. When a CP14 access is trapped to Undefined mode or generates an Undefined Instruction exception, no side-effects occur before the exception is taken, see *Traps of register access instructions* on page G1-3477.

If EL3 is implemented and using AArch32, and NSACR.NSTRCDIS is set to 1, then CPACR.TRCDIS is RAO/WI in Non-secure state.

Enabling PL0 and PL1 accesses to Advanced SIMD and floating-point registers

CPACR.{cp11, cp10} enables PL0 and PL1 accesses to the Advanced SIMD and floating-point register file. CPACR.{cp11, cp10} can also enable access to the Advanced SIMD and floating-point register file from PL1 without enabling accesses from PL0.

Note

Software must set CPACR.cp11 and CPACR.cp10 to the same value. See the register description for more information.

Table G1-27 shows the registers for which accesses are enabled by CPACR.{cp11, cp10}.

Table G1-27 Register accesses enabled by the CPACR.{cp11, cp10}

Enabling access from	Registers
PL0 and PL1, or PL1 only[a], using AArch32	FPSCR, FPEXC, FPSID, MVFR0, MVFR1, MVFR2 and any of the Advanced SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers.

a. Depending on the value of CPACR.{cp11, cp10}. See the register description for details.

If EL3 is implemented and using AArch32, and the value of NSACR.{cp11, cp10} is `0b00`, then CPACR.{cp11, cp10} are RAZ/WI in Non-secure state.

FPEXC.EN enables a trap to Undefined mode of PL0 and PL1 access to the Advanced SIMD and floating-point registers.

Table G1-27 shows the registers for which accesses are trapped to Undefined mode when FPEXC.EN is 1.

Table G1-28 Register accesses trapped to Undefined mode when FPEXC.EN is 1

Enabling access from	Registers
PL0 and PL1, or PL1 only[a], using AArch32	FPSCR, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers.

a. Depending on the value of CPACR.{cp11, cp10}. See the register description for details.

For more information, see *Advanced SIMD and floating-point support* on page G1-3466.

Disabling PL0 and PL1 access to Advanced SIMD functionality

CPACR.ASEDIS disables PL0 and PL1 access to the Advanced SIMD instructions.

Table G1-27 shows the instructions disabled by CPACR.ASEDIS.

Table G1-29 Instructions disabled by CPACR.ASEDIS

Enabling access from	Instructions
PL0 and PL1 using AArch32	All Advanced SIMD instructions. See Chapter F5 *T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings*

If EL3 is implemented and using AArch32, and NSACR.NSASEDIS is set to1, then CPACR.ASEDIS is RAO/WI in Non-secure state.

For more information, see *Additional controls on Advanced SIMD functionality* on page G1-3470.

Traps to Undefined mode of PL0 accesses to the Debug Communications Channel (DCC) registers

DBGDSCRext.UDCCdis enables a trap to Undefined mode of PL0 accesses to the DCC registers:

1 PL0 accesses to the DCC registers are trapped to Undefined mode

0 PL0 accesses to the DCC registers are not trapped to Undefined mode.

The traps of DBGDTRRXint and DBGDTRTXint are ignored when the PE is in Debug state.

Table G1-30 shows the accesses that are trapped to Undefined mode when DBGDSCRext.UDCCdis is 1.

Table G1-30 Accesses trapped to Undefined mode when DBGDSCRext.UDCCdis is 1

Traps from	Registers
PL0 using AArch32	DBGDSCRint, DBGDTRRXint, DBGDTRTXint, DBGDIDR, DBGDSAR, DBGDRAR

Note

All accesses to these registers are trapped, including `LDC` and `STC` accesses to DBGDTRTXint and DBGDTRRXint, and `MRRC` accesses to DBGDSAR and DBGDRAR,

Traps to Undefined mode of PL0 accesses to Performance Monitors registers

PMUSERENR.{ER, CR, SW, EN} enable PL0 accesses to the optional Performance Monitors Extension registers. For each of these controls:

1 Accesses from PL0 are enabled.

0 Accesses from PL0 are not enabled.

The accesses that these controls enable might be reads, writes, or both.

Note

- PL1 does not provide traps on Performance Monitors register accesses through the optional memory-mapped external debug interface.
- If the optional Performance Monitors Extension is not implemented, then the Performance Monitors registers, including PMUSERENR, are reserved.

Table G1-31 shows the registers for which PL0 accesses are enabled. If no bit enables access to the register, the access is trapped to Undefined mode. For each register, the table shows the type of access enabled.

Table G1-31 Register accesses trapped to Undefined mode when disabled from PL0

Traps from	Enable control	Registers	Access type
PL0 using AArch32	ER	PMXEVCNTR, PMEVCNTR<n>	R
		PMSELR	RW
	CR	PMCCNTR, accessed using an `MRC`	R
	CR	PMCCNTR, accessed using an `MRRC`	R
	SW	PMSWINC	W
	EN	PMCNTENSET, PMCNTENCLR, PMOVSR, PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTYPER, PMXEVCNTR, PMUSERENR, PMOVSSET, PMEVCNTR<n>, PMEVTYPER<n>, PMCCFILTR.	RW

G1.17.2 EL2 configurable instruction enables, disables, and traps

The trapping and related mechanisms provided by EL2 include:

- Trapping attempted execution of certain instructions to Hyp mode, so that a hypervisor can emulate the instruction. This section describes these traps.
- Routing certain exceptions to Hyp mode, see:
  - *Routing general exceptions to EL2* on page G1-3410.
  - *Routing debug exceptions to EL2* on page G1-3411.
  - *Asynchronous exception routing controls* on page G1-3420.
- Providing aliased versions of some system control registers, see *Traps to Hyp mode of Non-secure EL0 and EL1 reads of ID registers* on page G1-3491.

Software configures enables, disables, and traps for instructions executed in Non-secure state at EL0, EL1, and EL2, using AArch32 EL2-mode System registers. Some controls only apply to instructions executed at EL0, and EL1. Some controls only apply to instructions executed at EL2.

Disabled instructions generate an Undefined Instruction exception taken from AArch32 state. The Undefined Instruction exception is taken to:

- Undefined mode, if taken from EL0 or EL1.
- Hyp mode if taken from EL2.

Trapped instructions generate a Hyp Trap exception taken from AArch32 state to Hyp mode, and present exception syndrome information in the HSR.

For more information about exception reporting, see *Use of the HSR* on page G4-3728.

The exception is only generated if when all of the following apply:

- The PE is in Non-secure EL0, EL1, or EL2.
- The instruction that generates the exception does not also generate a higher priority exception. *Exception priority order* on page G1-3400 defines the prioritization of different exceptions on the same instruction.

Table G1-32 shows the AArch32 System registers that contain trap enable controls.

Table G1-32 Summary of the registers that control trapping to Hyp mode

Register description	Register name
Hypervisor Configuration Register	HCR
Hypervisor System Trap Register	HSTR
Hyp Architectural Feature Trap Register	HCPTR
Hyp Debug Control Register	HDCR.

Table G1-33 summarizes the trap enable controls that are in the AArch32 System registers.

Table G1-33 Summary of the EL2 controls that control trapping to Hyp mode

Control	Type of control	Trap
HSCTLR.{SED, ITD}	Disable	*Enable and disable controls for AArch32 deprecated functionality* on page G1-3485
HSCTLR.CP15BEN	Enable	
HCR.{TRVM, TVM}	Trap	*Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers* on page G1-3485

Table G1-33 Summary of the EL2 controls that control trapping to Hyp mode (continued)

Control	Type of control	Trap
HCR.HCD	Disable	*Disabling Non-secure state execution of HVC instructions* on page G1-3486
HCR.TTLB	Trap	*Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions* on page G1-3487
HCR.{TSW, TPC, TPU}	Trap	*Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions* on page G1-3488

HCPTR.TTA	Trap	*Trapping CP14 accesses to trace registers* on page G1-3496
HSTR.{T0-T3, T5-T13, T15}	Trap	*General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to CP15 System registers* on page G1-3497
HDCR.{TDRA, TDOSA, TDA}	Trap	*Traps to Hyp mode of CP14 accesses to debug registers* on page G1-3499
HDCR.{TPM, TPMCR}	Trap	*Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers* on page G1-3501

Also see the following for more general information about traps to Hyp mode:

- *Hyp traps on instructions that fail their condition code check*.
- *Hyp traps on instructions that are UNPREDICTABLE* on page G1-3484.
- *Traps of register access instructions* on page G1-3484.

Hyp traps on instructions that fail their condition code check

If the PE executes an instruction that has a Hyp trap set, and that instruction fails its condition code check, unless the specific trap description states otherwise, it is IMPLEMENTATION DEFINED which of the following occurs:

- The instruction generates a Hyp Trap exception.
- The instruction executes as a `NOP`.

Note

The architecture requires that a Hyp trap on a conditional SMC instruction generates an exception only if the instruction passes its condition code check, see *Traps to Hyp mode of Non-secure EL1 execution of SMC instructions* on page G1-3491.

This is consistent with the treatment of conditional undefined instructions, as described in *Conditional execution of undefined instructions* on page G1-3430. Any implementation must be consistent in its handling of instructions that fail their condition code check, meaning that whenever a Hyp trap is set on such an instruction it must either:

- Always generate a Hyp Trap exception.
- Always treat the instruction as a NOP.

This requirement that an implementation is consistent in its handling of instructions that fail their condition code check also means that the IMPLEMENTATION DEFINED part of the requirements of *Conditional execution of undefined instructions* on page G1-3430 must be consistent with the handling of Hyp traps on instructions that fail their condition code check, as Table G1-34 shows:

Table G1-34 Consistent handling of instructions that fail their condition code check

Behavior of conditional UNDEFINED instruction[a]	Hyp trap on instruction that fails its condition code check[b]
Executes as a NOP	Executes as a NOP
Generates an Undefined Instruction exception	Generates a Hyp Trap exception

a. As defined in *Conditional execution of undefined instructions* on page G1-3430. In Non-secure EL0 and EL1 modes, this applies only if no Hyp trap is set for the instruction, otherwise see the behavior in the other column of the table.

b. For a trapped instruction executed in a Non-secure EL1 or EL0 mode.

Hyp traps on instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE, but is in a class that has a Hyp trap, the behavior of the instruction when the Hyp trap is enabled is UNPREDICTABLE. The architecture permits such an instruction to generate a Hyp Trap exception, but does not require it to do so.

Note

UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE. This means that setting a Hyp trap on an instruction changes the set of instructions that might be executed in Non-secure state at EL1 or EL0. This indirectly affects the permitted behavior of UNPREDICTABLE instructions.

If no instructions are configured to generate Hyp traps, then the attempted execution of an UNPREDICTABLE instruction in a Non-secure EL1 or EL0 mode cannot generate a Hyp Trap exception.

Traps of register access instructions

When an attempt to execute an instruction is trapped to Hyp mode, the trap is taken before execution of the instruction. This means that, if the trapped instruction is a register access instruction, before taking the Hyp Trap exception:

- No register access is made.
- No side-effects normally associated with the register access occur.

Enable and disable controls for AArch32 deprecated functionality

When a particular functionality shown in Table G1-35 is disabled, any attempt to access that functionality at EL2 using AArch32 generates an Undefined Instruction exception taken to Hyp mode.

Table G1-35 Traps to Undefined mode on EL2 accesses to deprecated functionality

Deprecated AArch32 functionality	Enable or disable control in the HSCTLR	Trapped instructions, or trapped accesses
SETEND instructions	SED	SETEND instructions
Some uses of IT instructions	ITD	See *The effect of setting HSCTLR.ITD to 1*.
Accesses to the CP15 DMB, DSB, and ISB barrier operations.	CP15BEN	MCR accesses to the CP15DMB, CP15DSB, and CP15ISB

Note

These controls have no effect on instructions executed at EL0 or EL1.

The effect of setting HSCTLR.ITD to 1

When the value of the HSCTLR.ITD bit is 1, the IT instruction functionality is disabled when executing at EL2. For more information see the bit description.

Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers

EL2 provides the following traps for reads and writes to the virtual memory control registers:

- HCR.TRVM, for read accesses:
  - **1** Non-secure EL1 reads of the virtual memory control registers are trapped to Hyp mode.
  - **0** Non-secure EL1 reads of the virtual memory control registers are not trapped to Hyp mode.
- HCR.TVM, for write access:
  - **1** Non-secure EL1 writes to the virtual memory control registers are trapped to Hyp mode.
  - **0** Non-secure EL1 writes to the virtual memory control registers are not trapped to Hyp mode.

Table G1-36 shows:

- The registers for which:
  - Reads are trapped to Hyp mode when HCR.TRVM is 1.
  - Writes are trapped to Hyp mode when HCR.TVM is 1.
- How exceptions are reported in the HSR, when the exception is taken to AArch32 state.

Table G1-36 Register read and write accesses trapped when HCR.{TRVM, TVM} are 1

Traps from	Registers	Syndrome reporting in HSR
Non-secure EL1 using AArch32	SCTLR, TTBR0, TTBR1, TTBCR, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR, NMRR, MAIR0, MAIR1, CONTEXTIDR.	Trapped MCR or MRC access to CP15, using EC value 0x03 Trapped MCRR or MRRC access to CP15, using EC value 0x04

Note

These registers are not accessible at EL0.

Disabling Non-secure state execution of HVC instructions

HCR.HCD is only implemented if EL3 is not implemented. Otherwise, it is RES0. See the HCR register description.

HCR.HCD disables HVC instruction execution in Non-secure state:

1 Any attempt to execute a HVC instruction in Non-secure state generates an Undefined Instruction exception that is taken without a change of Exception level.

0 HVC instruction execution is enabled at EL2 and Non-secure EL1.

Table G1-37 shows how the exceptions are reported in HSR when the exception is taken from Hyp mode as an Undefined Instruction exception.

Table G1-37 Instruction that causes exceptions when HCR.HCD is 1

Attempted execution in	Instruction	Syndrome reporting in HSR
Hyp mode	HVC	Exception for an unknown reason, using EC value 0x00
Mode other than Hyp mode	HVC	Not applicable

Note

HVC instructions are always UNDEFINED at EL0.

Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions

In the ARMv8-A architecture, the system instruction encoding space includes TLB maintenance instructions.

HCR.TTLB enables a trap to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions:

1 Any attempt to execute a `TLBI` instruction at Non-secure EL1 is trapped to Hyp mode.

0 Non-secure EL1 execution of `TLBI` instructions is not trapped to Hyp mode.

Table G1-38 shows the instructions that are trapped, and how the exceptions that are generated because HCR.TTLB is 1 are reported in HSR.

Table G1-38 Instructions trapped to Hyp mode when HCR.TTLB is 1

Traps from	Trapped instructions	Syndrome reporting in HSR
Non-secure EL1 using AArch32	TLBIALLIS, TLBIMVAIS, TLBIASIDIS, TLBIMVAAIS, TLBIALL, TLBIMVA, TLBIASID, DTLBIALL, DTLBIMVA, DTLBIASID, ITLBIALL, ITLBIMVA, ITLBIASID, TLBIMVAA, TLBIMVALIS, TLBIMVAALIS, TLBIMVAL, TLBIMVAAL	Trapped `MCR` or `MRC` access to CP15, using EC value `0x03`

Note

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see *The scope of TLB maintenance instructions* on page G4-3696.

Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions

Table G1-39 shows the HCR trap controls that trap cache maintenance instructions to Hyp mode. When one of these controls is set to 1, any attempt to execute one of the corresponding CP15 c7 operations from a Non-secure EL1 mode is trapped to Hyp mode.

Table G1-39 Controls for trapping cache maintenance instructions to Hyp mode

Trap control	Trapped instructions
HCR.TSW	Data cache maintenance by set/way
HCR.TPC	Data cache maintenance to point of coherency
HCR.TPU	Cache maintenance to point of unification

For HCR.{TSW, TPC,TPU} == 1, Table G1-40 shows the instructions that are trapped to Hyp mode, and how the exceptions are reported in HSR.

Table G1-40 Instructions trapped to Hyp mode when HCR.{TSW, TPC, TPU} are 1

Traps from	Trap control	Trapped instructions	Syndrome reporting in HSR
Non-secure EL1 using AArch32	TSW	DCISW, DCCSW, DCCISW	Trapped `MCR` or `MRC` access to CP15, using EC value `0x3`
	TPC	DCIMVAC, DCCIMVAC, DCCMVAC	
	TPU	ICIMVAU, ICIALLU, ICIALLUIS, DCCMVAU	

Note

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see *Cache maintenance instructions, functional group* on page G4-3794.

Traps to Hyp mode of Non-secure EL1 accesses to the Auxiliary Control Register

HCR.TAC enables a trap to Hyp mode of accesses to the Auxiliary Control Register from Non-secure EL1:

1 Non-secure EL1 accesses to the Auxiliary Control Register are trapped to Hyp mode.

0 Non-secure EL1 accesses to the Auxiliary Control Register are not trapped to Hyp mode.

Table G1-41 shows the registers for which accesses are trapped to Hyp mode, and how the exceptions that are generated because HCR.TAC is 1 are reported in HSR:

Table G1-41 Register accesses trapped to Hyp mode when HCR.TAC is 1

Traps from	Registers	Syndrome reporting in HSR
Non-secure EL1 using AArch32	ACTLR	Trapped `MCR` or `MRC` access to CP15 access, using EC value `0x03`

Note

- Setting HCR.TAC to 1 means that any attempt to access the ACTLR from Non-secure state other than from Hyp mode generates a Hyp Trap exception, unless the IMPLEMENTATION DEFINED register description indicates that the attempted access is UNDEFINED.
- These registers are not accessible at EL0.

Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations

The lockdown, DMA, and TCM features of the ARM architecture are IMPLEMENTATION DEFINED. However ARMv8-A architecture reserves the encodings the CP15 register listed in Table G1-42 for control of these features.

The HCR.TIDCP bit can be used as a trap enable control, to enable a trap that traps accesses to lockdown, DMA, and TCM operations from Non-secure EL0 and EL1 to Hyp mode. Whether HCR.TIDCP is used as a trap enable control is IMPLEMENTATION DEFINED. If it is, then when HCR.TIDCP is set to 1:

- Any attempt to use an `MCR` or `MRC` instruction with one of these encodings from a Non-secure EL1 mode generates a Hyp Trap exception.
- On an attempt to use an `MCR` or `MRC` instruction with one of these encodings from Non-secure EL0 mode, it is IMPLEMENTATION DEFINED which of the following occurs:
  - The PE takes the Hyp Trap exception.
  - The PE treats the instruction as UNDEFINED, and takes the Undefined Instruction exception to Non-secure Undefined mode.
- Any lockdown fault in the memory system caused by the use of these operations in Non-secure state generates a Data Abort exception that is taken to Hyp mode.

Note

This means that a Hyp Trap exception taken from EL1 to EL2, generated because of a configuration setting in HCR.TIDCP is a higher priority exception than an Undefined Instruction exception generated because either the CP15 register is unallocated or because it is never accessible at EL1. This an exception to the general exception prioritization described in *Exception priority order* on page G1-3400.

If HCR.TIDCP is used as a trap enable control, Table G1-42 shows the register encodings for which accesses are trapped to Hyp mode when it is 1, and how the exceptions are reported in HSR.

Table G1-42 Encodings trapped to Hyp mode when HCR.TIDCP is 1

Traps from	Register encodings	Syndrome reporting in HSR
Non-secure EL0 and EL1 using AArch32	An access to any of the following encodings: • CRn==c9, opc1=={0-7}, CRm=={c0-c2, c5-c8}, opc2=={0-7}. See *VMSAv8-32 CP15 c9 register summary* on page G4-3770. • CRn==c10, opc1=={0-7}, CRm=={c0, c1, c4, c8}, opc2=={0-7}. See *VMSAv8-32 CP15 c10 register summary* on page G4-3771. • CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}. See *VMSAv8-32 CP15 c11 register summary* on page G4-3771.	Trapped `MCR` or `MRC` access to CP15, using EC value `0x03`

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

Note

ARM expects the trapping of Non-secure User mode access to these functions to Hyp mode to be unusual, and used only when the hypervisor is virtualizing User mode operation. ARM strongly recommends that, unless the hypervisor must virtualize User mode operation, a Non-secure User mode access to any of these functions generates an Undefined Instruction exception, as it would if the implementation did not include EL2. The PE then takes this exception to Non-secure Undefined mode.

Traps to Hyp mode of Non-secure EL1 execution of SMC instructions

HCR.TSC enables a trap to Hyp mode of Non-secure EL1 execution of SMC instructions:

1 Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to Hyp mode, regardless of the value of SCR.SCD.

0 Non-secure EL1 execution of SMC instructions is not trapped to Hyp mode.

Table G1-43 shows how the exceptions that are generated because HCR.TSC is 1 are reported in HSR:

Table G1-43 SMC Instruction trapped to Hyp mode when HCR.TSC is 1

Traps from	Trapped instruction	Syndrome reporting in HSR
Non-secure EL1 using AArch32	*SMC* on page F7-3022	Trapped SMC instruction execution in AArch32 state, using EC value 0x13

The trap that HCR.TSC enables traps the attempted execution of a conditional SMC instruction only if the instruction passes its condition code check.

Note

- This trap is implemented only if the implementation includes EL3.
- SMC instructions are UNDEFINED at EL0.

For more information about SMC instructions, see *SMC* on page F7-3022.

Traps to Hyp mode of Non-secure EL0 and EL1 reads of ID registers

Other than the MIDR, MPIDR, and PMCR.N, the ID registers are divided into groups, with a trap enable control in the HCR for each group. Setting one of these HCR bits to 1 means that any attempt at Non-secure EL1 or EL0 to read a register from that group from a Non-secure mode other than Hyp mode generates a Hyp Trap exception, unless the register description indicates that the attempted access is UNDEFINED. These traps have no effect on writes to these registers.

Note

Most, but not all, of the ID registers are RO registers, and write accesses to these registers behave as described in *Read-only and write-only register encodings* on page G4-3747. Each register description identifies whether the register is RO.

Table G1-44 shows the trap enable controls for the ID register groups, and shows the subsections that list the ID registers in each group. Each subsection describes how the trap is reported in HSR.

Table G1-44 ID register groups for traps of Non-secure EL0 and EL1 reads of the ID registers

Trap control	Register group
HCR_EL2.TID0	*ID group 0, Primary device identification registers* on page G1-3492
HCR_EL2.TID1	*ID group 1, Implementation identification registers-* on page G1-3493
HCR_EL2.TID2	*ID group 2, Cache identification registers* on page G1-3493
HCR_EL2.TID3	*ID group 3, Detailed feature identification registers* on page G1-3493

For the MIDR, MPIDR, and PMCR.N registers, EL2 provides read/write aliases of the registers. The original register becomes accessible only from Hyp mode or Secure state, and a read of the original register from Non-secure EL0 and EL1 returns the value of the read/write alias. This register substitution is invisible to the software reading the register.

Table G1-45 ID register substitution provided by EL2 using AArch32

Register	Original	Alias, EL2 using AArch32
Main ID	MIDR	VPIDR
Multiprocessor Affinity	MPIDR	VMPIDR
Performance Monitors Control Register	PMCR.N	HDCR.HPMN

Note

- If the optional Performance Monitors Extension is not implemented, HDCR.HPMN is RES0 and PMCR is reserved.
- HDCR.HPMN also affects whether a Performance Monitors counter can be accessed from Non-secure EL1 or EL0. See the register description of HDCR for more information.
- PMCR contains other fields that identify the implementation. For more information about trapping PMCR, see *Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers* on page G1-3501.

A reset into AArch32 state sets VPIDR to the MIDR value, VMPIDR to the MPIDR value, and HDCR.HPMN to the PMCR.N value.

Reads of the MIDR, the MPIDR, or the PMCR from EL2 or Secure state are unchanged by the implementation of EL2, and access the physical registers. This also applies to accesses from Monitor mode with SCR.NS set to 1.

Note

- A hypervisor often has to virtualize one or both of the MIDR and MPIDR because:
  - The MIDR provides information about the implementation, the PE name, and revision information.
  - In a multiprocessor implementation, the MPIDR defines the position of a PE within a cluster.
- The PE ID registers that can be accessed from Non-secure state can present a virtualization hole, because system software can use them to determine information about the PE that a hypervisor might want to conceal.

  However, many uses of virtualization do not require the hypervisor to disguise the identity of the PE.

ID group 0, Primary device identification registers

In AArch32 state, these registers identify some top-level implementation choices.

Table G1-46 shows the ID registers that are in ID group 0 for traps to Hyp mode, and how the exceptions that are generated because HCR.TID0 is set to 1 are reported in HSR.

Table G1-46 ID group 0 registers

Traps from	Group 0 registers	Syndrome reporting in HSR
Non-secure EL0 and EL1 using AArch32	FPSID	Trapped `MRC` or `VMRS` access to CP10, for ID group traps, using EC value `0x08`
	JIDR	Trapped `MCR` or `MRC` access to CP14, using EC value `0x05`

Note

If HCPTR traps accesses to Advanced SIMD and floating-point functionality, then for a read of FPSID, the HCPTR trap has priority over the trap in Table G1-46 on page G1-3492.

ID group 1, Implementation identification registers-

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

Table G1-47 shows the ID registers that are in ID group 1 for traps to Hyp mode, and how the exceptions that are generated because HCR.TID1 is set to 1 are reported in HSR.

Table G1-47 ID group 1 registers

Traps from	Group 1 registers	Syndrome reporting in HSR
Non-secure EL0 and EL1 using AArch32	TCMTR, TLBTR, REVIDR, AIDR	Trapped `MCR` or `MRC` access to CP15, using EC value `0x03`

ID group 2, Cache identification registers

These registers describe and control the cache implementation.

Table G1-48 shows the ID registers that are in ID group 2 for traps to EL2, and how the exceptions that are generated because HCR.TID2 is set to 1 are reported in HSR:

Table G1-48 ID group 2 registers

Traps from	Group 2 registers	Syndrome reporting in HSR
Non-secure EL0 and EL1 using AArch32	CTR, CCSIDR, CLIDR, CSSELR	Trapped `MCR` or `MRC` access to CP15, using EC value `0x03`

ID group 3, Detailed feature identification registers

These registers provide detailed information about the features of the implementation.

Note

In AArch32 state, these registers are called the CPUID registers. There is no requirement for this trap to apply to those registers that the CPUID Identification Scheme defines as reserved. See *The CPUID identification scheme* on page G4-3788.

Table G1-49 shows the ID registers that are in ID group 3 for traps to Hyp mode, and how the exceptions that are generated because HCR.TID3 is set to 1 are reported in HSR.

Table G1-49 ID group 3 registers

Traps from	Group 3 registers	Syndrome reporting in HSR
Non-secure EL0 and EL1 using AArch32	MVFR0, MVFR1, MVFR2.	Trapped `MRC` or `VMRS` access to CP10, using EC value `0x08`
	ID_PFR0, ID_PFR1. ID_DFR0. ID_AFR0. ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3. ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5.	Trapped `MCR` or `MRC` access to CP15, using EC value `0x03`
	An `MRC` access to any of the following encodings: • `opc1` == 0, `CRn` == c0, `CRm` == {c3-c7}, `opc2` == {0, 1}. • `opc1` == 0, `CRn` == c0, `CRm` == {c3-c7}, `opc2` == 2. • `opc1` == 0, `CRn` == c0, `CRm` == c5, `opc2` == {4, 5}.	

Note

If HCPTR traps accesses to Advanced SIMD and floating-point functionality, then for reads of MVFR0, MVFR1, and MVFR2 the HCPTR trap has priority over the traps in Table G1-49.

Traps to Hyp mode of Non-secure EL0 and EL1 execution of `WFE` and `WFI` instructions

EL2 provides the following traps for `WFE` and `WFI` instructions:

- HCR.TWE:
  - **1** Any attempt to execute a `WFE` instruction at Non-secure EL1 or EL0 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state.
  - **0** Non-secure EL1 or EL0 execution of `WFE` instructions is not trapped to Hyp mode.
- HCR.TWI:
  - **1** Any attempt to execute a `WFI` instruction at Non-secure EL1 or EL0 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state.
  - **0** Non-secure EL1 or EL0 execution of `WFI` instructions is not trapped to Hyp mode.

Table G1-50 shows how the exceptions that are generated because HCR.{TWE, TWI} are 1 are reported in HSR.

Table G1-50 Instructions trapped to Hyp mode when HCR.{TWE, TWI} are 1

Traps from	Trapped instructions	Syndrome reporting in HSR
Non-secure EL0 and EL1 usingAArch32	`WFE`	Trapped `WFI` or `WFE` instruction, using EC value `0x01`
	`WFI`	

The traps that HCR.{TWE, TWI} enable trap the attempted execution of conditional `WFE` or `WFI` instructions only if the instructions pass their condition code check.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- *Wait For Event and Send Event* on page G1-3457.
- *Wait For Interrupt* on page G1-3460.

General trapping to Hyp mode of Non-secure accesses to the Advanced SIMD and floating-point registers

HCPTR.{TCP11, TCP10} enable a trap to Hyp mode of accesses to Advanced SIMD and floating-point registers, from EL2 and Non-secure EL0 and EL1.

Setting HCPTR.{TCP11, TCP10} to 0b11 means that an access to an Advanced SIMD and floating-point register that is otherwise permitted:

- From a Non-secure mode other than Hyp mode, generates a Hyp Trap exception.
- From Hyp mode, generates an Undefined Instruction exception, taken to Hyp mode, with the HSR holding a syndrome for the instruction.

When HCPTR.{TCP11, TCP10} is:

0b11 EL2, and Non-secure EL1 and EL0, accesses to the Advanced SIMD and floating-point registers are trapped to Hyp mode.

0b00 EL2, and Non-secure EL1 and EL0, accesses to the Advanced SIMD and floating-point registers are not trapped to Hyp mode.

Note

Software must set HCPTR.TCP11 and HCPTR.TCP10 to the same value. See the register description for more information.

Table G1-51 shows the registers for which accesses are trapped to Hyp mode when HCPTR.{TCP11, TCP10} are `0b11`, and how the exceptions are reported in HSR.

Table G1-51 Register accesses trapped to Hyp mode when HCPTR.{TCP11, TCP10} is 0b11

Traps from	Registers	Syndrome reporting in HSR
EL2 and Non-secure EL0 and EL1 using AArch32	FPSID, MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See *Advanced SIMD and floating-point system registers* on page G1-3472.	Trapped access to Advanced SIMD and floating-point register, using EC value `0x07`[a, b]

a. The architecture defines writes to the FPSID from EL1 or higher as an access to an Advanced SIMD and floating-point register.

b. Writes to the MVFR0, MVFR1, and MVFR2 from EL1 using AArch32 are UNPREDICTABLE. This means that it is IMPLEMENTATION DEFINED whether these writes are defined as accesses to Advanced SIMD and floating-point registers.

Note

A hypervisor might use these traps when lazy switching between Guest OSs.

If EL3 is implemented and using AArch32, and NSACR.{cp11, cp10} is set to `0b11`, then HCPTR.{TCP11, TCP10} behave as RAO/WI, regardless of their actual value.

Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality

HCPTR.TASE enables a trap to Hyp mode of accesses to the Advanced SIMD instructions when HCPTR.{TCP11, TCP10} is `0b00`, from EL2 and Non-secure EL0 and EL1.

Setting HCPTR.TASE to 1 means that an Advanced SIMD instruction that is otherwise permitted:

- From a Non-secure mode other than Hyp mode, generates a Hyp Trap exception.
- From Hyp mode, generates an Undefined Instruction exception, taken to Hyp mode, with the HSR holding a syndrome for the instruction.

When HCPTR.TASE is:

1 An attempt to execute an Advanced SIMD instruction at EL2, Non-secure EL0 or EL1, is trapped to Hyp mode.

0 Execution of Advanced SIMD instructions at EL2, Non-secure EL0 or EL1, is not trapped to Hyp mode.

Table G1-27 on page G1-3479 shows the instructions which are trapped to Hyp mode when the HCPTR.TASE trap is enabled and how the exceptions are reported in HSR.

Table G1-52 Instructions trapped to Hyp mode when HCPTR.TASE is set to 1

Traps from	Instructions	Syndrome reporting in HSR
EL2, Non-secure EL1 and EL0 using AArch32	All Advanced SIMD instructions. See Chapter F5 *T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings*	Trapped access to Advanced SIMD and floating-point register, using EC value `0x07`

If EL3 is implemented and using AArch32, and NSACR.NSASEDIS is set to 1, then HCPTR.TASE behaves as RAO/WI, regardless of its actual value.

For more information, see *Additional controls on Advanced SIMD functionality* on page G1-3470.

Trapping to Hyp mode of Non-secure EL1 accesses to the CPACR

HCPTR.TCPAC enables a trap to EL2 of Non-secure EL1 accesses to the CPACR:

1 Non-secure EL1 accesses to the CPACR are trapped to Hyp mode.

0 Non-secure EL1 accesses to the CPACR are not trapped to Hyp mode.

Table G1-53 shows how the exceptions that are generated because HCPTR.TCPAC is 1 are reported in HSR:

Table G1-53 Register accesses trapped to Hyp mode when HCPTR.TCPAC is 1

Traps from	Register	Syndrome reporting in HSR
Non-secure EL1 using AArch32	CPACR	Trapped `MCR` or `MRC` access to CP15, using EC value `0x03`

Note

- In ARMv7 and earlier versions of the ARM architecture, one function of the CPACR is as an ID register that identifies what coprocessor functionality is implemented. Legacy software might use this identification mechanism. A hypervisor can use this trap to emulate this mechanism.
- CPACR is not accessible at EL0.

Trapping CP14 accesses to trace registers

HCPTR.TTA enables a trap to Hyp mode of CP14 register accesses to the trace registers, from both EL2 and Non-secure EL0 and EL1.

Setting HCPTR.TTA to 1 means that an access to a trace register that is otherwise permitted:

- From a Non-secure mode other than Hyp mode, generates a Hyp Trap exception.
- From Hyp mode, generates an Undefined Instruction exception, taken to Hyp mode, with the HSR holding a syndrome for the instruction.

When HCPTR.TTA is:

1 EL2, and Non-secure EL0 and EL1, CP14 register accesses to the trace registers, except for accesses that the appropriate Trace Architecture Specification describes as UNPREDICTABLE or as UNDEFINED, are trapped to Hyp mode.

0 EL2, and Non-secure EL0 or EL1, CP14 register accesses to the trace registers are not trapped to Hyp mode.

Note

- HCPTR.TTA might be implemented as RAO/WI. See the register description for more information.
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

CP14 register accesses to the trace registers can have side-effects. When a CP14 register access is trapped to Hyp mode or generates an Undefined Instruction exception, no side-effects occur before the exception is taken, see *Traps of register access instructions* on page G1-3484.

Table G1-54 shows the registers for which accesses are trapped to Hyp mode when HCPTR.TTA is 1, and how the exceptions are reported in HSR.

Table G1-54 Register accesses trapped to Hyp mode when HCPTR.TTA is 1

Traps from	Registers	Syndrome reporting in HSR
Non-secure EL0, EL1, and EL2 using AArch32	All implemented trace registers	For accesses using: • `MCR` or `MRC` instructions, trapped `MCR` or `MRC` access to CP14, using EC value `0x05`. • `MCRR` or `MRRC` instructions, trapped `MCRR` or `MRRC` access to CP14, using EC value `0x0C`.

If EL3 is implemented and using AArch32, and NSACR.NSTRCDIS is set to 1, then HCPTR.TTA behaves as RAO/WI, regardless of its actual value.

General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to CP15 System registers

HSTR.{T0-T3, T5-T13, T15} enable traps to Hyp mode of accesses to the CP15 System registers, by the accessed primary CP15 register number, {c0-c3, c5-c13, c15}. These traps are from AArch32 state only, so they are from both:

- Non-secure EL1 using AArch32.
- Non-secure EL0 using AArch32.

When the value of a HSTR.Tx trap control is:

1 Any EL1 access is trapped.

An EL0 access is trapped if it would not be UNDEFINED if the bit is zero.

0 AArch32 state Non-secure EL0 or EL1 accesses to the corresponding register are not trapped to Hyp mode.

Note

This means that a Hyp Trap exception taken from EL1 to EL2, generated because of a configuration setting in HSTR.Tx is a higher priority exception than an Undefined Instruction exception generated because either the CP15 register is unallocated or because it is never accessible at EL1. This an exception to the general exception prioritization described in *Exception priority order* on page G1-3400.

Table G1-55 shows the accesses that are trapped to Hyp mode, and how the exceptions are reported in HSR.

Table G1-55 Accesses trapped to Hyp mode when a HSTR.Tx trap is enabled

Traps from	Trap control	Trapped accesses	Syndrome reporting in HSR
EL0 and EL1 using AArch32	Tx	MCR and MRC instructions, with CRn set to x	Trapped MCR or MRC access to CP15, using EC value 0x03.
		MCRR and MRRC instructions, with CRm set to x	Trapped MCRR or MRRC access to CP15, using EC value 0x04.

For example, when HSTR.T7 is set to 1:

- Any 32-bit CP15 access from a Non-secure EL0 or EL1 mode, using an MRC or MCR instruction with CRn set to c7, is trapped to Hyp mode.
- Any 64-bit CP15 access from a Non-secure EL0 or EL1 mode, using an MRRC or MCRR instructions with CRm set to c7, is trapped to Hyp mode.

Note

- Bits[4,14] of the HSTR are reserved, RES0. Although the Generic Timer control registers are implemented in CP15 c14, EL2 does not provide a trap on accesses to the Generic Timer CP15 registers.
- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide finer-grained control of control of trapping of IMPLEMENTATION DEFINED features.

CP15 register with IMPLEMENTATION DEFINED access permission from EL0

For a trapped primary CP15 register, if it is IMPLEMENTATION DEFINED whether, when the corresponding trap bit has a value of 0, an access from Non-secure User mode is undefined, then, when the corresponding trap bit is set to 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure User mode generates:

- A Hyp Trap exception.
- An Undefined Instruction exception taken to Non-secure Undefined mode.

Note

ARM expects that trapping of Non-secure User mode accesses to CP15 to Hyp mode will be unusual, and used only when the hypervisor must virtualize User mode operation. ARM recommends that, whenever possible, Non-secure User mode accesses to CP15 behave as they would if the processor did not implement EL2, generating an Undefined Instruction exception taken to Non-secure Undefined mode if the architecture does not support the User mode access.

Traps to Hyp mode of CP14 accesses to debug registers

Bits in HDCR control the trapping of Non-secure CP14 accesses to Hyp mode. When the value of a HDCR control bit is 1, and the PE is executing in a Non-secure mode other than Hyp mode and is in Non-debug state, any access to an associated debug register through the CP14 interface generates a Hyp Trap exception.

Note

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interface.

CP14 register accesses to the debug registers can have side-effects. When a CP14 register access is trapped to Hyp mode, no side-effects occur before the exception is taken to Hyp mode. See *Traps of register access instructions* on page G1-3484.

Table G1-56 shows the trap enable controls, and shows the subsections that list the accesses trapped. Each subsection describes how the trap is reported in HSR.

Table G1-56 Traps of Non-secure EL0 and EL1 accesses to debug registers

Trap control	Trap
HDCR.TDRA	*Traps to Hyp mode of CP14 accesses to debug registers*
HDCR.TDOSA	*Trapping CP14 accesses to powerdown debug registers*
HDCR.TDA	*Trapping general CP14 accesses to debug registers* on page G1-3500

Trapping CP14 accesses to Debug ROM registers

HDCR.TDRA enables a trap to Hyp mode of Non-secure EL0 and EL1 CP14 accesses to the Debug ROM registers:

1 Non-secure EL0 or EL1 CP14 accesses to the Debug ROM registers are trapped to Hyp mode.

0 Non-secure EL0 or EL1 CP14 accesses to the Debug ROM registers are not trapped to Hyp mode.

This trap applies to Non-secure EL0 only if it is using AArch32.

Table G1-57 shows the register accesses that are trapped to Hyp mode when HDCR.TDRA is 1, and how the exceptions are reported in HSR:

Table G1-57 Register accesses trapped to Hyp mode when HDCR.TDRA is 1

Traps from	Registers	Syndrome reporting in HSR
Non-secure EL0 and EL1 using AArch32	DBGDRAR, DBGDSAR	For accesses using: • `MCR` or `MRC` instructions, trapped `MCR` or `MRC` access to CP14, using EC value `0x05`. • `MRRC` instructions, trapped `MRRC` access to CP14, using EC value `0x0C`.

If HDCR.TDE or HCR.TGE is 1, behavior is as if HDCR.TDRA is 1 other than for the purpose of a direct read of HDCR.

Trapping CP14 accesses to powerdown debug registers

HDCR.TDOSA enables a trap to Hyp mode of Non-secure EL1 CP14 accesses to the powerdown debug registers:

1 Non-secure EL1 CP14 accesses to the powerdown debug registers are trapped to Hyp mode.

0 Non-secure EL1 CP14 accesses to the powerdown debug registers are not trapped to Hyp mode.

Table G1-58 shows the register accesses that are trapped to Hyp mode when HDCR.TDOSA is 1, and how the exceptions are reported in HSR.

Table G1-58 Register accesses trapped to Hyp mode when HDCR.TDOSA is 1

Traps from	Registers	Syndrome reporting in HSR
Non-secure EL1 using AArch32	DBGOSLSR, DBGOSLAR, DBGOSDLR, DBGPRCR Any IMPLEMENTATION DEFINED integration registers Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by HDCR.TDOSA	For accesses using MCR or MRC instructions, trapped MCR or MRC acess to CP14, using EC value 0x05.

Note

These registers are not accessible at EL0.

If HDCR.TDE or HCR.TGE is 1, behavior is as if HDCR.TDOSA is 1 other than for the purpose of a direct read of HDCR.

Trapping general CP14 accesses to debug registers

HDCR.TDA enables a trap to Hyp mode of Non-secure EL0 and EL1 CP14 register accesses to those debug System registers that are not mentioned in either of the following:

- *Traps to Hyp mode of CP14 accesses to debug registers* on page G1-3499.
- *Trapping CP14 accesses to powerdown debug registers* on page G1-3499.

That is, HDCR.TDA enables a trap to Hyp mode of Non-secure EL0 and EL1 CP14 accesses to all debug System registers, except the following:

- Any access to DBGDRAR or DBGDSAR.

  These are the registers for which accesses from Non-secure EL0 and EL1 are trapped to Hyp mode when HDCR.TDRA is 1.

- Any access to DBGOSLSR, DBGOSLAR, DBGOSDLR, or DBGPRCR.

  These are the registers for which accesses from Non-secure EL0 and EL1 are trapped to Hyp mode when HDCR.TDOSA is 1.

- Accesses to DBGDTRTXint and DBGDTRRXint when the PE is in Debug state.

When HDCR.TDA is:

1 Non-secure EL0 or EL1 CP14 accesses to any of the registers shown in Table G1-59 on page G1-3501 are trapped to Hyp mode.

0 Non-secure EL0 or EL1 CP14 accesses to any of the registers shown in Table G1-59 on page G1-3501 are not trapped to Hyp mode.

Table G1-59 shows how the exceptions are reported in HSR.

Table G1-59 Accesses trapped to Hyp mode when HDCR.TDA is 1

Traps from	Trapped accesses	Syndrome reporting in HSR
Non-secure EL0 and EL1 using AArch32	Accesses to the DBGDIDR, DBGDSCRint, DBGDCCINT, DBGDTRRXint, DBGDTRTXint, DBGWFAR, DBGVCR, DBGDSCRext, DBGDTRTXext, DBGDTRRXext, DBGBVR<n>, DBGBCR<n>, DBGBXVR<n>, DBGWCR<n>, DBGWVR<n>, DBGCLAIMSET, DBGCLAIMCLR, DBGAUTHSTATUS, DBGDEVID, DBGDEVID1, DBGDEVID2, and DBGOSECCR.	For accesses using MCR or MRC instructions, trapped MCR or MRC access to CP14, using EC value 0x05.
	STC accesses to DBGDTRRXint. LDC accesses to DBGDTRTXint.	LDC or STC, trapped LDC or STC access to CP14, using EC value 0x06

If HDCR.TDE or HCR.TGE is 1, behavior is as if HDCR.TDA is 1 other than for the purpose of a direct read of HDCR.

Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers

The Performance Monitors Extension is an optional architectural extension. The PE accesses the Performance Monitors Extension registers through:

- The CP15 c14 registers with opc1 == {0}, CRm == {c8-c15}, opc2 == {0-7}.
- The CP15 c9 registers with opc1 == {0}, CRm == {c12-c14}, opc2 == {0-7}.

If the Performance Monitors Extension is implemented, EL2 provides the following traps associated with the performance monitors:

- HDCR.TPM:
  - **1** Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to Hyp mode.
  - **0** Non-secure EL0 and EL1 accesses to any Performance Monitors register is not trapped to Hyp mode.
- HDCR.TPMCR:
  - **1** Non-secure EL0 and EL1 accesses to the Performance Monitors Control Register are trapped to Hyp mode.

    Note

    The conditions for this trap are identical to those for the trap controlled by HDCR.TPM
  - **0** Non-secure EL0 and EL1 accesses to the Performance Monitors Control Registers are not trapped to Hyp mode.

Note

- EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.
- If the Performance Monitors Extension is not implemented, HDCR.{TPM, TPMCR} are RES0.

For HDCR.TPM == 1, and for HDCR.TPMCR == 1, Table G1-60 shows the registers for which accesses are trapped to Hyp mode, and how the exceptions are reported in HSR.

Table G1-60 Register accesses trapped to Hyp mode when HDCR.{TPM, TPMCR} are 1

Traps from	Trap control	Registers	Syndrome reporting in HSR
Non-secure EL0 and EL1 using AArch32	TPM	All of the following registers, unless the register description indicates that the attempted access is UNDEFINED. PMCR, PMCNTENSET, PMINTENCLR, PMOVSR, PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTYPER, PMXEVCNTR, PMUSERENR, PMINTENSET, PMINTENCLR, PMOVSSET, PMEVCNTR<n>, PMEVTYPER<n>, PMCCFILTR.	Trapped MCR or MRC access to CP15, using EC value 0x03
	TPMCR	PMCR	Trapped MCR or MRC access to CP15, using EC value 0x03

Note

HDCR.HPMN affects whether a counter can be accessed from Non-secure EL1 or EL0. See the register description of HDCR for more information.

G1.17.3 EL3 configurable instruction enables, disables, and traps

Software configures access to instructions using AArch32 Restricted access System registers. Some controls apply only in Non-secure state. The disabled instruction generates an Undefined Instruction exception taken from AArch32 state.

The Undefined Instruction exception is taken to:

- Undefined mode without a change in Security state, if taken from a PL0 or PL1 mode.
- Hyp mode if taken from PL2.

Secure software can also configure traps for instructions executed in any mode other than Monitor mode using AArch32 Restricted access System registers. These controls apply in both Secure and Non-secure state. The trapped instruction generates a Monitor Trap exception taken from AArch32 state to Monitor mode.

The exception is only generated when the instruction does not also generate a higher priority exception. *Exception priority order* on page G1-3400 define the prioritization of different exceptions on the same instruction.

Table G1-61 shows the AArch32 System registers that contain controls that control trapping to Monitor mode.

Table G1-61 Summary of the registers that control trapping to Monitor mode

Register description	Register name
Secure Configuration Register	SCR
Non-secure Access Control Register	NSACR

Table G1-62 summarizes the controls using Monitor mode.

Table G1-62 Summary of the EL3 controls that control trapping to Monitor mode

Control	Types of control	Trap
SCR.{TWE, TWI}	Trap	*Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode* on page G1-3504
SCR.HCE	Enable	*Enabling EL3, EL2, and EL1 execution of HVC instructions* on page G1-3504
SCR.SCD	Disable	*Disabling EL3, EL2, and EL1 execution of SMC instructions* on page G1-3505
NSACR.NSTRCDIS	Disable	*Disabling Non-secure CP14 access to the trace registers* on page G1-3506
NSACR.{cp11, cp10}	Enable	*Enabling Non-secure access to the Advanced SIMD and floating-point registers* on page G1-3507
NSACR.NSASEDIS	Disable	*Disabling Non-secure access to Advanced SIMD functionality* on page G1-3507

Monitor mode traps on instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE, but is in a class that has a Monitor mode trap, the behavior of the instruction when the Monitor mode trap is enabled is UNPREDICTABLE. The architecture permits such an instruction to generate a Monitor Trap exception, but does not require it to do so.

Note

UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE. This means that setting a Monitor mode trap on an instruction changes the set of instructions that might be executed in modes other than Monitor mode. This affects, indirectly, the permitted behavior of UNPREDICTABLE instructions.

If no instructions are configured to generate Monitor mode traps, then the attempted execution of an UNPREDICTABLE instruction in a mode other than Monitor mode cannot generate a Monitor Trap exception.

Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode

EL3 provides the following traps for WFE and WFI instructions:

- SCR.TWE:
  - **1** Any attempt to execute a WFE instruction from a mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state.
  - **0** Execution of WFE instructions from a mode other than Monitor mode is not trapped to Monitor mode.
- SCR.TWI
  - **1** Any attempt to execute a WFI instruction from a mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state.
  - **0** Execution of WFI instructions from a mode other than Monitor mode is not trapped to Monitor mode.

For EL0 and EL1, these traps apply to WFE and WFI instruction execution in both Security states.

Table G1-63 shows the instructions that are trapped to Monitor mode when SCR.{TWE, TWI} are 1.

Table G1-63 Instructions trapped to Monitor mode when SCR_EL3.{TWE, TWI} are 1.

Trap control	Traps from	Trapped instructions
SCR.TWE	Any mode other than Monitor mode	WFE
SCR.TWI		WFI

The traps that SCR.{TWE, TWI} enable trap the attempted execution of conditional WFE or WFI instructions only if the instructions pass their condition code check.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:
- *Wait For Event and Send Event* on page G1-3457.
- *Wait For Interrupt* on page G1-3460.

Enabling EL3, EL2, and EL1 execution of HVC instructions

If EL2 is implemented, SCR.HCE enables HVC instruction execution in Non-secure state at EL1 and above:

1 HVC instruction execution is enabled in Non-secure state at EL1 and above.

0 Any attempt to execute a HVC instruction at EL1 or above generates an Undefined Instruction exception that is taken without a change of Exception level.

Note

- If EL2 is not implemented, SCR.HCE is RES0 and HVC is UNDEFINED.

- HVC instructions are always UNDEFINED at EL0 and in Secure state when using AArch32 state.

Disabling EL3, EL2, and EL1 execution of SMC instructions

SCR.SCD disables SMC instruction execution at EL1 and above:

1 Any attempt to execute an SMC instruction at EL1 or above generates an Undefined Instruction exception without a change of Exception level.

0 SMC instructions are enabled at EL1 and above.

Note

- SMC instructions are always UNDEFINED at EL0.
- If HCR.TSC traps attempted EL1 execution of SMC instructions to Hyp mode, then the HCR.TSC trap has priority over the SCR.SCD disable.

Disabling Non-secure CP14 access to the trace registers

NSACR.NSTRCDIS disables Non-secure CP14 accesses to the trace registers, from all Exception levels:

1 The trace registers can be accessed only from Secure state. If the PE is in Non-secure state:

- CPACR.TRCDIS behaves as RAO/WI, regardless of its actual value. See *Traps to Undefined mode of PL0 and PL1 CP14 accesses to the trace registers* on page G1-3478.
- If EL2 is implemented. HCPTR.TTA behaves as RAO/WI, regardless of its actual value. See *Trapping CP14 accesses to trace registers* on page G1-3496

0 This bit has no effect on CPACR.TRCDIS and HCPTR.TTA.

Note

- NSACR.NSTRCDIS might be implemented as RAZ/WI. See the register description for more information.
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
- EL3 does not provide Non-secure access controls on trace register accesses through the optional memory-mapped external debug interface.

Enabling Non-secure access to the Advanced SIMD and floating-point registers

NSACR.{cp11, cp10} enable Non-secure access to the Advanced SIMD and floating-point registers, from all Exception levels:

0b11 The Advanced SIMD and floating-point registers can be accessed only from Secure state. If the PE is in Non-secure state:

- CPACR.{cp11, cp10} behave as RAZ/WI. See *Enabling PL0 and PL1 accesses to Advanced SIMD and floating-point registers* on page G1-3478.
- In an implementation that includes EL2, HCPTR.{TCP11, TCP10} behave as RAO/WI. See *General trapping to Hyp mode of Non-secure accesses to the Advanced SIMD and floating-point registers* on page G1-3495

0b00 There is no effect on CPACR.{cp11, cp10} and HCPTR.{TCP11, TCP10}.

Note

Software must set NSACR.cp11 and NSACR.cp10 to the same value. See the register description for more information.

For more information about Advanced SIMD and floating-point support, see *Advanced SIMD and floating-point support* on page G1-3466.

Disabling Non-secure access to Advanced SIMD functionality

NSACR.NSASEDIS disables access to the Non-secure Advanced SIMD functionality, from all Exception levels:

1 The Advanced SIMD functionality can be accessed only from Secure state. If the PE is in Non-secure state:

- CPACR.ASEDIS behaves as RAO/WI. See *Disabling PL0 and PL1 access to Advanced SIMD functionality* on page G1-3479.
- In an implementation that includes EL2, HCPTR.TASE behaves as RAO/WI. See *Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality* on page G1-3495.

0 There is no effect on CPACR.ASEDIS and HCPTR.TASE.

For more information, see *Additional controls on Advanced SIMD functionality* on page G1-3470.

G1.17.4 Pseudocode details for configurable instruction enables, disables, and traps

The pseudocode function `AArch32.CheckITEnabled()` checks whether the T32 IT instruction is enabled.

```
// AArch32.CheckITEnabled()
// ========================
// Check whether the T32 IT instruction is disabled.

AArch32.CheckITEnabled(bits(4) mask)

    if PSTATE.EL == EL2 then
        it_disabled = HSCTLR.ITD;
    else
        it_disabled = (if ELUsingAArch32(EL1) then SCTLR.ITD else SCTLR_EL1.ITD);

    if it_disabled == '1' then
        if mask != '1000' then UNDEFINED;

        // Otherwise whether the IT block is allowed depends on hw1 of the next instruction.
        next_instr = MemA_with_type[NextInstrAddr(), 2, AccType_IFETCH, TRUE];

        if next_instr IN {'11xxxxxxxxxxxxx', '1011xxxxxxxxxxx', '10100xxxxxxxxxx',
                          '01001xxxxxxxxxx', '010001xxx1111xxx', '010001xx1xxxx111'} then
            // It is IMPLEMENTATION DEFINED whether the Undefined Instruction exception is
```

```
            // taken on the IT instruction or the next instruction. This is not reflected in
            // the pseudocode, which always takes the exception on the IT instruction. This
            // also does not take into account cases where the next instruction is UNPREDICTABLE.
            UNDEFINED;

    return;
```

The pseudocode function `CheckSETENDEnabled()` checks whether the `SETEND` instruction is disabled.

```
// AArch32.CheckSETENDEnabled()
// ============================
// Check whether the AArch32 SETEND instruction is disabled.

AArch32.CheckSETENDEnabled()

    if PSTATE.EL == EL2 then
        setend_disabled = HSCTLR.SED;
    else
        setend_disabled = (if ELUsingAArch32(EL1) then SCTLR.SED else SCTLR_EL1.SED);

    if setend_disabled == '1' then
        UNDEFINED;

    return;
```

The pseudocode function for `CheckForSMCTrap()` checks for traps on an `SMC` instruction.

```
// AArch32.CheckForSMCTrap()
// =========================
// Check for trap on SMC instruction

AArch32.CheckForSMCTrap()

    if HaveEL(EL2) && !IsSecure() && !ELUsingAArch32(EL2) then
        AArch64.CheckForSMCTrap();
    else
        route_to_hyp = HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} && HCR.TSC == '1';
        if route_to_hyp then
            exception = ExceptionSyndrome(Exception_MonitorCall);
            AArch32.TakeHypTrapException(exception);
```

Chapter G2
AArch32 Self-hosted Debug

When the PE is using self-hosted debug, it generates *debug exceptions*. This chapter describes the AArch32 self-hosted debug exception model. It is organized as follows:

- Introductory information:
  - *About debug exceptions* on page G2-3510.
  - *The debug exception enable controls* on page G2-3513.
- The debug Exception model:
  - *Routing debug exceptions* on page G2-3514.
  - *Enabling debug exceptions from the current Exception level and Security state* on page G2-3516.
  - *The effect of powerdown on debug exceptions* on page G2-3519.
  - *Summary of permitted routing and enabling of debug exceptions* on page G2-3520.
  - *Pseudocode descriptions of debug exceptions* on page G2-3522.
- The debug exceptions:
  - *Software Breakpoint Instruction exceptions* on page G2-3523.
  - *Breakpoint exceptions* on page G2-3526.
  - *Watchpoint exceptions* on page G2-3550.
  - *Vector Catch exceptions* on page G2-3564.
- The behavior of self-hosted debug after changes to system registers, or after changes to the authentication interface, but before a *Context Synchronization Operation* (CSO) guarantees the effects of the changes:
  - *Synchronization and debug exceptions* on page G2-3572.

G2.1 About debug exceptions

Debug exceptions occur during normal program flow, if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions. The debug exceptions that can be generated in an AArch32 translation regime are:

- *Software Breakpoint Instruction exceptions*.
- *Breakpoint exceptions*, generated by hardware breakpoints.
- *Watchpoint exceptions* on page G2-3511, generated by hardware watchpoints.
- *Vector Catch exceptions* on page G2-3511.

Note

In addition, *Software Step exceptions* can be generated in an AArch32 stage 1 translation regime. However, these are always taken to AArch64 state. *Software Step exceptions* on page D2-1531 describes this.

The PE can only generate a particular debug exception when both:

1. Debug exceptions are enabled from the current Exception level and Security state.

   See *Enabling debug exceptions from the current Exception level and Security state* on page G2-3516. Software Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

2. A debugger has enabled that particular debug exception.

   All of the debug exceptions except for Software Breakpoint Instruction exceptions have an enable control contained in the DBGDSCRext. See *The debug exception enable controls* on page G2-3513.

Note

If *halting is allowed* and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.

For the definition of halting is allowed, see *Halting allowed and halting prohibited* on page H2-4395.

The following list summarizes each of the debug exceptions:

Software Breakpoint Instruction exceptions

Breakpoint instructions generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A32 and T32 instruction sets is `BKPT #<immediate>`. Whenever one of these is committed for execution, the PE takes a Software Breakpoint Instruction exception.

PE behavior

Software Breakpoint Instruction exceptions cannot be masked. The PE takes Software Breakpoint Instruction exceptions regardless of both of the following:

- The current Privilege level and AArch32 mode.
- The current Security state.

For more information, see *Software Breakpoint Instruction exceptions* on page G2-3523.

Breakpoint exceptions

The ARMv8-A architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address `0x1000` is committed for execution.

The ARMv8-A architecture supports the following types of hardware breakpoint for use in an AArch32 stage 1 translation regime:

- Address:
  - Address Match.
  - Address Mismatch.

  Comparisons are made with the virtual address of each instruction in the program flow.
- Context:
  - Context ID Match. Matches with the Context ID value held in the CONTEXTIDR.
  - VMID Match. Matches with the VMID value held in the VTTBR.
  - Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match or mismatch occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

PE behavior

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 *Debug State*.

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see *Breakpoint exceptions* on page G2-3526.

Watchpoint exceptions

The ARMv8-A architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range `0x1000 - 0x101F`.

A hardware watchpoint can link to a hardware breakpoint, if the hardware breakpoint is a *Linked Context* type. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

PE behavior

If halting is allowed and EDSCR.HDE is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See Chapter H2 *Debug State*.

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see *Watchpoint exceptions* on page G2-3550.

Vector Catch exceptions

These are used to trap exceptions. The ARMv8-A architecture provides two forms of vector catch, *address-matching* and *exception-trapping*. Only one form can be implemented.

Whichever form is implemented, a debugger must enable Vector Catch exceptions for one or more exception vectors by programming the DBGVCR. Generation of Vector Catch exceptions is then as follows:

- For the address-matching form, a Vector Catch exception is generated whenever the virtual address of an instruction matches a vector that Vector Catch exceptions are enabled for.
- For the Exception-trapping form, a Vector Catch exception is generated as part of exception entry for exception types that correspond to vectors that Vector Catch exceptions are enabled for.

PE behavior

If debug exceptions are:

- Enabled, Vector Catch exceptions can be generated.
- Disabled, vector catch is ignored.

For more information, see *Vector Catch exceptions* on page G2-3564.

Table G2-1 summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

Table G2-1 PE behavior and pseudocode for each of the debug exceptions

Debug exception	PE behavior if debug exceptions are:		Pseudocode
	Enabled	Disabled	
Software Breakpoint Instruction exceptions	Takes the exception	Takes the exception	page G2-3525
Breakpoint exceptions	Takes the exception[a]	Ignored	page G2-3546
Watchpoint exceptions	Takes the exception[a]	Ignored	page G2-3561
Vector Catch exceptions	Takes the exception	Ignored	page G2-3570

a. If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See Chapter H2 *Debug State*.

G2.2 The debug exception enable controls

The enable controls for each debug exception are as follows:

Software Breakpoint Instruction exceptions

None. Software Breakpoint Instruction exceptions are always enabled.

Breakpoint exceptions

DBGDSCRext.MDBGen, plus an enable control for each breakpoint, DBGBCR<n>.E.

Watchpoint exceptions

DBGDSCRext.MDBGen, plus an enable control for each watchpoint, DBGWCR<n>.E.

Vector Catch exceptions

DBGDSCRext.MDBGen.

In addition, for all debug exceptions other than Software Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level and Security state* on page G2-3516.

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Software Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

G2.3 Routing debug exceptions

Debug exceptions are usually taken to Abort mode. However, if EL2 is implemented:

- Software Breakpoint Instruction exceptions taken from Hyp mode are taken to Hyp mode.

  These are the only debug exceptions that can be taken from Hyp mode to Hyp mode. All other debug exceptions are disabled in Hyp mode.

- If HDCR.TDE is:

  1 All debug exceptions taken from Non-secure PL1 and PL0 are routed to Hyp mode.

  0 All debug exceptions taken from PL1 and PL0 are taken to Abort mode.

Note

If HCR.TGE is 1, HDCR.TDE is treated as being 1 except for the purpose of a direct read of HDCR.

Table G2-2 shows this.

Table G2-2 The effect of the TGE and TDE control bits on debug exception routing

HCR.TGE	HDCR.TDE	Debug exceptions taken from Non-secure PL1 and PL0 are taken to:
0	0	Abort mode
0	1	Hyp mode
1	X	Hyp mode

Note

If EL2 is not implemented, all of the following apply:

- The PE behaves as if both HCR.TDE and HDCR.TGE are 0.
- The HCR is RES0.
- The HDCR is RES0.

The following tables show the routing of debug exceptions:

Table G2-3 Routing when both EL3 and EL2 are implemented

HDCR.TDE[a]	Target AArch32 mode when executing in:			
	Non-secure:			Secure state
	PL0	PL1	PL2	
0	Non-secure Abort mode	Non-secure Abort mode	Hyp mode[b]	Secure Abort mode
1	Hyp mode	Hyp mode	Hyp mode[b]	Secure Abort mode

a. If HCR.TGE is 1, this bit is treated as being 1 other than for a direct read of HDCR.

b. Only Software Breakpoint Instruction exceptions can be taken to Hyp mode, and only if they are taken from Hyp mode.

Table G2-4 Routing when EL3 is implemented and EL2 is not implemented

Target AArch32 mode when executing in:	
Non-secure state	**Secure state**
Non-secure Abort mode	Secure Abort mode

Table G2-5 Routing when EL3 is not implemented and EL2 is implemented

HDCR.TDE[a]	Target AArch32 mode when executing in Non-secure:		
	PL0	**PL1**	**PL2**
0	Non-secure Abort mode	Non-secure Abort mode	Hyp mode[b]
1	Hyp mode	Hyp mode	Hyp mode[b]

a. If HCR.TGE is 1, this bit is treated as being 1 other than for a direct read of HDCR.

b. Only Software Breakpoint Instruction exceptions can be taken to Hyp mode, and only if they are taken from Hyp mode.

G2.3.1 Pseudocode description of routing debug exceptions

`DebugTarget()` returns the current debug target Exception level.

```
// DebugTarget()
// =============

bits(2) DebugTarget()
    secure = IsSecure();
    return DebugTargetFrom(secure);
```

`DebugTargetFrom()` returns the debug target Exception level for the specified Security state.

```
// DebugTargetFrom()
// =================
// Returns the debug exception target Exception level

bits(2) DebugTargetFrom(boolean secure)

    if HaveEL(EL2) && !secure then
        if ELUsingAArch32(EL2) then
            route_to_el2 = (HDCR.TDE == '1' || HCR.TGE == '1');
        else
            route_to_el2 = (MDCR_EL2.TDE == '1' || HCR_EL2.TGE == '1');
    else
        route_to_el2 = FALSE;

    if route_to_el2 then
        target = EL2;
    elsif HaveEL(EL3) && HighestELUsingAArch32() && secure then
        target = EL3;
    else
        target = EL1;

    return target;
```

G2.4 Enabling debug exceptions from the current Exception level and Security state

A debug exception can only be taken if it is enabled from both the current Exception level and the current Security state.

See the following:

- *Enabling debug exceptions from the current Exception level*.
- *Enabling debug exceptions from the current Security state*.
- *Pseudocode descriptions of enabling debug exceptions* on page G2-3518.

G2.4.1 Enabling debug exceptions from the current Exception level

Table G2-6 shows when debug exceptions are enabled from the current Exception level. In the table:

- Y means that those exceptions are enabled.
- N means that those exceptions are disabled.

Table G2-6 Whether debug exceptions are enabled from the current Exception level, if the current Exception level is EL2, EL1, or EL0

Current Exception level	Software Breakpoint Instruction exceptions	All other debug exceptions
EL2	Y	N
EL1	Y	N if either of the following is true: • The OS lock is locked. • EDPRSR.DLK is 1. Otherwise Y[a].
EL0		

a. If EL3 is implemented, there are two additional controls, SDCR.SPD and SDER.SUIDEN, that affect whether Breakpoint, Watchpoint, and Vector Catch exceptions are enabled from Secure state. See *Enabling debug exceptions from the current Security state*.

G2.4.2 Enabling debug exceptions from the current Security state

Table G2-7 shows when debug exceptions are enabled from the current Security state. In the table, Y means that those exceptions are enabled.

Table G2-7 Whether debug exceptions are enabled from the current Security state

Current Security state	Software Breakpoint Instruction exceptions	All other debug exceptions
Non-secure	Y	Enabled from PL1 and PL0 only[a].
Secure	Y	Whether these are enabled depends on SDCR.SPD and SDER.SUIDEN[a]. See *The Secure Privileged Debug and Secure User Invasive Debug Enable fields* on page G2-3517.

a. A Breakpoint, Watchpoint, or Vector Catch exception cannot be taken unless it is also enabled from the current Exception level. See *Enabling debug exceptions from the current Exception level*.

The ARMv8-A architecture does not support disabling debug in Non-secure state.

The Secure Privileged Debug and Secure User Invasive Debug Enable fields

If EL3 is implemented, whether debug exceptions other than Software Breakpoint Instruction exceptions are enabled from Secure state depends on both of the following:

The *Secure Privileged Debug* field, SDCR.SPD

Enables debug exceptions from Secure PL1.

The *Secure User Invasive Debug Enable* bit, SDER.SUIDEN

Enables debug exceptions from Secure PL0.

Note

If EL3 is using AArch64, EL3 can enable can enable debug exceptions from:

- Secure PL1 by using MDCR_EL3**.SPD32**.
- Secure PL0 by using SDER32_EL3**.SUIDEN**.

Figure G2-1 shows the permitted values of these controls. In the figure:

- **SPIDEN** is the Secure Privileged Invasive Debug Enable signal, that is an external input signal to the recommended external debug interface.
- Y means that debug exceptions are enabled, and N means that debug exceptions are disabled. For example, when SPD is `0b10` and SUIDEN is 1, debug exceptions are enabled from Secure PL0 but are disabled from Secure PL1.

		SPD32 or SPD		
		0b00	0b10	0b11
SUIDEN	0	If **SPIDEN** is high: • Secure PL1: Y • Secure PL0: Y If **SPIDEN** is low: • Secure PL1: N • Secure PL0: N	Secure PL1: N Secure PL0: N	Secure PL1: Y Secure PL0: Y
	1	If **SPIDEN** is high: • Secure PL1: Y Regardless of **SPIDEN**: • Secure PL0: Y	Secure PL1: N Secure PL0: Y	Secure PL1: Y Secure PL0: Y

Figure G2-1 Using SPD32 or SPD and SUIDEN to enable debug exceptions taken from Secure state

Figure G2-1 shows that if debug exceptions are enabled from Secure PL1, debug exceptions are also enabled from Secure PL0. If debug exceptions are disabled from Secure PL1, whether debug exceptions are enabled from PL0 depends on SUIDEN.

SPD == `0b01` is reserved, but must have the same behavior as SPD == `0b00`.

Note

Software must not use SPD == `0b01`, because in future revisions of the architecture `0b01` might not have the same behavior as `0b00`.

If EL3 and EL2 are not implemented, and the implementation is a Secure state only implementation, the:

- SDER is implemented.

- SDCR is not implemented. The PE behaves as if SPD32 or SPD is 0b11.

Note

If the boot software that is executed when reset is deasserted programs SUIDEN and SPD so that all debug exceptions are disabled from Secure state, software operating at EL3 never has to switch any of the debug registers between the Security states.

G2.4.3 Pseudocode descriptions of enabling debug exceptions

AArch32.GenerateDebugExceptions() determines whether debug exceptions are enabled from the current Exception level and Security state.

```
// AArch32.GenerateDebugExceptions()
// =================================

boolean AArch32.GenerateDebugExceptions()
    return AArch32.GenerateDebugExceptionsFrom(PSTATE.EL, IsSecure());
```

AArch32.GenerateDebugExceptionsFrom() determines whether debug exceptions are enabled from the specified Exception level and Security state.

```
// AArch32.GenerateDebugExceptionsFrom()
// =====================================

boolean AArch32.GenerateDebugExceptionsFrom(bits(2) from, boolean secure)

    if from == EL0 && !ELStateUsingAArch32(EL1, secure) then
        mask = bit UNKNOWN;                          // PSTATE.D mask, unused for EL0 case
        return AArch64.GenerateDebugExceptionsFrom(from, secure, mask);

    if DBGOSLSR.OSLK == '1' || DoubleLockStatus() || Halted() then
        return FALSE;

    if HaveEL(EL3) && secure then
        spd = (if ELUsingAArch32(EL3) then SDCR.SPD else MDCR_EL3.SPD32);
        if spd<1> == '1' then
            enabled = spd<0> == '1';
        else
            // SPD == 0b01 is reserved, but behaves the same as 0b00.
            enabled = AArch32SelfHostedSecurePrivilegedInvasiveDebugEnabled();
        if from == EL0 then enabled = enabled || SDER.SUIDEN == '1';
    else
        enabled = from != EL2;

    return enabled;
```

G2.5 The effect of powerdown on debug exceptions

Debug OS Save and Restore sequences on page H6-4502 describes the *powerdown save routine* and the *restore routine*.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

Debug exceptions other than Software Breakpoint Instruction exceptions are enabled only if both the OS Lock is unlocked and EDPRSR.DLK is 0.

Software Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and EDPRSR.DLK.

G2.6 Summary of permitted routing and enabling of debug exceptions

Behavior is as follows:

Software Breakpoint Instruction exceptions

These are always enabled, regardless of the current Privilege level and Security state. Table G2-8 shows the routing of these. In the table, n/a means not applicable.

Table G2-8 Routing of Software Breakpoint Instruction exceptions

Current Security state	HDCR.TDE is:	Target when enabled from:		
		PL0	PL1	PL2
Secure	X	Secure Abort mode[a]	Secure Abort mode[a]	n/a
Non-secure	0	Non-secure Abort mode	Non-secure Abort mode	Hyp mode
	1	Hyp mode	Hyp mode	Hyp mode

a. If EL3 is implemented and is using AArch32, Secure Abort mode is at EL3. Otherwise, Secure Abort mode is at EL1.

All other debug exceptions

The enabling and permitted routing is controlled by all of the following:

- SDCR.SPD.
- **SPIDEN**.
- SDER.SUIDEN.
- HDCR.TDE.

Table G2-9 shows the valid combinations of the values of SDCR.SPD, **SPIDEN**, SDER.SUIDEN, and HDCR.TDE, and for each combination shows where debug exceptions are enabled from and where they are taken to.

In the table, n/a means not applicable and a dash, -, means that debug exceptions are disabled from that Exception level.

Table G2-9 Breakpoint, Watchpoint, Software Step, and Vector Catch exceptions

Debug state	Lock[a]	Current Security state	SPD[b]	SPIDEN	SUIDEN	TDE[c]	Target AArch32 mode when enabled from:		
							PL0	PL1	PL2
Yes	X	X	0bXX	X	X	X	-	-	-
No	1	X	0bXX	X	X	X	-	-	-
No	0	Secure	0b0X	LOW	0	X	-	-	n/a
No	0	Secure	0b0X	LOW	1	X	Secure Abort mode[d]	-	n/a
No	0	Secure	0b0X	HIGH	X	X	Secure Abort mode[d]	Secure Abort mode[d]	n/a
No	0	Secure	0b10	X	0	X	-	-	n/a
No	0	Secure	0b10	X	1	X	Secure Abort mode[d]	-	n/a

Table G2-9 Breakpoint, Watchpoint, Software Step, and Vector Catch exceptions (continued)

Debug state	Lock[a]	Current Security state	SPD[b]	SPIDEN	SUIDEN	TDE[c]	Target AArch32 mode when enabled from:		
							PL0	PL1	PL2
No	0	Secure	0b11	X	X	X	Secure Abort mode[d]	Secure Abort mode[d]	n/a
No	0	Non-secure	0bXX	X	X	0	Non-secure Abort mode	Non-secure Abort mode	-
No	0	Non-secure	0bXX	X	X	1	Hyp mode	Hyp mode	-

a. The value of (OSLSR_EL1.OSLK OR EDPRSR.DLK).
b. If EL3 is not implemented, behavior is as if this is 0b11.
c. If HCR.TGE is 1, this bit is treated as being 1 other than for a direct read of HDCR. If EL2 is not implemented, behavior is as if TDE is 0.
d. If EL3 is implemented and is using AArch32, Secure Abort mode is at EL3. Otherwise, Secure Abort mode is at EL1

G2.7 Pseudocode descriptions of debug exceptions

`DebugFault()` returns a `FaultRecord()` that indicates that a memory access has generated a debug exception:

```
// AArch32.DebugFault()
// ====================

FaultRecord AArch32.DebugFault(AccType acctype, boolean iswrite, bits(4) debugmoe)

    ipaddress = bits(40) UNKNOWN;
    domain = bits(4) UNKNOWN;
    level = integer UNKNOWN;
    extflag = bit UNKNOWN;
    secondstage = FALSE;
    s2fs1walk = FALSE;

    return AArch32.CreateFaultRecord(Fault_Debug, ipaddress,  domain, level, acctype, iswrite,
                                     extflag, debugmoe, secondstage, s2fs1walk);
```

The `Abort()` function processes `FaultRecord()`, as described in *Abort exceptions* on page G3-3611, and generates:

- Data Abort exceptions for watchpoints.
- Prefetch Abort exceptions for all other debug exceptions.

G2.8 Software Breakpoint Instruction exceptions

This section describes Software Breakpoint Instruction exceptions in an AArch32 translation regime.

It contains the following subsections:

- *About Software Breakpoint Instruction exceptions*.
- *Breakpoint instruction in the A32 and T32 instruction sets*.
- *BKPT instructions as the first instruction in an IT block* on page G2-3524.
- *Exception syndrome information and preferred return address* on page G2-3524.
- *Pseudocode description of Software Breakpoint Instruction exceptions* on page G2-3525.

G2.8.1 About Software Breakpoint Instruction exceptions

A *breakpoint* is a debug event that results from the execution of an instruction, based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Software Breakpoint Instruction exceptions, that this section describes, are software breakpoints. *Breakpoint exceptions* on page G2-3526 describes hardware breakpoints.

There is no enable control for Software Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Software Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:

- The current Exception level.
- The current Security state.
- Whether the *debug target Exception level*, EL_D, is using AArch64 or AArch32.

Note

- EL_D is the Exception level that debug exceptions are targeting. See *Enabling debug exceptions from the current Exception level* on page G2-3516.
- Debuggers using breakpoint instructions must be aware of the ARMv8 rules for concurrent modification and execution of instructions. See *Concurrent modification and execution of instructions* on page B2-80.

G2.8.2 Breakpoint instruction in the A32 and T32 instruction sets

The breakpoint instruction, in both instruction sets, is:

- `BKPT #<immediate>`

For details of the instruction encoding, see *BKPT* on page F7-2493.

About whether the BKPT instruction is conditional

In the T32 instruction set, `BKPT` instructions are always unconditional.

In the A32 instruction set:

- If the condition code field is AL, the BKPT instruction is unconditional.
- If the condition code field is anything other than AL, behavior is CONSTRAINED UNPREDICTABLE, and is one of the following:
  - The instruction is UNDEFINED.
  - The instruction is treated as a `NOP` instruction.

— The instruction is executed unconditionally.
— The instruction is executed conditionally.

G2.8.3 BKPT instructions as the first instruction in an IT block

If the first instruction in an IT block is a T32 `BKPT` instruction, then if the *IT Disable* bit (ITD) associated with the current Exception level is:

0 The `BKPT` instruction generates a Software Breakpoint Instruction exception.

1 The combination of `IT` instruction and `BKPT` instruction is UNDEFINED. Either the `IT` instruction or the `BKPT` instruction generates an Undefined Instruction exception.

To ensure consistent behavior when making the first instruction in one or more IT blocks a `BKPT` instruction, the debugger must replace the `IT` instruction.

Note

T32 `BKPT` instructions are always unconditional, even when they are inside an IT block.

See both:
- *The effect of setting SCTLR.ITD to 1* on page G1-3478.
- *The effect of setting HSCTLR.ITD to 1* on page G1-3485.

G2.8.4 Exception syndrome information and preferred return address

See the following:
- *Exception syndrome information*.
- *Preferred return address* on page G2-3525.

Exception syndrome information

The PE takes a Software Breakpoint Instruction exception as either:

- A Prefetch Abort exception, if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp Trap exception, if it is taken to PL2 because either HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

PL1 Abort mode

The PE sets all of the following:
- DBGDSCRext.MOE to `0b0011`, to indicate a Software Breakpoint Instruction exception.
- IFSR.FS to the code for a debug event, `0b00010`.
- The IFAR with an UNKNOWN value.

PL2 Hyp mode

The PE does all of the following:
- Records information about the exception in the *Hypervisor Syndrome Register*, HSR. See Table G2-10 on page G2-3525.
- Sets DBGDSCRext.MOE to `0b0011`, to indicate a Software Breakpoint Instruction exception.

- Sets the HIFAR to an UNKNOWN value.

Table G2-10 Information recorded in the HSR

HSR field	Information recorded
Exception Class, EC	The PE sets this to the code for a Prefetch Abort exception routed to Hyp mode, `0x20`.
Instruction Length, IL	The PE sets this to: • 0 for a T32 `BKPT` instruction. • 1 for an A32 `BKPT` instruction.
Instruction Specific Syndrome, ISS	**ISS[24:10]** RES0. **ISS[9]** *External Abort type* (EA). The PE sets this to 0. **ISS[8:6]** RES0. **ISS[5:0]** *Instruction Fault Status Code* (IFSC). The PE sets this to the code for a debug exception, `0b100010`.

Note

For information about how debug exceptions can be routed to PL2, see *Routing debug exceptions on page G2-3514*.

Preferred return address

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like `SVC`.

G2.8.5 Pseudocode description of Software Breakpoint Instruction exceptions

`AArch32.BKPTInstrDebugEvent()` generates a Prefetch Abort exception that is taken from AArch32 state.

```
// AArch32.BKPTInstrDebugEvent()
// =============================

AArch32.BKPTInstrDebugEvent(bits(16) immediate)

    if (HaveEL(EL2) && !IsSecure() && !ELUsingAArch32(EL2) &&
        (HCR_EL2.TGE == '1' || MDCR_EL2.TDE == '1')) then
        AArch64.SoftwareBreakpoint(immediate);

    vaddress = bits(32) UNKNOWN;
    acctype = AccType_IFETCH;           // Take as a Prefetch Abort
    iswrite = FALSE;
    entry = DebugException_BKPT;

    fault = AArch32.DebugFault(acctype, iswrite, entry);
    AArch32.Abort(vaddress, fault);
```

G2.9 Breakpoint exceptions

This section describes Breakpoint exceptions in an AArch32 stage 1 translation regime.

It contains the following subsections:

- *About Breakpoint exceptions*.
- *Breakpoint types and linking of breakpoints* on page G2-3527.
- *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page G2-3533.
- *Instruction address comparisons* on page G2-3535.
- *Context comparisons* on page G2-3540.
- *Using breakpoints* on page G2-3540.
- *Exception syndrome information and preferred return address* on page G2-3545.
- *Pseudocode descriptions of Breakpoint exceptions taken from AArch32 state* on page G2-3546.

G2.9.1 About Breakpoint exceptions

A *breakpoint* is a debug event that results from the execution of an instruction, based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint exceptions are generated by *Breakpoint debug events*. Breakpoint debug events are generated by hardware Breakpoints. Software Breakpoints are described in *Software Breakpoint Instruction exceptions* on page G2-3523.

An implementation can include between 2-16 hardware breakpoints. DBGDIDR.BRPs shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:

- The *Breakpoint Control Register*, DBGBCR<n>. This contains controls for the breakpoint, for example an enable control.
- The *Breakpoint Value Register*, DBGBVR<n>. This holds a value used for breakpoint matching, that is one of:
  - An instruction virtual address.
  - A Context ID.
- If EL2 is implemented, the *Breakpoint Extended Value Register*, DBGBXVR<n>, that holds a VMID value used for breakpoint matching.

These registers are numbered, so that:

- DBGBCR1, DBGBVR1, and DBGBXVR1 are for breakpoint number one.
- DBGBCR1, DBGBVR2, and DBGBXVR2 are for breakpoint number two.
- …
- …
- DBGBCRn, DBGBVRn, and DBGBXVRn are for breakpoint number n.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the breakpoint enable control for it, DBGBCR<n>.E, is 1.
- The conditions specified in the DBGBCR<n> are met.

- The comparisons with the values held in one or both of the DBGBVR<n> and DBGBXVR<n>, as applicable, are successful.
- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:

- Whether the instruction passes its condition code check.
- The instruction type.

Note

The PE tests all breakpoints before it executes each instruction. The PE might test all breakpoints when an instruction is fetched speculatively. However, a breakpoint does not generate a Breakpoint debug event until the instruction is committed for execution.

If halting is allowed and EDSCR.HDE is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are

- Enabled, Breakpoint debug events generate Breakpoint exceptions
- Disabled, Breakpoint debug events are ignored.

Note

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions.

However, the behavior described also applies if breakpoints are causing entry to Debug state.

The debug exception enable controls on page G2-3513 describes the enable controls for Breakpoint debug events.

G2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A *context-aware* breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  - An instruction address match.
  - An instruction address mismatch.
  - A Context ID match, with the value held in the CONTEXTIDR.
  - A VMID match, with the value held in the VTTBR.
  - Both a Context ID match and a VMID match.
- A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match or an instruction address mismatch.

DBGDIDR.CTX_CMPs shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match or mismatch is categorized as an *Address breakpoint*. Breakpoints that are programmed to match on anything else are categorized as *Context breakpoints*.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case the breakpoint is called an *Unlinked breakpoint*.
- Enabled for linking to another breakpoint. In this case the breakpoint is called a *Linked breakpoint*.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match or mismatch occurs. For example, a debugger might:

1. Program breakpoint number one to be a *Linked Address Match breakpoint*.
2. Program breakpoint number five to be a *Linked Context ID Match breakpoint*.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The *Breakpoint Type* field for a breakpoint, DBGBCR<n>.BT, controls the breakpoint type and whether the breakpoint is enabled for linking. If BT[0] is 1, the breakpoint is enabled for linking.

Figure G2-2 shows all of the possible breakpoint types that an AArch32 stage 1 translation scheme supports, and their associated BT field values.

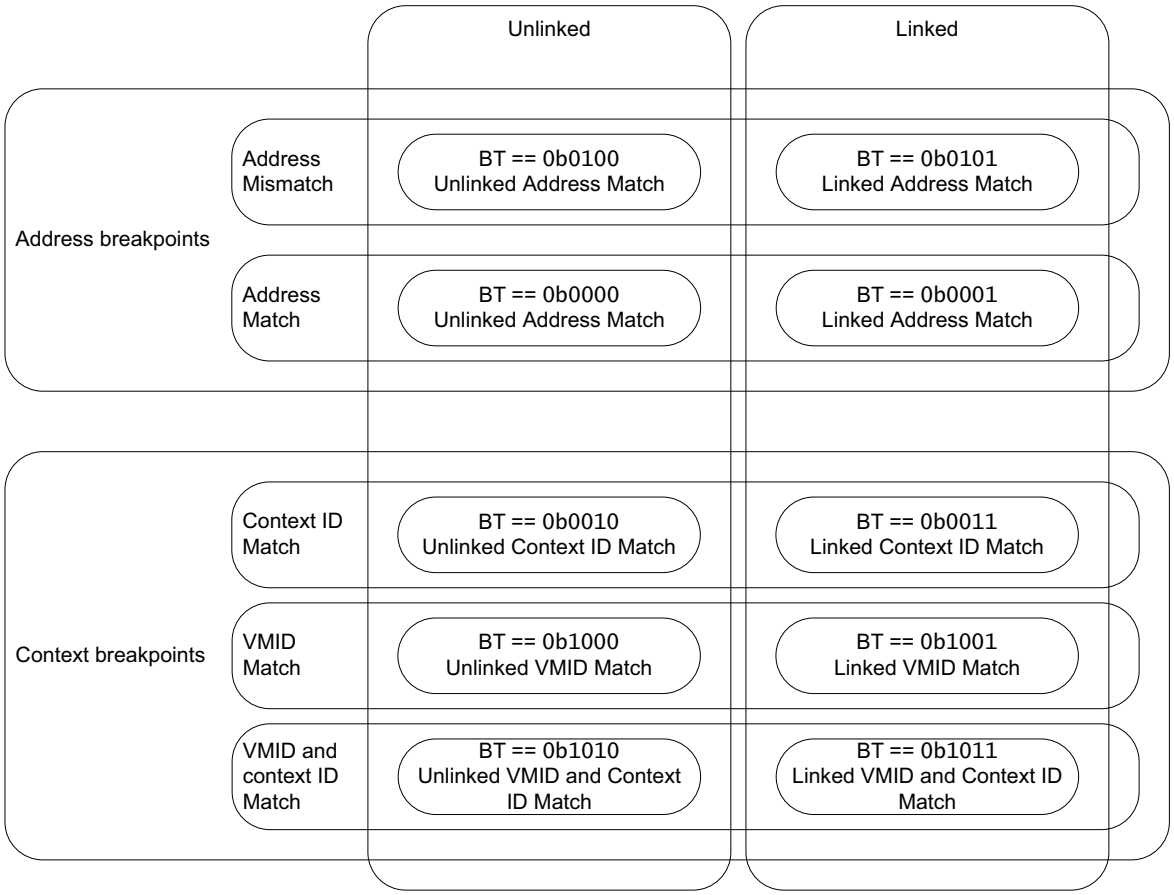

Figure G2-2 Breakpoint types and their associated BT field values

Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See *Specifying the halfword-aligned address that an Address breakpoint matches on* on page G2-3535.

Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked breakpoint types can be linked.

- Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, DBGBCR<n>.LBN, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
  - DBGBCR<n>.{SSC, HMC, PMC} for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page G2-3533.
  - DBGBCR<n>.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.
- Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.
- Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.
- If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See *Other usage constraints for Address breakpoints* on page G2-3544.
- If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.
- Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

  Note

  Multiple Linked watchpoints can also link to a single Linked Context breakpoint. *Watchpoint exceptions* on page G2-3550 describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

- Multiple Linked Address Match breakpoints.
- Multiple Linked Address Mismatch breakpoints.
- Multiple Linked watchpoints.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

Figure G2-3 on page G2-3530 shows an example of permitted breakpoint and watchpoint linking.

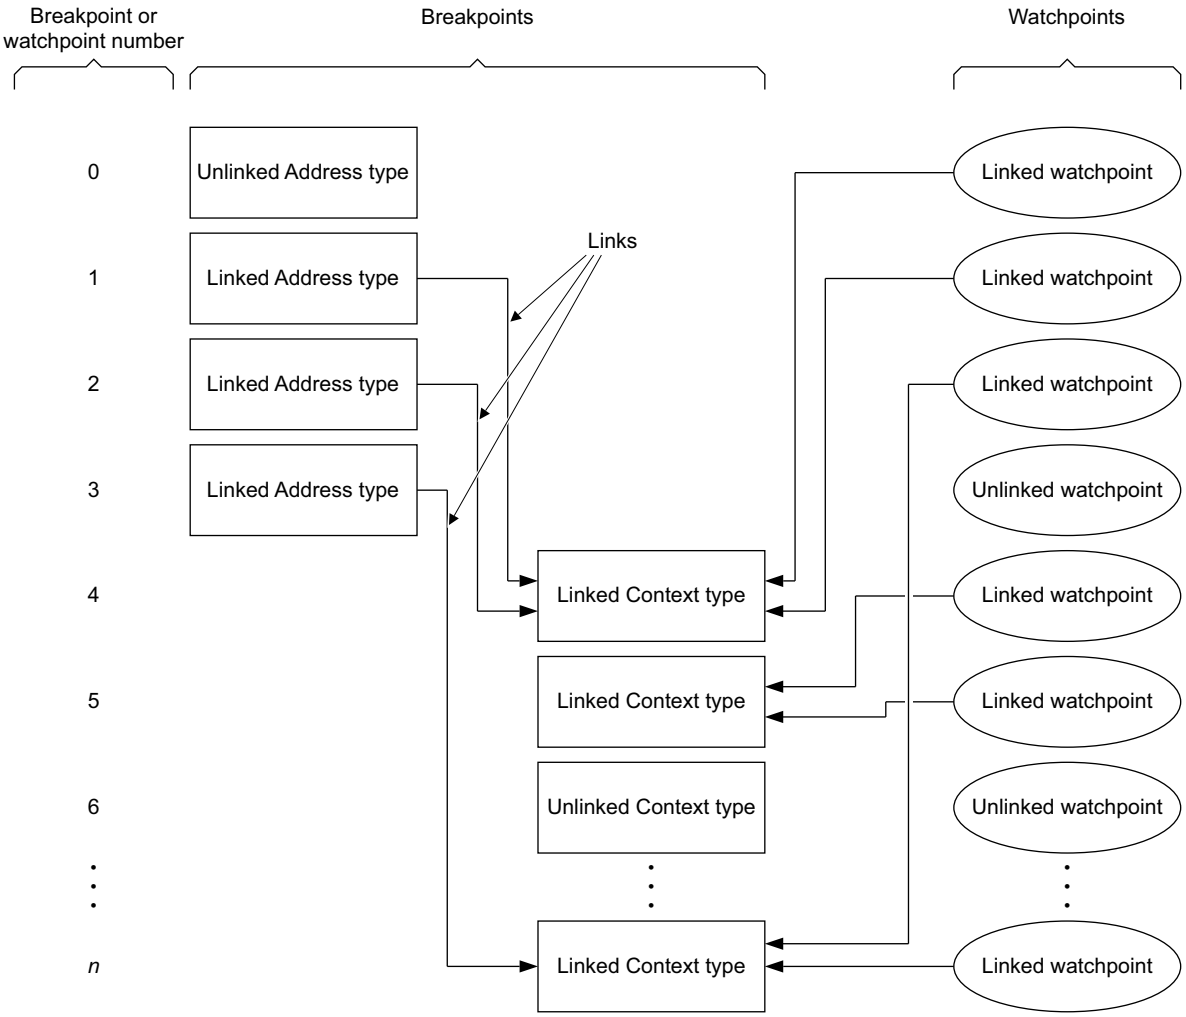

Figure G2-3 The role of linking in Breakpoint and Watchpoint exception generation

In Figure G2-3, each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

Breakpoint types defined by DBGBCRn.BT

The following list provides more detail about each breakpoint type:

`0b0000`, Unlinked Address Match breakpoint

Generation of a Breakpoint exception depends on both:

- DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page G2-3533.
- A successful address match, as described in *Instruction address comparisons* on page G2-3535.

DBGBCR<n>.LBN for this breakpoint is ignored.

`0b0001`, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- DBGBCR<n>.{SSC, HMC, PMC} for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page G2-3533.
- A successful address match defined by this breakpoint, as described in *Instruction address comparisons* on page G2-3535.
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

DBGBCR<n>.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

`0b0010`, Unlinked Context ID Match breakpoint

BT == `0b0010` is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page G2-3533.
- A successful Context ID match, as described in *Context comparisons* on page G2-3540.

DBGBCR<n>.{LBN, BAS} for this breakpoint are ignored

`0b0011`, Linked Context ID Match breakpoint

BT == `0b0011` is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see *Instruction address comparisons* on page G2-3535.
  - A successful Context ID match defined by this breakpoint, as described in *Context comparisons* on page G2-3540.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Data address comparisons* on page G2-3553.
  - A successful Context ID match defined by this breakpoint, as described in *Context comparisons* on page G2-3540.

DBGBCR<n>.{LBN, SSC, HMC, BAS PMC} for this breakpoint are ignored.

`0b0100`, Unlinked Address Mismatch breakpoint

Generation of a Breakpoint exception depends on both:

- DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page G2-3533.
- A successful address mismatch, as described in *Instruction address comparisons* on page G2-3535.

DBGBCR<n>.LBN is for this breakpoint is ignored.

`0b0101`, Linked Address Mismatch breakpoint

Generation of a Breakpoint exception depends on all of the following:

- DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page G2-3533.
- A successful address mismatch defined by this breakpoint, as described in *Instruction address comparisons* on page G2-3535.
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

DBGBCR<n>.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

`0b1000`, Unlinked VMID Match breakpoint

BT == `0b1000` is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for* on page G2-3533.
- A successful VMID match, as described in *Context comparisons* on page G2-3540.

DBGBCR<n>.{LBN, BAS} for this breakpoint are ignored.

`0b1001`, Linked VMID Match breakpoint

BT == `0b1000` is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See *Instruction address comparisons* on page G2-3535.
  - A successful VMID match defined by this breakpoint, as described in *Context comparisons* on page G2-3540.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Data address comparisons* on page G2-3553.
  - A successful VMID match defined by this breakpoint, as described in *Context comparisons* on page G2-3540.

DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

`0b1010`, Unlinked Context ID and VMID Match breakpoint

BT == `0b1010` is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-matching breakpoints, generation of a Breakpoint exception depends on all of the following:

- DBGBCR<n>.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions that a breakpoint generates Breakpoint exceptions for*.
- A successful Context ID match.
- A successful VMID match.

Context comparisons on page G2-3540 describes the requirements for a successful Context ID match and a successful VMID match.

DBGBCR<n>.{LBN, BAS} for this breakpoint are ignored.

`0b1011`, Linked Context ID and VMID Match breakpoint

BT == `0b1011` is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-matching breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on all of the following:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see *Instruction address comparisons* on page G2-3535.
  - A successful Context ID match defined by this breakpoint.
  - A successful VMID match defined by this breakpoint.
- Generation of a Watchpoint exception depends on all of the following:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Data address comparisons* on page G2-3553.
  - A successful Context ID match defined by this breakpoint.
  - A successful VMID match defined by this breakpoint.

Context comparisons on page G2-3540 describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

Note

See *Reserved DBGBCR<n>.BT values* on page G2-3542 for the behavior of breakpoints programmed with reserved BT values.

G2.9.3 Execution conditions that a breakpoint generates Breakpoint exceptions for

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at PL0 in Secure state.

DBGBCR<n>.{SSC, HMC, PMC} define the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states. The comparison is made with the Security state of the PE, not the NS attribute of the physical instruction fetch address.

Higher Mode Control, HMC, and Privileged Mode Control, PMC

HMC and PMC together control which AArch32 modes the breakpoint generates Breakpoint exceptions in.

Table G2-11 shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Privilege levels breakpoints generate Breakpoint exceptions in.

In the table:

Y or - Means that a breakpoint programmed with the values of HMC, SSC and PMC shown in that row:

- **Y** Can generate Breakpoint exceptions in AArch32 modes at that Privilege level.
- **-** Cannot generate Breakpoint exceptions in AArch32 modes at that Privilege level.

Res Means that the combination of HMC, SSC, and PMC is reserved. See *Reserved DBGBCR<n>.{HMC, SSC, PMC} values* on page G2-3543.

Table G2-11 Summary of breakpoint HMC, SSC, and PMC encodings

HMC	SSC	PMC	Security state the breakpoint is programmed to match in	PL2[a]	PL1	PL0	Implementation	
							No EL3	No EL2 and no EL3
0	00	00	Both	-	Y[b]	Y[b]	-	-
0	00	01		-	Y	-	-	-
0	00	10		-	-	Y	-	-
0	00	11		-	Y	Y	-	-
0	01	00	Non-secure	-	Y[b]	Y[b]	Res	Res
0	01	01		-	Y	-	Res	Res
0	01	10		-	-	Y	Res	Res
0	01	11		-	Y	Y	Res	Res
0	10	00	Secure	-	Y[b]	Y[b]	Res	Res
0	10	01		-	Y	-	Res	Res
0	10	10		-	-	Y	Res	Res
0	10	11		-	Y	Y	Res	Res
1	00	01	Both	Y	Y	-	-	Res
1	00	11		Y	Y	Y	-	Res
1	01	01	Non-secure	Y	Y	-	Res	Res
1	01	11		Y	Y	Y	Res	Res
1	10	01	Secure	-	Y	-	Res	Res
1	10	11		-	Y	Y	Res	Res
1	11	00	Non-secure	Y	-	-	Res	Res

a. Debug exceptions are not generated at PL2 using AArch32. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at PL2 using AArch32.

b. Only in User, System and Supervisor modes.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See *Reserved HMC, SSC, and PMC combinations* on page G2-3543.

G2.9.4 Instruction address comparisons

Address comparisons are made for each instruction in the program flow. The following subsections describe the criteria for a successful address comparison, for:

- *Address Match breakpoints*.
- *Address Mismatch breakpoints*.

Address Match breakpoints

An address match comparison is successful if both:

- Bits [31:2] of the current instruction address are equal to DBGBVR<n>[31:2].
- The word or halfword selected by DBGBCR<n>.BAS matches. That is, either:
  - DBGBCR<n>.BAS is programmed with `0b0011` or `0b1111`, and the instruction is at a word-aligned address.
  - DBGBCR<n>.BAS is programmed with `0b1100`, and the instruction is not at a word-aligned address.

  See *Specifying the halfword-aligned address that an Address breakpoint matches on*.

Note

DBGBVR<n>[1:0] are RES0 and are ignored.

Address Mismatch breakpoints

An address mismatch comparison is successful if either:

- Bits [31:2] of the current instruction address value are not equal to DBGBVR<n>[31:2].
- The word or halfword selected by DBGBCR<n>.BAS does not match. That is, either:
  - DBGBCR<n>.BAS is programmed with `0b0011` or `0b1111`, and the instruction is not at a word-aligned address.
  - DBGBCR<n>.BAS is programmed with `0b1100`, and the instruction is at a word-aligned address.

  See *Specifying the halfword-aligned address that an Address breakpoint matches on*.

Note

- DBGBVR<n>[1:0] are RES0 and are ignored.
- Address Mismatch breakpoints can be used to single-step through code. See *Using an Address Mismatch breakpoint to single-step an instruction* on page G2-3540.

Specifying the halfword-aligned address that an Address breakpoint matches on

For an Address breakpoint, a debugger can use the *Byte Address Selection* field, DBGBCR<n>.BAS, so that the address comparison is successful on one of:

- The whole word starting at address DBGBVR<n>[31:2]:00.
- The halfword starting at address DBGBVR<n>[31:2]:00.
- The halfword starting at address ((DBGBVR<n>[31:2]:00) + 2).

This makes it possible to breakpoint on T32 instructions.

Note

The address programmed into the DBGBVR<n> must be word-aligned.

DBGBCR<n>.BAS can be used in both Address Match breakpoints and Address Mismatch breakpoints, as follows:

- For an Address Match breakpoint, DBGBCR<n>.BAS selects which halfword-aligned address the breakpoint must generate a Breakpoint exception for. This means that an address comparison is successful only if both of the following match:
  - The instruction address held in bits [31:2] of the DBGBVR<n>.
  - The halfword defined by the BAS field.

  That is, a successful address comparison = DBGBVR<n>[31:2]match AND BAS match.
- For an Address Mismatch breakpoint, DBGBCR<n>.BAS selects which halfword-aligned address the breakpoint must not generate a Breakpoint exception for. This means that an address comparison is successful if either or both of the following do not match:
  - The instruction address held in bits [31:2] of the DBGBVR<n>.
  - The halfword defined by the BAS field.

  That is, a successful address comparison = NOT (DBGBVR<n>[31:2] match AND BAS match).

The following subsections show the supported BAS values:

- *Using the BAS field in Address Match breakpoints*.
- *Using the BAS field in Address Mismatch breakpoints* on page G2-3538.

For Context breakpoints, DBGBCR<n>.BAS is RES1 and is ignored.

Using the BAS field in Address Match breakpoints

The supported BAS values are:

`0b0000` This value is reserved. Behavior is a CONSTRAINED UNPREDICTABLE choice of:
- The breakpoint is disabled.
- The breakpoint behaves as if BAS is `0b0011`, `0b1100`, or `0b1111`.

`0b0011` The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:
- Bits [31:2] of the address equals DBGBVR<n>[31:2].
- Bits [1:0] of the address are `0b00`.

This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:
- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for T32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((DBGBVR<n>[31:2]:00) - 2).

`0b1100` The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:
- Bits [31:2] of the address equals DBGBVR<n>[31:2].
- Bits [1:0] of the address are `0b10`.

This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for both of the following:
- 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
- 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction starting at a word-aligned address.

`0b1111` The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] of the address equals DBGBVR<n>[31:2].
- Bits [1:0] of the address are `0b00`.

This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:

- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for A32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((DBGBVR<n>[31:2]:00) - 2).

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address ((DBGBVR<n>[31:2]:00) + 2).

All other BAS values are reserved. For these reserved other values, DBGBCR<n>.BAS[3,1] ignore writes and read the same values as DBGBCR<n>[2,0] respectively. This means that the smallest instruction size a debugger can program breakpoints to match on is a halfword.

Figure G2-4 on page G2-3538 shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example:

- Row 2 shows that a breakpoint with a BAS value of `0b1100` generates Breakpoint exceptions for 16-bit T32 instructions starting at the halfword-aligned address ((DBGBVR<n>[31:2]:00) + 2).
- Row 6 shows that a breakpoint with a BAS value of either `0b0011` or `0b1111` generates Breakpoint exceptions for A32 instructions. A32 instructions are always at word-aligned addresses.

In the figure:

Yes Means that the breakpoint generates a Breakpoint exception.

No Means that the breakpoint does not generate a Breakpoint exception.

UNP Means that is it CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See *Other usage constraints for Address breakpoints* on page G2-3544.

	Instruction set	Size	Location of instruction[a] -2	-1	0	+1	+2	+3	+4	+5	BAS[3:0] 0b0011	0b1100	0b1111
Row 1	T32	16-bit			■	■					Yes	No	Yes
Row 2		16-bit					■	■			No	Yes	UNP
Row 3	T32	32-bit	■	■	■	■					UNP	No	UNP
Row 4		32-bit			■	■	■	■			Yes	UNP	Yes
Row 5		32-bit					■	■	■	■	No	Yes	UNP
Row 6	A32	32-bit			■	■	■	■			Yes	UNP	Yes

a. 0 means the word-aligned address held in the DBGBVRn. The other locations are as follows:
- -2 means ((DBGBVRn[31:2]:00) - 2).
- -1 means ((DBGBVRn[31:2]:00) - 1).
- ...
- ...
- +5 means ((DBGBVRn[31:2]:00) + 5).

The solid areas show the location of the instruction.

Figure G2-4 Summary of BAS field meanings for Address Match breakpoints

Using the BAS field in Address Mismatch breakpoints

An Address Mismatch breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed to match.

The supported BAS values are:

`0b0000` The breakpoint ignores the address held in the DBGBVR<n> and generates Breakpoint exceptions for all instruction addresses.

`0b0011` The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:
- Bits [31:2] of the address equals DBGBVR<n>[31:2].
- Bits [1:0] of the address are `0b00`.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:
- 32-bit T32 instructions at word-aligned addresses.
- 16-bit T32 instructions at word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for T32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((DBGBVR<n>[31:2]:00) - 2).

`0b1100` The breakpoint does not generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:
- Bits [31:2] equals DBGBVR<n>[31:2].
- Bits [1:0] of the address are `0b10`.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for either of the following:
- 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
- 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction at a word-aligned address.

`0b1111` The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:

- Bits [31:2] os the address equals DBGBVR<n>[31:2].
- Bits [1:0] of the address are `0b00`.

This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:

- 32-bit T32 instructions at a word-aligned addresses.
- 16-bit T32 instructions at a word-aligned addresses.
- A32 instructions. These are always at word-aligned addresses.

However, ARM recommends that a debugger uses this BAS value only for A32 instructions.

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address ((DBGBVR<n>[31:2]:00) - 2).

It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address ((DBGBVR<n>[31:2]:00) + 2).

All other BAS values are reserved. For these reserved other values, DBGBCR<n>.BAS[3,1] ignore writes and read the same values as DBGBCR<n>[2,0] respectively. This means that the smallest instruction size that a breakpoint can never generate a Breakpoint exception for is a halfword.

Figure G2-5 on page G2-3540 shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example:

- Row 1 shows that a breakpoint with a BAS value of `0b1100` generates Breakpoint exceptions for 16-bit T32 instructions starting at the word-aligned address held in the DBGBVR<n>.
- Row 5 shows that a breakpoint with a BAS value of `0b0011` generates Breakpoint exceptions for 32-bit T32 instructions starting at the halfword-aligned address immediately after the word aligned address held in the DBGBVR<n>.

In the figure:

Yes Means that the breakpoint does generate a Breakpoint exception.

No Means that the breakpoint does not generate a Breakpoint exception.

UNP Means that is it CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See *Other usage constraints for Address breakpoints* on page G2-3544

.

	Instruction set	Size	Location of instruction[a] -2	-1	0	+1	+2	+3	+4	+5	BAS[3:0] 0b0000	0b0011	0b1100	0b1111
Row 1	T32	16-bit			■	■					Yes	No	Yes	No
Row 2		16-bit					■	■			Yes	Yes	No	UNP
Row 3	T32	32-bit	■	■	■	■					Yes	UNP	Yes	UNP
Row 4		32-bit			■	■	■	■			Yes	No	UNP	No
Row 5		32-bit					■	■	■	■	Yes	Yes	No	UNP
Row 6	A32	32-bit			■	■	■	■			Yes	No	UNP	No

a. 0 means the word-aligned address held in the DBGBVRn. The other locations are as follows:
- -2 means ((DBGBVRn[31:2]:00) - 2).
- -1 means ((DBGBVRn[31:2]:00) - 1).
- ...
- ...
- +5 means ((DBGBVRn[31:2]:00) + 5).

The solid areas show the location of the instruction.

Figure G2-5 Summary of BAS field meanings for Address Mismatch breakpoints

G2.9.5 Context comparisons

A context comparison is successful if, depending on the breakpoint type set by DBGBCR<n>.BT, one of the following is true:

- The current Context ID value is equal to DBGBVR<n>[31:0].
- The current VMID value is equal to DBGBXVR<n>[7:0].
- The current Context ID value is equal to DBGBVR<n>[31:0], and the current VMID value is equal to DBGBXVR<n>[7:0].

For all Context breakpoints, DBGBCR<n>.BAS is RES1 and is ignored.

In addition, for Linked Context breakpoints, DBGBCR<n>.{LBN, SSC, HMC, PMC} are RES0 and are ignored.

G2.9.6 Using breakpoints

This section contains the following:

- *Using an Address Mismatch breakpoint to single-step an instruction*.
- *Address breakpoints on the first instruction in an IT block* on page G2-3541.
- *Usage constraints* on page G2-3542.

Using an Address Mismatch breakpoint to single-step an instruction

In execution conditions that an Address Mismatch breakpoint matches, defined by DBGBCR<n>.{LBN, SSC, PMC}, the breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed with. Figure G2-6 on page G2-3541 shows an example of Address Mismatch breakpoint operation, for an Address Mismatch breakpoint programmed with address `0x1014`.

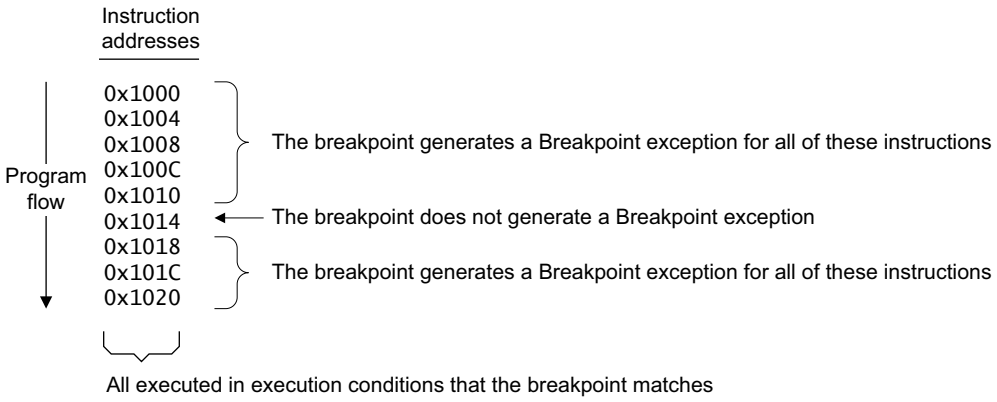

Figure G2-6 Operation of an Address Mismatch breakpoint

This means that an Address Mismatch breakpoint can be used to single-step an instruction.

In the example shown in Figure G2-6:

- If the target of a branch is an instruction other than the instruction at address `0x1014`, the breakpoint generates a Breakpoint exception when the instruction is committed for execution.
- If the target of a branch is the instruction at address `0x1014`, the PE executes the instruction at `0x1014` and the breakpoint does not generate a Breakpoint exception until the instruction at address `0x1018` is committed for execution. The instruction at address `0x1014` is therefore single-stepped.

  However, if the instruction at `0x1014` generates a synchronous exception, or if the PE takes an asynchronous exception while the instruction is being stepped, the breakpoint is evaluated again after taking the exception. This means that behavior is as follows:

  — If the exception handler executes in execution conditions that the breakpoint matches, the breakpoint generates a Breakpoint exception for the exception vector, because the exception vector is not address `0x1014`. This means that software execution steps into the exception.

  — If the exception handler executes in execution conditions that the breakpoint does not match, the breakpoint does not generate any Breakpoint exceptions after the PE has taken the exception, until the exception handler completes and executes an exception return instruction. The effect is to step over the exception. Whether the instruction is stepped again depends on whether the target of the exception return instruction the instruction at `0x1014` or the instruction at `0x1018`.

  If the instruction at `0x1014` is single-stepped and branches to itself, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception after the PE has executed the branch.

This means that an instruction is only single-stepped if it is the target of a branch instruction and its address matches the address the breakpoint is programmed for. In the example shown in Figure G2-6, this is `0x1014`.

Because Address Mismatch breakpoints can single-step instructions, the behavior of an address mismatch Breakpoint exception is similar to the behavior of a Software Step exception.

Note

- The example shown in Figure G2-6 assumes an A32 instruction. The same behavior applies for both 32-bit and 16-bit T32 instructions.
- Software Step exceptions are the highest priority exception. Breakpoint exceptions are lower priority. See *Synchronous exception prioritization* on page D1-1448.

Address breakpoints on the first instruction in an IT block

If the ITD bit associated with the current Exception level is 1, all of the following are true:

- An IT instruction can only be used to apply to one 16-bit T32 instruction.

- Only certain combinations of an IT instruction and second single 16-bit T32 instruction are permitted.
- For a permitted combination, it is IMPLEMENTATION DEFINED whether the implementation treats the combination as:
  - A pair of 16-bit instructions.
  - One 32-bit instruction.

If the implementation treats the combination as one 32-bit instruction, then as described in *Other usage constraints for Address breakpoints* on page G2-3544, an Address breakpoint might not generate a Breakpoint exception for an address match only on the second halfword of the instruction.

For this reason, if the ITD bit associated with the current Exception level is 1, ARM recommends that a debugger that wants to program a breakpoint to match on the second T32 instruction programs it to match on the IT instruction instead.

However, if returning from an exception whose preferred return address is the address of the second T32 instruction, then because the debugger is aware that the implementation has treated the combination as a pair of 16-bit instructions, the debugger is permitted to program the breakpoint to match on the second T32 instruction.

Note

- The ITD bit is the IT Disable bit. See both:
  - *The effect of setting SCTLR.ITD to 1* on page G1-3478.
  - *The effect of setting HSCTLR.ITD to 1* on page G1-3485.
- Programming the breakpoint to match on the second T32 instruction might be necessary when using an Address Mismatch breakpoint for single stepping.

Usage constraints

See the following:

- *Reserved DBGBCR<n>.BT values*.
- *Reserved DBGBCR<n>.{HMC, SSC, PMC} values* on page G2-3543.
- *Reserved DBGBCR<n>.BAS values* on page G2-3543.
- *Reserved DBGBCR<n>.LBN values* on page G2-3544.
- *Other usage constraints for Address breakpoints* on page G2-3544.
- *Other usage constraints for Context breakpoints* on page G2-3544.

Reserved DBGBCR<n>.BT values

Table G2-12 shows when particular DBGBCR<n>.BT values are reserved.

Table G2-12 Reserved BT values

BT value	Breakpoint type	Reserved
0b001x	Context ID Match	For non context-aware breakpoints.
0b010x	Address Mismatch	If EDSCR.HDE is 1 and halting is allowed.
0b011x	-	Always.
0b100x	VMID Match	For non context-aware breakpoints, or if EL2 is not implemented.
0b101x	Context ID and VMID Match	
0b11xx	-	Always.

If an enabled breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BT value that is not reserved, other than for a direct read of DBGBCR<n>.
- For a direct read of DBGBCR<n>, if the reserved BT value:
  - Has no function for any execution conditions, the value read back is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGBCR<n>.{HMC, SSC, PMC} values

Table G2-13 shows when particular combinations of DBGBCR<n>.{HMC, SSC, PMC} are reserved.

Table G2-13 Reserved HMC, SSC, and PMC combinations

HMC, SSC, and PMC combination	Reserved
All combinations with SSC set to `0b01` or `0b10`.	When EL3 is not implemented and EL2 is implemented.
Any combination where HMC or SSC is nonzero.	When both of EL2 and EL3 are not implemented.
Combinations not included in Table G2-11 on page G2-3534.	Always

For all breakpoints except Linked Context breakpoints, if an enabled breakpoint is programmed with one of these reserved combinations:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct read of DBGBCR<n>.
- For a direct read of DBGBCR<n>, if the reserved combination:
  - Has no function for any execution conditions, the value read back for each of HMC, SSC, and PMC is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the breakpoint functions for the other execution conditions.

Linked Context breakpoints ignore the values of HMC, SSC, and PMC. See *Other usage constraints for Context breakpoints* on page G2-3544.

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGBCR<n>.BAS values

For all Context breakpoints, DBGBCR<n>.BAS is RES1 and is ignored.

For all Address breakpoints:

- The BAS field values `0bxx01` and `0b01xx` are reserved. A breakpoint programmed with `0bxx01` or `0b01xx` must behave as if it is programmed with `0bxx11` or `0b11xx` respectively.

- The BAS field values 0bxx10 and 0b10xx are reserved. A breakpoint programmed with 0bxx10 or 0b10xx must behave as if it is programmed with 0bxx00 or 0b00xx respectively.
- The BAS field value 0b0000 is reserved. A breakpoint programmed with 0b0000 must behave either as if it is disabled, or programmed with 0b0011, 0b1100, or 0b1111.

Reserved DBGBCR<n>.LBN values

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any DBGBCR<n>.LBN value that is not for a context-aware breakpoint is reserved.

Other usage constraints for Address breakpoints

- For all Address breakpoints:
  - DBGBVR<n>[1:0] are RES0 and are ignored.
  - The DBGBXVR<n> is ignored.
- For Address Match breakpoints:
  - For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
  - If DBGBCR<n>.BAS is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address ((DBGBVR<n>[31:2]:00) + 2). For T32 instructions, ARM recommends that the debugger programs the BAS field with either 0b0011 or 0b1100.
- For Address Mismatch breakpoints:
  - The constraints are the same as those described in *For Address Match breakpoints*, except that if DBGBCR<n>.BAS is programmed with 0b0000, the breakpoint matches on all addresses, even for the address held in the DBGBVR<n>.

  That is, if DBGBCR<n>.BAS is programmed with 0b0000, the Address Mismatch breakpoint ignores the address held in the DBGBVR<n>.

For all Unlinked Address breakpoints, DBGBCR<n>.LBN reads UNKNOWN and its value is ignored.

For Linked Address breakpoints:

- If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:
  - Disabled, and DBGBCR<n>.LBN for it reads UNKNOWN.
  - Links to an UNKNOWN context-aware breakpoint. In this case, it generates Breakpoint exceptions and DBGBCR<n>.LBN indicates which context-aware breakpoint it has linked to.
- If a Linked Address breakpoint that links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

Other usage constraints for Context breakpoints

For all Context breakpoints,:

- Any bits of DBGBVR<n> and DBGBXVR<n> that are not used to specify Context ID or VMID are RES0 and are ignored.

  Note

  This means that for Context ID Match breakpoints, the DBGBXVR<n> is RES0 and is ignored, and for VMID Match breakpoints, the DBGBVR<n> is RES0 and is ignored.
- DBGBCR<n>.LBN reads UNKNOWN and its value is ignored.

For Linked Context breakpoints:

- DBGBCR<n>.{LBN, SSC, HMC, PMC} are ignored.
- If no Linked Address breakpoints or Linked Watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

G2.9.7 Exception syndrome information and preferred return address

See the following:

- *Exception syndrome information*.
- *Preferred return address* on page G2-3546.

Exception syndrome information

The PE takes a Breakpoint exception as either:

- A Prefetch Abort exception, if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

Abort mode

The PE sets all of the following:

- DBGDSCRext.MOE to `0b0001`, to indicate a Breakpoint exception.
- IFSR.FS to the code for a debug event, `0b00010`.
- The IFAR with an UNKNOWN value.

Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, HSR. See Table G2-14.
- Sets DBGDSCRext.MOE to `0b0001`, to indicate a Breakpoint exception.
- Sets the HIFAR to an UNKNOWN value.

Table G2-14 Information recorded in the HSR

HSR field	Information recorded
Exception Class, EC	The PE sets this to the code for a Prefetch Abort exception routed to Hyp mode, `0x20`.
Instruction Length, IL	The PE sets this to 1.
Instruction Specific Syndrome, ISS	**ISS[24:10]** RES0. **ISS[9]** *External Abort type* (EA). The PE sets this to 0. **ISS[8:6]** RES0. **ISS[5:0]** *Instruction Fault Status Code* (IFSC). The PE sets this to the code for a debug exception, `0b100010`.

Note

For information about how debug exceptions can be routed to PL2, see *Routing debug exceptions* on page G2-3514.

Preferred return address

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

G2.9.8 Pseudocode descriptions of Breakpoint exceptions taken from AArch32 state

`AArch32.BreakpointValueMatch()` returns a pair of results:

- A result for Address Match and Context breakpoints.
- A result for Address Mismatch breakpoints.

```
// AArch32.BreakpointValueMatch()
// ==============================
// The first result is whether an Address Match or Context breakpoint is programmed on the instruction
// at “address”. The second result is whether an Address Mismatch breakpoint is programmed on the
// instruction, that is, whether the instruction should be stepped.

(boolean,boolean) AArch32.BreakpointValueMatch(integer n, bits(32) vaddress, boolean linked_to)

    // “n” is the identity of the breakpoint unit to match against
    // “vaddress” is the current instruction address, ignored if linked_to is TRUE and for Context
    //    matching breakpoints.
    // “linked_to” is TRUE if this is a call from StateMatch for linking.

    // If a non-existant breakpoint then it is CONSTRAINED UNPREDICTABLE whether this gives
    // no match or the breakpoint is mapped to another UNKNOWN implemented breakpoint.
    if n > UInt(DBGDIDR.BRPs) then
        (c, n) = ConstrainUnpredictableInteger(0, UInt(DBGDIDR.BRPs));
        assert c IN {Constraint_NONE, Constraint_UNKNOWN};
        if c == Constraint_NONE then return (FALSE,FALSE);

    // If this breakpoint is not enabled, it cannot generate a match. (This could also happen on a
    // call from StateMatch for linking.)
    if DBGBCR[n].E == ‘0’ then return (FALSE,FALSE);

    context_aware = (n >= UInt(DBGDIDR.BRPs) - UInt(DBGDIDR.CTX_CMPs));

    // If BT is set to a reserved type, behaves either as disabled or as a not-reserved type.
    type = DBGBCR[n].BT;
    if (type IN {‘011x’,’11xx’} ||                                  // Reserved
          (type == ‘010x’ && !HaltOnBreakpointOrWatchpoint()) ||    // Address mismatch
          (type != ‘0x0x’ && !context_aware) ||                     // Context matching
          (type == ‘1xxx’ && !HaveEL(EL2))) then                    // VMID match
        (c, type) = ConstrainUnpredictableBits();
        assert c IN {Constraint_NONE, Constraint_UNKNOWN};
        if c == Constraint_NONE then return (FALSE,FALSE);
        // Otherwise the value returned by ConstrainUnpredictableBits must be a not-reserved value

    // Determine what to compare against.
    match_addr = type == ‘0x0x’;
    mismatch   = type == ‘010x’;
    match_vmid = type == ‘10xx’;
    match_cid  = type == ‘x01x’;
    linked     = type == ‘xxx1’;

    // If this is a call from StateMatch, return FALSE if the breakpoint is not programmed for a
    // VMID and/or context ID match, of if not context-aware. The above assertions mean that the
    // code can just test for match_addr == TRUE to confirm all these things.
    if linked_to && (!linked || match_addr) then return (FALSE,FALSE);

    // If this is a call from BreakpointMatch return FALSE for Linked context ID and/or VMID matches.
    if !linked_to && linked && !match_addr then return (FALSE,FALSE);

    // Do the comparison.
```

```
    if match_addr then
        byte = UInt(vaddress<1:0>);
        assert byte IN {0,2};                    // “vaddress” is halfword aligned.
        byte_select_match = (DBGBCR[n].BAS<byte> == ‘1’);
        BVR_match = vaddress<31:2> == DBGBVR[n]<31:2> && byte_select_match;
    elsif match_cid then
        BVR_match = (PSTATE.EL != EL2 && CONTEXTIDR == DBGBVR[n]<31:0>);
    if match_vmid then
        vmid = (if ELUsingAArch32(EL2) then VTTBR_EL2.VMID else VTTBR.VMID);
        BXVR_match = (HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} && vmid == DBGBXVR[n]<7:0>);

    match = (!match_vmid || BXVR_match) && (!(match_addr || match_cid) || BVR_match);
    return (match && !mismatch, !match && mismatch);
```

AArch32.StateMatch() tests the values in DBGBCR<n>.{SSC, HMC, PMC} and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

For a watchpoint, AArch32.StateMatch() tests the values in DBGWCR<n>.{SSC, HMC, PAC} and, if the watchpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

```
// AArch32.StateMatch()
// ====================
// Determine whether a breakpoint or watchpoint is enabled in the current mode and state.

boolean AArch32.StateMatch(bits(2) SSC, bit HMC, bits(2) PxC, boolean linked, bits(4) LBN,
                           boolean isbreakpnt, boolean ispriv)
    // “SSC”, “HMC”, “PxC” are the control fields from the DBGBCR[n] or DBGWCR[n] register.
    // “LBN” is the linked breakpoint number from the DBGBCR[n] or DBGWCR[n] register.
    // “ispriv” is valid for watchpoints, and selects between privileged and unprivileged accesses.
    // “linked” is TRUE if this is a linked breakpoint/watchpoint type.
    // “isbreakpnt” is TRUE for breakpoints, FALSE for watchpoints.

    // If parameters are set to a reserved type, behaves either as disabled or not a reserved-type
    ctl = HMC:SSC:PxC;
    if (ctl IN {‘011xx’, ‘100x0’,’101x0’,’110x0’,’11101’,’1111x’} ||           // Reserved
          (ctl == ‘0xx00’ && !isbreakpnt) ||                                   // Usr/Svc/Sys match
          (ctl IN {‘x01xx’,’x10xx’} && !HaveEL(EL3)) ||                        // No EL3
          (ctl != ‘000xx’ && !HaveEL(EL3) && !HaveEL(EL2))) then               // No EL3 or EL2
        (c, ctl) = ConstrainUnpredictableBits();
        assert c IN {Constraint_NONE, Constraint_UNKNOWN};
        if c == Constraint_NONE then return FALSE;
        // Otherwise the value returned by ConstrainUnpredictableBits must be a not-reserved value
        HMC = ctl<4>;  SSC = ctl<3:2>;  PxC = ctl<1:0>;

    PL3_match = HaveEL(EL3) && HMC == ‘1’ && SSC<0> == ‘0’;
    PL2_match = HaveEL(EL2) && HMC == ‘1’;
    PL1_match = PxC<0> == ‘1’;
    PL0_match = PxC<1> == ‘1’;
    SSU_match = isbreakpnt && HMC == ‘0’ && PxC == ‘00’ && SSC != ‘11’;

    if SSU_match then
        priv_match = PSTATE.M IN {M32_User,M32_Svc,M32_System};
    else
        case PSTATE.EL of
            when EL3, EL1  priv_match = if ispriv then PL1_match else PL0_match;
            when EL2       priv_match = PL2_match;
            when EL0       priv_match = PL0_match;

    case SSC of
        when ‘00’  security_state_match = TRUE;         // Both
        when ‘01’  security_state_match = !IsSecure();  // Non-secure only
        when ‘10’  security_state_match = IsSecure();   // Secure only
        when ‘11’  security_state_match = TRUE;         // Both

    if linked then
        // “LBN” must be an enabled context-aware breakpoint unit. If it is not context-aware then it
```

```
        // is CONSTRAINED UNPREDICTABLE whether this gives no match, or LBN is mapped to some UNKNOWN
        // breakpoint that is context-aware.
        lbn = UInt(LBN);
        first_ctx_cmp = (UInt(DBGDIDR.BRPs) - UInt(DBGDIDR.CTX_CMPs));
        last_ctx_cmp = UInt(DBGDIDR.BRPs);
        if (lbn < first_ctx_cmp || lbn > last_ctx_cmp) then
            (c, lbn) = ConstrainUnpredictableInteger(first_ctx_cmp, last_ctx_cmp);
            assert c IN {Constraint_NONE, Constraint_UNKNOWN};
            if c == Constraint_NONE then return FALSE;
        vaddress = bits(32) UNKNOWN;
        linked_to = TRUE;
        (linked_match,-) = AArch32.BreakpointValueMatch(lbn, vaddress, linked_to);

    return priv_match && security_state_match && (!linked || linked_match);
```

`AArch32.BreakpointMatch()` tests a committed instruction against all breakpoints.

```
// AArch32.BreakpointMatch()
// =========================
// Breakpoint matching in an AArch32 translation regime.

(boolean,boolean) AArch32.BreakpointMatch(integer n, bits(32) vaddress, integer size)
    assert ELUsingAArch32(TranslationRegime());
    assert n <= UInt(DBGDIDR.BRPs);

    enabled = DBGBCR[n].E == '1';
    ispriv = PSTATE.EL != EL0;
    linked = DBGBCR[n].BT == '0x01';
    isbreakpnt = TRUE;
    linked_to = FALSE;

    state_match = AArch32.StateMatch(DBGBCR[n].SSC, DBGBCR[n].HMC, DBGBCR[n].PMC,
                                     linked, DBGBCR[n].LBN, isbreakpnt, ispriv);
    (value_match, value_mismatch) = AArch32.BreakpointValueMatch(n, vaddress, linked_to);

    if size == 4 then                 // Check second halfword
        // If the breakpoint address and BAS of an Address breakpoint match the address of the
        // second halfword of an instruction, but not the address of the first halfword, it is
        // CONSTRAINED UNPREDICTABLE whether or not this breakpoint generates a Breakpoint debug
        // event.
        (match_i, mismatch_i) = AArch32.BreakpointValueMatch(n, vaddress + 2, linked_to);
        if !value_match && match_i then
            value_match = ConstrainUnpredictableBool();
        if value_mismatch && !mismatch_i then
            value_mismatch = ConstrainUnpredictableBool();

    if vaddress<1> == '1' && DBGBCR[n].BAS == '1111' then
        // The above notwithstanding, if DBGBCR[n].BAS == '1111', then it is CONSTRAINED
        // UNPREDICTABLE whether or not a Breakpoint debug event is generated for an instruction
        // at the address DBGBVR[n]+2.
        if value_match then value_match = ConstrainUnpredictableBool();
        if !value_mismatch then value_mismatch = ConstrainUnpredictableBool();

    match = value_match && state_match && enabled;
    mismatch = value_mismatch && state_match && enabled;

    return (match, mismatch);
```

`AArch32.CheckBreakpoint()` generates a FaultRecord that `AArch32.Abort` raises a Breakpoint exception for if all of the following are true:

- DBGDSCRext.MDBGen is 1.

- Debug exceptions are enabled from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level and Security state* on page G2-3516.
- All of the conditions required for Breakpoint exception generation are met. See *About Breakpoint exceptions* on page G2-3526.

Note

`AArch32.CheckBreakpoint()` might halt the PE and cause it to enter Debug state. External debug uses Debug state.

```
// AArch32.CheckBreakpoint()
// =========================
// Called before executing the instruction of length "size" bytes at "vaddress" in an AArch32
// translation regime.
// The breakpoint can in fact be evaluated well ahead of execution, for example, at instruction
// fetch. This is the simple sequential execution of the program.

FaultRecord AArch32.CheckBreakpoint(bits(32) vaddress, integer size)
    assert ELUsingAArch32(TranslationRegime());
    assert size IN {2,4};

    match = FALSE;
    mismatch = FALSE;

    for i = 0 to UInt(DBGDIDR.BRPs)
        (match_i, mismatch_i) = AArch32.BreakpointMatch(i, vaddress, size);
        match = match || match_i;
        mismatch = mismatch || mismatch_i;

    if match && HaltOnBreakpointOrWatchpoint() then
        reason = DebugHalt_Breakpoint;
        Halt(reason);
    elsif (match || mismatch) && DBGDSCRext.MDBGen == '1' && AArch32.GenerateDebugExceptions() then
        acctype = AccType_IFETCH;
        iswrite = FALSE;
        debugmoe = DebugException_Breakpoint;
        return AArch32.DebugFault(acctype, iswrite, debugmoe);
    else
        return AArch32.NoFault();
```

The `Abort()` function processes the Faultrecord object returned by `CheckBreakpoint`, as described in *Abort exceptions* on page G3-3611. If there is a Breakpoint exception, the `Abort()` function generates a Prefetch Abort exception.

G2.10 Watchpoint exceptions

This section describes Watchpoint exceptions in an AArch32 stage 1 translation regime.

It contains the following subsections:

G2.10.1 About Watchpoint exceptions

A *watchpoint* is a debug event that results from the execution of an instruction, based on a data address. Watchpoints are also known as *data breakpoints*.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a *Watchpoint debug event* on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, DBGDIDR.WRPs shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

- The *Watchpoint Control Register*, DBGWCR<n>. This holds control information for the watchpoint, for example an enable control.
- The *Watchpoint Value Register*, DBGWVR<n>. This holds the data address value used for watchpoint matching.

The registers are numbered, so that:

- DBGWCR1 and DBGWVR1 are for watchpoint number one.
- DBGWCR2 and DBGWVR2 are for watchpoint number two.
- …
- …
- DBGWCRn and DBGWVRn are for watchpoint number n.

A watchpoint can:

- Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
- Link to a *Linked Context breakpoint*, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.

A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the *Byte Address Select* field, DBGWCR<n>.BAS, to select the bytes. See *Programming a watchpoint with eight bytes or fewer* on page G2-3554.

- Eight bytes to 2GB, provided that both of the following are true:
  - The number of bytes is a power-of-two.
  - The range starts at an address that is aligned to the range size.

  A debugger uses the *MASK* field, DBGWCR<n>.MASK, to program a watchpoint with eight bytes to 2GB. See *Programming a watchpoint with eight or more bytes* on page G2-3556.

A debugger must use either the BAS field or the MASK field. If it uses both, whether the watchpoint generates Watchpoint exceptions is CONSTRAINED UNPREDICTABLE. See *Programming dependencies of the BAS and MASK fields* on page G2-3559.

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, DBGWCR<n>.E, is 1.
- The conditions specified in the DBGWCR<n> are met.
- The comparison with the address held in the DBGWVR<n> is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint are successful. See on page G2-3530 shows this. See also *Context comparisons* on page G2-3540.
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its condition code check.

Note

The debug logic tests all watchpoints before the execution of each instruction that initiates a memory access. The debug logic might test all watchpoints when data is fetched speculatively. However, a watchpoint does not generate a Watchpoint debug event unless the instruction that initiates the memory access passes its condition code check and is committed for execution.

If halting is allowed and EDSCR.HDE is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

Note

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.

However, the behavior described also applies if watchpoints are causing entry to Debug state.

The debug exception enable controls on page G2-3513 describes the enable controls for Watchpoint debug events.

G2.10.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case the watchpoint is called an *Unlinked watchpoint*.
- Enabled for linking to a Linked Context breakpoint. In this case the watchpoint is called a *Linked watchpoint*.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a *Linked VMID Match breakpoint*.

3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the VMID matches.

The *Watchpoint Type* field for a watchpoint, DBGWCR<n>.WT, controls whether the watchpoint is enabled for linking. If DBGWCR<n>.WT is 1, the watchpoint is enabled for linking.

Rules for linking watchpoints

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, DBGWCR<n>.LBN, for the Linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
  - DBGWCR<n>.WT.{SSC, HMC, PAC} for the Linked watchpoint define the execution conditions that the watchpoint generates Watchpoint exceptions for. See *Execution conditions a watchpoint generates Watchpoint exceptions for*.
  - DBGBCR<n>.{SSC, HMC, PMC} for the Linked Context breakpoint are ignored.
- A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
- If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is CONSTRAINED UNPREDICTABLE. See *Usage constraints* on page G2-3558
- If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.
- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

Note

Multiple Address breakpoints can also link to a single Linked Context breakpoint. *Breakpoint exceptions* on page G2-3526 describes breakpoints.

Figure G2-3 on page G2-3530 shows an example of permitted watchpoint linking.

G2.10.3 Execution conditions a watchpoint generates Watchpoint exceptions for

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only when the PE is executing at PL0 in Secure state.

DBGWCR<n>.{SSC, HMC, PAC} define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states. The comparison is made with the Security state of the PE, not the NS attribute of the physical instruction fetch address.

Higher Mode Control, HMC, and Privileged Access Control, PAC

HMC and PAC together control which Privilege level the watchpoint generates Watchpoint exceptions in.

Note

PAC controls which access privilege the watchpoint matches. This means that if the PE is executing an unprivileged load/store instruction at PL1, the data access might trigger a watchpoint that is programmed to match on PL0 accesses.

Table G2-15 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Privilege levels watchpoints generate Watchpoint exceptions in.

In the table:

Y or - Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:
- **Y** Can generate Watchpoint exceptions at that Privilege level.
- **-** Cannot generate Watchpoint exceptions at that Privilege level.

Res Means that the combination of HMC, SSC, and PAC is reserved. See *Reserved DBGWCR<n>.{HMC, SSC, PAC} values* on page G2-3559.

Table G2-15 Summary of watchpoint HMC, SSC, and PAC encodings

HMC	SSC	PAC	Security state the watchpoint is programmed to match in	PL2[a]	PL1	PL0	Implementation	
							No EL3	No EL2 and no EL3
0	00	01	Both	-	Y	-	-	-
0	00	10		-	-	Y	-	-
0	00	11		-	Y	Y	-	-
0	01	01	Non-secure	-	Y	-	Res	Res
0	01	10		-	-	Y	Res	Res
0	01	11		-	Y	Y	Res	Res
0	10	01	Secure	-	Y	-	Res	Res
0	10	10		-	-	Y	Res	Res
0	10	11		-	Y	Y	Res	Res
1	00	01	Both	Y	Y	-	-	Res
1	00	11		Y	Y	Y	-	Res
1	01	01	Non-secure	Y	Y	-	Res	Res
1	01	11		Y	Y	Y	Res	Res
1	10	01	Secure	-	Y	-	Res	Res
1	10	11		-	Y	Y	Res	Res
1	11	00	Non-secure	Y	-	-	-	Res

a. Debug exceptions are not generated at PL2 using AArch32. This means that these combinations of HMC, SSC, and PAC are only relevant if watchpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PAC that generate Watchpoint exceptions at PL2 using AArch32.

All combinations of HMC, SSC, and PAC that this table does not show are reserved. See *Reserved DBGWCR<n>.{HMC, SSC, PAC} values* on page G2-3559.

G2.10.4 Data address comparisons

An address comparison is successful if bits [31:2] of the current data address are equal to DBGWVR<n>[31:2], taking into account both:

- The size of the access. See *Size of the data access* on page G2-3554.
- The bytes selected by DBGWVR<n>.BAS. See *Programming a watchpoint with eight bytes or fewer*.

- Any address ranges indicated by DBGWVR<n>.MASK. See *Programming a watchpoint with eight or more bytes* on page G2-3556.

Note

DBGWVR<n>[1:0] are RES0 and are ignored.

Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each access must be taken into account. See Example G2-1.

Example G2-1 Why the size of each data access must be taken into account

1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address `0x1009` is accessed.
2. The PE accesses the unaligned doubleword starting at address `0x1003`.

In this scenario, the watchpoint must generate a Watchpoint exception.

The size of data accesses initiated by `DC IVAC` instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
  - The size that CTR.DminLine defines.
  - 2KB.
- A power-of-two.

The lowest address accessed by a `DC IVAC` instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.

The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, *Watchpoint behavior on accesses by cache maintenance instructions* on page G2-3558.

Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, DBGWCR<n>.BAS, selects which bytes in the doubleword starting at the address contained in the DBGWVR<n> the watchpoint generates Watchpoint exceptions for.

If the address programmed into the DBGWVR<n> is:

- Doubleword-aligned:
  - All eight bits of DBGWCR<n>.BAS are used, and the descriptions given in Table G2-16 on page G2-3555 apply.

- Word-aligned but not doubleword-aligned:
  - Only DBGWCR<n>.BAS[3:0] are used, and the descriptions given in Table G2-17 apply. In this case, DBGWCR<n>.BAS[7:4] are RES0.

Table G2-16 Supported BAS values when the DBGWVRn address alignment is doubleword

BAS value	Description
0b00000000	Watchpoint never generates a Watchpoint exception
BAS[0] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>[31:3]:000 is accessed
BAS[1] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>[31:3]:001 is accessed
BAS[2] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>[31:3]:010 is accessed
BAS[3] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>[31:3]:011 is accessed
BAS[4] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>[31:3]:100 is accessed
BAS[5] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>[31:3]:101 is accessed
BAS[6] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>[31:3]:110 is accessed
BAS[7] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>[31:3]:111 is accessed

Table G2-17 Supported BAS values when the DBGWVRn address alignment is word

BAS value[a]	Description
0b00000000	Watchpoint never generates a Watchpoint exception
BAS[0] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>[31:2]:00 is accessed
BAS[1] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>[31:2]:01 is accessed
BAS[2] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>[31:2]:10 is accessed
BAS[3] == 1	Generates a Watchpoint exception if byte at address DBGWVR<n>[31:2]:11 is accessed

a. DBGWCR<n>.BAS[7:4] are RES0.

If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see *Other usage constraints* on page G2-3560.

When programming the BAS field with anything other than 0b11111111, a debugger must also program DBGWCR<n>.MASK to be 0b00000. See *Programming dependencies of the BAS and MASK fields* on page G2-3559.

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the DBGWVR<n>[31:3]. See Example G2-1 on page G2-3554.

The following are some example configurations of the BAS field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
  - DBGWVR<n> with 0x1000.
  - DBGWCR<n>_EL1.BAS to be 0b00001000.

- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses `0x2003`, `0x2004` and `0x2005`, program:
  - DBGWVR<n> with `0x2000`.
  - DBGWCR<n>_EL1.BAS to be `0b00111000`.
- If the address programmed into the DBGWVR<n> is doubleword-aligned:
  - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program DBGWCR<n>.BAS to be `0b00001111`.
  - To generate a Watchpoint exception when any byte in the word starting at address DBGWVR<n>[31:3]:100 is accessed, program DBGWCR<n>.BAS to be `0b11110000`.

Note

ARM deprecates programming a DBGWVR<n> with an address that is not doubleword-aligned.

Programming a watchpoint with eight or more bytes

A debugger can use the *MASK* field, DBGWCR<n>.MASK, to program a single watchpoint with a data address range. The data address range must meet all of the following criteria:

- It is a size that is both:
  - A power-of-two.
  - Eight bytes to 2GB.
- It starts at an address that is aligned to the size.

The MASK field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

MASK	`0b00000`	No bits are masked.
	`0b00001`	Reserved.
	`0b00010`	Reserved.
	`0b00011`	Three least significant bits are masked.
	`0b00100`	Four least significant bits are masked.
	`0b00101`	Five least significant bits are masked.
	…	…
	`0b11111`	31 least significant bits are masked.

If *n* least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address DBGWVR<n>[31:*n*]:000…
- Address DBGWVR<n>[31:*n*]:111…
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between DBGWVR<n>[31:4]:0000 and DBGWVR<n>[31:4]:1111, including these addresses.

Note

- The most significant bit cannot be masked. This means that the full address cannot be masked.
- For watchpoint behavior when its MASK field is programmed with a reserved value, see *Reserved DBGWCR<n>.MASK values* on page G2-3560.

When masking address bits, a debugger must both:

- Program DBGWCR<n>.BAS to be `0b11111111`. See *Programming dependencies of the BAS and MASK fields* on page G2-3559.

- In the DBGWVR<n>, set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see *Other usage constraints* on page G2-3560.

G2.10.5 Determining the memory location that caused a Watchpoint exception

On a Watchpoint exception, the PE records an address in a *Fault Address Register* that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- DFAR, if the exception is taken to PL1.
- HDFAR, if the exception is taken to PL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the EDWAR.

For more information, see the subsections that follow. These are:

- *Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions*.
- *Address recorded for Watchpoint exceptions generated by Data Cache instructions*.

Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions

The address recorded must be both:

- From the inclusive range between:
  - The lowest address accessed by the memory access that triggered the watchpoint.
  - The highest *watchpointed address* accessed by the memory access. A watchpointed address is an address that the watchpoint is watching.
- Within a naturally-aligned block of memory that is all of the following:
  - A power-of-two size.
  - No larger than 2KB.

    Note

    It must also be no larger than the block size used by the A64 DC ZVA instruction.

    There is no architectural means to discover this block size from Arch32 state.
  - Contains a watchpointed address accessed by the memory access.

  The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

Example G2-2 Address recorded for a watchpoint programmed on `0x8019`

A debugger programs a watchpoint to generate a Watchpoint debug event on any access to the byte `0x8019`.

An A32 load multiple instruction then loads nine registers starting from address `0x8004` upwards. This triggers the watchpoint.

If the `DC ZVA` block size is:

- 32 bytes, the address that the PE records must be between `0x8004` and `0x8019` inclusive.
- 16 bytes, the address that the PE records must be between `0x8010` and `0x8019` inclusive.

Address recorded for Watchpoint exceptions generated by Data Cache instructions

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.

G2.10.6 Watchpoint behavior on instructions other than Load/Store instructions

See the following:

- *Watchpoint behavior on accesses by prefetch instructions*.
- *Watchpoint behavior on accesses by Store-Exclusive instructions*.
- *Watchpoint behavior on accesses by cache maintenance instructions*.

Watchpoint behavior on accesses by prefetch instructions

Memory prefetch instructions never cause Watchpoint exceptions.

Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the write to memory is successful, the watchpoint generates a Watchpoint exception.
- If the write to memory fails because the Store-Exclusive instruction does not have possession of the exclusive monitors, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.

Watchpoint behavior on accesses by cache maintenance instructions

It is IMPLEMENTATION DEFINED whether DCIMVAC operations can generate Watchpoint exceptions. If they can, they are treated as data stores. This means that for a watchpoint to match on an access caused by a DCIMVAC instruction, the debugger must program DBGWCR<n>.LSC to be one of the following:

10 Match on data stores only.

11 Match on data stores and data loads.

No other data cache maintenance instructions can generate Watchpoint exceptions.

Instruction cache maintenance instructions never generate Watchpoint exceptions.

Note

For the size of data accesses performed by cache maintenance instructions, see *Data address comparisons* on page G2-3553. The size of all data accesses must be considered because watchpoints can be programmed to match only on particular address bytes.

G2.10.7 Usage constraints

See the following:

- *Reserved DBGWCR<n>.{HMC, SSC, PAC} values* on page G2-3559.
- *Reserved DBGWCR<n>.LBN values* on page G2-3559.
- *Programming dependencies of the BAS and MASK fields* on page G2-3559.
- *Reserved DBGWCR<n>.BAS values* on page G2-3560.
- *Reserved DBGWCR<n>.MASK values* on page G2-3560.
- *Other usage constraints* on page G2-3560.

Reserved DBGWCR<n>.{HMC, SSC, PAC} values

Table G2-18 shows when particular combinations of DBGWCR<n>.{HMC, SSC, PAC} are reserved.

Table G2-18 Reserved HMC, SSC, and PAC combinations

HMC, SSC, and PMC combination	Reserved
All combinations with SSC set to `0b01` or `0b10`.	When EL3 is not implemented and EL2 is implemented.
All combinations where HMC or SSC is nonzero.	When both of EL2 and EL3 are not implemented.
Combinations not included in Table G2-15 on page G2-3553.	Always

If an enabled watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct read of DBGWCR<n>.
- For a direct read of DBGWCR<n>, if the reserved combination:
  - Has no function for any execution conditions, the value read back for each of HMC, SSC, and PMC is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of HMC, SSC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGWCR<n>.LBN values

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any DBGWCR<n>.LBN value that is not for a context-aware breakpoint is reserved.

Programming dependencies of the BAS and MASK fields

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the DBGWVR<n> the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be `0b11111111`, so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be `0b00000`, so that the MASK field does not indicate any address ranges.

If the debugger uses both of these fields, then behavior of the watchpoint is CONSTRAINED UNPREDICTABLE. Either:

- The watchpoint treats the MASK field as if it is programmed with `0b00000`. In this case, the watchpoint is programmed with a single address and it generates Watchpoint exceptions for the bytes that the BAS field indicates.
- For each byte in the masked region, it is constrained unpredictable whether the watchpoint generates a Watchpoint exception.

Reserved DBGWCR<n>.BAS values

If DBGWVR<n>[2] is 1, DBGWCR<n>.BAS[7:4] are RES0 and are ignored.

Reserved DBGWCR<n>.MASK values

If DBGWCR<n>.MASK is programmed with a reserved value, the watchpoint must behave as if it is either:

- Disabled.
- Programmed with an UNKNOWN value that is not reserved, that might be `0b00000`.

Other usage constraints

For all watchpoints:

- DBGWVR<n>[1:0] are RES0 and are ignored.
- If DBGWCR<n>.BAS is programmed with non-contiguous bytes of memory, it is CONSTRAINED UNPREDICTABLE whether the Watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the DBGWCR<n>.
- If DBGWVR<n>.MASK is non-zero, and any masked bits of DBGWVR<n> are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if DBGWCR<n>.LSC is `0b00`.

For Unlinked watchpoints, DBGBCR<n>.LBN reads UNKNOWN and its value is ignored.

For Linked watchpoints:

- If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, behavior is CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:
  - Disabled, and DBGBCR<n>.LBN for it reads UNKNOWN.
  - Links to an UNKNOWN context-aware breakpoint. In this case, it generates Watchpoint exceptions and DBGBCR<n>.LBN indicates which context-aware breakpoint it has linked to.
- If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

G2.10.8 Exception syndrome information and preferred return address

See the following:

- *Exception syndrome information*.
- *Preferred return address* on page G2-3561.

Exception syndrome information

The PE takes a Watchpoint exception as either:

- A Data Abort exception, if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

Abort mode

The PE sets all of the following:

- DBGDSCRext.MOE to `0b1010`, to indicate a Watchpoint exception.
- DFSR.CM to indicate whether a cache maintenance instruction caused the exception.

- DFSR.WnR to indicate whether the exception was generated on a read instruction or a write instruction.
- DFAR to an address that the debugger can use to determine the memory location that triggered the watchpoint. See *Determining the memory location that caused a Watchpoint exception* on page G2-3557.

In addition, if using the:

- Short-descriptor format, the PE sets DFSR.FS to the code for a debug event, `0b00010`, and DFSR.Domain to an UNKNOWN value.
- Long-descriptor format, the PE sets DFSR.STATUS to the code for a debug event, `0b100010`.

Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, HSR. See Table G2-19.
- Sets DBGDSCRext.MOE to `0b1001`, to indicate a Watchpoint exception.
- Sets the HDFAR to an address that the debugger can use to determine the memory location that triggered the watchpoint. See *Determining the memory location that caused a Watchpoint exception* on page G2-3557.

Table G2-19 Information recorded in the HSR

HSR field	Information recorded
Exception Class, EC	The PE sets this to the code for a Data Abort exception routed to Hyp mode, `0x24`.
Instruction Length, IL	The PE sets this to 1.
Instruction Specific Syndrome, ISS	**ISV[24]** *Instruction Syndrome Valid* (ISV). The PE sets this to 0. **ISS[23:10]** RES0. **ISS[9]** *External Abort type* (EA). The PE sets this to 0. **ISS[8]** *Cache Maintenance* (CM). The PE sets this to indicate whether a cache maintenance instruction caused the exception. **ISS[7]** RES0. **ISS[6]** *Write not Read* (WnR). The PE sets this to indicate whether the exception was generated on a read instruction or a write instruction. **ISS[5:0]** *Data Fault Status Code* (DFSC). The PE sets this to the code for a debug exception, `0b100010`.

Note

For information about how debug exceptions can be routed to PL2, see *Routing debug exceptions* on page G2-3514.

Preferred return address

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

G2.10.9 Pseudocode description of Watchpoint exceptions taken from AArch32 state

`AArch32.WatchpointByteMatch()` tests an individual byte accessed by an operation.

```
// AArch32.WatchpointByteMatch()
// =============================
```

```
boolean AArch32.WatchpointByteMatch(integer n, bits(32) vaddress)

    bottom = if DBGWVR[n]<2> == '1' then 2 else 3;
    byte_select_match = (DBGWCR[n].BAS<UInt(vaddress<bottom-1:0>)> != '0');
    mask = UInt(DBGWCR[n].MASK);

    // If the address mask is set to a reserved value, the behavior is CONSTRAINED UNPREDICTABLE.
    if mask <= 2 then
        if ConstrainUnpredictableBool() then return FALSE;            // Disabled
        else (-, mask) = ConstrainUnpredictableInteger(bottom, 31); // Map to a not reserved value

    // If masked bits of DBGWVR_EL1[n] are not zero, the behavior is CONSTRAINED UNPREDICTABLE.
    if mask > bottom then
        WVR_match = (vaddress<31:mask> == DBGWVR[n]<31:mask> &&
                     (IsZero(DBGWVR[n]<mask-1:bottom>) || ConstrainUnpredictableBool()));
    else
        WVR_match = vaddress<31:bottom> == DBGWVR[n]<31:bottom>;

    // If DBGWCR[n].MASK is non-zero value and DBGWCR[n].BAS is not set to '11111111', the
    // behavior is CONSTRAINED UNPREDICTABLE.
    if !IsZero(DBGWCR[n].MASK) && !IsOnes(DBGWCR[n].BAS) then
        c = ConstrainUnpredictable();
        case c of
            when Constraint_IGNOREMASK
                WVR_match = vaddress<31:bottom> == DBGWVR[n]<31:bottom>;
            when Constraint_IGNOREBAS
                byte_select_match = TRUE;
            when Constraint_REPEATBAS
                /*do nothing*/
            otherwise  Unreachable();
    else
        // If DBGWCR[n].BAS specifies a non-contiguous set of bytes, the generation of
        // Watchpoint debug events for the doubleword is CONSTRAINED UNPREDICTABLE.
        LSB = (DBGWCR[n].BAS AND NOT(DBGWCR[n].BAS - 1));  MSB = (DBGWCR[n].BAS + LSB);
        if !IsZero(MSB AND (MSB - 1)) && vaddress<31:3> == DBGWVR[n]<31:3> then
            byte_select_match = ConstrainUnpredictableBool();

    return WVR_match && byte_select_match;
```

`AArch32.StateMatch()` tests the values in DBGWCR<n>.{HMC, SSC, PAC}, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to. AArch32.StateMatch() is given in the Breakpoint exceptions section. See page G2-3547.

`AArch32.WatchpointMatch()` tests the value in DBGWVR<n>.

```
// AArch32.WatchpointMatch()
// =========================
// Watchpoint matching in an AArch32 translation regime.

boolean AArch32.WatchpointMatch(integer n, bits(32) vaddress, integer size, boolean ispriv,
                                boolean iswrite)
    assert ELUsingAArch32(TranslationRegime());
    assert n <= UInt(DBGDIDR.WRPs);

    // "ispriv" is FALSE for LDRT/STRT instructions executed at EL1 and all
    // load/stores at EL0, TRUE for all other load/stores. "iswrite" is TRUE for stores, FALSE for
    // loads.
    enabled = DBGWCR[n].E == '1';
    linked = DBGWCR[n].WT == '1';
    isbreakpnt = FALSE;

    state_match = AArch32.StateMatch(DBGWCR[n].SSC, DBGWCR[n].HMC, DBGWCR[n].PAC,
                                     linked, DBGWCR[n].LBN, isbreakpnt, ispriv);
```

```
    ls_match = (DBGWCR[n].LSC<(if iswrite then 1 else 0)> == '1');

    value_match = FALSE;
    for byte = 0 to size - 1
        value_match = value_match || AArch32.WatchpointByteMatch(n, vaddress + byte);

    return value_match && state_match && ls_match && enabled;
```

`AArch32.CheckWatchpoint()` generates a FaultRecord that `AArch32.Abort` raises a Watchpoint exception for if all of the following are true:

- DBGDSCRext.MDBGen is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level and Security state* on page G2-3516.
- All of the conditions required for Watchpoint exception generation are met. See *About Watchpoint exceptions* on page G2-3550.

Note

`AArch32.CheckWatchpoint()` might halt the PE and cause it to enter Debug state. External debug uses Debug state.

```
// AArch32.CheckWatchpoint()
// =========================
// Called before accessing the memory location of "size" bytes at "address".

FaultRecord AArch32.CheckWatchpoint(bits(32) vaddress, AccType acctype,
                                    boolean iswrite, integer size)
    assert ELUsingAArch32(TranslationRegime());

    match = FALSE;
    ispriv = PSTATE.EL != EL0 && !(PSTATE.EL == EL1 && acctype == AccType_UNPRIV);

    for i = 0 to UInt(DBGDIDR.WRPs)
        match = match || AArch32.WatchpointMatch(i, vaddress, size, ispriv, iswrite);

    if match && HaltOnBreakpointOrWatchpoint() then
        reason = DebugHalt_Watchpoint;
        Halt(reason);
    elsif match && DBGDSCRext.MDBGen == '1' && AArch32.GenerateDebugExceptions() then
        debugmoe = DebugException_Watchpoint;
        return AArch32.DebugFault(acctype, iswrite, debugmoe);
    else
        return AArch32.NoFault();
```

The `Abort()` function processes the Faultrecord object returned by `CheckWatchpoint`, as described in *Abort exceptions* on page G3-3611. If there is a Watchpoint exception, the `Abort()` function generates a Data Abort exception.

G2.11 Vector Catch exceptions

ARM deprecates the use of vector catch.

The following subsections describe Vector Catch exceptions:

- *About Vector Catch exceptions*.
- *Exception vectors that Vector Catch exceptions can be enabled for* on page G2-3566.
- *Generation of Vector Catch exceptions* on page G2-3568.
- *Usage constraints* on page G2-3569.
- *Exception syndrome information and preferred return address* on page G2-3569.
- *Pseudocode description of Vector Catch exceptions* on page G2-3570.

G2.11.1 About Vector Catch exceptions

Whenever the PE takes an exception, execution is forced to an address that is the *exception vector* for that exception. Vector catch permits a debugger to trap exceptions based on the exception vector, or based on the exception type associated with the exception vector, as follows:

- If the *address-matching* form of vector catch is implemented, the debugger can trap exceptions based on the exception vector.
- If the *exception-trapping* form of vector catch is implemented, the debugger can trap exceptions based on the exception type associated with the exception vector.

The ARMv8-A architecture supports only these two forms of vector catch. Only one form can be implemented, and which is implemented is IMPLEMENTATION DEFINED. The DBGDEVID indicates which form is implemented.

Regardless of the form of vector catch implemented, a debugger enables Vector Catch exceptions for exception types or vectors by programming the DBGVCR. This register contains *vector catch enable bits*. Each of these bits corresponds to a different vector. When a debugger sets a vector catch enable bit to 1, Vector Catch exceptions are enabled for that exception type or vector.

Note

EL2 using AArch64 or EL3 using AArch64 can enable Vector Catch exceptions for vectors by programming the DBGVCR32_EL2. The DBGVCR32_EL2 is architecturally mapped to the DBGVCR.

When Vector Catch exceptions are enabled for an exception vector, this is called an *enabled vector catch*. The set of exception vectors that Vector Catch exceptions are enabled for is called the *enabled vector catch set*.

If the form of vector catch implemented is the:

Address-matching form:

The PE compares the virtual address of each instruction in the program flow with a subset of the enabled vector catch set.

If an address match occurs, a Vector Catch exception is generated when the instruction that caused the match is committed for execution.

Exception-trapping form

Whenever the PE takes an exception, if the exception type is associated with a vector that is included in a subset of the enabled vector catch set, a Vector Catch exception is generated.

The Vector Catch exception is generated as part of entry to the exception, before the exception handler either executes any instructions or takes any further exceptions.

The addresses that comprise the subset depend on whether EL3 is implemented and, for the:

- Address-matching form, the current Security state.
- Exception-trapping form, the Security state that the exception is handled in.

See *Generation of Vector Catch exceptions* on page G2-3568.

Table G2-20 summarizes the differences between the address-matching and exception-trapping forms.

Table G2-20 Differences in behavior of the address-matching and exception-trapping forms of vector catch

Address-matching	Exception-trapping
An enabled vector catch generates a Vector Catch exception when an instruction that is fetched from the vector is committed for execution. This means that spurious Vector Catch exceptions might occur, where the Vector Catch exception does not result from an exception entry, but is instead caused by a branch to the vector. A branch to the vector might occur, for example, on a return from a nested exception or when simulating an exception entry.	An enabled vector catch generates a Vector Catch exception immediately after the PE takes the exception that is associated with the vector. This means that Vector Catch exceptions always result from exception entry, and not from branches to exception vectors.
A Vector Catch exception is generated as a result of an instruction fetch. This means that the Vector Catch exception has a priority relative to the other synchronous exceptions that result from an instruction fetch. *Synchronous exception prioritization* on page D1-1448 describes this prioritization.	A Vector Catch exception is generated as a result of an exception entry. This means that the Vector Catch exception is part of the exception that caused the Vector Catch exception. Therefore, the Vector Catch exception has no priority associated with it. For this reason, Vector Catch exceptions are outside the scope of the prioritization that *Synchronous exception prioritization* on page D1-1448 describes.
A Vector Catch exception can be preempted by another exception. If this happens, the Vector Catch exception is generated again when the exception handler branches back to the vector.	Vector Catch exceptions must be taken before other exceptions.
A Vector Catch exception can be taken as a result of a fetch instruction executed in any AArch32 mode.	Because a Vector Catch exception is generated as the result of an exception entry, the Vector Catch exception is only generated when the PE is in the exception handling mode.

Depending on the implementation, some vector catch enable bits in the DBGVCR might be RES0. For example, if EL3 is not implemented or is implemented but is using AArch64, Monitor mode is not implemented, and so the enable bits for exception vectors for exceptions taken to Monitor mode are RES0. See *Exception vectors that Vector Catch exceptions can be enabled for* on page G2-3566 for the vector catch enable bits that exist for different implementations.

Note

A warm PE reset resets the DBGVCR.

The debug exception enable controls on page G2-3513 describes the enable controls for Vector Catch exceptions.

G2.11.2 Exception vectors that Vector Catch exceptions can be enabled for

When the PE takes an exception, the exception vector is contained in a *vector table* at the Privilege level the exception is taken to.

Depending on the Security state and AArch32 mode the exception is taken to, when the exception is taken, the vector table used is the table that contains one of:

- *Local exception vectors*.
- *Non-secure Local exception vectors*.
- *Secure Local exception vectors*.
- *Hyp exception vectors*.
- *Monitor exception vectors*.

Table G2-21 shows the which vector tables are implemented for different implementations. In the table:

- A dash, -, means that the Exception level is not implemented.
- 64 means that the Exception level is using AArch64.
- 32 means that the Exception level is using AArch32.

Table G2-21 Vector tables implemented for different implementations

Implementation				Vector table or tables implemented
EL0	EL1	EL2	EL3	
32	32	-	-	Local exception vectors.
		64	-	Non-secure Local exception vectors.
		32	-	Non-secure Local exception vectors. Hyp exception vectors.
		-	64	Secure Local exception vectors. Non-secure Local exception vectors.
		-	32	Secure Local exception vectors. Non-secure Local exception vectors. Monitor exception vectors.
		64	64	Non-secure Local exception vectors. Hyp exception vectors.
		32	64	Secure Local exception vectors. Non-secure Local exception vectors. Hyp exception vectors.
		32	32	Secure Local exception vectors. Non-secure Local exception vectors. Hyp exception vectors. Monitor exception vectors.

For example, in an AArch32-only implementation that includes EL0, EL1, and EL3, when the PE takes an exception to Monitor mode, it uses the vector table containing Monitor exception vectors.

The tables that follow show the vectors that Vector Catch exceptions can be enabled for, and their corresponding vector catch enable bits in the DBGVCR:

- Table G2-22 shows the Local exception vectors, Secure Local exception vectors, and Non-secure Local exception vectors that Vector Catch exceptions can be enabled for.
- Table G2-23 shows the Monitor exception vectors that Vector Catch exceptions can be enabled for.

The ARMv8-A architecture does not provide vector catch enable bits for exceptions taken to Hyp mode.

Table G2-22 Local exception vectors, Secure Local exception vectors, and Non-secure Local exception vectors that Vector Catch exceptions can be enabled for

Vector catch enable bit		Exception type	Local exception vectors	
Local and Secure Local exception vectors	Non-secure Local exception vectors		Normal. SCTLR.V is 0.[a]	High. SCTLR.V is 1.
SF	NSF	FIQ interrupt	VBAR + 0x0000001C	0xFFFF001C
SI	NSI	IRQ interrupt	VBAR + 0x00000018	0xFFFF0018
SD	NSD	Data Abort	VBAR + 0x00000010	0xFFFF0010
SP	NSP	Prefetch Abort	VBAR + 0x0000000C	0xFFFF000C
SS	NSS	Supervisor Call	VBAR + 0x00000008	0xFFFF0008
SU	NSU	Undefined Instruction	VBAR + 0x00000004	0xFFFF0004

a. If EL3 is implemented and is using AArch32, VBAR is banked. This means that there is a $VBAR_S$ and a $VBAR_{NS}$.

Table G2-23 Monitor exception vectors that Vector Catch exceptions can be enabled for

Vector catch enable bit	Exception type	Monitor exception vectors
MF	FIQ interrupt	MVBAR + 0x0000001C
MI	IRQ interrupt	MVBAR + 0x00000018
MD	Data Abort	MVBAR + 0x00000010
MP	Prefetch Abort	MVBAR + 0x0000000C
MS	Secure Monitor Call	MVBAR + 0x00000008

Note

There is no Vector catch enable bit for Monitor trap exceptions.

The Monitor trap exceptions are:

When

- SCR.TWE is 1, a WFE instruction executed in a mode other than Monitor mode is trapped to Monitor mode.
- When SCR.TWI is 1, a WFI instruction executed in a mode other than Monitor mode is trapped to Monitor mode.

Vector catch cannot be used for these.

G2.11.3 Generation of Vector Catch exceptions

How Vector Catch exceptions are generated depends on which form is implemented:

- *Address-matching form*.
- *Exception-trapping form*.

Address-matching form

The PE compares the virtual address of each instruction in the program flow is with some or all of the addresses in the enabled vector catch set, as follows:

- If EL3 is not implemented, the enabled vector catch set contains only Local exception vectors. The PE compares the virtual address of each instruction in the program flow, including those executed at EL0, with all addresses in the enabled vector catch set.
- If EL3 is implemented, the enabled vector catch set might contain one or more of the following:
  - Monitor exception vectors, if EL3 is using AArch32.
  - Secure Local exception vectors.
  - Non-secure Local exception vectors.

  In this case, Table G2-24 shows which addresses, in the enabled vector catch set, the virtual address of each instruction in the program flow is compared with.

Table G2-24 Comparisons made if the implementation includes EL3

EL3 is using	For exceptions taken to:	
	Secure PL1 modes	Non-secure PL1 modes
AArch64	Secure Local exception vectors	Non-secure Local exception vectors
AArch32	Secure Local exception vectors and Monitor exception vectors	

For example, for exceptions taken to a Secure PL1 mode when EL3 is using AArch64, the virtual address of each instruction in the program flow is compared with each Secure Local exception vector in the enabled vector catch set.

For each instruction in the program flow, the PE tests for any possible Vector Catch exceptions before executing the instruction. If a match occurs, a Vector Catch exception is generated when the instruction is committed for execution, regardless of all of the following:

- Whether the instruction passes its condition code check.
- Whether the instruction is executed as part of exception entry.
- If EL2 is implemented, what HCR.{IMO, FMO, AMO} are set to.
- If EL3 is implemented, what SCR.{IRQ, FIQ, EA} are set to.

Exception-trapping form

When the PE takes an exception, it tests whether the exception is by branching to an exception vector in a subset of the enabled vector catch set, as follows:

- If EL3 is not implemented, the enabled vector catch set contains only Local exception vectors. The PE tests whether the exception is by branching to any address in the enabled vector catch set.
- If EL3 is implemented, the enabled vector catch set might contain one or more of the following:
  - Monitor exception vectors, if EL3 is using AArch32.
  - Secure Local exception vectors.
  - Non-secure Local exception vectors.

In this case, the PE tests whether the exception is by branching to a vector in one of the subsets that Table G2-25 shows. In the table, n/a means not applicable.

Table G2-25 Subsets that the PE tests within if EL3 is implemented

EL3 is using	For exceptions taken to:		
	Monitor mode	Secure PL1 modes	Non-secure PL1 modes
AArch64	n/a	Secure Local exception vectors	Non-secure Local exception vectors
AArch32	Monitor exception vectors		

For example, for an exception taken to a Secure PL1 mode when EL3 is using AArch64, the PE tests whether the exception is by branching to any of the Secure Local exception vectors in the enabled vector address set.

If the exception is by branching to an vector in the subset, a Vector Catch exception is generated as part of exception entry. That is, a Vector Catch exception is generated instead of the exception handler executing its first instruction.

G2.11.4 Usage constraints

See the following subsections:

- *Usage constraints that apply to both forms of vector catch*.
- *Usage constraints that apply only to the address-matching form*.

Usage constraints that apply to both forms of vector catch

For Vector Catch exceptions enabled for either the Prefetch Abort exception vector or the Data Abort exception vector, if one of these exception types is taken to the Exception level that debug exceptions are targeting, behavior is CONSTRAINED UNPREDICTABLE. Either:

- Vector catch is ignored, therefore a Vector Catch exception is not generated.
- Vector catch generates a Prefetch Abort debug exception. For Vector Catch exceptions enabled for the Prefetch Abort exception vector, the PE might enter a recursive loop of Prefetch Abort exceptions causing Vector Catch exceptions and Vector Catch exceptions causing Prefetch Abort exceptions.

Note

The Exception level that debug exceptions are targeting is called the *debug target Exception level*, EL_D. *Routing debug exceptions* on page G2-3514 describes how EL_D is derived.

Usage constraints that apply only to the address-matching form

Exception vectors are at word-aligned addresses, and:

- It is CONSTRAINED UNPREDICTABLE whether an enabled vector catch generates a Vector Catch exception for a 32-bit T32 instruction starting at the halfword-aligned address immediately prior to the vector address.
- T32 instructions that start at the halfword-aligned address immediately after the exception vector do not generate Vector Catch exceptions.

For the address-matching form, Vector Catch exceptions have the same priority as Breakpoint exceptions. If a single instruction causes both a Vector Catch exception and a Breakpoint exception, it is CONSTRAINED UNPREDICTABLE which of these debug exceptions the PE takes.

G2.11.5 Exception syndrome information and preferred return address

See the following:

- *Exception syndrome information* on page G2-3570.

- *Preferred return address*.

Exception syndrome information

The PE takes a Vector Catch exception as either:

- A Prefetch Abort exception, if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because HCR.TGE or HDCR.TDE is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

PL1 Abort mode

The PE sets all of the following:

- IFSR.FS to the code for a debug event, `0b00010`.
- DBGDSCRext.MOE to `0b0101`, to indicate a Vector Catch exception.
- The IFAR with an UNKNOWN value.

PL2 Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, HSR. See Table G2-26.
- Sets DBGDSCRext.MOE to `0b0101`, to indicate a Vector Catch exception.
- Sets the HIFAR to an unknown value.

Table G2-26 Information recorded in the HSR

HSR field	Information recorded
Exception Class, EC	The PE sets this to the code for a Prefetch Abort exception routed to Hyp mode, `0x20`.
Instruction Length, IL	The PE sets this to 1.
Instruction Specific Syndrome, ISS	**ISS[24:10]** RES0. **ISS[9]** *External Abort type* (EA). The PE sets this to 0. **ISS[8:6]** RES0. **ISS[5:0]** *Instruction Fault Status Code* (IFSC). The PE sets this to the code for a debug exception, `0b100010`.

Note

For information about how debug exceptions can be routed to PL2, see *Routing debug exceptions on page G2-3514*.

Preferred return address

The preferred return address of a Vector Catch exceptions is the address of the instruction that was not executed because the PE took the Vector Catch exception instead.

This means that the preferred return address is the exception vector. This is true regardless of whether the address-matching form or the exception trapping form is implemented.

G2.11.6 Pseudocode description of Vector Catch exceptions

The `AArch32.VCRMatch()` pseudocode function checks whether the instruction at `address` generates a Vector Catch exception. It therefore shows the address-matching form of vector catch.

```
// AArch32.VCRMatch()
// ==================

boolean AArch32.VCRMatch(bits(32) vaddress)

    if UsingAArch32() && ELUsingAArch32(EL1) && IsZero(vaddress<1:0>) && PSTATE.EL != EL2 then
        // Each bit position in this string corresponds to a bit in DBGVCR and an exception vector.
        match_word = Zeros(32);

        if vaddress<31:5> == ExcVectorBase()<31:5> then
            if HaveEL(EL3) && !IsSecure() then
                match_word<UInt(vaddress<4:2>) + 24> = '1';     // Non-secure vectors
            else
                match_word<UInt(vaddress<4:2>) + 0> = '1';      // Secure vectors (or no EL3)
        if HaveEL(EL3) && ELUsingAArch32(EL3) && IsSecure() && vaddress<31:5> == MVBAR<31:5> then
            match_word<UInt(vaddress<4:2>) + 8> = '1';          // Monitor vectors

        // Mask out bits not corresponding to vectors.
        if !HaveEL(EL3) then
            mask = '00000000':'00000000':'00000000':'11011110'; // DBGVCR[31:8] are RES0
        elsif !ELUsingAArch32(EL3) then
            mask = '11011110':'00000000':'00000000':'11011110'; // DBGVCR[15:8] are RES0
        else
            mask = '11011110':'00000000':'11011100':'11011110';

        match_word = match_word AND DBGVCR AND mask;
        match = !IsZero(match_word);

        // Check for UNPREDICTABLE case - match on Prefetch Abort and Data Abort vectors
        if !IsZero(match_word<28:27,12:11,4:3>) && DebugTarget() == PSTATE.EL then
            match = ConstrainUnpredictableBool();
    else
        match = FALSE;

    return match;
```

The AArch32.CheckVectorCatch() pseudocode function uses VCRMatch() to test whether the instruction generates a Vector Catch exception, and if VCRMatch() returns TRUE it generates that event.

```
// AArch32.CheckVectorCatch()
// ==========================
// Called before executing the instruction of length "size" bytes at "vaddress" in an AArch32
// translation regime.
// Vector Catch can in fact be evaluated well ahead of execution, for example, at instruction
// fetch. This is the simple sequential execution of the program.

FaultRecord AArch32.CheckVectorCatch(bits(32) vaddress, integer size)
    assert ELUsingAArch32(TranslationRegime());

    match = AArch32.VCRMatch(vaddress);
    if size == 4 && !match && AArch32.VCRMatch(vaddress + 2) then
        match = ConstrainUnpredictableBool();

    if match && DBGDSCRext.MDBGen == '1' && AArch32.GenerateDebugExceptions() then
        acctype = AccType_IFETCH;
        iswrite = FALSE;
        debugmoe = DebugException_VectorCatch;
        return AArch32.DebugFault(acctype, iswrite, debugmoe);
    else
        return AArch32.NoFault();
```

The Abort() function processes the Faultrecord object returned by CheckVectorCatch, as described in *Abort exceptions* on page G3-3611. If there is a Vector Catch exception, the Abort() function generates a Prefetch Abort exception.

G2.12 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a *Context Synchronization Operation* (CSO) has occurred. Similarly, the effect of the change on the software step state machine cannot be relied on until after a CSO has occurred.

For any instructions executed between the time when the change is made and the time when the next CSO occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

The following gives examples:

Example G2-3

1. Software changes DBGDSCRext.MDBGen from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A CSO occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

Example G2-4

1. Software unlocks the OS lock.
2. The PE executes some instructions.
3. A CSO occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Software Breakpoint Instruction exceptions can be generated.

Note

- See *Context synchronization operation* for the definition of this term.
- Some register updates are self synchronizing. Others require an explicit CSO. For more information, see both:
  - *Synchronization requirements for System registers* on page D7-1794.
  - *Synchronization of changes to the external debug registers* on page H8-4517.

G2.12.1 State and mode changes without explicit context synchronization operations

Most changes to the Privilege level, and the Security state if EL3 is implemented, happen as a result of operations that are an explicit CSO. This is because taking an exception and returning from an exception are both explicit CSOs, and the Privilege level and Security state can only change as a result of taking or returning from an exception.

However, some Security state and AArch32 mode changes can happen because of operations that are not an explicit CSO. These are:

- AArch32 mode changes caused by `MSR` and `CPS` instructions. A mode change might be to a mode at a lower Privilege level.
- If EL3 is using AArch32, a Security state change caused by a direct write to the SCR in a privileged mode other than Monitor mode, to set SCR.NS to 1.

Chapter G3
The AArch32 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

G3.1 About the memory system architecture

The ARM architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see *Memory hierarchy* on page E2-2251.

G3.1.1 Form of the memory system architecture

The ARMv8 A-profile architecture includes a *Virtual Memory System Architecture* (VMSA), described in Chapter G4 *The AArch32 Virtual Memory System Architecture*.

G3.1.2 Memory attributes

Memory types and attributes on page E2-2273 describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

Table G3-1 shows the memory attributes that are visible at the system level.

Table G3-1 Memory attribute summary

Memory type	Shareability	Cacheability
Device[a]	Outer Shareable	Non-cacheable.
Normal	One of: • Non-shareable. • Inner Shareable. • Outer Shareable.	One of: • Non-cacheable[b]. • Write-Through Cacheable. • Write-Back Cacheable.

a. Takes additional attributes, see *Device memory* on page E2-2275.

b. See also *Cacheability, cache allocation hints, and cache transient hints* on page G3-3582.

For more information on cacheability and shareability see *The cacheability and shareability memory attributes* on page E2-2252, *Non-shareable Normal memory* on page E2-2275, and *Caches and memory hierarchy* on page E2-2251.

G3.2 Address space

The ARMv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of *physical address* (PA) sizes, and provides associated control and identification mechanisms. For more information, see *About VMSAv8-32* on page G4-3618.

G3.2.1 Address space overflow or underflow

This subsection describes address space overflow or underflow:

Instruction address space overflow

When a PE performs a normal, sequential execution of instructions, it calculates:

```
(address_of_current_instruction) + (size_of_executed_instruction)
```

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an A32 or T32 instruction overflows `0xFFFF FFFF`, the program counter becomes UNKNOWN.

If the PE executes an instruction for which the instruction address, size, and alignment mean that it contains the bytes `0xFFFFFFFF` and `0x00000000`, the bytes that apparently from `0x00000000` onwards come from an UNKNOWN address.

Data address space overflow and underflow

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean that it accesses bytes `0xFFFFFFFF` and `0x00000000`, then the bytes that apparently from `0x00000000` onwards come from an UNKNOWN address.

G3.3 Mixed-endian support

Table G3-2 shows the endianness of explicit data accesses and translation table walks.

Table G3-2 Endianness support

Exception level	Explicit data accesses	Stage 1 translation table walks	Stage 2 translation table walks
EL0	CPSR.E	SCTLR(S/NS).EE	HSCTLR.EE
EL1	CPSR.E	SCTLR(S/NS).EE	HSCTLR.EE
EL2	CPSR.E	HSCTLR.EE	N/A
EL3	CPSR.E	SCTLR(S).EE	N/A

ARMv8 provides the following options for endianness support:

- All Exception levels support mixed-endianness:
  - SCTLR(S/NS).EE, HSCTLR.EE, and CPSR.E are R/W.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
  - SCTLR(S/NS).EE and HSCTLR.EE are RES0. CPSR.E is R/W when in EL0 and RES0 when in EL1, EL2, or EL3. SPSR.E is also RES0 when not returning to EL0.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
  - SCTLR(S/NS).EE and HSCTLR.EE are RES1. CPSR.E is R/W when in EL0 and RES1 when in EL1, EL2, or EL3. SPSR.E is also RES1 when not returning to EL0.
- All Exception levels support only little-endianness:
  - SCTLR(S/NS).EE and HSCTLR.EE are RES0, and CPSR.E is RES0. SPSR.E is RES0.
- All Exception levels support only big-endianness:
  - SCTLR(S/NS).EE and HSCTLR.EE are RES1, and CPSR.E is RES1. SPSR.E is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by CPSR.E. For exception returns to AArch32 state, CPSR.E is copied from SPSR_ELx.E. If the target Exception level supports only little-endian accesses, SPSR_ELx.E is RES0. If the target Exception level supports only big-endian accesses, SPSR_ELx.E is RES1.

Note

- When using AArch32, ARM deprecates CPSR.E having a different value from the equivalent System control register EE bit when in EL1, EL2 or EL3. The use of the SETEND instruction is also deprecated.
- If the higher Exception levels are using AArch64, the corresponding registers are:
  - SCTLR_EL1 for SCTLR(NS).
  - SCTLR_EL2 for HSCTLR.
  - SCTLR_EL3 for SCTLR(S).

The BigEndian() function determines whether the current Exception level and Execution state is using big-endian data:

```
// BigEndian()
// ===========

boolean BigEndian()
    boolean bigend;
    if UsingAArch32() then
        bigend = (PSTATE.E != '0');
    elsif PSTATE.EL == EL0 then
```

```
    bigend = (SCTLR_EL1.E0E != '0');
else
    bigend = (SCTLR[].EE != '0');
return bigend;
```

G3.4 Cache support

Cache support includes:

- Cache identification. See *Cache identification* on page G3-3581.
- Write-through and Write-back attributes, and cache allocation hints and cache transient hints. See *Cacheability, cache allocation hints, and cache transient hints* on page G3-3582.
- Caches and reset. See *Behavior of caches at reset* on page G3-3583.
- Enabling and disabling caches. See *Cache enabling and disabling* on page G3-3583.
- Cache maintenance. See *Cache maintenance instructions* on page G3-3589.

Additional information relating to caches is provided in the following subsections:

- *The ARMv8 cache maintenance functionality* on page G3-3585.
- *Cache lockdown* on page G3-3598.
- *System level caches* on page G3-3599.

See also Chapter G4 *The AArch32 Virtual Memory System Architecture*.

Note

- Branch predictors typically use a form of cache to hold branch target data. Therefore, they are included in this section.
- In the instruction mnemonics, MVA is a synonym for VA.

G3.4.1 General behavior of the caches

When a memory location is marked with a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
  - A particular implementation.
  - Some memory attributes.
- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.
- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

Note

For more information, see *The interaction of cache lockdown with cache maintenance instructions* on page G3-3598.

- If a memory location both has permissions that mean it can be accessed, either by reads or by writes, for the translation scheme at either the current Exception level or at a higher Exception level, and is marked as Cacheable for that translation regime, then there is no mechanism that can guarantee that the memory location cannot be allocated to an enabled cache at any time.

  Any application must assume that any memory location with such access permissions and cacheability attributes can be allocated to any enabled cache at any time.

- If the cache is disabled, it is guaranteed that no new allocation of memory locations into the cache occurs.
- If the cache is enabled, it is guaranteed that no memory location that does not have a Cacheable attribute is allocated into the cache.
- If the cache is enabled, it is guaranteed that no memory location is allocated to the cache if the access permissions for that location are such that the location cannot be accessed by reads and cannot be accessed by writes in both:
  — The translation regime at the current Exception level.
  — The translation regime at a higher Exception level.
- For data accesses, any memory location that is marked as Normal Shareable is guaranteed to be coherent with all masters in that shareability domain.
- Any memory location is not guaranteed to remain incoherent with the rest of memory.
- The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the *Cache Write-back Granule*. In some implementations the CTR identifies the Cache Write-back Granule, see *CTR, Cache Type Register* on page G5-3866.
- The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer, if it was previously visible to that observer.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to its size.

In the following situations it is UNPREDICTABLE whether the location is returned from cache or from memory:

- The location is not marked as Cacheable but is contained in the cache. This situation can occur if a location is marked as Non-cacheable after it has been allocated into the cache.
- The location is marked as Cacheable and might be contained in the cache, but the cache is disabled.

G3.4.2 Cache identification

The ARMv8 cache identification consists of a set of registers that describe the implemented caches that are under the control of the PE:

- A single Cache Type Register defines:
  — The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
  — The minimum line length of any of the data or unified caches, affected by the data cache maintenance instructions.
  — The cache indexing and tagging policy of the Level 1 instruction cache.

  For more information, see *CTR, Cache Type Register* on page G5-3866.
- A single Cache Level ID Register defines:
  — The type of cache implemented at each cache level, up to the maximum of seven levels.

— The Level of Coherence and the Level of Unification for the caches. See *Terms used in describing the maintenance instructions* on page G3-3585 for a definition of these terms.

For more information, see *CLIDR, Cache Level ID Register* on page G5-3852.

- A single Cache Size Selection Register selects the cache level and cache type of the current Cache Size Identification Register, see *CSSELR, Cache Size Selection Register* on page G5-3864.
- For each implemented cache, across all the levels of caching, a Cache Size Identification Register defines:
  — Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
  — The number of sets, associativity and line length of the cache. See *Terms used in describing the maintenance instructions* on page G3-3585 for a definition of these terms.

  For more information, see *CCSIDR, Current Cache Size ID Register* on page G5-3850.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.
2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also provides the Level of Unification and the Level of Coherence for the cache implementation.
3. For each cache identified at stage 2:
   - Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
     — An instruction cache.
     — A data or unified cache.
   - Read the Cache Size ID Register to find details of the cache.

G3.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and can be defined independently for Inner and Outer cache locations.

As described in *Memory types and attributes* on page E2-2273, the memory attributes include a cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

Cacheability attributes other than Non-cacheable can be complemented by a *cache allocation hint*. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. A *cache transient hint* provides a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. These hints are used to limit cache pollution to a part of a cache, such as to a subset of ways.

The following cache allocation hints can be used in ARMv8:

- Read-Allocate, Transient Read-Allocate, or no Read-Allocate.
- Write-Allocate, Transient Write-Allocate, or no Write-Allocate.

Note

A Cacheable location with both no Read-Allocate and no Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, no Read-Allocate, no Write-Allocate.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

G3.4.4 Behavior of caches at reset

In ARMv8:

- All caches are disabled at reset.
- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.
- If an implementation permits cache hits when the cache is disabled the cache initialization routine must:
  - Provide a mechanism to ensure the correct initialization of the caches.
  - Be documented clearly as part of the documentation of the device.

  In particular, if an implementation permits cache hits when the cache is disabled and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.
- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 cache maintenance instructions.

When it is enabled, the state of a cache is UNPREDICTABLE if the appropriate initialization routine has not been performed.

Similar rules apply to:

- Branch predictor behavior, see *Behavior of the branch predictors at reset* on page G3-3591.
- TLB behavior, see *TLB behavior at reset* on page G4-3687.

G3.4.5 Cache enabling and disabling

When a data cache or unified cache is disabled for a translation regime, as determined by SCTLR.C or HSCTLR.C, data accesses and translation table walks from that translation regime to all Normal memory types behave as Non-cacheable for all levels of data caches and unified caches.

For the PL1&0 translation regime:

- When SCTLR.C == 0, this makes all stage 1 translations for data accesses to Normal memory Non-cacheable. It also makes all accesses to the PL1&0 stage 1 translation tables Non-cacheable.
- When HCR2.CD == 1, this makes all stage 2 translations for data accesses to Normal memory Non-cacheable. It also makes all accesses to the PL1&0 stage 2 translation tables Non-cacheable.

  Note

  — The stage 1 and stage 2 cacheability attributes are combined as described in *Combining the cacheability attribute* on page G4-3684.

  — The SCTLR.C bit has no effect on the EL2 and EL3 translation regimes.

  — The HCR2.CD bit affects only stage 2 of the Non-secure PL1&0 translation regime.
- If HCR2.CD is set to 1, then stage 1 PL1&0 translation regime is cacheable regardless of the value of SCTLR.C.

For the EL2 translation regime:

- When the value of the HSCTLR.C bit is 0, all data accesses to Normal memory using the EL2 translation regime are Non-cacheable. This means all accesses made by the EL2 translation table walks are Non-cacheable.

Note

The HSCTLR.C bit has no effect on the PL1&0 and EL3 translation regimes.

For the EL3 translation regime:

- When the value of the SCTLR.C bit is 0, all data accesses to Normal memory using the EL3 translation regime are Non-cacheable. This means all accessed made by the EL3 translation table walks are Non-cacheable.

  Note

  The SCTLR.C bit has no effect on the PL1&0 and EL2 translation regimes.

The effect of the SCTLR.C or HSCTLR.C and HCR2.CD bits is reflected in the result of the address translation instructions in the PAR.

Disabling the instruction cache for a translation regime, as determined by the SCTLR.I or HSCTLR.I, makes instruction accesses to all Normal memory types behave as Non-cacheable for all levels of instruction or unified cache.

For the PL1&0 translation regime:

- When SCTLR.I == 0, all instruction accesses to Normal memory are made Non-cacheable at the first stage of translation.
- When HCR2.ID == 1, all instruction accesses to Normal memory are made Non-cacheable at the second stage of translation.

  Note

  — The stage 1 and stage 2 cacheability attributes are combined as described in *Combining the cacheability attribute* on page G4-3684.

  — The SCTLR.I bit has no effect on the EL2 and EL3 translation regimes.

  — The HCR2.ID bit affects only stage 2 of the Non-secure PL1&0 translation regime.

- If HCR2.DC is set to 1, then the Non-secure stage 1 PL1&0 translation regime is cacheable regardless of the value of SCTLR.I.

For the EL2 translation regime:

- When the value of the HSCTLR.I bit is 0, all instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

  Note

  The HSCTLR.I bit has no effect on the PL1&0 and EL3 translation regimes.

For the EL3 translation regime:

- When the value of the SCTLR.I bit is 0, all instruction accesses to Normal memory using the EL3 translation regime are Non-cacheable.

  Note

  The SCTLR.I bit has no effect on the PL1&0 and EL2 translation regimes

In addition, for the Secure EL1, EL2, and EL3 translation regimes, when the value of SCTLR.M or HSCTLR.M is 0, indicating that the stage 1 translations are disabled for that translation regime, SCTLR.I or HSCTLR.I has the following effect:

- If SCTLR.I ==0 or HSCTLR.I == 0, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.

- If SCTLR.I == 1 or HSCTLR.I == 0, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Write-Through, Outer Write-Through.

For the Non-secure EL1 translation regime, when the value of SCTLR.M is 0, indicating that the stage 1 translations are disabled for that translation regime, and HCR_EL2.DC == 0, the SCTLR.I bit has the following effect:

- If SCTLR.I == 0 or HSCTLR.I == 0, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If SCTLR.I == 1 or HSCTLR.I == 1, instruction accesses to Normal memory from stage 1 of that translation regime are Outer Shareable, Inner Write-Through, Outer Write-Through.

Note

This means that the architecturally required effect of SCTLR.I or HSCTLR.I is limited to its effect on caching instruction accesses in unified caches.

G3.4.6 The ARMv8 cache maintenance functionality

The following sections give general information about the ARMv8 cache maintenance functionality:

- *Terms used in describing the maintenance instructions*.
- *The ARMv8 abstraction of the cache hierarchy* on page G3-3588.

The following sections describe cache maintenance instructions for ARMv8:

- *Instruction cache maintenance instructions (IC*)* on page G3-3589.
- *Data cache maintenance instructions (DC*)* on page G3-3590.

Terms used in describing the maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instructions can be defined:

- By the address of the memory location to be maintained, referred to as operating *by VA*.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating *by set/way*.

In addition, for instruction caches and branch predictors, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- *Terminology for cache maintenance instruction operating by virtual address, VA*.
- *Terminology for cache maintenance instructions operating by set/way* on page G3-3586.
- *Terminology for Clean, Invalidate, and Clean and Invalidate instructions* on page G3-3586.

Terminology for cache maintenance instruction operating by virtual address, VA

In a VMSA implementation, the addresses used by the PE are VAs. When all applicable stages of translation are disabled, the VA is identical to the PA.

Note

For more information about memory system behavior when MMUs are disabled, see *The effects of disabling address translation stages on VMSAv8-32 behavior* on page G4-3625.

For the cache maintenance instruction, any instruction described as operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current system *Address Space IDentifier* (ASID).
- The current Security state.
- Whether the instruction was performed from Hyp mode, or from Non-secure EL1 state.
- For an instruction executed from a Non-secure EL1 state, the *Virtual Machine IDentifier*, VMID.

For a data or unified cache maintenance instruction by VA, the operation cannot generate a Data Abort exception for a Domain fault or a Permission fault, except for the Permission fault cases described in:

- *Effects of virtualization and security on the cache maintenance instructions* on page G3-3593.
- *Stage 2 fault on a stage 1 translation table walk* on page G4-3710.

For an instruction cache maintenance instruction by VA:

- It is IMPLEMENTATION DEFINED whether the operation can generate a Data Abort exception for a Translation fault or an Access flag fault.
- The operation cannot generate a Data Abort exception for a Domain fault or a Permission fault, except for the Permission fault case described in *Stage 2 fault on a stage 1 translation table walk* on page G4-3710.

For more information about these faults, see *MMU faults in AArch32 state* on page G4-3711.

Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

Level The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED and can be determined from the Cache Level ID register. See *CLIDR, Cache Level ID Register* on page G5-3852.

In the ARM architecture, the lower numbered levels are those closest to the PE. See *Memory hierarchy* on page E2-2251.

Set Each level of a cache is split up into a number of *sets*. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.

In the ARM architecture, sets are numbered from 0.

Way The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The *way* number specifies one of these locations.

In the ARM architecture, ways are numbered from 0.

Note

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, ARM expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.
2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or *stale*, copy of the memory location that has been updated.

The *Clean* and *Invalidate* instructions address these two issues. The definitions of these instructions are:

Clean A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the shareability domain of that memory location.

Invalidate A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates does not have a Normal Cacheable attribute, or if the cache is disabled, then an invalidate instruction also ensures that this address is not present in the cache.

Note

Entries for addresses with a Normal Cacheable attribute can be allocated to an enabled cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in an enabled cache.

Clean and Invalidate

A cache *clean and invalidate* instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.
- For instruction operating by VA, two conceptual points are defined:

  Point of Coherency (PoC)

  For a particular VA, the PoC is the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. In many cases, this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherence between memory system agents.

  Point of Unification (PoU)

  The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

  The PoU for an Inner Shareable shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

  1. Clean data cache entry by address.
  2. Invalidate instruction cache entry by address.

  The following fields in the CLIDR relate to these conceptual points:

  LoC, Level of Coherence

  This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

  - A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
  - Level 4 cache is the first level that does not have to be maintained.

  If the LoC field value is `0x0`, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

LoUU, Level of Unification, uniprocessor

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is `0x0`, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the Point of Unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

LoUIS, Level of Unification, Inner Shareable

In any implementation:

- This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is `0x0`, this means that no levels of cache need to cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

For more information, see *CLIDR, Cache Level ID Register* on page G5-3852.

The ARMv8 abstraction of the cache hierarchy

The following subsections describe the ARMv8 abstraction of the cache hierarchy:

- *Cache maintenance instructions that operate by address*.
- *Cache maintenance instructions that operate by set/way*.

Cache maintenance instructions that operate by address

The address-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being either:

- Performed to the Point of Coherency.
- Performed to the Point of Unification.

See *Terms used in describing the maintenance instructions* on page G3-3585 for definitions of Point of Coherency and Point of Unification, and more information about possible meanings of VA.

Cache maintenance instructions on page G3-3589 lists the address-based maintenance instructions.

The CTR holds minimum line length values for:

- The instruction caches.
- The data and unified caches.

These values support efficient invalidation of a range of addresses, because this value is the most efficient address stride to use to apply a sequence of address-based maintenance instructions to a range of addresses.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the CTR defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

Cache maintenance instructions that operate by set/way

Cache maintenance instructions on page G3-3589 lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.

- An invalidate instruction invalidates only at the level specified.

G3.4.7 Cache maintenance instructions

The instruction and data cache maintenance instructions have the same functionality in AArch32 state and in AArch64 state. Table G3-3 shows these system instructions. Instructions that take an argument include Rt in the instruction description.

Note

- In Table G3-3 the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.
- In AArch32 state, all of the accesses are available from EL1 or higher.

Table G3-3 System instructions for cache maintenance

Register	Instruction
Instruction cache maintenance instructions	
ICIALLUIS	Invalidate all to Point of Unification, Inner Shareable
ICIALLU	Invalidate all to Point of Unification
ICIMVAU, Rt	Invalidate by virtual address to Point of Unification
Data cache maintenance instructions	
DCIMVAC, Rt	Invalidate by virtual address to Point of Coherency
DCISW, Rt	Invalidate by set/way
DCCMVAC, Rt	Clean by virtual address to Point of Coherency
DCCSW, Rt	Clean by set/way
DCCMVAU, Rt	Clean by virtual address to Point of Unification
DCCIMVAC, Rt	Clean and invalidate by virtual address to Point of Coherency
DCCISW, Rt	Clean and invalidate by set/way
Branch prediction instructions	
BPIMVA, Rt	Invalidate the virtual address from the branch predictors
BPIALLIS, Rt	Invalidate all entries from branch predictors, Inner Shareable
BPIALL, Rt	Invalidate all entries from branch predictors

Instruction cache maintenance instructions (IC*)

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

All instruction cache maintenance instructions can execute in any order relative to other instruction cache maintenance instructions, data cache maintenance instructions, and loads and stores, unless a `DSB` is executed between the instructions.

An instruction cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction.

Data cache maintenance instructions (DC*)

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Data cache maintenance instructions that take a set/way/level argument take a 32-bit register.

A data or unified cache invalidation by virtual address instruction performed in a Non-secure EL1 mode must not change data in any location for which the stage 2 translation permissions do not permit write access. Where such a permission violation occurs, it is IMPLEMENTATION DEFINED whether:

- A stage 2 Permission fault is generated for the DCIMVAC operation.
- The DCIMVAC operation is upgraded to DCCIMVAC.

DCIMVAC and DCISW at EL1 is performed by hardware as clean and invalidate, that is DCCIMVAC or DCCISW if all of the following apply:

- EL2 is implemented.
- HCR.VM is set to 1 to enable the second stage of address translation, meaning that execution is in Non-secure state.
- SCR.NS is set to 1 or EL3 is not implemented.

Note

Similarly, DCIMVAC and DCISW at EL1 must be performed as clean and invalidate, that is DCCIMVAC and DCCISW at EL1 when EL1 is using AArch32, if all of the following apply:

- EL2 is implemented.
- EL2 is using AArch32 and HCR.VM is set to the value of 1, or EL2 is using AArch64 and HCR_EL2.VM is set to the value of 1.
- EL3 is using AArch32 and SCR.NS is set to the value of 1, or EL3 is using AArch64 and SCR.NS is set to the value of 1, or EL3 is not implemented.

If a memory fault that sets FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.

Branch predictors

In AArch32 state it is IMPLEMENTATION DEFINED whether branch prediction is architecturally visible. This means that under some circumstances software must perform branch predictor maintenance to avoid incorrect execution caused by out-of-date entries in the branch predictor. For example, to ensure correct operation it might be necessary to invalidate branch predictor entries on a change to instruction memory, or a change of instruction address mapping. For more information, see *Specific requirements for branch predictor maintenance instructions* on page G3-3591.

An invalidate all operation on the branch predictor ensures that any location held in the branch predictor has no functional effect on execution. An invalidate branch predictor by VA instruction operates on the address of the branch instruction, but can affect other branch predictor entries.

Note

The architecture does not make visible the range of addresses in a branch predictor to which the invalidate operation applies. This means the address used in the invalidate by VA operation must be the address of the branch to be invalidated.

If branch prediction is architecturally visible, an instruction cache invalidate all operation also invalidates all branch predictors.

Specific requirements for branch predictor maintenance instructions

If, for a given translation regime and a given ASID and VMID as appropriate, the instructions at any virtual address change, then branch predictor maintenance instructions must be performed to invalidate entries in the branch predictor, to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

- Enabling or disabling the MMU.
- Writing new mappings to the translation tables.
- Any change to the TTBR0, TTBR1 or TTBCR registers, unless accompanied by a change to the ContextID, or a change to the VMID.
- Changes to the VTTBR or VTCR registers, unless accompanied by a change to the VMID.

Note

Invalidation is not required if the changes to the translations are such that the instructions associated with the non-faulting translations of a virtual address, for a given translation regime and a given ASID and VMID, as appropriate, remain unchanged throughout the sequence of changes to the translations. Examples of translation changes to which this applies are:

- Changing a valid translation to a translation that generates a MMU fault.
- Changing a translation that generates a MMU fault to a valid translation.

Failure to invalidate entries might give UNPREDICTABLE results, caused by the execution of old branches. For more information, see *Ordering of cache and branch predictor maintenance instructions* on page G3-3595.

Note

- In ARMv8, there is no requirement to use the branch predictor maintenance operations to invalidate the branch predictor after:
  - Changing the ContextID or VMID.
  - A cache maintenance instruction that is identified as also flushing the branch predictors, see *Cache maintenance instructions* on page G3-3589.

Cache maintenance instructions, functional group on page G4-3794 shows the branch predictor maintenance operations in a VMSA implementation.

Behavior of the branch predictors at reset

In ARMv8:

- If branch predictors are not architecturally invisible the branch prediction logic is disabled at reset.
- An implementation can require the use of a specific branch predictor initialization routine to invalidate the branch predictor storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, but the routine must be documented clearly as part of the documentation of the device.
- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 branch predictor maintenance operations.

When it is enabled, the state of the branch predictor logic is UNPREDICTABLE if the appropriate initialization routine has not been performed.

Similar rules apply:

- To cache behavior, see *Behavior of caches at reset* on page G3-3583.
- To TLB behavior, see *TLB behavior at reset* on page G4-3687.

General requirements for the scope of cache and branch predictor maintenance instructions

The ARMv8 specification of the cache maintenance and branch predictor instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in *General behavior of the caches* on page G3-3580, *Behavior of caches at reset* on page G3-3583, and *Preloading caches* on page E2-2254.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

As a side-effect of a branch predictor maintenance instruction, any entry in the branch predictor might be invalidated.

Note

ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

Effects of instructions that operate by virtual address to the Point of Coherency

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the Point of Coherency.

Table G3-4 PEs affected by cache maintenance instructions to the Point of Coherency

Shareability	PEs affected	Effective to
Non-shareable	The PE performing the operation	The Point of Coherency of the entire system
Inner Shareable	All PEs in the same Inner Shareable shareability domain as the PE performing the operation	The Point of Coherency of the entire system
Outer Shareable	All PEs in the same Outer Shareable shareability domain as the PE performing the operation	The Point of Coherency of the entire system

Effects of instructions that operate by virtual address but not to the Point of Coherency

The following instruction operate by virtual address but not to the Point of Coherency:

- Clean data or unified cache line by MVA to the Point of Unification, DCCMVAU.
- Invalidate instruction cache line by MVA to Point of Unification, ICIMVAU.
- Invalidate by MVA from branch predictors, BPIMVA.

For these instructions, Table G3-5 shows how, for a VA in a Normal or Device memory location, the shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

Table G3-5 PEs affected by cache maintenance instructions to the Point of Unification

Shareability	PEs affected	Effective to
Non-shareable	The PE executing the instruction	The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction
Inner Shareable or Outer Shareable	All PEs in the same Inner Shareable shareability domain as the PE executing the instruction	The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain as the PE executing the instruction

Note

The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable shareability domain containing the PE executing the instruction.

Effects of All and set/way maintenance instructions

The ICIALLU, BPIALL and DC* set/way instructions apply only to the caches and branch predictors of the PE that performs the instruction. If the branch predictors are architecturally-visible, ICIALLU also performs a BPIALL operation.

The ICIALLUIS and BPIALLIS instructions can affect the caches and branch predictors of all PEs in the same Inner Shareable shareability domain as the PE that performs the instruction. If the branch predictors are architecturally-visible, ICIALLUIS also performs a BPIALLIS operation. These instructions have an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain.

Effects of virtualization and security on the cache maintenance instructions

Each Security state has its own physical address space, and therefore cache entries are associated with physical address space. In addition, cache maintenance and branch predictor instructions performed in Non-secure state have to take account of:

- Whether the instruction was performed at EL1 or at EL2.
- For instructions that operate by VA, the current VMID.

Table G3-6 shows the effects of virtualization and security on these maintenance instructions.

Table G3-6 Effects of virtualization and security on the maintenance instructions

Cache maintenance instructions	Security state	Targeted entry
Data or unified cache maintenance instructions		

Table G3-6 Effects of virtualization and security on the maintenance instructions (continued)

Cache maintenance instructions	Security state	Targeted entry
Invalidate, Clean, or Clean and Invalidate by VA: DCIMVAC, DCCMVAC, DCCMVAU, DCCIMVAC	Either	All lines that hold the PA that, in the current security state, is mapped to by the combination of all of: • The specified VA. • For an instruction executed at EL1, the current ASID. • For an instruction executed at Non-secure EL1, the current VMID[b].
Invalidate, Clean, or Clean and Invalidate by set/way: DCISW, DCCSW, DCCISW	Non- secure	Line specified by set/way provided that the entry comes from the Non-secure PA space.
	Secure	Line specified by set/way regardless of the PA space that the entry has come from.
Instruction cache maintenance instructions		
Invalidate by VA: ICIMVAU	Either	Implementation without the IVIPT Extension[a]:
		All Lines that match the specified VA, and, for an instruction executed at EL1, the current ASID, and come from the same VA space as the current security state. For an instruction executed in Non-secure state, lines are invalidated only if they also match the current VMID[b] and security level, EL1 or EL2.
		Implementation with the IVIPT Extension:[a]
		All Lines that hold the PA that, in the current security state, is mapped to by the combination of all of: • The specified VA. • For an instruction executed at EL1, the current ASID. • For an instruction executed in Non-secure EL1, the current VMID[b].
Invalidate All: ICIALLU, ICIALLUIS		• Can invalidate any unlocked entry in the instruction cache. • Are required to invalidate any entries relevant to the software component that executed it. The Non-secure and Secure descriptions give more information: **Non-secure** An instruction executed at EL1 must operate on all instruction cache lines that contain entries associated with the current virtual machine, meaning any entry with the current VMID[b]. An instruction executed at EL2 must operate on all instruction cache lines that contain entries that can be accessed from Non-secure state. **Secure** The instruction must invalidate all instruction cache lines.
Branch predictor operations		
Invalidate by VA: BPIMVA	Either	All entries that match the specified VA and the current ASID, and come from the same VA space as the current security state. For an operation performed in Non-secure state, entries are invalidated only if they also match the current VMID[b] and security level, EL1 or EL2.
Invalidate all: BPIALL, BPIALLIS	• Can invalidate any unlocked entry in the instruction cache. • Are required to invalidate any entries relevant to the software component that executed it. The Non-secure and Secure descriptions give more information.	

a. See *IVIPT architecture Extension* on page G4-3702.

b. Dependencies on the VMID apply even when HCR_EL2.VM is set to 0. However, VTTBR_EL2.VMID resets to zero, meaning there is a valid VMID from reset.

For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in *The interaction of cache lockdown with cache maintenance instructions* on page G3-3598 applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, Non-secure clean by set/way operations can be upgraded to clean and invalidate by set/way.
- The AArch64 Data Cache Invalidate instructions, DC IVAC and DC ISW, at EL1 and EL0, and the AArch32 Data Cache Invalidate instructions DCIMVAC and DCISW, perform a cache clean as well as a cache invalidation if all of the following apply:
  - EL2 is implemented.
  - HCR.VM is set.
  - SCR.NS is set or EL3 is not implemented.
- When the value of HCR.FB is 1, TLB and instruction cache invalidate instructions executed in the Non-secure EL1 Exception level are broadcast across the Inner Shareable domain. When Non-secure EL1 is using AArch32, this applies to the TLBIMVA, TLBIASID, TLBIMVAA, TLBIMVAL, TLBIMVAAL, and ICIALLU instructions. This means the instruction is upgraded to the corresponding Inner Shareable instruction, for example ICIALLU is upgraded to ICIALLUIS, and BPIALL is upgraded to BPIALLIS.
- When the value of HCR.SWIO is 1, a cache invalidate by set/way instructions executed in the Non-secure EL1 Exception level is upgraded to a clean and invalidate by set/way. When Non-secure EL1 is using AArch64, this means the DCISW instruction is upgraded to DCCISW.

For more information about the cache maintenance instructions, see *The ARMv8 cache maintenance functionality* on page G3-3585, *Cache maintenance instructions* on page G3-3589, and Chapter G4 *The AArch32 Virtual Memory System Architecture*.

Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches when the caches are enabled or when they are disabled.

For address-based cache maintenance instructions, the instructions operate on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
  - Is Normal memory or Device memory.
  - Has the Cacheable attribute or the Non-cacheable attribute.
- Any applicable domain control of the address accessed.
- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

Ordering of cache and branch predictor maintenance instructions

The following rules describe the effect of the memory order model on the cache and branch predictor maintenance instructions:

- All cache and branch predictor maintenance instructions that do not specify an address execute, relative to each other, in program order.

All cache and branch predictor instructions that specify an address:

— Execute in program order relative to all cache and branch predictor operations that do not specify an address.

— Execute in program order relative to all cache and branch predictor operations that specify the same address.

— Can execute in any order relative to cache and branch predictor operations that specify a different address.

- Where a cache maintenance or branch predictor instruction appears in program order before a change to the translation tables, the architecture guarantees that the cache or branch predictor maintenance instruction uses the translations that were visible before the change to the translation tables

- Where a change of the translation tables appears in program order before a cache maintenance or branch predictor instruction, software must execute the sequence outlined in *TLB maintenance instructions and the memory order model* on page G4-3691 before performing the cache or branch predictor maintenance instruction, to ensure that the maintenance operation uses the new translations.

- A `DMB` instruction causes the effect of all data or unified cache maintenance instructions appearing in program order before the `DMB` to be visible to all explicit load and store operations appearing in program order after the `DMB`.

  Also, a `DMB` instruction ensures that the effects of any data or unified cache maintenance instruction appearing in program order before the `DMB` are observable by any observer in the same required shareability domain before any data or unified cache maintenance or explicit memory operations appearing in program order after the `DMB` are observed by the same observer. Completion of the `DMB` does not guarantee the visibility of all data to other observers. For example, all data might not be visible to a translation table walk, or to instruction fetches.

- A `DSB` is required to guarantee the completion of all cache maintenance instruction that appear in program order before the `DSB` instruction.

- A context synchronization operation is required to guarantee the effects of any branch predictor maintenance operation. This means a context synchronization operation causes the effect of all completed branch predictor maintenance operations appearing in program order before the context synchronization operation to be visible to all instructions after the context synchronization operation.

  Note

  See *Context synchronization operation* in the *Glossary* for the definition of this term.

  This means that, if a branch instruction appears after an invalidate branch predictor operation and before any context synchronization operation, it is UNPREDICTABLE whether the branch instruction is affected by the invalidate. Software must avoid this ordering of instructions, because it might cause UNPREDICTABLE behavior.

- Any data or unified cache maintenance instruction by VA must be executed in program order relative to any explicit load or store on the same PE to an address covered by the VA of the cache instruction if that load or store is to Normal Cacheable memory. The order of memory accesses that result from the cache maintenance instruction, relative to any other memory accesses to Normal Cacheable memory, are subject to the memory ordering rules. For more information, see *Memory ordering* on page E2-2266.

  Any data or unified cache maintenance instruction by VA can be executed in any order relative to any explicit load or store on the same PE to an address covered by the VA of the cache maintenance instruction if that load or store is not to Normal Cacheable memory.

- There is no restriction on the ordering of data or unified cache maintenance instruction by VA relative to any explicit load or store on the same PE where the address of the explicit load or store is not covered by the VA of the cache instruction. Where the ordering must be restricted, a `DMB` instruction must be inserted to enforce ordering.

- There is no restriction on the ordering of a data or unified cache maintenance instruction by set/way relative to any explicit load or store on the same PE. Where the ordering must be restricted, a `DMB` instruction must be inserted to enforce ordering.

- Software must execute a context synchronization operation after the completion of an instruction cache maintenance instruction, to guarantee that the effect of the maintenance instruction is visible to any instruction fetch.

The scope of instruction cache maintenance depends on the type of the instruction cache. For more information see *Instruction caches* on page G4-3700.

Example G3-1 Cache cleaning operations for self-modifying code

The sequence of cache cleaning operations for a line of self-modifying code on a uniprocessor system is:

```
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line
; instead of STR for a 16-bit instruction.
        STR Rt, [Rn]
        DCCMVAU Rn           ; Clean data cache by MVA to point of unification (PoU)
        DSB                  ; Ensure visibility of the data cleaned from cache
        ICIMVAU Rn           ; Invalidate instruction cache by MVA to PoU
        BPIMVA  Rn           ; Invalidate branch predictor by MVA to PoU
        DSB                  ; Ensure completion of the invalidations
        ISB                  ; Synchronize the fetched instruction stream
```

Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

- For data or unified cache maintenance, uses the CTR.DMinLine value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the CTR.IMinLine value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

Example code for cache maintenance instructions

The cache maintenance instructions by set/way can be used to clean or invalidate, or both, the entirety of one or more levels of cache attached to a processing element. However, unless all processing elements attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

Note

In multi-processing environments, the cache maintenance instructions that operate by set/way are not broadcast within the shareability domains, and so allocations can occur from other, unmaintained, locations, in caches in other locations. For this reason, the use of cache maintenance instructions that operate by set/way for the maintenance of large buffers of memory is not recommended in the architectural sequence. The expected usage of the cache maintenance instructions that operate by set/way is associated with the cache maintenance instructions associated with the powerdown and powerup of caches, if this is required by the implementation.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency.

```
 MRC p15, 1, R0, c0, c0, 1   ; Read CLIDR into R0
    ANDS R3, R0, #0x07000000
    MOV R3, R3, LSR #23         ; Cache level value (naturally aligned)
    BEQ Finished
    MOV R10, #0
Loop1
    ADD R2, R10, R10, LSR #1    ; Work out 3 x cachelevel
    MOV R1, R0, LSR R2          ; bottom 3 bits are the Cache type for this level
```

```
    AND R1, R1, #7              ; get those 3 bits alone
    CMP R1, #2
    BLT Skip                    ; no cache or only instruction cache at this level
    MCR p15, 2, R10, c0, c0, 0  ; write CSSELR from R10
    ISB                         ; ISB to sync the change to the CCSIDR
    MRC p15, 1, R1, c0, c0, 0   ; read current CCSIDR to R1
    AND R2, R1, #7              ; extract the line length field
    ADD R2, R2, #4              ; add 4 for the line length offset (log2 16 bytes)
    LDR R4, =0x3FF
    ANDS R4, R4, R1, LSR #3     ; R4 is the max number on the way size (right aligned)
    CLZ R5, R4                  ; R5 is the bit position of the way size increment
    MOV R9, R4                  ; R9 working copy of the max way size (right aligned)
Loop2
    LDR R7, =0x00007FFF
    ANDS R7, R7, R1, LSR #13    ; R7 is the max number of the index size (right aligned)
Loop3
    ORR R11, R10, R9, LSL R5    ; factor in the way number and cache number into R11
    ORR R11, R11, R7, LSL R2    ; factor in the index number
    MCR p15, 0, R11, c7, c10, 2 ; DCCSW, clean by set/way
    SUBS R7, R7, #1             ; decrement the index
    BGE Loop3
    SUBS R9, R9, #1             ; decrement the way number
    BGE Loop2

Skip
    ADD R10, R10, #2            ; increment the cache number
    CMP R3, R10
    BGT Loop1
    DSB
Finished
```

Similar approaches can be used for all cache maintenance instructions.

G3.4.8 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
  - Cache clean by set/way, DCCSW.
  - Cache invalidate by set/way, DCISW.
  - Cache clean and invalidate by set/way, DCISW.
  - Instruction cache invalidate all, ICIALLU and ICIALLUIS.

  However, one of the following approaches must be adopted in all these cases:

  1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
  2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.

3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See *Data Abort exception on page G1-3439*.

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, DCCMVAC and DCCMVAU.
- Cache invalidate by virtual address, DCIMVAC.
- Cache clean and invalidate by virtual address, DCCIMVAC.

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See DFSR or HSR.

In an implementation that includes EL2, if HCR.TIDCP is set to 1, any exception relating to lockdown of an entry associated with Non-secure memory is routed to EL2.

Note

An implementation that uses an abort mechanisms for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

Additional cache functions for the implementation of lockdown

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED space. See *IMPLEMENTATION DEFINED registers, functional group on page G4-3803*.

G3.4.9 System level caches

The system level architecture might define further aspects of the software view of caches and the memory model that are not defined by the ARMv8 architecture. These aspects of the system level architecture can affect the requirements for software management of caches and coherency. For example, a system design might introduce additional levels of caching that cannot be managed using the architecturally-defined maintenance instructions. Such caches are referred to as *system caches* and are managed through the use of memory-mapped operations. The ARMv8 architecture does not forbid the presence of system caches that are outside the scope of the architecture, but ARM strongly recommends that such caches are always placed after the Point of Coherency for all memory locations that might be held in a cache. Placing such system caches after the Point of Coherency means that coherency management does not require maintenance of these system caches.

ARM also strongly recommends:

- For the maintenance of any such system cache:
  - Physical, rather than virtual, addresses are used for address-based cache maintenance instructions.
  - Any IMPLEMENTATION DEFINED system cache maintenance instruction includes at least the set of maintenance options defined by *Cache maintenance instructions* on page G3-3589, with the number of levels of system cache operated on by the cache maintenance instructions being IMPLEMENTATION DEFINED.
- Wherever possible, all caches that require maintenance to ensure coherency are included in the caches affected by the architecturally-defined cache maintenance instructions, so that the architecturally-defined software sequences for managing the memory model and coherency are sufficient for managing all caches in the system.

G3.5 ARMv8 CP15 register support for IMPLEMENTATION DEFINED features

The ARMv8 CP15 registers implementation includes the following support for IMPLEMENTATION DEFINED features of the memory system:

- The TCM Type Register,TCMTR, in CP15 c0, must be implemented. The following conditions apply to this register:
  - If no TCMs are implemented, the TCMTR indicates zero-size TCMs.
  - If bits[31:29] are `0b100`, the format of the rest of the register is IMPLEMENTATION DEFINED. This value indicates that the implementation includes TCMs that do not follow the legacy usage model. Other fields in the register might give more information about the TCMs.
- The CP15 c9 encoding space with `<CRm>` = {0-2, 5-7} is IMPLEMENTATION DEFINED for all values of `<opc2>` and `<opc1>`. This space is reserved for branch predictor, cache and TCM functionality, for example maintenance, override behaviors and lockdown.

  For more information, see*VMSAv8-32 CP15 c9 register summary* on page G4-3770.
- In a VMSAv8 implementation, part of the CP15 c10 encoding space is IMPLEMENTATION DEFINED and reserved for TLB functionality, see *TLB lockdown* on page G4-3687.
- The CP15 c11 encoding space with `<CRm>` = {0-8, 15} is IMPLEMENTATION DEFINED for all values of `<opc2>` and `<opc1>`. This space is reserved for DMA operations to and from the TCMs

  For more information, see *VMSAv8-32 CP15 c11 register summary* on page G4-3771.

G3.6 External aborts

The ARM architecture defines external aborts as errors that occur in the memory system, other than those that are detected by the MMU or Debug hardware. External aborts include parity errors detected by the caches or other parts of the memory system. For example, an uncorrectable parity or ECC failure on a Level 2 Memory structure might generate an external abort.

An external abort is one of:

- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see *Exception terminology* on page G1-3368.

The ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous aborts.

In AArch32 state, asynchronous aborts are reported using the Data Abort exception.

Synchronous external aborts are reported using the Data Abort exception. See *Handling exceptions that are taken to an Exception level using AArch32* on page G1-3396.

VMSAv8-32 permits external aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous. The reported fault code identifies whether the external abort is synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which external aborts, if any, are supported.

Normally, external aborts are rare. An imprecise asynchronous external abort is likely to be fatal to the process that is running. ARM recommends that implementations make external aborts precise wherever possible.

The following subsections give more information about possible external aborts:

- *External abort on instruction fetch*.
- *External abort on data read or write*.
- *Provision for classification of external aborts* on page G3-3603.
- *Parity error reporting* on page G3-3603.

The section *Exception reporting in a VMSAv8-32 implementation* on page G4-3715 describes the reporting of external aborts.

G3.6.1 External abort on instruction fetch

An external abort on an instruction fetch can be either synchronous or asynchronous. A synchronous external abort on an instruction fetch is taken precisely.

An implementation can report the external abort asynchronously from the instruction that it applies to. In such an implementation these aborts behave essentially as interrupts. The aborts are masked when CPSR.A is set to 1, otherwise they are reported using the Data Abort exception.

G3.6.2 External abort on data read or write

Externally-generated errors during a data read or write can be either synchronous or asynchronous.

An implementation can report the external abort asynchronously from the instruction that generated the access. In such an implementation these aborts behave essentially as interrupts. The aborts are masked when CPSR.A is set to 1, otherwise they are reported using the Data Abort exception.

G3.6.3 Provision for classification of external aborts

For a synchronous external abort taken to a privileged mode other than Hyp mode, an implementation can use the DFSR.ExT and IFSR.ExT bits to provide more information about synchronous external aborts:

- DFSR.ExT provides an IMPLEMENTATION DEFINED classification of synchronous external aborts on data accesses.
- IFSR.ExT provides an IMPLEMENTATION DEFINED classification of synchronous external aborts on instruction accesses.

For a synchronous external abort taken to Hyp mode, the HSR.EA, ISS[9] bit, provides an IMPLEMENTATION DEFINED classification of external aborts.

For all aborts other than synchronous external aborts these bits return a value of 0.

G3.6.4 Parity error reporting

The ARM architecture supports the reporting of both synchronous and asynchronous parity errors from the cache systems. It is IMPLEMENTATION DEFINED what parity errors in the cache systems, if any, result in synchronous or asynchronous parity errors.

A fault code is defined for reporting parity errors, see *Exception reporting in a VMSAv8-32 implementation* on page G4-3715. However when parity error reporting is implemented it is IMPLEMENTATION DEFINED whether a parity error is reported using the assigned fault code, or using another appropriate encoding.

For all purposes other than the fault status encoding, parity errors are treated as external aborts.

G3.7 Memory barrier instructions

Memory barriers on page E2-2268 describes the memory barrier instructions. This section describes the system level controls of those instructions.

G3.7.1 EL2 control of the shareability of data barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 and supports shareability limitations on the data barrier instructions, the HCR.BSU field can upgrade the required shareability of an instruction that is executed at EL0 or EL1 in Non-secure state. Table G3-7 shows the encoding of this field:

Table G3-7 EL2 control of shareability of barrier instructions executed at EL0 or EL1

HCR.BSU	Minimum shareability of barrier instructions
00	No effect, shareability is as specified by the instruction
01	Inner Shareable
10	Outer Shareable
11	Full system

For an instruction executed at EL0 or EL1 in Non-secure state, Table G3-8 shows how the HCR.BSU is combined with the shareability specified by the argument of the `DMB` or `DSB` instruction to give the scope of the instruction:

Table G3-8 Effect of the HCR_EL2.BSU on barrier instructions executed at Non-secure EL1 or EL1

Shareability specified by the `DMB` or `DSB` argument	HCR.BSU	Resultant shareability
Full system	Any	Full system
Outer Shareable	`00`, `01`, or `10`	Outer Shareable
	`11`, Full system	Full system
Inner Shareable	`00` or `01`	Inner Shareable
	`10`, Outer Shareable	Outer Shareable
	`11`, Full system	Full system
Non-shareable	`00`, No effect	Non-shareable
	`01`, Inner Shareable	Inner Shareable
	`10`, Outer Shareable	Outer Shareable
	`11`, Full system	Full system

G3.8 Pseudocode details of general memory system instructions

This section contains the following pseudocode describing general memory operations:

G3.8.1 Memory data type definitions

This section describes the memory data type definitions.

The address descriptor type is defined as follows:

```
type AddressDescriptor is (
    FaultRecord      fault,      // fault.type indicates whether the address is valid
    MemoryAttributes memattrs,
    FullAddress      paddress
)
```

The full address type is defined as follows:

```
type FullAddress is (
    bits(48) physicaladdress,
    bit      NS                  // '0' = Secure, '1' = Non-secure
)
```

The memory attributes types are defined is as follows:

```
type MemoryAttributes is (
    MemType      type,

    DeviceType   device,     // For Device memory types
    MemAttrHints inner,      // Inner hints and attributes
    MemAttrHints outer,      // Outer hints and attributes

    boolean      shareable,
    boolean      outershareable
)
```

The memory type is defined as follows.

```
enumeration MemType {MemType_Normal, MemType_Device};
```

The Device memory types are defined as follows:

```
enumeration DeviceType {DeviceType_GRE, DeviceType_nGRE, DeviceType_nGnRE, DeviceType_nGnRnE};
```

For Normal memory, the inner and outer attributes are defined is as follows:

```
type MemAttrHints is (
    bits(2) attrs,  // The possible encodings for each attributes field are as below
    bits(2) hints,  // The possible encodings for the hints are below
    boolean transient
)
```

The cacheability attributes are defined as follows:

```
constant bits(2) MemAttr_NC = '00';     // Non-cacheable
constant bits(2) MemAttr_WT = '10';     // Write-through
constant bits(2) MemAttr_WB = '11';     // Write-back
```

The allocation hints are defined as follows:

```
constant bits(2) MemHint_No = '00';     // No allocate
constant bits(2) MemHint_WA = '01';     // Write-allocate, Read-no-allocate
constant bits(2) MemHint_RA = '10';     // Read-allocate, Write-no-allocate
constant bits(2) MemHint_RWA = '11';    // Read-allocate and Write-allocate
```

The access permissions type is defined as follows:

```
type Permissions is (
    bits(3) ap,   // Access permission bits
    bit     xn,   // Execute-never bit
    bit     pxn   // Privileged execute-never bit
)
```

G3.8.2 Basic memory access

The two _Mem[] accessors, Non-assignment (memory read) and Assignment (memory write), are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

```
bits(8*size) _Mem[AddressDescriptor desc, integer size, AccType acctype];

_Mem[AddressDescriptor desc, integer size, AccType acctype] = bits(8*size) value;
```

The functions address the array using desc.paddress which supplies:

- A 48-bit physical address.
- A single NS bit to select between Secure and Non-secure parts of the array.

The AccType parameter describes the access type, such as normal, exclusive, ordered, and streaming. For a definition of AccType, see *Address space* on page E2-2248.

The actual implemented array of memory might be smaller than the 2^{48} bytes implied. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space might give rise to external aborts or a System Error.

The attributes in memaddrdesc.memattrs are used by the memory system to determine caching and ordering behaviors as described in *Memory types and attributes* on page E2-2273, *Memory ordering* on page E2-2266, and *Atomicity in the ARM architecture* on page E2-2261.

PAMax() returns the IMPLEMENTATION DEFINED size of the physical address.

```
integer PAMax();
```

Note

In AArch32 a translation regime can never generate more than 40 bits of an address.

G3.8.3 Aligned memory access

The MemA_with_type[] function makes an atomic, little-endian accesses of size bytes.

```
// MemA_with_type[] - non-assignment (read) form
// =============================================

bits(size*8) MemA_with_type[bits(32) address, integer size, AccType acctype, boolean wasaligned]
    assert size IN {1, 2, 4, 8, 16};
    assert address == Align(address, size);

    AddressDescriptor memaddrdesc;
    bits(size*8) value;
    iswrite = FALSE;

    // MMU or MPU
    memaddrdesc = AArch32.TranslateAddress(address, acctype, iswrite, wasaligned, size);
```

```
    // Check for aborts or debug exceptions
    if IsFault(memaddrdesc) then
        AArch32.Abort(address, memaddrdesc.fault);

    // Memory array access
    value = _Mem[memaddrdesc, size, acctype];
    return value;

// MemA_with_type[] - assignment (write) form
// ==========================================

MemA_with_type[bits(32) address, integer size, AccType acctype, boolean wasaligned] = bits(size*8) value
    assert size IN {1, 2, 4, 8, 16};
    assert address == Align(address, size);

    AddressDescriptor memaddrdesc;
    iswrite = TRUE;

    // MMU or MPU
    memaddrdesc = AArch32.TranslateAddress(address, acctype, iswrite, wasaligned, size);

    // Check for aborts or debug exceptions
    if IsFault(memaddrdesc) then
        AArch32.Abort(address, memaddrdesc.fault);

    // Effect on exclusives
    if memaddrdesc.mematttrs.shareable then
        ClearExclusiveByAddress(memaddrdesc.paddress, ProcessorID(), size);

    // Memory array access
    _Mem[memaddrdesc, size, acctype] = value;
    return;
```

G3.8.4 Unaligned memory access

The `MemU_with_type[]` function makes an access of the required type. If that access is architecturally defined to be atomic, it synthesizes accesses from multiple calls to `MemA_with_type[]` or multiple accesses, depending on whether the access is required to be atomic. It also reverses the byte order if the access is big-endian.

```
// MemU_with_type[] - non-assignment (read) form
// =============================================

bits(size*8) MemU_with_type[bits(32) address, integer size, AccType acctype]
    assert size IN {1, 2, 4, 8, 16};
    bits(size*8) value;
    integer i;
    boolean iswrite = FALSE;

    aligned = AArch32.CheckAlignment(address, size, acctype, iswrite);

    if !aligned then
        assert size > 1;
        value<7:0> = MemA_with_type[address, 1, acctype, aligned];

        // For subsequent bytes it is CONSTRAINED UNPREDICTABLE whether an unaligned Device memory
        // access will generate an Alignment Fault, as to get this far means the first byte did
        // not, so we must be changing to a new translation page.
        c = ConstrainUnpredictable();
        assert c IN {Constraint_FAULT, Constraint_NONE};
        if c == Constraint_NONE then aligned = TRUE;

        for i = 1 to size-1
            value<8*i+7:8*i> = MemA_with_type[address+i, 1, acctype, aligned];
    else
        value = MemA_with_type[address, size, acctype, aligned];
```

```
    if BigEndian() then
        value = BigEndianReverse(value);
    return value;

// MemU_with_type[] - assignment (write) form
// ==========================================

MemU_with_type[bits(32) address, integer size, AccType acctype] = bits(size*8) value
    integer i;
    boolean iswrite = TRUE;

    if BigEndian() then
        value = BigEndianReverse(value);

    aligned = AArch32.CheckAlignment(address, size, acctype, iswrite);

    if !aligned then
        assert size > 1;
        MemA_with_type[address, 1, acctype, aligned] = value<7:0>;

        // For subsequent bytes it is CONSTRAINED UNPREDICTABLE whether an unaligned Device memory
        // access will generate an Alignment Fault, as to get this far means the first byte did
        // not, so we must be changing to a new translation page.
        c = ConstrainUnpredictable();
        assert c IN {Constraint_FAULT, Constraint_NONE};
        if c == Constraint_NONE then aligned = TRUE;

        for i = 1 to size-1
            MemA_with_type[address+i, 1, acctype, aligned] = value<8*i+7:8*i>;
    else
        MemA_with_type[address, size, acctype, aligned] = value;
    return;
```

G3.8.5 Exclusive monitors operations

The `SetExclusiveMonitors()` function sets the exclusive monitors for a Load-Exclusive instruction, for a block of bytes. The size of the blocks is determined by `size`, at the VA `address`. The `ExclusiveMonitorsPass()` function checks whether a Store-Exclusive instruction still has possession of the exclusive monitors and therefore completes successfully.

```
// AArch32.SetExclusiveMonitors()
// ==============================

// Sets the Exclusive Monitors for the current PE to record the addresses associated
// with the virtual address region of size bytes starting at address.

AArch32.SetExclusiveMonitors(bits(32) address, integer size)

    acctype = AccType_ATOMIC;
    iswrite = FALSE;
    aligned = (address != Align(address, size));

    memaddrdesc = AArch32.TranslateAddress(address, acctype, iswrite, aligned, size);

    // Check for aborts or debug exceptions
    if IsFault(memaddrdesc) then
        return;

    if memaddrdesc.memattrs.shareable then
        MarkExclusiveGlobal(memaddrdesc.paddress, ProcessorID(), size);

    MarkExclusiveLocal(memaddrdesc.paddress, ProcessorID(), size);

    AArch32.MarkExclusiveVA(address, ProcessorID(), size);
```

The ExclusiveMonitorsPass() function checks whether a Store-Exclusive instruction still has possession of the exclusive monitors, by checking whether the exclusive monitors are set to include the location of the memory block specified by size, at the virtual address defined by address. The atomic write that follows after the exclusive monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to SetExclusiveMonitors().

```
// AArch32.ExclusiveMonitorsPass()
// ===============================

// Return TRUE if the Exclusive Monitors for the current PE include all of the addresses
// associated with the virtual address region of size bytes starting at address.
// The immediately following memory write must be to the same addresses.

boolean AArch32.ExclusiveMonitorsPass(bits(32) address, integer size)

    // It is IMPLEMENTATION DEFINED whether the detection of memory aborts happens
    // before or after the check on the local Exclusive Monitor. As a result a failure
    // of the local monitor can occur on some implementations even if the memory
    // access would give an memory abort.

    acctype = AccType_ATOMIC;
    iswrite = TRUE;
    aligned = (address == Align(address, size));

    if !aligned then
        secondstage = FALSE;
        AArch32.Abort(address, AArch32.AlignmentFault(acctype, iswrite, secondstage));

    passed = AArch32.IsExclusiveVA(address, ProcessorID(), size);
    if !passed then
        return FALSE;

    memaddrdesc = AArch32.TranslateAddress(address, acctype, iswrite, aligned, size);

    // Check for aborts or debug exceptions
    if IsFault(memaddrdesc) then
        AArch32.Abort(address, memaddrdesc.fault);

    passed = IsExclusiveLocal(memaddrdesc.paddress, ProcessorID(), size);
    if passed && memaddrdesc.memattrs.shareable then
        passed = IsExclusiveGlobal(memaddrdesc.paddress, ProcessorID(), size);

    if passed then
        ClearExclusiveLocal(ProcessorID());

    return passed;
```

The ExclusiveMonitorsStatus() function returns 0 if the previous atomic write was to the same physical memory locations selected by ExclusiveMonitorsPass() and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

```
bit ExclusiveMonitorsStatus();
```

The MarkExclusiveGlobal() procedure takes as arguments a FullAddress.paddress, the PE identifier processorid and the size of the transfer. The procedure records that the PE processorid has requested exclusive access covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

```
MarkExclusiveGlobal(FullAddress paddress, integer processorid, integer size);
```

The MarkExclusiveLocal() procedure takes as arguments a FullAddress paddress, the PE identifier processorid and the size of the transfer. The procedure records in a local record that PE processorid has requested exclusive access to an address covering at least size bytes from address paddress. The size of the location marked as exclusive is

IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a `MarkExclusiveGlobal()` using the same parameters.

```
MarkExclusiveLocal(FullAddress paddress, integer processorid, integer size);
```

The `IsExclusiveGlobal()` function takes as arguments a FullAddress `paddress`, the PE identifier `processorid` and the size of the transfer. The function returns TRUE if the PE `processorid` has marked in a global record an address range as exclusive access requested that covers at least `size` bytes from address `paddress`. It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, `IsExclusiveGlobal()` returns FALSE.

```
boolean IsExclusiveGlobal(FullAddress paddress, integer processorid, integer size);
```

The `IsExclusiveLocal()` function takes as arguments a FullAddress `paddress`, the PE identifier `processorid` and the size of the transfer. The function returns TRUE if the PE `processorid` has marked an address range as exclusive access requested that covers at least the `size` bytes from address `paddress`. It is IMPLEMENTATION DEFINED whether this function returns TRUE or FALSE if the address marked as exclusive access requested does not cover all of `size` bytes from address `paddress`. If no address is marked as exclusive access requested, then this function returns FALSE. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

```
boolean IsExclusiveLocal(FullAddress paddress, integer processorid, integer size);
```

The `ClearExclusiveByAddress()` procedure takes as arguments a `FullAddress` `paddress`, the PE identifier `processorid` and the size of the transfer. The procedure clears the global records of all PEs, other than `processorid`, for which an address region including any of `size` bytes starting from `paddress` has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE `processorid` is also cleared if any of `size` bytes starting from `paddress` has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

```
ClearExclusiveByAddress(FullAddress paddress, integer processorid, integer size);
```

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier `processorid`. The procedure clears the local record of PE `processorid` for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE `processorid` that an address has had a request for an exclusive access.

```
ClearExclusiveLocal(integer processorid);
```

G3.8.6 Access permission checking

The function `CheckPermission()` is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors.

The interpretation of access permission is shown in *Memory access control* on page G4-3665.

The pseudocode function for checking access permissions is as follows:

```
// AArch32.CheckPermission()
// =========================
// Function used for permission checking from AArch32 stage 1 translations

FaultRecord AArch32.CheckPermission(Permissions perms, bits(32) vaddress, integer level,
                                    bits(4) domain, bit NS, AccType acctype, boolean iswrite)
    assert ELUsingAArch32(TranslationRegime());

    if PSTATE.EL != EL2 then
        wxn = SCTLR.WXN == '1';
        if TTBCR.EAE == '1' || SCTLR.AFE == '1' || perms.ap<0> == '1' then
            priv_r = TRUE;
            priv_w = perms.ap<2> == '0';
            user_r = perms.ap<1> == '1';
            user_w = perms.ap<2:1> == '01';
        else
```

```
            priv_r = perms.ap<2:1> != '00';
            priv_w = perms.ap<2:1> == '01';
            user_r = perms.ap<1> == '1';
            user_w = FALSE;
        uwxn = SCTLR.UWXN == '1';
        user_xn = !user_r || perms.xn == '1' || (user_w && wxn);
        priv_xn = (!priv_r || perms.xn == '1' || perms.pxn == '1' ||
                   (priv_w && wxn) || (user_w && uwxn));
        ispriv = PSTATE.EL == EL1 && acctype != AccType_UNPRIV;

        if ispriv then
            (r, w, xn) = (priv_r, priv_w, priv_xn);
        else
            (r, w, xn) = (user_r, user_w, user_xn);
    else
        // Access from EL2
        wxn = HSCTLR.WXN == '1';
        r = TRUE;
        w = perms.ap<2> == '0';
        xn = perms.xn == '1' || (w && wxn);

    // Restriction on Secure instruction fetch
    if HaveEL(EL3) && IsSecure() && NS == '1' then
        secure_instr_fetch = if ELUsingAArch32(EL3) then SCR.SIF else SCR_EL3.SIF;
        if secure_instr_fetch == '1' then xn = TRUE;

    if acctype == AccType_IFETCH then
        fail = xn;
    elsif iswrite then
        fail = !w;
    else
        fail = !r;

    if fail then
        secondstage = FALSE;
        s2fs1walk = FALSE;
        ipaddress = bits(40) UNKNOWN;
        return AArch32.PermissionFault(ipaddress, domain, level, acctype, iswrite, secondstage,
                                       s2fs1walk);
    else
        return AArch32.NoFault();
```

G3.8.7 Abort exceptions

The `Abort()` function generates a Data Abort exception or a Prefetch Abort exception by calling the `TakeDataAbortException()` or `TakePrefetchAbortException()` function.

```
// AArch32.Abort()
// ===============
// Abort and Debug exception handling in an AArch32 translation regime.

AArch32.Abort(bits(32) vaddress, FaultRecord fault)

    // Check if routed to AArch64 state
    route_to_aarch64 = PSTATE.EL == EL0 && !ELUsingAArch32(EL1);

    if !route_to_aarch64 && HaveEL(EL2) && !IsSecure() && !ELUsingAArch32(EL2) then
        route_to_aarch64 = (HCR_EL2.TGE == '1' || IsSecondStage(fault) ||
                            (IsDebugException(fault) && MDCR_EL2.TDE == '1'));

    if !route_to_aarch64 && HaveEL(EL3) && !ELUsingAArch32(EL3) then
        route_to_aarch64 = SCR_EL3.EA == '1' && IsExternalAbort(fault);

    if route_to_aarch64 then
        AArch64.Abort(ZeroExtend(vaddress), fault);
    elsif fault.acctype == AccType_IFETCH then
        AArch32.TakePrefetchAbortException(vaddress, fault);
```

```
    else
        AArch32.TakeDataAbortException(vaddress, fault);
```

The FaultRecord type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. *Pseudocode details of VMSAv8-32 memory system operations* on page G4-3807 provides a number of wrappers to generate a FaultRecord.

The NoFault() function returns a null record that indicates no fault. The IsFault() function tests whether a FaultRecord contains a fault.

```
enumeration Fault {Fault_None,
                   Fault_AccessFlag,
                   Fault_Alignment,
                   Fault_Background,
                   Fault_Domain,
                   Fault_Permission,
                   Fault_Translation,
                   Fault_AddressSize,
                   Fault_SyncExternal,
                   Fault_SyncExternalOnWalk,
                   Fault_SyncParity,
                   Fault_SyncParityOnWalk,
                   Fault_AsyncParity,
                   Fault_AsyncExternal,
                   Fault_Debug,
                   Fault_TLBConflict,
                   Fault_Lockdown,
                   Fault_Coproc,
                   Fault_ICacheMaint};

type FaultRecord is (Fault    type,         // Fault Status
                     AccType  acctype,      // Type of access that faulted
                     bits(48) ipaddress,    // Intermediate physical address
                     boolean  s2fs1walk,    // Is on a Stage 1 page table walk
                     boolean  write,        // TRUE for a read, FALSE for a write
                     integer  level,        // For translation, access flag and permission faults
                     bit      extflag,      // IMPLEMENTATION DEFINED syndrome for external aborts
                     boolean  secondstage,  // Is a Stage 2 abort
                     bits(4)  domain,       // Domain number, AArch32 only
                     bits(4)  debugmoe)     // Debug method of entry, from AArch32 only
// AArch32.NoFault()
// =================

FaultRecord AArch32.NoFault()

    ipaddress = bits(40) UNKNOWN;
    domain = bits(4) UNKNOWN;
    level = integer UNKNOWN;
    acctype = AccType_NORMAL;
    iswrite = boolean UNKNOWN;
    extflag = bit UNKNOWN;
    debugmoe = bits(4) UNKNOWN;
    secondstage = FALSE;
    s2fs1walk = FALSE;

    return AArch32.CreateFaultRecord(Fault_None, ipaddress,  domain, level, acctype, iswrite,
                                     extflag, debugmoe, secondstage, s2fs1walk);
// IsFault()
// =========
// Return true if a fault is associated with an address descriptor

boolean IsFault(AddressDescriptor addrdesc)
    return addrdesc.fault.type != Fault_None;
```

G3.8.8 Memory barriers

The definition for the memory barrier functions is:

```
enumeration MBReqDomain    {MBReqDomain_Nonshareable, MBReqDomain_InnerShareable,
                            MBReqDomain_OuterShareable, MBReqDomain_FullSystem};

enumeration MBReqTypes     {MBReqTypes_Reads, MBReqTypes_Writes, MBReqTypes_All};
```

These functions define the required shareability domains and required access types used as arguments for `DMB` and `DSB` instructions.

The following procedures perform the memory barriers:

```
DataMemoryBarrier(MBReqDomain domain, MBReqTypes types);

DataSynchronizationBarrier(MBReqDomain domain, MBReqTypes types);

InstructionSynchronizationBarrier();
```

Chapter G4
The AArch32 Virtual Memory System Architecture

This chapter describes the ARMv8-A AArch32 Virtual Memory System Architecture (VMSA), that is backwards-compatible with VMSAv7. It includes the following section.

Note

This chapter must be read with Chapter G3 *The AArch32 System Level Memory Model*.

G4.1 Execution privilege, Exception levels, and AArch32 Privilege levels

In ARMv8, the hierarchy of software execution privilege, within a particular Security state, is defined by the Exception levels, with higher Exception level numbers indicating higher privilege. Table G4-1 shows this hierarchy for each Security state.

Table G4-1 Execution privilege and Exception levels, by Security state

Execution privilege	Secure state	Non-secure state	Typical use
Highest	EL3	-[a]	Secure monitor
-	-[a]	EL2	Hypervisor
-	EL1	EL1	Secure or Non-secure OS
Lowest, Unprivileged	EL0	EL0	Secure or Non-secure application

a. EL2 is never implemented in Secure state, and EL3 is never implemented in Non-secure state.

When executing in AArch32 state, within a given Security state, the current PE state, including the execution privilege, is primarily indicated by the current *PE mode*. In Secure state, how the PE modes map onto the Exception levels depends on whether EL3 is using AArch32 or is using AArch64, and:

- Figure G1-1 on page G1-3374 shows this mapping when EL3 is using AArch32.
- Figure G1-2 on page G1-3381 shows this mapping when EL3 is using AArch64.

Table G4-2 shows this mapping. In interpreting this table:

- Monitor mode is implemented only in Secure state, and only if EL3 is using AArch32.
- Hyp mode is implemented only in Non-secure state, and only if EL2 is using AArch32.
- System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented:
  - **In Secure state** If either:
    - EL3 is using AArch32.
    - EL3 is using AArch64 and EL1 is using AArch32.
  - **In Non-secure state** If EL1 is using AArch32.
- User mode is implemented if EL0 is using AArch32.

Table G4-2 Mapping of AArch32 PE modes to Exception levels

Exception level	PE modes in the given Security state, and EL3 Execution state		
	Secure state, EL3 using AArch32	Secure state, EL3 using AArch64	Non-secure state
EL3	Monitor, System, FIQ, IRQ, Supervisor, Abort, Undefined	-	-
EL2	-	-	Hyp
EL1	-	System, FIQ, IRQ, Supervisor, Abort, Undefined	System, FIQ, IRQ, Supervisor, Abort, Undefined
EL0	User	User	User

Because AArch32 behavior is described in terms of the PE modes, and transitions between PE modes, the Exception levels are implicit in most of the description of operation in AArch32 state.

However, the *translation regimes* provided by the VMSA cannot be described only in terms of the PE modes. In AArch64 state these regimes are defined by the Exception levels that use them. However, in AArch32 state this would result in descriptions that, for Secure state operation in modes other than User mode, would depend on the Exception level being used by AArch32.

To provide a consistent description of address translation as seen from AArch32 state, the translation regimes are described in terms of the Privilege levels originally defined in the ARMv7 descriptions of AArch32 state. Table G4-3 shows this.

Table G4-3 Mapping of PE modes to AArch32 Privilege levels

Privilege level	Secure state	Non-secure state
PL2	-	Hyp[a]
PL1	Monitor[b], System, FIQ, IRQ, Supervisor, Abort, Undefined	System, FIQ, IRQ, Supervisor, Abort, Undefined
PL0	User	User

a. Implemented only in Non-secure state, and only if EL2 is using AArch32
b. Implemented only in Secure state, and only if EL3 is using AArch32.

Comparing Table G4-3 with Table G4-2 on page G4-3616 shows that:

In Non-secure state

Each privilege level maps to the corresponding Exception level. For example PL1 maps to EL1.

In Secure state

PL0 maps to EL0.

The mapping of PL1 depends on the Execution state being used by EL3, as follows:

EL3 using AArch64 Secure PL1 maps to Secure EL1. Monitor mode is not implemented.

EL3 using AArch32 Secure PL1 maps to Secure EL3. Monitor mode is implemented as one of the Secure PL1 modes.

G4.2 About VMSAv8-32

Note

- This chapter describes the ARMv8 VMSA for AArch32 state, VMSAv8-32. This is generally equivalent to VMSAv7 for an implementation that includes all of the Security Extensions, the Multiprocessing Extension, the Large Physical Address Extension, and the Virtualization Extensions.
- This chapter describes the control of the VMSA by Exception levels that are using AArch32. *Execution privilege, Exception levels, and AArch32 Privilege levels* on page G4-3616 summarizes how the AArch32 PE modes map onto the Exception levels.

  Chapter D4 *The AArch64 Virtual Memory System Architecture* describes the control of the VMSA by exception levels that are using AArch64.
- For details of the VMSA differences in previous versions of the ARM architecture see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

The main function of the VMSA is to perform address translation, and access permissions and memory attribute determination and checking, for memory accesses made by the PE. Address translation, and permissions and attribute determination and checking, is performed by a *stage* of address translation.

In VMSAv8-32, the *Memory Management Unit* (MMU) provides a number of stages of address translation. This chapter describes only the stages that are visible from Exception levels that are using AArch32, which are as follows:

For operation in Secure state

A single stage of address translation, for use when executing at PL1 or PL0. This is the *Secure PL1&0 stage 1* address translation stage.

For operation in Non-secure state

- A single stage of address translation for use when executing at PL2. This is the *Non-secure PL2 stage 1* address translation stage.
- Two stages of address translation for use when executing at PL1 or PL0. These are:
  - The *Non-secure PL1&0 stage 1* address translation stage.
  - The *Non-secure PL1&0 stage 2* address translation stage.

The System registers provide independent control of each supported stage of address translation, including a control to disable that stage of translation.

These features mean the VMSAv8-32 can support a hierarchy of software supervision, for example an Operating System and a hypervisor.

Each stage of address translation uses address translations and associated memory properties held in memory mapped tables called *translation tables*.

For information about how the MMU features differ if an implementation does not include all of the Exception levels, see *About address translation for VMSAv8-32* on page G4-3621.

The translation tables define the following properties:

Access to the Secure or Non-secure address map

The translation table entries determine whether an access from Secure state accesses the Secure or the Non-secure address map. Any access from Non-secure state accesses the Non-secure address map.

Memory access permission control

This controls whether a program is permitted to access a memory region. For instruction and data access, the possible settings are:

- No access.
- Read-only.

- Write-only. This is possible only in a translation regime with two stages of translation.
- Read/write.

For instruction accesses, additional controls determine whether instructions can be fetched and executed from the memory region.

If a PE attempts an access that is not permitted, a memory fault is signaled to the PE.

Memory region attributes

These describe the properties of a memory region. The top level attribute, the Memory type, is one of Normal, or a type of Device memory, as follows:

- Both translation table formats support the following Device memory types:
  - Device-nGnRnE
  - Device-nGnRE
- The Long-descriptor translation table format supports, in addition, the following Device memory types:
  - Device-nGRE
  - Device-GRE

Note

ARMv8 added the Device-nGRE and Device-GRE memory types. Also, in versions of the ARM architecture before ARMv8:

- Device-nGnRnE memory is described as Strongly-ordered memory.
- Device-nGnRE memory is described as Device memory.

Normal memory regions can have additional attributes.

For more information, see *Memory types and attributes* on page E2-2273.

Address translation mappings

An address translation maps an *input address* to an *output address*.

A stage 1 translation takes the address of an explicit data access or instruction fetch, a *virtual address* (VA), as the input address, and translates it to a different output address:

- If only one stage of translation is provided, this output address is the *physical address* (PA).
- If two stages of address translation are provided, the output address of the stage 1 translation is an *intermediate physical address* (IPA).

Note

In the ARMv8-32 architecture, a software agent, such as an Operating System, that uses or defines stage 1 memory translations, might be unaware of the distinction between IPA and PA.

A stage 2 translation translates the IPA to a PA.

The possible security states and privilege levels of memory accesses define a set of *translation regimes*. Figure G4-1 shows the VMSAv8-32 translation regimes, and their associated translation stages and the Exception levels from which they are controlled.

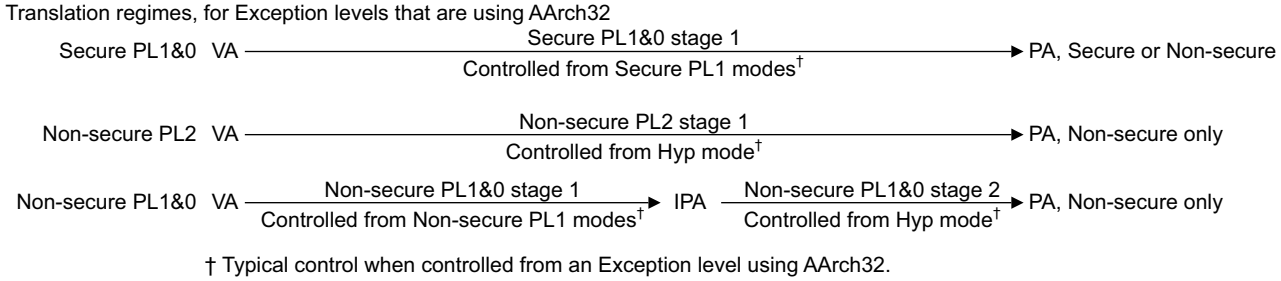

Figure G4-1 VMSAv8-32 translation regimes, and associated control

Note

Conceptually, a translation regime that has only a stage 1 address translation is equivalent to a regime with a fixed, flat stage 2 mapping from IPA to PA.

System registers control VMSAv8-32, including defining the location of the translation tables, and enabling and configuring the MMU, including enabling and disabling the different address translation stages. Also, they report any faults that occur on a memory access. For more information, see *Functional grouping of VMSAv8-32 System registers* on page G4-3786.

The following sections give an overview of VMSAv8-32, and of the implementation options for VMSAv8-32:

- *Address types used in a VMSAv8-32 description*.
- *Address spaces in VMSAv8-32*.
- *About address translation for VMSAv8-32* on page G4-3621.

The remainder of the chapter fully describes the VMSA, including the different implementation options, as summarized in *Organization of this chapter* on page G4-3623.

G4.2.1 Address types used in a VMSAv8-32 description

A description of VMSAv8-32 refers to the following address types.

Note

These descriptions relate to a VMSAv8-32 description and therefore sometimes differ from the generic definitions given in the Glossary.

Virtual Address (VA)

An address used in an instruction, as a data or instruction address, is a Virtual Address (VA).

An address held in the PC, LR, or SP, is a VA.

The VA map runs from zero to the size of the VA space. For AArch32 state, the maximum VA space is 4GB, giving a maximum VA range of `0x00000000-0xFFFFFFFF`.

Intermediate Physical Address (IPA)

In a translation regime that provides two stages of address translation, the IPA is the address after the stage 1 translation, and is the input address for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the PA.

A VMSAv8-32 implementation provides only one stage of address translation:

- If the implementation does not include EL2.
- When executing in Secure state.
- When executing in Hyp mode.

Physical Address (PA)

The address of a location in the Secure or Non-secure memory map. That is, an output address from the PE to the memory system.

G4.2.2 Address spaces in VMSAv8-32

For execution in AArch32 state, the ARMv8 architecture supports:

- A VA space of up to 32 bits. The actual width is IMPLEMENTATION DEFINED.
- An IPA space of up to 40 bits. The translation tables and associated System registers define the width of the implemented address space.

Note

AArch32 defines two translation table formats. The *Long-descriptor* format gives access to the full 40-bit IPA or PA space at a granularity of 4KB. The *Short-descriptor* format:

- Gives access to a 32-bit PA space at 4KB granularity.
- Gives access to a 40-bit PA space, but only at 16MB granularity, by the use of Supersections.

If an implementation includes EL3, the address maps are defined independently for Secure and Non-secure operation, providing two independent 40-bit address spaces, where:

- A VA accessed from Non-secure state can only be translated to the Non-secure address map.
- A VA accessed from Secure state can be translated to either the Secure or the Non-secure address map.

G4.2.3 About address translation for VMSAv8-32

Address translation is the process of mapping one address type to another, for example, mapping VAs to IPAs, or mapping VAs to PAs. A *translation table* defines the mapping from one address type to another, and a *Translation table base register* indicates the start of a translation table. Each implemented stage of address translation shown in Figure G4-1 on page G4-3619 requires its own translation tables.

For PL1&0 stage 1 translations, the mapping can be split between two tables, one controlling the lower part of the VA space, and the other controlling the upper part of the VA space. This can be used, for example, so that:

- One table defines the mapping for operating system and I/O addresses, that do not change on a context switch.
- A second table defines the mapping for application-specific addresses, and therefore might require updating on a context switch.

The VMSAv8-32 implementation options determine the supported address translation stages. The following descriptions apply when all implemented Exception levels are using AArch32:

VMSAv8-32 without EL2 or EL3

Supports only a single PL1&0 stage 1 address translation. Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by TTBR0 and TTBR1, and controlled by TTBCR.

VMSAv8-32 with EL3 but without EL2

Supports only the Secure PL1&0 stage 1 address translation and the Non-secure PL1&0 stage 1 address translation. In each security state, this stage of translation can be split between two sets of translation tables, with base addresses defined by the Secure and Non-secure copies of TTBR0 and TTBR1, and controlled by the Secure and Non-secure copies of TTBCR.

VMSAv8-32 with EL2 but without EL3

The implementation supports the following stages of address translation:

Non-secure PL2 stage 1 address translation

The HTTBR defines the base address of the translation table for this stage of address translation, controlled by HTCR.

Non-secure PL1&0 stage 1 address translation

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of TTBR0 and TTBR1 and controlled by the Non-secure instance of TTBCR.

Non-secure PL1&0 stage 2 address translation

The VTTBR defines the base address of the translation table for this stage of address translation, controlled by VTCR.

VMSAv8-32 with EL2 and EL3

The implementation supports all of the stages of address translation, as follows:

Secure PL1&0 stage 1 address translation

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Secure copies of TTBR0 and TTBR1, and controlled by the Secure instance of TTBCR.

Non-secure PL2 stage 1 address translation

The HTTBR defines the base address of the translation table for this stage of address translation, controlled by HTCR.

Non-secure PL1&0 stage 1 address translation

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of TTBR0 and TTBR1 and controlled by the Non-secure instance of TTBCR.

Non-secure PL1&0 stage 2 address translation

The VTTBR defines the base address of the translation table for this stage of address translation, controlled by VTCR.

Figure G4-2 shows the translation regimes and stages in a VMSAv8-32 implementation that includes all of the Exception levels, and indicates the PE mode that, typically, defines each set of translation tables, if that stage of address translation is controlled by a Privilege level that is using AArch32:

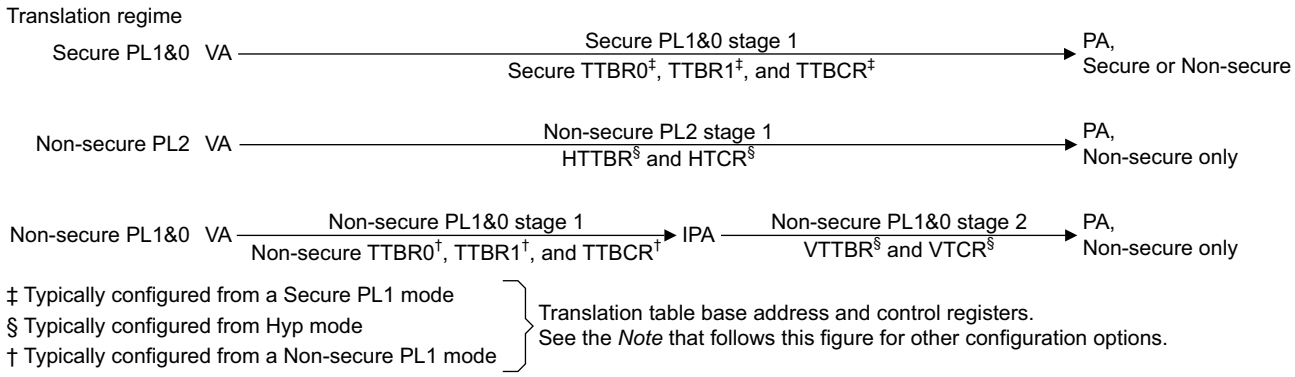

Figure G4-2 VMSAv8-32 address translation summary

Note

The term *Typically configured* is used in Figure G4-2 to indicate the expected software usage. However, stages of address translation used in AArch32 state can also be configured:

- From an Exception level higher than the Exception level of the configuring PE mode shown in Figure G4-2, regardless of whether that Exception level is using AArch32 or is using AArch64, except that a Non-secure Exception level can never configure a stage of address translation that is used in Secure state.
- From an Exception level that is using AArch64 and is higher than the level at which the translation stage is being used. For example, if Non-secure EL0 is the only Non-secure Exception level that is using AArch32, then the Non-secure PL1&0 stage of address translation is configured from Non-secure EL1, that is using AArch64.

In general:

- The translation from VA to PA can require multiple *stages* of address translation, as Figure G4-2 shows.
- A single stage of address translation takes an *input address* and translates it to an *output address*.

A full translation table lookup is called a *translation table walk*. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single input address to output address translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a *level* of address lookup. The final level of the lookup defines:

- The required output address.
- The *attributes* and *access permissions* of the addressed memory.

Translation Lookaside Buffers (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and VMSAv8-32 provides TLB maintenance instructions for the management of TLB contents.

Note

The ARM architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

To reduce the software overhead of TLB maintenance, for the PL1&0 translation regimes VMSAv8-32 distinguishes between *Global pages* and *Process-specific pages*. The *Address Space Identifier* (ASID) identifies pages associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures.

If an implementation includes EL2, the *virtual machine identifier* (VMID) identifies the current virtual machine, with its own independent ASID space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another, if the virtual machines have different VMIDs. For stage 2 translations, all translations are associated with the current VMID. There is no mechanism to associate a particular stage 2 translation with multiple virtual machines.

G4.2.4 Organization of this chapter

The remainder of this chapter is organized as follows.

The first part of the chapter describes address translation and the associated memory properties held in the translation table entries, in the following sections:

- *The effects of disabling address translation stages on VMSAv8-32 behavior* on page G4-3625.
- *Translation tables* on page G4-3629.
- *Secure and Non-secure address spaces* on page G4-3632.
- *The VMSAv8-32 Short-descriptor translation table format* on page G4-3634.
- *The VMSAv8-32 Long-descriptor translation table format* on page G4-3647.
- *Memory access control* on page G4-3665.
- *Memory region attributes* on page G4-3674.
- *Translation Lookaside Buffers (TLBs)* on page G4-3686.
- *TLB maintenance requirements* on page G4-3689.

Caches in VMSAv8-32 on page G4-3700 describes VMSAv8-32-specific cache requirements.

The following sections describe aborts on VMSAv8-32 memory accesses, and how these and other faults are reported:

- *VMSAv8-32 memory aborts* on page G4-3703.
- *Exception reporting in a VMSAv8-32 implementation* on page G4-3715.

Virtual Address to Physical Address translation instructions on page G4-3737 describes these operations, and how they relate to address translation.

A number of sections then describe the System registers for VMSAv8-32. The following sections give general information about the System registers, and the organization of the registers in the two coprocessor encoding spaces, CP14 and CP15, that provide the interface to these registers:

- *About the System registers for VMSAv8-32* on page G4-3743.
- *Organization of the CP14 registers in VMSAv8-32* on page G4-3764.
- *Organization of the CP15 registers in VMSAv8-32* on page G4-3767.

- *Functional grouping of VMSAv8-32 System registers* on page G4-3786.

The following sections then describe each of the functional groups of CP15 registers, including a full description of each register in the group:

- *Identification registers, functional group* on page G4-3787.
- *Virtual memory control registers, functional group* on page G4-3788.
- *Exception and fault handling registers, functional group* on page G4-3792.
- *Other system control registers, functional group* on page G4-3788.
- *Lockdown, DMA, and TCM features, functional group* on page G4-3798.
- *Cache maintenance instructions, functional group* on page G4-3794.
- *TLB maintenance instructions, functional group* on page G4-3795.
- *Address translation instructions, functional group* on page G4-3796.
- *Legacy feature registers, functional group* on page G4-3803.
- *Performance Monitors Extension registers, functional group* on page G4-3798.
- *Security registers, functional group* on page G4-3792.
- *Virtualization registers, functional group* on page G4-3789.
- *IMPLEMENTATION DEFINED registers, functional group* on page G4-3803.

Pseudocode details of VMSAv8-32 memory system operations on page G4-3807 then describes many feature of VMSAv8-32 operation.

G4.3 The effects of disabling address translation stages on VMSAv8-32 behavior

About VMSAv8-32 on page G4-3618 defines the translation regimes and the associated stages of address translation, each of which has its own System registers for control and configuration. VMSAv8-32 includes an enable bit for each stage of address translation, as follows:

- SCTLR.M, in the Secure instance of the register, controls Secure PL1&0 stage 1 address translation.
- SCTLR.M, in the Non-secure instance of the register, controls Non-secure PL1&0 stage 1 address translation.
- HCR.VM controls Non-secure PL1&0 stage 2 address translation.
- HSCTLR.M controls Non-secure PL2 stage 1 address translation.

Note

- The descriptions throughout this chapter describe address translation as seen by Exception levels that are using AArch32. However, for the Non-secure PL1&0 translation regime, the stage 2 translation:
  — Is controlled by the HCR if EL2 is using AArch32.
  — Is controlled by the HCR_EL2 if EL2 is using AArch64.

  For this reason, links to the HCR link to a table that disambiguates between the AArch32 HCR and the AArch64 HCR_EL2.
- If EL2 is using AArch64, then the equivalent of the Non-secure PL2 translation regime is described in Chapter D4 *The AArch64 Virtual Memory System Architecture*, not in this chapter.

The following sections describe the effect on VMSAv8-32 behavior of disabling each stage of translation:

- *VMSAv8-32 behavior when stage 1 address translation is disabled*.
- *VMSAv8-32 behavior when stage 2 address translation is disabled* on page G4-3627.
- *Behavior of instruction fetches when all associated address translations are disabled* on page G4-3627.

Enabling stages of address translation on page G4-3628 gives more information about each stage of address translation, in particular after a reset on an implementation that includes EL3.

G4.3.1 VMSAv8-32 behavior when stage 1 address translation is disabled

When stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of address translation are treated as follows:

Non-secure PL1 and PL0 accesses when EL2 is implemented and HCR.DC is set to 1

In an implementation that includes EL2, for an access from a Non-secure PL1 or PL0 mode when HCR.DC is set to 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Write-Allocate, Outer Write-Back Write-Allocate memory attributes.

See also *Effect of the HCR.DC bit* on page G4-3626.

All other accesses

For all other accesses, when a stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

Data access
